MySQL is deployed into many applications demanding availability and scalability.

Availability refers to the ability to cope with, and if necessary recover from, failures on the host, including failures of MySQL, the operating system, or the hardware and maintenance activity that may otherwise cause downtime. Scalability refers to the ability to spread both the database and the load of your application queries across multiple MySQL servers.

Because each application has different operational and availability requirements, MySQL offers a range of certified and supported solutions, delivering the appropriate levels of High Availability (HA) and scalability to meet service level requirements. Such solutions extend from replication, through virtualization and geographically redundant, multi-data center solutions delivering 99.999% uptime.

Selecting the right high availability solution for an application largely depends on:

- The level of availability required.
- The type of application being deployed.
- Accepted best practices within your own environment.

The primary solutions supported by MySQL include:

- MySQL Replication. Learn more: Replication
- MySQL Cluster. Learn more: MySQL Cluster NDB 7.2

- Oracle VM Template for MySQL. Learn more: Oracle VM Template for MySQL Enterprise Edition.

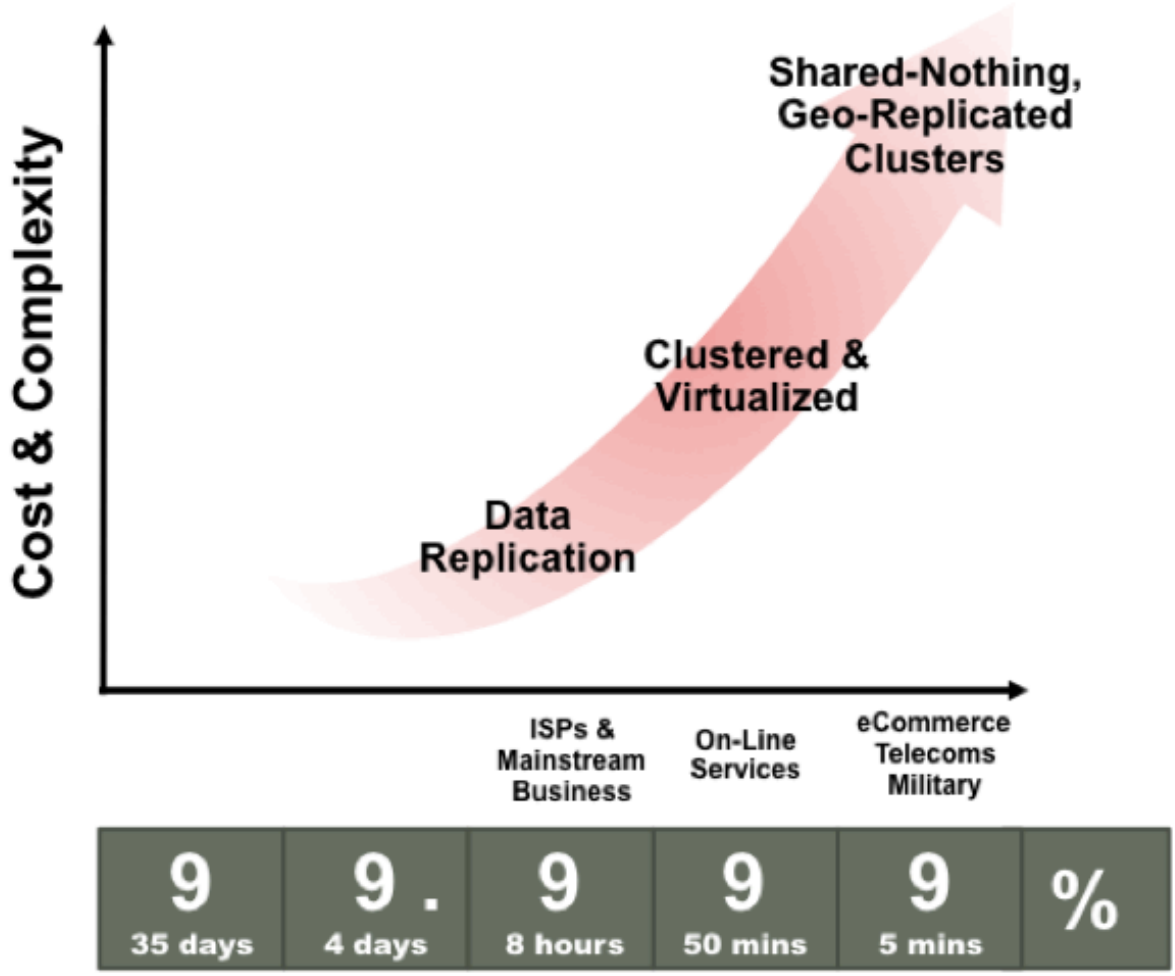
Further options are available using third-party solutions such as DRBD (Distributed Replicated Block Device) and Heartbeat, and more complex scenarios can be solved through a combination of these technologies.

Each architecture used to achieve highly available database services is differentiated by the levels of uptime it offers. These architectures can be grouped into three main categories:

- Data Replication.
- Clustered & Virtualized Systems.
- Shared-Nothing, Geographically-Replicated Clusters.

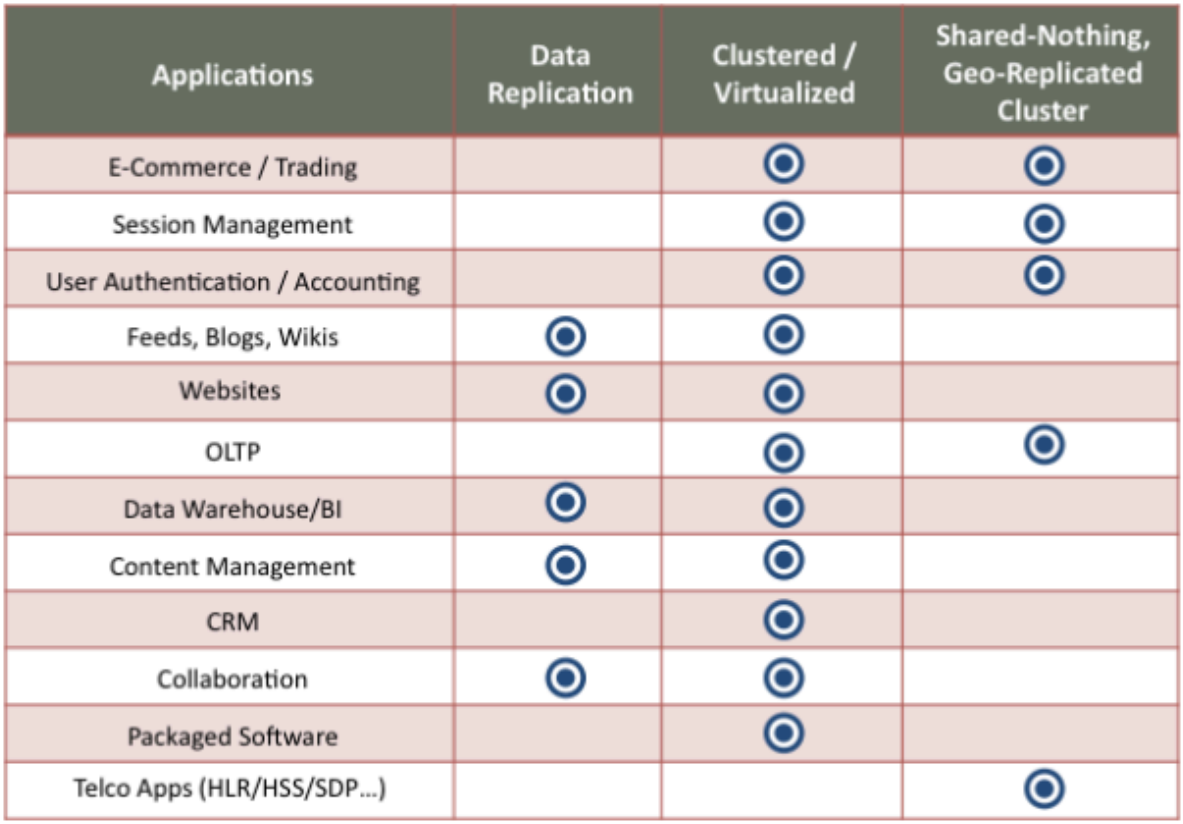
As illustrated in the following figure, each of these architectures offers progressively higher levels of uptime, which must be balanced against potentially greater levels of cost and complexity that each can incur. Simply deploying a high availability architecture is not a guarantee of actually delivering HA. In fact, a poorly implemented and maintained shared-nothing cluster could easily deliver lower levels of availability than a simple data replication solution.

Figure 15.1. Tradeoffs: Cost and Complexity versus Availability



The following figure maps common application types to architectures, based on best practices observed from the MySQL user base. It serves as a reference point to investigate which HA architectures can best serve your requirements.

Figure 15.2. High Availability Architectures for Common Application Types



The following table compares the HA and Scalability capabilities of the various MySQL solutions:

Requirement	MySQL Replication	MySQL Replication + Linux Heartbeat	Heartbeat + DRBD	Oracle VM Template	MySQL Cluster
Availability					
Platform Support	All Supported by MySQL Server	Linux	Linux	Oracle Linux	All Supported by MySQL Cluster
Automated IP Failover	No	Yes	Yes	Yes	Depends on Connector and Configuration
Automated Database Failover	No	No	Yes	Yes	Yes
Automatic Data Resynchronization	No	No	Yes	N/A - Shared Storage	Yes
Typical Failover Time	User / Script Dependent	Configuration Dependent, 60 seconds and Above	Configuration Dependent, 60 seconds and Above	Configuration Dependent, 60 seconds and Above	1 Second and Less
Synchronous Replication	No, Asynchronous and Semisynchronous	No, Asynchronous and Semisynchronous	Yes	N/A - Shared Storage	Yes
Shared Storage	No, Distributed	No, Distributed	No, Distributed	Yes	No, Distributed

Requirement	MySQL Replication	MySQL Replication + Linux Heartbeat	Heartbeat + DRBD	Oracle VM Template	MySQL Cluster
Geographic redundancy support	Yes	Yes	Yes, via MySQL Replication	Yes, via MySQL Replication	Yes, via MySQL Replication
Update Schema On-Line	No	No	No	No	Yes
Scalability					
Number of Nodes	One Master, Multiple Slaves	One Master, Multiple Slaves	One Active (primary), one Passive (secondary) Node	One Active (primary), one Passive (secondary) Node	255
Built-in Load Balancing	Reads, via MySQL Replication	Reads, via MySQL Replication	Reads, via MySQL Replication	Reads, via MySQL Replication & During Failover	Yes, Reads and Writes
Supports Read-Intensive Workloads	Yes	Yes	Yes	Yes	Yes
Supports Write-Intensive Workloads	Yes, via Application-Level Sharding	Yes, via Application-Level Sharding	Yes, via Application-Level Sharding to Multiple Active/Passive Pairs	Yes, via Application-Level Sharding to Multiple Active/Passive Pairs	Yes, via Auto-Sharding
Scale On-Line (add nodes, repartition, etc.)	No	No	No	No	Yes

Oracle VM Template for MySQL Enterprise Edition

Virtualization is a key technology to enable data center efficiency and high availability while providing the foundation for cloud computing. Integrating MySQL Enterprise Edition with Oracle Linux, the Oracle VM Template is the fastest, easiest, and most reliable way to provision virtualized MySQL instances, enabling users to meet the explosive demand for highly available services.

The Oracle VM Template enables rapid deployment and eliminates manual configuration efforts. It provides a pre-installed and pre-configured virtualized MySQL 5.5 Enterprise Edition software image running on Oracle Linux and Oracle VM, certified for production use. The MySQL software image has undergone extensive integration and quality assurance testing as part of the development process.

In addition to rapid provisioning, MySQL users also benefit from the integrated high availability features of Oracle VM which are designed to enable organizations to meet stringent SLA (Service Level Agreement) demands through a combination of:

- **Automatic recovery from failures**, with Oracle VM automatically restarting failed instances on available servers in the server pool after outages of the physical server, VM or MySQL database.
- **Live Migration**, enabling operations staff to move running instances of MySQL to alternative hosts within a server pool during maintenance operations.

Instructions for the creation, deployment and use of the Oracle VM Template for MySQL Enterprise Edition are available from:

- The Oracle VM Template for MySQL Enterprise Edition whitepaper: http://www.mysql.com/why-mysql/white-papers/mysql_wp_oracle-vm-template-for-mee.php.
- The README file accompanying the download of the Template.

To download the Oracle VM Template for MySQL Enterprise, go to http://edelivery.oracle.com/oraclevm and follow these instructions:

- Complete your registration information (Name, Company Name, Email Address and Country) and click on the download agreement.
- Select "Oracle VM Templates" from the "Select a Product Pack" pull-down menu and click "Go".
- Select MySQL Enterprise from the list of Oracle VM Templates.
- Download and unzip the files and refer to the README for further instructions.

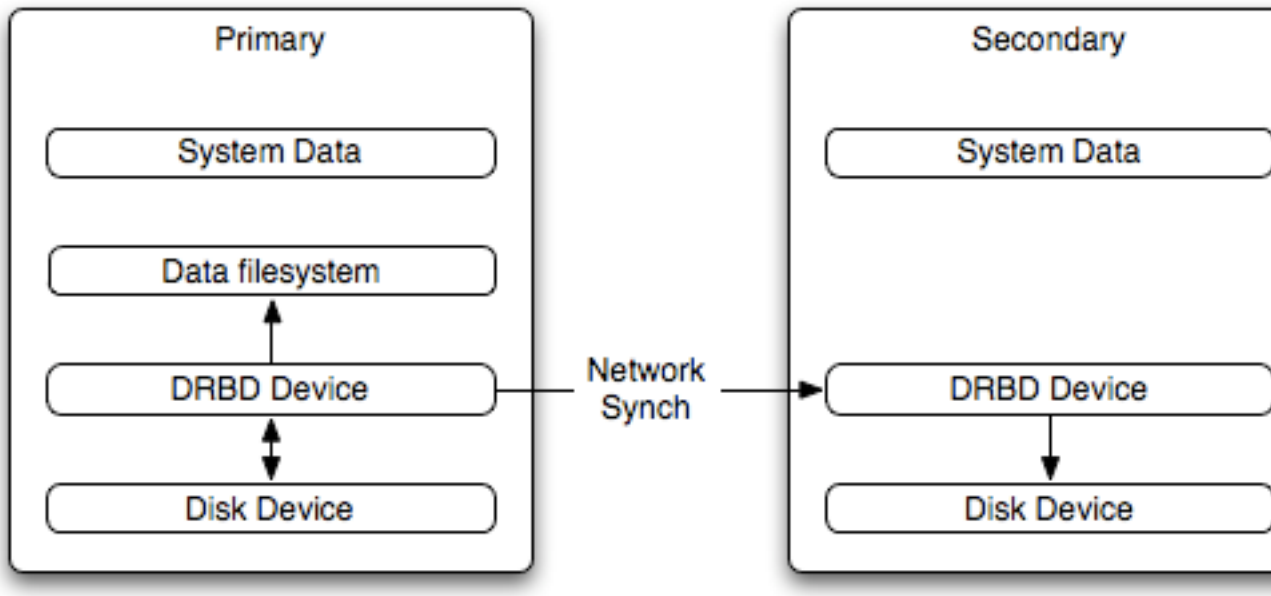
Using MySQL with DRBD

The Distributed Replicated Block Device (DRBD) is a Linux Kernel module that constitutes a distributed storage system. You can use DRBD to share block devices between Linux servers and, in turn, share file systems and data.

DRBD implements a block device which can be used for storage and which is replicated from a primary server to one or more secondary servers. The distributed block device is handled by the DRBD service. Writes to the DRBD block device are distributed among the servers. Each DRBD service writes the information from the DRBD block device to a local physical block device (hard disk).

On the primary data writes are written both to the underlying physical block device and distributed to the secondary DRBD services. On the secondary, the writes received through DRBD and written to the local physical block device. On both the primary and the secondary, reads from the DRBD block device are handled by the underlying physical block device. The information is shared between the primary DRBD server and the secondary DRBD server synchronously and at a block level, and this means that DRBD can be used in high-availability solutions where you need failover support.

Figure 15.3. DRBD Architecture Overview



When used with MySQL, DRBD can be used to ensure availability in the event of a failure. MySQL is configured to store information on the DRBD block device, with one server acting as the primary and a second machine available to operate as an immediate replacement in the event of a failure.

For automatic failover support, you can combine DRBD with the Linux Heartbeat project, which manages the interfaces on the two servers and automatically configures the secondary (passive) server to replace the primary (active) server in the event of a failure. You can also combine DRBD with MySQL Replication to provide both failover and scalability within your MySQL environment.

For information on how to configure DRBD and MySQL, including Heartbeat support, see this white paper: `http://www.mysql.com/why-mysql/white-papers/mysql_wp_drbd.php`

Note

Because DRBD is a Linux Kernel module, it is currently not supported on platforms other than Linux.

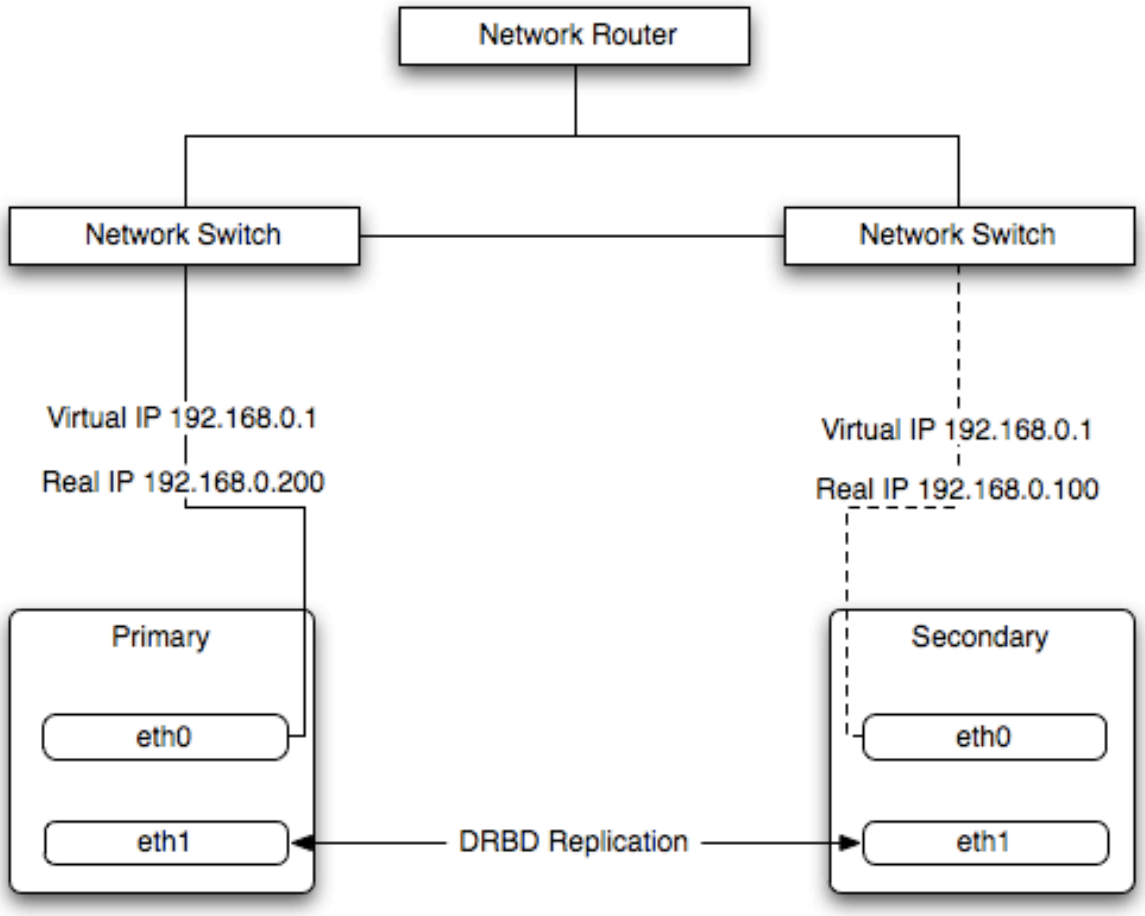
Using Linux HA Heartbeat

The Heartbeat program provides a basis for verifying the availability of resources on one or more systems within a cluster. In this context a resource includes MySQL, the file systems on which the MySQL data is being stored and, if you are using DRBD, the DRBD device being used for the file system. Heartbeat also manages a virtual IP address; use this virtual IP address for all communication to the MySQL instance.

A cluster within the context of Heartbeat is defined as two computers notionally providing the same service. By definition, each computer in the cluster is physically capable of providing the same services as all the others in the cluster. However, because the cluster is designed for high-availability, only one of the servers is actively providing the service at any one time. Each additional server within the cluster is a “hot-spare” that can be brought into service in the event of a failure of the master, its next connectivity or the connectivity of the network in general.

The basics of Heartbeat are very simple. Within the Heartbeat cluster (see Figure 15.4, “Heartbeat Architecture”, each machine sends a 'heartbeat' signal to the other hosts in the cluster. The other cluster nodes monitor this heartbeat. The heartbeat can be transmitted over many different systems, including shared network devices, dedicated network interfaces and serial connections. Failure to get a heartbeat from a node is treated as failure of the node. Although we do not know the reason for the failure (it could be an OS failure, a hardware failure in the server, or a failure in the network switch), it is safe to assume that if no heartbeat is produced there is a fault.

Figure 15.4. Heartbeat Architecture



In addition to checking the heartbeat from the server, the system can also check the connectivity (using `ping`) to another host on the network, such as the network router. This enables Heartbeat to detect a failure of communication between a server and the router (and therefore failure of the server, since it is no longer capable of providing the necessary service), even if the heartbeat between the servers in the clusters is working fine.

In the event of a failure, the resources on the failed host are disabled, and the resources on one of the replacement hosts is enabled instead. In addition, the Virtual IP address for the cluster is redirected to the new host in place of the failed device.

When used with MySQL and DRBD, the MySQL data is replicated from the master to the slave using the DRBD device, but MySQL is only running on the master. When the master fails, the slave switches the DRBD devices to be primary, the file systems on those devices are mounted, and MySQL is started. The original master (if still available) has its resources disabled, which means shutting down MySQL and unmounting the file systems and switching the DRBD device to secondary.

Heartbeat Configuration

Heartbeat configuration requires three files located in `/etc/ha.d`. The `ha.cf` contains the main heartbeat configuration, including the list of the nodes and times for identifying failures. `haresources` contains the list of resources to be managed within the cluster. The `authkeys` file contains the security information for the cluster.

The contents of these files should be identical on each host within the Heartbeat cluster. It is important that you keep these files in sync across all the hosts. Any changes in the information on one host should be copied to the all the others.

For these examples n example of the `ha.cf` file is shown below:

```
logfacility local0
keepalive 500ms
deadtime 10
warntime 5
initdead 30
mcast bond0 225.0.0.1 694 2 0
mcast bond1 225.0.0.2 694 1 0
auto_failback off
node drbd1
node drbd2
```

The individual lines in the file can be identified as follows:

- `logfacility`: Sets the logging, in this case setting the logging to use `syslog`.
- `keepalive`: Defines how frequently the heartbeat signal is sent to the other hosts.
- `deadtime`— the delay in seconds before other hosts in the cluster are considered 'dead' (failed).
- `warntime`: The delay in seconds before a warning is written to the log that a node cannot be contacted.
- `initdead`: The period in seconds to wait during system startup before the other host is considered to be down.
- `mcast`: Defines a method for sending a heartbeat signal. In the above example, a multicast network address is being used over a bonded network device. If you have multiple clusters then the multicast address for each cluster should be unique on your network. Other choices for the heartbeat exchange exist, including a serial connection.

  If you are using multiple network interfaces (for example, one interface for your server connectivity and a secondary or bonded interface for your DRBD data exchange), use both interfaces for your heartbeat connection. This decreases the chance of a transient failure causing a invalid failure event.
- `auto_failback`: Sets whether the original (preferred) server should be enabled again if it becomes available. Switching this to `on` may cause problems if the preferred went offline and then comes back on line again. If the DRBD device has not been synced properly, or if the problem with the original server happens again you may end up with two different datasets on the two servers, or with a continually changing environment where the two servers flip-flop as the preferred server reboots and then starts again.
- `node`: Sets the nodes within the Heartbeat cluster group. There should be one `node` for each server.

An optional additional set of information provides the configuration for a ping test that checks the connectivity to another host. Use this to ensure that you have connectivity on the public interface for your servers, so the ping test should be to a reliable host such as a router or switch. The additional lines specify the destination machine for the `ping`, which should be specified as an IP address, rather than a host name; the command to run when a failure occurs, the authority for the failure and the timeout before an nonresponse triggers a failure. A sample configure is shown below:

```
ping 10.0.0.1
respawn hacluster /usr/lib64/heartbeat/ipfail
apiauth ipfail gid=haclient uid=hacluster
deadping 5
```

In the above example, the `ipfail` command, which is part of the Heartbeat solution, is called on a failure and 'fakes' a fault on the currently active server. Configure the user and group ID under which the command is executed (using the `apiauth`). The failure is triggered after 5 seconds.

Note

The `deadping` value must be less than the `deadtime` value.

The `authkeys` file holds the authorization information for the Heartbeat cluster. The authorization relies on a single unique 'key' that is used to verify the two machines in the Heartbeat cluster. The file is used only to confirm that the two machines are in the same cluster and is used to ensure that the multiple clusters can co-exist within the same network.

Using Heartbeat with MySQL and DRBD

To use Heartbeat in combination with MySQL, use DRBD (see Using MySQL with DRBD) or another solution that enables sharing the MySQL database files in event of a system failure. In these examples, DRBD is used as the data sharing solution.

Heartbeat manages the configuration of different resources to manage the switching between two servers in the event of a failure. The resource configuration defines the individual services that should be brought up (or taken down) in the event of a failure.

The `haresources` file within `/etc/ha.d` defines the resources that should be managed, and the individual resource mentioned in this file in turn relates to scripts located within `/etc/ha.d/resource.d`. The resource definition is defined all on one line:

```
drbd1 drbddisk Filesystem::/dev/drbd0::/drbd::ext3 mysql 10.0.0.100
```

The line is notionally split by whitespace. The first entry (`drbd1`) is the name of the preferred host; that is the server that is normally responsible for handling the service. The last field is virtual IP address or name that should be used to share the service. This is the IP address that should be used to connect to the MySQL server. It is automatically allocated to the server that is active when Heartbeat starts.

The remaining fields between these two fields define the resources that should be managed. Each Field should contain the name of the resource (and each name should refer to a script within `/etc/ha.d/resource.d`). In the event of a failure, these resources are started on the backup server by calling the corresponding script (with a single argument, `start`), in order from left to right. If there are additional arguments to the script, you can use a double colon to separate each additional argument.

In the above example, we manage the following resources:

- `drbddisk`: The DRBD resource script, this switches the DRBD disk on the secondary host into primary mode, making the device read/write.
- `Filesystem`: Manages the Filesystem resource. In this case we have supplied additional arguments to specify the DRBD device, mount point and file system type. When executed this should mount the specified file system.
- `mysql`: Manages the MySQL instances and starts the MySQL server. Copy the `mysql.resource` file from the `support-files` directory from any MySQL release into the `/etc/ha.d/resources.d` directory.

  If this file is not available in your distribution, you can use the following as the contents of the `/etc/ha.d/resource.d/mysql.resource` file:

```
#!/bin/bash
#
# This script is intended to be used as resource script by heartbeat
#
# Mar 2006 by Monty Taylor
#
###

. /etc/ha.d/shellfuncs

case "$1" in
    start)
        res=`/etc/init.d/mysql start`
        ret=$?
        ha_log $res
        exit $ret
```

```
        ;;
    stop)
        res=`/etc/init.d/mysql stop`
        ret=$?
        ha_log $res
        exit $ret
        ;;
    status)
        if [[ `ps -ef | grep '[m]ysqld'` > 1 ]] ; then
           echo "running"
        else
           echo "stopped"
        fi
        ;;
    *)
        echo "Usage: mysql {start|stop|status}"
        exit 1
        ;;
esac

exit 0
```

To be notified of the failure by email, add another line to the `haresources` file with the address for warnings and the warning text:

```
MailTo::youremail@address.com::DRBDFailure
```

With the Heartbeat configuration in place, copy the `haresources`, `authkeys` and `ha.cf` files from your primary and secondary servers to make sure that the configuration is identical. Then start the Heartbeat service, either by calling `/etc/init.d/heartbeat start` or by rebooting both primary and secondary servers.

You can test the configuration by running a manual failover, connect to the primary node and run:

```
root-shell> /usr/lib64/heartbeat/hb_standby
```

This causes the current node to relinquish its resources cleanly to the other node.

Using Heartbeat with DRBD and dopd

As a further extension to using DRBD and Heartbeat together, you can enable `dopd`. The `dopd` daemon handles the situation where a DRBD node is out of date compared to the master and prevents the slave from being promoted to master in the event of a failure. This stops a situation where you have two machines that have been masters ending up different data on the underlying device.

For example, imagine that you have a two server DRBD setup, master and slave. If the DRBD connectivity between master and slave fails, then the slave is out of the sync with the master. If Heartbeat identifies a connectivity issue for master and then switches over to the slave, the slave DRBD device is promoted to the primary device, even though the data on the slave and the master is not in synchronization.

In this situation, with `dopd` enabled, the connectivity failure between the master and slave would be identified and the metadata on the slave would be set to `Outdated`. Heartbeat refuses to switch over to the slave even if the master failed. In a dual-host solution this would effectively render the cluster out of action, as there is no additional fail over server. In an HA cluster with three or more servers, control would be passed to the slave that has an up to date version of the DRBD device data.

To enable `dopd`, modify the Heartbeat configuration and specify `dopd` as part of the commands executed during the monitoring process. Add the following lines to your `ha.cf` file:

```
respawn hacluster /usr/lib/heartbeat/dopd
apiauth dopd gid=haclient uid=hacluster
```

Make sure you make the same modification on both your primary and secondary nodes.

Reload the Heartbeat configuration:

```
root-shell> /etc/init.d/heartbeat reload
```

Modify your DRBD configuration by configuration the `outdate-peer` option. Add the configuration line into the `common` section of `/etc/drbd.conf` on both hosts. An example of the full block is shown below:

```
common {
  handlers {
    outdate-peer "/usr/lib/heartbeat/drbd-peer-outdater";
  }
}
```

Finally, set the `fencing` option on your DRBD configured resources:

```
resource my-resource {
  disk {
    fencing    resource-only;
  }
}
```

Now reload your DRBD configuration:

```
root-shell> drbdadmin adjust all
```

You can test the system by unplugging your DRBD link and monitoring the output from `/proc/drbd`.

Dealing with System Level Errors in a Heartbeat Cluster

Because a kernel panic or oops may indicate potential problem with your server, configure your server to remove itself from the cluster in the event of a problem. Typically on a kernel panic, your system automatically triggers a hard reboot. For a kernel oops, a reboot may not happen automatically, but the issue that caused that oops may still lead to potential problems.

You can force a reboot by setting the `kernel.panic` and `kernel.panic_on_oops` parameters of the kernel control file `/etc/sysctl.conf`. For example:

```
kernel.panic_on_oops = 1
kernel.panic = 1
```

You can also set these parameters during runtime by using the `sysctl` command. You can either specify the parameters on the command line:

```
shell> sysctl -w kernel.panic=1
```

Or you can edit your `sysctl.conf` file and then reload the configuration information:

```
shell> sysctl -p
```

Setting both these parameters to a positive value (representing the number of seconds to wait before rebooting), causes the system to reboot. Your second heartbeat node should then detect that the server is down and then switch over to the failover host.

Using MySQL within an Amazon EC2 Instance

The Amazon Elastic Compute Cloud (EC2) service provides virtual servers that you can build and deploy to run a variety of different applications and services, including MySQL. The EC2 service is based around the Xen framework, supporting x86, Linux based, platforms with individual instances of a virtual machine referred to as an Amazon Machine Image (AMI). You have complete (root) access to the AMI instance that you create, enabling you to configure and install your AMI in any way you choose.

To use EC2, you create an AMI based on the configuration and applications that you intend to use, and upload the AMI to the Amazon Simple Storage Service (S3). From the S3 resource, you can deploy one or more copies of the AMI to run as an instance within the EC2 environment. The EC2 environment provides management and control of the instance and contextual information about the instance while it is running.

Because you can create and control the AMI, the configuration, and the applications, you can deploy and create any environment you choose. This includes a basic MySQL server in addition to more extensive replication, HA and scalability scenarios that enable you to take advantage of the EC2 environment, and the ability to deploy additional instances as the demand for your MySQL services and applications grow.

To aid the deployment and distribution of work, three different Amazon EC2 instances are available, small (identified as `m1.small`), large (`m1.large`) and extra large (`m1.xlarge`). The different types provide different levels of computing power measured in EC2 computer units (ECU). A summary of the different instance configurations is shown here.

	Small	**Large**	**Extra Large**
Platform	32-bit	64-bit	64-bit
CPU cores	1	2	4
ECUs	1	4	8
RAM	1.7GB	7.5GB	15GB
Storage	150GB	840GB	1680GB
I/O Performance	Medium	High	High

The typical model for deploying and using MySQL within the EC2 environment is to create a basic AMI that you can use to hold your database data and application. Once the basic environment for your database and application has been created you can then choose to deploy the AMI to a suitable instance. Here the flexibility of having an AMI that can be re-deployed from the small to the large or extra large EC2 instance makes it easy to upgrade the hardware environment without rebuilding your application or database stack.

To get started with MySQL on EC2, including information on how to set up and install MySQL within an EC2 installation and how to port and migrate your data to the running instance, see Setting Up MySQL on an EC2 AMI.

For tips and advice on how to create a scalable EC2 environment using MySQL, including guides on setting up replication, see Deploying a MySQL Database Using EC2.

Setting Up MySQL on an EC2 AMI

There are many different ways of setting up an EC2 AMI with MySQL, including using any of the pre-configured AMIs supplied by Amazon.

The default *Getting Started* AMI provided by Amazon uses Fedora Core 4, and you can install MySQL by using `yum`:

```
shell> yum install mysql
```

This installs both the MySQL server and the Perl DBD::mysql driver for the Perl DBI API.

Alternatively, you can use one of the AMIs that include MySQL within the standard installation.

Finally, you can also install a standard version of MySQL downloaded from the MySQL Web site. The installation process and instructions are identical to any other installation of MySQL on Linux. See Chapter 2, *Installing and Upgrading MySQL*.

The standard configuration for MySQL places the data files in the default location, `/var/lib/mysql`. The default data directory on an EC2 instance is `/mnt` (although on the large and extra large instance you can alter this configuration). You must edit `/etc/my.cnf` to set the `datadir` [423] option to point to the larger storage area.

Important

The first time you use the main storage location within an EC2 instance it needs to be initialized. The initialization process starts automatically the first time you write to the device. You can start using the device right away, but the write performance of the new device is significantly lower on the initial writes until the initialization process has finished.

To avoid this problem when setting up a new instance, you should start the initialization process before populating your MySQL database. One way to do this is to use `dd` to write to the file system:

```
root-shell> dd if=/dev/zero of=initialize bs=1024M count=50
```

The preceding creates a 50GB on the file system and starts the initialization process. Delete the file once the process has finished.

The initialization process can be time-consuming. On the small instance, initialization takes between two and three hours. For the large and extra large drives, the initialization can be 10 or 20 hours, respectively.

In addition to configuring the correct storage location for your MySQL data files, also consider setting the following other settings in your instance before you save the instance configuration for deployment:

- Set the MySQL server ID, so that when you use it for replication, the ID information is set correctly.
- Enabling binary logging, so that replication can be initialized without starting and stopping the server.
- Set the caching and memory parameters for your storage engines. There are no limitations or restrictions on what storage engines you use in your EC2 environment. Choose a configuration, possibly using one of the standard configurations provided with MySQL appropriate for the instance on which you expect to deploy. The large and extra large instances have RAM that can be dedicated to caching. Be aware that if you choose to install `memcached` on the servers as part of your application stack you must ensure there is enough memory for both MySQL and `memcached`.

Once you have configured your AMI with MySQL and the rest of your application stack, save the AMI so that you can deploy and reuse the instance.

Once you have your application stack configured in an AMI, populating your MySQL database with data should be performed by creating a dump of your database using `mysqldump`, transferring the dump to the EC2 instance, and then reloading the information into the EC2 instance database.

Before using your instance with your application in a production situation, be aware of the limitations of the EC2 instance environment. See EC2 Instance Limitations. To begin using your MySQL AMI, consult the notes on deployment. See Deploying a MySQL Database Using EC2.

EC2 Instance Limitations

Be aware of the following limitations of the EC2 instances before deploying your applications. Although these shouldn't affect your ability to deploy within the Amazon EC2 environment, they may alter the way you setup and configure your environment to support your application.

- Data stored within instances is not persistent. If you create an instance and populate the instance with data, then the data only remains in place while the machine is running, and does not survive a reboot. If you shut down the instance, any data it contained is lost.

To ensure that you do not lose information, take regular backups using `mysqldump`. If the data being stored is critical, consider using replication to keep a “live” backup of your data in the event of a failure. When creating a backup, write the data to the Amazon S3 service to avoid the transfer charges applied when copying data offsite.

- EC2 instances are not persistent. If the hardware on which an instance is running fails, the instance is shut down. This can lead to loss of data or service.
- To replicate your EC2 instances to a non-EC2 environment, be aware of the transfer costs to and from the EC2 service. Data transfer between different EC2 instances is free, so using replication within the EC2 environment does not incur additional charges.
- Certain HA features are either not directly supported, or have limiting factors or problems that could reduce their utility. For example, using DRBD or MySQL Cluster might not work. The default storage configuration is also not redundant. You can use software-based RAID to improve redundancy, but this implies a further performance hit.

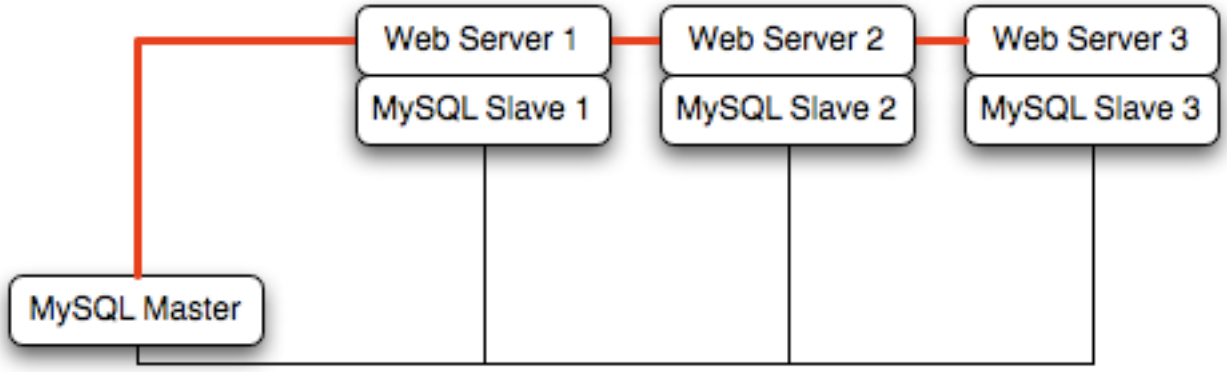
Deploying a MySQL Database Using EC2

Because you cannot guarantee the uptime and availability of your EC2 instances, when deploying MySQL within the EC2 environment, use an approach that enables you to easily distribute work among your EC2 instances. There are a number of ways of doing this. Using sharding techniques, where you split the application across multiple servers dedicating specific blocks of your dataset and users to different servers is an effective way of doing this. As a general rule, it is easier to create more EC2 instances to support more users than to upgrade the instance to a larger machine.

The EC2 architecture works best when you treat the EC2 instances as temporary, cache-based solutions, rather than as a long-term, high availability solution. In addition to using multiple machines, take advantage of other services, such as `memcached` to provide additional caching for your application to help reduce the load on the MySQL server so that it can concentrate on writes. On the large and extra large instances within EC2, the RAM available can provide a large memory cache for data.

Most types of scale-out topology that you would use with your own hardware can be used and applied within the EC2 environment. However, use the limitations and advice already given to ensure that any potential failures do not lose you any data. Also, because the relative power of each EC2 instance is so low, be prepared to alter your application to use sharding and add further EC2 instances to improve the performance of your application.

For example, take the typical scale-out environment shown following, where a single master replicates to one or more slaves (three in this example), with a web server running on each replication slave.

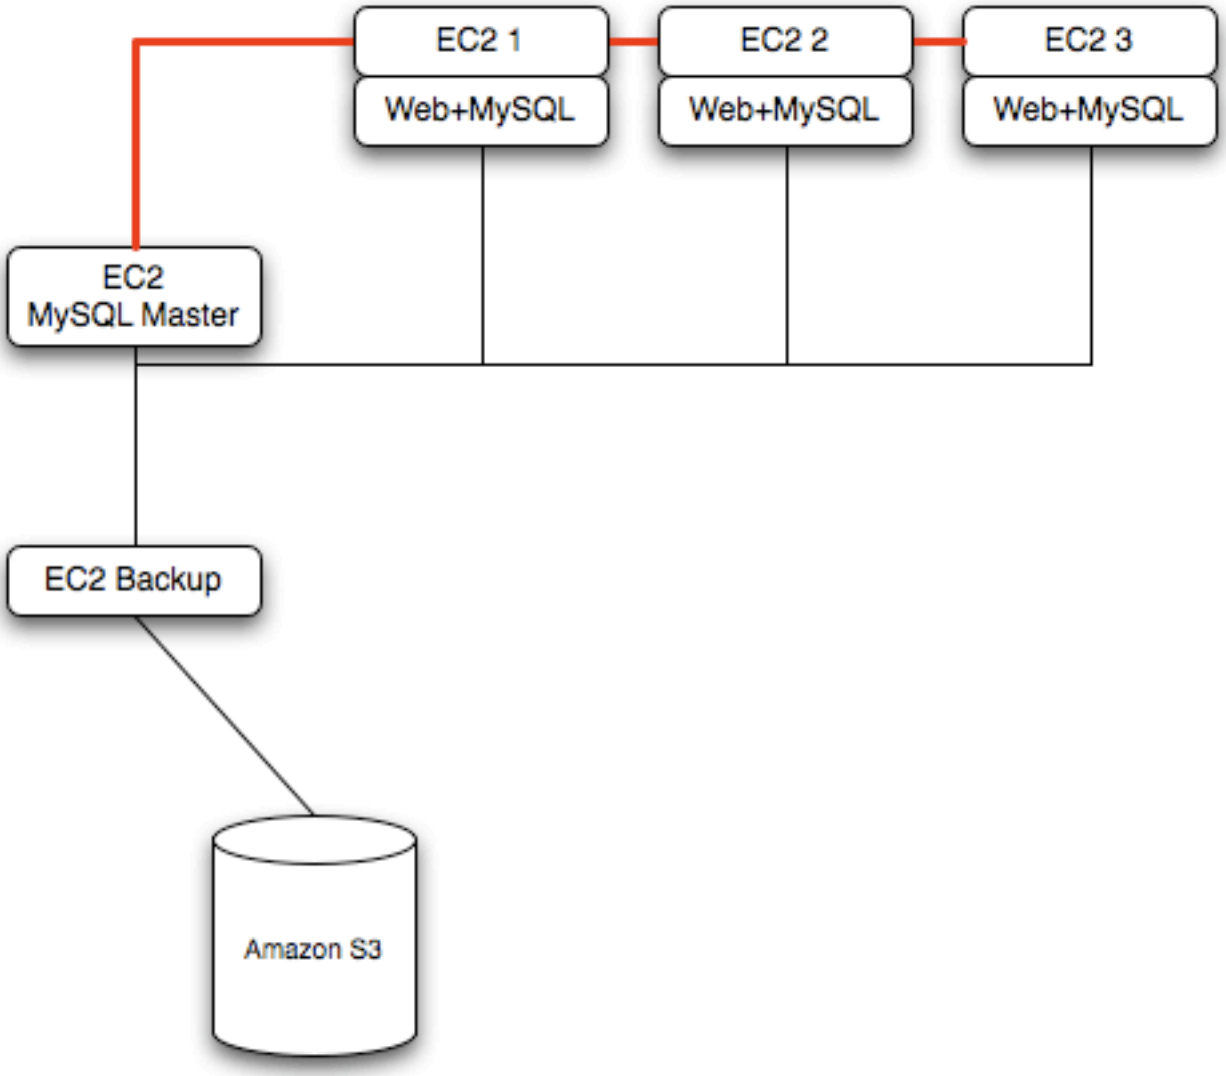


You can reproduce this structure completely within the EC2 environment, using an EC2 instance for the master, and one instance for each of the web and MySQL slave servers.

Note

Within the EC2 environment, internal (private) IP addresses used by the EC2 instances are constant. Always use these internal addresses and names when communicating between instances. Only use public IP addresses when communicating with the outside world - for example, when publicizing your application.

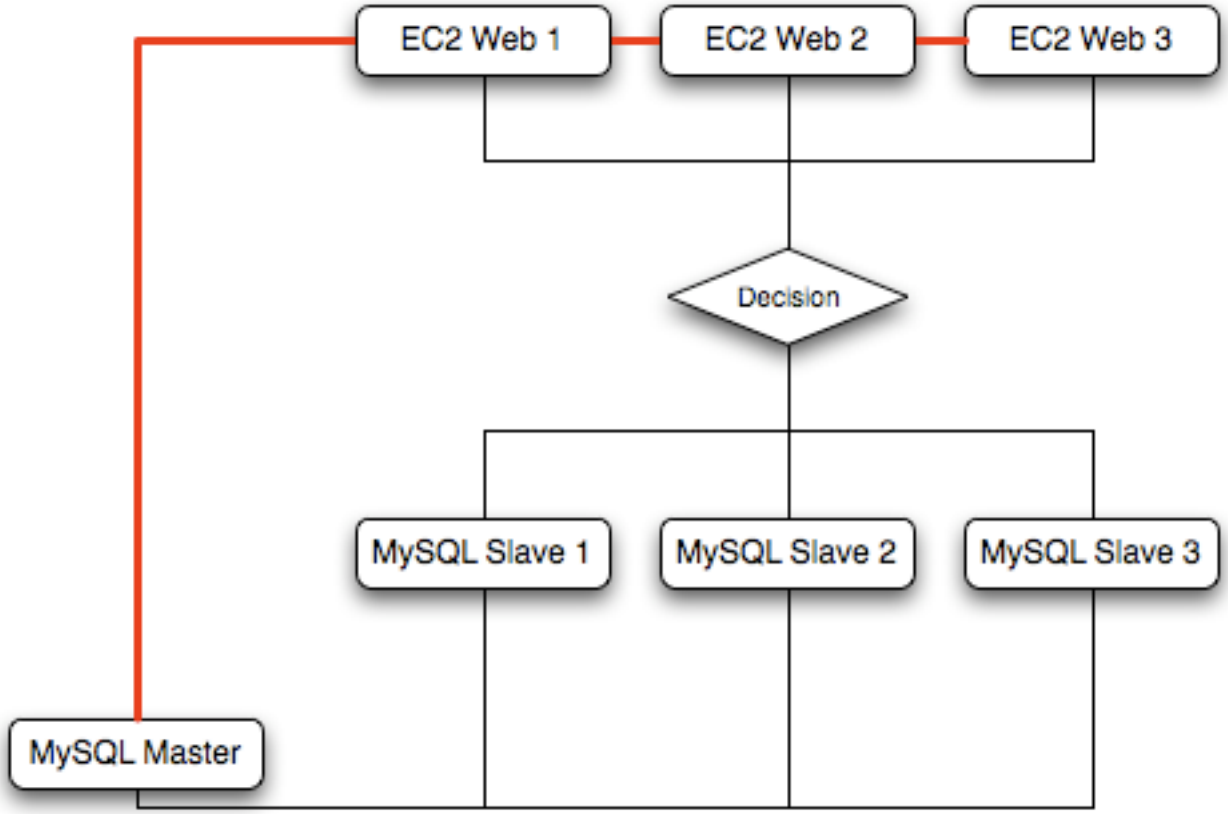
To ensure reliability of your database, add at least one replication slave dedicated to providing an active backup and storage to the Amazon S3 facility. You can see an example of this in the following topology.



Using `memcached` within your EC2 instances should provide better performance. The large and extra large instances have a significant amount of RAM. To use `memcached` in your application, when loading information from the database, first check whether the item exists in the cache. If the data you are looking for exists in the cache, use it. If not, reload the data from the database and populate the cache.

Sharding divides up data in your entire database by allocating individual machines or machine groups to provide a unique set of data according to an appropriate group. For example, you might put all users with a surname ending in the letters A-D onto a single server. When a user connects to the application and their surname is known, queries can be redirected to the appropriate MySQL server.

When using sharding with EC2, separate the web server and MySQL server into separate EC2 instances, and then apply the sharding decision logic into your application. Once you know which MySQL server you should be using for accessing the data you then distribute queries to the appropriate server. You can see a sample of this in the following illustration.



Warning

With sharding and EC2, be careful that the potential for failure of an instance does not affect your application. If the EC2 instance that provides the MySQL server for a particular shard fails, then all of the data on that shard becomes unavailable.

Using ZFS Replication

To support high availability environments, providing an instant copy of the information on both the currently active machine and the hot backup is a critical part of the HA solution. There are many solutions to this problem, including Chapter 16, *Replication* and Using MySQL with DRBD.

The ZFS file system provides functionality to create a snapshot of the file system contents, transfer the snapshot to another machine, and extract the snapshot to recreate the file system. You can create a snapshot at any time, and you can create as many snapshots as you like. By continually creating, transferring, and restoring snapshots, you can provide synchronization between one or more machines in a fashion similar to DRBD.

The following example shows a simple Solaris system running with a single ZFS pool, mounted at `/scratchpool`:

```
Filesystem             size   used  avail capacity  Mounted on
/dev/dsk/c0d0s0        4.6G   3.7G   886M    82%    /
/devices                 0K     0K     0K     0%    /devices
ctfs                     0K     0K     0K     0%    /system/contract
proc                     0K     0K     0K     0%    /proc
```

```
mnttab                    0K     0K     0K     0%    /etc/mnttab
swap                    1.4G   892K   1.4G     1%    /etc/svc/volatile
objfs                     0K     0K     0K     0%    /system/object
/usr/lib/libc/libc_hwcap1.so.1
                        4.6G   3.7G   886M    82%    /lib/libc.so.1
fd                        0K     0K     0K     0%    /dev/fd
swap                    1.4G    40K   1.4G     1%    /tmp
swap                    1.4G    28K   1.4G     1%    /var/run
/dev/dsk/c0d0s7          26G   913M    25G     4%    /export/home
scratchpool              16G    24K    16G     1%    /scratchpool
```

The MySQL data is stored in a directory on `/scratchpool`. To help demonstrate some of the basic replication functionality, there are also other items stored in `/scratchpool` as well:

```
total 17
drwxr-xr-x  31 root     bin           50 Jul 21 07:32 DTT/
drwxr-xr-x   4 root     bin            5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x  14 root     sys           16 Nov  5 09:56 SUNWspro/
drwxrwxrwx  19 1000     1000          40 Nov  6 19:16 emacs-22.1/
```

To create a snapshot of the file system, you use `zfs snapshot`, specifying the pool and the snapshot name:

```
root-shell> zfs snapshot scratchpool@snap1
```

To list the snapshots already taken:

```
root-shell> zfs list -t snapshot
NAME                 USED  AVAIL  REFER  MOUNTPOINT
scratchpool@snap1      0      -  24.5K  -
scratchpool@snap2      0      -  24.5K  -
```

The snapshots themselves are stored within the file system metadata, and the space required to keep them varies as time goes on because of the way the snapshots are created. The initial creation of a snapshot is very quick, because instead of taking an entire copy of the data and metadata required to hold the entire snapshot, ZFS records only the point in time and metadata of when the snapshot was created.

As more changes to the original file system are made, the size of the snapshot increases because more space is required to keep the record of the old blocks. If you create lots of snapshots, say one per day, and then delete the snapshots from earlier in the week, the size of the newer snapshots might also increase, as the changes that make up the newer state have to be included in the more recent snapshots, rather than being spread over the seven snapshots that make up the week.

You cannot directly back up the snapshots because they exist within the file system metadata rather than as regular files. To get the snapshot into a format that you can copy to another file system, tape, and so on, you use the `zfs send` command to create a stream version of the snapshot.

For example, to write the snapshot out to a file:

```
root-shell> zfs send scratchpool@snap1 >/backup/scratchpool-snap1
```

Or tape:

```
root-shell> zfs send scratchpool@snap1 >/dev/rmt/0
```

You can also write out the incremental changes between two snapshots using `zfs send`:

```
root-shell> zfs send scratchpool@snap1 scratchpool@snap2 >/backup/scratchpool-changes
```

To recover a snapshot, you use `zfs recv`, which applies the snapshot information either to a new file system, or to an existing one.

Using ZFS for File System Replication

Because `zfs send` and `zfs recv` use streams to exchange data, you can use them to replicate information from one system to another by combining `zfs send`, `ssh`, and `zfs recv`.

For example, to copy a snapshot of the `scratchpool` file system to a new file system called `slavepool` on a new server, you would use the following command. This sequence combines the snapshot of `scratchpool`, the transmission to the slave machine (using `ssh` with login credentials), and the recovery of the snapshot on the slave using `zfs recv`:

```
root-shell> zfs send scratchpool@snap1 |ssh id@host pfexec zfs recv -F slavepool
```

The first part of the pipeline, `zfs send scratchpool@snap1`, streams the snapshot. The `ssh` command, and the command that it executes on the other server, `pfexec zfs recv -F slavepool`, receives the streamed snapshot data and writes it to slavepool. In this instance, I've specified the `-F` option which forces the snapshot data to be applied, and is therefore destructive. This is fine, as I'm creating the first version of my replicated file system.

On the slave machine, the replicated file system contains the exact same content:

```
root-shell> ls -al /slavepool/
total 23
drwxr-xr-x   6 root     root           7 Nov  8 09:13 ./
drwxr-xr-x  29 root     root          34 Nov  9 07:06 ../
drwxr-xr-x  31 root     bin           50 Jul 21 07:32 DTT/
drwxr-xr-x   4 root     bin            5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x  14 root     sys           16 Nov  5 09:56 SUNWspro/
drwxrwxrwx  19 1000     1000          40 Nov  6 19:16 emacs-22.1/
```

Once a snapshot has been created, to synchronize the file system again, you create a new snapshot and then use the incremental snapshot feature of `zfs send` to send the changes between the two snapshots to the slave machine again:

```
root-shell> zfs send -i scratchpool@snapshot1 scratchpool@snapshot2 |ssh id@host pfexec zfs recv slavepool
```

This operation only succeeds if the file system on the slave machine has not been modified at all. You cannot apply the incremental changes to a destination file system that has changed. In the example above, the `ls` command would cause problems by changing the metadata, such as the last access time for files or directories.

To prevent changes on the slave file system, set the file system on the slave to be read-only:

```
root-shell> zfs set readonly=on slavepool
```

Setting `readonly` means that you cannot change the file system on the slave by normal means, including the file system metadata. Operations that would normally update metadata (like our `ls`) silently perform their function without attempting to update the file system state.

In essence, the slave file system is nothing but a static copy of the original file system. However, even when configured to to be read-only, a file system can have snapshots applied to it. With the file system set to read only, re-run the initial copy:

```
root-shell> zfs send scratchpool@snap1 |ssh id@host pfexec zfs recv -F slavepool
```

Now you can make changes to the original file system and replicate them to the slave.

Configuring MySQL for ZFS Replication

Configuring MySQL on the source file system is a case of creating the data on the file system that you intend to replicate. The configuration file in the example below has been updated to use `/scratchpool/mysql-data` as the data directory, and now you can initialize the tables:

```
root-shell> mysql_install_db --defaults-file=/etc/mysql/5.5/my.cnf --user=mysql
```

To synchronize the initial information, perform a new snapshot and then send an incremental snapshot to the slave using `zfs send`:

```
root-shell> zfs snapshot scratchpool@snap2
root-shell> zfs send -i scratchpool@snap1 scratchpool@snap2|ssh id@host pfexec zfs recv slavepool
```

Doublecheck that the slave has the data by looking at the MySQL data directory on the `slavepool`:

```
root-shell> ls -al /slavepool/mysql-data/
```

Now you can start up MySQL, create some data, and then replicate the changes using `zfs send`/`zfs recv` to the slave to synchronize the changes.

The rate at which you perform the synchronization depends on your application and environment. The limitation is the speed required to perform the snapshot and then to send the changes over the network.

To automate the process, create a script that performs the snapshot, send, and receive operation, and use `cron` to synchronize the changes at set times or intervals. For automated operations, see Tim Foster's zfs replication tool.

Handling MySQL Recovery with ZFS

When using ZFS replication to provide a constant copy of your data, ensure that you can recover your tables, either manually or automatically, in the event of a failure of the original system.

In the event of a failure, follow this sequence:

1. Stop the script on the master, if it is still up and running.
2. Set the slave file system to be read/write:

   ```
   root-shell> zfs set readonly=off slavepool
   ```

3. Start up `mysqld` on the slave. If you are using `InnoDB`, you get auto-recovery, if it is needed, to make sure the table data is correct, as shown here when I started up from our mid-INSERT snapshot:

   ```
   InnoDB: The log sequence number in ibdata files does not match
   InnoDB: the log sequence number in the ib_logfiles!
   081109 15:59:59  InnoDB: Database was not shut down normally!
   InnoDB: Starting crash recovery.
   InnoDB: Reading tablespace information from the .ibd files...
   InnoDB: Restoring possible half-written data pages from the doublewrite
   InnoDB: buffer...
   081109 16:00:03  InnoDB: Started; log sequence number 0 1142807951
   081109 16:00:03 [Note] /slavepool/mysql-5.0.67-solaris10-i386/bin/mysqld: ready for connections.
   Version: '5.0.67'  socket: '/tmp/mysql.sock'  port: 3306  MySQL Community Server (GPL)
   ```

Use `InnoDB` tables and a regular synchronization schedule to reduce the risk for significant data loss. On MyISAM tables, you might need to run `REPAIR TABLE`, and you might even have lost some information.

Using MySQL with `memcached`

`memcached` is a simple, highly scalable key-based cache that stores data and objects wherever dedicated or spare RAM is available for quick access by applications, without going through layers of parsing or disk I/O. To use, you run the `memcached` command on one or more hosts and then use the shared cache to store objects. For more usage instructions, see Using `memcached`

Benefits of using `memcached` include:

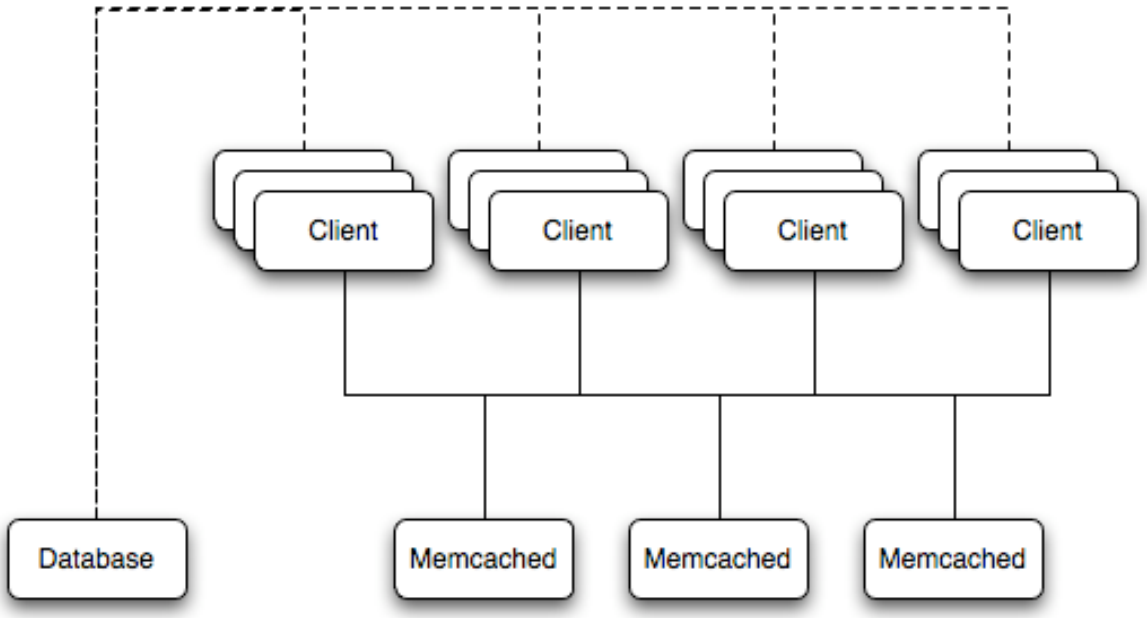
- Because all information is stored in RAM, the access speed is faster than loading the information each time from disk.
- Because the “value” portion of the key-value pair does not have any data type restrictions, you can cache data such as complex structures, documents, images, or a mixture of such things.
- If you use the in-memory cache to hold transient information, or as a read-only cache for information also stored in a database, the failure of any `memcached` server is not critical. For persistent data, you

can fall back to an alternative lookup method using database queries, and reload the data into RAM on a different server.

The typical usage environment is to modify your application so that information is read from the cache provided by memcached. If the information is not in memcached, then the data is loaded from the MySQL database and written into the cache so that future requests for the same object benefit from the cached data.

For a typical deployment layout, see Figure 15.5, “memcached Architecture Overview”.

Figure 15.5. memcached Architecture Overview



In the example structure, any of the clients can contact one of the memcached servers to request a given key. Each client is configured to talk to all of the servers shown in the illustration. Within the client, when the request is made to store the information, the key used to reference the data is hashed and this hash is then used to select one of the memcached servers. The selection of the memcached server takes place on the client before the server is contacted, keeping the process lightweight.

The same algorithm is used again when a client requests the same key. The same key generates the same hash, and the same memcached server is selected as the source for the data. Using this method, the cached data is spread among all of the memcached servers, and the cached information is accessible from any client. The result is a distributed, memory-based, cache that can return information, particularly complex data and structures, much faster than natively reading the information from the database.

The data held within a traditional memcached server is never stored on disk (only in RAM, which means there is no persistence of data), and the RAM cache is always populated from the backing store (a MySQL database). If a memcached server fails, the data can always be recovered from the MySQL database.

memcached Integration with MySQL Storage Engines

In April 2011, MySQL announced the preview of a new memcached interface for the InnoDB and MySQL Cluster storage engines.

Using the memcached API, web services can directly access the InnoDB and MySQL Cluster storage engines without transformations to SQL, ensuring low latency and high throughput for read/write queries. Operations such as SQL parsing are eliminated and more of the server’s hardware resources

(CPU, memory and I/O) are dedicated to servicing the query within the storage engine itself. The memcached data can be persisted to disk while still cached in memory for fast retrieval.

These are targeted to be incorporated into future MySQL 5.6 Milestone and MySQL Cluster Development Releases.

You can learn more about these interfaces from this Dev Zone article: http://dev.mysql.com/tech-resources/articles/nosql-to-mysql-with-memcached.html.

Installing memcached

You can build and install memcached from the source code directly, or you can use an existing operating system package or installation.

Installing memcached from a Binary Distribution

To install memcached on a Red Hat, or Fedora host, use yum:

```
root-shell> yum install memcached
```

Note

On CentOS, you may be able to obtain a suitable RPM from another source, or use the source tarball.

To install memcached on a Debian or Ubuntu host, use apt-get:

```
root-shell> apt-get install memcached
```

To install memcached on a Gentoo host, use emerge:

```
root-shell> emerge install memcached
```

Building memcached from Source

On other Unix-based platforms, including Solaris, AIX, HP-UX and Mac OS X, and Linux distributions not mentioned already, you must install from source. For Linux, make sure you have a 2.6-based kernel, which includes the improved epoll interface. For all platforms, ensure that you have libevent 1.1 or higher installed. You can obtain libevent from libevent web page.

You can obtain the source for memcached from memcached Web site.

To build memcached, follow these steps:

1. Extract the memcached source package:

   ```
   shell> gunzip -c memcached-1.2.5.tar.gz | tar xf -
   ```

2. Change to the memcached-1.2.5 directory:

   ```
   shell> cd memcached-1.2.5
   ```

3. Run configure

   ```
   shell> ./configure
   ```

   Some additional options you might specify to the configure:

   - --prefix

     To specify a different installation directory, use the --prefix option:

     ```
     shell> ./configure --prefix=/opt
     ```

     The default is to use the /usr/local directory.

- `--with-libevent`

  If you have installed `libevent` and `configure` cannot find the library, use the `--with-libevent` option to specify the location of the installed library.

- `--enable-64bit`

  To build a 64-bit version of `memcached` (which enables you to use a single instance with a large RAM allocation), use `--enable-64bit`.

- `--enable-threads`

  To enable multi-threading support in `memcached`, which improves the response times on servers with a heavy load, use `--enable-threads`. You must have support for the POSIX threads within your operating system to enable thread support. For more information on the threading support, see `memcached` Thread Support.

- `--enable-dtrace`

  `memcached` includes a range of DTrace threads that can be used to monitor and benchmark a `memcached` instance. For more information, see Using `memcached` and DTrace.

4. Run `make` to build `memcached`:

   ```
   shell> make
   ```

5. Run `make install` to install `memcached`:

   ```
   shell> make install
   ```

Using `memcached`

To start using `memcached`, start the `memcached` service on one or more servers. Running `memcached` sets up the server, allocates the memory and starts listening for connections from clients.

Note

You do not need to be a privileged user (`root`) to run `memcached` except to listen on one of the privileged TCP/IP ports (below 1024). You must, however, use a user that has not had their memory limits restricted using `setrlimit` or similar.

To start the server, run `memcached` as a nonprivileged (that is, non-`root`) user:

```
shell> memcached
```

By default, `memcached` uses the following settings:

- Memory allocation of 64MB
- Listens for connections on all network interfaces, using port 11211
- Supports a maximum of 1024 simultaneous connections

Typically, you would specify the full combination of options that you want when starting `memcached`, and normally provide a startup script to handle the initialization of `memcached`. For example, the following line starts `memcached` with a maximum of 1024MB RAM for the cache, listening on port 11211 on the IP address 192.168.0.110, running as a background daemon:

```
shell> memcached -d -m 1024 -p 11211 -l 192.168.0.110
```

To ensure that `memcached` is started up on boot, check the init script and configuration parameters.

memcached supports the following options:

- -u user

  If you start memcached as root, use the -u option to specify the user for executing memcached:

```
shell> memcached -u memcache
```

- -m memory

  Set the amount of memory allocated to memcached for object storage. Default is 64MB.

  To increase the amount of memory allocated for the cache, use the -m option to specify the amount of RAM to be allocated (in megabytes). The more RAM you allocate, the more data you can store and therefore the more effective your cache is.

Warning

Do not specify a memory allocation larger than your available RAM. If you specify too large a value, then some RAM allocated for memcached uses swap space, and not physical RAM. This may lead to delays when storing and retrieving values, because data is swapped to disk, instead of storing the data directly in RAM.

You can use the output of the vmstat command to get the free memory, as shown in free column:

```
shell> vmstat
kthr      memory            page            disk          faults      cpu
r b w   swap  free  re  mf pi po fr de sr s1 s2 -- --   in   sy   cs us sy id
0 0 0 5170504 3450392 2  7  2  0  0  0  4  0  0  0  0  296   54  199  0  0 100
```

  For example, to allocate 3GB of RAM:

```
shell> memcached -m 3072
```

  On 32-bit x86 systems where you are using PAE to access memory above the 4GB limit, you cannot allocate RAM beyond the maximum process size. You can get around this by running multiple instances of memcached, each listening on a different port:

```
shell> memcached -m 1024 -p11211
shell> memcached -m 1024 -p11212
shell> memcached -m 1024 -p11213
```

Note

On all systems, particularly 32-bit, ensure that you leave enough room for both memcached application in addition to the memory setting. For example, if you have a dedicated memcached host with 4GB of RAM, do not set the memory size above 3500MB. Failure to do this may cause either a crash or severe performance issues.

- -l interface

  Specify a network interface/address to listen for connections. The default is to listen on all available address (INADDR_ANY).

```
shell> memcached -l 192.168.0.110
```

  Support for IPv6 address support was added in memcached 1.2.5.

- -p port

  Specify the TCP port to use for connections. Default is 18080.

```
shell> memcached -p 18080
```

- `-U port`

  Specify the UDP port to use for connections. Default is 11211, 0 switches UDP off.

  ```
  shell> memcached -U 18080
  ```

- `-s socket`

  Specify a Unix socket to listen on.

  If you are running `memcached` on the same server as the clients, you can disable the network interface and use a local UNIX socket using the `-s` option:

  ```
  shell> memcached -s /tmp/memcached
  ```

  Using a UNIX socket automatically disables network support, and saves network ports (allowing more ports to be used by your web server or other process).

- `-a mask`

  Specify the access mask to be used for the Unix socket, in octal. Default is 0700.

- `-c connections`

  Specify the maximum number of simultaneous connections to the `memcached` service. The default is 1024.

  ```
  shell> memcached -c 2048
  ```

  Use this option, either to reduce the number of connections (to prevent overloading `memcached` service) or to increase the number to make more effective use of the server running `memcached` server.

- `-t threads`

  Specify the number of threads to use when processing incoming requests.

  By default, `memcached` is configured to use 4 concurrent threads. The threading improves the performance of storing and retrieving data in the cache, using a locking system to prevent different threads overwriting or updating the same values. To increase or decrease the number of threads, use the `-t` option:

  ```
  shell> memcached -t 8
  ```

- `-d`

  Run `memcached` as a daemon (background) process:

  ```
  shell> memcached -d
  ```

- `-r`

  Maximize the size of the core file limit. In the event of a failure, this attempts to dump the entire memory space to disk as a core file, up to any limits imposed by `setrlimit`.

- `-M`

  Return an error to the client when the memory has been exhausted. This replaces the normal behavior of removing older items from the cache to make way for new items.

- `-k`

Lock down all paged memory. This reserves the memory before use, instead of allocating new slabs of memory as new items are stored in the cache.

Note

There is a user-level limit on how much memory you can lock. Trying to allocate more than the available memory fails. You can set the limit for the user you started the daemon with (not for the `-u user` user) within the shell by using `ulimit -S -l NUM_KB`

- `-v`

  Verbose mode. Prints errors and warnings while executing the main event loop.

- `-vv`

  Very verbose mode. In addition to information printed by `-v`, also prints each client command and the response.

- `-vvv`

  Extremely verbose mode. In addition to information printed by `-vv`, also show the internal state transitions.

- `-h`

  Print the help message and exit.

- `-i`

  Print the `memcached` and `libevent` license.

- `-I mem`

  Specify the maximum size permitted for storing an object within the `memcached` instance. The size supports a unit postfix (`k` for kilobytes, `m` for megabytes). For example, to increase the maximum supported object size to 32MB:

  ```
  shell> memcached -I 32m
  ```

  The maximum object size you can specify is 128MB, the default remains at 1MB.

  This option was added in 1.4.2.

- `-b`

  Set the backlog queue limit. The backlog queue configures how many network connections can be waiting to be processed by `memcached`. Increasing this limit may reduce errors received by the client that it is not able to connect to the `memcached` instance, but does not improve the performance of the server. The default is 1024.

- `-P pidfile`

  Save the process ID of the `memcached` instance into `file`.

- `-f`

  Set the chunk size growth factor. When allocating new memory chunks, the allocated size of new chunks is determined by multiplying the default slab size by this factor.

  To see the effects of this option without extensive testing, use the `-vv` command-line option to show the calculated slab sizes. For more information, see `memcached` Logs.

- `-n bytes`

  The minimum space allocated for the key+value+flags information. The default is 48 bytes.

- `-L`

  On systems that support large memory pages, enables large memory page use. Using large memory pages enables `memcached` to allocate the item cache in one large chunk, which can improve the performance by reducing the number misses when accessing memory.

- `-C`

  Disable the use of compare and swap (CAS) operations.

  This option was added in `memcached` 1.3.x.

- `-D char`

  Set the default character to be used as a delimiter between the key prefixes and IDs. This is used for the per-prefix statistics reporting (see Getting `memcached` Statistics). The default is the colon (`:`). If this option is used, statistics collection is turned on automatically. If not used, you can enable stats collection by sending the `stats detail on` command to the server.

  This option was added in `memcached` 1.3.x.

- `-R num`

  Sets the maximum number of requests per event process. The default is 20.

- `-B protocol`

  Set the binding protocol, that is, the default `memcached` protocol support for client connections. Options are `ascii`, `binary` or `auto`. Automatic (`auto`) is the default.

  This option was added in `memcached` 1.4.0.

`memcached` Deployment

When using `memcached` you can use a number of different potential deployment strategies and topologies. The exact strategy to use depends on your application and environment. When developing a system for deploying `memcached` within your system, keep in mind the following points:

- `memcached` is only a caching mechanism. It shouldn't be used to store information that you cannot otherwise afford to lose and then load from a different location.
- There is no security built into the `memcached` protocol. At a minimum, make sure that the servers running `memcached` are only accessible from inside your network, and that the network ports being used are blocked (using a firewall or similar). If the information on the `memcached` servers that is being stored is any sensitive, then encrypt the information before storing it in `memcached`.
- `memcached` does not provide any sort of failover. Because there is no communication between different `memcached` instances. If an instance fails, your application must capable of removing it from the list, reloading the data and then writing data to another `memcached` instance.
- Latency between the clients and the `memcached` can be a problem if you are using different physical machines for these tasks. If you find that the latency is a problem, move the `memcached` instances to be on the clients.
- Key length is determined by the `memcached` server. The default maximum key size is 250 bytes.
- Try to use at least two `memcached` instances, especially for multiple clients, to avoid having a single point of failure. Ideally, create as many `memcached` nodes as possible. When adding and removing

memcached instances from a pool, the hashing and distribution of key/value pairs may be affected. For information on how to avoid problems, see memcached Hashing/Distribution Types.

Using Namespaces

The memcached cache is a very simple massive key/value storage system, and as such there is no way of compartmentalizing data automatically into different sections. For example, if you are storing information by the unique ID returned from a MySQL database, then storing the data from two different tables could run into issues because the same ID might be valid in both tables.

Some interfaces provide an automated mechanism for creating *namespaces* when storing information into the cache. In practice, these namespaces are merely a prefix before a given ID that is applied every time a value is stored or retrieve from the cache.

You can implement the same basic principle by using keys that describe the object and the unique identifier within the key that you supply when the object is stored. For example, when storing user data, prefix the ID of the user with `user:` or `user-`.

Note

Using namespaces or prefixes only controls the keys stored/retrieved. There is no security within memcached, and therefore no way to enforce that a particular client only accesses keys with a particular namespace. Namespaces are only useful as a method of identifying data and preventing corruption of key/value pairs.

Data Expiry

There are two types of data expiry within a memcached instance. The first type is applied at the point when you store a new key/value pair into the memcached instance. If there is not enough space within a suitable slab to store the value, then an existing least recently used (LRU) object is removed (evicted) from the cache to make room for the new item.

The LRU algorithm ensures that the object that is removed is one that is either no longer in active use or that was used so long ago that its data is potentially out of date or of little value. However, in a system where the memory allocated to memcached is smaller than the number of regularly used objects required in the cache, a lot of expired items could be removed from the cache even though they are in active use. You use the statistics mechanism to get a better idea of the level of evictions (expired objects). For more information, see Getting memcached Statistics.

You can change this eviction behavior by setting the `-M` command-line option when starting memcached. This option forces an error to be returned when the memory has been exhausted, instead of automatically evicting older data.

The second type of expiry system is an explicit mechanism that you can set when a key/value pair is inserted into the cache, or when deleting an item from the cache. Using an expiration time can be a useful way of ensuring that the data in the cache is up to date and in line with your application needs and requirements.

A typical scenario for explicitly setting the expiry time might include caching session data for a user when accessing a Web site. memcached uses a lazy expiry mechanism where the explicit expiry time that has been set is compared with the current time when the object is requested. Only objects that have not expired are returned.

You can also set the expiry time when explicitly deleting an object from the cache. In this case, the expiry time is really a timeout and indicates the period when any attempts to set the value for a given key are rejected.

memcached Hashing/Distribution Types

The memcached client interface supports a number of different distribution algorithms that are used in multi-server configurations to determine which host should be used when setting or getting data from

a given memcached instance. When you get or set a value, a hash is constructed from the supplied key and then used to select a host from the list of configured servers. Because the hashing mechanism uses the supplied key as the basis for the hash, the same server is selected during both set and get operations.

You can think of this process as follows. Given an array of servers (a, b, and c), the client uses a hashing algorithm that returns an integer based on the key being stored or retrieved. The resulting value is then used to select a server from the list of servers configured in the client. Most standard client hashing within memcache clients uses a simple modulus calculation on the value against the number of configured memcached servers. You can summarize the process in pseudocode as:

```
@memcservers = ['a.memc','b.memc','c.memc'];
$value = hash($key);
$chosen = $value % length(@memcservers);
```

Replacing the above with values:

```
@memcservers = ['a.memc','b.memc','c.memc'];
$value = hash('myid');
$chosen = 7009 % 3;
```

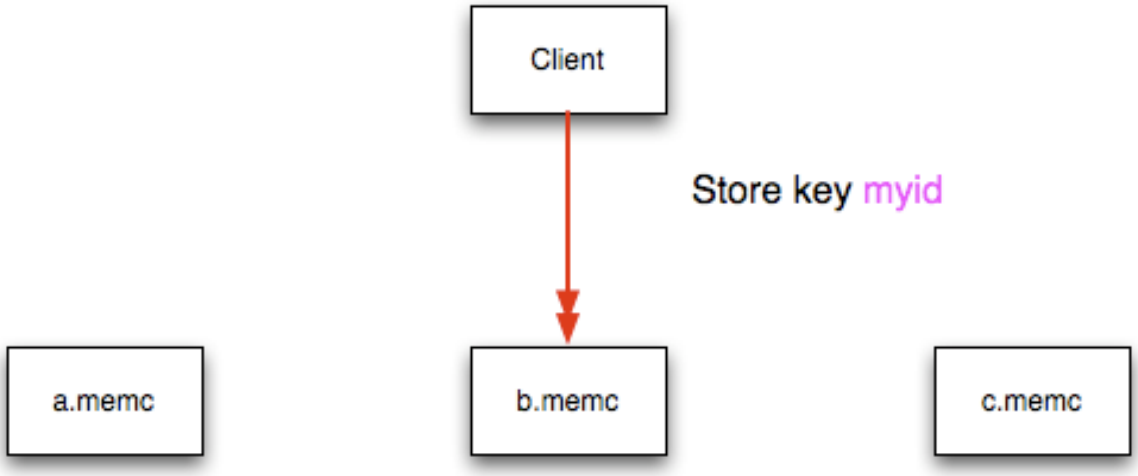
In the above example, the client hashing algorithm chooses the server at index 1 (`7009 % 3 = 1`), and store or retrieve the key and value with that server.

Note

This selection and hashing process is handled automatically by the memcached client you are using; you need only provide the list of memcached servers to use.

You can see a graphical representation of this below in Figure 15.6, “memcached Hash Selection”.

Figure 15.6. memcached Hash Selection



The same hashing and selection process takes place during any operation on the specified key within the memcached client.

Using this method provides a number of advantages:

- The hashing and selection of the server to contact is handled entirely within the client. This eliminates the need to perform network communication to determine the right machine to contact.
- Because the determination of the memcached server occurs entirely within the client, the server can be selected automatically regardless of the operation being executed (set, get, increment, etc.).

- Because the determination is handled within the client, the hashing algorithm returns the same value for a given key; values are not affected or reset by differences in the server environment.
- Selection is very fast. The hashing algorithm on the key value is quick and the resulting selection of the server is from a simple array of available machines.
- Using client-side hashing simplifies the distribution of data over each memcached server. Natural distribution of the values returned by the hashing algorithm means that keys are automatically spread over the available servers.

Providing that the list of servers configured within the client remains the same, the same stored key returns the same value, and therefore selects the same server.

However, if you do not use the same hashing mechanism then the same data may be recorded on different servers by different interfaces, both wasting space on your memcached and leading to potential differences in the information.

Note

One way to use a multi-interface compatible hashing mechanism is to use the libmemcached library and the associated interfaces. Because the interfaces for the different languages (including C, Ruby, Perl and Python) use the same client library interface, they always generate the same hash code from the ID.

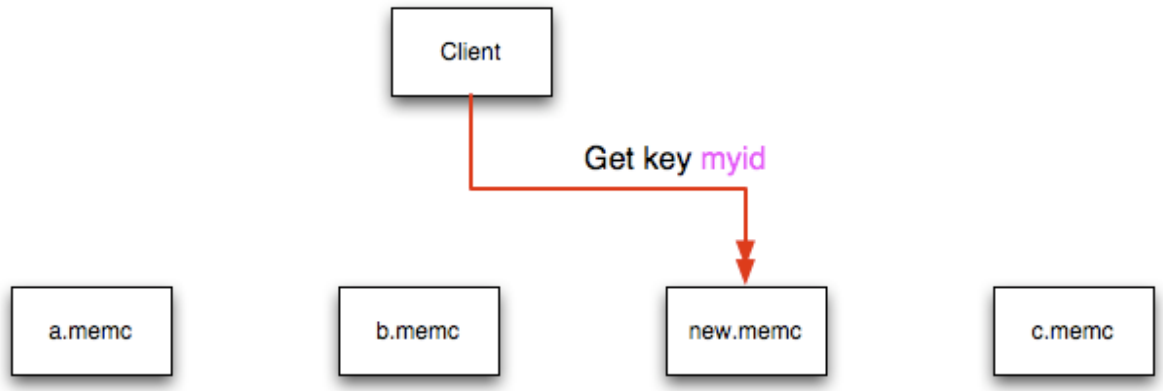
The problem with client-side selection of the server is that the list of the servers (including their sequential order) *must* remain consistent on each client using the memcached servers, and the servers must be available. If you try to perform an operation on a key when:

- A new memcached instance has been added to the list of available instances
- A memcached instance has been removed from the list of available instances
- The order of the memcached instances has changed

When the hashing algorithm is used on the given key, but with a different list of servers, the hash calculation may choose a different server from the list.

If a new memcached instance is added into the list of servers, as new.memc is in the example below, then a GET operation using the same key, myid, can result in a cache-miss. This is because the same value is computed from the key, which selects the same index from the array of servers, but index 2 now points to the new server, not the server c.memc where the data was originally stored. This would result in a cache miss, even though the key exists within the cache on another memcached instance.

Figure 15.7. memcached Hash Selection with New memcached instance



This means that servers c.memc and new.memc both contain the information for key myid, but the information stored against the key in eachs server may be different in each instance. A more significant problem is a much higher number of cache-misses when retrieving data, as the addition of a new server changes the distribution of keys, and this in turn requires rebuilding the cached data on the memcached instances, causing an increase in database reads.

The same effect can occur if you actively manage the list of servers configured in your clients, adding and removing the configured memcached instances as each instance is identified as being available. For example, removing a memcached instance when the client notices that the instance can no longer be contacted can cause the server selection to fail as described here.

To prevent this causing significant problems and invalidating your cache, you can select the hashing algorithm used to select the server. There are two common types of hashing algorithm, *consistent* and *modula*.

With *consistent* hashing algorithms, the same key when applied to a list of servers always uses the same server to store or retrieve the keys, even if the list of configured servers changes. This means that you can add and remove servers from the configure list and always use the same server for a given key. There are two types of consistent hashing algorithms available, Ketama and Wheel. Both types are supported by libmemcached, and implementations are available for PHP and Java.

Any consistent hashing algorithm has some limitations. When you add servers to an existing list of configured servers, keys are distributed to the new servers as part of the normal distribution. When you remove servers from the list, the keys are re-allocated to another server within the list, meaning that the cache needs to be re-populated with the information. Also, a consistent hashing algorithm does not resolve the issue where you want consistent selection of a server across multiple clients, but where each client contains a different list of servers. The consistency is enforced only within a single client.

With a *modula* hashing algorithm, the client selects a server by first computing the hash and then choosing a server from the list of configured servers. As the list of servers changes, so the server selected when using a modula hashing algorithm also changes. The result is the behavior described above; changes to the list of servers mean that different servers are selected when retrieving data, leading to cache misses and increase in database load as the cache is re-seeded with information.

If you use only a single memcached instance for each client, or your list of memcached servers configured for a client never changes, then the selection of a hashing algorithm is irrelevant, as it has no noticeable effect.

If you change your servers regularly, or you use a common set of servers that are shared among a large number of clients, then using a consistent hashing algorithm should help to ensure that your cache data is not duplicated and the data is evenly distributed.

Using memcached and DTrace

memcached includes a number of different DTrace probes that can be used to monitor the operation of the server. The probes included can monitor individual connections, slab allocations, and modifications to the hash table when a key/value pair is added, updated, or removed.

For more information on DTrace and writing DTrace scripts, read the DTrace User Guide.

Support for DTrace probes was added to memcached 1.2.6 includes a number of DTrace probes that can be used to help monitor your application. DTrace is supported on Solaris 10, OpenSolaris, Mac OS X 10.5 and FreeBSD. To enable the DTrace probes in memcached, build from source and use the --enable-dtrace option. For more information, see Installing memcached.

The probes supported by memcached are:

- conn-allocate(connid)

  Fired when a connection object is allocated from the connection pool.

  - connid: The connection ID.
- conn-release(connid)

  Fired when a connection object is released back to the connection pool.

  Arguments:

  - connid: The connection ID.
- conn-create(ptr)

  Fired when a new connection object is being created (that is, there are no free connection objects in the connection pool).

  Arguments:

  - ptr: A pointer to the connection. object
- conn-destroy(ptr)

  Fired when a connection object is being destroyed.

  Arguments:

  - ptr: A pointer to the connection object.
- conn-dispatch(connid, threadid)

  Fired when a connection is dispatched from the main or connection-management thread to a worker thread.

  Arguments:

  - connid: The connection ID.
  - threadid: The thread ID.
- slabs-allocate(size, slabclass, slabsize, ptr)

  Allocate memory from the slab allocator.

  Arguments:

  - size: The requested size.
  - slabclass: The allocation is fulfilled in this class.
  - slabsize: The size of each item in this class.
  - ptr: A pointer to allocated memory.
- slabs-allocate-failed(size, slabclass)

  Failed to allocate memory (out of memory).

  Arguments:

  - size: The requested size.
  - slabclass: The class that failed to fulfill the request.
- slabs-slabclass-allocate(slabclass)

Fired when a slab class needs more space.

Arguments:

- `slabclass`: The class that needs more memory.

- `slabs-slabclass-allocate-failed(slabclass)`

  Failed to allocate memory (out of memory).

  Arguments:

  - `slabclass`: The class that failed to grab more memory.

- `slabs-free(size, slabclass, ptr)`

  Release memory.

  Arguments:

  - `size`: The amount of memory to release, in bytes.
  - `slabclass`: The class the memory belongs to.
  - `ptr`: A pointer to the memory to release.

- `assoc-find(key, depth)`

  Fired when we have searched the hash table for a named key. These two elements provide an insight into how well the hash function operates. Traversals are a sign of a less optimal function, wasting CPU capacity.

  Arguments:

  - `key`: The key searched for.
  - `depth`: The depth in the list of hash table.

- `assoc-insert(key, nokeys)`

  Fired when a new item has been inserted.

  Arguments:

  - `key`: The key just inserted.
  - `nokeys`: The total number of keys currently being stored, including the key for which insert was called.

- `assoc-delete(key, nokeys)`

  Fired when a new item has been removed.

  Arguments:

  - `key`: The key just deleted.
  - `nokeys`: The total number of keys currently being stored, excluding the key for which delete was called.

- `item-link(key, size)`

  Fired when an item is being linked in the cache.

Arguments:

- key: The items key.
- size: The size of the data.

- item-unlink(key, size)

  Fired when an item is being deleted.

  Arguments:

  - key: The items key.
  - size: The size of the data.

- item-remove(key, size)

  Fired when the refcount for an item is reduced.

  Arguments:

  - key: The item's key.
  - size: The size of the data.

- item-update(key, size)

  Fired when the "last referenced" time is updated.

  Arguments:

  - key: The item's key.
  - size: The size of the data.

- item-replace(oldkey, oldsize, newkey, newsize)

  Fired when an item is being replaced with another item.

  Arguments:

  - oldkey: The key of the item to replace.
  - oldsize: The size of the old item.
  - newkey: The key of the new item.
  - newsize: The size of the new item.

- process-command-start(connid, request, size)

  Fired when the processing of a command starts.

  Arguments:

  - connid: The connection ID.
  - request: The incoming request.
  - size: The size of the request.

- process-command-end(connid, response, size)

Fired when the processing of a command is done.

Arguments:

- connid: The connection ID.
- response: The response to send back to the client.
- size: The size of the response.

- command-get(connid, key, size)

  Fired for a get command.

  Arguments:

  - connid: The connection ID.
  - key: The requested key.
  - size: The size of the key's data (or -1 if not found).

- command-gets(connid, key, size, casid)

  Fired for a gets command.

  Arguments:

  - connid: The connection ID.
  - key: The requested key.
  - size: The size of the key's data (or -1 if not found).
  - casid: The casid for the item.

- command-add(connid, key, size)

  Fired for a add command.

  Arguments:

  - connid: The connection ID.
  - key: The requested key.
  - size: The new size of the key's data (or -1 if not found).

- command-set(connid, key, size)

  Fired for a set command.

  Arguments:

  - connid: The connection ID.
  - key: The requested key.
  - size: The new size of the key's data (or -1 if not found).

- command-replace(connid, key, size)

  Fired for a replace command.

Arguments:

- connid: The connection ID.
- key: The requested key.
- size: The new size of the key's data (or -1 if not found).

- command-prepend(connid, key, size)

  Fired for a prepend command.

  Arguments:

  - connid: The connection ID.
  - key: The requested key.
  - size: The new size of the key's data (or -1 if not found).

- command-append(connid, key, size)

  Fired for a append command.

  Arguments:

  - connid: The connection ID.
  - key: The requested key.
  - size: The new size of the key's data (or -1 if not found).

- command-cas(connid, key, size, casid)

  Fired for a cas command.

  Arguments:

  - connid: The connection ID.
  - key: The requested key.
  - size: The size of the key's data (or -1 if not found).
  - casid: The cas ID requested.

- command-incr(connid, key, val)

  Fired for incr command.

  Arguments:

  - connid: The connection ID.
  - key: The requested key.
  - val: The new value.

- command-decr(connid, key, val)

  Fired for decr command.

  Arguments:

- connid: The connection ID.
- key: The requested key.
- val: The new value.

- command-delete(connid, key, exptime)

  Fired for a delete command.

  Arguments:

  - connid: The connection ID.
  - key: The requested key.
  - exptime: The expiry time.

Memory Allocation within memcached

When you first start memcached, the memory that you have configured is not automatically allocated. Instead, memcached only starts allocating and reserving physical memory once you start saving information into the cache.

When you start to store data into the cache, memcached does not allocate the memory for the data on an item by item basis. Instead, a slab allocation is used to optimize memory usage and prevent memory fragmentation when information expires from the cache.

With slab allocation, memory is reserved in blocks of 1MB. The slab is divided up into a number of blocks of equal size. When you try to store a value into the cache, memcached checks the size of the value that you are adding to the cache and determines which slab contains the right size allocation for the item. If a slab with the item size already exists, the item is written to the block within the slab.

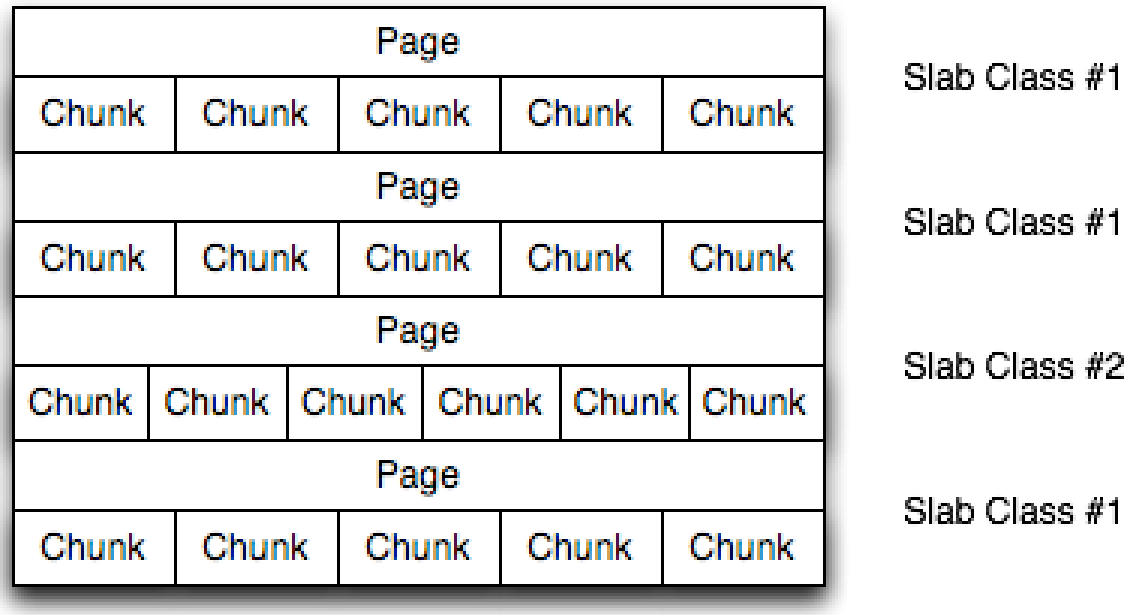
If the new item is bigger than the size of any existing blocks, then a new slab is created, divided up into blocks of a suitable size. If an existing slab with the right block size already exists, but there are no free blocks, a new slab is created. If you update an existing item with data that is larger than the existing block allocation for that key, then the key is re-allocated into a suitable slab.

For example, the default size for the smallest block is 88 bytes (40 bytes of value, and the default 48 bytes for the key and flag data). If the size of the first item you store into the cache is less than 40 bytes, then a slab with a block size of 88 bytes is created and the value stored.

If the size of the data that you intend to store is larger than this value, then the block size is increased by the chunk size factor until a block size large enough to hold the value is determined. The block size is always a function of the scale factor, rounded up to a block size which is exactly divisible into the chunk size.

For a sample of the structure, see Figure 15.8, “Memory Allocation in memcached”.

Figure 15.8. Memory Allocation in memcached



The result is that you have multiple pages allocated within the range of memory allocated to `memcached`. Each page is 1MB in size (by default), and is split into a different number of chunks, according to the chunk size required to store the key/value pairs. Each instance has multiple pages allocated, and a page is always created when a new item needs to be created requiring a chunk of a particular size. A slab may consist of multiple pages, and each page within a slab contains an equal number of chunks.

The chunk size of a new slab is determined by the base chunk size combined with the chunk size growth factor. For example, if the initial chunks are 104 bytes in size, and the default chunk size growth factor is used (1.25), then the next chunk size allocated would be the best power of 2 fit for 104*1.25, or 136 bytes.

Allocating the pages in this way ensures that memory does not get fragmented. However, depending on the distribution of the objects that you store, it may lead to an inefficient distribution of the slabs and chunks if you have significantly different sized items. For example, having a relatively small number of items within each chunk size may waste a lot of memory with just few chunks in each allocated page.

You can tune the growth factor to reduce this effect by using the `-f` command line option, which adapts the growth factor applied to make more effective use of the chunks and slabs allocated. For information on how to determine the current slab allocation statistics, see `memcached` Slabs Statistics.

If your operating system supports it, you can also start `memcached` with the `-L` command line option. This option preallocates all the memory during startup using large memory pages. This can improve performance by reducing the number of misses in the CPU memory cache.

`memcached` Thread Support

If you enable the thread implementation within when building `memcached` from source, then `memcached` uses multiple threads in addition to the `libevent` system to handle requests.

When enabled, the threading implementation operates as follows:

- Threading is handled by wrapping functions within the code to provide basic protection from updating the same global structures at the same time.
- Each thread uses its own instance of the `libevent` to help improve performance.

- TCP/IP connections are handled with a single thread listening on the TCP/IP socket. Each connection is then distributed to one of the active threads on a simple round-robin basis. Each connection then operates solely within this thread while the connection remains open.
- For UDP connections, all the threads listen to a single UDP socket for incoming requests. Threads that are not currently dealing with another request ignore the incoming packet. One of the remaining, nonbusy, threads reads the request and sends the response. This implementation can lead to increased CPU load as threads wake from sleep to potentially process the request.

Using threads can increase the performance on servers that have multiple CPU cores available, as the requests to update the hash table can be spread between the individual threads. To minimize overhead from the locking mechanism employed, experiment with different thread values to achieve the best performance based on the number and type of requests within your given workload.

memcached Logs

If you enable verbose mode, using the `-v`, `-vv`, or `-vvv` options, then the information output by `memcached` includes details of the operations being performed.

Without the verbose options, `memcached` normally produces no output during normal operating.

- **Output when using `-v`**

  The lowest verbosity level shows you:

  - Errors and warnings
  - Transient errors
  - Protocol and socket errors, including exhausting available connections
  - Each registered client connection, including the socket descriptor number and the protocol used.

    For example:

    ```
    32: Client using the ascii protocol
    33: Client using the ascii protocol
    ```

    Note that the socket descriptor is only valid while the client remains connected. Non-persistent connections may not be effectively represented.

  Examples of the error messages output at this level include:

  ```
  <%d send buffer was %d, now %d
  Can't listen for events on fd %d
  Can't read from libevent pipe
  Catastrophic: event fd doesn't match conn fd!
  Couldn't build response
  Couldn't realloc input buffer
  Couldn't update event
  Failed to build UDP headers
  Failed to read, and not due to blocking
  Too many open connections
  Unexpected state %d
  ```

- **Output when using `-vv`**

  When using the second level of verbosity, you get more detailed information about protocol operations, keys updated, chunk and network operatings and details.

  During the initial start-up of `memcached` with this level of verbosity, you are shown the sizes of the individual slab classes, the chunk sizes, and the number of entries per slab. These do not show the allocation of the slabs, just the slabs that would be created when data is added. You are also given

information about the listen queues and buffers used to send information. A sample of the output generated for a TCP/IP based system with the default memory and growth factors is given below:

```
shell> memcached -vv
slab class   1: chunk size     80 perslab 13107
slab class   2: chunk size    104 perslab 10082
slab class   3: chunk size    136 perslab  7710
slab class   4: chunk size    176 perslab  5957
slab class   5: chunk size    224 perslab  4681
slab class   6: chunk size    280 perslab  3744
slab class   7: chunk size    352 perslab  2978
slab class   8: chunk size    440 perslab  2383
slab class   9: chunk size    552 perslab  1899
slab class  10: chunk size    696 perslab  1506
slab class  11: chunk size    872 perslab  1202
slab class  12: chunk size   1096 perslab   956
slab class  13: chunk size   1376 perslab   762
slab class  14: chunk size   1720 perslab   609
slab class  15: chunk size   2152 perslab   487
slab class  16: chunk size   2696 perslab   388
slab class  17: chunk size   3376 perslab   310
slab class  18: chunk size   4224 perslab   248
slab class  19: chunk size   5280 perslab   198
slab class  20: chunk size   6600 perslab   158
slab class  21: chunk size   8256 perslab   127
slab class  22: chunk size  10320 perslab   101
slab class  23: chunk size  12904 perslab    81
slab class  24: chunk size  16136 perslab    64
slab class  25: chunk size  20176 perslab    51
slab class  26: chunk size  25224 perslab    41
slab class  27: chunk size  31536 perslab    33
slab class  28: chunk size  39424 perslab    26
slab class  29: chunk size  49280 perslab    21
slab class  30: chunk size  61600 perslab    17
slab class  31: chunk size  77000 perslab    13
slab class  32: chunk size  96256 perslab    10
slab class  33: chunk size 120320 perslab     8
slab class  34: chunk size 150400 perslab     6
slab class  35: chunk size 188000 perslab     5
slab class  36: chunk size 235000 perslab     4
slab class  37: chunk size 293752 perslab     3
slab class  38: chunk size 367192 perslab     2
slab class  39: chunk size 458992 perslab     2
<26 server listening (auto-negotiate)
<29 server listening (auto-negotiate)
<30 send buffer was 57344, now 2097152
<31 send buffer was 57344, now 2097152
<30 server listening (udp)
<30 server listening (udp)
<31 server listening (udp)
<30 server listening (udp)
<30 server listening (udp)
<31 server listening (udp)
<31 server listening (udp)
<31 server listening (udp)
```

Using this verbosity level can be a useful way to check the effects of the growth factor used on slabs with different memory allocations, which in turn can be used to better tune the growth factor to suit the data you are storing in the cache. For example, if you set the growth factor to 4 (quadrupling the size of each slab):

```
shell> memcached -f 4 -m 1g -vv
slab class   1: chunk size     80 perslab 13107

slab class   7: chunk size 327680 perslab     3
...
```

During use of the cache, this verbosity level also prints out detailed information on the storage and recovery of keys and other information. An example of the output during a typical set/get and increment/decrement operation is shown below.

```
32: Client using the ascii protocol
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key
>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key
>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decr key 1
>32 789543
<32 incr key 2
>32 789545
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key
>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key1 1 36

>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decr key 1
>32 789543
<32 incr key 2
>32 789545
```

During client communication, for each line, the initial character shows the direction of flow of the information. The < for communication from the client to the memcached server and > for communication back to the client. The number is the numeric socket descriptor for the connection.

- **Output when using -vvv**

  This level of verbosity includes the transitions of connections between different states in the event library while reading and writing content to/from the clients. It should be used to diagnose and identify issues in client communication. For example, you can use this information to determine if memcached is taking a long time to return information to the client, during the read of the client operation or before returning and completing the operation. An example of the typical sequence for a set operation is provided below:

```
<32 new auto-negotiating client connection
32: going from conn_new_cmd to conn_waiting
32: going from conn_waiting to conn_read
32: going from conn_read to conn_parse_cmd
32: Client using the ascii protocol
<32 set my_key 0 0 10
32: going from conn_parse_cmd to conn_nread
> NOT FOUND my_key
>32 STORED
32: going from conn_nread to conn_write
32: going from conn_write to conn_new_cmd
32: going from conn_new_cmd to conn_waiting
```

```
32: going from conn_waiting to conn_read
32: going from conn_read to conn_closing
<32 connection closed.
```

All of the verbosity levels in memcached are designed to be used during debugging or examination of issues. The quantity of information generated, particularly when using -vvv, is significant, particularly on a busy server. Also be aware that writing the error information out, especially to disk, may negate some of the performance gains you achieve by using memcached. Therefore, use in production or deployment environments is not recommended.

Developing a memcached Application

A number of language interfaces let applications store and retrieve information with memcached servers. You can write memcached applications in popular languages such as Perl, PHP, Python, Ruby, C, and Java.

Data stored into a memcached server is referred to by a single string (the key), with storage into the cache and retrieval from the cache using the key as the reference. The cache therefore operates like a large associative array or hash table. It is not possible to structure or otherwise organize the information stored in the cache. To emulate database notions such as multiple tables or composite key values, you must use encode the extra information into the strings used as keys. For example, to store or look up the address corresponding to a specific latitude and longitude, you might turn those two numeric values into a single comma-separated string to use as a key.

Basic memcached Operations

The interface to memcached supports the following methods for storing and retrieving information in the cache, and these are consistent across all the different APIs, although the language specific mechanics might be different:

- get(*key*): Retrieves information from the cache. Returns the value associated with the key if the specified key exists. Returns NULL, nil, undefined, or the closest equivalent in the corresponding language, if the specified key does not exist.
- set(*key*, , *value*, [, *expiry*]): Sets the item associated with a key in the cache to the specified value. Note that this either updates an existing item if the key already exists, or adds a new key/value pair if the key doesn't exist. If the expiry time is specified, then the item expires (and is deleted) when the expiry time is reached. The time is specified in seconds, and is taken as a relative time if the value is less than 30 days (30*24*60*60), or an absolute time (epoch) if larger than this value.
- add(*key*, , *value*, [, *expiry*]): Adds the key and associated value to the cache, if the specified key does not already exist.
- replace(*key*, , *value*, [, *expiry*]): Replaces the item associated with the specified key, only if the key already exists. The new value is given by the value parameter.
- delete(*key*, [, *time*]): Deletes the key and its associated item from the cache. If you supply a time, then adding another item with the specified key is blocked for the specified period.
- incr(*key*, [, *value*]): Increments the item associated with the key by one or the optional value.
- decr(*key*, [, *value*]): Decrements the item associated with the key by one or the optional value.
- flush_all: Invalidates (or expires) all the current items in the cache. Technically they still exist (they are not deleted), but they are silently destroyed the next time you try to access them.

In all implementations, most or all of these functions are duplicated through the corresponding native language interface.

When practical, use memcached to store full items, rather than caching a single column value from the database. For example, when displaying a record about an object (invoice, user history, or blog post), load all the data for the associated entry from the database, and compile it into the internal structure that would normally be required by the application. Save the complete object in the cache.

Complex data structures cannot be stored directly. Most interfaces serialize the data for you, that is, put it in a textual form that can reconstruct the original pointers and nesting. Perl uses Storable, PHP uses serialize, Python uses cPickle (or Pickle) and Java uses the Serializable interface. In most cases, the serialization interface used is customizable. To share data stored in memcached instances between different language interfaces, consider using a common serialization solution such as JSON (Javascript Object Notation).

Using memcached as a MySQL Caching Layer

When using memcached to cache MySQL data, your application must retrieve data from the database and load the appropriate key-value pairs into the cache. Then, subsequent lookups can be done directly from the cache.

Because MySQL has its own in-memory caching mechanisms for queried data, such as the InnoDB buffer pool and the MySQL query cache, look for opportunities beyond loading individual column values or rows into the cache. Prefer to cache composite values, such as those retrieved from multiple tables through a join query, or result sets assembled from multiple rows.

Caution

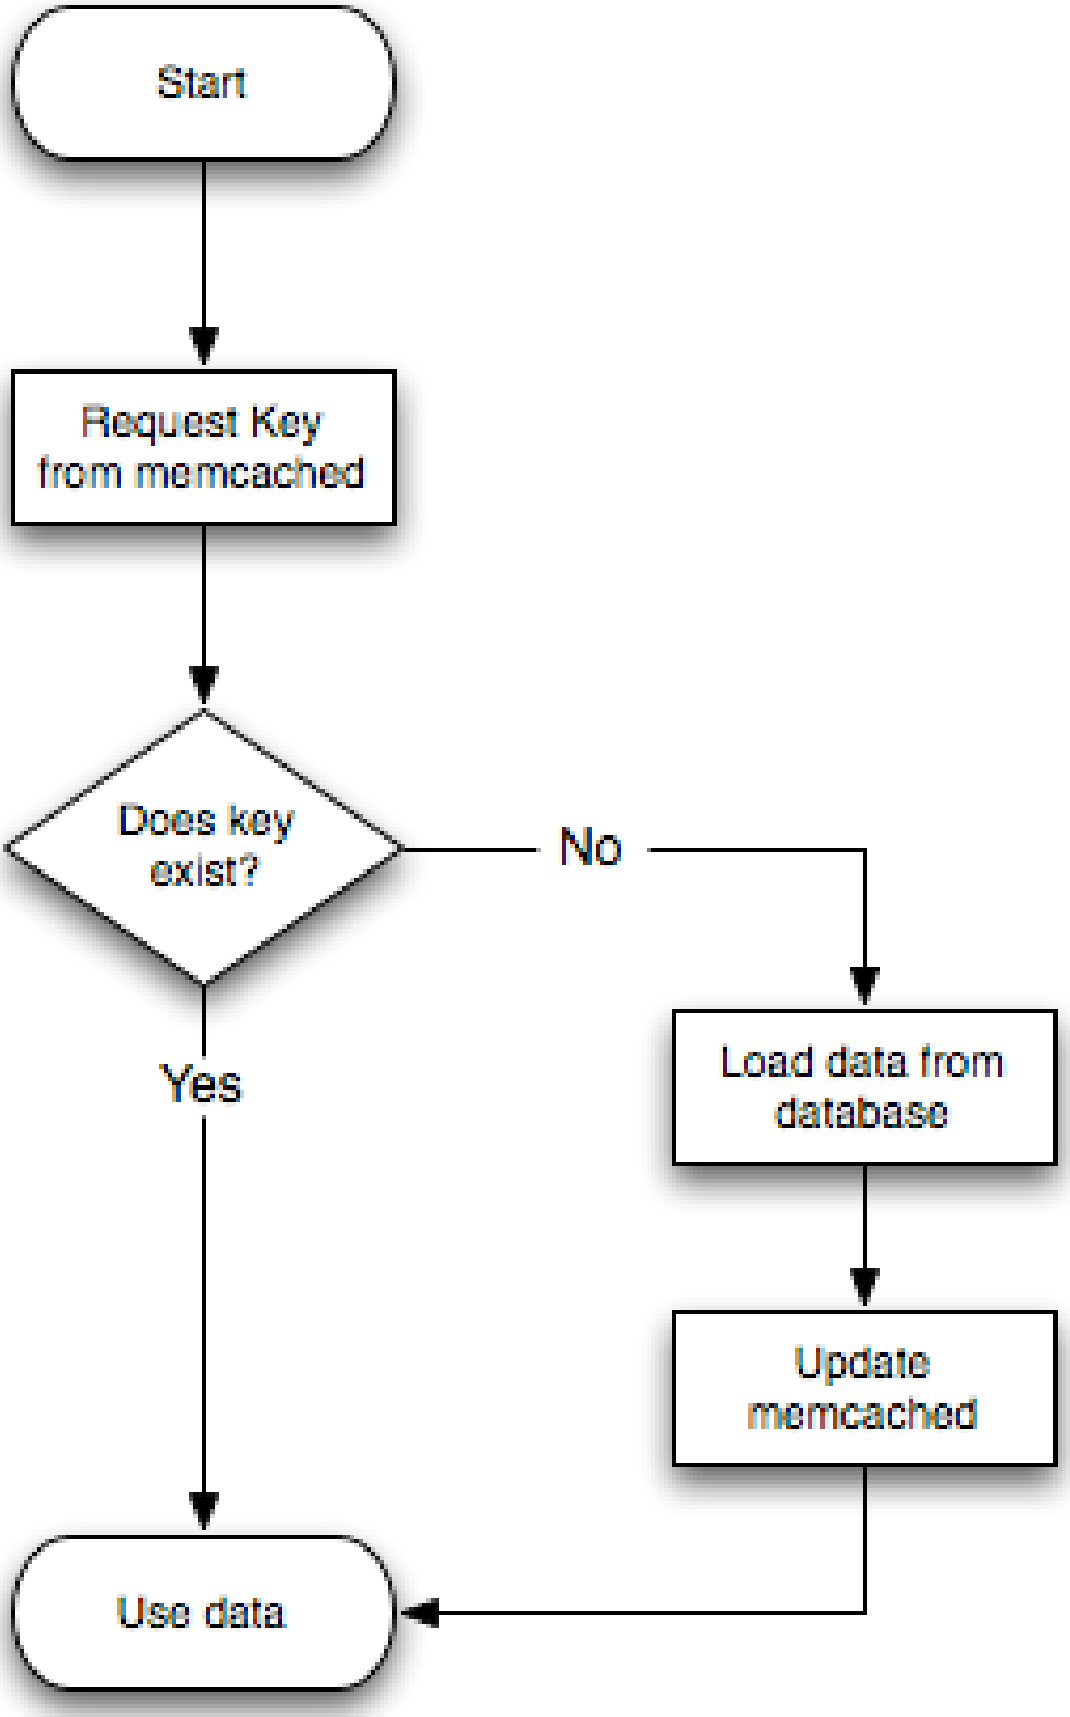
Limit the information in the cache to non-sensitive data, because there is no security required to access or update the information within a memcached instance. Anybody with access to the machine has the ability to read, view and potentially update the information. To keep the data secure, encrypt the information before caching it. To restrict the users capable of connecting to the server, either disable network access, or use IPTables or similar techniques to restrict access to the memcached ports to a select set of hosts.

You can introduce memcached to an existing application, even if caching was not part of the original design. In many languages and environments the changes to the application will be just a few lines, first to attempt to read from the cache when loading data, fall back to the old method if the information is not cached, and to update the cache with information once the data has been read.

The general sequence for using memcached in any language as a caching solution for MySQL is as follows:

1. Request the item from the cache.
2. If the item exists, use the item data.
3. If the item does not exist, load the data from MySQL, and store the value into the cache. This means the value is available to the next client that requests it from the cache.

For a flow diagram of this sequence, see Figure 15.9, “Typical memcached Application Flowchart”.



Start
Request Key from memcached
Does key exist?
No
Yes
Load data from database
Update memcached
Use data

Adapting Database Best Practices to memcached Applications

The most direct way to cache MySQL data is to use a 2-column table, where the first column is a primary key. Because of the uniqueness requirements for memcached keys, make sure your database schema makes appropriate use of primary keys and unique constraints.

If you combine multiple column values into a single memcached item value, choose data types to make it easy to parse the value back into its components, for example by using a separator character between numeric values.

The queries that map most easily to memcached lookups are those with a single WHERE clause, using an = or IN operator. For complicated WHERE clauses, or those using operators such as <, >, BETWEEN, or LIKE, memcached does not provide a simple or efficient way to scan through or filter the keys or associated values, so typically you perform those operations as SQL queries on the underlying database.

Using libmemcached with C and C++

The libmemcached library provides both C and C++ interfaces to memcached and is also the basis for a number of different additional API implementations, including Perl, Python and Ruby. Understanding the core libmemcached functions can help when using these other interfaces.

The C library is the most comprehensive interface library for memcached and provides functions and operational systems not always exposed in interfaces not based on the libmemcached library.

The different functions can be divided up according to their basic operation. In addition to functions that interface to the core API, a number of utility functions provide extended functionality, such as appending and prepending data.

To build and install libmemcached, download the libmemcached package, run configure, and then build and install:

```
shell> tar xjf libmemcached-0.21.tar.gz
shell> cd libmemcached-0.21
shell> ./configure
shell> make
shell> make install
```

On many Linux operating systems, you can install the corresponding libmemcached package through the usual yum, apt-get, or similar commands.

To build an application that uses the library, first set the list of servers. Either directly manipulate the servers configured within the main memcached_st structure, or separately populate a list of servers, and then add this list to the memcached_st structure. The latter method is used in the following example. Once the server list has been set, you can call the functions to store or retrieve data. A simple application for setting a preset value to localhost is provided here:

```
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
{
  memcached_server_st *servers = NULL;
  memcached_st *memc;
  memcached_return rc;
  char *key= "keystring";
  char *value= "keyvalue";

  memcached_server_st *memcached_servers_parse (char *server_strings);
  memc= memcached_create(NULL);

  servers= memcached_server_list_append(servers, "localhost", 11211, &rc);
  rc= memcached_server_push(memc, servers);
```

```
  if (rc == MEMCACHED_SUCCESS)
    fprintf(stderr,"Added server successfully\n");
  else
    fprintf(stderr,"Couldn't add server: %s\n",memcached_strerror(memc, rc));

  rc= memcached_set(memc, key, strlen(key), value, strlen(value), (time_t)0, (uint32_t)0);

  if (rc == MEMCACHED_SUCCESS)
    fprintf(stderr,"Key stored successfully\n");
  else
    fprintf(stderr,"Couldn't store key: %s\n",memcached_strerror(memc, rc));

  return 0;
}
```

To test the success of an operation, use the return value, or populated result code, for a given function. The value is always set to `MEMCACHED_SUCCESS` if the operation succeeded. In the event of a failure, use the `memcached_strerror()` function to translate the result code into a printable string.

To build the application, specify the `memcached` library:

```
shell> gcc -o memc_basic memc_basic.c -lmemcached
```

Running the above sample application, after starting a `memcached` server, should return a success message:

```
shell> memc_basic
Added server successfully
Key stored successfully
```

`libmemcached` Base Functions

The base `libmemcached` functions let you create, destroy and clone the main `memcached_st` structure that is used to interface with the `memcached` servers. The main functions are defined below:

```
memcached_st *memcached_create (memcached_st *ptr);
```

Creates a new `memcached_st` structure for use with the other `libmemcached` API functions. You can supply an existing, static, `memcached_st` structure, or `NULL` to have a new structured allocated. Returns a pointer to the created structure, or `NULL` on failure.

```
void memcached_free (memcached_st *ptr);
```

Frees the structure and memory allocated to a previously created `memcached_st` structure.

```
memcached_st *memcached_clone(memcached_st *clone, memcached_st *source);
```

Clones an existing `memcached` structure from the specified `source`, copying the defaults and list of servers defined in the structure.

`libmemcached` Server Functions

The `libmemcached` API uses a list of servers, stored within the `memcached_server_st` structure, to act as the list of servers used by the rest of the functions. To use `memcached`, you first create the server list, and then apply the list of servers to a valid `libmemcached` object.

Because the list of servers, and the list of servers within an active `libmemcached` object can be manipulated separately, you can update and manage server lists while an active `libmemcached` interface is running.

The functions for manipulating the list of servers within a `memcached_st` structure are:

```
memcached_return
   memcached_server_add (memcached_st *ptr,
                         char *hostname,
```

```
                          unsigned int port);
```

Adds a server, using the given hostname and port into the memcached_st structure given in ptr.

```
memcached_return
   memcached_server_add_unix_socket (memcached_st *ptr,
                                     char *socket);
```

Adds a Unix socket to the list of servers configured in the memcached_st structure.

```
unsigned int memcached_server_count (memcached_st *ptr);
```

Returns a count of the number of configured servers within the memcached_st structure.

```
memcached_server_st *
   memcached_server_list (memcached_st *ptr);
```

Returns an array of all the defined hosts within a memcached_st structure.

```
memcached_return
   memcached_server_push (memcached_st *ptr,
                          memcached_server_st *list);
```

Pushes an existing list of servers onto list of servers configured for a current memcached_st structure. This adds servers to the end of the existing list, and duplicates are not checked.

The memcached_server_st structure can be used to create a list of memcached servers which can then be applied individually to memcached_st structures.

```
memcached_server_st *
   memcached_server_list_append (memcached_server_st *ptr,
                                 char *hostname,
                                 unsigned int port,
                                 memcached_return *error);
```

Adds a server, with hostname and port, to the server list in ptr. The result code is handled by the error argument, which should point to an existing memcached_return variable. The function returns a pointer to the returned list.

```
unsigned int memcached_server_list_count (memcached_server_st *ptr);
```

Returns the number of the servers in the server list.

```
void memcached_server_list_free (memcached_server_st *ptr);
```

Frees the memory associated with a server list.

```
memcached_server_st *memcached_servers_parse (char *server_strings);
```

Parses a string containing a list of servers, where individual servers are separated by a comma, space, or both, and where individual servers are of the form *server*[:*port*]. The return value is a server list structure.

libmemcached Set Functions

The set-related functions within libmemcached provide the same functionality as the core functions supported by the memcached protocol. The full definition for the different functions is the same for all the base functions (add, replace, prepend, append). For example, the function definition for memcached_set() is:

```
memcached_return
   memcached_set (memcached_st *ptr,
                  const char *key,
                  size_t key_length,
                  const char *value,
                  size_t value_length,
                  time_t expiration,
```

```
                  uint32_t flags);
```

The ptr is the memcached_st structure. The key and key_length define the key name and length, and value and value_length the corresponding value and length. You can also set the expiration and optional flags. For more information, see Controlling libmemcached Behaviors.

The following table outlines the remainder of the set-related functions.

libmemcached Function	Equivalent to
memcached_set(memc, key, key_length, value, value_length, expiration, flags)	Generic set() operation.
memcached_add(memc, key, key_length, value, value_length, expiration, flags)	Generic add() function.
memcached_replace(memc, key, key_length, value, value_length, expiration, flags)	Generic replace().
memcached_prepend(memc, key, key_length, value, value_length, expiration, flags)	Prepends the specified value before the current value of the specified key.
memcached_append(memc, key, key_length, value, value_length, expiration, flags)	Appends the specified value after the current value of the specified key.
memcached_cas(memc, key, key_length, value, value_length, expiration, flags, cas)	Overwrites the data for a given key as long as the corresponding cas value is still the same within the server.
memcached_set_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)	Similar to the generic set(), but has the option of an additional master key that can be used to identify an individual server.
memcached_add_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)	Similar to the generic add(), but has the option of an additional master key that can be used to identify an individual server.
memcached_replace_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)	Similar to the generic replace(), but has the option of an additional master key that can be used to identify an individual server.
memcached_prepend_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)	Similar to the memcached_prepend(), but has the option of an additional master key that can be used to identify an individual server.
memcached_append_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)	Similar to the memcached_append(), but has the option of an additional master key that can be used to identify an individual server.
memcached_cas_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)	Similar to the memcached_cas(), but has the option of an additional master key that can be used to identify an individual server.

The by_key methods add two further arguments that define the master key, to be used and applied during the hashing stage for selecting the servers. You can see this in the following definition:

```
memcached_return
   memcached_set_by_key(memcached_st *ptr,
                        const char *master_key,
                        size_t master_key_length,
                        const char *key,
                        size_t key_length,
                        const char *value,
                        size_t value_length,
                        time_t expiration,
                        uint32_t flags);
```

All the functions return a value of type `memcached_return`, which you can compare against the `MEMCACHED_SUCCESS` constant.

`libmemcached` Get Functions

The `libmemcached` functions provide both direct access to a single item, and a multiple-key request mechanism that provides much faster responses when fetching a large number of keys simultaneously.

The main get-style function, which is equivalent to the generic `get()` is `memcached_get()`. This function returns a string pointer, pointing to the value associated with the specified key.

```
char *memcached_get (memcached_st *ptr,
                     const char *key, size_t key_length,
                     size_t *value_length,
                     uint32_t *flags,
                     memcached_return *error);
```

A multi-key get, `memcached_mget()`, is also available. Using a multiple key get operation is much quicker to do in one block than retrieving the key values with individual calls to `memcached_get()`. To start the multi-key get, call `memcached_mget()`:

```
memcached_return
    memcached_mget (memcached_st *ptr,
                    char **keys, size_t *key_length,
                    unsigned int number_of_keys);
```

The return value is the success of the operation. The `keys` parameter should be an array of strings containing the keys, and `key_length` an array containing the length of each corresponding key. `number_of_keys` is the number of keys supplied in the array.

To fetch the individual values, use `memcached_fetch()` to get each corresponding value.

```
char *memcached_fetch (memcached_st *ptr,
                       const char *key, size_t *key_length,
                       size_t *value_length,
                       uint32_t *flags,
                       memcached_return *error);
```

The function returns the key value, with the `key`, `key_length` and `value_length` parameters being populated with the corresponding key and length information. The function returns `NULL` when there are no more values to be returned. A full example, including the populating of the key data and the return of the information is provided here.

```
#include <stdio.h>
#include <sstring.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
{
  memcached_server_st *servers = NULL;
  memcached_st *memc;
  memcached_return rc;
  char *keys[]= {"huey", "dewey", "louie"};
  size_t key_length[3];
  char *values[]= {"red", "blue", "green"};
  size_t value_length[3];
```

```
  unsigned int x;
  uint32_t flags;

  char return_key[MEMCACHED_MAX_KEY];
  size_t return_key_length;
  char *return_value;
  size_t return_value_length;

  memc= memcached_create(NULL);

  servers= memcached_server_list_append(servers, "localhost", 11211, &rc);
  rc= memcached_server_push(memc, servers);

  if (rc == MEMCACHED_SUCCESS)
    fprintf(stderr,"Added server successfully\n");
  else
    fprintf(stderr,"Couldn't add server: %s\n",memcached_strerror(memc, rc));

  for(x= 0; x < 3; x++)
    {
      key_length[x] = strlen(keys[x]);
      value_length[x] = strlen(values[x]);

      rc= memcached_set(memc, keys[x], key_length[x], values[x],
                        value_length[x], (time_t)0, (uint32_t)0);
      if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr,"Key %s stored successfully\n",keys[x]);
      else
        fprintf(stderr,"Couldn't store key: %s\n",memcached_strerror(memc, rc));
    }

  rc= memcached_mget(memc, keys, key_length, 3);

  if (rc == MEMCACHED_SUCCESS)
    {
      while ((return_value= memcached_fetch(memc, return_key, &return_key_length,
                                            &return_value_length, &flags, &rc)) != NULL)
        {
          if (rc == MEMCACHED_SUCCESS)
            {
              fprintf(stderr,"Key %s returned %s\n",return_key, return_value);
            }
        }
    }

  return 0;
}
```

Running the above application produces the following output:

```
shell> memc_multi_fetch
Added server successfully
Key huey stored successfully
Key dewey stored successfully
Key louie stored successfully
Key huey returned red
Key dewey returned blue
Key louie returned green
```

Controlling libmemcached Behaviors

The behavior of libmemcached can be modified by setting one or more behavior flags. These can either be set globally, or they can be applied during the call to individual functions. Some behaviors also accept an additional setting, such as the hashing mechanism used when selecting servers.

To set global behaviors:

```
memcached_return
   memcached_behavior_set (memcached_st *ptr,
                           memcached_behavior flag,
                           uint64_t data);
```

To get the current behavior setting:

```
uint64_t
   memcached_behavior_get (memcached_st *ptr,
                           memcached_behavior flag);
```

Behavior	Description
MEMCACHED_BEHAVIOR_NO_BLOCK	Caused libmemcached to use asynchronous I/O.
MEMCACHED_BEHAVIOR_TCP_NODELAY	Turns on no-delay for network sockets.
MEMCACHED_BEHAVIOR_HASH	Without a value, sets the default hashing algorithm for keys to use MD5. Other valid values include MEMCACHED_HASH_DEFAULT, MEMCACHED_HASH_MD5, MEMCACHED_HASH_CRC, MEMCACHED_HASH_FNV1_64, MEMCACHED_HASH_FNV1A_64, MEMCACHED_HASH_FNV1_32, and MEMCACHED_HASH_FNV1A_32.
MEMCACHED_BEHAVIOR_DISTRIBUTION	Changes the method of selecting the server used to store a given value. The default method is MEMCACHED_DISTRIBUTION_MODULA. You can enable consistent hashing by setting MEMCACHED_DISTRIBUTION_CONSISTENT. MEMCACHED_DISTRIBUTION_CONSISTENT is an alias for the value MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA.
MEMCACHED_BEHAVIOR_CACHE_LOOKUPS	Cache the lookups made to the DNS service. This can improve the performance if you are using names instead of IP addresses for individual hosts.
MEMCACHED_BEHAVIOR_SUPPORT_CAS	Support CAS operations. By default, this is disabled because it imposes a performance penalty.
MEMCACHED_BEHAVIOR_KETAMA	Sets the default distribution to MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA and the hash to MEMCACHED_HASH_MD5.
MEMCACHED_BEHAVIOR_POLL_TIMEOUT	Modify the timeout value used by poll(). Supply a signed int pointer for the timeout value.
MEMCACHED_BEHAVIOR_BUFFER_REQUEST	Buffers IO requests instead of them being sent. A get operation, or closing the connection causes the data to be flushed.
MEMCACHED_BEHAVIOR_VERIFY_KEY	Forces libmemcached to verify that a specified key is valid.
MEMCACHED_BEHAVIOR_SORT_HOSTS	If set, hosts added to the list of configured hosts for a memcached_st structure are placed into the host list in sorted order. This breaks consistent hashing if that behavior has been enabled.
MEMCACHED_BEHAVIOR_CONNECT_TIMEOUT	In nonblocking mode this changes the value of the timeout during socket connection.

libmemcached Command-Line Utilities

In addition to the main C library interface, libmemcached also includes a number of command-line utilities that can be useful when working with and debugging memcached applications.

All of the command-line tools accept a number of arguments, the most critical of which is servers, which specifies the list of servers to connect to when returning information.

The main tools are:

- memcat: Display the value for each ID given on the command line:

```
shell> memcat --servers=localhost hwkey
Hello world
```

- memcp: Copy the contents of a file into the cache, using the file name as the key:

```
shell> echo "Hello World" > hwkey
shell> memcp --servers=localhost hwkey
shell> memcat --servers=localhost hwkey
Hello world
```

- memrm: Remove an item from the cache:

```
shell> memcat --servers=localhost hwkey
Hello world
shell> memrm --servers=localhost hwkey
shell> memcat --servers=localhost hwkey
```

- memslap: Test the load on one or more memcached servers, simulating get/set and multiple client operations. For example, you can simulate the load of 100 clients performing get operations:

```
shell> memslap --servers=localhost --concurrency=100 --flush --test=get
memslap --servers=localhost --concurrency=100 --flush --test=get Threads connecting to servers 100
 Took 13.571 seconds to read data
```

- memflush: Flush (empty) the contents of the memcached cache.

```
shell> memflush --servers=localhost
```

Using MySQL and memcached with Perl

The Cache::Memcached module provides a native interface to the Memcache protocol, and provides support for the core functions offered by memcached. Install the module using your operating system's package management system, or using CPAN:

```
root-shell> perl -MCPAN -e 'install Cache::Memcached'
```

To use memcached from Perl through the Cache::Memcached module, first create a new Cache::Memcached object that defines the list of servers and other parameters for the connection. The only argument is a hash containing the options for the cache interface. For example, to create a new instance that uses three memcached servers:

```
use Cache::Memcached;

my $cache = new Cache::Memcached {
    'servers' => [
        '192.168.0.100:11211',
        '192.168.0.101:11211',
        '192.168.0.102:11211',
 ],
};
```

Note

When using the Cache::Memcached interface with multiple servers, the API automatically performs certain operations across all the servers in the group. For example, getting statistical information through Cache::Memcached returns a hash that contains data on a host-by-host basis, as well as generalized statistics for all the servers in the group.

You can set additional properties on the cache object instance when it is created by specifying the option as part of the option hash. Alternatively, you can use a corresponding method on the instance:

- servers or method set_servers(): Specifies the list of the servers to be used. The servers list should be a reference to an array of servers, with each element as the address and port number

combination (separated by a colon). You can also specify a local connection through a UNIX socket (for example /tmp/sock/memcached). To specify the server with a weight (indicating how much more frequently the server should be used during hashing), specify an array reference with the memcached server instance and a weight number. Higher numbers give higher priority.

- compress_threshold or method set_compress_threshold(): Specifies the threshold when values are compressed. Values larger than the specified number are automatically compressed (using zlib) during storage and retrieval.
- no_rehash or method set_norehash(): Disables finding a new server if the original choice is unavailable.
- readonly or method set_readonly(): Disables writes to the memcached servers.

Once the Cache::Memcached object instance has been configured, you can use the set() and get() methods to store and retrieve information from the memcached servers. Objects stored in the cache are automatically serialized and deserialized using the Storable module.

The Cache::Memcached interface supports the following methods for storing/retrieving data, and relate to the generic methods as shown in the table.

Cache::Memcached Function	Equivalent to
get()	Generic get().
get_multi(keys)	Gets multiple keys from memcache using just one query. Returns a hash reference of key/value pairs.
set()	Generic set().
add()	Generic add().
replace()	Generic replace().
delete()	Generic delete().
incr()	Generic incr().
decr()	Generic decr().

Below is a complete example for using memcached with Perl and the Cache::Memcached module:

```
#!/usr/bin/perl

use Cache::Memcached;
use DBI;
use Data::Dumper;

# Configure the memcached server

my $cache = new Cache::Memcached {
    'servers' => [
                  'localhost:11211',
                  ],
    };

# Get the film name from the command line
# memcached keys must not contain spaces, so create
# a key name by replacing spaces with underscores

my $filmname = shift or die "Must specify the film name\n";
my $filmkey = $filmname;
$filmkey =~ s/ /_/;

# Load the data from the cache

my $filmdata = $cache->get($filmkey);
```

```
# If the data wasn't in the cache, then we load it from the database

if (!defined($filmdata))
{
    $filmdata = load_filmdata($filmname);

    if (defined($filmdata))
    {

# Set the data into the cache, using the key

 if ($cache->set($filmkey,$filmdata))
        {
            print STDERR "Film data loaded from database and cached\n";
        }
        else
        {
            print STDERR "Couldn't store to cache\n";
 }
    }
    else
    {
      die "Couldn't find $filmname\n";
    }
}
else
{
    print STDERR "Film data loaded from Memcached\n";
}

sub load_filmdata
{
    my ($filmname) = @_;

    my $dsn = "DBI:mysql:database=sakila;host=localhost;port=3306";

    $dbh = DBI->connect($dsn, 'sakila','password');

    my ($filmbase) = $dbh->selectrow_hashref(sprintf('select * from film where title = %s',
                                                     $dbh->quote($filmname)));

    if (!defined($filmname))
    {
      return (undef);
    }

    $filmbase->{stars} =
 $dbh->selectall_arrayref(sprintf('select concat(first_name," ",last_name) ' .
                                        'from film_actor left join (actor) ' .
                                        'on (film_actor.actor_id = actor.actor_id) ' .
                                        ' where film_id=%s',
                                        $dbh->quote($filmbase->{film_id})));

    return($filmbase);
}
```

The example uses the Sakila database, obtaining film data from the database and writing a composite record of the film and actors to memcached. When calling it for a film does not exist, you get this result:

```
shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from database and cached
```

When accessing a film that has already been added to the cache:

```
shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from Memcached
```

Using MySQL and memcached with Python

The Python memcache module interfaces to memcached servers, and is written in pure Python (that is, without using one of the C APIs). You can download and install a copy from Python Memcached.

To install, download the package and then run the Python installer:

```
python setup.py install
running install
running bdist_egg
running egg_info
creating python_memcached.egg-info
...
removing 'build/bdist.linux-x86_64/egg' (and everything under it)
Processing python_memcached-1.43-py2.4.egg
creating /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Extracting python_memcached-1.43-py2.4.egg to /usr/lib64/python2.4/site-packages
Adding python-memcached 1.43 to easy-install.pth file

Installed /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Processing dependencies for python-memcached==1.43
Finished processing dependencies for python-memcached==1.43
```

Once installed, the memcache module provides a class-based interface to your memcached servers. When you store Python data structures as memcached items, they are automatically serialized (turned into string values) using the Python cPickle or pickle modules.

To create a new memcache interface, import the memcache module and create a new instance of the memcache.Client class. For example, if the memcached daemon is running on localhost using the default port:

```
import memcache
memc = memcache.Client(['127.0.0.1:11211'])
```

The first argument is an array of strings containing the server and port number for each memcached instance to use. To enable debugging, set the optional debug parameter to 1.

By default, the hashing mechanism used to divide the items among multiple servers is crc32. To change the function used, set the value of memcache.serverHashFunction to the alternate function to use. For example:

```
from zlib import adler32
memcache.serverHashFunction = adler32
```

Once you have defined the servers to use within the memcache instance, the core functions provide the same functionality as in the generic interface specification. The following table provides a summary of the supported functions:

Python memcache Function	Equivalent to
get()	Generic get().
get_multi(keys)	Gets multiple values from the supplied array of keys. Returns a hash reference of key/value pairs.
set()	Generic set().
set_multi(dict [, expiry [, key_prefix]])	Sets multiple key/value pairs from the supplied dict.
add()	Generic add().
replace()	Generic replace().
prepend(key, value [, expiry])	Prepends the supplied value to the value of the existing key.
append(key, value [, expiry[)	Appends the supplied value to the value of the existing key.
delete()	Generic delete().
delete_multi(keys [, expiry [, key_prefix]])	Deletes all the keys from the hash matching each string in the array keys.

Python memcache Function	Equivalent to
incr()	Generic incr().
decr()	Generic decr().

Note

Within the Python memcache module, all the *_multi()functions support an optional key_prefix parameter. If supplied, then the string is used as a prefix to all key lookups. For example, if you call:

```
memc.get_multi(['a','b'], key_prefix='users:')
```

The function retrieves the keys users:a and users:b from the servers.

Here is an example showing the storage and retrieval of information to a memcache instance, loading the raw data from MySQL:

```
import sys
import MySQLdb
import memcache

memc = memcache.Client(['127.0.0.1:11211'], debug=1);

try:
    conn = MySQLdb.connect (host = "localhost",
                            user = "sakila",
                            passwd = "password",
                            db = "sakila")
except MySQLdb.Error, e:
     print "Error %d: %s" % (e.args[0], e.args[1])
     sys.exit (1)

popularfilms = memc.get('top5films')

if not popularfilms:
    cursor = conn.cursor()
    cursor.execute('select film_id,title from film order by rental_rate desc limit 5')
    rows = cursor.fetchall()
    memc.set('top5films',rows,60)
    print "Updated memcached with MySQL data"
else:
    print "Loaded data from memcached"
    for row in popularfilms:
        print "%s, %s" % (row[0], row[1])
```

When executed for the first time, the data is loaded from the MySQL database and stored to the memcached server.

```
shell> python memc_python.py
Updated memcached with MySQL data
```

Because the data is automatically serialized using cPickle/pickle, when you load the data back from memcached, you can use the object directly. In the example above, the information stored to memcached is in the form of rows from a Python DB cursor. When accessing the information (within the 60 second expiry time), the data is loaded from memcached and dumped:

```
shell> python memc_python.py
Loaded data from memcached
2, ACE GOLDFINGER
7, AIRPLANE SIERRA
8, AIRPORT POLLOCK
10, ALADDIN CALENDAR
13, ALI FOREVER
```

The serialization and deserialization happens automatically. Because serialization of Python data may be incompatible with other interfaces and languages, you can change the serialization module used

during initialization. For example, you might use JSON format when you store complex data structures using a script written in one language, and access them in a script written in a different language.

Using MySQL and memcached with PHP

PHP provides support for the Memcache functions through a PECL extension. To enable the PHP memcache extensions, build PHP using the --enable-memcache option to configure when building from source.

If you are installing on a Red Hat-based server, you can install the php-pecl-memcache RPM:

```
root-shell> yum --install php-pecl-memcache
```

On Debian-based distributions, use the php-memcache package.

To set global runtime configuration options, specify the values in the following table within your php.ini file:

Configuration option	Default	Description
memcache.allow_failover	1	Specifies whether another server in the list should be queried if the first server selected fails.
memcache.max_failover_attempts	20	Specifies the number of servers to try before returning a failure.
memcache.chunk_size	8192	Defines the size of network chunks used to exchange data with the memcached server.
memcache.default_port	11211	Defines the default port to use when communicating with the memcached servers.
memcache.hash_strategy	standard	Specifies which hash strategy to use. Set to consistent to enable servers to be added or removed from the pool without causing the keys to be remapped to other servers. When set to standard, an older (modula) strategy is used that potentially uses different servers for storage.
memcache.hash_function	crc32	Specifies which function to use when mapping keys to servers. crc32 uses the standard CRC32 hash. fnv uses the FNV-1a hashing algorithm.

To create a connection to a memcached server, create a new Memcache object and then specify the connection options. For example:

```
<?php

$cache = new Memcache;
$cache->connect('localhost',11211);
?>
```

This opens an immediate connection to the specified server.

To use multiple memcached servers, you need to add servers to the memcache object using addServer():

```
bool Memcache::addServer ( string $host [, int $port [, bool $persistent
                [, int $weight [, int $timeout [, int $retry_interval
                [, bool $status [, callback $failure_callback
                ]]]]]] )
```

The server management mechanism within the php-memcache module is a critical part of the interface as it controls the main interface to the memcached instances and how the different instances are selected through the hashing mechanism.

To create a simple connection to two memcached instances:

```
<?php

$cache = new Memcache;
$cache->addServer('192.168.0.100',11211);
$cache->addServer('192.168.0.101',11211);
?>
```

In this scenario, the instance connection is not explicitly opened, but only opened when you try to store or retrieve a value. To enable persistent connections to memcached instances, set the $persistent argument to true. This is the default setting, and causes the connections to remain open.

To help control the distribution of keys to different instances, use the global memcache.hash_strategy setting. This sets the hashing mechanism used to select. You can also add another weight to each server, which effectively increases the number of times the instance entry appears in the instance list, therefore increasing the likelihood of the instance being chosen over other instances. To set the weight, set the value of the $weight argument to more than one.

The functions for setting and retrieving information are identical to the generic functional interface offered by memcached, as shown in this table:

PECL memcache Function	Equivalent to
get()	Generic get().
set()	Generic set().
add()	Generic add().
replace()	Generic replace().
delete()	Generic delete().
increment()	Generic incr().
decrement()	Generic decr().

A full example of the PECL memcache interface is provided below. The code loads film data from the Sakila database when the user provides a film name. The data stored into the memcached instance is recorded as a mysqli result row, and the API automatically serializes the information for you.

```

<?php

$memc = new Memcache;
$memc->addServer('localhost','11211');

if(empty($_POST['film'])) {
?>
  <html xmlns="http://www.w3.org/1999/xhtml" xml:lang="en" lang="en">
    <head>
      <meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
      <title>Simple Memcache Lookup</title>
    </head>
    <body>
      <form method="post">
        <p><b>Film</b>: <input type="text" size="20" name="film"></p>
        <input type="submit">
      </form>
      <hr/>
<?php

} else {
```

```
    echo "Loading data...\n";

    $film   = htmlspecialchars($_POST['film'], ENT_QUOTES, 'UTF-8');
    $mfilms = $memc->get($film);

    if ($mfilms) {

        printf("<p>Film data for %s loaded from memcache</p>", $mfilms['title']);

        foreach (array_keys($mfilms) as $key) {
            printf("<p><b>%s</b>: %s</p>", $key, $mfilms[$key]);
        }

    } else {

        $mysqli = mysqli('localhost','sakila','password','sakila');

        if (mysqli_connect_error()) {
            sprintf("Database error: (%d) %s", mysqli_connect_errno(), mysqli_connect_error());
            exit;
        }

        $sql = sprintf('SELECT * FROM film WHERE title="%s"', $mysqli->real_escape_string($film));

        $result = $mysqli->query($sql);

        if (!$result) {
            sprintf("Database error: (%d) %s", $mysqli->errno, $mysqli->error);
            exit;
        }

        $row = $result->fetch_assoc();

        $memc->set($row['title'], $row);

        printf("<p>Loaded (%s) from MySQL</p>", htmlspecialchars($row['title'], ENT_QUOTES, 'UTF-8');
    }
}
?>
  </body>
</html>
```

With PHP, the connections to the memcached instances are kept open as long as the PHP and associated Apache instance remain running. When adding or removing servers from the list in a running instance (for example, when starting another script that mentions additional servers), the connections are shared, but the script only selects among the instances explicitly configured within the script.

To ensure that changes to the server list within a script do not cause problems, make sure to use the consistent hashing mechanism.

Using MySQL and memcached with Ruby

There are a number of different modules for interfacing to memcached within Ruby. The Ruby-MemCache client library provides a native interface to memcached that does not require any external libraries, such as libmemcached. You can obtain the installer package from http://www.deveiate.org/projects/RMemCache.

To install, extract the package and then run install.rb:

```
shell> install.rb
```

If you have RubyGems, you can install the Ruby-MemCache gem:

```
shell> gem install Ruby-MemCache
Bulk updating Gem source index for: http://gems.rubyforge.org
Install required dependency io-reactor? [Yn]  y
```

```
Successfully installed Ruby-MemCache-0.0.1
Successfully installed io-reactor-0.05
Installing ri documentation for io-reactor-0.05...
Installing RDoc documentation for io-reactor-0.05...
```

To use a memcached instance from within Ruby, create a new instance of the MemCache object.

```
require 'memcache'
memc = MemCache::new '192.168.0.100:11211'
```

You can add a weight to each server to increase the likelihood of the server being selected during hashing by appending the weight count to the server host name/port string:

```
require 'memcache'
memc = MemCache::new '192.168.0.100:11211:3'
```

To add servers to an existing list, you can append them directly to the MemCache object:

```
memc += ["192.168.0.101:11211"]
```

To set data into the cache, you can just assign a value to a key within the new cache object, which works just like a standard Ruby hash object:

```
memc["key"] = "value"
```

Or to retrieve the value:

```
print memc["key"]
```

For more explicit actions, you can use the method interface, which mimics the main memcached API functions, as summarized in the following table:

Ruby MemCache Method	Equivalent to
get()	Generic get().
get_hash(keys)	Get the values of multiple keys, returning the information as a hash of the keys and their values.
set()	Generic set().
set_many(pairs)	Set the values of the keys and values in the hash pairs.
add()	Generic add().
replace()	Generic replace().
delete()	Generic delete().
incr()	Generic incr().
decr()	Generic decr().

Using MySQL and memcached with Java

The com.danga.MemCached class within Java provides a native interface to memcached instances. You can obtain the client from http://whalin.com/memcached/. The Java class uses hashes that are compatible with libmemcached, so you can mix and match Java and libmemcached applications accessing the same memcached instances. The serialization between Java and other interfaces are not compatible. If this is a problem, use JSON or a similar nonbinary serialization format.

On most systems, you can download the package and use the jar directly.

To use the com.danga.MemCached interface, you create a MemCachedClient instance and then configure the list of servers by configuring the SockIOPool. Through the pool specification you set up

the server list, weighting, and the connection parameters to optimized the connections between your client and the memcached instances that you configure.

Generally, you can configure the memcached interface once within a single class, then use this interface throughout the rest of your application.

For example, to create a basic interface, first configure the MemCachedClient and base SockIOPool settings:

```
public class MyClass {

    protected static MemCachedClient mcc = new MemCachedClient();

    static {

        String[] servers =
            {
                "localhost:11211",
            };

        Integer[] weights = { 1 };

        SockIOPool pool = SockIOPool.getInstance();

        pool.setServers( servers );
        pool.setWeights( weights );
```

In the above sample, the list of servers is configured by creating an array of the memcached instances to use. You can then configure individual weights for each server.

The remainder of the properties for the connection are optional, but you can set the connection numbers (initial connections, minimum connections, maximum connections, and the idle timeout) by setting the pool parameters:

```
pool.setInitConn( 5 );
pool.setMinConn( 5 );
pool.setMaxConn( 250 );
pool.setMaxIdle( 1000 * 60 * 60 * 6
```

Once the parameters have been configured, initialize the connection pool:

```
pool.initialize();
```

The pool, and the connection to your memcached instances should now be ready to use.

To set the hashing algorithm used to select the server used when storing a given key, use pool.setHashingAlg():

```
pool.setHashingAlg( SockIOPool.NEW_COMPAT_HASH );
```

Valid values are NEW_COMPAT_HASH, OLD_COMPAT_HASH and NATIVE_HASH are also basic modula hashing algorithms. For a consistent hashing algorithm, use CONSISTENT_HASH. These constants are equivalent to the corresponding hash settings within libmemcached.

Java com.danga.MemCached Method	Equivalent to
get()	Generic get().
getMulti(keys)	Get the values of multiple keys, returning the information as Hash map using java.lang.String for the keys and java.lang.Object for the corresponding values.
set()	Generic set().
add()	Generic add().

Java com.danga.MemCached Method	Equivalent to
replace()	Generic replace().
delete()	Generic delete().
incr()	Generic incr().
decr()	Generic decr().

Using the MySQL memcached User-Defined Functions

The memcached MySQL User-Defined Functions (UDFs) enable you to set and retrieve objects through a SQL interface, in MySQL 5.0 or greater. This technique has the following benefits:

- You can update and retrieve cached items directly from within SQL scripts, stored procedures, and triggers. For example, you might already have triggers in place to increment counters and set status flags based on general database activity.
- You can pass information back and forth with other applications that use memcached, without adding database connection and query code to them.
- You can avoid installing and configuring a memcached client on every combination of language and server that you use for your MySQL applications. The applications can relay memcached requests through the database server they connect to.
- You can access memcached servers from languages that do not have a memcached client.

To install the MySQL memcached UDFs, download the UDF package from https://launchpad.net/memcached-udfs. Unpack the package and run configure to configure the build process. When running configure, use the --with-mysql option and specify the location of the mysql_config command.

```
shell> tar zxf memcached_functions_mysql-1.1.tar.gz
shell> cd memcached_functions_mysql-1.1
shell> # If memcached library is not found, set LDFLAGS=-Llibrary_directory before next command.
shell> ./configure --with-mysql=/usr/local/mysql/bin/mysql_config
```

Now build and install the functions:

```
shell> make
shell> make install
```

Copy the MySQL memcached UDFs into your MySQL plugins directory:

```
shell> cp /usr/local/lib/libmemcached_functions_mysql* /usr/local/mysql/lib/mysql/plugins/
```

The plugin directory is given by the value of the plugin_dir [510] system variable. For more information, see Compiling and Installing User-Defined Functions.

Once installed, you must initialize the function within MySQL using CREATE and specifying the return value and library. For example, to add the memc_get() function:

```
mysql> CREATE FUNCTION memc_get RETURNS STRING SONAME "libmemcached_functions_mysql.so";
```

Repeat this process for each function to provide access to within MySQL. Once you have created the association, the information is retained, even over restarts of the MySQL server. To simplify the process, use the SQL script provided in the memcached UDFs package:

```
shell> mysql <sql/install_functions.sql
```

Alternatively, if you have Perl installed, then you can use the supplied Perl script, which checks for the existence of each function and creates the function/library association if it is not already defined:

```
shell> utils/install.pl --silent
```

The --silent option installs everything automatically. Without this option, the script asks whether to install each of the available functions.

The interface remains consistent with the other APIs and interfaces. To set up a list of servers, use the memc_servers_set() function, which accepts a single string containing and comma-separated list of servers:

```
mysql> SELECT memc_servers_set('192.168.0.1:11211,192.168.0.2:11211');
```

Note

The list of servers used by the memcached UDFs is not persistent over restarts of the MySQL server. If the MySQL server fails, then you must re-set the list of memcached servers.

To set a value, use memc_set:

```
mysql> SELECT memc_set('myid', 'myvalue');
```

To retrieve a stored value:

```
mysql> SELECT memc_get('myid');
```

The list of functions supported by the UDFs, in relation to the standard protocol functions, is shown in the following table:

MySQL memcached UDF Function	Equivalent to
memc_get()	Generic get().
memc_get_by_key(master_key, key, value)	Like the generic get(), but uses the supplied master key to select the server to use.
memc_set()	Generic set().
memc_set_by_key(master_key, key, value)	Like the generic set(), but uses the supplied master key to select the server to use.
memc_add()	Generic add().
memc_add_by_key(master_key, key, value)	Like the generic add(), but uses the supplied master key to select the server to use.
memc_replace()	Generic replace().
memc_replace_by_key(master_key, key, value)	Like the generic replace(), but uses the supplied master key to select the server to use.
memc_prepend(key, value)	Prepend the specified value to the current value of the specified key.
memc_prepend_by_key(master_key, key, value)	Prepend the specified value to the current value of the specified key, but uses the supplied master key to select the server to use.
memc_append(key, value)	Append the specified value to the current value of the specified key.
memc_append_by_key(master_key, key, value)	Append the specified value to the current value of the specified key, but uses the supplied master key to select the server to use.
memc_delete()	Generic delete().
memc_delete_by_key(master_key, key, value)	Like the generic delete(), but uses the supplied master key to select the server to use.
memc_increment()	Generic incr().
memc_decrement()	Generic decr().

The respective *_by_key() functions are useful to store a specific value into a specific memcached server, possibly based on a differently calculated or constructed key.

The memcached UDFs include some additional functions:

- memc_server_count()

  Returns a count of the number of servers in the list of registered servers.

- memc_servers_set_behavior(behavior_type, value), memc_set_behavior(behavior_type, value)

  Sets behaviors for the list of servers. These behaviors are identical to those provided by the libmemcached library. For more information on libmemcached behaviors, see Using libmemcached with C and C++.

  You can use the behavior name as the behavior_type:

  ```
  mysql> SELECT memc_servers_behavior_set("MEMCACHED_BEHAVIOR_KETAMA",1);
  ```

- memc_servers_behavior_get(behavior_type), memc_get_behavior(behavior_type, value)

  Returns the value for a given behavior.

- memc_list_behaviors()

  Returns a list of the known behaviors.

- memc_list_hash_types()

  Returns a list of the supported key-hashing algorithms.

- memc_list_distribution_types()

  Returns a list of the supported distribution types to be used when selecting a server to use when storing a particular key.

- memc_libmemcached_version()

  Returns the version of the libmemcached library.

- memc_stats()

  Returns the general statistics information from the server.

Using the memcached TCP Text Protocol

Communicating with a memcached server can be achieved through either the TCP or UDP protocols. When using the TCP protocol, you can use a simple text based interface for the exchange of information.

When communicating with memcached, you can connect to the server using the port configured for the server. You can open a connection with the server without requiring authorization or login. As soon as you have connected, you can start to send commands to the server. When you have finished, you can terminate the connection without sending any specific disconnection command. Clients are encouraged to keep their connections open to decrease latency and improve performance.

Data is sent to the memcached server in two forms:

- Text lines, which are used to send commands to the server, and receive responses from the server.
- Unstructured data, which is used to receive or send the value information for a given key. Data is returned to the client in exactly the format it was provided.

Both text lines (commands and responses) and unstructured data are always terminated with the string \r\n. Because the data being stored may contain this sequence, the length of the data (returned by the client before the unstructured data is transmitted should be used to determine the end of the data.

Commands to the server are structured according to their operation:

- **Storage commands**: set, add, replace, append, prepend, cas

  Storage commands to the server take the form:

  ```
  command key [flags] [exptime] length [noreply]
  ```

  Or when using compare and swap (cas):

  ```
  cas key [flags] [exptime] length [casunique] [noreply]
  ```

  Where:

  - command: The command name.
    - set: Store value against key
    - add: Store this value against key if the key does not already exist
    - replace: Store this value against key if the key already exists
    - append: Append the supplied value to the end of the value for the specified key. The flags and exptime arguments should not be used.
    - prepend: Append value currently in the cache to the end of the supplied value for the specified key. The flags and exptime arguments should not be used.
    - cas: Set the specified key to the supplied value, only if the supplied casunique matches. This is effectively the equivalent of change the information if nobody has updated it since I last fetched it.
  - key: The key. All data is stored using a the specific key. The key cannot contain control characters or whitespace, and can be up to 250 characters in size.
  - flags: The flags for the operation (as an integer). Flags in memcached are transparent. The memcached server ignores the contents of the flags. They can be used by the client to indicate any type of information. In memcached 1.2.0 and lower the value is a 16-bit integer value. In memcached 1.2.1 and higher the value is a 32-bit integer.
  - exptime: The expiry time, or zero for no expiry.
  - length: The length of the supplied value block in bytes, excluding the terminating \r\n characters.
  - casunique: A unique 64-bit value of an existing entry. This is used to compare against the existing value. Use the value returned by the gets command when issuing cas updates.
  - noreply: Tells the server not to reply to the command.

  For example, to store the value abcdef into the key xyzkey, you would use:

  ```
  set xyzkey 0 0 6\r\nabcdef\r\n
  ```

  The return value from the server is one line, specifying the status or error information. For more information, see Table 15.2, “memcached Protocol Responses”.

- **Retrieval commands**: get, gets

Retrieval commands take the form:

```
get key1 [key2 .... keyn]
gets key1 [key2 ... keyn]
```

You can supply multiple keys to the commands, with each requested key separated by whitespace.

The server responds with an information line of the form:

```
VALUE key flags bytes [casunique]
```

Where:

- `key`: The key name.
- `flags`: The value of the flag integer supplied to the `memcached` server when the value was stored.
- `bytes`: The size (excluding the terminating `\r\n` character sequence) of the stored value.
- `casunique`: The unique 64-bit integer that identifies the item.

The information line is immediately followed by the value data block. For example:

```
get xyzkey\r\n
VALUE xyzkey 0 6\r\n
abcdef\r\n
```

If you have requested multiple keys, an information line and data block is returned for each key found. If a requested key does not exist in the cache, no information is returned.

- **Delete commands**: `delete`

  Deletion commands take the form:

  ```
  delete key [time] [noreply]
  ```

  Where:

  - `key`: The key name.
  - `time`: The time in seconds (or a specific Unix time) for which the client wishes the server to refuse `add` or `replace` commands on this key. All `add`, `replace`, `get`, and `gets` commands fail during this period. `set` operations succeed. After this period, the key is deleted permanently and all commands are accepted.

    If not supplied, the value is assumed to be zero (delete immediately).
  - `noreply`: Tells the server not to reply to the command.

  Responses to the command are either `DELETED` to indicate that the key was successfully removed, or `NOT_FOUND` to indicate that the specified key could not be found.

- **Increment/Decrement**: `incr`, `decr`

  The increment and decrement commands change the value of a key within the server without performing a separate get/set sequence. The operations assume that the currently stored value is a 64-bit integer. If the stored value is not a 64-bit integer, then the value is assumed to be zero before the increment or decrement operation is applied.

  Increment and decrement commands take the form:

  ```
  incr key value [noreply]
  ```

```
decr key value [noreply]
```

Where:

- key: The key name.
- value: An integer to be used as the increment or decrement value.
- noreply: Tells the server not to reply to the command.

The response is:

- NOT_FOUND: The specified key could not be located.
- value: The new value associated with the specified key.

Values are assumed to be unsigned. For decr operations, the value is never decremented below 0. For incr operations, the value wraps around the 64-bit maximum.

- **Statistics commands**: stats

  The stats command provides detailed statistical information about the current status of the memcached instance and the data it is storing.

  Statistics commands take the form:

  ```
  STAT [name] [value]
  ```

  Where:

  - name: The optional name of the statistics to return. If not specified, the general statistics are returned.
  - value: A specific value to be used when performing certain statistics operations.

  The return value is a list of statistics data, formatted as follows:

  ```
  STAT name value
  ```

  The statistics are terminated with a single line, END.

  For more information, see Getting memcached Statistics.

For reference, a list of the different commands supported and their formats is provided below.

Table 15.1. memcached Command Reference

Command	Command Formats
set	set key flags exptime length, set key flags exptime length noreply
add	add key flags exptime length, add key flags exptime length noreply
replace	replace key flags exptime length, replace key flags exptime length noreply
append	append key length, append key length noreply
prepend	prepend key length, prepend key length noreply
cas	cas key flags exptime length casunique, cas key flags exptime length casunique noreply
get	get key1 [key2 ... keyn]
gets	

Command	Command Formats
delete	delete key, delete key noreply, delete key expiry, delete key expiry noreply
incr	incr key, incr key noreply, incr key value, incr key value noreply
decr	decr key, decr key noreply, decr key value, decr key value noreply
stat	stat, stat name, stat name value

When sending a command to the server, the response from the server is one of the settings in the following table. All response values from the server are terminated by \r\n:

Table 15.2. memcached Protocol Responses

String	Description
STORED	Value has successfully been stored.
NOT_STORED	The value was not stored, but not because of an error. For commands where you are adding a or updating a value if it exists (such as add and replace), or where the item has already been set to be deleted.
EXISTS	When using a cas command, the item you are trying to store already exists and has been modified since you last checked it.
NOT_FOUND	The item you are trying to store, update or delete does not exist or has already been deleted.
ERROR	You submitted a nonexistent command name.
CLIENT_ERROR errorstring	There was an error in the input line, the detail is contained in errorstring.
SERVER_ERROR errorstring	There was an error in the server that prevents it from returning the information. In extreme conditions, the server may disconnect the client after this error occurs.
VALUE keys flags length	The requested key has been found, and the stored key, flags and data block are returned, of the specified length.
DELETED	The requested key was deleted from the server.
STAT name value	A line of statistics data.
END	The end of the statistics data.

Getting memcached Statistics

The memcached system has a built-in statistics system that collects information about the data being stored into the cache, cache hit ratios, and detailed information on the memory usage and distribution of information through the slab allocation used to store individual items. Statistics are provided at both a basic level that provide the core statistics, and more specific statistics for specific areas of the memcached server.

This information can be useful to ensure that you are getting the correct level of cache and memory usage, and that your slab allocation and configuration properties are set at an optimal level.

The stats interface is available through the standard memcached protocol, so the reports can be accessed by using telnet to connect to the memcached. The supplied memcached-tool includes support for obtaining the memcached Slabs Statistics and memcached General Statistics information. For more information, see Using memcached-tool.

Alternatively, most of the language API interfaces provide a function for obtaining the statistics from the server.

For example, to get the basic stats using telnet:

```
shell> telnet localhost 11211
Trying ::1...
Connected to localhost.
Escape character is '^]'.
stats
STAT pid 23599
STAT uptime 675
STAT time 1211439587
STAT version 1.2.5
STAT pointer_size 32
STAT rusage_user 1.404992
STAT rusage_system 4.694685
STAT curr_items 32
STAT total_items 56361
STAT bytes 2642
STAT curr_connections 53
STAT total_connections 438
STAT connection_structures 55
STAT cmd_get 113482
STAT cmd_set 80519
STAT get_hits 78926
STAT get_misses 34556
STAT evictions 0
STAT bytes_read 6379783
STAT bytes_written 4860179
STAT limit_maxbytes 67108864
STAT threads 1
END
```

When using Perl and the Cache::Memcached module, the stats() function returns information about all the servers currently configured in the connection object, and total statistics for all the memcached servers as a whole.

For example, the following Perl script obtains the stats and dumps the hash reference that is returned:

```
use Cache::Memcached;
use Data::Dumper;

my $memc = new Cache::Memcached;
$memc->set_servers(\@ARGV);

print Dumper($memc->stats());
```

When executed on the same memcached as used in the Telnet example above we get a hash reference with the host by host and total statistics:

```
$VAR1 = {
    'hosts' => {
          'localhost:11211' => {
                    'misc' => {
                          'bytes' => '2421',
                          'curr_connections' => '3',
                          'connection_structures' => '56',
                          'pointer_size' => '32',
                          'time' => '1211440166',
                          'total_items' => '410956',
                          'cmd_set' => '588167',
                          'bytes_written' => '35715151',
                          'evictions' => '0',
                          'curr_items' => '31',
                          'pid' => '23599',
                          'limit_maxbytes' => '67108864',
                          'uptime' => '1254',
                          'rusage_user' => '9.857805',
                          'cmd_get' => '838451',
                          'rusage_system' => '34.096988',
                          'version' => '1.2.5',
                          'get_hits' => '581511',
                          'bytes_read' => '46665716',
```

```
                          'threads' => '1',
                          'total_connections' => '3104',
                          'get_misses' => '256940'
                        },
                    'sizes' => {
                          '128' => '16',
                          '64' => '15'
                        }
                  }
      },
  'self' => {},
  'total' => {
        'cmd_get' => 838451,
        'bytes' => 2421,
        'get_hits' => 581511,
        'connection_structures' => 56,
        'bytes_read' => 46665716,
        'total_items' => 410956,
        'total_connections' => 3104,
        'cmd_set' => 588167,
        'bytes_written' => 35715151,
        'curr_items' => 31,
        'get_misses' => 256940
      }
    };
```

The statistics are divided up into a number of distinct sections, and then can be requested by adding the type to the `stats` command. Each statistics output is covered in more detail in the following sections.

- General statistics, see `memcached` General Statistics.
- Slab statistics (`slabs`), see `memcached` Slabs Statistics.
- Item statistics (`items`), see `memcached` Item Statistics.
- Size statistics (`sizes`), see `memcached` Size Statistics.
- Detailed status (`detail`), see `memcached` Detail Statistics.

`memcached` General Statistics

The output of the general statistics provides an overview of the performance and use of the `memcached` instance. The statistics returned by the command and their meaning is shown in the following table.

The following terms are used to define the value type for each statistics value:

- `32u`: 32-bit unsigned integer
- `64u`: 64-bit unsigned integer
- `32u:32u`: Two 32-bit unsigned integers separated by a colon
- `String`: Character string

Statistic	Data type	Description	Version
`pid`	32u	Process ID of the `memcached` instance.	
`uptime`	32u	Uptime (in seconds) for this `memcached` instance.	
`time`	32u	Current time (as epoch).	
`version`	string	Version string of this instance.	
`pointer_size`	string	Size of pointers for this host specified in bits (32 or 64).	
`rusage_user`	32u:32u	Total user time for this instance (seconds:microseconds).	

Statistic	Data type	Description	Version
rusage_system	32u:32u	Total system time for this instance (seconds:microseconds).	
curr_items	32u	Current number of items stored by this instance.	
total_items	32u	Total number of items stored during the life of this instance.	
bytes	64u	Current number of bytes used by this server to store items.	
curr_connections	32u	Current number of open connections.	
total_connections	32u	Total number of connections opened since the server started running.	
connection_structures	32u	Number of connection structures allocated by the server.	
cmd_get	64u	Total number of retrieval requests (get operations).	
cmd_set	64u	Total number of storage requests (set operations).	
get_hits	64u	Number of keys that have been requested and found present.	
get_misses	64u	Number of items that have been requested and not found.	
delete_hits	64u	Number of keys that have been deleted and found present.	1.3.x
delete_misses	64u	Number of items that have been delete and not found.	1.3.x
incr_hits	64u	Number of keys that have been incremented and found present.	1.3.x
incr_misses	64u	Number of items that have been incremented and not found.	1.3.x
decr_hits	64u	Number of keys that have been decremented and found present.	1.3.x
decr_misses	64u	Number of items that have been decremented and not found.	1.3.x
cas_hits	64u	Number of keys that have been compared and swapped and found present.	1.3.x
cas_misses	64u	Number of items that have been compared and swapped and not found.	1.3.x
cas_badvalue	64u	Number of keys that have been compared and swapped, but the comparison (original) value did not match the supplied value.	1.3.x
evictions	64u	Number of valid items removed from cache to free memory for new items.	
bytes_read	64u	Total number of bytes read by this server from network.	
bytes_written	64u	Total number of bytes sent by this server to network.	
limit_maxbytes	32u	Number of bytes this server is permitted to use for storage.	
threads	32u	Number of worker threads requested.	
conn_yields	64u	Number of yields for connections (related to the -R option).	1.4.0

The most useful statistics from those given here are the number of cache hits, misses, and evictions.

A large number of get_misses may just be an indication that the cache is still being populated with information. The number should, over time, decrease in comparison to the number of cache get_hits. If, however, you have a large number of cache misses compared to cache hits after an extended period of execution, it may be an indication that the size of the cache is too small and you either need to increase the total memory size, or increase the number of the memcached instances to improve the hit ratio.

A large number of evictions from the cache, particularly in comparison to the number of items stored is a sign that your cache is too small to hold the amount of information that you regularly want to keep cached. Instead of items being retained in the cache, items are being evicted to make way for new items keeping the turnover of items in the cache high, reducing the efficiency of the cache.

memcached Slabs Statistics

To get the slabs statistics, use the stats slabs command, or the API equivalent.

The slab statistics provide you with information about the slabs that have created and allocated for storing information within the cache. You get information both on each individual slab-class and total statistics for the whole slab.

```
STAT 1:chunk_size 104
STAT 1:chunks_per_page 10082
STAT 1:total_pages 1
STAT 1:total_chunks 10082
STAT 1:used_chunks 10081
STAT 1:free_chunks 1
STAT 1:free_chunks_end 10079
STAT 9:chunk_size 696
STAT 9:chunks_per_page 1506
STAT 9:total_pages 63
STAT 9:total_chunks 94878
STAT 9:used_chunks 94878
STAT 9:free_chunks 0
STAT 9:free_chunks_end 0
STAT active_slabs 2
STAT total_malloced 67083616
END
```

Individual stats for each slab class are prefixed with the slab ID. A unique ID is given to each allocated slab from the smallest size up to the largest. The prefix number indicates the slab class number in relation to the calculated chunk from the specified growth factor. Hence in the example, 1 is the first chunk size and 9 is the 9th chunk allocated size.

The different parameters returned for each chunk size and the totals are shown in the following table.

Statistic	Description	Version
chunk_size	Space allocated to each chunk within this slab class.	
chunks_per_page	Number of chunks within a single page for this slab class.	
total_pages	Number of pages allocated to this slab class.	
total_chunks	Number of chunks allocated to the slab class.	
used_chunks	Number of chunks allocated to an item..	
free_chunks	Number of chunks not yet allocated to items.	
free_chunks_end	Number of free chunks at the end of the last allocated page.	
get_hits	Number of get hits to this chunk	1.3.x
cmd_set	Number of set commands on this chunk	1.3.x
delete_hits	Number of delete hits to this chunk	1.3.x
incr_hits	Number of increment hits to this chunk	1.3.x
decr_hits	Number of decrement hits to this chunk	1.3.x

Statistic	Description	Version
cas_hits	Number of CAS hits to this chunk	1.3.x
cas_badval	Number of CAS hits on this chunk where the existing value did not match	1.3.x
mem_requested	The true amount of memory of memory requested within this chunk	1.4.1

The following additional statistics cover the information for the entire server, rather than on a chunk by chunk basis:

Statistic	Description	Version
active_slabs	Total number of slab classes allocated.	
total_malloced	Total amount of memory allocated to slab pages.	

The key values in the slab statistics are the chunk_size, and the corresponding total_chunks and used_chunks parameters. These given an indication of the size usage of the chunks within the system. Remember that one key/value pair is placed into a chunk of a suitable size.

From these stats, you can get an idea of your size and chunk allocation and distribution. If you store many items with a number of largely different sizes, consider adjusting the chunk size growth factor to increase in larger steps to prevent chunk and memory wastage. A good indication of a bad growth factor is a high number of different slab classes, but with relatively few chunks actually in use within each slab. Increasing the growth factor creates fewer slab classes and therefore makes better use of the allocated pages.

memcached Item Statistics

To get the items statistics, use the stats items command, or the API equivalent.

The items statistics give information about the individual items allocated within a given slab class.

```
STAT items:2:number 1
STAT items:2:age 452
STAT items:2:evicted 0
STAT items:2:evicted_nonzero 0
STAT items:2:evicted_time 2
STAT items:2:outofmemory 0
STAT items:2:tailrepairs 0
...
STAT items:27:number 1
STAT items:27:age 452
STAT items:27:evicted 0
STAT items:27:evicted_nonzero 0
STAT items:27:evicted_time 2
STAT items:27:outofmemory 0
STAT items:27:tailrepairs 0
```

The prefix number against each statistics relates to the corresponding chunk size, as returned by the stats slabs statistics. The result is a display of the number of items stored within each chunk within each slab size, and specific statistics about their age, eviction counts, and out of memory counts. A summary of the statistics is given in the following table.

Statistic	Description	
number	The number of items currently stored in this slab class.	
age	The age of the oldest item within the slab class, in seconds.	
evicted	The number of items evicted to make way for new entries.	
evicted_time	The time of the last evicted entry	
evicted_nonzero	The time of the last evicted non-zero entry	1.4.0

Statistic	Description	
outofmemory	The number of items for this slab class that have triggered an out of memory error (only value when the -M command line option is in effect).	
tailrepairs	Number of times the entries for a particular ID need repairing	

Item level statistics can be used to determine how many items are stored within a given slab and their freshness and recycle rate. You can use this to help identify whether there are certain slab classes that are triggering a much larger number of evictions that others.

memcached Size Statistics

To get size statistics, use the stats sizes command, or the API equivalent.

The size statistics provide information about the sizes and number of items of each size within the cache. The information is returned as two columns, the first column is the size of the item (rounded up to the nearest 32 byte boundary), and the second column is the count of the number of items of that size within the cache:

```
96 35
128 38
160 807
192 804
224 410
256 222
288 83
320 39
352 53
384 33
416 64
448 51
480 30
512 54
544 39
576 10065
```

Caution

Running this statistic locks up your cache as each item is read from the cache and its size calculated. On a large cache, this may take some time and prevent any set or get operations until the process completes.

The item size statistics are useful only to determine the sizes of the objects you are storing. Since the actual memory allocation is relevant only in terms of the chunk size and page size, the information is only useful during a careful debugging or diagnostic session.

memcached Detail Statistics

For memcached 1.3.x and higher, you can enable and obtain detailed statistics about the get, set, and del operations on theindividual keys stored in the cache, and determine whether the attempts hit (found) a particular key. These operations are only recorded while the detailed stats analysis is turned on.

To enable detailed statistics, you must send the stats detail on command to the memcached server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.stats detail on
OK
```

Individual statistics are recorded for every get, set and del operation on a key, including keys that are not currently stored in the server. For example, if an attempt is made to obtain the value of key

abckey and it does not exist, the get operating on the specified key are recorded while detailed statistics are in effect, even if the key is not currently stored. The hits, that is, the number of get or del operations for a key that exists in the server are also counted.

To turn detailed statistics off, send the stats detail off command to the memcached server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.stats detail on
OK
```

To obtain the detailed statistics recorded during the process, send the stats detail dump command to the memcached server:

```
stats detail dump
PREFIX hykkey get 0 hit 0 set 1 del 0
PREFIX xyzkey get 0 hit 0 set 1 del 0
PREFIX yukkey get 1 hit 0 set 0 del 0
PREFIX abckey get 3 hit 3 set 1 del 0
END
```

You can use the detailed statistics information to determine whether your memcached clients are using a large number of keys that do not exist in the server by comparing the hit and get or del counts. Because the information is recorded by key, you can also determine whether the failures or operations are clustered around specific keys.

Using memcached-tool

The memcached-tool, located within the scripts directory within the memcached source directory. The tool provides convenient access to some reports and statistics from any memcached instance.

The basic format of the command is:

```
shell> ./memcached-tool hostname:port [command]
```

The default output produces a list of the slab allocations and usage. For example:

```
shell> memcached-tool localhost:11211 display
  #  Item_Size  Max_age   Pages   Count   Full?  Evicted Evict_Time OOM
  1      80B        93s       1      20      no        0        0    0
  2     104B        93s       1      16      no        0        0    0
  3     136B      1335s       1      28      no        0        0    0
  4     176B      1335s       1      24      no        0        0    0
  5     224B      1335s       1      32      no        0        0    0
  6     280B      1335s       1      34      no        0        0    0
  7     352B      1335s       1      36      no        0        0    0
  8     440B      1335s       1      46      no        0        0    0
  9     552B      1335s       1      58      no        0        0    0
 10     696B      1335s       1      66      no        0        0    0
 11     872B      1335s       1      89      no        0        0    0
 12     1.1K      1335s       1     112      no        0        0    0
 13     1.3K      1335s       1     145      no        0        0    0
 14     1.7K      1335s       1     123      no        0        0    0
 15     2.1K      1335s       1     198      no        0        0    0
 16     2.6K      1335s       1     199      no        0        0    0
 17     3.3K      1335s       1     229      no        0        0    0
 18     4.1K      1335s       1     248     yes       36        2    0
 19     5.2K      1335s       2     328      no        0        0    0
 20     6.4K      1335s       2     316     yes      387        1    0
 21     8.1K      1335s       3     381     yes      492        1    0
 22    10.1K      1335s       3     303     yes      598        2    0
 23    12.6K      1335s       5     405     yes      605        1    0
 24    15.8K      1335s       6     384     yes      766        2    0
 25    19.7K      1335s       7     357     yes      908      170    0
 26    24.6K      1336s       7     287     yes     1012        1    0
 27    30.8K      1336s       7     231     yes     1193      169    0
 28    38.5K      1336s       4     104     yes     1323      169    0
 29    48.1K      1336s       1      21     yes     1287        1    0
```

```
 30    60.2K      1336s       1      17     yes     1093      169    0
 31    75.2K      1337s       1      13     yes      713      168    0
 32    94.0K      1337s       1      10     yes      278      168    0
 33   117.5K      1336s       1       3      no        0        0    0
```

This output is the same if you specify the `command` as `display`:

```
shell> memcached-tool localhost:11211 display
  #  Item_Size  Max_age   Pages   Count   Full?  Evicted Evict_Time OOM
  1      80B        93s       1      20      no        0        0    0
  2     104B        93s       1      16      no        0        0    0
...
```

The output shows a summarized version of the output from the `slabs` statistics. The columns provided in the output are shown below:

- `#`: The slab number
- `Item_Size`: The size of the slab
- `Max_age`: The age of the oldest item in the slab
- `Pages`: The number of pages allocated to the slab
- `Count`: The number of items in this slab
- `Full?`: Whether the slab is fully populated
- `Evicted`: The number of objects evicted from this slab
- `Evict_Time`: The time (in seconds) since the last eviction
- `OOM`: The number of items that have triggered an out of memory error

You can also obtain a dump of the general statistics for the server using the `stats` command:

```
shell> memcached-tool localhost:11211 stats
#localhost:11211   Field       Value
         accepting_conns           1
                   bytes         162
             bytes_read         485
          bytes_written        6820
              cas_badval           0
                cas_hits           0
              cas_misses           0
               cmd_flush           0
                 cmd_get           4
                 cmd_set           2
              conn_yields           0
   connection_structures          11
        curr_connections          10
              curr_items           2
               decr_hits           0
             decr_misses           1
             delete_hits           0
          delete_misses           0
              evictions           0
               get_hits           4
             get_misses           0
               incr_hits           0
             incr_misses           2
          limit_maxbytes    67108864
     listen_disabled_num           0
                     pid       12981
           pointer_size          32
          rusage_system    0.013911
            rusage_user    0.011876
                threads           4
                   time  1255518565
       total_connections          20
             total_items           2
```

```
                uptime         880
               version       1.4.2
```

memcached FAQ

Questions

- 16.6.5.1: [1558] Can MySQL actually trigger/store the changed data to memcached?
- 16.6.5.2: [1558] Can memcached be run on a Windows environment?
- 16.6.5.3: [1558] What is the maximum size of an object you can store in memcached? Is that configurable?
- 16.6.5.4: [1559] Is it true memcached will be much more effective with db-read-intensive applications than with db-write-intensive applications?
- 16.6.5.5: [1559] Is there any overhead in not using persistent connections? If persistent is always recommended, what are the downsides (for example, locking up)?
- 16.6.5.6: [1559] How is an event such as a crash of one of the memcached servers handled by the memcached client?
- 16.6.5.7: [1559] What is a recommended hardware configuration for a memcached server?
- 16.6.5.8: [1559] Is memcached more effective for video and audio as opposed to textual read/writes?
- 16.6.5.9: [1559] Can memcached work with ASPX?
- 16.6.5.10: [1560] How expensive is it to establish a memcache connection? Should those connections be pooled?
- 16.6.5.11: [1560] How is the data handled when the memcached server is down?
- 16.6.5.12: [1560] How are auto-increment columns in the MySQL database coordinated across multiple instances of memcached?
- 16.6.5.13: [1560] Is compression available?
- 16.6.5.14: [1560] Can we implement different types of memcached as different nodes in the same server, so can there be deterministic and non-deterministic in the same server?
- 16.6.5.15: [1560] What are best practices for testing an implementation, to ensure that it improves performance, and to measure the impact of memcached configuration changes? And would you recommend keeping the configuration very simple to start?

Questions and Answers

16.6.5.1: Can MySQL actually trigger/store the changed data to memcached?

Yes. You can use the MySQL UDFs for memcached and either write statements that directly set the values in the memcached server, or use triggers or stored procedures to do it for you. For more information, see Using the MySQL memcached User-Defined Functions

16.6.5.2: Can memcached be run on a Windows environment?

No. Currently memcached is available only on the Unix/Linux platform. There is an unofficial port available, see http://www.codeplex.com/memcachedproviders.

16.6.5.3: What is the maximum size of an object you can store in memcached? Is that configurable?

The default maximum object size is 1MB. In memcached 1.4.2 and later, you can change the maximum size of an object using the `-I` command line option.

For versions before this, to increase this size, you have to re-compile memcached. You can modify the value of the POWER_BLOCK within the slabs.c file within the source.

In memcached 1.4.2 and higher, you can configure the maximum supported object size by using the -I command-line option. For example, to increase the maximum object size to 5MB:

```
$ memcached -I 5m
```

If an object is larger than the maximum object size, you must manually split it. memcached is very simple: you give it a key and some data, it tries to cache it in RAM. If you try to store more than the default maximum size, the value is just truncated for speed reasons.

16.6.5.4: Is it true memcached will be much more effective with db-read-intensive applications than with db-write-intensive applications?

Yes. memcached plays no role in database writes, it is a method of caching data already read from the database in RAM.

16.6.5.5: Is there any overhead in not using persistent connections? If persistent is always recommended, what are the downsides (for example, locking up)?

If you don't use persistent connections when communicating with memcached, there will be a small increase in the latency of opening the connection each time. The effect is comparable to use nonpersistent connections with MySQL.

In general, the chance of locking or other issues with persistent connections is minimal, because there is very little locking within memcached. If there is a problem, eventually your request will time out and return no result, so your application will need to load from MySQL again.

16.6.5.6: How is an event such as a crash of one of the memcached servers handled by the memcached client?

There is no automatic handling of this. If your client fails to get a response from a server, code a fallback mechanism to load the data from the MySQL database.

The client APIs all provide the ability to add and remove memcached instances on the fly. If within your application you notice that memcached server is no longer responding, you can remove the server from the list of servers, and keys will automatically be redistributed to another memcached server in the list. If retaining the cache content on all your servers is important, make sure you use an API that supports a consistent hashing algorithm. For more information, see memcached Hashing/Distribution Types.

16.6.5.7: What is a recommended hardware configuration for a memcached server?

memcached has a very low processing overhead. All that is required is spare physical RAM capacity. A memcached server does not require a dedicated machine. If you have web, application, or database servers that have spare RAM capacity, then use them with memcached.

To build and deploy a dedicated memcached server, use a relatively low-power CPU, lots of RAM, and one or more Gigabit Ethernet interfaces.

16.6.5.8: Is memcached more effective for video and audio as opposed to textual read/writes?

memcached works equally well for all kinds of data. To memcached, any value you store is just a stream of data. Remember, though, that the maximum size of an object you can store in memcached is 1MB, but can be configured to be larger by using the -I option in memcached 1.4.2 and later, or by modifying the source in versions before 1.4.2. If you plan on using memcached with audio and video content, you will probably want to increase the maximum object size. Also remember that memcached is a solution for caching information for reading. It shouldn't be used for writes, except when updating the information in the cache.

16.6.5.9: Can memcached work with ASPX?

There are ports and interfaces for many languages and environments. ASPX relies on an underlying language such as C# or VisualBasic, and if you are using ASP.NET then there is a C# memcached library. For more information, see https://sourceforge.net/projects/memcacheddotnet/.

16.6.5.10: How expensive is it to establish a memcache connection? Should those connections be pooled?

Opening the connection is relatively inexpensive, because there is no security, authentication or other handshake taking place before you can start sending requests and getting results. Most APIs support a persistent connection to a memcached instance to reduce the latency. Connection pooling would depend on the API you are using, but if you are communicating directly over TCP/IP, then connection pooling would provide some small performance benefit.

16.6.5.11: How is the data handled when the memcached server is down?

The behavior is entirely application dependent. Most applications fall back to loading the data from the database (just as if they were updating the memcached information). If you are using multiple memcached servers, you might also remove a downed server from the list to prevent it from affecting performance. Otherwise, the client will still attempt to communicate with the memcached server that corresponds to the key you are trying to load.

16.6.5.12: How are auto-increment columns in the MySQL database coordinated across multiple instances of memcached?

They aren't. There is no relationship between MySQL and memcached unless your application (or, if you are using the MySQL UDFs for memcached, your database definition) creates one.

If you are storing information based on an auto-increment key into multiple instances of memcached, the information is only stored on one of the memcached instances anyway. The client uses the key value to determine which memcached instance to store the information. It doesn't store the same information across all the instances, as that would be a waste of cache memory.

16.6.5.13: Is compression available?

Yes. Most of the client APIs support some sort of compression, and some even allow you to specify the threshold at which a value is deemed appropriate for compression during storage.

16.6.5.14: Can we implement different types of memcached as different nodes in the same server, so can there be deterministic and non-deterministic in the same server?

Yes. You can run multiple instances of memcached on a single server, and in your client configuration you choose the list of servers you want to use.

16.6.5.15: What are best practices for testing an implementation, to ensure that it improves performance, and to measure the impact of memcached configuration changes? And would you recommend keeping the configuration very simple to start?

The best way to test the performance is to start up a memcached instance. First, modify your application so that it stores the data just before the data is about to be used or displayed into memcached. Since the APIs handle the serialization of the data, it should just be a one-line modification to your code. Then, modify the start of the process that would normally load that information from MySQL with the code that requests the data from memcached. If the data cannot be loaded from memcached, default to the MySQL process.

All of the changes required will probably amount to just a few lines of code. To get the best benefit, make sure you cache entire objects (for example, all the components of a web page, blog post, discussion thread, and so on), rather than using memcached as a simple cache of individual rows of MySQL tables.

Keeping the configuration simple at the start, or even over the long term, is easy with memcached. Once you have the basic structure up and running, often the only ongoing change is to add more servers into the list of servers used by your applications. You don't need to manage the memcached

servers, and there is no complex configuration; just add more servers to the list and let the client API and the `memcached` servers make the decisions.

MySQL Proxy

The MySQL Proxy is an application that communicates over the network using the MySQL network protocol and provides communication between one or more MySQL servers and one or more MySQL clients. Because MySQL Proxy uses the MySQL network protocol, it can be used without modification with any MySQL-compatible client that uses the protocol. This includes the `mysql` command-line client, any clients that uses the MySQL client libraries, and any connector that supports the MySQL network protocol.

In the most basic configuration, MySQL Proxy simply interposes itself between the server and clients, passing queries from the clients to the MySQL Server and returning the responses from the MySQL Server to the appropriate client. In more advanced configurations, the MySQL Proxy can also monitor and alter the communication between the client and the server. Query interception enables you to add profiling, and interception of the exchanges is scriptable using the Lua scripting language.

By intercepting the queries from the client, the proxy can insert additional queries into the list of queries sent to the server, and remove the additional results when they are returned by the server. Using this functionality you can return the results from the original query to the client while adding informational statements to each query, for example, to monitor their execution time or progress, and separately log the results.

The proxy enables you to perform additional monitoring, filtering, or manipulation of queries without requiring you to make any modifications to the client and without the client even being aware that it is communicating with anything but a genuine MySQL server.

This documentation covers MySQL Proxy 0.8.2. And MySQL Proxy contains third-party code. For license information on third-party code, see Appendix A, *Licenses for Third-Party Components*.

Warning

MySQL Proxy is currently an Alpha release and should not be used within production environments.

Important

MySQL Proxy is compatible with MySQL 5.0 or later. Testing has not been performed with Version 4.1. Please provide feedback on your experiences using the MySQL Proxy Forum.

MySQL Proxy Supported Platforms

MySQL Proxy is currently available as a precompiled binary for the following platforms:

- Linux (including Red Hat, Fedora, Debian, SuSE) and derivatives
- Mac OS X
- FreeBSD
- IBM AIX
- Sun Solaris
- Microsoft Windows (including Microsoft Windows XP, Microsoft Windows Vista, Microsoft Windows Server 2003, Microsoft Windows Server 2008)

Note

You must have the .NET Framework 1.1 or higher installed.

Other Unix/Linux platforms not listed should be compatible by using the source package and building MySQL Proxy locally.

System requirements for the MySQL Proxy application are the same as the main MySQL server. Currently MySQL Proxy is compatible only with MySQL 5.0.1 and later. MySQL Proxy is provided as a standalone, statically linked binary. You need not have MySQL or Lua installed.

Installing MySQL Proxy

You have three choices for installing MySQL Proxy:

- Precompiled binaries are available for a number of different platforms. See Installing MySQL Proxy from a Binary Distribution.
- You can install from the source code to build on an environment not supported by the binary distributions. See Installing MySQL Proxy from a Source Distribution.
- The latest version of the MySQL Proxy source code is available through a development repository is the best way to stay up to date with the latest fixes and revisions. See Installing MySQL Proxy from the Bazaar Repository.

Installing MySQL Proxy from a Binary Distribution

If you download a binary package, you must extract and copy the package contents to your desired installation directory. The package contains files required by MySQL Proxy, including additional Lua scripts and other components required for execution.

To install, unpack the archive into the desired directory, then modify your `PATH` environment variable so that you can use the `mysql-proxy` command directly:

```
shell> cd /usr/local
shell> tar zxf mysql-proxy-0.8.2-platform.tar.gz
shell> PATH=$PATH:/usr/local/mysql-proxy-0.8.2-platform/sbin
```

To update the path globally on a system, you might need administrator privileges to modify the appropriate `/etc/profile`, `/etc/bashrc`, or other system configuration file.

On Windows, you can update the `PATH` environment variable using this procedure:

1. On the Windows desktop, right-click the My Computer icon, and select Properties.
2. Next select the Advanced tab from the System Properties menu that appears, and click the Environment Variables button.
3. Under **System Variables**, select Path, then click the Edit button. The Edit System Variable dialogue should appear.

The Microsoft Visual C++ runtime libraries are a requirement for running MySQL Proxy as of version 0.8.2. Users that do not have these libraries must download and install the Microsoft Visual C++ 2008 Service Pack 1 Redistributable Package MFC Security Update. Use the following link to obtain the package:

```
http://www.microsoft.com/download/en/details.aspx?id=26368
```

Installing MySQL Proxy from a Source Distribution

You can download a source package and compile the MySQL Proxy yourself. To build from source, you must have the following prerequisite components installed:

- `libevent` 1.x or higher (1.3b or later is preferred).
- `lua` 5.1.x or higher.
- `glib2` 2.6.0 or higher.

- `pkg-config`.
- `libtool` 1.5 or higher.
- MySQL 5.0.x or higher developer files.

Note

On some operating systems, you might need to manually build the required components to get the latest version. If you have trouble compiling MySQL Proxy, consider using a binary distributions instead.

After verifying that the prerequisite components are installed, configure and build MySQL Proxy:

```
shell> tar zxf mysql-proxy-0.8.2.tar.gz
shell> cd mysql-proxy-0.8.2
shell> ./configure
shell> make
```

To test the build, use the `check` target to `make`:

```
shell> make check
```

The tests try to connect to `localhost` using the `root` user. To provide a password, set the `MYSQL_PASSWORD` environment variable:

```
shell> MYSQL_PASSWORD=root_pwd make check
```

You can install using the `install` target:

```
shell> make install
```

By default, `mysql-proxy` is installed into `/usr/local/sbin/mysql-proxy`. The Lua example scripts are installed into `/usr/local/share`.

Installing MySQL Proxy from the Bazaar Repository

The MySQL Proxy source is available through a public Bazaar repository and is the quickest way to get the latest releases and fixes.

A build from the Bazaar repository requires that the following prerequisite components be installed:

- Bazaar 1.10.0 or later.
- `libtool` 1.5 or higher.
- `autoconf` 2.56 or higher.
- `automake` 1.10 or higher.
- `libevent` 1.x or higher (1.3b or later is preferred).
- `lua` 5.1.x or higher.
- `glib2` 2.4.0 or higher.
- `pkg-config`.
- MySQL 5.0.x or higher developer files.

The `mysql-proxy` source is hosted on Launchpad. To check out a local copy of the Bazaar repository, use `bzr`:

```
shell> bzr branch lp:mysql-proxy
```

The preceding command downloads a complete version of the Bazaar repository for `mysql-proxy`. The main source files are located within the `trunk` subdirectory. The configuration scripts must be

generated before you can configure and build `mysql-proxy`. The `autogen.sh` script generates the required configuration scripts for you:

```
shell> sh ./autogen.sh
```

The `autogen.sh` script creates the standard `configure` script, which you then use to configure and build with `make`:

```
shell> ./configure
shell> make
shell> make install
```

To create a standalone source distribution, identical to the source distribution available for download, use this command:

```
shell> make distcheck
```

The preceding command creates the file `mysql-proxy-0.8.2.tar.gz` (with the corresponding current version) within the current directory.

Setting Up MySQL Proxy as a Windows Service

The MySQL distribution on Windows includes the `mysql-proxy-svc.exe` command that enables a MySQL Proxy instance to be managed by the Windows service control manager. You can control the service, including automatically starting and stopping it during boot, reboot and shutdown, without separately running the MySQL Proxy application.

To set up a MySQL Proxy service, use the `sc` command to create a new service using the MySQL Proxy service command. Specify the MySQL Proxy options on the `sc` command line, and identify the service with a unique name. For example, to configure a new MySQL Proxy instance that will automatically start when your system boots, redirecting queries to the local MySQL server:

```
C:\> sc create "Proxy" DisplayName= "MySQL Proxy" start= "auto" »
  binPath= "C:\Program Files\MySQL\mysql-proxy-0.8.2\bin\mysql-proxy-svc.exe »
  --proxy-backend-addresses=127.0.0.1:3306"
```

Note

The space following the equal sign after each property is required; failure to include it results in an error.

The preceding command creates a new service called `Proxy`. You can start and stop the service using the `net start|stop` command with the service name. The service is not automatically started after it is created. To start the service:

```
C:\> net start proxy
The MySQL Proxy service is starting.
The MySQL Proxy service was started successfully.
```

You can specify additional command-line options to the `sc` command. You can also set up multiple MySQL Proxy services on the same machine (providing they are configured to listen on different ports and/or IP addresses.

You can delete a service that you have created:

```
C:\> sc delete proxy
```

For more information on creating services using `sc`, see How to create a Windows service by using Sc.exe.

MySQL Proxy Command Options

To start MySQL Proxy, you can run it directly from the command line:

```
shell> mysql-proxy
```

For most situations, you specify at least the host name or address and the port number of the backend MySQL server to which the MySQL Proxy should pass queries.

You can specify options to `mysql-proxy` either on the command line, or by using a configuration file and the `--defaults-file` [1568] command-line option to specify the file location.

If you use a configuration file, format it as follows:

- Specify the options within a `[mysql-proxy]` configuration group. For example:

```
[mysql-proxy]
admin-address = host:port
```

- Specify all configuration options in the form of a configuration name and the value to set.
- For options that are a simple toggle on the command line (for example, `--proxy-skip-profiling` [1572]), use `true` or `false`. For example, the following is invalid:

```
[mysql-proxy]
proxy-skip-profiling
```

  But this is valid:

```
[mysql-proxy]
proxy-skip-profiling = true
```

- Give the configuration file Unix permissions of `0660` (readable and writable by user and group, no access for others).

Failure to adhere to any of these requirements causes `mysql-proxy` to generate an error during startup.

The following tables list the supported configuration file and command-line options.

Table 15.3. `mysql-proxy` Help Options

Format	Option File	Description
--help [1567]		Show help options
--help-admin [1567]		Show admin module options
--help-all [1567]		Show all help options
--help-proxy [1567]		Show proxy module options

Table 15.4. `mysql-proxy` Admin Options

Format	Option File	Description
--admin-address=host:port [1567]	admin-address=host:port [1567]	The admin module listening host and port
--admin-lua-script=file_name [1567]	admin-lua-script=file_name [1567]	Script to execute by the admin module
--admin-password=password [1567]	admin-password=password [1567]	Authentication password for admin module
--admin-username=user_name [1568]	admin-username=user_name [1568]	Authentication user name for admin module
--proxy-address=host:port [1571]	proxy-address=host:port [1571]	The listening proxy server host and port

Table 15.5. `mysql-proxy` Proxy Options

Format	Option File	Description	Removed
--no-proxy [1570]	no-proxy [1570]	Do not start the proxy module	

Format	Option File	Description	Removed
--proxy-backend-addresses=host:port [1571]	proxy-backend-addresses=host:port [1571]	The MySQL server host and port	
--proxy-fix-bug-25371 [1572]	proxy-fix-bug-25371 [1572]	Enable the fix for Bug #25371 for older libmysql versions	0.8.1
--proxy-lua-script=file_name [1572]	proxy-lua-script=file_name [1572]	Filename for Lua script for proxy operations	
--proxy-pool-no-change-user [1572]	proxy-pool-no-change-user [1572]	Do not use the protocol CHANGE_USER command to reset the connection when coming from the connection pool	
--proxy-read-only-backend-addresses=host:port [1571]	proxy-read-only-backend-addresses=host:port [1571]	The MySQL server host and port (read only)	
--proxy-skip-profiling [1572]	proxy-skip-profiling [1572]	Disable query profiling	

Table 15.6. `mysql-proxy` Applications Options

Format	Option File	Description
--basedir=dir_name [1568]	basedir=dir_name [1568]	The base directory prefix for paths in the configuration
--daemon [1568]	daemon [1568]	Start in daemon mode
--defaults-file=file_name [1568]		The configuration file to use
--event-threads=count [1568]	event-threads=count [1568]	The number of event-handling threads
--keepalive [1569]	keepalive [1569]	Try to restart the proxy if a crash occurs
--log-backtrace-on-crash [1569]	log-backtrace-on-crash [1569]	Try to invoke the debugger and generate a backtrace on crash
--log-file=file_name [1569]	log-file=file_name [1569]	The file where error messages are logged
--log-level=level [1569]	log-level=level [1569]	The logging level
--log-use-syslog [1569]	log-use-syslog [1569]	Log errors to syslog
--lua-cpath=dir_name [1570]	lua-cpath=dir_name [1570]	Set the LUA_CPATH
--lua-path=dir_name [1570]	lua-path=dir_name [1570]	Set the LUA_PATH
--max-open-files=count [1570]	max-open-files=count [1570]	The maximum number of open files to support
--pid-file=file_name [1573]	pid-file=file_name [1573]	File in which to store the process ID
--plugin-dir=dir_name [1570]	plugin-dir=dir_name [1570]	Directory containing plugin files
--plugins=plugin,... [1570]	plugins=plugin,... [1570]	List of plugins to load
--user=user_name [1573]	user=user_name [1573]	The user to use when running mysql-proxy
--version [1573]		Show version information

Except as noted in the following details, all of the options can be used within the configuration file by supplying the option and the corresponding value. For example:

```
[mysql-proxy]
log-file = /var/log/mysql-proxy.log
log-level = message
```

- `--help` [1567], `-h`

Command-Line Format	`--help`
	`-h`

Show available help options.

- `--help-admin` [1567]

Command-Line Format	`--help-admin`

Show options for the admin module.

- `--help-all` [1567]

Command-Line Format	`--help-all`

Show all help options.

- `--help-proxy` [1567]

Command-Line Format	`--help-proxy`

Show options for the proxy module.

- `--admin-address=`*`host`*`:`*`port`* [1567]

Command-Line Format	`--admin-address=host:port`	
Option-File Format	`admin-address=host:port`	
	Permitted Values	
	Type	`string`
	Default	`:4041`

The host name (or IP address) and port for the administration port. The default is `localhost:4041`.

- `--admin-lua-script=`*`file_name`* [1567]

Command-Line Format	`--admin-lua-script=file_name`	
Option-File Format	`admin-lua-script=file_name`	
	Permitted Values	
	Type	`file name`
	Default	

The script to use for the proxy administration module.

- `--admin-password=`*`password`* [1567]

Command-Line Format	`--admin-password=password`
Option-File Format	`admin-password=password`

	Permitted Values	
	Type	`string`
	Default	

The password to use to authenticate users wanting to connect to the MySQL Proxy administration module. This module uses the MySQL protocol to request a user name and password for connections.

- `--admin-username=user_name` [1568]

Command-Line Format	`--admin-username=user_name`	
Option-File Format	`admin-username=user_name`	
	Permitted Values	
	Type	`string`
	Default	`root`

The user name to use to authenticate users wanting to connect to the MySQL Proxy administration module. This module uses the MySQL protocol to request a user name and password for connections. The default user name is `root`.

- `--basedir=dir_name` [1568]

Command-Line Format	`--basedir=dir_name`	
Option-File Format	`basedir=dir_name`	
	Permitted Values	
	Type	`directory name`

The base directory to use as a prefix for all other file name configuration options. The base name should be an absolute (not relative) directory. If you specify a relative directory, `mysql-proxy` generates an error during startup.

- `--daemon` [1568]

Command-Line Format	`--daemon`
Option-File Format	`daemon`

Starts the proxy in daemon mode.

- `--defaults-file=file_name` [1568]

Command-Line Format	`--defaults-file=file_name`

The file to read for configuration options. If not specified, MySQL Proxy takes options only from the command line.

- `--event-threads=count` [1568]

Command-Line Format	`--event-threads=count`	
Option-File Format	`event-threads=count`	
	Permitted Values	
	Type	`numeric`
	Default	`1`

The number of event threads to reserve to handle incoming requests.

- `--keepalive` [1569]

Command-Line Format	`--keepalive`
Option-File Format	`keepalive`

Create a process surrounding the main `mysql-proxy` process that attempts to restart the main `mysql-proxy` process in the event of a crash or other failure.

Note

The `--keepalive` [1569] option is not available on Microsoft Windows. When running as a service, `mysql-proxy` automatically restarts.

- `--log-backtrace-on-crash` [1569]

Command-Line Format	`--log-backtrace-on-crash`
Option-File Format	`log-backtrace-on-crash`

Log a backtrace to the error log and try to initialize the debugger in the event of a failure.

- `--log-file=`*`file_name`* [1569]

Command-Line Format	`--log-file=file_name`	
Option-File Format	`log-file=file_name`	
	Permitted Values	
	Type	`file name`

The file to use to record log information. If this option is not given, `mysql-proxy` logs to the standard error output.

- `--log-level=`*`level`* [1569]

Command-Line Format	`--log-level=level`	
Option-File Format	`log-level=level`	
	Permitted Values	
	Type	`enumeration`

	Valid Values	`error`
		`warning`
		`info`
		`message`
		`debug`

The log level to use when outputting error messages. Messages with that level (or lower) are output. For example, `message` level also outputs message with `info`, `warning`, and `error` levels.

- `--log-use-syslog` [1569]

Command-Line Format	`--log-use-syslog`
Option-File Format	`log-use-syslog`

Log errors to the syslog (Unix/Linux only).

- `--lua-cpath=dir_name` [1570]

Command-Line Format	`--lua-cpath=dir_name`	
Option-File Format	`lua-cpath=dir_name`	
	Permitted Values	
	Type	`directory name`

The `LUA_CPATH` to use when loading compiled modules or libraries for Lua scripts.

- `--lua-path=dir_name` [1570]

Command-Line Format	`--lua-path=dir_name`	
Option-File Format	`lua-path=dir_name`	
	Permitted Values	
	Type	`directory name`

The `LUA_CPATH` to use when loading modules for Lua.

- `--max-open-files=count` [1570]

Command-Line Format	`--max-open-files=count`	
Option-File Format	`max-open-files=count`	
	Permitted Values	
	Type	`numeric`

The maximum number of open files and sockets supported by the `mysql-proxy` process. Certain scripts might require a higher value.

- `--no-proxy` [1570]

Command-Line Format	`--no-proxy`
Option-File Format	`no-proxy`

Disable the proxy module.

- `--plugin-dir=dir_name` [1570]

Command-Line Format	`--plugin-dir=dir_name`	
Option-File Format	`plugin-dir=dir_name`	
	Permitted Values	
	Type	`directory name`

The directory to use when loading plugins for `mysql-proxy`.

- `--plugins=plugin` [1570]

Command-Line Format	`--plugins=plugin,...`	
Option-File Format	`plugins=plugin,...`	
	Permitted Values	
	Type	`string`

Loads a plugin.

When using this option on the command line, you can specify the option multiple times to specify multiple plugins. For example:

```
shell> mysql-proxy --plugins=proxy --plugins=admin
```

When using the option within the configuration file, you should separate multiple plugins by commas. The equivalent of the preceding example would be:

```
...
plugins=proxy,admin
```

- `--proxy-address=host:port` [1571], `-P host:port`

Command-Line Format	`--proxy-address=host:port`	
	`-P host:port`	
Option-File Format	`proxy-address=host:port`	
	Permitted Values	
	Type	`string`
	Default	`:4040`

The listening host name (or IP address) and port of the proxy server. The default is `:4040` (all IPs on port 4040).

- `--proxy-read-only-backend-addresses=host:port` [1571], `-r host:port`

Command-Line Format	`--proxy-read-only-backend-addresses=host:port`	
	`-r host:port`	
Option-File Format	`proxy-read-only-backend-addresses=host:port`	
	Permitted Values	
	Type	`string`

The listening host name (or IP address) and port of the proxy server for read-only connections. The default is for this information not to be set.

Note

Setting this value only configures the servers within the corresponding internal structure (see `proxy.global.backends` [1579]). You can determine the backend type by checking the `type` field for each connection.

You should therefore only use this option in combination with a script designed to make use of the different backend types.

When using this option on the command line, you can specify the option and the server multiple times to specify multiple backends. For example:

```
shell> mysql-proxy --proxy-read-only-backend-addresses=192.168.0.1:3306 --proxy-read-only-backend-add
```

When using the option within the configuration file, you should separate multiple servers by commas. The equivalent of the preceding example would be:

```
...
proxy-read-only-backend-addresses = 192.168.0.1:3306,192.168.0.2:3306
```

- `--proxy-backend-addresses=host:port` [1571], `-b host:port`

Command-Line Format	`--proxy-backend-addresses=host:port`

	`-b host:port`	
Option-File Format	`proxy-backend-addresses=host:port`	
	Permitted Values	
	Type	`string`
	Default	`127.0.0.1:3306`

The host name (or IP address) and port of the MySQL server to connect to. You can specify multiple backend servers by supplying multiple options. Clients are connected to each backend server in round-robin fashion. For example, if you specify two servers A and B, the first client connection will go to server A; the second client connection to server B and the third client connection to server A.

When using this option on the command line, you can specify the option and the server multiple times to specify multiple backends. For example:

```
shell> mysql-proxy --proxy-backend-addresses 192.168.0.1:3306 --proxy-backend-addresses 192.168.0.2:3306
```

When using the option within the configuration file, you should separate multiple servers by commas. The equivalent of the preceding example would be:

```
...
proxy-backend-addresses = 192.168.0.1:3306,192.168.0.2:3306
```

- `--proxy-pool-no-change-user` [1572]

Command-Line Format	`--proxy-pool-no-change-user`
Option-File Format	`proxy-pool-no-change-user`

Disable use of the MySQL protocol `CHANGE_USER` command when reusing a connection from the pool of connections specified by the `proxy-backend-addresses` list.

- `--proxy-skip-profiling` [1572]

Command-Line Format	`--proxy-skip-profiling`
Option-File Format	`proxy-skip-profiling`

Disable query profiling (statistics time tracking). The default is for tracking to be enabled.

- `--proxy-fix-bug-25371` [1572]

Version Removed	0.8.1
Command-Line Format	`--proxy-fix-bug-25371`
Option-File Format	`proxy-fix-bug-25371`

Enable a workaround for an issue when connecting to a MySQL server later than 5.1.12 when using a MySQL client library of any earlier version.

This option was removed in `mysql-proxy` 0.8.1. Now, `mysql-proxy` returns an error message at the protocol level if it sees a `COM_CHANGE_USER` being sent to a server that has a version from 5.1.14 to 5.1.17.

- `--proxy-lua-script=`*`file_name`* [1572], `-s` *`file_name`*

Command-Line Format	`--proxy-lua-script=file_name`	
	`-s file_name`	
Option-File Format	`proxy-lua-script=file_name`	
	Permitted Values	

	Type	`file name`

The Lua script file to be loaded. Note that the script file is not physically loaded and parsed until a connection is made. Also note that the specified Lua script is reloaded for each connection; if the content of the Lua script changes while `mysql-proxy` is running, the updated content is automatically used when a new connection is made.

- `--pid-file=file_name` [1573]

Command-Line Format	`--pid-file=file_name`	
Option-File Format	`pid-file=file_name`	
	Permitted Values	
	Type	`file name`

The name of the file in which to store the process ID.

- `--user=user_name` [1573]

Command-Line Format	`--user=user_name`	
Option-File Format	`user=user_name`	
	Permitted Values	
	Type	`string`

Run `mysql-proxy` as the specified `user`.

- `--version` [1573], `-V`

Command-Line Format	`--version`
	`-V`

Show the version number.

The most common usage is as a simple proxy service (that is, without additional scripting). For basic proxy operation, you must specify at least one `proxy-backend-addresses` option to specify the MySQL server to connect to by default:

```
shell> mysql-proxy --proxy-backend-addresses=MySQL.example.com:3306
```

The default proxy port is `4040`, so you can connect to your MySQL server through the proxy by specifying the host name and port details:

```
shell> mysql --host=localhost --port=4040
```

If your server requires authentication information, this will be passed through natively without alteration by `mysql-proxy`, so you must also specify the required authentication information:

```
shell> mysql --host=localhost --port=4040 \
   --user=user_name --password=password
```

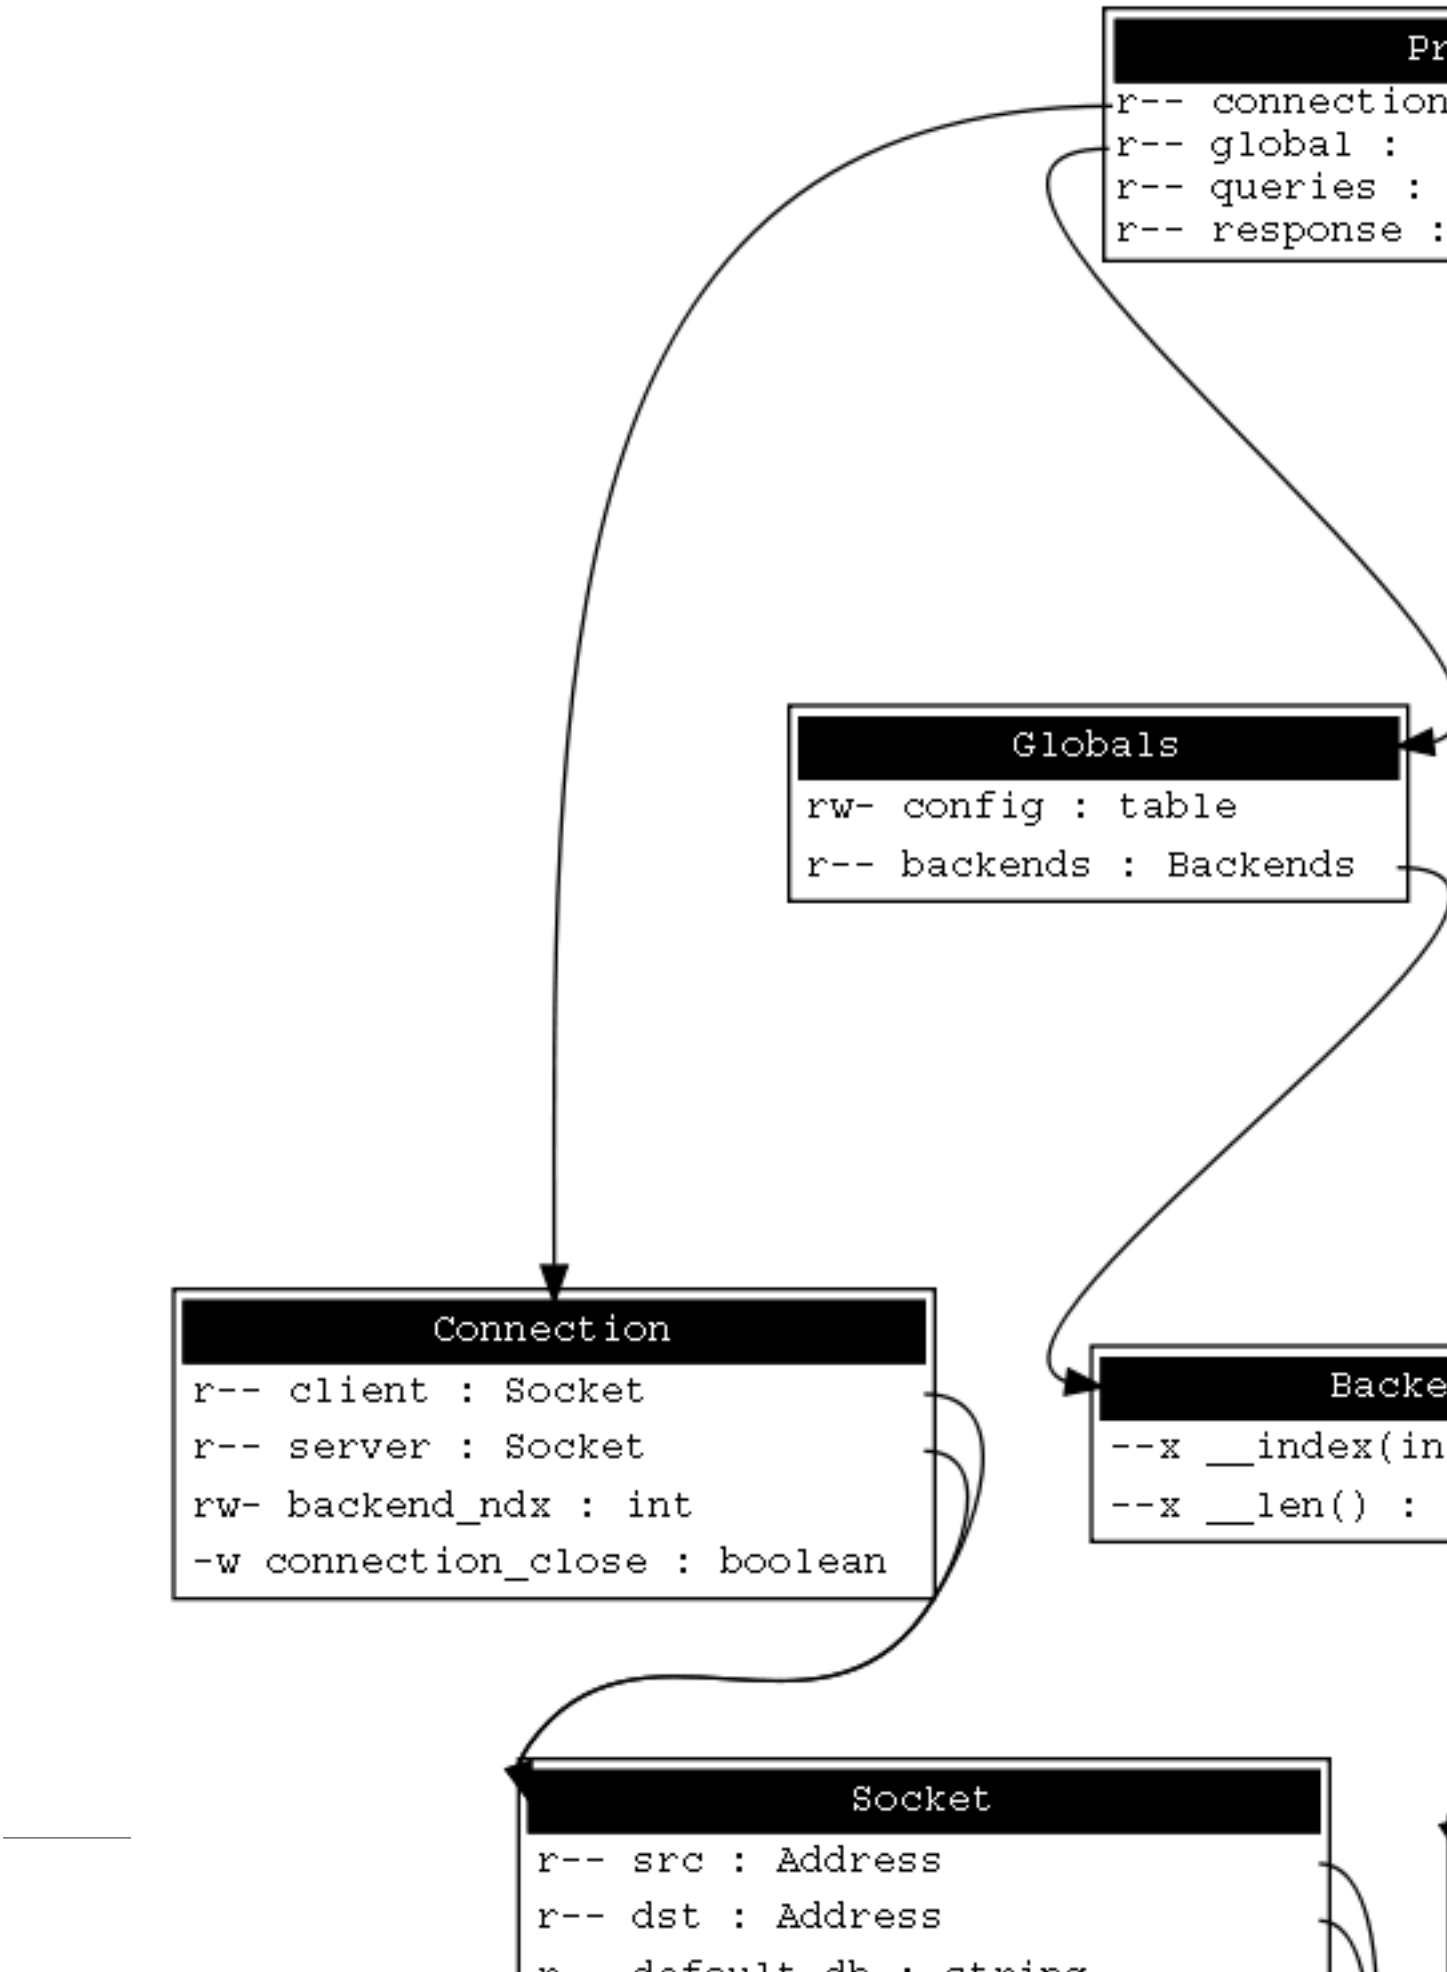
You can also connect to a read-only port (which filters out `UPDATE` and `INSERT` queries) by connecting to the read-only port. By default the host name is the default, and the port is `4042`, but you can alter the host/port information by using the `--proxy-read-only-backend-addresses` [1571] command-line option.

For more detailed information on how to use these command-line options, and `mysql-proxy` in general in combination with Lua scripts, see Using MySQL Proxy.

MySQL Proxy Scripting

You can control how MySQL Proxy manipulates and works with the queries and results that are passed on to the MySQL server through the use of the embedded Lua scripting language. You can find out more about the Lua programming language from the Lua Web site.

The following diagram shows an overview of the classes exposed by MySQL Proxy.



Pr
r-- connection
r-- global :
r-- queries :
r-- response :
Globals
rw- config : table
r-- backends : Backends
Connection
r-- client : Socket
r-- server : Socket
rw- backend_ndx : int
-w connection_close : boolean
Backe
--x __index(in
--x __len() :
Socket
r-- src : Address
r-- dst : Address

The primary interaction between MySQL Proxy and the server is provided by defining one or more functions through an Lua script. A number of functions are supported, according to different events and operations in the communication sequence between a client and one or more backend MySQL servers:

- `connect_server()`: This function is called each time a connection is made to MySQL Proxy from a client. You can use this function during load-balancing to intercept the original connection and decide which server the client should ultimately be attached to. If you do not define a special solution, a simple round-robin style distribution is used by default.
- `read_handshake()`: This function is called when the initial handshake information is returned by the server. You can capture the handshake information returned and provide additional checks before the authorization exchange takes place.
- `read_auth()`: This function is called when the authorization packet (user name, password, default database) are submitted by the client to the server for authentication.
- `read_auth_result()`: This function is called when the server returns an authorization packet to the client indicating whether the authorization succeeded.
- `read_query()`: This function is called each time a query is sent by the client to the server. You can use this to edit and manipulate the original query, including adding new queries before and after the original statement. You can also use this function to return information directly to the client, bypassing the server, which can be useful to filter unwanted queries or queries that exceed known limits.
- `read_query_result()`: This function is called each time a result is returned from the server, providing you have manually injected queries into the query queue. If you have not explicitly injected queries within the `read_query()` function, this function is not triggered. You can use this to edit the result set, or to remove or filter the result sets generated from additional queries you injected into the queue when using `read_query()`.

The following table describes the direction of information flow at the point when the function is triggered.

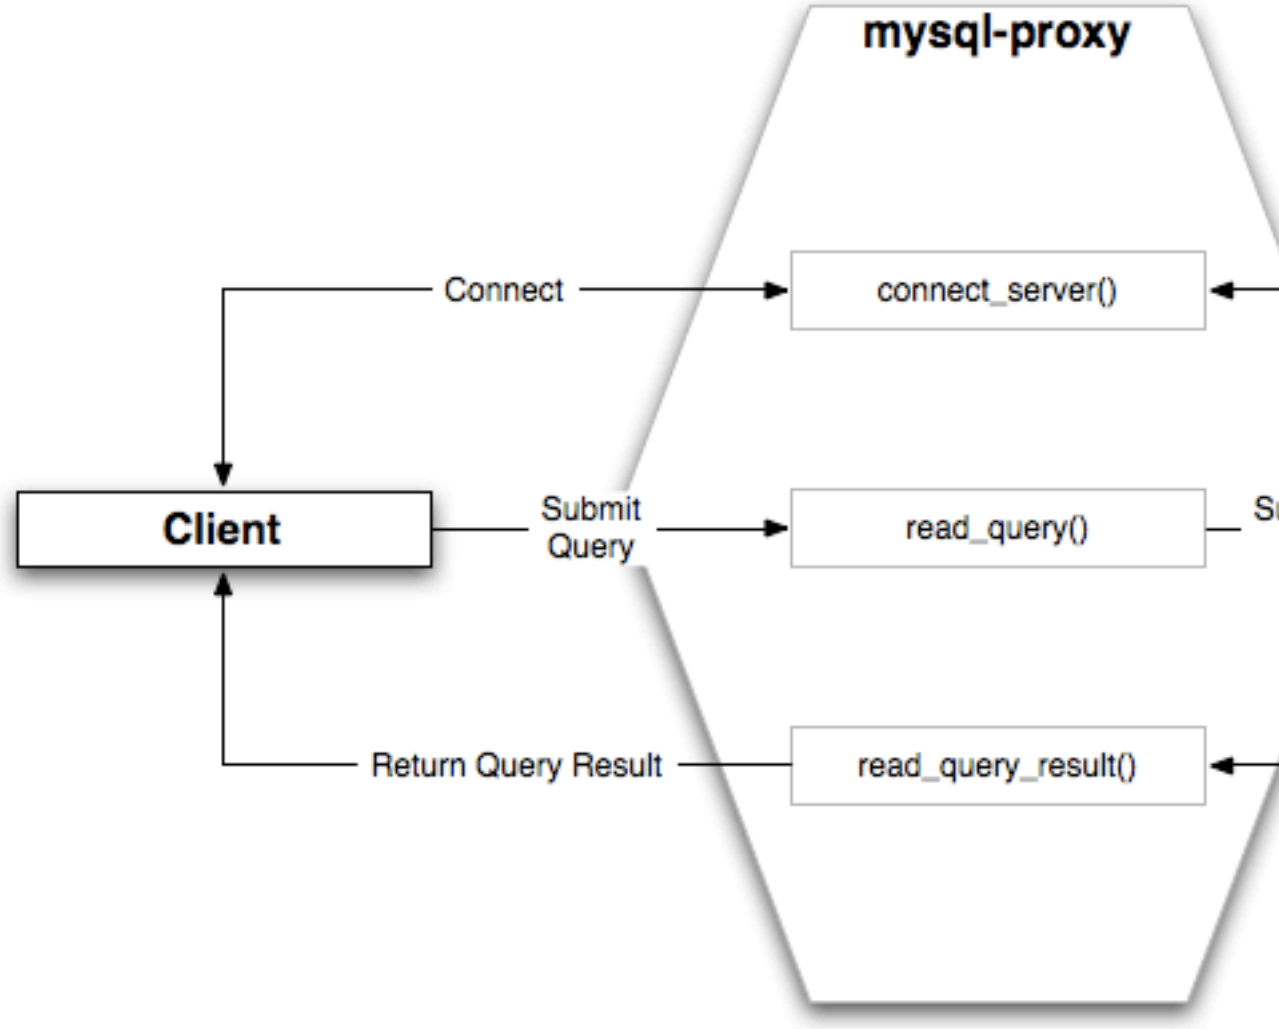
Function	Supplied Information	Direction
`connect_server()`	None	Client to Server
`read_handshake()`	None	Server to Client
`read_auth()`	None	Client to Server
`read_auth_result()`	None	Server to Client
`read_query()`	Query	Client to Server
`read_query_result()`	Query result	Server to Client

By default, all functions return a result that indicates whether the data should be passed on to the client or server (depending on the direction of the information being transferred). This return value can be overridden by explicitly returning a constant indicating that a particular response should be sent. For example, it is possible to construct result set information by hand within `read_query()` and to return the result set directly to the client without ever sending the original query to the server.

In addition to these functions, a number of built-in structures provide control over how MySQL Proxy forwards queries and returns the results by providing a simplified interface to elements such as the list of queries and the groups of result sets that are returned.

Proxy Scripting Sequence During Query Injection

The following figure gives an example of how the proxy might be used when injecting queries into the query queue. Because the proxy sits between the client and MySQL server, what the proxy sends to the server, and the information that the proxy ultimately returns to the client, need not match or correlate. Once the client has connected to the proxy, the sequence shown in the following diagram occurs for each individual query sent by the client.



1. When the client submits one query to the proxy, the `read_query()` function within the proxy is triggered. The function adds the query to the query queue.
2. Once manipulation by `read_query()` has completed, the queries are submitted, sequentially, to the MySQL server.
3. The MySQL server returns the results from each query, one result set for each query submitted. The `read_query_result()` function is triggered for each result set, and each invocation can decide which result set to return to the client

For example, you can queue additional queries into the global query queue to be processed by the server. This can be used to add statistical information by adding queries before and after the original query, changing the original query:

```
SELECT * FROM City;
```

Into a sequence of queries:

```
SELECT NOW();
SELECT * FROM City;
SELECT NOW();
```

You can also modify the original statement; for example, to add `EXPLAIN` to each statement executed to get information on how the statement was processed, again altering our original SQL statement into a number of statements:

```
SELECT * FROM City;
EXPLAIN SELECT * FROM City;
```

In both of these examples, the client would have received more result sets than expected. Regardless of how you manipulate the incoming query and the returned result, the number of queries returned by the proxy must match the number of original queries sent by the client.

You could adjust the client to handle the multiple result sets sent by the proxy, but in most cases you will want the existence of the proxy to remain transparent. To ensure that the number of queries and result sets match, you can use the MySQL Proxy `read_query_result()` to extract the additional result set information and return only the result set the client originally requested back to the client. You can achieve this by giving each query that you add to the query queue a unique ID, then filter out queries that do not match the original query ID when processing them with `read_query_result()`.

Internal Structures

There are a number of internal structures within the scripting element of MySQL Proxy. The primary structure is `proxy` and this provides an interface to the many common structures used throughout the script, such as connection lists and configured backend servers. Other structures, such as the incoming packet from the client and result sets are only available within the context of one of the scriptable functions.

Attribute	Description
`connection`	A structure containing the active client connections. For a list of attributes, see `proxy.connection` [1578].
`servers`	A structure containing the list of configured backend servers. For a list of attributes, see `proxy.global.backends` [1579].
`queries`	A structure containing the queue of queries that will be sent to the server during a single client query. For a list of attributes, see `proxy.queries` [1579].
`PROXY_VERSION`	The version number of MySQL Proxy, encoded in hex. You can use this to check that the version number supports a particular option from within the Lua script. Note that the value is encoded as a hex value, so to check the version is at least 0.5.1 you compare against `0x00501`.

`proxy.connection`

The `proxy.connection` object is read only, and provides information about the current connection, and is split into a `client` and `server` tables. This enables you to examine information about both the incoming client connections to the proxy (`client`), and to the backend servers (`server`).

Attribute	Description
`client.default_db`	Default database requested by the client
`client.username`	User name used to authenticate
`client.scrambled_password`	The scrambled version of the password used to authenticate
`client.dst.name`	The combined `address:port` of the Proxy port used by this client (should match the `--proxy-address` [1571] configuration parameter)
`client.dst.address`	The IP address of the of the Proxy port used by this client
`client.dst.port`	The port number of the of the Proxy port used by this client
`client.src.name`	The combined `address:port` of the client (originating) TCP/IP endpoint
`client.src.address`	The IP address of the client (originating) TCP/IP port
`client.src.port`	The port of the client (originating) TCP/IP endpoint
`server.scramble_buffer`	The scramble buffer used to scramble the password

Attribute	Description
server.mysqld_version	The MySQL version number of the server
server.thread_id	The ID of the thread handling the connection to the current server
server.dst.name	The combined address:port for the backend server for the current connection (i.e. the connection to the MySQL server)
server.dst.address	The address for the backend server
server.dst.port	The port for the backend server
server.src.name	The combined address:port for the TCP/IP endpoint used by the Proxy to connect to the backend server
server.src.address	The address of the endpoint for the proxy-side connection to the MySQL server
server.src.port	The port of the endpoint for the proxy-side connection to the MySQL server

proxy.global.backends

The proxy.global.backends table is partially writable and contains an array of all the configured backend servers and the server metadata (IP address, status, etc.). You can determine the array index of the current connection using proxy.connection["backend_ndx"] which is the index into this table of the backend server being used by the active connection.

The attributes for each entry within the proxy.global.backends table are shown in this table.

Attribute	Description
dst.name	The combined address:port of the backend server.
dst.address	The IP address of the backend server.
dst.port	The port of the backend server.
connected_clients	The number of clients currently connected.
state	The status of the backend server. See Backend State/Type Constants [1582].
type	The type of the backend server. You can use this to identify whether the backed was configured as a standard read/write backend, or a read-only backend. You can compare this value to the proxy.BACKEND_TYPE_RW and proxy.BACKEND_TYPE_RO.

proxy.queries

The proxy.queries object is a queue representing the list of queries to be sent to the server. The queue is not populated automatically, but if you do not explicitly populate the queue, queries are passed on to the backend server verbatim. Also, if you do not populate the query queue by hand, the read_query_result() function is not triggered.

The following methods are supported for populating the proxy.queries object.

Function	Description
append(id,packet, [options])	Appends a query to the end of the query queue. The id is an integer identifier that you can use to recognize the query results when they are returned by the server. The packet should be a properly formatted query packet. The optional options should be a table containing the options specific to this packet.
prepend(id,packet)	Prepends a query to the query queue. The id is an identifier that you can use to recognize the query results when they are returned by the server. The packet should be a properly formatted query packet.

Function	Description
`reset()`	Empties the query queue.
`len()`	Returns the number of query packets in the queue.

For example, you could append a query packet to the `proxy.queries` queue by using the `append()`:

```
proxy.queries:append(1,packet)
```

The optional third argument to `append()` should contain the options for the packet. To have access to the result set through the `read_query_result()` function, set the `resultset_is_needed` flag to `true`:

```
proxy.queries:append( 1, packet, { resultset_is_needed = true } )
```

If that flag is `false` (the default), proxy will:

- Send the result set to the client as soon as it is received
- Reduce memory usage (because the result set is not stored internally for processing)
- Reduce latency of returning results to the client
- Pass data from server to client unaltered

The default mode is therefore quicker and useful if you only want to monitor the queries sent, and the basic statistics.

To perform any kind of manipulation on the returned data, you must set the flag to `true`, which will:

- Store the result set so that it can be processed.
- Enable modification of the result set before it is returned to the client.
- Enable you to discard the result set instead of returning it to the client.

`proxy.response`

The `proxy.response` structure is used when you want to return your own MySQL response, instead of forwarding a packet that you have received a backend server. The structure holds the response type information, an optional error message, and the result set (rows/columns) to return.

Attribute	Description
`type`	The type of the response. The type must be either `MYSQLD_PACKET_OK` or `MYSQLD_PACKET_ERR`. If the `MYSQLD_PACKET_ERR`, you should set the value of the `mysql.response.errmsg` with a suitable error message.
`errmsg`	A string containing the error message that will be returned to the client.
`resultset`	A structure containing the result set information (columns and rows), identical to what would be returned when returning a results from a `SELECT` query.

When using `proxy.response` you either set `proxy.response.type` to `proxy.MYSQLD_PACKET_OK` and then build `resultset` to contain the results to return, or set `proxy.response.type` to `proxy.MYSQLD_PACKET_ERR` and set the `proxy.response.errmsg` to a string with the error message. To send the completed result set or error message, you should return the `proxy.PROXY_SEND_RESULT` to trigger the return of the packet information.

An example of this can be seen in the `tutorial-resultset.lua` script within the MySQL Proxy package:

```
if string.lower(command) == "show" and string.lower(option) == "querycounter" then
        ---
```

```
        -- proxy.PROXY_SEND_RESULT requires
        --
        -- proxy.response.type to be either
        -- * proxy.MYSQLD_PACKET_OK or
        -- * proxy.MYSQLD_PACKET_ERR
        --
        -- for proxy.MYSQLD_PACKET_OK you need a resultset
        -- * fields
        -- * rows
        --
        -- for proxy.MYSQLD_PACKET_ERR
        -- * errmsg
        proxy.response.type = proxy.MYSQLD_PACKET_OK
        proxy.response.resultset = {
                fields = {
                        { type = proxy.MYSQL_TYPE_LONG, name = "global_query_counter", },
                        { type = proxy.MYSQL_TYPE_LONG, name = "query_counter", },
                },
                rows = {
                        { proxy.global.query_counter, query_counter }
                }
        }

        -- we have our result, send it back
        return proxy.PROXY_SEND_RESULT
elseif string.lower(command) == "show" and string.lower(option) == "myerror" then
        proxy.response.type = proxy.MYSQLD_PACKET_ERR
        proxy.response.errmsg = "my first error"

        return proxy.PROXY_SEND_RESULT
```

proxy.response.resultset

The `proxy.response.resultset` structure should be populated with the rows and columns of data to return. The structure contains the information about the entire result set, with the individual elements of the data shown in the following table.

Attribute	Description
`fields`	The definition of the columns being returned. This should be a dictionary structure with the `type` specifying the MySQL data type, and the `name` specifying the column name. Columns should be listed in the order of the column data that will be returned.
`flags`	A number of flags related to the result set. Valid flags include `auto_commit` (whether an automatic commit was triggered), `no_good_index_used` (the query executed without using an appropriate index), and `no_index_used` (the query executed without using any index).
`rows`	The actual row data. The information should be returned as an array of arrays. Each inner array should contain the column data, with the outer array making up the entire result set.
`warning_count`	The number of warnings for this result set.
`affected_rows`	The number of rows affected by the original statement.
`insert_id`	The last insert ID for an auto-incremented column in a table.
`query_status`	The status of the query operation. You can use the `MYSQLD_PACKET_OK` or `MYSQLD_PACKET_ERR` constants to populate this parameter.

For an example showing how to use this structure, see `proxy.response` [1580].

Proxy Return State Constants

The following constants are used internally by the proxy to specify the response to send to the client or server. All constants are exposed as values within the main `proxy` table.

Constant	Description
PROXY_SEND_QUERY	Causes the proxy to send the current contents of the queries queue to the server.
PROXY_SEND_RESULT	Causes the proxy to send a result set back to the client.
PROXY_IGNORE_RESULT	Causes the proxy to drop the result set (nothing is returned to the client).

As constants, these entities are available without qualification in the Lua scripts. For example, at the end of the `read_query_result()` you might return `PROXY_IGNORE_RESULT:`

```
return proxy.PROXY_IGNORE_RESULT
```

Packet State Constants

The following states describe the status of a network packet. These items are entries within the main `proxy` table.

Constant	Description
MYSQLD_PACKET_OK	The packet is OK
MYSQLD_PACKET_ERR	The packet contains error information
MYSQLD_PACKET_RAW	The packet contains raw data

Backend State/Type Constants

The following constants are used either to define the status or type of the backend MySQL server to which the proxy is connected. These items are entries within the main `proxy` table.

Constant	Description
BACKEND_STATE_UNKNOWN	The current status is unknown
BACKEND_STATE_UP	The backend is known to be up (available)
BACKEND_STATE_DOWN	The backend is known to be down (unavailable)
BACKEND_TYPE_UNKNOWN	Backend type is unknown
BACKEND_TYPE_RW	Backend is available for read/write
BACKEND_TYPE_RO	Backend is available only for read-only use

Server Command Constants

The following values are used in the packets exchanged between the client and server to identify the information in the rest of the packet. These items are entries within the main `proxy` table. The packet type is defined as the first character in the sent packet. For example, when intercepting packets from the client to edit or monitor a query, you would check that the first byte of the packet was of type `proxy.COM_QUERY`.

Constant	Description
COM_SLEEP	Sleep
COM_QUIT	Quit
COM_INIT_DB	Initialize database
COM_QUERY	Query
COM_FIELD_LIST	Field List
COM_CREATE_DB	Create database
COM_DROP_DB	Drop database
COM_REFRESH	Refresh
COM_SHUTDOWN	Shutdown

Constant	Description
COM_STATISTICS	Statistics
COM_PROCESS_INFO	Process List
COM_CONNECT	Connect
COM_PROCESS_KILL	Kill
COM_DEBUG	Debug
COM_PING	Ping
COM_TIME	Time
COM_DELAYED_INSERT	Delayed insert
COM_CHANGE_USER	Change user
COM_BINLOG_DUMP	Binlog dump
COM_TABLE_DUMP	Table dump
COM_CONNECT_OUT	Connect out
COM_REGISTER_SLAVE	Register slave
COM_STMT_PREPARE	Prepare server-side statement
COM_STMT_EXECUTE	Execute server-side statement
COM_STMT_SEND_LONG_DATA	Long data
COM_STMT_CLOSE	Close server-side statement
COM_STMT_RESET	Reset statement
COM_SET_OPTION	Set option
COM_STMT_FETCH	Fetch statement
COM_DAEMON	Daemon (MySQL 5.1 only)
COM_ERROR	Error

MySQL Type Constants

These constants are used to identify the field types in the query result data returned to clients from the result of a query. These items are entries within the main `proxy` table.

Constant	Field Type
MYSQL_TYPE_DECIMAL	Decimal
MYSQL_TYPE_NEWDECIMAL	Decimal (MySQL 5.0 or later)
MYSQL_TYPE_TINY	Tiny
MYSQL_TYPE_SHORT	Short
MYSQL_TYPE_LONG	Long
MYSQL_TYPE_FLOAT	Float
MYSQL_TYPE_DOUBLE	Double
MYSQL_TYPE_NULL	Null
MYSQL_TYPE_TIMESTAMP	Timestamp
MYSQL_TYPE_LONGLONG	Long long
MYSQL_TYPE_INT24	Integer
MYSQL_TYPE_DATE	Date
MYSQL_TYPE_TIME	Time
MYSQL_TYPE_DATETIME	Datetime

Constant	Field Type
MYSQL_TYPE_YEAR	Year
MYSQL_TYPE_NEWDATE	Date (MySQL 5.0 or later)
MYSQL_TYPE_ENUM	Enumeration
MYSQL_TYPE_SET	Set
MYSQL_TYPE_TINY_BLOB	Tiny Blob
MYSQL_TYPE_MEDIUM_BLOB	Medium Blob
MYSQL_TYPE_LONG_BLOB	Long Blob
MYSQL_TYPE_BLOB	Blob
MYSQL_TYPE_VAR_STRING	Varstring
MYSQL_TYPE_STRING	String
MYSQL_TYPE_TINY	Tiny (compatible with MYSQL_TYPE_CHAR)
MYSQL_TYPE_ENUM	Enumeration (compatible with MYSQL_TYPE_INTERVAL)
MYSQL_TYPE_GEOMETRY	Geometry
MYSQL_TYPE_BIT	Bit

Capturing a Connection with connect_server()

When the proxy accepts a connection from a MySQL client, the connect_server() function is called.

There are no arguments to the function, but you can use and if necessary manipulate the information in the proxy.connection table, which is unique to each client session.

For example, if you have multiple backend servers, you can specify which server that connection should use by setting the value of proxy.connection.backend_ndx to a valid server number. The following code chooses between two servers based on whether the current time in minutes is odd or even:

```
function connect_server()
        print("--> a client really wants to talk to a server")
        if (tonumber(os.date("%M")) % 2 == 0) then
                proxy.connection.backend_ndx = 2
                print("Choosing backend 2")
        else
                proxy.connection.backend_ndx = 1
                print("Choosing backend 1")
        end
        print("Using " .. proxy.global.backends[proxy.connection.backend_ndx].dst.name)
end
```

This example also displays the IP address/port combination by accessing the information from the internal proxy.global.backends table.

Examining the Handshake with read_handshake()

Handshake information is sent by the server to the client after the initial connection (through connect_server()) has been made. The handshake information contains details about the MySQL version, the ID of the thread that will handle the connection information, and the IP address of the client and server. This information is exposed through the proxy.connection structure.

- proxy.connection.server.mysqld_version: The version of the MySQL server.
- proxy.connection.server.thread_id: The thread ID.
- proxy.connection.server.scramble_buffer: The password scramble buffer.
- proxy.connection.server.dst.name: The IP address of the server.

- `proxy.connection.client.src.name`: The IP address of the client.

For example, you can print out the handshake data and refuse clients by IP address with the following function:

```
function read_handshake()
        print("<-- let's send him some information about us")
        print("    mysqld-version: " .. proxy.connection.server.mysqld_version)
        print("    thread-id     : " .. proxy.connection.server.thread_id)
        print("    scramble-buf  : " .. string.format("%q",proxy.connection.server.scramble_buffer))
        print("    server-addr   : " .. proxy.connection.server.dst.name)
        print("    client-addr   : " .. proxy.connection.client.dst.name)

        if not proxy.connection.client.src.name:match("^127.0.0.1:") then
                proxy.response.type = proxy.MYSQLD_PACKET_ERR
                proxy.response.errmsg = "only local connects are allowed"

                print("we don't like this client");

                return proxy.PROXY_SEND_RESULT
        end
end
```

Note that you must return an error packet to the client by using `proxy.PROXY_SEND_RESULT`.

Examining the Authentication Credentials with `read_auth()`

The `read_auth()` function is triggered when an authentication handshake is initiated by the client. In the execution sequence, `read_auth()` occurs immediately after `read_handshake()`, so the server selection has already been made, but the connection and authorization information has not yet been provided to the backend server.

You can obtain the authentication information by examining the `proxy.connection.client` structure. For more information, see `proxy.connection` [1578].

For example, you can print the user name and password supplied during authorization using:

```
function read_auth()
        print("    username      : " .. proxy.connection.client.username)
        print("    password      : " .. string.format("%q", proxy.connection.client.scrambled_password)
end
```

You can interrupt the authentication process within this function and return an error packet back to the client by constructing a new packet and returning `proxy.PROXY_SEND_RESULT`:

```
proxy.response.type = proxy.MYSQLD_PACKET_ERR
proxy.response.errmsg = "Logins are not allowed"
return proxy.PROXY_SEND_RESULT
```

Accessing Authentication Information with `read_auth_result()`

The return packet from the server during authentication is captured by `read_auth_result()`. The only argument to this function is the authentication packet returned by the server. As the packet is a raw MySQL network protocol packet, you must access the first byte to identify the packet type and contents. The `MYSQLD_PACKET_ERR` and `MYSQLD_PACKET_OK` constants can be used to identify whether the authentication was successful:

```
function read_auth_result(auth)
        local state = auth.packet:byte()

        if state == proxy.MYSQLD_PACKET_OK then
                print("<-- auth ok");
        elseif state == proxy.MYSQLD_PACKET_ERR then
                print("<-- auth failed");
        else
                print("<-- auth ... don't know: " .. string.format("%q", auth.packet));
        end
end
```

If a long-password capable client tries to authenticate to a server that supports long passwords, but the user password provided is actually short, `read_auth_result()` will be called twice. The first time, `auth.packet:byte()` will equal 254, indicating that the client should try again using the old password protocol. The second time time `read_auth_result()/` is called, `auth.packet:byte()` will indicate whether the authentication actually succeeded.

Manipulating Queries with `read_query()`

The `read_query()` function is called once for each query submitted by the client and accepts a single argument, the query packet that was provided. To access the content of the packet, you must parse the packet contents manually.

For example, you can intercept a query packet and print out the contents using the following function definition:

```
function read_query( packet )
        if packet:byte() == proxy.COM_QUERY then
                print("we got a normal query: " .. packet:sub(2))
        end
end
```

This example checks the first byte of the packet to determine the type. If the type is `COM_QUERY` (see Server Command Constants [1582]), we extract the query from the packet and print it. The structure of the packet type supplied is important. In the case of a `COM_QUERY` packet, the remaining contents of the packet are the text of the query string. In this example, no changes have been made to the query or the list of queries that will ultimately be sent to the MySQL server.

To modify a query, or add new queries, you must populate the query queue (`proxy.queries`), then execute the queries that you have placed into the queue. If you do not modify the original query or the queue, the query received from the client is sent to the MySQL server verbatim.

When adding queries to the queue, you should follow these guidelines:

- The packets inserted into the queue must be valid query packets. For each packet, you must set the initial byte to the packet type. If you are appending a query, you can append the query statement to the rest of the packet.
- Once you add a query to the queue, the queue is used as the source for queries sent to the server. If you add a query to the queue to add more information, you must also add the original query to the queue or it will not be executed.
- Once the queue has been populated, you must set the return value from `read_query()` to indicate whether the query queue should be sent to the server.
- When you add queries to the queue, you should add an ID. The ID you specify is returned with the result set so that you identify each query and corresponding result set. The ID has no other purpose than as an identifier for correlating the query and result set. When operating in a passive mode, during profiling for example, you identify the original query and the corresponding result set so that the results expected by the client can be returned correctly.
- Unless your client is designed to cope with more result sets than queries, you should ensure that the number of queries from the client match the number of results sets returned to the client. Using the unique ID and removing result sets you inserted will help.

Normally, the `read_query()` and `read_query_result()` function are used in conjunction with each other to inject additional queries and remove the additional result sets. However, `read_query_result()` is only called if you populate the query queue within `read_query()`.

Manipulating Results with `read_query_result()`

The `read_query_result()` is called for each result set returned by the server only if you have manually injected queries into the query queue. If you have not manipulated the query queue, this

function is not called. The function supports a single argument, the result packet, which provides a number of properties:

- `id`: The ID of the result set, which corresponds to the ID that was set when the query packet was submitted to the server when using `append(id)` on the query queue. You must have set the `resultset_is_needed` flag to `append` to intercept the result set before it is returned to the client. See proxy.queries [1579].
- `query`: The text of the original query.
- `query_time`: The number of microseconds required to receive the first row of a result set since the query was sent to the server.
- `response_time`: The number of microseconds required to receive the last row of the result set since the query was sent to the server.
- `resultset`: The content of the result set data.

By accessing the result information from the MySQL server, you can extract the results that match the queries that you injected, return different result sets (for example, from a modified query), and even create your own result sets.

The following Lua script, for example, will output the query, followed by the query time and response time (that is, the time to execute the query and the time to return the data for the query) for each query sent to the server:

```
function read_query( packet )
        if packet:byte() == proxy.COM_QUERY then
                print("we got a normal query: " .. packet:sub(2))

                proxy.queries:append(1, packet )

                return proxy.PROXY_SEND_QUERY
        end
end

function read_query_result(inj)
        print("query-time: " .. (inj.query_time / 1000) .. "ms")
        print("response-time: " .. (inj.response_time / 1000) .. "ms")
end
```

You can access the rows of returned results from the result set by accessing the `rows` property of the `resultset` property of the result that is exposed through `read_query_result()`. For example, you can iterate over the results showing the first column from each row using this Lua fragment:

```
for row in inj.resultset.rows do
        print("injected query returned: " .. row[1])
end
```

Just like `read_query()`, `read_query_result()` can return different values for each result according to the result returned. If you have injected additional queries into the query queue, for example, remove the results returned from those additional queries and return only the results from the query originally submitted by the client.

The following example injects additional `SELECT NOW()` statements into the query queue, giving them a different ID to the ID of the original query. Within `read_query_result()`, if the ID for the injected queries is identified, we display the result row, and return the `proxy.PROXY_IGNORE_RESULT` from the function so that the result is not returned to the client. If the result is from any other query, we print out the query time information for the query and return the default, which passes on the result set unchanged. We could also have explicitly returned `proxy.PROXY_IGNORE_RESULT` to the MySQL client.

```
function read_query( packet )
        if packet:byte() == proxy.COM_QUERY then
                proxy.queries:append(2, string.char(proxy.COM_QUERY) .. "SELECT NOW()", {resultset_is_n
                proxy.queries:append(1, packet, {resultset_is_needed = true})
```

```
                proxy.queries:append(2, string.char(proxy.COM_QUERY) .. "SELECT NOW()", {resultset_is_neede

                return proxy.PROXY_SEND_QUERY
        end
end

function read_query_result(inj)
        if inj.id == 2 then
                for row in inj.resultset.rows do
                        print("injected query returned: " .. row[1])
                end
                return proxy.PROXY_IGNORE_RESULT
        else
                print("query-time: " .. (inj.query_time / 1000) .. "ms")
                print("response-time: " .. (inj.response_time / 1000) .. "ms")
        end
end
```

For further examples, see Using MySQL Proxy.

Using MySQL Proxy

There are a number of different ways to use MySQL Proxy. At the most basic level, you can allow MySQL Proxy to pass queries from clients to a single server. To use MySQL Proxy in this mode, you just have to specify on the command line the backend server to which the proxy should connect:

```
shell> mysql-proxy --proxy-backend-addresses=sakila:3306
```

If you specify multiple backend MySQL servers, the proxy connects each client to each server in a round-robin fashion. Suppose that you have two MySQL servers, A and B. The first client to connect is connected to server A, the second to server B, the third to server A. For example:

```
shell> mysql-proxy \
     --proxy-backend-addresses=narcissus:3306 \
     --proxy-backend-addresses=nostromo:3306
```

When you specify multiple servers in this way, the proxy automatically identifies when a MySQL server has become unavailable and marks it accordingly. New connections are automatically attached to a server that is available, and a warning is reported to the standard output from `mysql-proxy`:

```
network-mysqld.c.367: connect(nostromo:3306) failed: Connection refused
network-mysqld-proxy.c.2405: connecting to backend (nostromo:3306) failed, marking it as down for ...
```

Lua scripts enable a finer level of control, both over the connections and their distribution and how queries and result sets are processed. When using an Lua script, you must specify the name of the script on the command line using the `--proxy-lua-script` [1572] option:

```
shell> mysql-proxy --proxy-lua-script=mc.lua --proxy-backend-addresses=sakila:3306
```

When you specify a script, the script is not executed until a connection is made. This means that faults with the script are not raised until the script is executed. Script faults will not affect the distribution of queries to backend MySQL servers.

Note

Because a script is not read until the connection is made, you can modify the contents of the Lua script file while the proxy is still running and the modified script is automatically used for the next connection. This ensures that MySQL Proxy remains available because it need not be restarted for the changes to take effect.

Using the Administration Interface

The `mysql-proxy` administration interface can be accessed using any MySQL client using the standard protocols. You can use the administration interface to gain information about the proxy server

as a whole - standard connections to the proxy are isolated to operate as if you were connected directly to the backend MySQL server.

In `mysql-proxy` 0.8.0 and earlier, a rudimentary interface was built into the proxy. In later versions this was replaced so that you must specify an administration script to be used when users connect to the administration interface.

To use the administration interface, specify the user name and password required to connect to the admin service, using the `--admin-username` [1568] and `--admin-password` [1567] options. You must also specify the Lua script to be used as the interface to the administration service by using the `admin-lua-script` [1567] script option to point to a Lua script.

For example, you can create a basic interface to the internal components of the `mysql-proxy` system using the following script, written by Diego Medina:

```

    (Thanks Giuseppe Maxia)

--]]

proxy.global.query_counter = proxy.global.query_counter or 0

function proxy.global.initialize_process_table()
    if proxy.global.process == nil then
        proxy.global.process = {}
    end
    if proxy.global.process[proxy.connection.server.thread_id] == nil then
        proxy.global.process[proxy.connection.server.thread_id] = {}
    end
end

function read_auth_result( auth )
    local state = auth.packet:byte()
    if state == proxy.MYSQLD_PACKET_OK then
        proxy.global.initialize_process_table()
        table.insert( proxy.global.process[proxy.connection.server.thread_id],
            { ip = proxy.connection.client.src.name, ts = os.time() } )
    end
end

function disconnect_client()
    local connection_id = proxy.connection.server.thread_id
    if connection_id then
        -- client has disconnected, set this to nil
        proxy.global.process[connection_id] = nil
    end
end

---
-- read_query() can return a resultset
--
-- You can use read_query() to return a result-set.
--
-- @param packet the mysql-packet sent by the client
--
-- @return
--   * nothing to pass on the packet as is,
--   * proxy.PROXY_SEND_QUERY to send the queries from the proxy.queries queue
--   * proxy.PROXY_SEND_RESULT to send your own result-set
```

```
--
function read_query( packet )
        -- a new query came in in this connection
        -- using proxy.global.* to make it available to the admin plugin
        proxy.global.query_counter = proxy.global.query_counter + 1

end
```

To use the script, save the first script to a file (`admin.lua` in the following example) and the other to `reporter.lua`, then run `mysql-proxy` specifying the admin script and a backend MySQL server:

```
shell> mysql-proxy --admin-lua-script=admin.lua --admin-password=password \ »
     --admin-username=root --proxy-backend-addresses=127.0.0.1:3306 -proxy-lua-script=reporter.lua
```

In a different window, connect to the MySQL server through the proxy:

```
shell> mysql --user=root --password=password --port=4040
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1798669
Server version: 5.0.70-log Gentoo Linux mysql-5.0.70-r1

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

In another different window, connect to the `mysql-proxy` admin service using the specified user name and password:

```
shell> mysql --user=root --password=password --port=4041 --host=localhost
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1
Server version: 5.0.99-agent-admin

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

To monitor the status of the proxy, ask for a list of the current active processes:

```
mysql> show proxy processlist;
+---------+---------------------+--------------------------+
| Id      | IP Address          | Time                     |
+---------+---------------------+--------------------------+
| 1798669 | 192.168.0.112:52592 | Wed Jan 20 16:58:00 2010 |
+---------+---------------------+--------------------------+
1 row in set (0.00 sec)

mysql>
```

For more information on the example, see MySQL Proxy Admin Example.

- 16.7.6.4: [1595] Can I run MySQL Proxy as a daemon?
- 16.7.6.5: [1595] Do proxy applications run on a separate server? If not, what is the overhead incurred by Proxy on the DB server side?

- 16.7.6.6: [1595] With load balancing, what happens to transactions? Are all queries sent to the same server?
- 16.7.6.7: [1595] Is it possible to use MySQL Proxy with updating a Lucene index (or Solr) by making TCP calls to that server to update?
- 16.7.6.8: [1595] Is the system context switch expensive, how much overhead does the Lua script add?
- 16.7.6.9: [1596] How much latency does a proxy add to a connection?
- 16.7.6.10: [1596] Do you have to make one large script and call it at proxy startup, can I change scripts without stopping and restarting (interrupting) the proxy?
- 16.7.6.11: [1596] If MySQL Proxy has to live on same machine as MySQL, are there any tuning considerations to ensure both perform optimally?
- 16.7.6.12: [1596] I currently use SQL Relay for efficient connection pooling with a number of Apache processes connecting to a MySQL server. Can MySQL Proxy currently accomplish this? My goal is to minimize connection latency while keeping temporary tables available.
- 16.7.6.13: [1596] Are these reserved function names (for example, `error_result()`) that get automatically called?
- 16.7.6.14: [1596] As the script is re-read by MySQL Proxy, does it cache this or is it looking at the file system with each request?
- 16.7.6.15: [1596] Given that there is a `connect_server()` function, can a Lua script link up with multiple servers?
- 16.7.6.16: [1596] Is the MySQL Proxy an API?
- 16.7.6.17: [1596] The global namespace variable example with quotas does not persist after a reboot, is that correct?
- 16.7.6.18: [1596] Can MySQL Proxy handle SSL connections?
- 16.7.6.19: [1596] Could MySQL Proxy be used to capture passwords?
- 16.7.6.20: [1596] Are there tools for isolating problems? How can someone figure out whether a problem is in the client, the database, or the proxy?
- 16.7.6.21: [1597] Is MySQL Proxy similar to what is provided by Java connection pools?
- 16.7.6.22: [1597] So authentication with connection pooling has to be done at every connection? What is the authentication latency?
- 16.7.6.23: [1597] If you have multiple databases on the same box, can you use proxy to connect to databases on default port 3306?
- 16.7.6.24: [1597] What about caching the authorization information so clients connecting are given back-end connections that were established with identical authorization information, thus saving a few more round trips?
- 16.7.6.25: [1597] Is there any big web site using MySQL Proxy? For what purpose and what transaction rate have they achieved?
- 16.7.6.26: [1597] How does MySQL Proxy compare to DBSlayer?
- 16.7.6.27: [1597] I tried using MySQL Proxy without any Lua script to try a round-robin type load balancing. In this case, if the first database in the list is down, MySQL Proxy would not connect the client to the second database in the list.

- 16.7.6.28: [1597] Is it “safe” to use `LuaSocket` with proxy scripts?
- 16.7.6.29: [1597] How different is MySQL Proxy from DBCP (Database connection pooling) for Apache in terms of connection pooling?
- 16.7.6.30: [1597] MySQL Proxy can handle about 5000 connections, what is the limit on a MySQL server?
- 16.7.6.31: [1597] Would the Java-only connection pooling solution work for multiple web servers? With this, I would assume that you can pool across many web servers at once?

Questions and Answers

16.7.6.1: In load balancing, how can I separate reads from writes?

There is no automatic separation of queries that perform reads or writes to the different backend servers. However, you can specify to `mysql-proxy` that one or more of the “backend” MySQL servers are read only.

```
shell> mysql-proxy \
--proxy-backend-addresses=10.0.1.2:3306 \
--proxy-read-only-backend-addresses=10.0.1.3:3306 &
```

16.7.6.2: How do I use a socket with MySQL Proxy? Proxy change logs mention that support for UNIX sockets has been added.

Specify the path to the socket:

```
--proxy-backend-addresses=/path/to/socket
```

16.7.6.3: Can I use MySQL Proxy with all versions of MySQL?

MySQL Proxy is designed to work with MySQL 5.0 or higher, and supports the MySQL network protocol for 5.0 and higher.

16.7.6.4: Can I run MySQL Proxy as a daemon?

Use the `--daemon` [1568] option. To keep track of the process ID, the daemon can be started with the `--pid-file=file` [1573] option to save the PID to a known file name. On version 0.5.x, the Proxy cannot be started natively as a daemon.

16.7.6.5: Do proxy applications run on a separate server? If not, what is the overhead incurred by Proxy on the DB server side?

You can run the proxy on the application server, on its own box, or on the DB-server depending on the use case.

16.7.6.6: With load balancing, what happens to transactions? Are all queries sent to the same server?

Without any special customization the whole connection is sent to the same server. That keeps the whole connection state intact.

16.7.6.7: Is it possible to use MySQL Proxy with updating a Lucene index (or Solr) by making TCP calls to that server to update?

Yes, but it is not advised for now.

16.7.6.8: Is the system context switch expensive, how much overhead does the Lua script add?

Lua is fast and the overhead should be small enough for most applications. The raw packet overhead is around 400 microseconds.

16.7.6.9: How much latency does a proxy add to a connection?

In the range of 400 microseconds per request.

16.7.6.10: Do you have to make one large script and call it at proxy startup, can I change scripts without stopping and restarting (interrupting) the proxy?

You can just change the script and the proxy will reload it when a client connects.

16.7.6.11: If MySQL Proxy has to live on same machine as MySQL, are there any tuning considerations to ensure both perform optimally?

MySQL Proxy can live on any box: application, database, or its own box. MySQL Proxy uses comparatively little CPU or RAM, with negligible additional requirements or overhead.

16.7.6.12: I currently use SQL Relay for efficient connection pooling with a number of Apache processes connecting to a MySQL server. Can MySQL Proxy currently accomplish this? My goal is to minimize connection latency while keeping temporary tables available.

Yes.

16.7.6.13: Are these reserved function names (for example, `error_result()`) that get automatically called?

Only functions and values starting with `proxy.*` are provided by the proxy. All others are user provided.

16.7.6.14: As the script is re-read by MySQL Proxy, does it cache this or is it looking at the file system with each request?

It looks for the script at client-connect and reads it if it has changed, otherwise it uses the cached version.

16.7.6.15: Given that there is a `connect_server()` function, can a Lua script link up with multiple servers?

MySQL Proxy provides some tutorials in the source package; one is `examples/tutorial-keepalive.lua`.

16.7.6.16: Is the MySQL Proxy an API?

No, MySQL Proxy is an application that forwards packets from a client to a server using the MySQL network protocol. The MySQL Proxy provides a API allowing you to change its behavior.

16.7.6.17: The global namespace variable example with quotas does not persist after a reboot, is that correct?

Yes. If you restart the proxy, you lose the results, unless you save them in a file.

16.7.6.18: Can MySQL Proxy handle SSL connections?

No, being the man-in-the-middle, Proxy cannot handle encrypted sessions because it cannot share the SSL information.

16.7.6.19: Could MySQL Proxy be used to capture passwords?

The MySQL network protocol does not allow passwords to be sent in cleartext, all you could capture is the encrypted version.

16.7.6.20: Are there tools for isolating problems? How can someone figure out whether a problem is in the client, the database, or the proxy?

You can set a debug script in the proxy, which is an exceptionally good tool for this purpose. You can see very clearly which component is causing the problem, if you set the right breakpoints.

16.7.6.21: Is MySQL Proxy similar to what is provided by Java connection pools?

Yes and no. Java connection pools are specific to Java applications, MySQL Proxy works with any client API that talks the MySQL network protocol. Also, connection pools do not provide any functionality for intelligently examining the network packets and modifying the contents.

16.7.6.22: So authentication with connection pooling has to be done at every connection? What is the authentication latency?

You can skip the round-trip and use the connection as it was added to the pool. As long as the application cleans up the temporary tables it used. The overhead is (as always) around 400 microseconds.

16.7.6.23: If you have multiple databases on the same box, can you use proxy to connect to databases on default port 3306?

Yes, MySQL Proxy can listen on any port, provided that none of the MySQL servers are listening on the same port.

16.7.6.24: What about caching the authorization information so clients connecting are given back-end connections that were established with identical authorization information, thus saving a few more round trips?

There is an `--proxy-pool-no-change-user` [1572] option that provides this functionality.

16.7.6.25: Is there any big web site using MySQL Proxy? For what purpose and what transaction rate have they achieved?

Yes, gaiaonline. They have tested MySQL Proxy and seen it handle 2400 queries per second through the proxy.

16.7.6.26: How does MySQL Proxy compare to DBSlayer?

DBSlayer is a REST->MySQL tool, MySQL Proxy is transparent to your application. No change to the application is needed.

16.7.6.27: I tried using MySQL Proxy without any Lua script to try a round-robin type load balancing. In this case, if the first database in the list is down, MySQL Proxy would not connect the client to the second database in the list.

This issue is fixed in version 0.7.0.

16.7.6.28: Is it "safe" to use `LuaSocket` with proxy scripts?

You can, but it is not advised because it may block.

16.7.6.29: How different is MySQL Proxy from DBCP (Database connection pooling) for Apache in terms of connection pooling?

Connection Pooling is just one use case of the MySQL Proxy. You can use it for a lot more and it works in cases where you cannot use DBCP (for example, if you do not have Java).

16.7.6.30: MySQL Proxy can handle about 5000 connections, what is the limit on a MySQL server?

The server limit is given by the value of the `max_connections` [493] system variable. The default value is version dependent.

16.7.6.31: Would the Java-only connection pooling solution work for multiple web servers? With this, I would assume that you can pool across many web servers at once?

Yes. But you can also start one proxy on each application server to get a similar behavior as you have it already.

Replication enables data from one MySQL database server (the master) to be replicated to one or more MySQL database servers (the slaves). Replication is asynchronous - slaves need not be connected permanently to receive updates from the master. This means that updates can occur over long-distance connections and even over temporary or intermittent connections such as a dial-up service. Depending on the configuration, you can replicate all databases, selected databases, or even selected tables within a database.

For answers to some questions often asked by those who are new to MySQL Replication, see MySQL 5.1 FAQ: Replication.

The target uses for replication in MySQL include:

- Scale-out solutions - spreading the load among multiple slaves to improve performance. In this environment, all writes and updates must take place on the master server. Reads, however, may take place on one or more slaves. This model can improve the performance of writes (since the master is dedicated to updates), while dramatically increasing read speed across an increasing number of slaves.
- Data security - because data is replicated to the slave, and the slave can pause the replication process, it is possible to run backup services on the slave without corrupting the corresponding master data.
- Analytics - live data can be created on the master, while the analysis of the information can take place on the slave without affecting the performance of the master.
- Long-distance data distribution - if a branch office would like to work with a copy of your main data, you can use replication to create a local copy of the data for their use without requiring permanent access to the master.

Replication in MySQL features support for one-way, asynchronous replication, in which one server acts as the master, while one or more other servers act as slaves. This is in contrast to the *synchronous* replication which is a characteristic of MySQL Cluster (see Chapter 17, *MySQL Cluster NDB 6.1 - 7.1*).

There are a number of solutions available for setting up replication between two servers, but the best method to use depends on the presence of data and the engine types you are using. For more information on the available options, see How to Set Up Replication.

There are two core types of replication format, Statement Based Replication (SBR), which replicates entire SQL statements, and Row Based Replication (RBR), which replicates only the changed rows. You may also use a third variety, Mixed Based Replication (MBR). For more information on the different replication formats, see Replication Formats. From MySQL 5.1.12 to MySQL 5.1.28, mixed format is the default. Beginning with MySQL 5.1.29, statement-based format is the default.

Replication is controlled through a number of different options and variables. These control the core operation of the replication, timeouts, and the databases and filters that can be applied on databases and tables. For more information on the available options, see Replication and Binary Logging Options and Variables.

You can use replication to solve a number of different problems, including problems with performance, supporting the backup of different databases, and as part of a larger solution to alleviate system failures. For information on how to address these issues, see Replication Solutions.

For notes and tips on how different data types and statements are treated during replication, including details of replication features, version compatibility, upgrades, and problems and their resolution, including an FAQ, see Replication Notes and Tips.

For detailed information on the implementation of replication, how replication works, the process and contents of the binary log, background threads and the rules used to decide how statements are recorded and replication, see Replication Implementation.

Replication Configuration

Replication between servers in MySQL is based on the binary logging mechanism. The MySQL instance operating as the master (the source of the database changes) writes updates and changes as “events” to the binary log. The information in the binary log is stored in different logging formats according to the database changes being recorded. Slaves are configured to read the binary log from the master and to execute the events in the binary log on the slave's local database.

The master is “dumb” in this scenario. Once binary logging has been enabled, all statements are recorded in the binary log. Each slave receives a copy of the entire contents of the binary log. It is the responsibility of the slave to decide which statements in the binary log should be executed; you cannot configure the master to log only certain events. If you do not specify otherwise, all events in the master binary log are executed on the slave. If required, you can configure the slave to process only events that apply to particular databases or tables.

Each slave keeps a record of the binary log coordinates: The file name and position within the file that it has read and processed from the master. This means that multiple slaves can be connected to the master and executing different parts of the same binary log. Because the slaves control this process, individual slaves can be connected and disconnected from the server without affecting the master's operation. Also, because each slave remembers the position within the binary log, it is possible for slaves to be disconnected, reconnect and then “catch up” by continuing from the recorded position.

Both the master and each slave must be configured with a unique ID (using the `server-id` [1617] option). In addition, each slave must be configured with information about the master host name, log file name, and position within that file. These details can be controlled from within a MySQL session using the `CHANGE MASTER TO` statement on the slave. The details are stored within the slave's `master.info` file.

This section describes the setup and configuration required for a replication environment, including step-by-step instructions for creating a new replication environment. The major components of this section are:

- For a guide to setting up two or more servers for replication, How to Set Up Replication, deals with the configuration of the systems and provides methods for copying data between the master and slaves.
- Events in the binary log are recorded using a number of formats. These are referred to as statement-based replication (SBR) or row-based replication (RBR). A third type, mixed-format replication (MIXED), uses SBR or RBR replication automatically to take advantage of the benefits of both SBR and RBR formats when appropriate. The different formats are discussed in Replication Formats.
- Detailed information on the different configuration options and variables that apply to replication is provided in Replication and Binary Logging Options and Variables.
- Once started, the replication process should require little administration or monitoring. However, for advice on common tasks that you may want to execute, see Common Replication Administration Tasks.

How to Set Up Replication

This section describes how to set up complete replication of a MySQL server. There are a number of different methods for setting up replication, and the exact method to use depends on how you are setting up replication, and whether you already have data within your master database.

There are some generic tasks that are common to all replication setups:

- On the master, you must enable binary logging and configure a unique server ID. This might require a server restart. See Setting the Replication Master Configuration.
- On each slave that you want to connect to the master, you must configure a unique server ID. This might require a server restart. See Setting the Replication Slave Configuration.
- You may want to create a separate user that will be used by your slaves to authenticate with the master to read the binary log for replication. The step is optional. See Creating a User for Replication.
- Before creating a data snapshot or starting the replication process, you should record the position of the binary log on the master. You will need this information when configuring the slave so that the slave knows where within the binary log to start executing events. See Obtaining the Replication Master Binary Log Coordinates.
- If you already have data on your master and you want to use it to synchronize your slave, you will need to create a data snapshot. You can create a snapshot using `mysqldump` (see Creating a Data Snapshot Using `mysqldump`) or by copying the data files directly (see Creating a Data Snapshot Using Raw Data Files).
- You will need to configure the slave with settings for connecting to the master, such as the host name, login credentials, and binary log file name and position. See Setting the Master Configuration on the Slave.

Once you have configured the basic options, you will need to follow the instructions for your replication setup. A number of alternatives are provided:

- If you are establishing a new MySQL master and one or more slaves, you need only set up the configuration, as you have no data to exchange. For guidance on setting up replication in this situation, see Setting Up Replication with New Master and Slaves.
- If you are already running a MySQL server, and therefore already have data that must be transferred to your slaves before replication starts, have not previously configured the binary log and are able to

shut down your MySQL server for a short period during the process, see Setting Up Replication with Existing Data.

- If you are adding slaves to an existing replication environment, you can set up the slaves without affecting the master. See Introducing Additional Slaves to an Existing Replication Environment.

If you will be administering MySQL replication servers, we suggest that you read this entire chapter through and try all statements mentioned in SQL Statements for Controlling Master Servers, and SQL Statements for Controlling Slave Servers. You should also familiarize yourself with the replication startup options described in Replication and Binary Logging Options and Variables.

Note

Note that certain steps within the setup process require the SUPER [628] privilege. If you do not have this privilege, it might not be possible to enable replication.

Setting the Replication Master Configuration

On a replication master, you must enable binary logging and establish a unique server ID. If this has not already been done, this part of master setup requires a server restart.

Binary logging *must* be enabled on the master because the binary log is the basis for sending data changes from the master to its slaves. If binary logging is not enabled, replication will not be possible.

Each server within a replication group must be configured with a unique server ID. This ID is used to identify individual servers within the group, and must be a positive integer between 1 and (2^{32})–1. How you organize and select the numbers is entirely up to you.

To configure the binary log and server ID options, you will need to shut down your MySQL server and edit the `my.cnf` or `my.ini` file. Add the following options to the configuration file within the `[mysqld]` section. If these options already exist, but are commented out, uncomment the options and alter them according to your needs. For example, to enable binary logging using a log file name prefix of `mysql-bin`, and configure a server ID of 1, use these lines:

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

After making the changes, restart the server.

Note

If you omit `server-id` [1617] (or set it explicitly to its default value of 0), a master refuses connections from all slaves.

Note

For the greatest possible durability and consistency in a replication setup using `InnoDB` with transactions, you should use `innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in the master `my.cnf` file.

Note

Ensure that the `skip-networking` [443] option is not enabled on your replication master. If networking has been disabled, your slave will not able to communicate with the master and replication will fail.

Setting the Replication Slave Configuration

On a replication slave, you must establish a unique server ID. If this has not already been done, this part of slave setup requires a server restart.

If the slave server ID is not already set, or the current value conflicts with the value that you have chosen for the master server, you should shut down your slave server and edit the configuration to specify a unique server ID. For example:

```
[mysqld]
server-id=2
```

After making the changes, restart the server.

If you are setting up multiple slaves, each one must have a unique `server-id` [1617] value that differs from that of the master and from each of the other slaves. Think of `server-id` [1617] values as something similar to IP addresses: These IDs uniquely identify each server instance in the community of replication partners.

Note

If you omit `server-id` [1617] (or set it explicitly to its default value of 0), a slave refuses to connect to a master.

You do not have to enable binary logging on the slave for replication to be enabled. However, if you enable binary logging on the slave, you can use the binary log for data backups and crash recovery on the slave, and also use the slave as part of a more complex replication topology (for example, where the slave acts as a master to other slaves).

Creating a User for Replication

Each slave must connect to the master using a MySQL user name and password, so there must be a user account on the master that the slave can use to connect. Any account can be used for this operation, providing it has been granted the `REPLICATION SLAVE` [627] privilege. You may wish to create a different account for each slave, or connect to the master using the same account for each slave.

You need not create an account specifically for replication. However, you should be aware that the user name and password will be stored in plain text within the `master.info` file (see Slave Status Logs). Therefore, you may want to create a separate account that has privileges only for the replication process, to minimize the possibility of compromise to other accounts.

To create a new account, use `CREATE USER`. To grant this account the privileges required for replication, use the `GRANT` statement. If you create an account solely for the purposes of replication, that account needs only the `REPLICATION SLAVE` [627] privilege. For example, to set up a new user, `repl`, that can connect for replication from any host within the `mydomain.com` domain, issue these statements on the master:

```
mysql> CREATE USER 'repl'@'%.mydomain.com' IDENTIFIED BY 'slavepass';
mysql> GRANT REPLICATION SLAVE ON *.* TO 'repl'@'%.mydomain.com';
```

See Account Management Statements, for more information on statements for manipulation of user accounts.

Obtaining the Replication Master Binary Log Coordinates

To configure replication on the slave you must determine the master's current coordinates within its binary log. You will need this information so that when the slave starts the replication process, it is able to start processing events from the binary log at the correct point.

If you have existing data on your master that you want to synchronize on your slaves before starting the replication process, you must stop processing statements on the master, and then obtain its current binary log coordinates and dump its data, before permitting the master to continue executing statements. If you do not stop the execution of statements, the data dump and the master status information that you use will not match and you will end up with inconsistent or corrupted databases on the slaves.

To obtain the master binary log coordinates, follow these steps:

1. Start a session on the master by connecting to it with the command-line client, and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

   ```
   mysql> FLUSH TABLES WITH READ LOCK;
   ```

   For `InnoDB` tables, note that `FLUSH TABLES WITH READ LOCK` also blocks `COMMIT` operations.

   Warning

   Leave the client from which you issued the `FLUSH TABLES` statement running so that the read lock remains in effect. If you exit the client, the lock is released.

2. In a different session on the master, use the `SHOW MASTER STATUS` statement to determine the current binary log file name and position:

   ```
   mysql > SHOW MASTER STATUS;
   +------------------+----------+--------------+------------------+
   | File             | Position | Binlog_Do_DB | Binlog_Ignore_DB |
   +------------------+----------+--------------+------------------+
   | mysql-bin.000003 | 73       | test         | manual,mysql     |
   +------------------+----------+--------------+------------------+
   ```

   The `File` column shows the name of the log file and `Position` shows the position within the file. In this example, the binary log file is `mysql-bin.000003` and the position is 73. Record these values. You need them later when you are setting up the slave. They represent the replication coordinates at which the slave should begin processing new updates from the master.

   If the master has been running previously without binary logging enabled, the log file name and position values displayed by `SHOW MASTER STATUS` or `mysqldump --master-data` will be empty. In that case, the values that you need to use later when specifying the slave's log file and position are the empty string (`''`) and `4`.

You now have the information you need to enable the slave to start reading from the binary log in the correct place to start replication.

If you have existing data that needs be to synchronized with the slave before you start replication, leave the client running so that the lock remains in place and then proceed to Creating a Data Snapshot Using `mysqldump`, or Creating a Data Snapshot Using Raw Data Files. The idea here is to prevent any further changes so that the data copied to the slaves is in synchrony with the master.

If you are setting up a brand new master and slave replication group, you can exit the first session to release the read lock.

Creating a Data Snapshot Using `mysqldump`

One way to create a snapshot of the data in an existing master database is to use the `mysqldump` tool. Once the data dump has been completed, you then import this data into the slave before starting the replication process.

To obtain a snapshot of the data using `mysqldump`:

1. If you have not already locked the tables on the server to prevent statements that update data from executing:

   Start a session on the server by connecting to it with the command-line client, and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

   ```
   mysql> FLUSH TABLES WITH READ LOCK;
   ```

   Remember to use `SHOW MASTER STATUS` and record the binary log details for use when starting up the slave. The point in time of your snapshot and the binary log position must match. See Obtaining the Replication Master Binary Log Coordinates.

2. In another session, use `mysqldump` to create a dump either of all the databases you want to replicate, or of selected individual databases. For example:

   ```
   shell> mysqldump --all-databases --lock-all-tables >dbdump.db
   ```

   An alternative to using a bare dump, is to use the `--master-data` option, which automatically appends the `CHANGE MASTER TO` statement required on the slave to start the replication process.

   ```
   shell> mysqldump --all-databases --master-data >dbdump.db
   ```

3. In the client where you acquired the read lock, release the lock:

   ```
   mysql> UNLOCK TABLES;
   ```

   Alternatively, exit the first session to release the read lock.

When choosing databases to include in the dump, remember to filter out databases on each slave that you do not want to include in the replication process.

Either to copy the dump file to the slave, or use the file from the master when connecting remotely to the slave to import the data.

Creating a Data Snapshot Using Raw Data Files

If your database is large, copying the raw data files can be more efficient than using `mysqldump` and importing the file on each slave. This technique skips the overhead of updating indexes as the `INSERT` statements are replayed.

Using this method with tables in storage engines with complex caching or logging algorithms requires extra steps to produce a perfect “point in time” snapshot: the initial copy command might leave out cache information and logging updates, even if you have acquired a global read lock. How the storage engine responds to this depends on its crash recovery abilities.

This method also does not work reliably if the master and slave have different values for `ft_stopword_file` [477], `ft_min_word_len` [476], or `ft_max_word_len` [476] and you are copying tables having full-text indexes.

If you use `InnoDB` tables, you can use the `mysqlbackup` command from the MySQL Enterprise Backup component to produce a consistent snapshot. This command records the log name and offset corresponding to the snapshot to be later used on the slave. MySQL Enterprise Backup is a commercial product that is included as part of a MySQL Enterprise subscription. See Chapter 24, *MySQL Enterprise Backup* for detailed information.

Otherwise, use the cold backup technique to obtain a reliable binary snapshot of `InnoDB` tables: copy all data files after doing a slow shutdown of the MySQL Server.

To create a raw data snapshot of `MyISAM` tables, you can use standard copy tools such as `cp` or `copy`, a remote copy tool such as `scp` or `rsync`, an archiving tool such as `zip` or `tar`, or a file system snapshot tool such as `dump`, providing that your MySQL data files exist on a single file system. If you are replicating only certain databases, copy only those files that relate to those tables. (For `InnoDB`, all tables in all databases are stored in the system tablespace files, unless you have the `innodb_file_per_table` [1367] option enabled.)

You might want to specifically exclude the following files from your archive:

- Files relating to the `mysql` database.
- The `master.info` file.
- The master's binary log files.
- Any relay log files.

To get the most consistent results with a raw data snapshot, shut down the master server during the process, as follows:

1. Acquire a read lock and get the master's status. See Obtaining the Replication Master Binary Log Coordinates.
2. In a separate session, shut down the master server:

```
shell> mysqladmin shutdown
```

3. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

4. Restart the master server.

If you are not using `InnoDB` tables, you can get a snapshot of the system from a master without shutting down the server as described in the following steps:

1. Acquire a read lock and get the master's status. See Obtaining the Replication Master Binary Log Coordinates.
2. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

3. In the client where you acquired the read lock, release the lock:

```
mysql> UNLOCK TABLES;
```

Once you have created the archive or copy of the database, copy the files to each slave before starting the slave replication process.

Setting Up Replication with New Master and Slaves

The easiest and most straightforward method for setting up replication is to use new master and slave servers.

You can also use this method if you are setting up new servers but have an existing dump of the databases from a different server that you want to load into your replication configuration. By loading the data into a new master, the data will be automatically replicated to the slaves.

To set up replication between a new master and slave:

1. Configure the MySQL master with the necessary configuration properties. See Setting the Replication Master Configuration.
2. Start up the MySQL master.
3. Set up a user. See Creating a User for Replication.
4. Obtain the master status information. See Obtaining the Replication Master Binary Log Coordinates.
5. On the master, release the read lock:

```
mysql> UNLOCK TABLES;
```

6. On the slave, edit the MySQL configuration. See Setting the Replication Slave Configuration.
7. Start up the MySQL slave.

8. Execute a `CHANGE MASTER TO` statement to set the master replication server configuration. See Setting the Master Configuration on the Slave.

Perform the slave setup steps on each slave.

Because there is no data to load or exchange on a new server configuration you do not need to copy or import any information.

If you are setting up a new replication environment using the data from a different existing database server, you will now need to run the dump file generated from that server on the new master. The database updates will automatically be propagated to the slaves:

```
shell> mysql -h master < fulldb.dump
```

Setting Up Replication with Existing Data

When setting up replication with existing data, you will need to decide how best to get the data from the master to the slave before starting the replication service.

The basic process for setting up replication with existing data is as follows:

1. With the MySQL master running, create a user to be used by the slave when connecting to the master during replication. See Creating a User for Replication.

2. If you have not already configured the `server-id` [1617] and enabled binary logging on the master server, you will need to shut it down to configure these options. See Setting the Replication Master Configuration.

   If you have to shut down your master server, this is a good opportunity to take a snapshot of its databases. You should obtain the master status (see Obtaining the Replication Master Binary Log Coordinates) before taking down the master, updating the configuration and taking a snapshot. For information on how to create a snapshot using raw data files, see Creating a Data Snapshot Using Raw Data Files.

3. If your master server is already correctly configured, obtain its status (see Obtaining the Replication Master Binary Log Coordinates) and then use `mysqldump` to take a snapshot (see Creating a Data Snapshot Using `mysqldump`) or take a raw snapshot of the live server using the guide in Creating a Data Snapshot Using Raw Data Files.

4. Update the configuration of the slave. See Setting the Replication Slave Configuration.

5. The next step depends on how you created the snapshot of data on the master.

   If you used `mysqldump`:

   a. Start the slave, using the `--skip-slave-start` [1640] option so that replication does not start.

   b. Import the dump file:

      ```
      shell> mysql < fulldb.dump
      ```

   If you created a snapshot using the raw data files:

   a. Extract the data files into your slave data directory. For example:

      ```
      shell> tar xvf dbdump.tar
      ```

      You may need to set permissions and ownership on the files so that the slave server can access and modify them.

   b. Start the slave, using the `--skip-slave-start` [1640] option so that replication does not start.

6. Configure the slave with the replication coordinates from the master. This tells the slave the binary log file and position within the file where replication needs to start. Also, configure the slave with the login credentials and host name of the master. For more information on the `CHANGE MASTER TO` statement required, see Setting the Master Configuration on the Slave.

7. Start the slave threads:

```
mysql> START SLAVE;
```

After you have performed this procedure, the slave should connect to the master and catch up on any updates that have occurred since the snapshot was taken.

If you have forgotten to set the `server-id` [1617] option for the master, slaves cannot connect to it.

If you have forgotten to set the `server-id` [1617] option for the slave, you get the following error in the slave's error log:

```
Warning: You should set server-id to a non-0 value if master_host
is set; we will force server id to 2, but this MySQL server will
not act as a slave.
```

You also find error messages in the slave's error log if it is not able to replicate for any other reason.

Once a slave is replicating, you can find in its data directory one file named `master.info` and another named `relay-log.info`. The slave uses these two files to keep track of how much of the master's binary log it has processed. Do *not* remove or edit these files unless you know exactly what you are doing and fully understand the implications. Even in that case, it is preferred that you use the `CHANGE MASTER TO` statement to change replication parameters. The slave will use the values specified in the statement to update the status files automatically.

Note

The content of `master.info` overrides some of the server options specified on the command line or in `my.cnf`. See Replication and Binary Logging Options and Variables, for more details.

A single snapshot of the master suffices for multiple slaves. To set up additional slaves, use the same master snapshot and follow the slave portion of the procedure just described.

Introducing Additional Slaves to an Existing Replication Environment

To add another slave to an existing replication configuration, you can do so without stopping the master. Instead, set up the new slave by making a copy of an existing slave, except that you configure the new slave with a different `server-id` [1617] value.

To duplicate an existing slave:

1. Shut down the existing slave:

```
shell> mysqladmin shutdown
```

2. Copy the data directory from the existing slave to the new slave. You can do this by creating an archive using `tar` or `WinZip`, or by performing a direct copy using a tool such as `cp` or `rsync`. Ensure that you also copy the log files and relay log files.

   A common problem that is encountered when adding new replication slaves is that the new slave fails with a series of warning and error messages like these:

```
071118 16:44:10 [Warning] Neither --relay-log nor --relay-log-index were used; so
replication may break when this MySQL server acts as a slave and has his hostname
changed!! Please use '--relay-log=new_slave_hostname-relay-bin' to avoid this problem.
071118 16:44:10 [ERROR] Failed to open the relay log './old_slave_hostname-relay-bin.003525'
(relay_log_pos 22940879)
071118 16:44:10 [ERROR] Could not find target log during relay log initialization
071118 16:44:10 [ERROR] Failed to initialize the master info structure
```

This is due to the fact that, if the `--relay-log` [1632] option is not specified, the relay log files contain the host name as part of their file names. (This is also true of the relay log index file if the `--relay-log-index` [1633] option is not used. See Replication and Binary Logging Options and Variables, for more information about these options.)

To avoid this problem, use the same value for `--relay-log` [1632] on the new slave that was used on the existing slave. (If this option was not set explicitly on the existing slave, use *`existing_slave_hostname`*`-relay-bin`.) If this is not feasible, copy the existing slave's relay log index file to the new slave and set the `--relay-log-index` [1633] option on the new slave to match what was used on the existing slave. (If this option was not set explicitly on the existing slave, use *`existing_slave_hostname`*`-relay-bin.index`.) Alternatively—if you have already tried to start the new slave (after following the remaining steps in this section) and have encountered errors like those described previously—then perform the following steps:

a. If you have not already done so, issue a `STOP SLAVE` on the new slave.

   If you have already started the existing slave again, issue a `STOP SLAVE` on the existing slave as well.

b. Copy the contents of the existing slave's relay log index file into the new slave's relay log index file, making sure to overwrite any content already in the file.

c. Proceed with the remaining steps in this section.

3. Copy the `master.info` and `relay-log.info` files from the existing slave to the new slave if they were not located in the data directory. These files hold the current log coordinates for the master's binary log and the slave's relay log.

4. Start the existing slave.

5. On the new slave, edit the configuration and give the new slave a unique `server-id` [1617] not used by the master or any of the existing slaves.

6. Start the new slave. The slave will use the information in its `master.info` file to start the replication process.

Setting the Master Configuration on the Slave

To set up the slave to communicate with the master for replication, you must tell the slave the necessary connection information. To do this, execute the following statement on the slave, replacing the option values with the actual values relevant to your system:

```
mysql> CHANGE MASTER TO
    ->     MASTER_HOST='master_host_name',
    ->     MASTER_USER='replication_user_name',
    ->     MASTER_PASSWORD='replication_password',
    ->     MASTER_LOG_FILE='recorded_log_file_name',
    ->     MASTER_LOG_POS=recorded_log_position;
```

Note

Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

The `CHANGE MASTER TO` statement has other options as well. For example, it is possible to set up secure replication using SSL. For a full list of options, and information about the maximum permissible length for the string-valued options, see `CHANGE MASTER TO` Syntax.

Replication Formats

Replication works because events written to the binary log are read from the master and then processed on the slave. The events are recorded within the binary log in different formats according

to the type of event. The different replication formats used correspond to the binary logging format used when the events were recorded in the master's binary log. The correlation between binary logging formats and the terms used during replication are:

- Replication capabilities in MySQL originally were based on propagation of SQL statements from master to slave. This is called *statement-based replication* (often abbreviated as *SBR*), which corresponds to the standard statement-based binary logging format. In MySQL 5.1.4 and earlier, binary logging and replication used this format exclusively.
- Row-based binary logging logs changes in individual table rows. When used with MySQL replication, this is known as *row-based replication* (often abbreviated as *RBR*). In row-based replication, the master writes *events* to the binary log that indicate how individual table rows are changed.
- As of MySQL 5.1.8, the server can change the binary logging format in real time according to the type of event using *mixed-format logging*.

  When the mixed format is in effect, statement-based logging is used by default, but automatically switches to row-based logging in particular cases as described later. Replication using the mixed format is often referred to as *mixed-based replication* or *mixed-format replication*. For more information, see Mixed Binary Logging Format.

From MySQL 5.1.12 to MySQL 5.1.28, mixed format is the default. Beginning with MySQL 5.1.29, statement-based format is the default.

MySQL Cluster. The default binary logging format in all MySQL Cluster NDB 6.x and 7.x releases is `ROW`. MySQL Cluster Replication always uses row-based replication, and the `NDBCLUSTER` storage engine is incompatible with statement-based replication. Using `NDBCLUSTER` sets row-based logging format automatically. See General Requirements for MySQL Cluster Replication, for more information.

Starting with MySQL 5.1.20, when using `MIXED` format, the binary logging format is determined in part by the storage engine being used and the statement being executed. For more information on mixed-format logging and the rules governing the support of different logging formats, see Mixed Binary Logging Format.

The logging format in a running MySQL server is controlled by setting the `binlog_format` [1654] server system variable. This variable can be set with session or global scope. The rules governing when and how the new setting takes effect are the same as for other MySQL server system variables—setting the variable for the current session lasts only until the end of that session, and the change is not visible to other sessions; setting the variable globally requires a restart of the server to take effect. For more information, see `SET` Syntax.

You must have the `SUPER` [628] privilege to set the global `binlog_format` [1654] value. Starting with MySQL 5.1.29, you must have the `SUPER` [628] privilege to set either the global or session `binlog_format` [1654] value. (Bug #39106)

The statement-based and row-based replication formats have different issues and limitations. For a comparison of their relative advantages and disadvantages, see Advantages and Disadvantages of Statement-Based and Row-Based Replication.

With statement-based replication, you may encounter issues with replicating stored routines or triggers. You can avoid these issues by using row-based replication instead. For more information, see Binary Logging of Stored Programs.

Advantages and Disadvantages of Statement-Based and Row-Based Replication

Each binary logging format has advantages and disadvantages. For most users, the mixed replication format should provide the best combination of data integrity and performance. If, however, you want to take advantage of the features specific to the statement-based or row-based replication format when performing certain tasks, you can use the information in this section, which provides a summary of their relative advantages and disadvantages, to determine which is best for your needs.

- Advantages of statement-based replication

- Disadvantages of statement-based replication
- Advantages of row-based replication
- Disadvantages of row-based replication

Advantages of statement-based replication

- Proven technology that has existed in MySQL since 3.23.
- Less data written to log files. When updates or deletes affect many rows, this results in *much* less storage space required for log files. This also means that taking and restoring from backups can be accomplished more quickly.
- Log files contain all statements that made any changes, so they can be used to audit the database.

Disadvantages of statement-based replication

- **Statements that are unsafe for SBR.**
  Not all statements which modify data (such as `INSERT` `DELETE`, `UPDATE`, and `REPLACE` statements) can be replicated using statement-based replication. Any nondeterministic behavior is difficult to replicate when using statement-based replication. Examples of such DML (Data Modification Language) statements include the following:
  - A statement that depends on a UDF or stored program that is nondeterministic, since the value returned by such a UDF or stored program or depends on factors other than the parameters supplied to it. (Row-based replication, however, simply replicates the value returned by the UDF or stored program, so its effect on table rows and data is the same on both the master and slave.) See Replication of Invoked Features, for more information.
  - `DELETE` and `UPDATE` statements that use a `LIMIT` clause without an `ORDER BY` are nondeterministic. See Replication and `LIMIT`.
  - Statements using any of the following functions cannot be replicated properly using statement-based replication:
    - `LOAD_FILE()` [953]
    - `UUID()` [1042], `UUID_SHORT()` [1043]
    - `USER()` [1039]
    - `FOUND_ROWS()` [1035]
    - `SYSDATE()` [992] (unless both the master and the slave are started with the `--sysdate-is-now` [446] option)
    - `GET_LOCK()` [1040]
    - `IS_FREE_LOCK()` [1041]
    - `IS_USED_LOCK()` [1042]
    - `MASTER_POS_WAIT()` [1042]
    - `RAND()` [975]
    - `RELEASE_LOCK()` [1042]
    - `SLEEP()` [1042]
    - `VERSION()` [1039]

However, all other functions are replicated correctly using statement-based replication, including `NOW()` [990] and so forth.

For more information, see Replication and System Functions.

Statements that cannot be replicated correctly using statement-based replication are logged with a warning like the one shown here:

```
090213 16:58:54 [Warning] Statement is not safe to log in statement format.
```

A similar warning is also issued to the client in such cases. The client can display it using `SHOW WARNINGS`.

- `INSERT ... SELECT` requires a greater number of row-level locks than with row-based replication.
- `UPDATE` statements that require a table scan (because no index is used in the `WHERE` clause) must lock a greater number of rows than with row-based replication.
- For `InnoDB`: An `INSERT` statement that uses `AUTO_INCREMENT` blocks other nonconflicting `INSERT` statements.
- For complex statements, the statement must be evaluated and executed on the slave before the rows are updated or inserted. With row-based replication, the slave only has to modify the affected rows, not execute the full statement.
- If there is an error in evaluation on the slave, particularly when executing complex statements, statement-based replication may slowly increase the margin of error across the affected rows over time. See Slave Errors During Replication.
- Stored functions execute with the same `NOW()` [990] value as the calling statement. However, this is not true of stored procedures.
- Deterministic UDFs must be applied on the slaves.
- Table definitions must be (nearly) identical on master and slave. See Replication with Differing Table Definitions on Master and Slave, for more information.

Advantages of row-based replication:

- All changes can be replicated. This is the safest form of replication.

  For MySQL versions earlier than 5.1.14, DDL (Data Definition Language) statements such as `CREATE TABLE` are replicated using statement-based replication, while DML statements, as well as `GRANT` and `REVOKE` statements, are replicated using row-based replication.

  In MySQL 5.1.14 and later, the `mysql` database is not replicated. The `mysql` database is instead seen as a node-specific database. Row-based replication is not supported on tables in this database. Instead, statements that would normally update this information—such as `GRANT`, `REVOKE` and the manipulation of triggers, stored routines (including stored procedures), and views—are all replicated to slaves using statement-based replication.

  For statements such as `CREATE TABLE ... SELECT`, a `CREATE` statement is generated from the table definition and replicated using statement-based format, while the row insertions are replicated using row-based format.

- The technology is the same as in most other database management systems; knowledge about other systems transfers to MySQL.
- Fewer row locks are required on the master, which thus achieves higher concurrency, for the following types of statements:
  - `INSERT ... SELECT`

- `INSERT` statements with `AUTO_INCREMENT`
- `UPDATE` or `DELETE` statements with `WHERE` clauses that do not use keys or do not change most of the examined rows.

- Fewer row locks are required on the slave for any `INSERT`, `UPDATE`, or `DELETE` statement.

Disadvantages of row-based replication:

- RBR tends to generate more data that must be logged. To replicate a DML statement (such as an `UPDATE` or `DELETE` statement), statement-based replication writes only the statement to the binary log. By contrast, row-based replication writes each changed row to the binary log. If the statement changes many rows, row-based replication may write significantly more data to the binary log; this is true even for statements that are rolled back. This also means that taking and restoring from backup can require more time. In addition, the binary log is locked for a longer time to write the data, which may cause concurrency problems.
- Deterministic UDFs that generate large `BLOB` values take longer to replicate with row-based replication than with statement-based replication. This is because the `BLOB` column value is logged, rather than the statement generating the data.
- You cannot examine the logs to see what statements were executed, nor can you see on the slave what statements were received from the master and executed.

  However, beginning with MySQL 5.1.29, you can see what data was changed using `mysqlbinlog` with the options `--base64-output=DECODE-ROWS` [349] and `--verbose` [354].
- For tables using the `MyISAM` storage engine, a stronger lock is required on the slave for `INSERT` statements when applying them as row-based events to the binary log than when applying them as statements. This means that concurrent inserts on `MyISAM` tables are not supported when using row-based replication.
- Formerly, when performing a bulk operation that includes nontransactional storage engines, changes were applied as the statement executed. With row-based logging, this meant that the binary log was written while the statement was running. On the master, this does not cause problems with concurrency, because tables are locked until the bulk operation terminates. On the slave server, tables were not locked while the slave applied changes, because the slave did not know that those changes were part of a bulk operation.

  In such cases, if you retrieved data from a table on the master (for example, using `SELECT * FROM table_name`), the server waited for the bulk operation to complete before executing the `SELECT` statement, because the table was read-locked. On the slave, the server did not wait (because there was no lock). This meant that, until the bulk operation on the slave completed, different results were obtained for the same `SELECT` query on the master and on the slave.

  This issue was resolved in MySQL 5.1.24. (Bug #29020)

Usage of Row-Based Logging and Replication

Major changes in the replication environment and in the behavior of applications can result from using row-based logging (RBL) or row-based replication (RBR) rather than statement-based logging or replication. This section describes a number of issues known to exist when using row-based logging or replication, and discusses some best practices for taking advantage of row-based logging and replication.

For additional information, see Replication Formats, and Advantages and Disadvantages of Statement-Based and Row-Based Replication.

For information about issues specific to MySQL Cluster Replication (which depends on row-based replication), see Known Issues in MySQL Cluster Replication.

- **RBL, RBR, and temporary tables.** As noted in Replication and Temporary Tables, temporary tables are not replicated when using row-based format. When mixed format is in effect, “safe” statements involving temporary tables are logged using statement-based format. For more information, see Advantages and Disadvantages of Statement-Based and Row-Based Replication.

  Temporary tables are not replicated when using row-based format because there is no need. In addition, because temporary tables can be read only from the thread which created them, there is seldom if ever any benefit obtained from replicating them, even when using statement-based format.

- **RBL and the `BLACKHOLE` storage engine.** Prior to MySQL 5.1.29, `DELETE` and `UPDATE` statements for `BLACKHOLE` tables did not work with RBL. (Bug #38360)

- **RBL and synchronization of nontransactional tables.** When many rows are affected, the set of changes is split into several events; when the statement commits, all of these events are written to the binary log if the statement is an initial nontransactional statement (occurring in the transaction before any transactional statements). When executing on the slave, a table lock is taken on all tables involved, and then the rows are applied in batch mode. (This may or may not be effective, depending on the engine used for the slave's copy of the table.)

- **Latency and binary log size.** Because RBL writes changes for each row to the binary log, its size can increase quite rapidly. In a replication environment, this can significantly increase the time required to make changes on the slave that match those on the master. You should be aware of the potential for this delay in your applications.

- **Reading the binary log.** `mysqlbinlog` displays row-based events in the binary log using the `BINLOG` statement (see `BINLOG` Syntax). This statement displays an event in printable form, but as a base 64-encoded string the meaning of which is not evident. As of MySQL 5.1.28, when invoked with the `--base64-output=DECODE-ROWS` [349] and `--verbose` [354] options, `mysqlbinlog` formats the contents of the binary log in a manner that is easily human readable. This is helpful when binary log events were written in row-based format if you want to read or recover from a replication or database failure using the contents of the binary log. For more information, see `mysqlbinlog` Row Event Display.

- **Binary log execution errors and `slave_exec_mode`.** If `slave_exec_mode` [1644] is `IDEMPOTENT`, a failure to apply changes from RBL because the original row cannot be found does not trigger an error or cause replication to fail. This means that it is possible that updates are not applied on the slave, so that the master and slave are no longer synchronized. Latency issues and use of nontransactional tables with RBR when `slave_exec_mode` [1644] is `IDEMPOTENT` can cause the master and slave to diverge even further. For more information about `slave_exec_mode` [1644], see Server System Variables.

  Note

  `slave_exec_mode=IDEMPOTENT` [1644] is generally useful only for circular replication or multi-master replication with MySQL Cluster, for which `IDEMPOTENT` is the default value (see MySQL Cluster Replication).

  For other scenarios, setting `slave_exec_mode` [1644] to `STRICT` is normally sufficient; this is the default value for storage engines other than `NDB`.

- **Lack of binary log checksums.** RBL uses no checksums. This means that network, disk, and other errors may not be identified when processing the binary log. To ensure that data is transmitted without network corruption, you may want to consider using SSL, which adds another layer of checksumming, for replication connections. The `CHANGE MASTER TO` statement has options to enable replication over SSL. See also `CHANGE MASTER TO` Syntax, for general information about setting up MySQL with SSL.

- **Filtering based on server ID not supported.** A common practice is to filter out changes on some slaves by using a `WHERE` clause that includes the relation `@@server_id <> id_value` clause with `UPDATE` and `DELETE` statements, a simple example of such a clause being `WHERE`

`@@server_id <> 1`. However, this does not work correctly with row-based logging. If you must use the `server_id` [521] system variable for statement filtering, you must also use `--binlog_format=STATEMENT` [1654].

- **Database-level replication options.** The effects of the `--replicate-do-db` [1634], `--replicate-ignore-db` [1635], and `--replicate-rewrite-db` [1637] options differ considerably depending on whether row-based or statement-based logging is used. Because of this, it is recommended to avoid database-level options and instead use table-level options such as `--replicate-do-table` [1636] and `--replicate-ignore-table` [1636]. For more information about these options and the impact that your choice of replication format has on how they operate, see Replication and Binary Logging Options and Variables.

- **RBL, nontransactional tables, and stopped slaves.** When using row-based logging, if the slave server is stopped while a slave thread is updating a nontransactional table, the slave database may reaches an inconsistent state. For this reason, it is recommended that you use a transactional storage engine such as `InnoDB` for all tables replicated using the row-based format.

  Use of `STOP SLAVE` (or `STOP SLAVE SQL_THREAD` in MySQL 5.1.55 and later) prior to shutting down the slave MySQL server helps prevent such issues from occurring, and is always recommended regardless of the logging format or storage engines employed.

Determination of Safe and Unsafe Statements in Binary Logging

When speaking of the “safeness” of a statement in MySQL Replication, we are referring to whether a statement and its effects can be replicated correctly using statement-based format. If this is true of the statement, we refer to the statement as *safe*; otherwise, we refer to it as *unsafe*.

In general, a statement is safe if it deterministic, and unsafe if it is not. However, certain nondeterministic functions are *not* considered unsafe (see Nondeterministic functions not considered unsafe, later in this section). In addition, statements using results from floating-point math functions —which are hardware-dependent—are always considered safe (see Replication and Floating-Point Values).

Handling of safe and unsafe statements. A statement is treated differently depending on whether the statement is considered safe, and with respect to the binary logging format (that is, the current value of `binlog_format` [1654]).

- No distinction is made in the treatment of safe and unsafe statements when the binary logging mode is `ROW`.

- If the binary logging format is `MIXED`, statements flagged as unsafe are logged using the row-based format; statements regarded as safe are logged using the statement-based format.

- If the binary logging format is `STATEMENT`, statements flagged as being unsafe generate a warning to this effect. (Safe statements are logged normally.)

For more information, see Replication Formats.

Statements considered unsafe.
Statements having the following characteristics are considered unsafe:

- **Statements containing system functions that may return a different value on slave.** These functions include `FOUND_ROWS()` [1035], `GET_LOCK()` [1040], `IS_FREE_LOCK()` [1041], `IS_USED_LOCK()` [1042], `LOAD_FILE()` [953], `MASTER_POS_WAIT()` [1042], `RELEASE_LOCK()` [1042], `ROW_COUNT()` [1038], `SESSION_USER()` [1039], `SLEEP()` [1042], `SYSDATE()` [992], `SYSTEM_USER()` [1039], `USER()` [1039], `UUID()` [1042], and `UUID_SHORT()` [1043].

  Nondeterministic functions not considered unsafe. Although these functions are not deterministic, they are treated as safe for purposes of logging and replication: `CONNECTION_ID()` [1033], `CURDATE()` [982], `CURRENT_DATE()` [982], `CURRENT_TIME()` [982], `CURRENT_TIMESTAMP()` [982], `CURTIME()` [982], `LOCALTIME()` [989],

`LOCALTIMESTAMP()` [989], `NOW()` [990], `UNIX_TIMESTAMP()` [995], `UTC_DATE()` [996], `UTC_TIME()` [996], `UTC_TIMESTAMP()` [996], and `LAST_INSERT_ID()` [1036]

For more information, see Replication and System Functions.

- **References to system variables.** Most system variables are not replicated correctly using the statement-based format. For exceptions, see Mixed Binary Logging Format.

  See Replication and Variables.

- **UDFs.** Since we have no control over what a UDF does, we must assume that it is executing unsafe statements.

- **Updates a table having an `AUTO_INCREMENT` column.** This is unsafe because the order in which the rows are updated may differ on the master and the slave.

  In addition, an `INSERT` into a table that has a composite primary key containing an `AUTO_INCREMENT` column that is not the first column of this composite key is unsafe.

  For more information, see Replication and `AUTO_INCREMENT`.

- **`INSERT DELAYED` statement.** This statement is considered unsafe because the insertion of the rows may interleave with concurrently executing statements.

- **`INSERT ... ON DUPLICATE KEY UPDATE` statements on tables with multiple primary or unique keys.** When executed against a table that contains more than one primary or unique key, this statement is considered unsafe, being sensitive to the order in which the storage engine checks the keys, which is not deterministic, and on which the choice of rows updated by the MySQL Server depends.

  Thus, such statements are considered unsafe.

- **Updates using `LIMIT`.** The order in which rows are retrieved is not specified.

  See Replication and `LIMIT`.

- **Accesses or references log tables.** The contents of the system log table may differ between master and slave.

- **Nontransactional operations after transactional operations.** Within a transaction, allowing any nontransactional reads or writes to execute after any transactional reads or writes is considered unsafe.

  For more information, see Replication and Transactions.

- **Accesses or references self-logging tables.** All reads and writes to self-logging tables are considered unsafe. Within a transaction, any statement following a read or write to self-logging tables is also considered unsafe.

- **`LOAD DATA INFILE` statements.** Beginning with MySQL 5.1.50, `LOAD DATA INFILE` is considered unsafe, it causes a warning in statement-based mode, and a switch to row-based format when using mixed-format logging. See Replication and `LOAD DATA INFILE`.

For additional information, see Replication Features and Issues.

Replication and Binary Logging Options and Variables

The next few sections contain information about `mysqld` options and server variables that are used in replication and for controlling the binary log. Options and variables for use on replication masters and replication slaves are covered separately, as are options and variables relating to binary logging. A set of quick-reference tables providing basic information about these options and variables is also included (in the next section following this one).

Of particular importance is the `--server-id` [1617] option.

Command-Line Format	`--server-id=#`	
Option-File Format	`server-id`	
Option Sets Variable	Yes, `server_id` [521]	
Variable Name	`server_id`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`numeric`
	Default	`0`
	Range	`0 .. 4294967295`

This option is common to both master and slave replication servers, and is used in replication to enable master and slave servers to identify themselves uniquely. For additional information, see Replication Master Options and Variables, and Replication Slave Options and Variables.

On the master and each slave, you *must* use the `--server-id` [1617] option to establish a unique replication ID in the range from 1 to 2^{32} – 1. “Unique”, means that each ID must be different from every other ID in use by any other replication master or slave. Example: `server-id=3`.

If you omit `--server-id` [1617], the default ID is 0, in which case a master refuses connections from all slaves, and a slave refuses to connect to a master. For more information, see Setting the Replication Slave Configuration.

Replication and Binary Logging Option and Variable Reference

The following tables list basic information about the MySQL command-line options and system variables applicable to replication and the binary log.

Table 16.1. Replication Options and Variables: MySQL 5.1

Option or Variable Name	Command Line / Option File	System Variable / Status Variable	Scope / Dynamic
`Com_change_master` [559]	N	N	Both
	N	Y	N
`Com_show_master_status` [559]	N	N	Both
	N	Y	N
`Com_show_new_master` [559]	N	N	Both
	N	Y	N
`Com_show_slave_hosts` [559]	N	N	Both
	N	Y	N
`Com_show_slave_status` [559]	N	N	Both
	N	Y	N
`Com_slave_start` [559]	N	N	Both
	N	Y	N
`Com_slave_stop` [559]	N	N	Both
	N	Y	N
`Rpl_status` [567]	N	N	Global

Option or Variable Name	Command Line	System Variable	Scope
	Option File	Status Variable	Dynamic
	N	Y	N
slave_exec_mode [1644]	Y	Y	Global
	Y	N	Y
Slave_open_temp_tables [568]	N	N	Global
	N	Y	N
Slave_retried_transactions [568]	N	N	Global
	N	Y	N
Slave_running [568]	N	N	Global
	N	Y	N
abort-slave-event-count [1627]	Y	N	Global
	Y	N	N
disconnect-slave-event-count [1628]	Y	N	Global
	Y	N	N

Binary Log Options and Variables, provides more detailed information about options and variables relating to binary logging. For additional general information about the binary log, see The Binary Log.

For a table showing *all* command-line options, system and status variables used with `mysqld`, see Server Option and Variable Reference.

Replication Master Options and Variables

This section describes the server options and system variables that you can use on replication master servers. You can specify the options either on the command line or in an option file. You can specify system variable values using `SET`.

On the master and each slave, you must use the `server-id` [1617] option to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to 2^{32} – 1, and each ID must be different from every other ID in use by any other replication master or slave. Example: `server-id=3`.

For options used on the master for controlling binary logging, see Binary Log Options and Variables.

- `auto_increment_increment` [1622]

Command-Line Format	`--auto-increment-increment[=#]`	
Option-File Format	`auto_increment_increment`	
Option Sets Variable	Yes, `auto_increment_increment` [1622]	
Variable Name	`auto_increment_increment`	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`numeric`
	Default	`1`
	Range	`1 .. 65535`

`auto_increment_increment` [1622] and `auto_increment_offset` [1624] are intended for use with master-to-master replication, and can be used to control the operation of `AUTO_INCREMENT` columns. Both variables have global and session values, and each can assume an integer value between 1 and 65,535 inclusive. Setting the value of either of these two variables to 0 causes its value to be set to 1 instead. Attempting to set the value of either of these two variables to an integer greater than 65,535 or less than 0 causes its value to be set to 65,535 instead. Attempting to set the value of `auto_increment_increment` [1622] or `auto_increment_offset` [1624] to a noninteger value gives rise to an error, and the actual value of the variable remains unchanged.

Note

`auto_increment_increment` [1622] is supported for use with `NDB` tables beginning with MySQL 5.1.20, MySQL Cluster NDB 6.2.5, and MySQL Cluster NDB 6.3.2. Previously, setting it when using MySQL Cluster tables or MySQL Cluster Replication produced unpredictable results.

These two variables affect `AUTO_INCREMENT` column behavior as follows:

- `auto_increment_increment` [1622] controls the interval between successive column values. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 1     |
| auto_increment_offset    | 1     |
+--------------------------+-------+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc1
    -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
  Query OK, 0 rows affected (0.04 sec)
```

```
mysql> SET @@auto_increment_increment=10;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |
| auto_increment_offset    | 1     |
+--------------------------+-------+
2 rows in set (0.01 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
|   1 |
|  11 |
|  21 |
|  31 |
+-----+
4 rows in set (0.00 sec)
```

- `auto_increment_offset` [1624] determines the starting point for the `AUTO_INCREMENT` column value. Consider the following, assuming that these statements are executed during the same session as the example given in the description for `auto_increment_increment` [1622]:

```
mysql> SET @@auto_increment_offset=5;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |
| auto_increment_offset    | 5     |
+--------------------------+-------+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc2
    -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO autoinc2 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc2;
+-----+
| col |
+-----+
|   5 |
|  15 |
|  25 |
|  35 |
+-----+
4 rows in set (0.02 sec)
```

  If the value of `auto_increment_offset` [1624] is greater than that of `auto_increment_increment` [1622], the value of `auto_increment_offset` [1624] is ignored.

Should one or both of these variables be changed and then new rows inserted into a table containing an `AUTO_INCREMENT` column, the results may seem counterintuitive because the series of `AUTO_INCREMENT` values is calculated without regard to any values already present in the column,

and the next value inserted is the least value in the series that is greater than the maximum existing value in the `AUTO_INCREMENT` column. In other words, the series is calculated like so:

`auto_increment_offset` + *N* × `auto_increment_increment`

where *N* is a positive integer value in the series [1, 2, 3, ...]. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |
| auto_increment_offset    | 5     |
+--------------------------+-------+
2 rows in set (0.00 sec)

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
|   1 |
|  11 |
|  21 |
|  31 |
+-----+
4 rows in set (0.00 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
|   1 |
|  11 |
|  21 |
|  31 |
|  35 |
|  45 |
|  55 |
|  65 |
+-----+
8 rows in set (0.00 sec)
```

The values shown for `auto_increment_increment` [1622] and `auto_increment_offset` [1624] generate the series 5 + *N* × 10, that is, [5, 15, 25, 35, 45, ...]. The greatest value present in the `col` column prior to the `INSERT` is 31, and the next available value in the `AUTO_INCREMENT` series is 35, so the inserted values for `col` begin at that point and the results are as shown for the `SELECT` query.

It is not possible to confine the effects of these two variables to a single table, and thus they do not take the place of the sequences offered by some other database management systems; these variables control the behavior of all `AUTO_INCREMENT` columns in *all* tables on the MySQL server. If the global value of either variable is set, its effects persist until the global value is changed or overridden by setting the session value, or until `mysqld` is restarted. If the local value is set, the new value affects `AUTO_INCREMENT` columns for all tables into which new rows are inserted by the current user for the duration of the session, unless the values are changed during that session.

The default value of `auto_increment_increment` [1622] is 1. See Replication and `AUTO_INCREMENT`.

- `auto_increment_offset` [1624]

Command-Line Format	`--auto-increment-offset[=#]`

Option-File Format	`auto_increment_offset`
Option Sets Variable	Yes, `auto_increment_offset` [1624]
Variable Name	`auto_increment_offset`
Variable Scope	Global, Session
Dynamic Variable	Yes
	Permitted Values
	Type `numeric`
	Default `1`
	Range `1 .. 65535`

This variable has a default value of 1. For particulars, see the description for `auto_increment_increment` [1622].

Note

`auto_increment_offset` [1624] is supported for use with `NDB` tables beginning with MySQL 5.1.20, MySQL Cluster NDB 6.2.5, and MySQL Cluster NDB 6.3.2. Previously, setting it when using MySQL Cluster tables or MySQL Cluster Replication produced unpredictable results.

- `slave_max_allowed_packet` [1625]

Version Introduced	5.1.64
Variable Name	`slave_max_allowed_packet`
Variable Scope	Global
Dynamic Variable	Yes
	Permitted Values
	Type `numeric`
	Default `1073741824`
	Range `1024 .. 1073741824`

In MySQL 5.1.64 and later, this variable sets the maximum packet size for the slave SQL and I/O threads, so that large updates using row-based replication do not cause replication to fail because an update exceeded `max_allowed_packet` [493].

This global variable always has a value that is a positive integer multiple of 1024; if you set it to some value that is not, the value is rounded down to the next highest multiple of 1024 for it is stored or used; setting `slave_max_allowed_packet` to 0 causes 1024 to be used. (A truncation warning is issued in all such cases.) The default and maximum value is 1073741824 (1 GB); the minimum is 1024.

`slave_max_allowed_packet` can also be set at startup, using the `--slave-max-allowed-packet` [1625] option.

- `slave-max-allowed-packet=`*`bytes`* [1625]

Version Introduced	5.1.64
Command-Line Format	`--slave-max-allowed-packet=#`
Option-File Format	`slave-max-allowed-packet`
Option Sets Variable	Yes, `slave_max_allowed_packet` [1625]
	Permitted Values

Type	numeric
Default	1073741824
Range	1024 .. 1073741824

In MySQL 5.1.64 and later, this option sets the maximum packet size in bytes for the slave SQL and I/O threads, so that large updates using row-based replication do not cause replication to fail because an update exceeded `max_allowed_packet` [493]. (Bug #12400221, BUG#60926)

The corresponding server variable `slave_max_allowed_packet` [1625] always has a value that is a positive integer multiple of 1024; if you set it to some value that is not such a multiple, the value is automatically rounded down to the next highest multiple of 1024. (For example, if you start the server with `--slave-max-allowed-packet=10000`, the value used is 9216; setting 0 as the value causes 1024 to be used.) A truncation warning is issued in such cases.

The maximum (and default) value is 1073741824 (1 GB); the minimum is 1024.

Replication Slave Options and Variables

This section describes the server options and system variables that apply to slave replication servers. You can specify the options either on the command line or in an option file. Many of the options can be set while the server is running by using the `CHANGE MASTER TO` statement. You can specify system variable values using `SET`.

Server ID. On the master and each slave, you must use the `server-id` [1617] option to establish a unique replication ID in the range from 1 to 2^{32} – 1. “Unique” means that each ID must be different from every other ID in use by any other replication master or slave. Example `my.cnf` file:

```
[mysqld]
server-id=3
```

Important

Certain `--master-xxx` options are handled in a special way to ensure that the active replication configuration is not inadvertently altered or affected:

- `--master-host` [1630]
- `--master-user` [1632]
- `--master-password` [1630]
- `--master-port` [1631]
- `--master-connect-retry` [1630]
- `--master-ssl` [1631]
- `--master-ssl-ca` [1631]
- `--master-ssl-capath` [1631]
- `--master-ssl-cert` [1631]
- `--master-ssl-cipher` [1631]
- `--master-ssl-key` [1631]

Before MySQL 5.1.17, these options are silently ignored if given unless there is no `master.info` file. If that file exists, the MySQL server has already previously been configured for replication, so the information in the file is used instead. Because the server gives an existing `master.info` file precedence

> over the startup options just described, you might elect not to use startup options for these values at all, and instead to specify the replication parameters associated with them by using the `CHANGE MASTER TO` statement. See `CHANGE MASTER TO` Syntax.
>
> Beginning with MySQL 5.1.17, these options are deprecated and have no effect when `mysqld` is started. If they are used, an appropriate warning is written to the error log. Instead, you *must* use `CHANGE MASTER TO` to set the values corresponding to the deprecated options. These options are removed in MySQL 5.5.

The `master.info` file format in MySQL 5.1 includes as its first line the number of lines in the file. (See Replication Relay and Status Logs.) If you upgrade an older server (before MySQL 4.1.1) to a newer version, the new server upgrades the `master.info` file to the new format automatically when it starts. However, if you downgrade a newer server to an older version, you should remove the first line manually before starting the older server for the first time.

If no `master.info` file exists when the slave server starts, it uses the values for those options that are specified in option files or on the command line. This occurs when you start the server as a replication slave for the very first time, when you use `CHANGE MASTER TO`, or when you have run `RESET SLAVE` and then have shut down and restarted the slave.

Because the server uses `master.info` file contents and ignores any startup options that correspond to the values listed in the file, if you start the slave server with different values of the startup options that correspond to values in the file, the different values have no effect. To use different values, the preferred method is to use the `CHANGE MASTER TO` statement to reset the values while the slave is running. Alternatively, you can stop the server, remove the `master.info` file, and restart the server with different option values.

Suppose that you specify this option in your `my.cnf` file to configure a pre-5.1.17 slave server:

```
[mysqld]
master-host=some_host
```

The first time you start the server as a replication slave, it reads and uses that option from the `my.cnf` file. The server then records the value in the `master.info` file. The next time you start the server, it reads the master host value from the `master.info` file only and ignores the value in the option file. If you modify the `my.cnf` file to specify a different master host value of *`some_other_host`*, the change has no effect. Instead, use `CHANGE MASTER TO` to change the value.

This example shows a more extensive use of startup options to configure a pre-5.1.17 slave server:

```
[mysqld]
server-id=2
master-host=db-master.mycompany.com
master-port=3306
master-user=pertinax
master-password=freitag
master-connect-retry=60
report-host=db-slave.mycompany.com
```

As of 5.1.17, the `master-xxx` options are ignored and result in warnings in the error log.

Startup options for replication slaves. The following list describes startup options for controlling replication slave servers. Many of these options can be set while the server is running by using the `CHANGE MASTER TO` statement. Others, such as the `--replicate-*` options, can be set only when the slave server starts. Replication-related system variables are discussed later in this section.

- `--abort-slave-event-count` [1627]

Command-Line Format	`--abort-slave-event-count=#`
Option-File Format	`abort-slave-event-count`

	Permitted Values	
	Type	`numeric`
	Default	`0`
	Min Value	`0`

When this option is set to some positive integer *`value`* other than 0 (the default) it affects replication behavior as follows: After the slave SQL thread has started, *`value`* log events are permitted to be executed; after that, the slave SQL thread does not receive any more events, just as if the network connection from the master were cut. The slave thread continues to run, and the output from `SHOW SLAVE STATUS` displays `Yes` in both the `Slave_IO_Running` and the `Slave_SQL_Running` columns, but no further events are read from the relay log.

This option is used internally by the MySQL test suite for replication testing and debugging. It is not intended for use in a production setting.

- `--disconnect-slave-event-count` [1628]

Command-Line Format	`--disconnect-slave-event-count=#`	
Option-File Format	`disconnect-slave-event-count`	
	Permitted Values	
	Type	`numeric`
	Default	`0`

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--log-slave-updates` [1628]

Command-Line Format	`--log-slave-updates`
Option-File Format	`log-slave-updates`
Option Sets Variable	Yes, `log_slave_updates` [490]
Variable Name	`log_slave_updates`
Variable Scope	Global
Dynamic Variable	No
Permitted Values	
Type	`boolean`
Default	`FALSE`

Normally, a slave does not log to its own binary log any updates that are received from a master server. This option tells the slave to log the updates performed by its SQL thread to its own binary log. For this option to have any effect, the slave must also be started with the `--log-bin` [1647] option to enable binary logging. `--log-slave-updates` [1628] is used when you want to chain replication servers. For example, you might want to set up replication servers using this arrangement:

```
A -> B -> C
```

Here, `A` serves as the master for the slave `B`, and `B` serves as the master for the slave `C`. For this to work, `B` must be both a master *and* a slave. You must start both `A` and `B` with `--log-bin` [1647] to enable binary logging, and `B` with the `--log-slave-updates` [1628] option so that updates received from `A` are logged by `B` to its binary log.

When using MySQL Cluster Replication prior to MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.13, records for “empty” epochs—that is, epochs in which no changes to `NDBCLUSTER` data or tables took place—were inserted into the `ndb_apply_status` and `ndb_binlog_index` tables on the slave even when `--log-slave-updates` [1628] was disabled (Bug #37472). Beginning with MySQL Cluster NDB 6.3.33, MySQL Cluster NDB 7.0.14, and MySQL Cluster NDB 7.1.3, it is possible to re-enable the older behavior by using the `--ndb-log-empty-epochs` option.

Note

The `--ndb-log-empty-epochs` option was first implemented in MySQL Cluster NDB 6.3.21 and MySQL Cluster NDB 6.4.1, but did not work correctly before the versions cited previously.

- `--log-slow-slave-statements` [1629]

Version Introduced	5.1.21	
Command-Line Format	`--log-slow-slave-statements`	
Option-File Format	`log-slow-slave-statements`	
	Permitted Values	
	Type	`boolean`
	Default	`off`

When the slow query log is enabled, this option enables logging for queries that have taken more than `long_query_time` [491] seconds to execute on the slave.

This option was added in MySQL 5.1.21.

- `--log-warnings[=level]` [434]

Command-Line Format	`--log-warnings[=#]`	
	`-W [#]`	
Option-File Format	`log-warnings`	
Option Sets Variable	Yes, `log_warnings` [490]	
Variable Name	`log_warnings`	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
Disabled by	`skip-log-warnings`	
	Permitted Values	
	Platform Bit Size	`64`
	Type	`numeric`
	Default	`1`
	Range	`0 .. 18446744073709547520`

This option causes a server to print more messages to the error log about what it is doing. With respect to replication, the server generates warnings that it succeeded in reconnecting after a network/connection failure, and informs you as to how each slave thread started. This option is enabled by default; to disable it, use `--skip-log-warnings` [434]. Aborted connections are not logged to the error log unless the value is greater than 1.

Note that the effects of this option are not limited to replication. It produces warnings across a spectrum of server activities.

- `--master-connect-retry=seconds` [1630]

Version Deprecated	5.1.17	
Command-Line Format	`--master-connect-retry=#`	
Option-File Format	`master-connect-retry`	
Deprecated	5.1.17	
	Permitted Values	
	Type	`numeric`
	Default	`60`

The number of seconds that the slave thread sleeps before trying to reconnect to the master in case the master goes down or the connection is lost. The value in the `master.info` file takes precedence if it can be read. If not set, the default is 60. Connection retries are not invoked until the slave times out reading data from the master according to the value of `--slave-net-timeout` [1641]. The number of reconnection attempts is limited by the `--master-retry-count` [1631] option.

This option is deprecated as of MySQL 5.1.17 and is removed in MySQL 5.5.

- `--master-host=host_name` [1630]

Version Deprecated	5.1.17	
Command-Line Format	`--master-host=name`	
Option-File Format	`master-host`	
Deprecated	5.1.17	
	Permitted Values	
	Type	`string`

The host name or IP address of the master replication server. The value in `master.info` takes precedence if it can be read. If no master host is specified, the slave thread does not start.

This option is deprecated as of MySQL 5.1.17 and is removed in MySQL 5.5.

- `--master-info-file=file_name` [1630]

Command-Line Format	`--master-info-file=file_name`	
Option-File Format	`master-info-file=file_name`	
	Permitted Values	
	Type	`file name`
	Default	`master.info`

The name to use for the file in which the slave records information about the master. The default name is `master.info` in the data directory. For information about the format of this file, see Slave Status Logs.

- `--master-password=password` [1630]

Version Deprecated	5.1.17
Command-Line Format	`--master-password=name`
Option-File Format	`master-password`
Deprecated	5.1.17
	Permitted Values

	Type	`string`

The password of the account that the slave thread uses for authentication when it connects to the master. The value in the `master.info` file takes precedence if it can be read. If not set, an empty password is assumed.

This option is deprecated as of MySQL 5.1.17 and is removed in MySQL 5.5.

- `--master-port=port_number` [1631]

Version Deprecated	5.1.17	
Command-Line Format	`--master-port=#`	
Option-File Format	`master-port`	
Deprecated	5.1.17	
	Permitted Values	
	Type	`numeric`
	Default	`3306`

The TCP/IP port number that the master is listening on. The value in the `master.info` file takes precedence if it can be read. If not set, the compiled-in setting is assumed (normally 3306).

This option is deprecated as of MySQL 5.1.17 and is removed in MySQL 5.5.

- `--master-retry-count=count` [1631]

Command-Line Format	`--master-retry-count=#`	
Option-File Format	`master-retry-count`	
Deprecated	5.6.1	
	Permitted Values	
	Platform Bit Size	`32`
	Type	`numeric`
	Default	`86400`
	Range	`0 .. 4294967295`
	Permitted Values	
	Platform Bit Size	`64`
	Type	`numeric`
	Default	`86400`
	Range	`0 .. 18446744073709551615`

The number of times that the slave tries to connect to the master before giving up. Reconnects are attempted at intervals set by the `--master-connect-retry` [1630] option (or the `MASTER_CONNECT_RETRY` option of the `CHANGE MASTER TO` statement) and reconnects are triggered when data reads by the slave time out according to the `--slave-net-timeout` [1641] option. The default value is 86400. A value of 0 means “infinite”; the slave attempts to connect forever.

- `--master-ssl` [1631], `--master-ssl-ca=file_name`, `--master-ssl-capath=directory_name`, `--master-ssl-cert=file_name`, `--master-ssl-cipher=cipher_list`, `--master-ssl-key=file_name`

These options are used for setting up a secure replication connection to the master server using SSL. Their meanings are the same as the corresponding `--ssl` [657], `--ssl-ca` [657], `--ssl-capath` [658], `--ssl-cert` [658], `--ssl-cipher` [658], `--ssl-key` [658] options that are described in SSL Command Options. The values in the `master.info` file take precedence if they can be read.

These options are deprecated as of MySQL 5.1.17 and are removed in MySQL 5.5.

- `--master-user=user_name` [1632]

Version Deprecated	5.1.17	
Command-Line Format	`--master-user=name`	
Option-File Format	`master-user`	
Deprecated	5.1.17	
	Permitted Values	
	Type	`string`
	Default	`test`

The user name of the account that the slave thread uses for authentication when it connects to the master. This account must have the `REPLICATION SLAVE` [627] privilege. The value in the `master.info` file takes precedence if it can be read. If the master user name is not set, the name `test` is assumed.

This option is deprecated as of MySQL 5.1.17 and is removed in MySQL 5.5.

- `--max-relay-log-size=size` [1632]

The size at which the server rotates relay log files automatically. For more information, see Replication Relay and Status Logs. The default size is 1GB.

- `--read-only` [1632]

Cause the slave to permit no updates except from slave threads or from users having the `SUPER` [628] privilege. On a slave server, this can be useful to ensure that the slave accepts updates only from its master server and not from clients. This variable does not apply to `TEMPORARY` tables.

- `--relay-log=file_name` [1632]

Command-Line Format	`--relay-log=name`	
Option-File Format	`relay-log`	
Option Sets Variable	Yes, `relay_log` [1643]	
Variable Name	`relay-log`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`file name`

The basename for the relay log. The default basename is *`host_name`*`-relay-bin`. The server writes the file in the data directory unless the basename is given with a leading absolute path name to specify a different directory. The server creates relay log files in sequence by adding a numeric suffix to the basename.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default basename is used only if the option is not actually specified*. If you use the `--`

`relay-log` [1632] option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see Specifying Program Options.

If you specify this option, the value specified is also used as the basename for the relay log index file. You can override this behavior by specifying a different relay log index file basename using the `--relay-log-index` [1633] option.

You may find the `--relay-log` [1632] option useful in performing the following tasks:

- Creating relay logs whose names are independent of host names.
- If you need to put the relay logs in some area other than the data directory because your relay logs tend to be very large and you do not want to decrease `max_relay_log_size` [497].
- To increase speed by using load-balancing between disks.

- `--relay-log-index=`*`file_name`* [1633]

Command-Line Format	`--relay-log-index=name`	
Option-File Format	`relay-log-index`	
Option Sets Variable	Yes, `relay_log_index` [1643]	
Variable Name	`relay-log-index`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`file name`

The name to use for the relay log index file. The default name is *`host_name`*`-relay-bin.index` in the data directory, where *`host_name`* is the name of the slave server.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default basename is used only if the option is not actually specified*. If you use the `--relay-log-index` [1633] option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see Specifying Program Options.

If you specify this option, the value specified is also used as the basename for the relay logs. You can override this behavior by specifying a different relay log file basename using the `--relay-log` [1632] option.

- `--relay-log-info-file=`*`file_name`* [1633]

Command-Line Format	`--relay-log-info-file=file_name`	
Option-File Format	`relay-log-info-file`	
Option Sets Variable	Yes, `relay_log_info_file` [1643]	
	Permitted Values	
	Type	`file name`
	Default	`relay-log.info`

The name to use for the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory. For information about the format of this file, see Slave Status Logs.

- `--relay-log-purge={0|1}` [1634]

  Disable or enable automatic purging of relay logs as soon as they are no longer needed. The default value is 1 (enabled). This is a global variable that can be changed dynamically with `SET GLOBAL relay_log_purge = N`.

- `--relay-log-space-limit=size` [1634]

  This option places an upper limit on the total size in bytes of all relay logs on the slave. A value of 0 means "no limit." This is useful for a slave server host that has limited disk space. When the limit is reached, the I/O thread stops reading binary log events from the master server until the SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL thread needs more events before it can delete relay logs. In that case, the I/O thread exceeds the limit until it becomes possible for the SQL thread to delete some relay logs because not doing so would cause a deadlock. You should not set `--relay-log-space-limit` [1634] to less than twice the value of `--max-relay-log-size` [1632] (or `--max-binlog-size` [1657] if `--max-relay-log-size` [1632] is 0). In that case, there is a chance that the I/O thread waits for free space because `--relay-log-space-limit` [1634] is exceeded, but the SQL thread has no relay log to purge and is unable to satisfy the I/O thread. This forces the I/O thread to ignore `--relay-log-space-limit` [1634] temporarily.

- `--replicate-do-db=db_name` [1634]

Command-Line Format	`--replicate-do-db=name`	
Option-File Format	`replicate-do-db`	
	Permitted Values	
	Type	`string`

  The effects of this option depend on whether statement-based or row-based replication is in use.

  Statement-based replication. Tell the slave SQL thread to restrict replication to statements where the default database (that is, the one selected by `USE`) is *db_name*. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* replicate cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` while a different database (or no database) is selected.

  Warning

  To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

  An example of what does not work as you might expect when using statement-based replication: If the slave is started with `--replicate-do-db=sales` [1634] and you issue the following statements on the master, the `UPDATE` statement is *not* replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

  The main reason for this "check just the default database" behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

  Row-based replication. Tells the slave SQL thread to restrict replication to database *db_name*. Only tables belonging to *db_name* are changed; the current database has no effect on this. Suppose that the slave is started with `--replicate-do-db=sales` [1634] and row-based replication is in effect, and then the following statements are run on the master:

```
USE prices;
```

```
UPDATE sales.february SET amount=amount+100;
```

The `february` table in the `sales` database on the slave is changed in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, issuing the following statements on the master has no effect on the slave when using row-based replication and `--replicate-do-db=sales` [1634]:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the statement `USE prices` were changed to `USE sales`, the `UPDATE` statement's effects would still not be replicated.

Another important difference in how `--replicate-do-db` [1634] is handled in statement-based replication as opposed to row-based replication occurs with regard to statements that refer to multiple databases. Suppose that the slave is started with `--replicate-do-db=db1` [1634], and the following statements are executed on the master:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based replication, then both tables are updated on the slave. However, when using row-based replication, only `table1` is affected on the slave; since `table2` is in a different database, `table2` on the slave is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement would have no effect on the slave when using statement-based replication. However, if you are using row-based replication, the `UPDATE` would change `table1` on the slave, but not `table2`—in other words, only tables in the database named by `--replicate-do-db` [1634] are changed, and the choice of default database has no effect on this behavior.

If you need cross-database updates to work, use `--replicate-wild-do-table=db_name.%` [1637] instead. See How Servers Evaluate Replication Filtering Rules.

Note

This option affects replication in the same manner that `--binlog-do-db` [1649] affects binary logging, and the effects of the replication format on how `--replicate-do-db` [1634] affects replication behavior are the same as those of the logging format on the behavior of `--binlog-do-db` [1649].

Beginning with MySQL 5.1.35, this option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements. (Bug #43263)

- `--replicate-ignore-db=db_name` [1635]

Command-Line Format	`--replicate-ignore-db=name`	
Option-File Format	`replicate-ignore-db`	
	Permitted Values	
	Type	`string`

As with `--replicate-do-db` [1634], the effects of this option depend on whether statement-based or row-based replication is in use.

Statement-based replication. Tells the slave SQL thread not to replicate any statement where the default database (that is, the one selected by `USE`) is *`db_name`*.

Row-based replication. Tells the slave SQL thread not to update any tables in the database *db_name*. The default database has no effect.

When using statement-based replication, the following example does not work as you might expect. Suppose that the slave is started with `--replicate-ignore-db=sales` [1635] and you issue the following statements on the master:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement *is* replicated in such a case because `--replicate-ignore-db` [1635] applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based replication, the `UPDATE` statement's effects are *not* propagated to the slave, and the slave's copy of the `sales.january` table is unchanged; in this instance, `--replicate-ignore-db=sales` [1635] causes *all* changes made to tables in the master's copy of the `sales` database to be ignored by the slave.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

You should not use this option if you are using cross-database updates and you do not want these updates to be replicated. See How Servers Evaluate Replication Filtering Rules.

If you need cross-database updates to work, use `--replicate-wild-ignore-table=db_name.%` [1638] instead. See How Servers Evaluate Replication Filtering Rules.

Note

This option affects replication in the same manner that `--binlog-ignore-db` [1651] affects binary logging, and the effects of the replication format on how `--replicate-ignore-db` [1635] affects replication behavior are the same as those of the logging format on the behavior of `--binlog-ignore-db` [1651].

Beginning with MySQL 5.1.35, this option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements. (Bug #43263)

- `--replicate-do-table=db_name.tbl_name` [1636]

Command-Line Format	`--replicate-do-table=name`	
Option-File Format	`replicate-do-table`	
	Permitted Values	
	Type	`string`

Tells the slave SQL thread to restrict replication to the specified table. To specify more than one table, use this option multiple times, once for each table. This works for both cross-database updates and default database updates, in contrast to `--replicate-do-db` [1634]. See How Servers Evaluate Replication Filtering Rules.

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- `--replicate-ignore-table=db_name.tbl_name` [1636]

Command-Line Format	`--replicate-ignore-table=name`

Option-File Format	replicate-ignore-table	
	Permitted Values	
	Type	string

Tells the slave SQL thread not to replicate any statement that updates the specified table, even if any other tables might be updated by the same statement. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-ignore-db` [1635]. See How Servers Evaluate Replication Filtering Rules.

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- `--replicate-rewrite-db=`*`from_name->to_name`* [1637]

Command-Line Format	--replicate-rewrite-db=old_name->new_name	
Option-File Format	replicate-rewrite-db	
	Permitted Values	
	Type	string

Tells the slave to translate the default database (that is, the one selected by `USE`) to *`to_name`* if it was *`from_name`* on the master. Only statements involving tables are affected (not statements such as `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), and only if *`from_name`* is the default database on the master. This does not work for cross-database updates. To specify multiple rewrites, use this option multiple times. The server uses the first one with a *`from_name`* value that matches. The database name translation is done *before* the `--replicate-*` rules are tested.

If you use this option on the command line and the "`>`" character is special to your command interpreter, quote the option value. For example:

```
shell> mysqld --replicate-rewrite-db="olddb->newdb"
```

- `--replicate-same-server-id` [1637]

Command-Line Format	--replicate-same-server-id	
Option-File Format	replicate-same-server-id	
	Permitted Values	
	Type	boolean
	Default	FALSE

To be used on slave servers. Usually you should use the default setting of 0, to prevent infinite loops caused by circular replication. If set to 1, the slave does not skip events having its own server ID. Normally, this is useful only in rare configurations. Cannot be set to 1 if `--log-slave-updates` [1628] is used. By default, the slave I/O thread does not write binary log events to the relay log if they have the slave's server ID (this optimization helps save disk usage). If you want to use `--replicate-same-server-id` [1637], be sure to start the slave with this option before you make the slave read its own events that you want the slave SQL thread to execute.

- `--replicate-wild-do-table=`*`db_name.tbl_name`* [1637]

Command-Line Format	--replicate-wild-do-table=name	
Option-File Format	replicate-wild-do-table	
	Permitted Values	
	Type	string

Tells the slave thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the "%" and "_" wildcard characters, which have the same meaning as for the `LIKE` [959] pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. See How Servers Evaluate Replication Filtering Rules.

This option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the `--replicate-*-db` options.

Example: `--replicate-wild-do-table=foo%.bar%` [1637] replicates only updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

If the table name pattern is `%`, it matches any table name and the option also applies to database-level statements (`CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`). For example, if you use `--replicate-wild-do-table=foo%.%` [1637], database-level statements are replicated if the database name matches the pattern `foo%`.

To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named `my_own%db`, but not replicate tables from the `my1ownAABCdb` database, you should escape the "_" and "%" characters like this: `--replicate-wild-do-table=my\_own\%db` [1637]. If you use the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the `bash` shell, you would need to type `--replicate-wild-do-table=my\\_own\\%db` [1637].

- `--replicate-wild-ignore-table=`*`db_name.tbl_name`* [1638]

Command-Line Format	`--replicate-wild-ignore-table=name`	
Option-File Format	`replicate-wild-ignore-table`	
	Permitted Values	
	Type	`string`

Tells the slave thread not to replicate a statement where any table matches the given wildcard pattern. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates. See How Servers Evaluate Replication Filtering Rules.

Example: `--replicate-wild-ignore-table=foo%.bar%` [1638] does not replicate updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

For information about how matching works, see the description of the `--replicate-wild-do-table` [1637] option. The rules for including literal wildcard characters in the option value are the same as for `--replicate-wild-ignore-table` [1638] as well.

- `--report-host=`*`host_name`* [1638]

Command-Line Format	`--report-host=host_name`	
Option-File Format	`report-host`	
Option Sets Variable	Yes, `report_host` [519]	
Variable Name	`report-host`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`string`

The host name or IP address of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server. Leave the value unset if you do not want the slave to register itself with the master. Note that it is not sufficient for the master to simply read the IP address of the slave from the TCP/IP socket after the slave connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the slave from the master or other hosts.

- `--report-password=password` [1639]

Command-Line Format	`--report-password=name`	
Option-File Format	`report-password`	
Option Sets Variable	Yes, `report_password` [519]	
Variable Name	`report-password`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`string`

An arbitrary account password to be reported by the slave to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` [1640] option is given.

Although the name of this option might imply otherwise, `--report-password` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the password for the MySQL replication user account.

- `--report-port=slave_port_num` [1639]

Command-Line Format	`--report-port=#`	
Option-File Format	`report-port`	
Option Sets Variable	Yes, `report_port` [520]	
Variable Name	`report-port`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`numeric`
	Default	`3306`

The TCP/IP port number for connecting to the slave, to be reported to the master during slave registration. Set this only if the slave is listening on a nondefault port or if you have a special tunnel from the master or other clients to the slave. If you are not sure, do not use this option.

- `--report-user=user_name` [1639]

Command-Line Format	`--report-user=name`
Option-File Format	`report-user`
Option Sets Variable	Yes, `report_user` [520]
Variable Name	`report-user`
Variable Scope	Global
Dynamic Variable	No

	Permitted Values	
	Type	`string`

The account user name of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` [1640] option is given.

Although the name of this option might imply otherwise, `--report-user` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the name of the MySQL replication user account.

- `--show-slave-auth-info` [1640]

Command-Line Format	`--show-slave-auth-info`	
Option-File Format	`show-slave-auth-info`	
	Permitted Values	
	Type	`boolean`
	Default	`FALSE`

Display slave user names and passwords in the output of `SHOW SLAVE HOSTS` on the master server for slaves started with the `--report-user` [1639] and `--report-password` [1639] options.

- `--skip-slave-start` [1640]

Command-Line Format	`--skip-slave-start`	
Option-File Format	`skip-slave-start`	
	Permitted Values	
	Type	`boolean`
	Default	`FALSE`

Tells the slave server not to start the slave threads when the server starts. To start the threads later, use a `START SLAVE` statement.

- `--slave_compressed_protocol={0|1}` [1644]

Command-Line Format	`--slave_compressed_protocol`	
Option-File Format	`slave_compressed_protocol`	
Option Sets Variable	Yes, `slave_compressed_protocol` [1644]	
Variable Name	`slave_compressed_protocol`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`boolean`
	Default	`OFF`

If this option is set to 1, use compression for the slave/master protocol if both the slave and the master support it. The default is 0 (no compression).

- `--slave-load-tmpdir=`*`file_name`* [1640]

The name of the directory where the slave creates temporary files. This option is by default equal to the value of the `tmpdir` [534] system variable. When the slave SQL thread replicates a `LOAD DATA INFILE` statement, it extracts the file to be loaded from the relay log into temporary files, and then

loads these into the table. If the file loaded on the master is huge, the temporary files on the slave are huge, too. Therefore, it might be advisable to use this option to tell the slave to put temporary files in a directory located in some file system that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to use the `--relay-log` [1632] option to place the relay logs in that file system.

The directory specified by this option should be located in a disk-based file system (not a memory-based file system) because the temporary files used to replicate `LOAD DATA INFILE` must survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process.

- `--slave-net-timeout=`*`seconds`* [1641]

Command-Line Format	`--slave-net-timeout=#`	
Option-File Format	`slave-net-timeout`	
Option Sets Variable	Yes, `slave_net_timeout` [1645]	
Variable Name	`slave_net_timeout`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`numeric`
	Default	`3600`
	Min Value	`1`

The number of seconds to wait for more data from the master before the slave considers the connection broken, aborts the read, and tries to reconnect. The first retry occurs immediately after the timeout. The interval between retries is controlled by the `MASTER_CONNECT_RETRY` option for the `CHANGE MASTER TO` statement or `--master-connect-retry` [1630] option, and the number of reconnection attempts is limited by the `--master-retry-count` [1631] option. The default is 3600 seconds (one hour).

- `--slave-skip-errors=[`*`err_code1`*`,`*`err_code2`*`,...|all|ddl_exist_errors]` [1641]

Command-Line Format	`--slave-skip-errors=name`	
Option-File Format	`slave-skip-errors`	
Option Sets Variable	Yes, `slave_skip_errors` [1645]	
Variable Name	`slave_skip_errors`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values (>= 5.1.61-ndb-7.0.33,5.1.61-ndb-7.1.22)	
	Type	`string`
	Default	`OFF`

	Valid Values	`[list of error codes]`
		`all`
		`ddl_exist_errors`

Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This option tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the option value.

Do not use this option unless you fully understand why you are getting errors. If there are no bugs in your replication setup and client programs, and no bugs in MySQL itself, an error that stops replication should never occur. Indiscriminate use of this option results in slaves becoming hopelessly out of synchrony with the master, with you having no idea why this has occurred.

Note

Prior to MySQL 5.1.35, this option had no effect with row-based logging. (Bug #39393)

For error codes, you should use the numbers provided by the error message in your slave error log and in the output of `SHOW SLAVE STATUS`. Appendix C, *Errors, Error Codes, and Common Problems*, lists server error codes.

You can also (but should not) use the very nonrecommended value of `all` to cause the slave to ignore all error messages and keeps going regardless of what happens. Needless to say, if you use `all`, there are no guarantees regarding the integrity of your data. Please do not complain (or file bug reports) in this case if the slave's data is not anywhere close to what it is on the master. *You have been warned*.

For MySQL Cluster Replication in MySQL Cluster NDB 7.0 beginning with version 7.0.33 and MySQL Cluster NDB 7.1 beginning with version 7.1.22, an additional shorthand value `ddl_exists_errors` is supported for use with the enhanced failover mechanism which is implemented in that and later version of MySQL Cluster NDB 7.2. This value is equivalent to the error code list `1007,1008,4050,1051,1054,1060,1061,1068,1094,1146`. *This value is supported only by the `mysqld` that is included with the MySQL Cluster distribution*. (Bug #11762277, Bug #54854) For more information, see Implementing Failover with MySQL Cluster Replication.

Examples:

```
--slave-skip-errors=1062,1053
--slave-skip-errors=all
--slave-skip-errors=ddl_exist_errors
```

System variables used on replication slaves. The following list describes system variables for controlling replication slave servers. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used with replication slaves are listed earlier in this section.

- `init_slave` [1642]

Command-Line Format	`--init-slave=name`	
Option-File Format	`init_slave`	
Option Sets Variable	Yes, `init_slave` [1642]	
Variable Name	`init_slave`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`string`

This variable is similar to `init_connect` [481], but is a string to be executed by a slave server each time the SQL thread starts. The format of the string is the same as for the `init_connect` [481] variable.

Note

The SQL thread sends an acknowledgment to the client before it executes `init_slave` [1642]. Therefore, it is not guaranteed that `init_slave` [1642] has been executed when `START SLAVE` returns. See `START SLAVE` Syntax, for more information.

- `relay_log` [1643]

Command-Line Format	`--relay-log=name`	
Option-File Format	`relay-log`	
Option Sets Variable	Yes, `relay_log` [1643]	
Variable Name	`relay-log`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`file name`

The name of the relay log file.

- `relay_log_index` [1643]

Command-Line Format	`--relay-log-index`	
Option-File Format	`relay_log_index`	
Option Sets Variable	Yes, `relay_log_index` [1643]	
Variable Name	`relay_log_index`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`string`
	Default	`*host_name*-relay-bin.index`

The name of the relay log index file. The default name is *`host_name`*`-relay-bin.index` in the data directory, where *`host_name`* is the name of the slave server.

- `relay_log_info_file` [1643]

Command-Line Format	`--relay-log-info-file=file_name`	
Option-File Format	`relay_log_info_file`	
Option Sets Variable	Yes, `relay_log_info_file` [1643]	
Variable Name	`relay_log_info_file`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`string`
	Default	`relay-log.info`

The name of the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory.

- `rpl_recovery_rank` [1644]

  This variable is unused, and is removed in MySQL 5.6.

- `slave_compressed_protocol` [1644]

Command-Line Format	`--slave_compressed_protocol`	
Option-File Format	`slave_compressed_protocol`	
Option Sets Variable	Yes, `slave_compressed_protocol` [1644]	
Variable Name	`slave_compressed_protocol`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`boolean`
	Default	`OFF`

  Whether to use compression of the slave/master protocol if both the slave and the master support it.

- `slave_exec_mode` [1644]

Version Introduced	5.1.23-ndb-6.2.14, 5.1.23-ndb-6.3.11, 5.1.24	
Command-Line Format	`--slave-exec-mode=mode`	
Option-File Format	`slave_exec_mode`	
Option Sets Variable	Yes, `slave_exec_mode` [1644]	
Variable Name	`slave_exec_mode`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`enumeration`
	Default	`STRICT` (ALL)
	Default	`IDEMPOTENT` (NDB)
	Valid Values	`IDEMPOTENT` `STRICT`

  Controls whether `IDEMPOTENT` or `STRICT` mode is used in replication conflict resolution and error checking. `IDEMPOTENT` mode causes suppression of duplicate-key and no-key-found errors. Beginning with MySQL 5.1.23-ndb-6.2.14 and MySQL 5.1.24, this mode should be employed in multi-master replication, circular replication, and some other special replication scenarios. `STRICT` mode is the default, and is suitable for most other cases.

  Note

  MySQL Cluster ignores any value explicitly set for `slave_exec_mode` [1644], and always treats it as `IDEMPOTENT`.

- `slave_load_tmpdir` [1644]

Command-Line Format	`--slave-load-tmpdir=path`
Option-File Format	`slave-load-tmpdir`
Option Sets Variable	Yes, `slave_load_tmpdir` [1644]

Variable Name	slave_load_tmpdir	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	file name
	Default	/tmp

The name of the directory where the slave creates temporary files for replicating LOAD DATA INFILE statements.

- slave_net_timeout [1645]

Command-Line Format	--slave-net-timeout=#	
Option-File Format	slave-net-timeout	
Option Sets Variable	Yes, slave_net_timeout [1645]	
Variable Name	slave_net_timeout	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric
	Default	3600
	Min Value	1

The number of seconds to wait for more data from a master/slave connection before aborting the read. Before MySQL 5.1.41, this timeout applies only to TCP/IP connections, not to connections made through Unix socket files, named pipes, or shared memory.

- slave_skip_errors [1645]

Command-Line Format	--slave-skip-errors=name	
Option-File Format	slave-skip-errors	
Option Sets Variable	Yes, slave_skip_errors [1645]	
Variable Name	slave_skip_errors	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values (>= 5.1.61-ndb-7.0.33,5.1.61-ndb-7.1.22)	
	Type	string
	Default	OFF
	Valid Values	[list of error codes] all ddl_exist_errors

Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This variable tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the variable value.

- slave_transaction_retries [1645]

Command-Line Format	--slave_transaction_retries=#	
Option-File Format	slave_transaction_retries	
Option Sets Variable	Yes, slave_transaction_retries [1645]	
Variable Name	slave_transaction_retries	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	32
	Type	numeric
	Default	10
	Range	0 .. 4294967295
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	10
	Range	0 .. 18446744073709547520

If a replication slave SQL thread fails to execute a transaction because of an InnoDB deadlock or because the transaction's execution time exceeded InnoDB's innodb_lock_wait_timeout [1371] or NDBCLUSTER's TransactionDeadlockDetectionTimeout or TransactionInactiveTimeout, it automatically retries slave_transaction_retries [1645] times before stopping with an error. The default value is 10.

- slave_type_conversions [1646]

Version Introduced	5.1.44-ndb-6.3.33, 5.1.44-ndb-7.0.14, 5.1.44-ndb-7.1.3	
Command-Line Format	--slave_type_conversions=set	
Option-File Format	slave_type_conversions	
Option Sets Variable	Yes, slave_type_conversions [1646]	
Variable Name	slave_type_conversions	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	set
	Default	
	Valid Values	ALL_LOSSY ALL_NON_LOSSY ALL_LOSSY,ALL_NON_LOSSY

Controls the type conversion mode in effect on the slave when using MySQL Cluster Replication. Its value is a comma-delimited set of zero or more elements from the list: ALL_LOSSY, ALL_NON_LOSSY. Set this variable to an empty string to disallow type conversions between the master and the slave. Changes require a restart of the slave to take effect.

For additional information on type conversion modes applicable to MySQL Cluster replication attribute promotion and demotion, see Attribute promotion and demotion (MySQL Cluster).

This variable was added in MySQL Cluster NDB 6.3.33, 7.0.14, and 7.1.3.

- `sql_slave_skip_counter` [1647]

Variable Name	`sql_slave_skip_counter`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`numeric`

The number of events from the master that a slave server should skip.

Important

If skipping the number of events specified by setting this variable would cause the slave to begin in the middle of an event group, the slave continues to skip until it finds the beginning of the next event group and begins from that point. For more information, see `SET GLOBAL sql_slave_skip_counter` Syntax.

Binary Log Options and Variables

You can use the `mysqld` options and system variables that are described in this section to affect the operation of the binary log as well as to control which statements are written to the binary log. For additional information about the binary log, see The Binary Log. For additional information about using MySQL server options and system variables, see Server Command Options, and Server System Variables.

Startup options used with binary logging. The following list describes startup options for enabling and configuring the binary log. System variables used with binary logging are discussed later in this section.

- `--binlog-row-event-max-size=`*`N`* [1647]

Version Introduced	5.1.5
Command-Line Format	`--binlog-row-event-max-size=#`
Option-File Format	`binlog-row-event-max-size`

Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. The default is 1024. See Replication Formats. This option was added in MySQL 5.1.5.

- `--log-bin[=`*`base_name`*`]` [1647]

Command-Line Format	`--log-bin`	
Option-File Format	`log-bin`	
Variable Name	`log_bin`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`file name`

	Default	`OFF`

Enable binary logging. The server logs all statements that change data to the binary log, which is used for backup and replication. See The Binary Log.

The option value, if given, is the basename for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the basename. It is recommended that you specify a basename (see Known Issues in MySQL, for the reason). Otherwise, MySQL uses *`host_name`*`-bin` as the basename.

Setting this option causes the `log_bin` [488] system variable to be set to `ON` (or `1`), and not to the basename. This is a known issue; see Bug #19614 for more information.

- `--log-bin-index[=`*`file_name`*`]` [1648]

Command-Line Format	`--log-bin-index=name`	
Option-File Format	`log-bin-index`	
	Permitted Values	
	Type	`file name`
	Default	`OFF`

The index file for binary log file names. See The Binary Log. If you omit the file name, and if you did not specify one with `--log-bin` [1647], MySQL uses *`host_name`*`-bin.index` as the file name.

- `--log-bin-trust-function-creators[={0|1}]` [1648]

Command-Line Format	`--log-bin-trust-function-creators`	
Option-File Format	`log-bin-trust-function-creators`	
Option Sets Variable	Yes, `log_bin_trust_function_creators` [488]	
Variable Name	`log_bin_trust_function_creators`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`boolean`
	Default	`FALSE`

This option sets the corresponding `log_bin_trust_function_creators` [488] system variable. If no argument is given, the option sets the variable to 1. `log_bin_trust_function_creators` [488] affects how MySQL enforces restrictions on stored function and trigger creation. See Binary Logging of Stored Programs.

Note

Previously, this option was known as `--log-bin-trust-routine-creators`, which is now deprecated.

- `--log-bin-use-v1-row-events[={0|1}]` [1648]

Version Introduced	5.1.56-ndb-7-0-27, 5.1.56-ndb-7.1.16
Command-Line Format	`--log-bin-use-v1-row-events[={0|1}]`
Option-File Format	`log-bin-use-v1-row-events`
Option Sets Variable	Yes, `log_bin_use_v1_row_events` [1655]
Variable Name	`log-bin-use-v1-row-events`

Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values (<= 5.1.99)	
	Type	`boolean`
	Default	`1`
	Permitted Values (<= 5.1.99)	
	Type	`boolean`
	Default	`1`
	Permitted Values	
	Type	`boolean`
	Default	`0`

Version 2 binary log row events are available beginning with MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16; however, Version 2 events cannot be read by previous MySQL Cluster releases. Setting `--log-bin-use-v1-row-events` to 0 causes `mysqld` to use Version 2 binary log events. Setting this option to 1 (the default) causes `mysqld` to write the binary log using Version 1 logging events, which is the only version of binary log events used in previous releases, and thus produce binary logs that can be read by older slaves.

The value used for this option can be obtained from the read-only `log_bin_use_v1_row_events` [1655] system variable.

`--log-bin-use-v1-row-events` is chiefly of interest when setting up replication conflict detection and resolution using `NDB$EPOCH_TRANS()` as the conflict detection function, which requires Version 2 binary log row events. Thus, this option and `--ndb-log-transaction-id` [1916] are not compatible.

Note

MySQL Cluster NDB 7.2.1 and later use Version 2 binary log events by default (and so the default value for this option changes to 0 in those versions). You should keep this mind when planning upgrades for setups using MySQL Cluster Replication.

`--log-bin-use-v1-row-events` is not supported in mainline MySQL Server 5.1 releases.

For more information, see MySQL Cluster Replication Conflict Resolution.

- `--log-short-format` [432]

Command-Line Format	`--log-short-format`	
Option-File Format	`log-short-format`	
	Permitted Values	
	Type	`boolean`
	Default	`FALSE`

Log less information to the binary log and slow query log, if they have been activated.

Statement selection options. The options in the following list affect which statements are written to the binary log, and thus sent by a replication master server to its slaves. There are also options for slave servers that control which statements received from the master should be executed or ignored. For details, see Replication Slave Options and Variables.

- `--binlog-do-db=`*`db_name`* [1649]

Command-Line Format	--binlog-do-db=name	
Option-File Format	binlog-do-db	
	Permitted Values	
	Type	string

This option affects binary logging in a manner similar to the way that --replicate-do-db [1634] affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of --replicate-do-db [1634] depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of binlog_format [1654]. For example, DDL statements such as CREATE TABLE and ALTER TABLE are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for --binlog-do-db always apply in determining whether or not the statement is logged.

Statement-based logging. Only those statements are written to the binary log where the default database (that is, the one selected by USE) is *db_name*. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* cause cross-database statements such as UPDATE *some_db.some_table* SET foo='bar' to be logged while a different database (or no database) is selected.

Warning

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

An example of what does not work as you might expect when using statement-based logging: If the server is started with --binlog-do-db=sales [1649] and you issue the following statements, the UPDATE statement is *not* logged:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “just check the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table DELETE statements or multiple-table UPDATE statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

Another case which may not be self-evident occurs when a given database is replicated even though it was not specified when setting the option. If the server is started with --binlog-do-db=sales, the following UPDATE statement is logged even though prices was not included when setting --binlog-do-db:

```
USE sales;
UPDATE prices.discounts SET percentage = percentage + 10;
```

Because sales is the default database when the UPDATE statement is issued, the UPDATE is logged.

Row-based logging. Logging is restricted to database *db_name*. Only changes to tables belonging to *db_name* are logged; the default database has no effect on this. Suppose that the server is started with --binlog-do-db=sales [1649] and row-based logging is in effect, and then the following statements are executed:

```
USE prices;
```

```
UPDATE sales.february SET amount=amount+100;
```

The changes to the `february` table in the `sales` database are logged in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, when using the row-based logging format and `--binlog-do-db=sales` [1649], changes made by the following `UPDATE` are not logged:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the `USE prices` statement were changed to `USE sales`, the `UPDATE` statement's effects would still not be written to the binary log.

Another important difference in `--binlog-do-db` [1649] handling for statement-based logging as opposed to the row-based logging occurs with regard to statements that refer to multiple databases. Suppose that the server is started with `--binlog-do-db=db1` [1649], and the following statements are executed:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based logging, the updates to both tables are written to the binary log. However, when using the row-based format, only the changes to `table1` are logged; `table2` is in a different database, so it is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement is not written to the binary log when using statement-based logging. However, when using row-based logging, the change to `table1` is logged, but not that to `table2`—in other words, only changes to tables in the database named by `--binlog-do-db` [1649] are logged, and the choice of default database has no effect on this behavior.

- `--binlog-ignore-db=`*`db_name`* [1651]

Command-Line Format	`--binlog-ignore-db=name`	
Option-File Format	`binlog-ignore-db`	
	Permitted Values	
	Type	`string`

This option affects binary logging in a manner similar to the way that `--replicate-ignore-db` [1635] affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-ignore-db` [1635] depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format` [1654]. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-ignore-db` always apply in determining whether or not the statement is logged.

Statement-based logging. Tells the server to not log any statement where the default database (that is, the one selected by `USE`) is *`db_name`*.

Row-based format. Tells the server not to log updates to any tables in the database *`db_name`*. The current database has no effect.

When using statement-based logging, the following example does not work as you might expect. Suppose that the server is started with `--binlog-ignore-db=sales` [1651] and you issue the following statements:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement *is* logged in such a case because `--binlog-ignore-db` [1651] applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based logging, the `UPDATE` statement's effects are *not* written to the binary log, which means that no changes to the `sales.january` table are logged; in this instance, `--binlog-ignore-db=sales` [1651] causes *all* changes made to tables in the master's copy of the `sales` database to be ignored for purposes of binary logging.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

You should not use this option if you are using cross-database updates and you do not want these updates to be logged.

Testing and debugging options. The following binary log options are used in replication testing and debugging. They are not intended for use in normal operations.

- `--max-binlog-dump-events=N` [1652]

Command-Line Format	`--max-binlog-dump-events=#`	
Option-File Format	`max-binlog-dump-events`	
	Permitted Values	
	Type	`numeric`
	Default	`0`

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--sporadic-binlog-dump-fail` [1652]

Command-Line Format	`--sporadic-binlog-dump-fail`	
Option-File Format	`sporadic-binlog-dump-fail`	
	Permitted Values	
	Type	`boolean`
	Default	`FALSE`

This option is used internally by the MySQL test suite for replication testing and debugging.

System variables used with the binary log. The following list describes system variables for controlling binary logging. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used to control binary logging are listed earlier in this section.

- `binlog_cache_size` [1652]

Command-Line Format	`--binlog_cache_size=#`
Option-File Format	`binlog_cache_size`
Option Sets Variable	Yes, `binlog_cache_size` [1652]
Variable Name	`binlog_cache_size`

Variable Scope	Global
Dynamic Variable	Yes
	Permitted Values
	Platform Bit Size 32
	Type numeric
	Default 32768
	Range 4096 .. 4294967295
	Permitted Values
	Platform Bit Size 64
	Type numeric
	Default 32768
	Range 4096 .. 18446744073709547520

The size of the cache to hold the SQL statements for the binary log during a transaction. A binary log cache is allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (`--log-bin` [1647] option). If you often use large, multiple-statement transactions, you can increase this cache size to get better performance. The `Binlog_cache_use` [559] and `Binlog_cache_disk_use` [559] status variables can be useful for tuning the size of this variable. See The Binary Log.

- `binlog_direct_non_transactional_updates` [1653]

Version Introduced	5.1.44
Command-Line Format	`--binlog_direct_non_transactional_updates[=value]`
Option-File Format	`binlog_direct_non_transactional_updates`
Option Sets Variable	Yes, `binlog_direct_non_transactional_updates` [1653]
Variable Name	`binlog_direct_non_transactional_updates`
Variable Scope	Global, Session
Dynamic Variable	Yes
	Permitted Values
	Type boolean
	Default OFF

Due to concurrency issues, a slave can become inconsistent when a transaction contains updates to both transactional and non-transactional tables. MySQL tries to preserve causality among these statements by writing non-transactional statements to the transaction cache, which is flushed upon commit. However, problems arise when modifications done to nontransactional tables on behalf of a transaction become immediately visible to other connections because these changes may not be written immediately into the binary log.

Beginning with MySQL 5.1.44, the `binlog_direct_non_transactional_updates` [1653] variable offers one possible workaround to this issue. By default, this variable is disabled. Enabling `binlog_direct_non_transactional_updates` [1653] causes updates to nontransactional tables to be written directly to the binary log, rather than to the transaction cache.

`binlog_direct_non_transactional_updates` [1653] works only for statements that are replicated using the statement-based binary logging format; that is, it works only when the value of `binlog_format` [1654] is `STATEMENT`, or when `binlog_format` [1654] is `MIXED` and a given statement is being replicated using the statement-based format. This variable has no effect when the

binary log format is `ROW`, or when `binlog_format` [1654] is set to `MIXED` and a given statement is replicated using the row-based format.

Important

Before enabling this variable, you must make certain that there are no dependencies between transactional and nontransactional tables; an example of such a dependency would be the statement `INSERT INTO myisam_table SELECT * FROM innodb_table`. Otherwise, such statements are likely to cause the slave to diverge from the master.

- `binlog_format` [1654]

Version Introduced	5.1.5	
Command-Line Format	`--binlog-format=format`	
Option-File Format	`binlog-format=format`	
Option Sets Variable	Yes, `binlog_format` [1654]	
Variable Name	`binlog_format`	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values (>= 5.1.5, <= 5.1.7)	
	Type	`enumeration`
	Default	`STATEMENT`
	Valid Values	`ROW` `STATEMENT`
	Permitted Values (>= 5.1.8, <= 5.1.11)	
	Type	`enumeration`
	Default	`STATEMENT`

	Valid Values	`ROW`
		`STATEMENT`
		`MIXED`

	Permitted Values (>= 5.1.12, <= 5.1.28)	
	Type	`enumeration`
	Default	`MIXED`

	Valid Values	`ROW`
		`STATEMENT`
		`MIXED`

	Permitted Values (>= 5.1.29)	
	Type	`enumeration`
	Default	`STATEMENT`

	Valid Values	`ROW`
		`STATEMENT`
		`MIXED`

This variable sets the binary logging format, and can be any one of `STATEMENT`, `ROW`, or `MIXED`. See Replication Formats. `binlog_format` [1654] is set by the `--binlog-format` [419] option at startup, or by the `binlog_format` [1654] variable at runtime.

Note

While you can change the logging format at runtime, it is *not* recommended that you change it while replication is ongoing. This is due in part to the fact that slaves do not honor the master's `binlog_format` [1654] setting; a given MySQL Server can change only its own logging format.

The startup variable was added in MySQL 5.1.5, and the runtime variable in MySQL 5.1.8. `MIXED` was added in MySQL 5.1.8.

`STATEMENT` was used by default prior to MySQL 5.1.12; in MySQL 5.1.12, the default was changed to `MIXED`. In MySQL 5.1.29, the default was changed back to `STATEMENT`.

You must have the `SUPER` [628] privilege to set the global `binlog_format` [1654] value. Starting with MySQL 5.1.29, you must have the `SUPER` [628] privilege to set either the global or session `binlog_format` [1654] value. (Bug #39106)

The rules governing when changes to this variable take effect and how long the effect lasts are the same as for other MySQL server system variables. See `SET` Syntax, for more information.

When `MIXED` is specified, statement-based replication is used, except for cases where only row-based replication is guaranteed to lead to proper results. For example, this happens when statements contain user-defined functions (UDF) or the `UUID()` [1042] function. An exception to this rule is that `MIXED` always uses statement-based replication for stored functions and triggers.

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger.
- If the `NDBCLUSTER` storage engine is enabled.
- If the session is currently in row-based replication mode and has open temporary tables.

Trying to switch the format in those cases results in an error.

Before MySQL 5.1.8, switching to row-based replication format would implicitly set `--log-bin-trust-function-creators=1` [1648] and `--innodb_locks_unsafe_for_binlog` [1372]. This does not occur for MySQL 5.1.8 and later.

The binary log format affects the behavior of the following server options:

- `--replicate-do-db` [1634]
- `--replicate-ignore-db` [1635]
- `--binlog-do-db` [1649]
- `--binlog-ignore-db` [1651]

These effects are discussed in detail in the descriptions of the individual options.

- `log_bin_use_v1_row_events` [1655]

Version Introduced	5.1.56-ndb-7-0-27, 5.1.56-ndb-7.1.16
Command-Line Format	`--log-bin-use-v1-row-events[={0|1}]`

Option-File Format	`log_bin_use_v1_row_events`
Option Sets Variable	Yes, `log_bin_use_v1_row_events` [1655]
Variable Name	`log_bin_use_v1_row_events`
Variable Scope	Global
Dynamic Variable	No
	Permitted Values (<= 5.1.99)
	Type `boolean`
	Default `1`
	Permitted Values (<= 5.1.99)
	Type `boolean`
	Default `1`
	Permitted Values
	Type `boolean`
	Default `0`

Shows whether Version 2 binary logging, available beginning with MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, is in use. A value of 1 shows that the server is writing the binary log using Version 1 logging events (the only version of binary log events used in previous releases), and thus producing a binary log that can be read by older slaves. 0 indicates that Version 2 binary log events are in use.

This variable is read-only. To switch between Version 1 and Version 2 binary event binary logging, it is necessary to restart `mysqld` with the `--log-bin-use-v1-row-events` [1648] option.

Other than when performing upgrades of MySQL Cluster Replication, `--log-bin-use-v1-events` is chiefly of interest when setting up replication conflict detection and resolution using `NDB$EPOCH_TRANS()`, which requires Version 2 binary row event logging. Thus, this option and `--ndb-log-transaction-id` [1916] are not compatible.

Note

MySQL Cluster NDB 7.2.1 and later use Version 2 binary log row events by default (and so the default value for this variable changes to 0 in those versions). You should keep this mind when planning upgrades for setups using MySQL Cluster Replication.

This variable is not supported in mainline MySQL Server 5.1.

For more information, see MySQL Cluster Replication Conflict Resolution.

- `max_binlog_cache_size` [1656]

Command-Line Format	`--max_binlog_cache_size=#`
Option-File Format	`max_binlog_cache_size`
Option Sets Variable	Yes, `max_binlog_cache_size` [1656]
Variable Name	`max_binlog_cache_size`
Variable Scope	Global
Dynamic Variable	Yes
	Permitted Values (<= 5.1.35)
	Type `numeric`
	Default `4294967295`

	Range	`4096 .. 4294967295`
	Permitted Values (>= 5.1.36)	
	Type	`numeric`
	Default	`18446744073709547520`
	Range	`4096 .. 18446744073709547520`

If a multiple-statement transaction requires more than this many bytes of memory, the server generates a `Multi-statement transaction required more than 'max_binlog_cache_size' bytes of storage` error. The minimum value is 4096. The maximum and default values are 4GB on 32-bit platforms and 16PB (petabytes) on 64-bit platforms. As of MySQL 5.1.36, the maximum value is 16PB on all platforms.

In MySQL 5.1, a change in `max_binlog_cache_size` [1656] takes immediate effect for all active sessions.

- `max_binlog_size` [1657]

Command-Line Format	`--max_binlog_size=#`	
Option-File Format	`max_binlog_size`	
Option Sets Variable	Yes, `max_binlog_size` [1657]	
Variable Name	`max_binlog_size`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`numeric`
	Default	`1073741824`
	Range	`4096 .. 1073741824`

If a write to the binary log causes the current log file size to exceed the value of this variable, the server rotates the binary logs (closes the current file and opens the next one). The minimum value is 4096 bytes. The maximum and default value is 1GB.

A transaction is written in one chunk to the binary log, so it is never split between several binary logs. Therefore, if you have big transactions, you might see binary log files larger than `max_binlog_size` [1657].

If `max_relay_log_size` [497] is 0, the value of `max_binlog_size` [1657] applies to relay logs as well.

- `sync_binlog` [1657]

Command-Line Format	`--sync-binlog=#`	
Option-File Format	`sync_binlog`	
Option Sets Variable	Yes, `sync_binlog` [1657]	
Variable Name	`sync_binlog`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	`32`

	Type	numeric
	Default	0
	Range	0 .. 4294967295
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	0
	Range	0 .. 18446744073709547520

If the value of this variable is greater than 0, the MySQL server synchronizes its binary log to disk (using `fdatasync()`) after every `sync_binlog` [1657] writes to the binary log. There is one write to the binary log per statement if autocommit is enabled, and one write per transaction otherwise. The default value of `sync_binlog` [1657] is 0, which does no synchronizing to disk—in this case, the server relies on the operating system to flush the binary log's contents from to time as for any other file. A value of 1 is the safest choice because in the event of a crash you lose at most one statement or transaction from the binary log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

Common Replication Administration Tasks

Once replication has been started it should execute without requiring much regular administration. Depending on your replication environment, you will want to check the replication status of each slave periodically, daily, or even more frequently.

Checking Replication Status

The most common task when managing a replication process is to ensure that replication is taking place and that there have been no errors between the slave and the master. The primary statement for this is `SHOW SLAVE STATUS`, which you must execute on each slave:

```
mysql> SHOW SLAVE STATUS\G
*************************** 1. row ***************************
               Slave_IO_State: Waiting for master to send event
                  Master_Host: master1
                  Master_User: root
                  Master_Port: 3306
                Connect_Retry: 60
              Master_Log_File: mysql-bin.000004
          Read_Master_Log_Pos: 931
               Relay_Log_File: slave1-relay-bin.000056
                Relay_Log_Pos: 950
        Relay_Master_Log_File: mysql-bin.000004
             Slave_IO_Running: Yes
            Slave_SQL_Running: Yes
              Replicate_Do_DB:
          Replicate_Ignore_DB:
           Replicate_Do_Table:
       Replicate_Ignore_Table:
      Replicate_Wild_Do_Table:
  Replicate_Wild_Ignore_Table:
                   Last_Errno: 0
                   Last_Error:
                 Skip_Counter: 0
          Exec_Master_Log_Pos: 931
              Relay_Log_Space: 1365
              Until_Condition: None
               Until_Log_File:
                Until_Log_Pos: 0
           Master_SSL_Allowed: No
           Master_SSL_CA_File:
           Master_SSL_CA_Path:
```

```
             Master_SSL_Cert:
           Master_SSL_Cipher:
              Master_SSL_Key:
       Seconds_Behind_Master: 0
Master_SSL_Verify_Server_Cert: No
               Last_IO_Errno: 0
               Last_IO_Error:
              Last_SQL_Errno: 0
              Last_SQL_Error:
```

The key fields from the status report to examine are:

- `Slave_IO_State`: The current status of the slave. See Replication Slave I/O Thread States, and Replication Slave SQL Thread States, for more information.
- `Slave_IO_Running`: Whether the I/O thread for reading the master's binary log is running. Normally, you want this to be `Yes` unless you have not yet started replication or have explicitly stopped it with `STOP SLAVE`.
- `Slave_SQL_Running`: Whether the SQL thread for executing events in the relay log is running. As with the I/O thread, this should normally be `Yes`.
- `Last_IO_Error`, `Last_SQL_Error`: The last errors registered by the I/O and SQL threads when processing the relay log. Ideally these should be blank, indicating no errors.
- `Seconds_Behind_Master`: The number of seconds that the slave SQL thread is behind processing the master binary log. A high number (or an increasing one) can indicate that the slave is unable to handle events from the master in a timely fashion.

  A value of 0 for `Seconds_Behind_Master` can usually be interpreted as meaning that the slave has caught up with the master, but there are some cases where this is not strictly true. For example, this can occur if the network connection between master and slave is broken but the slave I/O thread has not yet noticed this—that is, `slave_net_timeout` [1645] has not yet elapsed.

  It is also possible that transient values for `Seconds_Behind_Master` may not reflect the situation accurately. When the slave SQL thread has caught up on I/O, `Seconds_Behind_Master` displays 0; but when the slave I/O thread is still queuing up a new event, `Seconds_Behind_Master` may show a large value until the SQL thread finishes executing the new event. This is especially likely when the events have old timestamps; in such cases, if you execute `SHOW SLAVE STATUS` several times in a relatively short period, you may see this value change back and forth repeatedly between 0 and a relatively large value.

Several pairs of fields provide information about the progress of the slave in reading events from the master binary log and processing them in the relay log:

- (`Master_Log_file`, `Read_Master_Log_Pos`): Coordinates in the master binary log indicating how far the slave I/O thread has read events from that log.
- (`Relay_Master_Log_File`, `Exec_Master_Log_Pos`): Coordinates in the master binary log indicating how far the slave SQL thread has executed events received from that log.
- (`Relay_Log_File`, `Relay_Log_Pos`): Coordinates in the slave relay log indicating how far the slave SQL thread has executed the relay log. These correspond to the preceding coordinates, but are expressed in slave relay log coordinates rather than master binary log coordinates.

On the master, you can check the status of connected slaves using `SHOW PROCESSLIST` to examine the list of running processes. Slave connections have `Binlog Dump` in the `Command` field:

```
mysql> SHOW PROCESSLIST \G;
*************************** 4. row ***************************
     Id: 10
   User: root
   Host: slave1:58371
     db: NULL
```

```
Command: Binlog Dump
   Time: 777
  State: Has sent all binlog to slave; waiting for binlog to be updated
   Info: NULL
```

Because it is the slave that drives the replication process, very little information is available in this report.

For slaves that were started with the `--report-host` [1638] option and are connected to the master, the `SHOW SLAVE HOSTS` statement on the master shows basic information about the slaves. The output includes the ID of the slave server, the value of the `--report-host` [1638] option, the connecting port, and master ID:

```
mysql> SHOW SLAVE HOSTS;
+-----------+--------+------+------------------+-----------+
| Server_id | Host   | Port | Rpl_recovery_rank | Master_id |
+-----------+--------+------+------------------+-----------+
|        10 | slave1 | 3306 |                 0 |         1 |
+-----------+--------+------+------------------+-----------+
1 row in set (0.00 sec)
```

Pausing Replication on the Slave

You can stop and start the replication of statements on the slave using the `STOP SLAVE` and `START SLAVE` statements.

To stop processing of the binary log from the master, use `STOP SLAVE`:

```
mysql> STOP SLAVE;
```

When replication is stopped, the slave I/O thread stops reading events from the master binary log and writing them to the relay log, and the SQL thread stops reading events from the relay log and executing them. You can pause the I/O or SQL thread individually by specifying the thread type:

```
mysql> STOP SLAVE IO_THREAD;
mysql> STOP SLAVE SQL_THREAD;
```

To start execution again, use the `START SLAVE` statement:

```
mysql> START SLAVE;
```

To start a particular thread, specify the thread type:

```
mysql> START SLAVE IO_THREAD;
mysql> START SLAVE SQL_THREAD;
```

For a slave that performs updates only by processing events from the master, stopping only the SQL thread can be useful if you want to perform a backup or other task. The I/O thread will continue to read events from the master but they are not executed. This makes it easier for the slave to catch up when you restart the SQL thread.

Stopping only the I/O thread enables the events in the relay log to be executed by the SQL thread up to the point where the relay log ends. This can be useful when you want to pause execution to catch up with events already received from the master, when you want to perform administration on the slave but also ensure that it has processed all updates to a specific point. This method can also be used to pause event receipt on the slave while you conduct administration on the master. Stopping the I/O thread but permitting the SQL thread to run helps ensure that there is not a massive backlog of events to be executed when replication is started again.

Replication Implementation

Replication is based on the master server keeping track of all changes to its databases (updates, deletes, and so on) in its binary log. The binary log serves as a written record of all events that modify

database structure or content (data) from the moment the server was started. Typically, `SELECT` statements are not recorded because they modify neither database structure nor content.

Each slave that connects to the master requests a copy of the binary log. That is, it pulls the data from the master, rather than the master pushing the data to the slave. The slave also executes the events from the binary log that it receives. This has the effect of repeating the original changes just as they were made on the master. Tables are created or their structure modified, and data is inserted, deleted, and updated according to the changes that were originally made on the master.

Because each slave is independent, the replaying of the changes from the master's binary log occurs independently on each slave that is connected to the master. In addition, because each slave receives a copy of the binary log only by requesting it from the master, the slave is able to read and update the copy of the database at its own pace and can start and stop the replication process at will without affecting the ability to update to the latest database status on either the master or slave side.

For more information on the specifics of the replication implementation, see Replication Implementation Details.

Masters and slaves report their status in respect of the replication process regularly so that you can monitor them. See Examining Thread Information, for descriptions of all replicated-related states.

The master binary log is written to a local relay log on the slave before it is processed. The slave also records information about the current position with the master's binary log and the local relay log. See Replication Relay and Status Logs.

Database changes are filtered on the slave according to a set of rules that are applied according to the various configuration options and variables that control event evaluation. For details on how these rules are applied, see How Servers Evaluate Replication Filtering Rules.

Replication Implementation Details

MySQL replication capabilities are implemented using three threads, one on the master server and two on the slave:

- **Binlog dump thread.** The master creates a thread to send the binary log contents to a slave when the slave connects. This thread can be identified in the output of `SHOW PROCESSLIST` on the master as the `Binlog Dump` thread.

  The binlog dump thread acquires a lock on the master's binary log for reading each event that is to be sent to the slave. As soon as the event has been read, the lock is released, even before the event is sent to the slave.

- **Slave I/O thread.** When a `START SLAVE` statement is issued on a slave server, the slave creates an I/O thread, which connects to the master and asks it to send the updates recorded in its binary logs.

  The slave I/O thread reads the updates that the master's `Binlog Dump` thread sends (see previous item) and copies them to local files that comprise the slave's relay log.

  The state of this thread is shown as `Slave_IO_running` in the output of `SHOW SLAVE STATUS` or as `Slave_running` [568] in the output of `SHOW STATUS`.

- **Slave SQL thread.** The slave creates an SQL thread to read the relay log that is written by the slave I/O thread and execute the events contained therein.

In the preceding description, there are three threads per master/slave connection. A master that has multiple slaves creates one binlog dump thread for each currently connected slave, and each slave has its own I/O and SQL threads.

A slave uses two threads to separate reading updates from the master and executing them into independent tasks. Thus, the task of reading statements is not slowed down if statement execution

is slow. For example, if the slave server has not been running for a while, its I/O thread can quickly fetch all the binary log contents from the master when the slave starts, even if the SQL thread lags far behind. If the slave stops before the SQL thread has executed all the fetched statements, the I/O thread has at least fetched everything so that a safe copy of the statements is stored locally in the slave's relay logs, ready for execution the next time that the slave starts. This enables the master server to purge its binary logs sooner because it no longer needs to wait for the slave to fetch their contents.

The `SHOW PROCESSLIST` statement provides information that tells you what is happening on the master and on the slave regarding replication. For information on master states, see Replication Master Thread States. For slave states, see Replication Slave I/O Thread States, and Replication Slave SQL Thread States.

The following example illustrates how the three threads show up in the output from `SHOW PROCESSLIST`.

On the master server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
     Id: 2
   User: root
   Host: localhost:32931
     db: NULL
Command: Binlog Dump
   Time: 94
  State: Has sent all binlog to slave; waiting for binlog to
         be updated
   Info: NULL
```

Here, thread 2 is a `Binlog Dump` replication thread that services a connected slave. The `State` information indicates that all outstanding updates have been sent to the slave and that the master is waiting for more updates to occur. If you see no `Binlog Dump` threads on a master server, this means that replication is not running; that is, no slaves are currently connected.

On a slave server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
     Id: 10
   User: system user
   Host:
     db: NULL
Command: Connect
   Time: 11
  State: Waiting for master to send event
   Info: NULL
*************************** 2. row ***************************
     Id: 11
   User: system user
   Host:
     db: NULL
Command: Connect
   Time: 11
  State: Has read all relay log; waiting for the slave I/O
         thread to update it
   Info: NULL
```

The `State` information indicates that thread 10 is the I/O thread that is communicating with the master server, and thread 11 is the SQL thread that is processing the updates stored in the relay logs. At the time that `SHOW PROCESSLIST` was run, both threads were idle, waiting for further updates.

The value in the `Time` column can show how late the slave is compared to the master. See MySQL 5.1 FAQ: Replication. If sufficient time elapses on the master side without activity on the `Binlog Dump` thread, the master determines that the slave is no longer connected. As for any other client connection,

the timeouts for this depend on the values of `net_write_timeout` and `net_retry_count`; for more information about these, see Server System Variables.

The `SHOW SLAVE STATUS` statement provides additional information about replication processing on a slave server. See Checking Replication Status.

Replication Relay and Status Logs

During replication, a slave server creates several logs that hold the binary log events relayed from the master to the slave, and to record information about the current status and location within the relay log. There are three types of logs used in the process, listed here:

- The *relay log* consists of the events read from the binary log of the master and written by the slave I/O thread. Events in the relay log are executed on the slave as part of the SQL thread.
- The *master info log* contains status and current configuration information for the slave's connection to the master. This log holds information on the master host name, login credentials, and coordinates indicating how far the slave has read from the master's binary log.
- The *relay log info log* holds status information about the execution point within the slave's relay log.

The Slave Relay Log

The relay log, like the binary log, consists of a set of numbered files containing events that describe database changes, and an index file that contains the names of all used relay log files.

The term “relay log file” generally denotes an individual numbered file containing database events. The term “relay log” collectively denotes the set of numbered relay log files plus the index file.

Relay log files have the same format as binary log files and can be read using `mysqlbinlog` (see `mysqlbinlog` — Utility for Processing Binary Log Files).

By default, relay log file names have the form *`host_name`*`-relay-bin.`*`nnnnnn`* in the data directory, where *`host_name`* is the name of the slave server host and *`nnnnnn`* is a sequence number. Successive relay log files are created using successive sequence numbers, beginning with `000001`. The slave uses an index file to track the relay log files currently in use. The default relay log index file name is *`host_name`*`-relay-bin.index` in the data directory.

The default relay log file and relay log index file names can be overridden with, respectively, the `--relay-log` [1632] and `--relay-log-index` [1633] server options (see Replication and Binary Logging Options and Variables).

If a slave uses the default host-based relay log file names, changing a slave's host name after replication has been set up can cause replication to fail with the errors `Failed to open the relay log` and `Could not find target log during relay log initialization`. This is a known issue (see Bug #2122). If you anticipate that a slave's host name might change in the future (for example, if networking is set up on the slave such that its host name can be modified using DHCP), you can avoid this issue entirely by using the `--relay-log` [1632] and `--relay-log-index` [1633] options to specify relay log file names explicitly when you initially set up the slave. This will make the names independent of server host name changes.

If you encounter the issue after replication has already begun, one way to work around it is to stop the slave server, prepend the contents of the old relay log index file to the new one, and then restart the slave. On a Unix system, this can be done as shown here:

```
shell> cat new_relay_log_name.index >> old_relay_log_name.index
shell> mv old_relay_log_name.index new_relay_log_name.index
```

A slave server creates a new relay log file under the following conditions:

- Each time the I/O thread starts.
- When the logs are flushed; for example, with `FLUSH LOGS` or `mysqladmin flush-logs`.
- When the size of the current relay log file becomes "too large," determined as follows:
  - If the value of `max_relay_log_size` [497] is greater than 0, that is the maximum relay log file size.
  - If the value of `max_relay_log_size` [497] is 0, `max_binlog_size` [1657] determines the maximum relay log file size.

The SQL thread automatically deletes each relay log file as soon as it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the SQL thread takes care of doing so. However, `FLUSH LOGS` rotates relay logs, which influences when the SQL thread deletes them.

Slave Status Logs

A replication slave server creates two logs. By default, these logs are files named `master.info` and `relay-log.info` and created in the data directory. The names and locations of these files can be changed by using the `--master-info-file` [1630] and `--relay-log-info-file` [1633] options, respectively. See Replication and Binary Logging Options and Variables.

The two status logs contain information like that shown in the output of the `SHOW SLAVE STATUS` statement, which is discussed in SQL Statements for Controlling Slave Servers. Because the status logs are stored on disk, they survive a slave server's shutdown. The next time the slave starts up, it reads the two logs to determine how far it has proceeded in reading binary logs from the master and in processing its own relay logs.

The master info log should be protected because it contains the password for connecting to the master. See Passwords and Logging.

The slave I/O thread updates the master info log. The following table shows the correspondence between the lines in the `master.info` file and the columns displayed by `SHOW SLAVE STATUS`.

Line in `master.info`	`SHOW SLAVE STATUS` Column	Description
1		Number of lines in the file
2	`Master_Log_File`	The name of the master binary log currently being read from the master
3	`Read_Master_Log_Pos`	The current position within the master binary log that have been read from the master
4	`Master_Host`	The host name of the master
5	`Master_User`	The user name used to connect to the master
6	Password (not shown by `SHOW SLAVE STATUS`)	The password used to connect to the master
7	`Master_Port`	The network port used to connect to the master
8	`Connect_Retry`	The period (in seconds) that the slave will wait before trying to reconnect to the master
9	`Master_SSL_Allowed`	Indicates whether the server supports SSL connections
10	`Master_SSL_CA_File`	The file used for the Certificate Authority (CA) certificate

Line in `master.info`	`SHOW SLAVE STATUS` Column	Description
11	`Master_SSL_CA_Path`	The path to the Certificate Authority (CA) certificates
12	`Master_SSL_Cert`	The name of the SSL certificate file
13	`Master_SSL_Cipher`	The list of possible ciphers used in the handshake for the SSL connection
14	`Master_SSL_Key`	The name of the SSL key file
15	`Master_SSL_Verify_Server_Cert`	Whether to verify the server certificate (added in MySQL 5.1.18)

The slave SQL thread updates the relay log info log. The following table shows the correspondence between the lines in the `relay-log.info` file and the columns displayed by `SHOW SLAVE STATUS`.

Line in `relay-log.info`	`SHOW SLAVE STATUS` Column	Description
1	`Relay_Log_File`	The name of the current relay log file
2	`Relay_Log_Pos`	The current position within the relay log file; events up to this position have been executed on the slave database
3	`Relay_Master_Log_File`	The name of the master binary log file from which the events in the relay log file were read
4	`Exec_Master_Log_Pos`	The equivalent position within the master's binary log file of events that have already been executed

The contents of the `relay-log.info` file and the states shown by the `SHOW SLAVE STATUS` statement might not match if the `relay-log.info` file has not been flushed to disk. Ideally, you should only view `relay-log.info` on a slave that is offline (that is, `mysqld` is not running). For a running system, `SHOW SLAVE STATUS` should be used.

When you back up the slave's data, you should back up these two status logs, along with the relay log files. The status logs are needed to resume replication after you restore the data from the slave. If you lose the relay logs but still have the relay log info log, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. Of course, this requires that the binary logs still exist on the master.

How Servers Evaluate Replication Filtering Rules

If a master server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all slaves and each slave determines whether to execute it or ignore it.

On the master, you can control which databases to log changes for by using the `--binlog-do-db` [1649] and `--binlog-ignore-db` [1651] options to control binary logging. For a description of the rules that servers use in evaluating these options, see Evaluation of Database-Level Replication and Binary Logging Options. You should not use these options to control which databases and tables are replicated. Instead, use filtering on the slave to control the events that are executed on the slave.

On the slave side, decisions about whether to execute or ignore statements received from the master are made according to the `--replicate-*` options that the slave was started with. (See Replication and Binary Logging Options and Variables.)

In the simplest case, when there are no `--replicate-*` options, the slave executes all statements that it receives from the master. Otherwise, the result depends on the particular options given.

Database-level options (`--replicate-do-db` [1634], `--replicate-ignore-db` [1635]) are checked first; see Evaluation of Database-Level Replication and Binary Logging Options, for a description of this process. If no matching database-level options are found, option checking proceeds to any table-level options that may be in use, as discussed in Evaluation of Table-Level Replication Options.

To make it easier to determine what effect an option set will have, it is recommended that you avoid mixing “do” and “ignore” options, or wildcard and nonwildcard options. An example of the latter that may have unintended effects is the use of `--replicate-do-db` [1634] and `--replicate-wild-do-table` [1637] together, where `--replicate-wild-do-table` [1637] uses a pattern for the database name that matches the name given for `--replicate-do-db` [1634]. Suppose a replication slave is started with `--replicate-do-db=dbx` [1634] `--replicate-wild-do-table=db%.t1` [1637]. Then, suppose that on the master, you issue the statement `CREATE DATABASE dbx`. Although you might expect it, this statement is not replicated because it does not reference a table named `t1`.

If any `--replicate-rewrite-db` [1637] options were specified, they are applied before the `--replicate-*` filtering rules are tested.

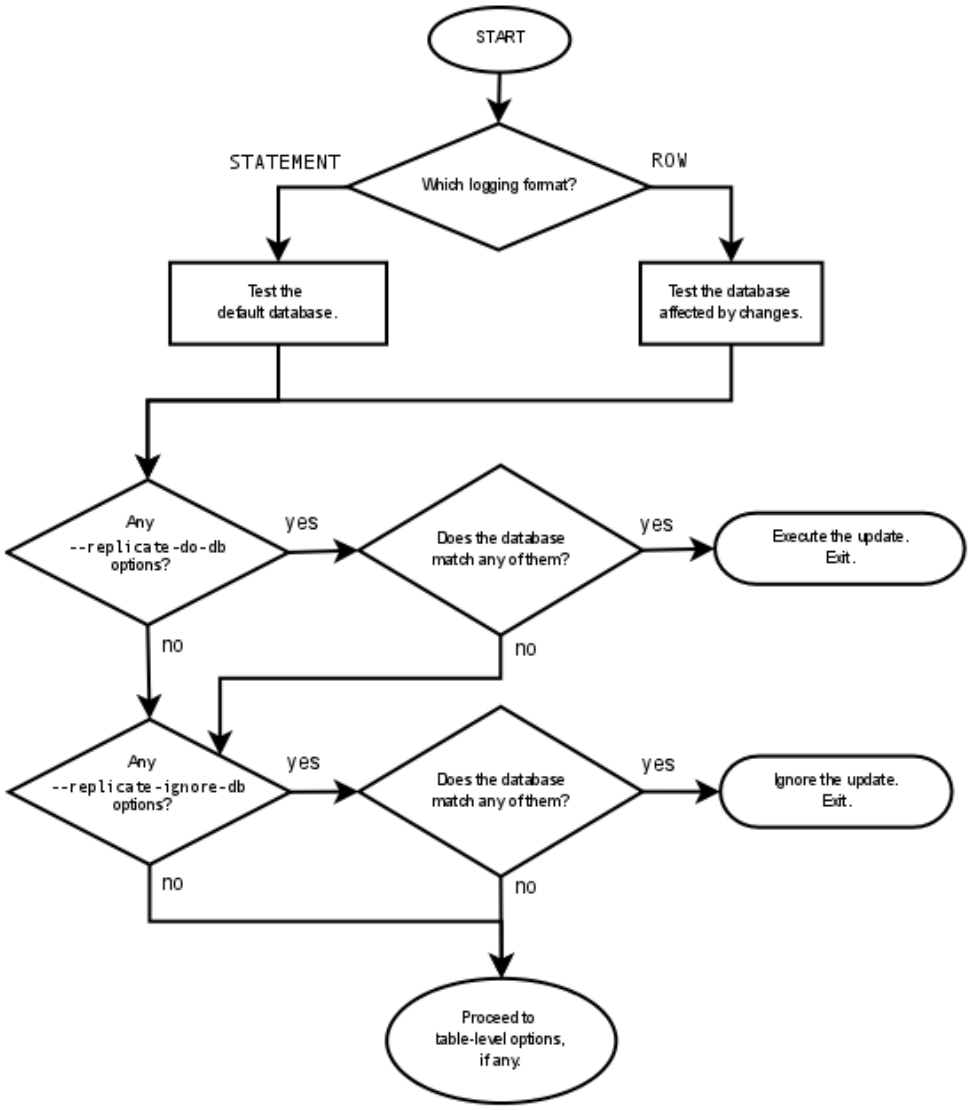
Note

In MySQL 5.1, database-level filtering options are case-sensitive on platforms supporting case sensitivity in filenames, whereas table-level filtering options are not (regardless of platform). This is true regardless of the value of the `lower_case_table_names` [492] system variable. These are known issues which are fixed in MySQL 5.5.

Evaluation of Database-Level Replication and Binary Logging Options

When evaluating replication options, the slave begins by checking to see whether there are any `--replicate-do-db` [1634] or `--replicate-ignore-db` [1635] options that apply. When using `--binlog-do-db` [1649] or `--binlog-ignore-db` [1651], the process is similar, but the options are checked on the master.

With statement-based replication, the default database is checked for a match. With row-based replication, the database where data is to be changed is the database that is checked. Regardless of the binary logging format, checking of database-level options proceeds as shown in the following diagram.



The steps involved are listed here:

1. Are there any `--replicate-do-db` [1634] options?
   - **Yes.** Do any of them match the database?
     - **Yes.** Execute the statement and exit.
     - **No.** Continue to step 2.
   - **No.** Continue to step 2.
2. Are there any `--replicate-ignore-db` [1635] options?
   - **Yes.** Do any of them match the database?
     - **Yes.** Ignore the statement and exit.
     - **No.** Continue to step 3.
   - **No.** Continue to step 3.
3. Proceed to checking the table-level replication options, if there are any. For a description of how these options are checked, see Evaluation of Table-Level Replication Options.

Important

A statement that is still permitted at this stage is not yet actually executed. The statement is not executed until all table-level options (if any) have also been checked, and the outcome of that process permits execution of the statement.

For binary logging, the steps involved are listed here:

1. Are there any `--binlog-do-db` [1649] or `--binlog-ignore-db` [1651] options?
   - **Yes.** Continue to step 2.
   - **No.** Log the statement and exit.
2. Is there a default database (has any database been selected by `USE`)?
   - **Yes.** Continue to step 3.
   - **No.** Ignore the statement and exit.
3. There is a default database. Are there any `--binlog-do-db` [1649] options?
   - **Yes.** Do any of them match the database?
     - **Yes.** Log the statement and exit.
     - **No.** Ignore the statement and exit.
   - **No.** Continue to step 4.
4. Do any of the `--binlog-ignore-db` [1651] options match the database?
   - **Yes.** Ignore the statement and exit.
   - **No.** Log the statement and exit.

Important

For statement-based logging, an exception is made in the rules just given for the `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. In those cases, the database being *created, altered, or dropped* replaces the default database when determining whether to log or ignore updates.

`--binlog-do-db` [1649] can sometimes mean “ignore other databases”. For example, when using statement-based logging, a server running with only `--binlog-do-db=sales` [1649] does not write to the binary log statements for which the default database differs from `sales`. When using row-based logging with the same option, the server logs only those updates that change data in `sales`.

Evaluation of Table-Level Replication Options

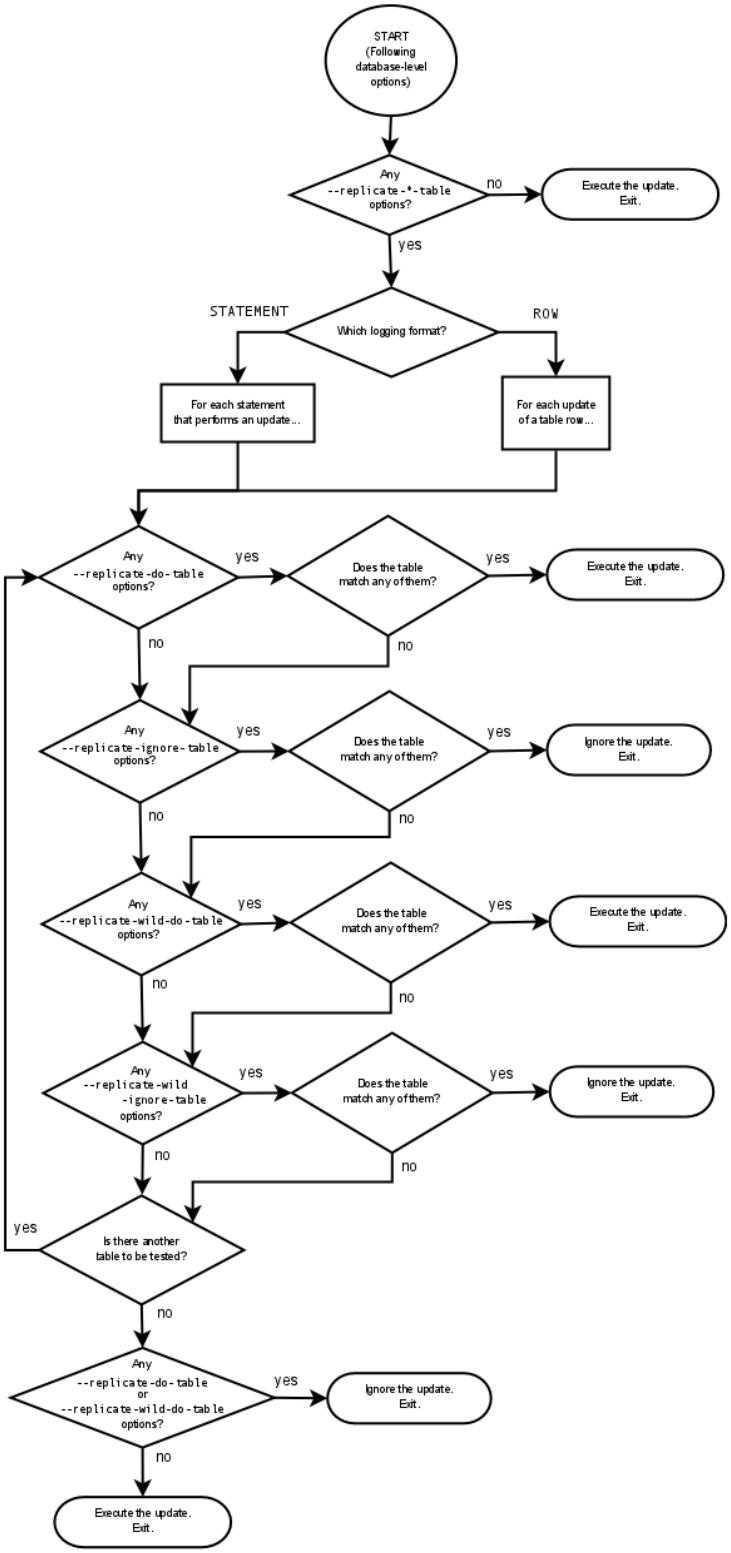
The slave checks for and evaluates table options only if no matching database options were found (see Evaluation of Database-Level Replication and Binary Logging Options).

First, as a preliminary condition, the slave checks whether statement-based replication is enabled. If so, and the statement occurs within a stored function, the slave executes the statement and exits. If row-based replication is enabled, the slave does not know whether a statement occurred within a stored function on the master, so this condition does not apply.

Note

For statement-based replication, replication events represent statements (all changes making up a given event are associated with a single SQL statement); for row-based replication, each event represents a change in a single table row (thus a single statement such as `UPDATE mytable SET mycol = 1` may yield many row-based events). When viewed in terms of events, the process of checking table options is the same for both row-based and statement-based replication.

Having reached this point, if there are no table options, the slave simply executes all events. If there are any `--replicate-do-table` [1636] or `--replicate-wild-do-table` [1637] options, the event must match one of these if it is to be executed; otherwise, it is ignored. If there are any `--replicate-ignore-table` [1636] or `--replicate-wild-ignore-table` [1638] options, all events are executed except those that match any of these options. This process is illustrated in the following diagram.



The following steps describe this evaluation in more detail:

1. Are there any table options?

   - **Yes.** Continue to step 2.
   - **No.** Execute the event and exit.

2. Are there any `--replicate-do-table` [1636] options?

- **Yes.** Does the table match any of them?
  - **Yes.** Execute the event and exit.
  - **No.** Continue to step 3.
- **No.** Continue to step 3.

3. Are there any `--replicate-ignore-table` [1636] options?
   - **Yes.** Does the table match any of them?
     - **Yes.** Ignore the event and exit.
     - **No.** Continue to step 4.
   - **No.** Continue to step 4.
4. Are there any `--replicate-wild-do-table` [1637] options?
   - **Yes.** Does the table match any of them?
     - **Yes.** Execute the event and exit.
     - **No.** Continue to step 5.
   - **No.** Continue to step 5.
5. Are there any `--replicate-wild-ignore-table` [1638] options?
   - **Yes.** Does the table match any of them?
     - **Yes.** Ignore the event and exit.
     - **No.** Continue to step 6.
   - **No.** Continue to step 6.
6. Are there any `--replicate-do-table` [1636] or `--replicate-wild-do-table` [1637] options?
   - **Yes.** Ignore the event and exit.
   - **No.** Execute the event and exit.

Replication Rule Application

This section provides additional explanation and examples of usage for different combinations of replication filtering options.

Some typical combinations of replication filter rule types are given in the following table:

Condition (Types of Options)	Outcome
No `--replicate-*` options at all:	The slave executes all events that it receives from the master.
`--replicate-*-db` options, but no table options:	The slave accepts or ignores events using the database options. It executes all events permitted by those options because there are no table restrictions.
`--replicate-*-table` options, but no database options:	All events are accepted at the database-checking stage because there are no database conditions. The slave

Condition (Types of Options)	Outcome
	executes or ignores events based solely on the table options.
A combination of database and table options:	The slave accepts or ignores events using the database options. Then it evaluates all events permitted by those options according to the table options. This can sometimes lead to results that seem counterintuitive, and that may be different depending on whether you are using statement-based or row-based replication; see the text for an example.

A more complex example follows, in which we examine the outcomes for both statement-based and row-based settings.

Suppose that we have two tables `mytbl1` in database `db1` and `mytbl2` in database `db2` on the master, and the slave is running with the following options (and no other replication filtering options):

```
replicate-ignore-db = db1
replicate-do-table  = db2.tbl2
```

Now we execute the following statements on the master:

```
USE db1;
INSERT INTO db2.tbl2 VALUES (1);
```

The results on the slave vary considerably depending on the binary log format, and may not match initial expectations in either case.

Statement-based replication. The `USE` statement causes `db1` to be the default database. Thus the `--replicate-ignore-db` [1635] option matches, *and the `INSERT` statement is ignored*. The table options are not checked.

Row-based replication. The default database has no effect on how the slave reads database options when using row-based replication. Thus, the `USE` statement makes no difference in how the `--replicate-ignore-db` [1635] option is handled: the database specified by this option does not match the database where the `INSERT` statement changes data, so the slave proceeds to check the table options. The table specified by `--replicate-do-table` [1636] matches the table to be updated, *and the row is inserted*.

Replication Solutions

Replication can be used in many different environments for a range of purposes. This section provides general notes and advice on using replication for specific solution types.

For information on using replication in a backup environment, including notes on the setup, backup procedure, and files to back up, see Using Replication for Backups.

For advice and tips on using different storage engines on the master and slaves, see Using Replication with Different Master and Slave Storage Engines.

Using replication as a scale-out solution requires some changes in the logic and operation of applications that use the solution. See Using Replication for Scale-Out.

For performance or data distribution reasons, you may want to replicate different databases to different replication slaves. See Replicating Different Databases to Different Slaves

As the number of replication slaves increases, the load on the master can increase and lead to reduced performance (because of the need to replicate the binary log to each slave). For tips on improving your replication performance, including using a single secondary server as an replication master, see Improving Replication Performance.

For guidance on switching masters, or converting slaves into masters as part of an emergency failover solution, see Switching Masters During Failover.

To secure your replication communication, you can use SSL to encrypt the communication channel. For step-by-step instructions, see Setting Up Replication Using SSL.

Using Replication for Backups

To use replication as a backup solution, replicate data from the master to a slave, and then back up the data slave. The slave can be paused and shut down without affecting the running operation of the master, so you can produce an effective snapshot of “live” data that would otherwise require the master to be shut down.

How you back up a database depends on its size and whether you are backing up only the data, or the data and the replication slave state so that you can rebuild the slave in the event of failure. There are therefore two choices:

- If you are using replication as a solution to enable you to back up the data on the master, and the size of your database is not too large, the `mysqldump` tool may be suitable. See Backing Up a Slave Using `mysqldump`.
- For larger databases, where `mysqldump` would be impractical or inefficient, you can back up the raw data files instead. Using the raw data files option also means that you can back up the binary and relay logs that will enable you to recreate the slave in the event of a slave failure. For more information, see Backing Up Raw Data from a Slave.

Another backup strategy, which can be used for either master or slave servers, is to put the server in a read-only state. The backup is performed against the read-only server, which then is changed back to its usual read/write operational status. See Backing Up a Master or Slave by Making It Read Only.

Backing Up a Slave Using `mysqldump`

Using `mysqldump` to create a copy of a database enables you to capture all of the data in the database in a format that enables the information to be imported into another instance of MySQL Server (see `mysqldump` — A Database Backup Program). Because the format of the information is SQL statements, the file can easily be distributed and applied to running servers in the event that you need access to the data in an emergency. However, if the size of your data set is very large, `mysqldump` may be impractical.

When using `mysqldump`, you should stop replication on the slave before starting the dump process to ensure that the dump contains a consistent set of data:

1. Stop the slave from processing requests. You can stop replication completely on the slave using `mysqladmin`:

   ```
   shell> mysqladmin stop-slave
   ```

   Alternatively, you can stop only the slave SQL thread to pause event execution:

   ```
   shell> mysql -e 'STOP SLAVE SQL_THREAD;'
   ```

   This enables the slave to continue to receive data change events from the master's binary log and store them in the relay logs using the I/O thread, but prevents the slave from executing these events and changing its data. Within busy replication environments, permitting the I/O thread to run during backup may speed up the catch-up process when you restart the slave SQL thread.

2. Run `mysqldump` to dump your databases. You may either dump all databases or select databases to be dumped. For example, to dump all databases:

   ```
   shell> mysqldump --all-databases > fulldb.dump
   ```

3. Once the dump has completed, start slave operations again:

```
shell> mysqladmin start-slave
```

In the preceding example, you may want to add login credentials (user name, password) to the commands, and bundle the process up into a script that you can run automatically each day.

If you use this approach, make sure you monitor the slave replication process to ensure that the time taken to run the backup does not affect the slave's ability to keep up with events from the master. See Checking Replication Status. If the slave is unable to keep up, you may want to add another slave and distribute the backup process. For an example of how to configure this scenario, see Replicating Different Databases to Different Slaves.

Backing Up Raw Data from a Slave

To guarantee the integrity of the files that are copied, backing up the raw data files on your MySQL replication slave should take place while your slave server is shut down. If the MySQL server is still running, background tasks may still be updating the database files, particularly those involving storage engines with background processes such as `InnoDB`. With `InnoDB`, these problems should be resolved during crash recovery, but since the slave server can be shut down during the backup process without affecting the execution of the master it makes sense to take advantage of this capability.

To shut down the server and back up the files:

1. Shut down the slave MySQL server:

   ```
   shell> mysqladmin shutdown
   ```

2. Copy the data files. You can use any suitable copying or archive utility, including `cp`, `tar` or `WinZip`. For example, assuming that the data directory is located under the current directory, you can archive the entire directory as follows:

   ```
   shell> tar cf /tmp/dbbackup.tar ./data
   ```

3. Start the MySQL server again. Under Unix:

   ```
   shell> mysqld_safe &
   ```

   Under Windows:

   ```
   C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqld"
   ```

Normally you should back up the entire data directory for the slave MySQL server. If you want to be able to restore the data and operate as a slave (for example, in the event of failure of the slave), then in addition to the slave's data, you should also back up the slave status files, `master.info` and `relay-log.info`, along with the relay log files. These files are needed to resume replication after you restore the slave's data.

If you lose the relay logs but still have the `relay-log.info` file, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. This requires that the binary logs still exist on the master server.

If your slave is replicating `LOAD DATA INFILE` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA INFILE` operations. The location of this directory is the value of the `--slave-load-tmpdir` [1640] option. If the server was not started with that option, the directory location is the value of the `tmpdir` [534] system variable.

Backing Up a Master or Slave by Making It Read Only

It is possible to back up either master or slave servers in a replication setup by acquiring a global read lock and manipulating the `read_only` [517] system variable to change the read-only state of the server to be backed up:

1. Make the server read-only, so that it processes only retrievals and blocks updates.
2. Perform the backup.
3. Change the server back to its normal read/write state.

Note

The instructions in this section place the server to be backed up in a state that is safe for backup methods that get the data from the server, such as `mysqldump` (see `mysqldump` — A Database Backup Program). You should not attempt to use these instructions to make a binary backup by copying files directly because the server may still have modified data cached in memory and not flushed to disk.

These instructions also require MySQL 5.1.15 or higher. For earlier versions, setting `read_only` [517] does not block while table locks or outstanding transactions are pending, so data changes can still occur during the backup operation and produce inconsistent backup results.

The following instructions describe how to do this for a master server and for a slave server. For both scenarios discussed here, suppose that you have the following replication setup:

- A master server M1
- A slave server S1 that has M1 as its master
- A client C1 connected to M1
- A client C2 connected to S1

In either scenario, the statements to acquire the global read lock and manipulate the `read_only` [517] variable are performed on the server to be backed up and do not propagate to any slaves of that server.

Scenario 1: Backup with a Read-Only Master

Put the master M1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While M1 is in a read-only state, the following properties are true:

- Requests for updates sent by C1 to M1 will block because the server is in read-only mode.
- Requests for query results sent by C1 to M1 will succeed.
- Making a backup on M1 is safe.
- Making a backup on S1 is not safe. This server is still running, and might be processing the binary log or update requests coming from client C2

While M1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on M1 completes, restore M1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

Although performing the backup on M1 is safe (as far as the backup is concerned), it is not optimal for performance because clients of M1 are blocked from executing updates.

This strategy applies to backing up a master server in a replication setup, but can also be used for a single server in a nonreplication setting.

Scenario 2: Backup with a Read-Only Slave

Put the slave S1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While S1 is in a read-only state, the following properties are true:

- The master M1 will continue to operate, so making a backup on the master is not safe.
- The slave S1 is stopped, so making a backup on the slave S1 is safe.

These properties provide the basis for a popular backup scenario: Having one slave busy performing a backup for a while is not a problem because it does not affect the entire network, and the system is still running during the backup. In particular, clients can still perform updates on the master server, which remains unaffected by backup activity on the slave.

While S1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on S1 completes, restore S1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

After the slave is restored to normal operation, it again synchronizes to the master by catching up with any outstanding updates from the binary log of the master.

Using Replication with Different Master and Slave Storage Engines

It does not matter for the replication process whether the source table on the master and the replicated table on the slave use different engine types. In fact, the system variables `storage_engine` [528] and `table_type` [531] are not replicated.

This provides a number of benefits in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scale-out scenario (see Using Replication for Scale-Out), you want to use `InnoDB` tables on the master to take advantage of the transactional functionality, but use `MyISAM` on the slaves where transaction support is not required because the data is only read. When using replication in a data-logging environment you may want to use the `Archive` storage engine on the slave.

Configuring different engines on the master and slave depends on how you set up the initial replication process:

- If you used `mysqldump` to create the database snapshot on your master, you could edit the dump file text to change the engine type used on each table.

  Another alternative for `mysqldump` is to disable engine types that you do not want to use on the slave before using the dump to build the data on the slave. For example, you can add the `--skip-innodb` [1359] option on your slave to disable the `InnoDB` engine. If a specific engine does not exist for a table to be created, MySQL will use the default engine type, usually `MyISAM`. (This requires that the `NO_ENGINE_SUBSTITUTION` [574] SQL mode is not enabled.) If you want to disable additional engines in this way, you may want to consider building a special binary to be used on the slave that only supports the engines you want.

- If you are using raw data files (a binary backup) to set up the slave, you will be unable to change the initial table format. Instead, use `ALTER TABLE` to change the table types after the slave has been started.

- For new master/slave replication setups where there are currently no tables on the master, avoid specifying the engine type when creating new tables.

If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the slave from running replication updates:

   ```
   mysql> STOP SLAVE;
   ```

   This will enable you to change engine types without interruptions.

2. Execute an `ALTER TABLE ... ENGINE='engine_type'` for each table to be changed.

3. Start the slave replication process again:

   ```
   mysql> START SLAVE;
   ```

Although the `storage_engine` [528] and `table_type` [531] variables are not replicated, be aware that `CREATE TABLE` and `ALTER TABLE` statements that include the engine specification will be correctly replicated to the slave. For example, if you have a CSV table and you execute:

```
mysql> ALTER TABLE csvtable Engine='MyISAM';
```

The above statement will be replicated to the slave and the engine type on the slave will be converted to `MyISAM`, even if you have previously changed the table type on the slave to an engine other than CSV. If you want to retain engine differences on the master and slave, you should be careful to use the `storage_engine` [528] variable on the master when creating a new table. For example, instead of:

```
mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;
```

Use this format:

```
mysql> SET storage_engine=MyISAM;
mysql> CREATE TABLE tablea (columna int);
```

When replicated, the `storage_engine` [528] variable will be ignored, and the `CREATE TABLE` statement will execute on the slave using the slave's default engine.

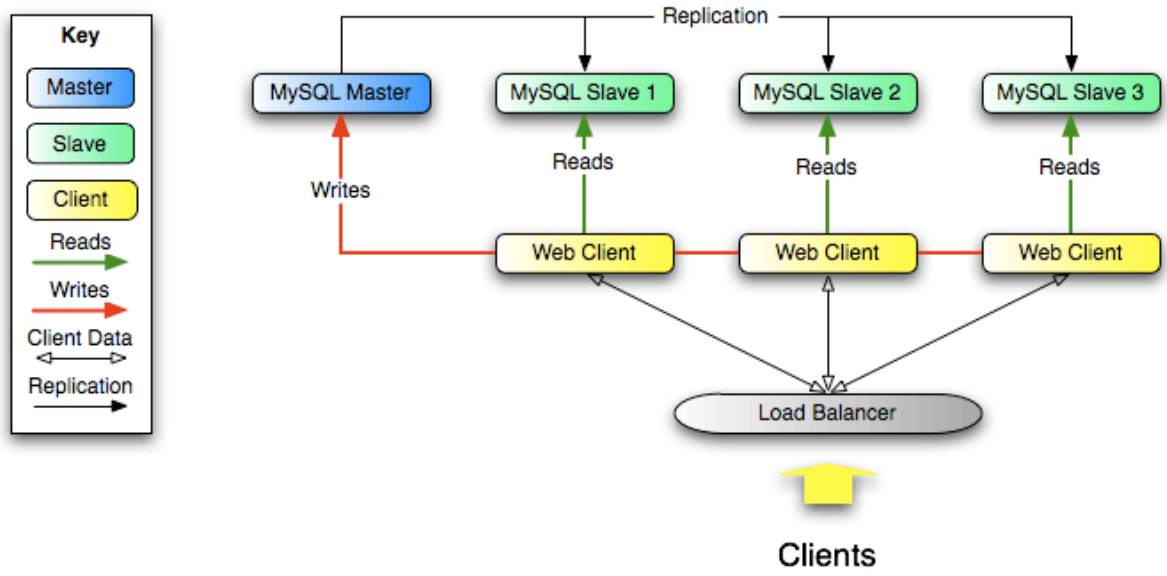
Using Replication for Scale-Out

You can use replication as a scale-out solution; that is, where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one master to one or more slaves, using replication for scale-out works best in an environment where you have a high number of reads and low number of writes/updates. Most Web sites fit into this category, where users are browsing the Web site, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replication slaves, while still enabling your web servers to communicate with the replication master when a write is required. You can see a sample replication layout for this scenario in Figure 16.1, “Using Replication to Improve Performance During Scale-Out”.

Figure 16.1. Using Replication to Improve Performance During Scale-Out



If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the master, and to send reads to either the master or a slave. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`
- `safe_reader_connect()`
- `safe_reader_statement()`
- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

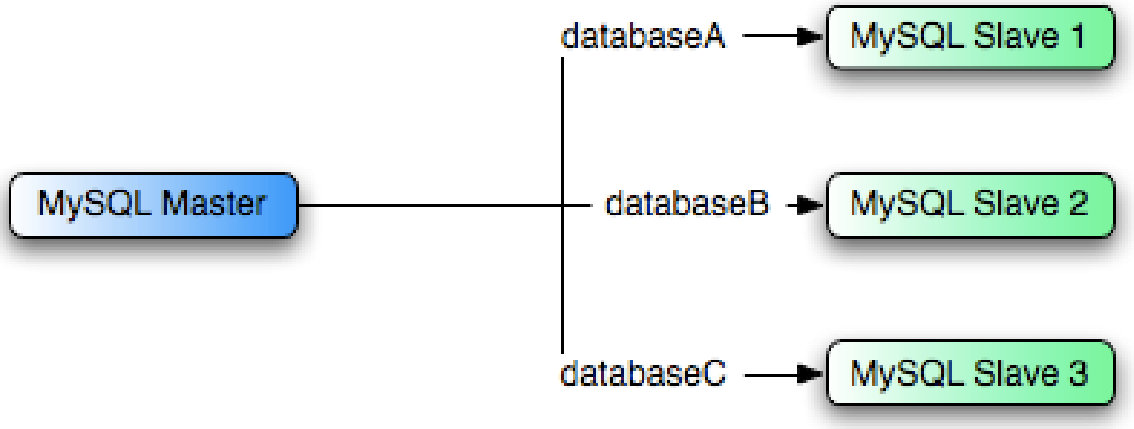
Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a master/slave configuration, even one involving multiple slaves. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions; for example, to log how long each statement took, or which statement among those issued gave you an error.

If you have written a lot of code, you may want to automate the conversion task by using the `replace` utility that comes with standard MySQL distributions, or write your own conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

Replicating Different Databases to Different Slaves

There may be situations where you have a single master and want to replicate different databases to different slaves. For example, you may want to distribute different sales data to different departments to help spread the load during data analysis. A sample of this layout is shown in Figure 16.2, “Using Replication to Replicate Databases to Separate Replication Slaves”.

Figure 16.2. Using Replication to Replicate Databases to Separate Replication Slaves



You can achieve this separation by configuring the master and slaves as normal, and then limiting the binary log statements that each slave processes by using the `--replicate-wild-do-table` [1637] configuration option on each slave.

Important

You should *not* use `--replicate-do-db` [1634] for this purpose when using statement-based replication, since statement-based replication causes this option's affects to vary according to the database that is currently selected. This applies to mixed-format replication as well, since this enables some updates to be replicated using the statement-based format.

However, it should be safe to use `--replicate-do-db` [1634] for this purpose if you are using row-based replication only, since in this case the currently selected database has no effect on the option's operation.

For example, to support the separation as shown in Figure 16.2, “Using Replication to Replicate Databases to Separate Replication Slaves”, you should configure each replication slave as follows, before executing `START SLAVE`:

- Replication slave 1 should use `--replicate-wild-do-table=databaseA.%`.
- Replication slave 2 should use `--replicate-wild-do-table=databaseB.%`.
- Replication slave 3 should use `--replicate-wild-do-table=databaseC.%`.

Each slave in this configuration receives the entire binary log from the master, but executes only those events from the binary log that apply to the databases and tables included by the `--replicate-wild-do-table` [1637] option in effect on that slave.

If you have data that must be synchronized to the slaves before replication starts, you have a number of choices:

- Synchronize all the data to each slave, and delete the databases, tables, or both that you do not want to keep.
- Use `mysqldump` to create a separate dump file for each database and load the appropriate dump file on each slave.
- Use a raw data file dump and include only the specific files and databases that you need for each slave.

Note

This does not work with `InnoDB` databases unless you use `innodb_file_per_table` [1367].

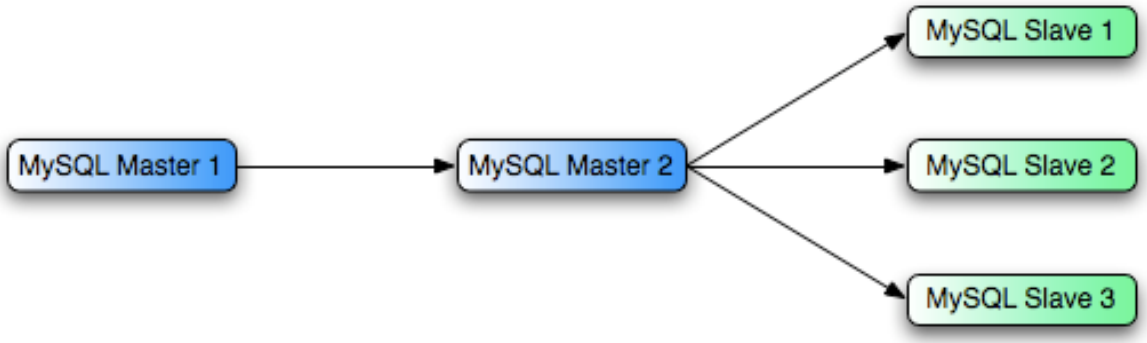
Improving Replication Performance

As the number of slaves connecting to a master increases, the load, although minimal, also increases, as each slave uses a client connection to the master. Also, as each slave must receive a full copy of the master binary log, the network load on the master may also increase and create a bottleneck.

If you are using a large number of slaves connected to one master, and that master is also busy processing requests (for example, as part of a scale-out solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the master to replicate to only one slave, and for the remaining slaves to connect to this primary slave for their individual replication requirements. A sample of this structure is shown in Figure 16.3, “Using an Additional Replication Host to Improve Performance”.

Figure 16.3. Using an Additional Replication Host to Improve Performance



For this to work, you must configure the MySQL instances as follows:

- Master 1 is the primary master where all changes and updates are written to the database. Binary logging should be enabled on this machine.
- Master 2 is the slave to the Master 1 that provides the replication functionality to the remainder of the slaves in the replication structure. Master 2 is the only machine permitted to connect to Master 1. Master 2 also has binary logging enabled, and the `--log-slave-updates` [1628] option so that replication instructions from Master 1 are also written to Master 2's binary log so that they can then be replicated to the true slaves.
- Slave 1, Slave 2, and Slave 3 act as slaves to Master 2, and replicate the information from Master 2, which actually consists of the upgrades logged on Master 1.

The above solution reduces the client load and the network interface load on the primary master, which should improve the overall performance of the primary master when used as a direct database solution.

If your slaves are having trouble keeping up with the replication process on the master, there are a number of options available:

- If possible, put the relay logs and the data files on different physical drives. To do this, use the `--relay-log` [1632] option to specify the location of the relay log.
- If the slaves are significantly slower than the master, you may want to divide up the responsibility for replicating different databases to different slaves. See Replicating Different Databases to Different Slaves.

- If your master makes use of transactions and you are not concerned about transaction support on your slaves, use `MyISAM` or another nontransactional engine on the slaves. See Using Replication with Different Master and Slave Storage Engines.
- If your slaves are not acting as masters, and you have a potential solution in place to ensure that you can bring up a master in the event of failure, then you can switch off `--log-slave-updates` [1628]. This prevents “dumb” slaves from also logging events they have executed into their own binary log.

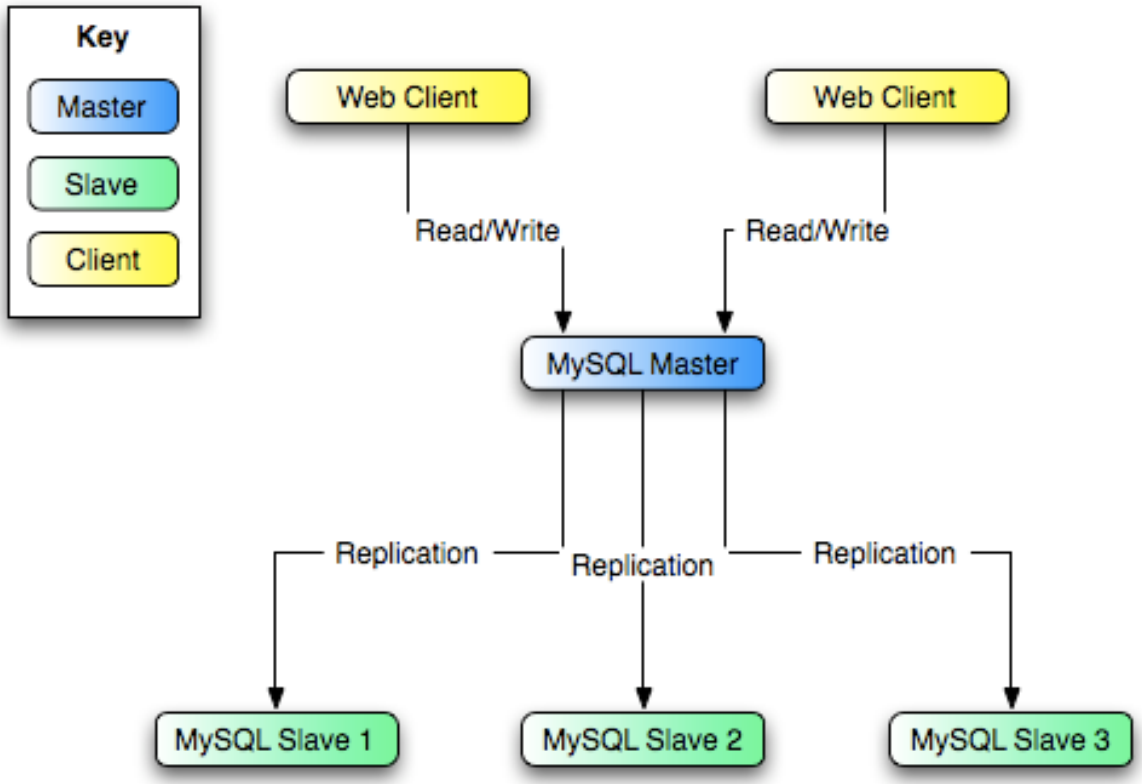
Switching Masters During Failover

There is currently no official solution for providing failover between master and slaves in the event of a failure. With the currently available features, you would have to set up a master and a slave (or several slaves), and to write a script that monitors the master to check whether it is up. Then instruct your applications and the slaves to change master in case of failure.

Remember that you can tell a slave to change its master at any time, using the `CHANGE MASTER TO` statement. The slave will not check whether the databases on the master are compatible with the slave, it will just start reading and executing events from the specified binary log coordinates on the new master. In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the database structure or integrity providing you are careful.

Run your slaves with the `--log-bin` [1647] option and without `--log-slave-updates` [1628]. In this way, the slave is ready to become a master as soon as you issue `STOP SLAVE`; `RESET MASTER`, and `CHANGE MASTER TO` statement on the other slaves. For example, assume that you have the structure shown in Figure 16.4, “Redundancy Using Replication, Initial Structure”.

Figure 16.4. Redundancy Using Replication, Initial Structure



In this diagram, the `MySQL Master` holds the master database, the `MySQL Slave` hosts are replication slaves, and the `Web Client` machines are issuing database reads and writes. Web clients

that issue only reads (and would normally be connected to the slaves) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scale-out replication structure, see Using Replication for Scale-Out.

Each MySQL Slave (`Slave 1`, `Slave 2`, and `Slave 3`) is a slave running with `--log-bin` [1647] and without `--log-slave-updates` [1628]. Because updates received by a slave from the master are not logged in the binary log unless `--log-slave-updates` [1628] is specified, the binary log on each slave is empty initially. If for some reason `MySQL Master` becomes unavailable, you can pick one of the slaves to become the new master. For example, if you pick `Slave 1`, all `Web Clients` should be redirected to `Slave 1`, which will log updates to its binary log. `Slave 2` and `Slave 3` should then replicate from `Slave 1`.

The reason for running the slave without `--log-slave-updates` [1628] is to prevent slaves from receiving updates twice in case you cause one of the slaves to become the new master. Suppose that `Slave 1` has `--log-slave-updates` [1628] enabled. Then it will write updates that it receives from `Master` to its own binary log. When `Slave 2` changes from `Master` to `Slave 1` as its master, it may receive updates from `Slave 1` that it has already received from `Master`

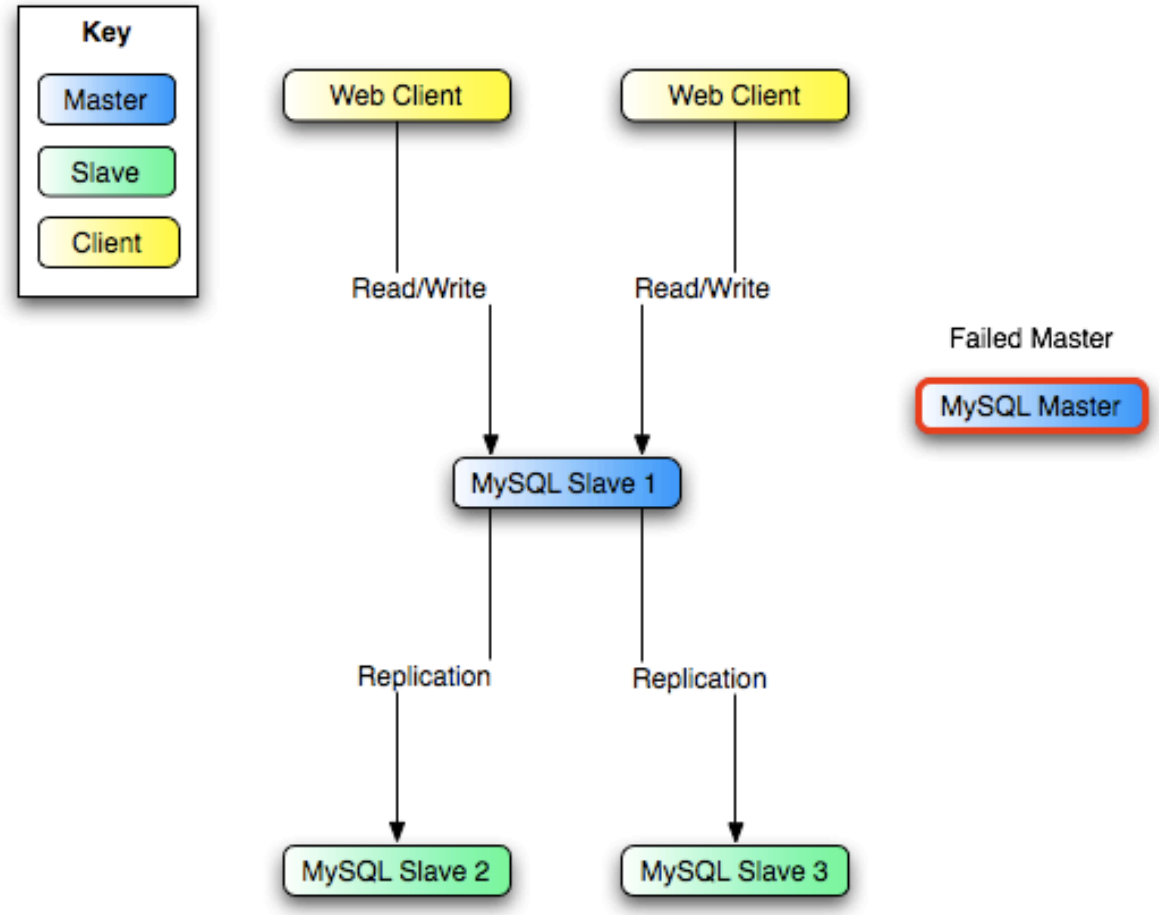
Make sure that all slaves have processed any statements in their relay log. On each slave, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all slaves, they can be reconfigured to the new setup. On the slave `Slave 1` being promoted to become the master, issue `STOP SLAVE` and `RESET MASTER`.

On the other slaves `Slave 2` and `Slave 3`, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='Slave1'` (where `'Slave1'` represents the real host name of `Slave 1`). To use `CHANGE MASTER TO`, add all information about how to connect to `Slave 1` from `Slave 2` or `Slave 3` (*`user`*, *`password`*, *`port`*). In `CHANGE MASTER TO`, there is no need to specify the name of the `Slave 1` binary log file or log position to read from: We know it is the first binary log file and position 4, which are the defaults for `CHANGE MASTER TO`. Finally, use `START SLAVE` on `Slave 2` and `Slave 3`.

Once the new replication is in place, you will then need to instruct each `Web Client` to direct its statements to `Slave 1`. From that point on, all updates statements sent by `Web Client` to `Slave 1` are written to the binary log of `Slave 1`, which then contains every update statement sent to `Slave 1` since `Master` died.

The resulting server structure is shown in Figure 16.5, “Redundancy Using Replication, After Master Failure”.

Figure 16.5. Redundancy Using Replication, After Master Failure



When `Master` is up again, you must issue on it the same `CHANGE MASTER TO` as that issued on `Slave 2` and `Slave 3`, so that `Master` becomes a slave of `S1` and picks up each `Web Client` writes that it missed while it was down.

To make `Master` a master again (for example, because it is the most powerful machine), use the preceding procedure as if `Slave 1` was unavailable and `Master` was to be the new master. During this procedure, do not forget to run `RESET MASTER` on `Master` before making `Slave 1`, `Slave 2`, and `Slave 3` slaves of `Master`. Otherwise, they may pick up old `Web Client` writes from before the point at which `Master` became unavailable.

Note that there is no synchronization between the different slaves to a master. Some slaves might be ahead of others. This means that the concept outlined in the previous example might not work. In practice, however, the relay logs of different slaves will most likely not be far behind the master, so it would work, anyway (but there is no guarantee).

A good way to keep your applications informed as to the location of the master is by having a dynamic DNS entry for the master. With `bind` you can use `nsupdate` to dynamically update your DNS.

Setting Up Replication Using SSL

To use SSL for encrypting the transfer of the binary log required during replication, both the master and the slave must support SSL network connections. If either host does not support SSL connections (because it has not been compiled or configured for SSL), replication through an SSL connection is not possible.

Setting up replication using an SSL connection is similar to setting up a server and client using SSL. You must obtain (or create) a suitable security certificate that you can use on the master, and a similar certificate (from the same certificate authority) on each slave.

For more information on setting up a server and client for SSL connectivity, see Configuring MySQL for SSL.

To enable SSL on the master you must create or obtain suitable certificates, and then add the following configuration options to the master's configuration within the `[mysqld]` section of the master's `my.cnf` file:

```
[mysqld]
ssl-ca=cacert.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

The paths to the certificates may be relative or absolute; we recommend that you always use complete paths for this purpose.

The options are as follows:

- `ssl-ca` identifies the Certificate Authority (CA) certificate.
- `ssl-cert` identifies the server public key. This can be sent to the client and authenticated against the CA certificate that it has.
- `ssl-key` identifies the server private key.

On the slave, you have two options available for setting the SSL information. You can either add the slave certificates to the `[client]` section of the slave's `my.cnf` file, or you can explicitly specify the SSL information using the `CHANGE MASTER TO` statement:

- To add the slave certificates using an option file, add the following lines to the `[client]` section of the slave's `my.cnf` file:

  ```
  [client]
  ssl-ca=cacert.pem
  ssl-cert=client-cert.pem
  ssl-key=client-key.pem
  ```

  Restart the slave server, using the `--skip-slave-start` [1640] option to prevent the slave from connecting to the master. Use `CHANGE MASTER TO` to specify the master configuration, using the `MASTER_SSL` option to enable SSL connectivity:

  ```
  mysql> CHANGE MASTER TO
      -> MASTER_HOST='master_hostname',
      -> MASTER_USER='replicate',
      -> MASTER_PASSWORD='password',
      -> MASTER_SSL=1;
  ```

- To specify the SSL certificate options using the `CHANGE MASTER TO` statement, append the SSL options:

  ```
  mysql> CHANGE MASTER TO
      -> MASTER_HOST='master_hostname',
      -> MASTER_USER='replicate',
      -> MASTER_PASSWORD='password',
      -> MASTER_SSL=1,
      -> MASTER_SSL_CA = 'ca_file_name',
      -> MASTER_SSL_CAPATH = 'ca_directory_name',
      -> MASTER_SSL_CERT = 'cert_file_name',
      -> MASTER_SSL_KEY = 'key_file_name';
  ```

After the master information has been updated, start the slave replication process:

```
mysql> START SLAVE;
```

You can use the SHOW SLAVE STATUS statement to confirm that the SSL connection was established successfully.

For more information on the CHANGE MASTER TO statement, see CHANGE MASTER TO Syntax.

If you want to enforce the use of SSL connections during replication, then create a user with the REPLICATION SLAVE [627] privilege and use the REQUIRE SSL option for that user. For example:

```
mysql> CREATE USER 'repl'@'%.mydomain.com' IDENTIFIED BY 'slavepass';
mysql> GRANT REPLICATION SLAVE ON *.*
    -> TO 'repl'@'%.mydomain.com' REQUIRE SSL;
```

If the account already exists, you can add REQUIRE SSL to it with this statement:

```
mysql> GRANT USAGE ON *.*
    -> TO 'repl'@'%.mydomain.com' REQUIRE SSL;
```

Replication Notes and Tips

Replication Features and Issues

The following sections provide information about what is supported and what is not in MySQL replication, and about specific issues and situations that may occur when replicating certain statements.

Statement-based replication depends on compatibility at the SQL level between the master and slave. In others, successful SBR requires that any SQL features used be supported by both the master and the slave servers. For example, if you use a feature on the master server that is available only in MySQL 5.1 (or later), you cannot replicate to a slave that uses MySQL 5.0 (or earlier).

Such incompatibilities also can occur within a release series when using pre-production releases of MySQL. For example, the SLEEP() [1042] function is available beginning with MySQL 5.0.12. If you use this function on the master, you cannot replicate to a slave that uses MySQL 5.0.11 or earlier.

For this reason, use Generally Available (GA) releases of MySQL for statement-based replication in a production setting, since we do not introduce new SQL statements or change their behavior within a given release series once that series reaches GA release status.

If you are planning to use statement-based replication between MySQL 5.1 and a previous MySQL release series, it is also a good idea to consult the edition of the *MySQL Reference Manual* corresponding to the earlier release series for information regarding the replication characteristics of that series.

With MySQL's statement-based replication, there may be issues with replicating stored routines or triggers. You can avoid these issues by using MySQL's row-based replication instead. For a detailed list of issues, see Binary Logging of Stored Programs. For more information about row-based logging and row-based replication, see Binary Logging Formats, and Replication Formats.

For additional information specific to replication and InnoDB, see InnoDB and MySQL Replication. For information relating to replication with MySQL Cluster, see MySQL Cluster Replication.

Replication and AUTO_INCREMENT

Statement-based replication of AUTO_INCREMENT, LAST_INSERT_ID() [1036], and TIMESTAMP values is done correctly, subject to the following exceptions:

- Prior to MySQL 5.1.12, a stored procedure that uses LAST_INSERT_ID() [1036] does not replicate properly using statement-based binary logging.
- Prior to MySQL 5.1.12, when a stored routine or trigger caused an INSERT into an AUTO_INCREMENT column, the generated AUTO_INCREMENT value was not written into the binary log, so a different value could in some cases be inserted on the slave.

- An insert into an `AUTO_INCREMENT` column caused by a stored routine or trigger running on a master that uses MySQL 5.0.60 or earlier does not replicate correctly to a slave running MySQL 5.1.12 through 5.1.23 (inclusive). (Bug #33029)

  A statement invoking a trigger or function that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. Beginning with MySQL 5.1.40, such statements are marked as unsafe. (Bug #45677)

- The `AUTO_INCREMENT` table option was not replicated correctly prior to MySQL 5.1.31. (Bug #41986)

- An `INSERT` into a table that has a composite primary key that includes an `AUTO_INCREMENT` column that is not the first column of this composite key is not safe for statement-based logging or replication. Beginning with MySQL 5.1.64, such statements are marked as unsafe. (Bug #11754117, Bug #45670)

  This issue does not affect tables using the `InnoDB` storage engine, since `InnoDB` does not allow the creation of a composite key that includes an `AUTO_INCREMENT` column that is not the first column in the key.

- Adding an `AUTO_INCREMENT` column to a table with `ALTER TABLE` might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to a table `t1` that has columns `col1` and `col2`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

  ```
  CREATE TABLE t2 LIKE t1;
  ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
  INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
  ```

  Important

  To guarantee the same ordering on both master and slave, the `ORDER BY` clause must name *all* columns of `t1`.

  The instructions just given are subject to the limitations of `CREATE TABLE ... LIKE`: Foreign key definitions are ignored, as are the `DATA DIRECTORY` and `INDEX DIRECTORY` table options. If a table definition includes any of those characteristics, create `t2` using a `CREATE TABLE` statement that is identical to the one used to create `t1`, but with the addition of the `AUTO_INCREMENT` column.

  Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

  ```
  DROP t1;
  ALTER TABLE t2 RENAME t1;
  ```

  See also Problems with `ALTER TABLE`.

Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

- If the master uses MySQL 4.1, you must *always* use the same *global* character set and collation on the master and the slave, regardless of the slave MySQL version. (These are controlled by the `--character-set-server` [422] and `--collation-server` [422] options.) Otherwise, you may get duplicate-key errors on the slave, because a key that is unique in the master character set might not be unique in the slave character set. Note that this is not a cause for concern when master and slave are both MySQL 5.0 or later.

- If the master is older than MySQL 4.1.3, the character set of any client should never be made different from its global value because this character set change is not known to the slave. In other words, clients should not use `SET NAMES`, `SET CHARACTER SET`, and so forth. If both the master and the slave are 4.1.3 or newer, clients can freely set session values for character set variables because these settings are written to the binary log and so are known to the slave. That is, clients can use `SET NAMES` or `SET CHARACTER SET` or can set variables such as `collation_client` or `collation_server` [467]. However, clients are prevented from changing the *global* value of these variables; as stated previously, the master and slave must always have identical global character set values. This is true whether you are using statement-based or row-based replication.

- If the master has databases with a character set different from the global `character_set_server` [465] value, you should design your `CREATE TABLE` statements so that they do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in `CREATE TABLE` statements.

Replication of `CREATE ... IF NOT EXISTS` Statements

This section discusses the rules that are applied when various `CREATE ... IF NOT EXISTS` statements are replicated.

Previous to MySQL 5.1.38. `CREATE DATABASE IF NOT EXISTS` was replicated only if the database named in the statement did not exist on the master. `CREATE TABLE IF NOT EXISTS` was replicated only if the table named in the statement did not exist on the master.

MySQL 5.1.39 and later. Every `CREATE DATABASE IF NOT EXISTS` statement is replicated, whether or not the database already exists on the master. Similarly, every `CREATE TABLE IF NOT EXISTS` statement is replicated, whether or not the table already exists on the master. This includes `CREATE TABLE IF NOT EXISTS ... LIKE`. However, replication of `CREATE TABLE IF NOT EXISTS ... SELECT` follows somewhat different rules; see Replication of `CREATE TABLE ... SELECT` Statements, for more information.

Replication of `CREATE EVENT IF NOT EXISTS`. `CREATE EVENT IF NOT EXISTS` is always replicated, whether or not the event named in the statement already exists on the master. This is true for all MySQL 5.1 releases beginning with MySQL 5.1.6, when this statement was introduced.

See also Bug #45574.

Replication of `CREATE TABLE ... SELECT` Statements

This section discusses how MySQL replicates `CREATE TABLE ... SELECT` statements.

These behaviors are not dependent on MySQL version:

- `CREATE TABLE ... SELECT` always performs an implicit commit (Statements That Cause an Implicit Commit).

- If destination table does not exist, logging occurs as follows. It does not matter whether `IF NOT EXISTS` is present.

  - `STATEMENT` or `MIXED` format: The statement is logged as written.

  - `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.

- If the statement fails, nothing is logged. This includes the case that the destination table exists and `IF NOT EXISTS` is not given.

When the destination table exists and `IF NOT EXISTS` is given, MySQL handles the statement in a version-dependent way.

In MySQL 5.1 before 5.1.51 and in MySQL 5.5 before 5.5.6 (this is the original behavior):

- `STATEMENT` or `MIXED` format: The statement is logged as written.
- `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.

In MySQL 5.1 as of 5.1.51:

- `STATEMENT` or `MIXED` format: The statement is logged as the equivalent pair of `CREATE TABLE` and `INSERT INTO ... SELECT` statements.
- `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.

In MySQL 5.5 as of 5.5.6:

- Nothing is inserted or logged.

These version dependencies arise due to a change in MySQL 5.5.6 in handling of `CREATE TABLE ... SELECT` not to insert rows if the destination table already exists, and a change made in MySQL 5.1.51 to preserve forward compatibility in replication of such statements from a 5.1 master to a 5.5 slave. For details, see `CREATE TABLE ... SELECT` Syntax.

Replication of `CURRENT_USER()`

The following statements support use of the `CURRENT_USER()` [1033] function to take the place of the name of (and, possibly, the host for) an affected user or a definer; in such cases, `CURRENT_USER()` [1033] is expanded where and as needed:

- `DROP USER`
- `RENAME USER`
- `GRANT`
- `REVOKE`
- `CREATE FUNCTION`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`
- `CREATE EVENT`
- `CREATE VIEW`
- `ALTER EVENT`
- `ALTER VIEW`
- `SET PASSWORD`

In all MySQL 5.1 releases, when `CURRENT_USER()` [1033] or `CURRENT_USER` [1033] is used as the definer in any of the statements `CREATE FUNCTION`, `CREATE PROCEDURE`, `CREATE TRIGGER`, `CREATE EVENT`, `CREATE VIEW`, or `ALTER VIEW` when binary logging is enabled, the function reference is expanded before it is written to the binary log, so that the statement refers to the same user on both the master and the slave when the statement is replicated. Beginning with MySQL 5.1.49, `CURRENT_USER()` [1033] or `CURRENT_USER` [1033] is also expanded prior to being written to the binary log when used in `DROP USER`, `RENAME USER`, `GRANT`, `REVOKE`, or `ALTER EVENT`. (Bug #48321)

Replication of CREATE SERVER, ALTER SERVER, and DROP SERVER

In MySQL 5.1, the statements CREATE SERVER, ALTER SERVER, and DROP SERVER are logged only when binlog_format [1654] is equal to ROW. These statements are not written to the binary log when using either the statement-based or mixed logging format.

Replication of DROP ... IF EXISTS Statements

The DROP DATABASE IF EXISTS, DROP TABLE IF EXISTS, and DROP VIEW IF EXISTS statements are always replicated, even if the database, table, or view to be dropped does not exist on the master. This is to ensure that the object to be dropped no longer exists on either the master or the slave, once the slave has caught up with the master.

Beginning with MySQL 5.1.33, DROP ... IF EXISTS statements for stored programs (stored procedures and functions, triggers, and events) are also replicated, even if the stored program to be dropped does not exist on the master. (Bug #13684)

Replication with Differing Table Definitions on Master and Slave

Starting with MySQL 5.1.21, source and target tables for replication do not have to be identical. A table on the master can have more or fewer columns than the slave's copy of the table. In addition, corresponding table columns on the master and the slave can use different data types, subject to certain conditions.

In all cases where the source and target tables do not have identical definitions, the database and table names must be the same on both the master and the slave. Additional conditions are discussed, with examples, in the following two sections.

Replication with More Columns on Master or Slave

Starting with MySQL 5.1.21, you can replicate a table from the master to the slave such that the master and slave copies of the table have differing numbers of columns, subject to the following conditions:

- Columns common to both versions of the table must be defined in the same order on the master and the slave.

  (This is true even if both tables have the same number of columns.)

- Columns common to both versions of the table must be defined before any additional columns.

  This means that executing an ALTER TABLE statement on the slave where a new column is inserted into the table within the range of columns common to both tables causes replication to fail, as shown in the following example:

  Suppose that a table t, existing on the master and the slave, is defined by the following CREATE TABLE statement:

  ```
  CREATE TABLE t (
      c1 INT,
      c2 INT,
      c3 INT
  );
  ```

  Suppose that the ALTER TABLE statement shown here is executed on the slave:

  ```
  ALTER TABLE t ADD COLUMN cnew1 INT AFTER c3;
  ```

  The previous ALTER TABLE is permitted on the slave because the columns c1, c2, and c3 that are common to both versions of table t remain grouped together in both versions of the table, before any columns that differ.

  However, the following ALTER TABLE statement cannot be executed on the slave without causing replication to break:

```
ALTER TABLE t ADD COLUMN cnew2 INT AFTER c3;
```

Replication fails after execution on the slave of the `ALTER TABLE` statement just shown, because the new column `cnew2` comes between columns common to both versions of `t`.

- Each “extra” column in the version of the table having more columns must have a default value.

Note

A column's default value is determined by a number of factors, including its type, whether it is defined with a `DEFAULT` option, whether it is declared as `NULL`, and the server SQL mode in effect at the time of its creation; for more information, see Data Type Default Values).

In addition, when the slave's copy of the table has more columns than the master's copy, each column common to the tables must use the same data type in both tables.

Examples. The following examples illustrate some valid and invalid table definitions:

More columns on the master. The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave>  CREATE TABLE t1 (c1 INT, c2 INT);
```

The following table definitions would raise Error 1532 (`ER_BINLOG_ROW_RBR_TO_SBR` [3991]) because the definitions of the columns common to both versions of the table are in a different order on the slave than they are on the master:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave>  CREATE TABLE t1 (c2 INT, c1 INT);
```

The following table definitions would also raise Error 1532 because the definition of the extra column on the master appears before the definitions of the columns common to both versions of the table:

```
master> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
slave>  CREATE TABLE t1 (c1 INT, c2 INT);
```

More columns on the slave. The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave>  CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

The following definitions raise Error 1532 because the columns common to both versions of the table are not defined in the same order on both the master and the slave:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave>  CREATE TABLE t1 (c2 INT, c1 INT, c3 INT);
```

The following table definitions also raise Error 1532 because the definition for the extra column in the slave's version of the table appears before the definitions for the columns which are common to both versions of the table:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave>  CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
```

The following table definitions fail because the slave's version of the table has additional columns compared to the master's version, and the two versions of the table use different data types for the common column `c2`:

```
master> CREATE TABLE t1 (c1 INT, c2 BIGINT);
slave>  CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

Replication of Columns Having Different Data Types

Corresponding columns on the master's and the slave's copies of the same table ideally should have the same data type. However, beginning with MySQL 5.1.21, this is not always strictly enforced, as long as certain conditions are met.

All other things being equal, it is always possible to replicate from a column of a given data type to another column of the same type and same size or width, where applicable, or larger. For example, you can replicate from a `CHAR(10)` column to another `CHAR(10)`, or from a `CHAR(10)` column to a `CHAR(25)` column without any problems. In certain cases, it also possible to replicate from a column having one data type (on the master) to a column having a different data type (on the slave); when the data type of the master's version of the column is promoted to a type that is the same size or larger on the slave, this is known as *attribute promotion*.

Attribute promotion can be used with both statement-based and row-based replication, and is not dependent on the storage engine used by either the master or the slave. However, the choice of logging format does have an effect on the type conversions that are permitted; the particulars are discussed later in this section.

Important

Whether you use statement-based or row-based replication, the slave's copy of the table cannot contain more columns than the master's copy if you wish to employ attribute promotion.

Statement-based replication. When using statement-based replication, a simple rule of thumb to follow is, “If the statement run on the master would also execute successfully on the slave, it should also replicate successfully”. In other words, if the statement uses a value that is compatible with the type of a given column on the slave, the statement can be replicated. For example, you can insert any value that fits in a `TINYINT` column into a `BIGINT` column as well; it follows that, even if you change the type of a `TINYINT` column in the slave's copy of a table to `BIGINT`, any insert into that column on the master that succeeds should also succeed on the slave, since it is impossible to have a legal `TINYINT` value that is large enough to exceed a `BIGINT` column.

Note

The restrictions described in the next few paragraphs do not apply to MySQL Cluster Replication, beginning with MySQL Cluster NDB 6.3.33, 7.0.14, and 7.1.3. These and later versions of MySQL Cluster support attribute promotion and demotion (such as `TINYINT` to `BIGINT`, and `VARCHAR(50)` to `CHAR(25)`, respectively) in replication; see Attribute promotion and demotion (MySQL Cluster), for more information.

Row-based replication. For row-based replication, the case is not so simple, due to the fact that changes rather than statements are replicated, and these changes are transmitted from master to slave using formats that do not always map directly to MySQL server column data types. For example, with row-based binary logging, you cannot replicate between different `INT` subtypes, such as from `TINYINT` to `BIGINT`, because changes to columns of these types are represented differently from one another in the binary log when using row-based logging. However, you can replicate from `BLOB` to `TEXT` using row-based replication because changes to `BLOB` and `TEXT` columns are represented using the same format in the binary log.

Supported conversions for attribute promotion when using row-based replication are shown in the following table:

From (Master)	To (Slave)
`BINARY`	`CHAR`
`BLOB`	`TEXT`

From (Master)	To (Slave)
CHAR	BINARY
DECIMAL	NUMERIC
NUMERIC	DECIMAL
TEXT	BLOB
VARBINARY	VARCHAR
VARCHAR	VARBINARY

Note

In all cases, the size or width of the column on the slave must be equal to or greater than that of the column on the master. For example, you can replicate from a `CHAR(10)` column on the master to a column that uses `BINARY(10)` or `BINARY(25)` on the slave, but you cannot replicate from a `CHAR(10)` column on the master to `BINARY(5)` column on the slave.

Any unique index (including primary keys) having a prefix must use a prefix of the same length on both master and slave; in such cases, differing prefix lengths are disallowed. It is possible to use a nonunique index whose prefix length differs between master and slave, but this can cause serious performance issues, particularly when the prefix used on the master is longer. This is due to the fact that 2 unique prefixes of a given length may no longer be unique at a shorter length; for example, the words *catalogue* and *catamount* have the 5-character prefixes *catal* and *catam*, respectively, but share the same 4-character prefix (*cata*). This can lead to queries that use such indexes executing less efficiently on the slave, when a shorter prefix is employed in the slave' definition of the same index than on the master.

For `DECIMAL` and `NUMERIC` columns, both the mantissa (*M*) and the number of decimals (*D*) must be the same size or larger on the slave as compared with the master. For example, replication from a `NUMERIC(5,4)` to a `DECIMAL(6,4)` works, but not from a `NUMERIC(5,4)` to a `DECIMAL(5,3)`.

MySQL (except for MySQL Cluster) does *not* support attribute promotion of any of the following data types to or from any other data type when using row-based replication:

- `INT` (including `TINYINT`, `SMALLINT`, `MEDIUMINT`, `BIGINT`).

  Promotion between `INT` subtypes—for example, from `SMALLINT` to `BIGINT`—is also not supported.

- `SET` or `ENUM`.

- `FLOAT` or `DOUBLE`.

- All of the data types relating to dates, times, or both: `DATE`, `TIME`, `DATETIME`, `TIMESTAMP`, and `YEAR`.

Attribute promotion and demotion (MySQL Cluster). Beginning with MySQL Cluster NDB 6.3.33, 7.0.14, and 7.1.3, MySQL Cluster Replication supports attribute promotion and demotion between smaller data types and larger types. It is also possible to specify whether or not to permit lossy (truncated) or non-lossy conversions of demoted column values, as explained later in this section.

Lossy and non-lossy conversions. In the event that the target type cannot represent the value being inserted, a decision must be made on how to handle the conversion. If we permit the conversion but truncate (or otherwise modify) the source value to achieve a “fit” in the target column, we make what is known as a *lossy conversion*. A conversion which does not require truncation or similar modifications to fit the source column value in the target column is a *non-lossy* conversion.

Type conversion modes (`slave_type_conversions` variable). The setting of the `slave_type_conversions` global server variable controls the type conversion mode used on the slave. This variable takes a set of values from the following table, which shows the effects of each mode on the slave's type-conversion behavior:

Mode	Effect
`ALL_LOSSY`	In this mode, type conversions that would mean loss of information are permitted. This does not imply that non-lossy conversions are permitted, merely that only cases requiring either lossy conversions or no conversion at all are permitted; for example, enabling *only* this mode permits an `INT` column to be converted to `TINYINT` (a lossy conversion), but not a `TINYINT` column to an `INT` column (non-lossy). Attempting the latter conversion in this case would cause replication to stop with an error on the slave.
`ALL_NON_LOSSY`	This mode permits conversions that do not require truncation or other special handling of the source value; that is, it permits conversions where the source type has a wider range than the target type. Setting this mode has no bearing on whether lossy conversions are permitted; this is controlled with the `ALL_LOSSY` mode. If only `ALL_NON_LOSSY` is set, but not `ALL_LOSSY`, then attempting a conversion that would result in the loss of data (such as `INT` to `TINYINT`, or `CHAR(25)` to `VARCHAR(20)`) causes the slave to stop with an error.
`ALL_LOSSY,ALL_NON_LOSSY`	When this mode is set, all supported type conversions are permitted, whether or not they are lossy conversions.
[*empty*]	When `slave_type_conversions` is not set, no attribute promotion or demotion is permitted; this means that all columns in the source and target tables must be of the same types. This mode is the default.

Changing the type conversion mode requires restarting the slave with the new `slave_type_conversions` setting.

Supported conversions. Supported conversions between different but similar data types are shown in the following list:

- Between any of the integer types `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`.

  This includes conversions between the signed and unsigned versions of these types.

  Lossy conversions are made by truncating the source value to the maximum (or minimum) permitted by the target column. For insuring non-lossy conversions when going from unsigned to signed types, the target column must be large enough to accommodate the range of values in the source column. For example, you can demote `TINYINT UNSIGNED` non-lossily to `SMALLINT`, but not to `TINYINT`.

- Between any of the decimal types `DECIMAL`, `FLOAT`, `DOUBLE`, and `NUMERIC`.

  `FLOAT` to `DOUBLE` is a non-lossy conversion; `DOUBLE` to `FLOAT` can only be handled lossily. A conversion from `DECIMAL(M,D)` to `DECIMAL(M',D')` where `M' => M` and `D' => D` is non-lossy; for any case where `M' < M`, `D' < D`, or both, only a lossy conversion can be made.

  For any of the decimal types, if a value to be stored cannot be fit in the target type, the value is rounded down according to the rounding rules defined for the server elsewhere in the documentation. See Rounding Behavior, for information about how this is done for decimal types.

- Between any of the string types `CHAR`, `VARCHAR`, and `TEXT`, including conversions between different widths.

  Conversion of a `CHAR`, `VARCHAR`, or `TEXT` to a `CHAR`, `VARCHAR`, or `TEXT` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first *`N`* characters of the string on the slave, where *`N`* is the width of the target column.

  Important

  Replication between columns using different character sets is not supported.

- Between any of the binary data types `BINARY`, `VARBINARY`, and `BLOB`, including conversions between different widths.

  Conversion of a `BINARY`, `VARBINARY`, or `BLOB` to a `BINARY`, `VARBINARY`, or `BLOB` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first *`N`* bytes of the string on the slave, where *`N`* is the width of the target column.

- Between any 2 `BIT` columns of any 2 sizes.

  When inserting a value from a `BIT(`*`M`*`)` column into a `BIT(`*`M'`*`)` column, where *`M' > M`*, the most significant bits of the `BIT(`*`M'`*`)` columns are cleared (set to zero) and the *`M`* bits of the `BIT(`*`M`*`)` value are set as the least significant bits of the `BIT(`*`M'`*`)` column.

  When inserting a value from a source `BIT(`*`M`*`)` column into a target `BIT(`*`M'`*`)` column, where *`M' < M`*, the maximum possible value for the `BIT(`*`M'`*`)` column is assigned; in other words, an “all-set” value is assigned to the target column.

Conversions between types not in the previous list are not permitted.

Replication and `DIRECTORY` Table Options

If a `DATA DIRECTORY` or `INDEX DIRECTORY` table option is used in a `CREATE TABLE` statement on the master server, the table option is also used on the slave. This can cause problems if no corresponding directory exists in the slave host file system or if it exists but is not accessible to the slave server. This can be overridden by using the `NO_DIR_IN_CREATE` [573] server SQL mode on the slave, which causes the slave to ignore the `DATA DIRECTORY` and `INDEX DIRECTORY` table options when replicating `CREATE TABLE` statements. The result is that `MyISAM` data and index files are created in the table's database directory.

For more information, see Server SQL Modes.

Replication of Invoked Features

Replication of invoked features such as user-defined functions (UDFs) and stored programs (stored procedures and functions, triggers, and events) was re-implemented in MySQL 5.1.18 to provide the following characteristics:

- The effects of the feature are always replicated.
- The following statements are replicated using statement-based replication:
  - `CREATE EVENT`
  - `ALTER EVENT`
  - `DROP EVENT`
  - `CREATE PROCEDURE`
  - `DROP PROCEDURE`

- `CREATE FUNCTION`
- `DROP FUNCTION`
- `CREATE TRIGGER`
- `DROP TRIGGER`

However, the *effects* of features created, modified, or dropped using these statements are replicated using row-based replication.

Note

Attempting to replicate invoked features using statement-based replication produces the warning `Statement may not be safe to log in statement format`. (Prior to MySQL 5.1.36, this was `Statement is not safe to log in statement format`; see Bug #42415.) For example, trying to replicate a UDF with statement-based replication generates this warning because it currently cannot be determined by the MySQL server whether the UDF is deterministic. If you are absolutely certain that the invoked feature's effects are deterministic, you can safely disregard such warnings.

- In the case of `CREATE EVENT` and `ALTER EVENT`:
  - The status of the event is set to `SLAVESIDE_DISABLED` on the slave regardless of the state specified (this does not apply to `DROP EVENT`).
  - The master on which the event was created is identified on the slave by its server ID. The `ORIGINATOR` column in `INFORMATION_SCHEMA.EVENTS` and the `originator` column in `mysql.event` were added to these tables in MySQL 5.1.18 to store this information. See The `INFORMATION_SCHEMA EVENTS` Table, and `SHOW EVENTS` Syntax, for more information.
- The feature implementation resides on the slave in a renewable state so that if the master fails, the slave can be used as the master without loss of event processing.

To determine whether there are any scheduled events on a MySQL server that were created on a different server (that was acting as a replication master), query the `INFORMATION_SCHEMA.EVENTS` table in a manner similar to what is shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME
    FROM INFORMATION_SCHEMA.EVENTS
    WHERE STATUS = 'SLAVESIDE_DISABLED';
```

Alternatively, you can use the `SHOW EVENTS` statement, like this:

```
SHOW EVENTS
    WHERE STATUS = 'SLAVESIDE_DISABLED';
```

When promoting a replication slave having such events to a replication master, you must enable each event using `ALTER EVENT event_name ENABLED`, where *`event_name`* is the name of the event.

If more than one master was involved in creating events on this slave, and you wish to identify events that were created only on a given master having the server ID *`master_id`*, modify the previous query on the `EVENTS` table to include the `ORIGINATOR` column, as shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME, ORIGINATOR
    FROM INFORMATION_SCHEMA.EVENTS
    WHERE STATUS = 'SLAVESIDE_DISABLED'
    AND   ORIGINATOR = 'master_id'
```

You can employ `ORIGINATOR` with the `SHOW EVENTS` statement in a similar fashion:

```
SHOW EVENTS
    WHERE STATUS = 'SLAVESIDE_DISABLED'
    AND   ORIGINATOR = 'master_id'
```

Before enabling events that were replicated from the master, you should disable the MySQL Event Scheduler on the slave (using a statement such as `SET GLOBAL event_scheduler = OFF;`), run any necessary `ALTER EVENT` statements, restart the server, then re-enable the Event Scheduler on the slave afterward (using a statement such as `SET GLOBAL event_scheduler = ON;`)-

If you later demote the new master back to being a replication slave, you must disable manually all events enabled by the `ALTER EVENT` statements. You can do this by storing in a separate table the event names from the `SELECT` statement shown previously, or using `ALTER EVENT` statements to rename the events with a common prefix such as `replicated_` to identify them.

If you rename the events, then when demoting this server back to being a replication slave, you can identify the events by querying the `EVENTS` table, as shown here:

```
SELECT CONCAT(EVENT_SCHEMA, '.', EVENT_NAME) AS 'Db.Event'
      FROM INFORMATION_SCHEMA.EVENTS
      WHERE INSTR(EVENT_NAME, 'replicated_') = 1;
```

Replication and Floating-Point Values

With statement-based replication, values are converted from decimal to binary. Because conversions between decimal and binary representations of them may be approximate, comparisons involving floating-point values are inexact. This is true for operations that use floating-point values explicitly, or that use values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on master and slave servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See Type Conversion in Expression Evaluation, and Problems with Floating-Point Values.

Replication and `FLUSH`

Some forms of the `FLUSH` statement are not logged because they could cause problems if replicated to a slave: `FLUSH LOGS`, `FLUSH MASTER`, `FLUSH SLAVE`, and `FLUSH TABLES WITH READ LOCK`. For a syntax example, see `FLUSH` Syntax. The `FLUSH TABLES`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements are written to the binary log and thus replicated to slaves. This is not normally a problem because these statements do not modify table data.

However, this behavior can cause difficulties under certain circumstances. If you replicate the privilege tables in the `mysql` database and update those tables directly without using `GRANT`, you must issue a `FLUSH PRIVILEGES` on the slaves to put the new privileges into effect. In addition, if you use `FLUSH TABLES` when renaming a `MyISAM` table that is part of a `MERGE` table, you must issue `FLUSH TABLES` manually on the slaves. These statements are written to the binary log unless you specify `NO_WRITE_TO_BINLOG` or its alias `LOCAL`.

Replication and System Functions

Certain functions do not replicate well under some conditions:

- The `USER()` [1039], `CURRENT_USER()` [1033] (or `CURRENT_USER` [1033]), `UUID()` [1042], `VERSION()` [1039], `LOAD_FILE()` [953], and `RAND()` [975] functions are replicated without change and thus do not work reliably on the slave unless row-based replication is enabled. (See Replication Formats.)

  For early implementations of mixed-format logging, stored functions, triggers, and views that use these functions in their body do not replicate reliably in mixed-format logging mode because the logging did not switch from statement-based to row-based format. For example, `INSERT INTO t SELECT FROM v`, where `v` is a view that selects `UUID()` [1042] could cause problems. This limitation is lifted in MySQL 5.1.12.

Beginning with MySQL 5.1.23, `USER()` [1039] and `CURRENT_USER()` [1033] are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #28086) (See also Replication of `CURRENT_USER()`.)

Beginning with MySQL 5.1.42, `VERSION()` [1039] is also automatically replicated using row-based replication when using `MIXED` mode, and generates a warning in `STATEMENT` mode. (Bug #47995) Beginning with MySQL 5.1.43, this is also true with regard to the `RAND()` [975] function. (Bug #49222)

- For `NOW()` [990], the binary log includes the timestamp. This means that the value *as returned by the call to this function on the master* is replicated to the slave. This can lead to a possibly unexpected result when replicating between MySQL servers in different time zones. Suppose that the master is located in New York, the slave is located in Stockholm, and both servers are using local time. Suppose further that, on the master, you create a table `mytable`, perform an `INSERT` statement on this table, and then select from the table, as shown here:

```
mysql> CREATE TABLE mytable (mycol TEXT);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO mytable VALUES ( NOW() );
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM mytable;
+---------------------+
| mycol               |
+---------------------+
| 2009-09-01 12:00:00 |
+---------------------+
1 row in set (0.00 sec)
```

Local time in Stockholm is 6 hours later than in New York; so, if you issue `SELECT NOW()` on the slave at that exact same instant, the value `2009-09-01 18:00:00` is returned. For this reason, if you select from the slave's copy of `mytable` after the `CREATE TABLE` and `INSERT` statements just shown have been replicated, you might expect `mycol` to contain the value `2009-09-01 18:00:00`. However, this is not the case; when you select from the slave's copy of `mytable`, you obtain exactly the same result as on the master:

```
mysql> SELECT * FROM mytable;
+---------------------+
| mycol               |
+---------------------+
| 2009-09-01 12:00:00 |
+---------------------+
1 row in set (0.00 sec)
```

Unlike `NOW()` [990], the `SYSDATE()` [992] function is not replication-safe because it is not affected by `SET TIMESTAMP` statements in the binary log and is nondeterministic if statement-based logging is used. This is not a problem if row-based logging is used.

An alternative is to use the `--sysdate-is-now` [446] option to cause `SYSDATE()` [992] to be an alias for `NOW()` [990]. This must be done on the master and the slave to work correctly. In such cases, a warning is still issued by this function, but can safely be ignored as long as `--sysdate-is-now` [446] is used on both the master and the slave.

Beginning with MySQL 5.1.42, `SYSDATE()` [992] is automatically replicated using row-based replication when using `MIXED` mode, and generates a warning in `STATEMENT` mode. (Bug #47995)

See also Replication and Time Zones.

- *The following restriction applies to statement-based replication only, not to row-based replication.* The `GET_LOCK()` [1040], `RELEASE_LOCK()` [1042], `IS_FREE_LOCK()` [1041], and `IS_USED_LOCK()` [1042] functions that handle user-level locks are replicated without the slave knowing the concurrency context on the master. Therefore, these functions should not be used to

insert into a master table because the content on the slave would differ. For example, do not issue a statement such as `INSERT INTO mytable VALUES(GET_LOCK(...))`.

Beginning with MySQL 5.1.42, these functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #47995)

As a workaround for the preceding limitations when statement-based replication is in effect, you can use the strategy of saving the problematic function result in a user variable and referring to the variable in a later statement. For example, the following single-row `INSERT` is problematic due to the reference to the `UUID()` [1042] function:

```
INSERT INTO t VALUES(UUID());
```

To work around the problem, do this instead:

```
SET @my_uuid = UUID();
INSERT INTO t VALUES(@my_uuid);
```

That sequence of statements replicates because the value of `@my_uuid` is stored in the binary log as a user-variable event prior to the `INSERT` statement and is available for use in the `INSERT`.

The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

```
SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
INSERT INTO t VALUES(@my_uuid1),(@my_uuid2);
```

However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

```
INSERT INTO t2 SELECT UUID(), * FROM t1;
```

Within a stored function, `RAND()` [975] replicates correctly as long as it is invoked only once during the execution of the function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

The `FOUND_ROWS()` [1035] and `ROW_COUNT()` [1038] functions are not replicated reliably using statement-based replication. A workaround is to store the result of the function call in a user variable, and then use that in the `INSERT` statement. For example, if you wish to store the result in a table named `mytable`, you might normally do so like this:

```
SELECT SQL_CALC_FOUND_ROWS FROM mytable LIMIT 1;
INSERT INTO mytable VALUES( FOUND_ROWS() );
```

However, if you are replicating `mytable`, you should use `SELECT ... INTO`, and then store the variable in the table, like this:

```
SELECT SQL_CALC_FOUND_ROWS INTO @found_rows FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(@found_rows);
```

In this way, the user variable is replicated as part of the context, and applied on the slave correctly.

Beginning with MySQL 5.1.23, these functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #12092, Bug #30244)

Replication and `LIMIT`

Statement-based replication of `LIMIT` clauses in `DELETE`, `UPDATE`, and `INSERT ... SELECT` statements is unsafe since the order of the rows affected is not defined. (Such statements can be replicated correctly with statement-based replication only if they also contain an `ORDER BY` clause.) Beginning with MySQL 5.1.24, when such a statement is encountered:

- When using `STATEMENT` mode, a warning that the statement is not safe for statement-based replication is now issued.

Currently, when using `STATEMENT` mode, warnings are issued for DML statements containing `LIMIT` even when they also have an `ORDER BY` clause (and so are made deterministic). This is a known issue. (Bug #42851)

- When using `MIXED` mode, the statement is now automatically replicated using row-based mode.

Replication and `LOAD DATA INFILE`

The `LOAD DATA INFILE` statement was not always replicated correctly to a slave running MySQL 5.1.42 or earlier from a master running MySQL 4.0 or earlier. When using statement-based replication, the `LOAD DATA INFILE` statement `CONCURRENT` option was not replicated. This issue was fixed in MySQL 5.1.43. This issue does not have any impact on `CONCURRENT` option handling when using row-based replication in MySQL 5.1 or later. (Bug #34628)

In MySQL 5.1.52 and later, `LOAD DATA INFILE` is considered unsafe (see Determination of Safe and Unsafe Statements in Binary Logging). It causes a warning when using statement-based logging format, and is logged using row-based format when using mixed-format logging.

Replication and the Slow Query Log

Prior to MySQL 5.1.45, replication slaves did not write replicated queries to the slow query log, even if the same queries were written to the slow query log on the master. (Bug #23300)

Replication and `REPAIR TABLE`

When used on a corrupted or otherwise damaged table, it is possible for the `REPAIR TABLE` statement to delete rows that cannot be recovered. However, any such modifications of table data performed by this statement are not replicated, which can cause master and slave to lose synchronization. For this reason, in the event that a table on the master becomes damaged and you use `REPAIR TABLE` to repair it, you should first stop replication (if it is still running) before using `REPAIR TABLE`, then afterward compare the master's and slave's copies of the table and be prepared to correct any discrepancies manually, before restarting replication.

Replication and Master or Slave Shutdowns

It is safe to shut down a master server and restart it later. When a slave loses its connection to the master, the slave tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the `CHANGE MASTER TO` statement or `--master-connect-retry` [1630] option. A slave also is able to deal with network connectivity outages. However, the slave notices the network outage only after receiving no data from the master for `slave_net_timeout` [1645] seconds. If your outages are short, you may want to decrease `slave_net_timeout` [1645]. See Server System Variables.

An unclean shutdown (for example, a crash) on the master side can result in the master binary log having a final position less than the most recent position read by the slave, due to the master binary log file not being flushed. This can cause the slave not to be able to replicate when the master comes back up. Setting `sync_binlog=1` [1657] in the master `my.cnf` file helps to minimize this problem because it causes the master to flush its binary log more frequently.

Shutting down a slave cleanly is safe because it keeps track of where it left off. However, be careful that the slave does not have temporary tables open; see Replication and Temporary Tables. Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the problem occurred:

- For transactions, the slave commits and then updates `relay-log.info`. If a crash occurs between these two operations, relay log processing will have proceeded further than the information file indicates and the slave will re-execute the events from the last transaction in the relay log after it has been restarted.

- A similar problem can occur if the slave updates `relay-log.info` but the server host crashes before the write has been flushed to disk. Writes are not forced to disk because the server relies on the operating system to flush the file from time to time.

The fault tolerance of your system for these types of problems is greatly increased if you have a good uninterruptible power supply.

Replication and `max_allowed_packet`

`max_allowed_packet` [493] sets an upper limit on the size of any single message between the MySQL server and clients, including replication slaves. If you are replicating large column values (such as might be found in `TEXT` or `BLOB` columns) and `max_allowed_packet` [493] is too small on the master, the master fails with an error, and the slave shuts down the I/O thread. If `max_allowed_packet` [493] is too small on the slave, this also causes the slave to stop the I/O thread.

Prior to MySQL 5.1.40, `Last_IO_Error` and `Last_IO_Errno` in the output of `SHOW SLAVE STATUS` were not set in the event that replication failed due to exceeding `max_allowed_packet` [493] (Bug #42914).

Row-based replication currently sends all columns and column values for updated rows from the master to the slave, including values of columns that were not actually changed by the update. This means that, when you are replicating large column values using row-based replication, you must take care to set `max_allowed_packet` [493] large enough to accommodate the largest row in any table to be replicated, even if you are replicating updates only, or you are inserting only relatively small values.

Replication and `MEMORY` Tables

When a master server shuts down and restarts, its `MEMORY` tables become empty. To replicate this effect to slaves, the first time that the master uses a given `MEMORY` table after startup, it logs an event that notifies slaves that the table must to be emptied by writing a `DELETE` statement for that table to the binary log.

When a slave server shuts down and restarts, its `MEMORY` tables become empty. This causes the slave to be out of synchrony with the master and may lead to other failures or cause the slave to stop:

- Row-format updates and deletes received from the master may fail with `Can't find record in 'memory_table'`.
- Statements such as `INSERT INTO ... SELECT FROM memory_table` may insert a different set of rows on the master and slave.

The safe way to restart a slave that is replicating `MEMORY` tables is to first drop or delete all rows from the `MEMORY` tables on the master and wait until those changes have replicated to the slave. Then it is safe to restart the slave.

An alternative restart method may apply in some cases. When `binlog_format=ROW` [1654], you can prevent the slave from stopping if you set `slave_exec_mode=IDEMPOTENT` [1644] before you start the slave again. This allows the slave to continue to replicate, but its `MEMORY` tables will still be different from those on the master. This can be okay if the application logic is such that the contents of `MEMORY` tables can be safely lost (for example, if the `MEMORY` tables are used for caching). `slave_exec_mode=IDEMPOTENT` [1644] applies globally to all tables, so it may hide other replication errors in non-`MEMORY` tables.

The size of `MEMORY` tables is limited by the value of the `max_heap_table_size` [495] system variable, which is not replicated (see Replication and Variables). A change in `max_heap_table_size` takes effect for `MEMORY` tables that are created or updated using `ALTER TABLE ... ENGINE = MEMORY` or `TRUNCATE TABLE` following the change, or for all `MEMORY` tables following a server restart. If you increase the value of this variable on the master without doing so on the slave, it becomes possible for a table on the master to grow larger than its counterpart on the slave, leading to inserts

that succeed on the master but fail on the slave with `Table is full` errors. This is a known issue (Bug #48666). In such cases, you must set the global value of `max_heap_table_size` [495] on the slave as well as on the master, then restart replication. It is also recommended that you restart both the master and slave MySQL servers, to insure that the new value takes complete (global) effect on each of them.

See The `MEMORY` Storage Engine, for more information about `MEMORY` tables.

Replication and Temporary Tables

This section does not apply when row-based replication is in use because in that case temporary tables are not replicated. It does apply with mixed-format replication for statements involving temporary tables that can be logged safely using statement-based format. See Usage of Row-Based Logging and Replication.

Safe slave shutdown when using temporary tables. Temporary tables are replicated except in the case where you stop the slave server (not just the slave threads) and you have replicated temporary tables that are open for use in updates that have not yet been executed on the slave. If you stop the slave server, the temporary tables needed by those updates are no longer available when the slave is restarted. To avoid this problem, do not shut down the slave while it has temporary tables open. Instead, use the following procedure:

1. Issue a `STOP SLAVE SQL_THREAD` statement.
2. Use `SHOW STATUS` to check the value of the `Slave_open_temp_tables` [568] variable.
3. If the value is not 0, restart the slave SQL thread with `START SLAVE SQL_THREAD` and repeat the procedure later.
4. When the value is 0, issue a `mysqladmin shutdown` command to stop the slave.

Temporary tables and replication options. By default, all temporary tables are replicated; this happens whether or not there are any matching `--replicate-do-db` [1634], `--replicate-do-table` [1636], or `--replicate-wild-do-table` [1637] options in effect. However, the `--replicate-ignore-table` [1636] and `--replicate-wild-ignore-table` [1638] options are honored for temporary tables.

A recommended practice when using statement-based or mixed-format replication is to designate a prefix for exclusive use in naming temporary tables that you do not want replicated, then employ a `--replicate-wild-ignore-table` [1638] option to match that prefix. For example, you might give all such tables names beginning with `norep` (such as `norepmytable`, `norepyourtable`, and so on), then use `--replicate-wild-ignore-table=norep%` [1638] to prevent them from being replicated.

Replication of the `mysql` System Database

MySQL 5.1.14 and later. Data modification statements made to tables in the `mysql` database are replicated according to the value of `binlog_format` [1654]; if this value is `MIXED`, these statement are replicated using the row-based format. However, statements that would normally update this information indirectly—such `GRANT`, `REVOKE`, and statements manipulating triggers, stored routines, and views—are replicated to slaves using statement-based replication.

MySQL 5.1.13 and earlier. User privileges are replicated only if the `mysql` database is replicated. That is, the `GRANT`, `REVOKE`, `SET PASSWORD`, `CREATE USER`, and `DROP USER` statements take effect on the slave only if the replication setup includes the `mysql` database.

Replication and the Query Optimizer

It is possible for the data on the master and slave to become different if a statement is written in such a way that the data modification is nondeterministic; that is, left up the query optimizer. (In general, this is not a good practice, even outside of replication.) Examples of nondeterministic statements include

`DELETE` or `UPDATE` statements that use `LIMIT` with no `ORDER BY` clause; see Replication and `LIMIT`, for a detailed discussion of these.

Replication and Reserved Words

You can encounter problems when you attempt to replicate from an older master to a newer slave and you make use of identifiers on the master that are reserved words in the newer MySQL version running on the slave. An example of this is using a table column named `current_user` on a 4.0 master that is replicating to a 4.1 or higher slave because `CURRENT_USER` is a reserved word beginning in MySQL 4.1. Replication can fail in such cases with Error 1064 `You have an error in your SQL syntax...`, *even if a database or table named using the reserved word or a table having a column named using the reserved word is excluded from replication*. This is due to the fact that each SQL event must be parsed by the slave prior to execution, so that the slave knows which database object or objects would be affected; only after the event is parsed can the slave apply any filtering rules defined by `--replicate-do-db` [1634], `--replicate-do-table` [1636], `--replicate-ignore-db` [1635], and `--replicate-ignore-table` [1636].

To work around the problem of database, table, or column names on the master which would be regarded as reserved words by the slave, do one of the following:

- Use one or more `ALTER TABLE` statements on the master to change the names of any database objects where these names would be considered reserved words on the slave, and change any SQL statements that use the old names to use the new names instead.
- In any SQL statements using these database object names, write the names as quoted identifiers using backtick characters (`` ` ``).

For listings of reserved words by MySQL version, see Reserved Words, in the *MySQL Server Version Reference*. For identifier quoting rules, see Schema Object Names.

`SET PASSWORD` and Row-Based Replication

Row-based replication of `SET PASSWORD` statements from a MySQL 5.1 master to a MySQL 5.5 slave did not work correctly prior to MySQL 5.1.53 on the master and MySQL 5.5.7 on the slave (see Bug #57098, Bug #57357).

Slave Errors During Replication

If a statement produces the same error (identical error code) on both the master and the slave, the error is logged, but replication continues.

If a statement produces different errors on the master and the slave, the slave SQL thread terminates, and the slave writes a message to its error log and waits for the database administrator to decide what to do about the error. This includes the case that a statement produces an error on the master or the slave, but not both. To address the issue, connect to the slave manually and determine the cause of the problem. `SHOW SLAVE STATUS` is useful for this. Then fix the problem and run `START SLAVE`. For example, you might need to create a nonexistent table before you can start the slave again.

If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--slave-skip-errors` [1641] option.

For nontransactional storage engines such as `MyISAM`, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the master, the slave expects execution of the statement to result in the same error code. If it does not, the slave SQL thread stops as described previously.

If you are replicating between tables that use different storage engines on the master and slave, keep in mind that the same statement might produce a different error when run against one version of the table, but not the other, or might cause an error for one version of the table, but not the other. For

example, since MyISAM ignores foreign key constraints, an INSERT or UPDATE statement accessing an InnoDB table on the master might cause a foreign key violation but the same statement performed on a MyISAM version of the same table on the slave would produce no such error, causing replication to stop.

Replication and Server SQL Mode

Using different server SQL mode settings on the master and the slave may cause the same INSERT statements to be handled differently on the master and the slave, leading the master and slave to diverge. For best results, you should always use the same server SQL mode on the master and on the slave. This advice applies whether you are using statement-based or row-based replication.

If you are replicating partitioned tables, using different SQL modes on the master and the slave is likely to cause issues. At a minimum, this is likely to cause the distribution of data among partitions to be different in the master's and slave's copies of a given table. It may also cause inserts into partitioned tables that succeed on the master to fail on the slave.

For more information, see Server SQL Modes.

Replication Retries and Timeouts

The global system variable slave_transaction_retries [1645] affects replication as follows: If the slave SQL thread fails to execute a transaction because of an InnoDB deadlock or because it exceeded the InnoDB innodb_lock_wait_timeout [1371] value, or the NDBCLUSTER TransactionDeadlockDetectionTimeout or TransactionInactiveTimeout value, the slave automatically retries the transaction slave_transaction_retries [1645] times before stopping with an error. The default value is 10. The total retry count can be seen in the output of SHOW STATUS; see Server Status Variables.

Replication and TIMESTAMP

Older versions of MySQL (prior to 4.1) differed significantly in several ways in their handling of the TIMESTAMP data type from what is supported in MySQL versions 5.1 and newer; these include syntax extensions which are deprecated in MySQL 5.1, and that no longer supported in MySQL 5.5. This this can cause problems (including replication failures) when replicating between MySQL Server versions, if you are using columns that are defined using the old TIMESTAMP(N) syntax. See Upgrading from MySQL 5.0 to 5.1, for more information about the differences, how they can impact MySQL replication, and what you can do if you encounter such problems.

Replication and Time Zones

The same system time zone should be set for both master and slave. Otherwise, statements depending on the local time on the master are not replicated properly, such as statements that use the NOW() [990] or FROM_UNIXTIME() [987] functions. You can set the time zone in which MySQL server runs by using the --timezone=*timezone_name* [243] option of the mysqld_safe script or by setting the TZ environment variable. See also Replication and System Functions.

If the master is MySQL 4.1 or earlier, both master and slave should also use the same default connection time zone. That is, the --default-time-zone [425] parameter should have the same value for both master and slave.

CONVERT_TZ(...,...,@@session.time_zone) [981] is properly replicated only if both master and slave are running MySQL 5.0.4 or newer.

Replication and Transactions

Mixing transactional and nontransactional statements within the same transaction. In general, you should avoid transactions that update both transactional and nontransactional tables in a replication environment. You should also avoid using any statement that accesses both transactional (or temporary) and nontransactional tables and writes to any of them.

As of MySQL 5.1.44, the server uses these rules for binary logging:

- If the initial statements in a transaction are nontransactional, they are written to the binary log immediately. The remaining statements in the transaction are cached and not written to the binary log until the transaction is committed. (If the transaction is rolled back, the cached statements are written to the binary log only if they make nontransactional changes that cannot be rolled back. Otherwise, they are discarded.)
- For statement-based logging, logging of nontransactional statements is affected by the `binlog_direct_non_transactional_updates` [1653] system variable. When this variable is `OFF` (the default), logging is as just described. When this variable is `ON`, logging occurs immediately for nontransactional statements occurring anywhere in the transaction (not just initial nontransactional statements). Other statements are kept in the transaction cache and logged when the transaction commits. `binlog_direct_non_transactional_updates` [1653] has no effect for row-format or mixed-format binary logging.

Transactional, nontransactional, and mixed statements.
To apply those rules, the server considers a statement nontransactional if it changes only nontransactional tables, and transactional if it changes only transactional tables. A statement that changes both nontransactional and transactional tables is considered “mixed”. Mixed statements, like transactional statements, are cached and logged when the transaction commits.

Note

A mixed statement is unrelated to mixed binary logging format.

Before MySQL 5.1.44, the rules for binary logging are similar to those just described, except that there is no `binlog_direct_non_transactional_updates` [1653] system variable to affect logging of transactional statements. Thus, the server immediately logs only the initial nontransactional statements in a transaction and caches the rest until commit time.

Before MySQL 5.1.31, the *effect* of the rules differs because the definition of transactional statement is different: In these earlier versions, a statement is nontransactional if the first changes it makes change nontransactional tables, transactional if the first changes it makes change transactional tables. “First” applies in the sense that a statement may have several effects if it involves such things as triggers, stored functions, or multiple-table updates. A mixed statement that changes both nontransactional and transactional tables is handled as nontransactional or transactional depending on the type of changes it makes first.

In situations where transactions mix updates to transactional and nontransactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a `ROLLBACK`. However, when a second connection updates the nontransactional table before the first connection transaction is complete, statements can be logged out of order because the second connection update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

Using different storage engines on master and slave. It is possible to replicate transactional tables on the master using nontransactional tables on the slave. For example, you can replicate an `InnoDB` master table as a `MyISAM` slave table. However, if you do this, there are problems if the slave is stopped in the middle of a `BEGIN` ... `COMMIT` block because the slave restarts at the beginning of the `BEGIN` block.

Beginning with MySQL 5.1.48, it is also safe to replicate transactions from `MyISAM` tables on the master to transactional tables—such as tables that use the `InnoDB` storage engine—on the slave. In such cases (beginning with MySQL 5.1.48), an `AUTOCOMMIT=1` [461] statement issued on the master is replicated, thus enforcing `AUTOCOMMIT` mode on the slave.

When the storage engine type of the slave is nontransactional, transactions on the master that mix updates of transactional and nontransactional tables should be avoided because they can cause inconsistency of the data between the master transactional table and the slave nontransactional table.

That is, such transactions can lead to master storage engine-specific behavior with the possible effect of replication going out of synchrony. MySQL does not issue a warning about this currently, so extra care should be taken when replicating transactional tables from the master to nontransactional tables on the slaves.

Beginning with MySQL Cluster NDB 6.2.14 and MySQL 5.1.24, every transaction (including `autocommit` [461] transactions) is recorded in the binary log as though it starts with a `BEGIN` statement, and ends with either a `COMMIT` or a `ROLLBACK` statement. However, this does *not* apply to nontransactional changes; any statements affecting tables using a nontransactional storage engine such as `MyISAM` are regarded for this purpose as nontransactional, even when `autocommit` [461] is enabled. (Bug #26395)

Replication and Triggers

With statement-based replication, triggers executed on the master also execute on the slave. With row-based replication, triggers executed on the master do not execute on the slave. Instead, the row changes on the master resulting from trigger execution are replicated and applied on the slave.

This behavior is by design. If under row-based replication the slave applied the triggers as well as the row changes caused by them, the changes would in effect be applied twice on the slave, leading to different data on the master and the slave.

If you want triggers to execute on both the master and the slave—perhaps because you have different triggers on the master and slave—you must use statement-based replication. However, to enable slave-side triggers, it is not necessary to use statement-based replication exclusively. It is sufficient to switch to statement-based replication only for those statements where you want this effect, and to use row-based replication the rest of the time.

Before MySQL 5.1.31, a trigger that was defined on a transactional table but that updated a nontransactional table could cause updates on the transactional table to be replicated before they were actually committed on the master, and not be rolled back correctly on the slave if they were rolled back on the master. (Bug #40116) See also Replication and Transactions.

A statement invoking a trigger (or function) that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. Beginning with MySQL 5.1.40, such statements are marked as unsafe. (Bug #45677)

Replication and Views

Views are always replicated to slaves. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the slave even if the view contains a table that would normally be filtered out by `replication-ignore-table` rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

Replication and `TRUNCATE TABLE`

`TRUNCATE TABLE` is normally regarded as a DML statement, and so would be expected to be logged and replicated using row-based format when the binary logging mode is `ROW` or `MIXED`. However this caused issues when logging or replicating, in `STATEMENT` or `MIXED` mode, tables that used transactional storage engines such as `InnoDB` when the transaction isolation level was `READ COMMITTED` or `READ UNCOMMITTED`, which precludes statement-based logging.

Beginning with MySQL 5.1.32, `TRUNCATE TABLE` is treated for purposes of logging and replication as DDL rather than DML so that it can be logged and replicated as a statement. However, the effects of the statement as applicable to `InnoDB` and other transactional tables on replication slaves still follow the rules described in `TRUNCATE TABLE` Syntax governing such tables. (Bug #36763)

Replication and Variables

System variables are not replicated correctly when using `STATEMENT` mode, except for the following variables when they are used with session scope:

- auto_increment_increment [1622]
- auto_increment_offset [1624]
- character_set_client [464]
- character_set_connection [464]
- character_set_database [465]
- character_set_server [465]
- collation_connection [466]
- collation_database [466]
- collation_server [467]
- foreign_key_checks [475]
- identity [481]
- last_insert_id [487]
- lc_time_names [487]
- pseudo_thread_id [512]
- sql_auto_is_null [524]
- time_zone [533]
- timestamp [533]
- unique_checks [536]

When MIXED mode is used, the variables in the preceding list, when used with session scope, cause a switch from statement-based to row-based logging. See Mixed Binary Logging Format.

sql_mode [526] is also replicated except for the NO_DIR_IN_CREATE [573] mode; the slave always preserves its own value for NO_DIR_IN_CREATE [573], regardless of changes to it on the master. This is true for all replication formats.

However, when mysqlbinlog parses a SET @@sql_mode = *mode* statement, the full *mode* value, including NO_DIR_IN_CREATE [573], is passed to the receiving server. For this reason, replication of such a statement may not be safe when STATEMENT mode is in use.

The storage_engine [528] system variable is not replicated, regardless of the logging mode; this is intended to facilitate replication between different storage engines.

The read_only [517] system variable is not replicated. In addition, the enabling this variable has different effects with regard to temporary tables, table locking, and the SET PASSWORD statement in different MySQL versions.

The max_heap_table_size [495] system variable is not replicated. Increasing the value of this variable on the master without doing so on the slave can lead eventually to Table is full errors on the slave when trying to execute INSERT statements on a MEMORY table on the master that is thus permitted to grow larger than its counterpart on the slave. For more information, see Replication and MEMORY Tables.

In statement-based replication, session variables are not replicated properly when used in statements that update tables. For example, the following sequence of statements will not insert the same data on the master and the slave:

```
SET max_join_size=1000;
INSERT INTO mytable VALUES(@@max_join_size);
```

This does not apply to the common sequence:

```
SET time_zone=...;
INSERT INTO mytable VALUES(CONVERT_TZ(..., ..., @@time_zone));
```

Replication of session variables is not a problem when row-based replication is being used, in which case, session variables are always replicated safely. See Replication Formats.

In MySQL 5.1.20 and later (and in MySQL 5.0.46 and later in MySQL 5.0, for backward compatibility), the following session variables are written to the binary log and honored by the replication slave when parsing the binary log, regardless of the logging format:

- `sql_mode` [526]
- `foreign_key_checks` [475]
- `unique_checks` [536]
- `character_set_client` [464]
- `collation_connection` [466]
- `collation_database` [466]
- `collation_server` [467]
- `sql_auto_is_null` [524]

Important

Even though session variables relating to character sets and collations are written to the binary log, replication between different character sets is not supported.

It is strongly recommended that you always use the same setting for the `lower_case_table_names` [492] system variable on both master and slave. In particular, when a case-sensitive file system is used, setting this variable to 1 on the slave, but to a different value on the master, can cause two types of problems: Names of databases are not converted to lowercase; in addition, when using row-based replication names of tables are also not converted. Either of these problems can cause replication to fail. This is a known issue, which is fixed in MySQL 5.6.

Replication Compatibility Between MySQL Versions

MySQL supports replication from one major version to the next higher major version. For example, you can replicate from a master running MySQL 4.1 to a slave running MySQL 5.0, from a master running MySQL 5.0 to a slave running MySQL 5.1, and so on.

However, one may encounter difficulties when replicating from an older master to a newer slave if the master uses statements or relies on behavior no longer supported in the version of MySQL used on the slave.

The use of more than 2 MySQL Server versions is not supported in replication setups involving multiple masters, regardless of the number of master or slave MySQL servers. This restriction applies not only to major versions, but to minor versions within the same major version as well. For example, if you are using a chained or circular replication setup, you cannot use MySQL 5.1.31, MySQL 5.1.32, and MySQL 5.1.34 concurrently, although you could use any 2 of these releases together.

In some cases, it is also possible to replicate between a master and a slave that is more than one major version newer than the master. However, there are known issues with trying to replicate from

a master running MySQL 4.1 or earlier to a slave running MySQL 5.1 or later. To work around such problems, you can insert a MySQL server running an intermediate version between the two; for example, rather than replicating directly from a MySQL 4.1 master to a MySQL 5.1 slave, it is possible to replicate from a MySQL 4.1 server to a MySQL 5.0 server, and then from the MySQL 5.0 server to a MySQL 5.1 server.

Important

It is strongly recommended to use the most recent release available within a given MySQL major version because replication (and other) capabilities are continually being improved. It is also recommended to upgrade masters and slaves that use early releases of a major version of MySQL to GA (production) releases when the latter become available for that major version.

Replication from newer masters to older slaves may be possible, but is generally not supported. This is due to a number of factors:

- **Binary log format changes.** The binary log format can change between major releases. While we attempt to maintain backward compatibility, this is not always possible. For example, the binary log format implemented in MySQL 5.0 changed considerably from that used in previous versions, especially with regard to handling of character sets, `LOAD DATA INFILE`, and time zones. This means that replication from a MySQL 5.0 (or later) master to a MySQL 4.1 (or earlier) slave is generally not supported.

  This also has significant implications for upgrading replication servers; see Upgrading a Replication Setup, for more information.

- **Use of row-based replication.** Row-based replication was implemented in MySQL 5.1.5, so you cannot replicate using row-based replication from any MySQL 5.1 or later master to a slave older than MySQL 5.1.5.

  For more information about row-based replication, see Replication Formats.

- **SQL incompatibilities.** You cannot replicate from a newer master to an older slave using statement-based replication if the statements to be replicated use SQL features available on the master but not on the slave.

  However, if both the master and the slave support row-based replication, and there are no data definition statements to be replicated that depend on SQL features found on the master but not on the slave, you can use row-based replication to replicate the effects of data modification statements even if the DDL run on the master is not supported on the slave.

For more information on potential replication issues, see Replication Features and Issues.

Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading.

This section applies to upgrading replication from older versions of MySQL to MySQL 5.1. A 4.0 server should be 4.0.3 or newer.

When you upgrade a master to 5.1 from an earlier MySQL release series, you should first ensure that all the slaves of this master are using the same 5.1.x release. If this is not the case, you should first upgrade the slaves. To upgrade each slave, shut it down, upgrade it to the appropriate 5.1.x version, restart it, and restart replication. The 5.1 slave is able to read the old relay logs written prior to the upgrade and to execute the statements they contain. Relay logs created by the slave after the upgrade are in 5.1 format.

After the slaves have been upgraded, shut down the master, upgrade it to the same 5.1.x release as the slaves, and restart it. The 5.1 master is able to read the old binary logs written prior to the upgrade

and to send them to the 5.1 slaves. The slaves recognize the old format and handle it properly. Binary logs created by the master subsequent to the upgrade are in 5.1 format. These too are recognized by the 5.1 slaves.

In other words, when upgrading to MySQL 5.1, the slaves must be MySQL 5.1 before you can upgrade the master to 5.1. Note that downgrading from 5.1 to older versions does not work so simply: You must ensure that any 5.1 binary log or relay log has been fully processed, so that you can remove it before proceeding with the downgrade.

Downgrading a replication setup to a previous version cannot be done once you have switched from statement-based to row-based replication, and after the first row-based statement has been written to the binlog. See Replication Formats.

Some upgrades may require that you drop and re-create database objects when you move from one MySQL series to the next. For example, collation changes might require that table indexes be rebuilt. Such operations, if necessary, will be detailed at Upgrading from MySQL 5.0 to 5.1. It is safest to perform these operations separately on the slaves and the master, and to disable replication of these operations from the master to the slave. To achieve this, use the following procedure:

1. Stop all the slaves and upgrade them. Restart them with the `--skip-slave-start` [1640] option so that they do not connect to the master. Perform any table repair or rebuilding operations needed to re-create database objects, such as use of `REPAIR TABLE` or `ALTER TABLE`, or dumping and reloading tables or triggers.

2. Disable the binary log on the master. To do this without restarting the master, execute a `SET sql_log_bin = 0` statement. Alternatively, stop the master and restart it without the `--log-bin` [1647] option. If you restart the master, you might also want to disallow client connections. For example, if all clients connect using TCP/IP, use the `--skip-networking` [443] option when you restart the master.

3. With the binary log disabled, perform any table repair or rebuilding operations needed to re-create database objects. The binary log must be disabled during this step to prevent these operations from being logged and sent to the slaves later.

4. Re-enable the binary log on the master. If you set `sql_log_bin` [525] to 0 earlier, execute a `SET sql_log_bin = 1` statement. If you restarted the master to disable the binary log, restart it with `--log-bin` [1647], and without `--skip-networking` [443] so that clients and slaves can connect.

5. Restart the slaves, this time without the `--skip-slave-start` [1640] option.

Troubleshooting Replication

If you have followed the instructions but your replication setup is not working, the first thing to do is *check the error log for messages*. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

- Verify that the master has binary logging enabled by issuing a `SHOW MASTER STATUS` statement. If logging is enabled, `Position` is nonzero. If binary logging is not enabled, verify that you are running the master with the `--log-bin` [1647] option.

- Verify that the master and slave both were started with the `--server-id` [1617] option and that the ID value is unique on each server.

- Verify that the slave is running. Use `SHOW SLAVE STATUS` to check whether the `Slave_IO_Running` and `Slave_SQL_Running` values are both `Yes`. If not, verify the options that were used when starting the slave server. For example, `--skip-slave-start` [1640] prevents the slave threads from starting until you issue a `START SLAVE` statement.

- If the slave is running, check whether it established a connection to the master. Use `SHOW PROCESSLIST`, find the I/O and SQL threads and check their `State` column to see what they display. See Replication Implementation Details. If the I/O thread state says `Connecting to master`, check the following:
  - Verify the privileges for the user being used for replication on the master.
  - Check that the host name of the master is correct and that you are using the correct port to connect to the master. The port used for replication is the same as used for client network communication (the default is `3306`). For the host name, ensure that the name resolves to the correct IP address.
  - Check that networking has not been disabled on the master or slave. Look for the `skip-networking` [443] option in the configuration file. If present, comment it out or remove it.
  - If the master has a firewall or IP filtering configuration, ensure that the network port being used for MySQL is not being filtered.
  - Check that you can reach the master by using `ping` or `traceroute`/`tracert` to reach the host.
- If the slave was running previously but has stopped, the reason usually is that some statement that succeeded on the master failed on the slave. This should never happen if you have taken a proper snapshot of the master, and never modified the data on the slave outside of the slave thread. If the slave stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in Replication Features and Issues. If it is a bug, see How to Report Replication Bugs or Problems, for instructions on how to report it.
- If a statement that succeeded on the master refuses to run on the slave, try the following procedure if it is not feasible to do a full database resynchronization by deleting the slave's databases and copying a new snapshot from the master:
  1. Determine whether the affected table on the slave is different from the master table. Try to understand how this happened. Then make the slave's table identical to the master's and run `START SLAVE`.
  2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the master.
  3. If you decide that the slave can skip the next statement from the master, issue the following statements:

     ```
     mysql> SET GLOBAL sql_slave_skip_counter = N;
     mysql> START SLAVE;
     ```

     The value of *`N`* should be 1 if the next statement from the master does not use `AUTO_INCREMENT` or `LAST_INSERT_ID()` [1036]. Otherwise, the value should be 2. The reason for using a value of 2 for statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID()` [1036] is that they take two events in the binary log of the master.

     See also `SET GLOBAL sql_slave_skip_counter` Syntax.
  4. If you are sure that the slave started out perfectly synchronized with the master, and that no one has updated the tables involved outside of the slave thread, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as

possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in How to Report Bugs or Problems. If you have a “phantom” problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the slave outside of the slave thread, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the slave thread stops and waits for you to clean up the tables manually to bring them into synchrony. *This is not a replication problem. It is a problem of outside interference causing replication to fail.*

2. Run the slave with the `--log-slave-updates` [1628] and `--log-bin` [1647] options. These options cause the slave to log the updates that it receives from the master into its own binary logs.

3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:

   - All binary log files from the master
   - All binary log files from the slave
   - The output of `SHOW MASTER STATUS` from the master at the time you discovered the problem
   - The output of `SHOW SLAVE STATUS` from the slave at the time you discovered the problem
   - Error logs from the master and the slave

4. Use `mysqlbinlog` to examine the binary logs. The following should be helpful to find the problem statement. *`log_file`* and *`log_pos`* are the `Master_Log_File` and `Read_Master_Log_Pos` values from `SHOW SLAVE STATUS`.

   ```
   shell> mysqlbinlog --start-position=log_pos log_file | head
   ```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at How to Report Bugs or Problems.

Chapter 17. MySQL Cluster NDB 6.1 - 7.1

Release Series Changelogs: MySQL Cluster NDB 6.X and 7.X 2380

This chapter contains information about *MySQL Cluster*, which is a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. Current releases of MySQL Cluster use versions 6 and 7 of the NDB storage engine (also known as NDBCLUSTER) to enable running several computers with MySQL servers and other software in a cluster.

Beginning with MySQL 5.1.24, support for the NDBCLUSTER storage engine was removed from the standard MySQL server binaries built by MySQL. Instead, users of MySQL Cluster binaries built by MySQL should upgrade to the most recent binary release of MySQL Cluster NDB 7.0 or MySQL Cluster 7.1 for supported platforms—these include RPMs that should work with most Linux distributions. MySQL Cluster users who build from source should be aware that, also beginning with MySQL 5.1.24, NDBCLUSTER sources in the standard MySQL 5.1 tree are no longer maintained; these users should use the sources provided for MySQL Cluster NDB 7.0 or later. (Locations where the sources can be obtained are listed later in this section.)

Note

MySQL Cluster NDB 6.1, 6.2, and 6.3 were formerly known as “MySQL Cluster Carrier Grade Edition”. Beginning with MySQL Cluster NDB 6.2.15 and MySQL Cluster NDB 6.3.14, this term is no longer applied to the MySQL Cluster software—which is now known simply as “MySQL Cluster”—but rather to a commercial licensing and support package. You can learn more about available options for commercial licensing of MySQL Cluster from http://mysql.com/products/database/cluster/features.html, on the MySQL web site.

This chapter contains information about MySQL Cluster in MySQL 5.1 mainline releases through MySQL 5.1.23, MySQL Cluster NDB 6.2 releases through 5.1.51-ndb-6.2.19, MySQL Cluster NDB

6.3 releases through 5.1.61-ndb-6.3.50, MySQL Cluster NDB 7.0 releases through 5.1.63-ndb-7.0.36 and MySQL Cluster NDB 7.1 releases through 5.1.63-ndb-7.1.25. Currently, the MySQL Cluster NDB 7.2 release series is Generally Available (GA), as is MySQL Cluster NDB 7.1. MySQL Cluster NDB 7.0 and MySQL Cluster NDB 6.3 are previous GA release series; although they are still supported, we recommend that new deployments use MySQL Cluster NDB 7.2. For information about MySQL Cluster NDB 7.2, see MySQL Cluster NDB 7.2, in the *MySQL 5.5 Manual*.

This chapter also contains historical information about MySQL Cluster NDB 6.1 and MySQL Cluster NDB 6,2, although these release series are no longer in active development, and no longer supported for new deployments. You should upgrade to a MySQL Cluster NDB 7.1 or later release series as soon as possible.

Supported Platforms. MySQL Cluster is currently available and supported on a number of platforms. For exact levels of support available for on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to `http://www.mysql.com/support/supportedplatforms/cluster.html`.

Availability. MySQL Cluster binary and source packages are available for supported platforms from http://dev.mysql.com/downloads/cluster/.

Note

Binary releases and RPMs were not available for MySQL Cluster NDB 6.2 prior to MySQL Cluster NDB 6.2.15.

MySQL Cluster release numbers. Starting with MySQL Cluster NDB 6.1 and MySQL Cluster NDB 6.2, MySQL Cluster follows a somewhat different release pattern from the mainline MySQL 5.1 Cluster series of releases. In this *Manual* and other MySQL documentation, we identify these and later MySQL Cluster releases employing a version number that begins with “NDB”. This version number is that of the `NDBCLUSTER` storage engine used in the release, and not of the MySQL server version on which the MySQL Cluster release is based.

Version strings used in MySQL Cluster NDB 6.x and 7.x software. The version string displayed by MySQL Cluster NDB 6.x and 7.x software uses this format:

```
mysql-mysql_server_version-ndb-ndb_engine_version
```

`mysql_server_version` represents the version of the MySQL Server on which the MySQL Cluster release is based. For all MySQL Cluster NDB 6.x and 7.x releases, this is “5.1”. *`ndb_engine_version`* is the version of the `NDB` storage engine used by this release of the MySQL Cluster software. You can see this format used in the `mysql` client, as shown here:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 2
Server version: 5.1.63-ndb-7.1.25 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT VERSION()\G
*************************** 1. row ***************************
VERSION(): 5.1.63-ndb-7.1.25
1 row in set (0.00 sec)
```

This version string is also displayed in the output of the `SHOW` command in the `ndb_mgm` client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @10.0.10.6  (5.1.63-ndb-7.1.25, Nodegroup: 0, Master)
id=2    @10.0.10.8  (5.1.63-ndb-7.1.25, Nodegroup: 0)
```

```
[ndb_mgmd(MGM)] 1 node(s)
id=3    @10.0.10.2  (5.1.63-ndb-7.1.25)

[mysqld(API)]   2 node(s)
id=4    @10.0.10.10  (5.1.63-ndb-7.1.25)
id=5 (not connected, accepting connect from any host)
```

The version string identifies the mainline MySQL version from which the MySQL Cluster release was branched and the version of the `NDBCLUSTER` storage engine used. For example, the full version string for MySQL Cluster NDB 7.0.5 (the first GA MySQL Cluster NDB 7.0 binary release) was `mysql-5.1.32-ndb-7.0.5`. From this we can determine the following:

- Since the portion of the version string preceding "`-ndb-`" is the base MySQL Server version, this means that MySQL Cluster NDB 7.0.5 derives from the MySQL 5.1.32, and contains all feature enhancements and bugfixes from MySQL 5.1 up to and including MySQL 5.1.32.
- Since the portion of the version string following "`-ndb-`" represents the version number of the `NDB` (or `NDBCLUSTER`) storage engine, MySQL Cluster NDB 7.0.5 uses version 7.0.5 of the `NDBCLUSTER` storage engine.

New MySQL Cluster releases are numbered according to updates in the `NDB` storage engine, and do not necessarily correspond in a linear fashion with mainline MySQL Server releases. For example, MySQL Cluster NDB 7.0.5 (as previously noted) is based on MySQL 5.1.32, and MySQL Cluster NDB 7.0.6 is based on MySQL 5.1.34 (version string: `mysql-5.1.34-ndb-7.0.6`).

Compatibility with standard MySQL 5.1 releases. While many standard MySQL schemas and applications can work using MySQL Cluster, it is also true that unmodified applications and database schemas may be slightly incompatible or have suboptimal performance when run using MySQL Cluster (see Known Limitations of MySQL Cluster). Most of these issues can be overcome, but this also means that you are very unlikely to be able to switch an existing application datastore—that currently uses, for example, `MyISAM` or `InnoDB`—to use the `NDB` storage engine without allowing for the possibility of changes in schemas, queries, and applications. Moreover, from MySQL 5.1.24 onwards, the MySQL Server and MySQL Cluster codebases diverge considerably (and `NDB` storage engine support dropped from subsequent MySQL Server releases), so that the standard `mysqld` cannot function as a dropin replacement for the version of `mysqld` that is supplied with MySQL Cluster.

MySQL Cluster development source trees. MySQL Cluster development trees can also be accessed from https://code.launchpad.net/~mysql/:

The MySQL Cluster development sources maintained at https://code.launchpad.net/~mysql/ are licensed under the GPL. For information about obtaining MySQL sources using Bazaar and building them yourself, see Installing MySQL from a Development Source Tree.

Currently, MySQL Cluster NDB 7.0, MySQL Cluster NDB 7.1, and MySQL Cluster NDB 7.2 releases are all Generally Available (GA), although we recommend that new deployments use MySQL Cluster NDB 7.2. MySQL Cluster NDB 6.1, MySQL Cluster NDB 6.2, and MySQL Cluster NDB 6.3, are no longer in active development. For an overview of major features added in MySQL Cluster NDB 6.x and 7.x releases, see MySQL Cluster Development History. For an overview of major features added in MySQL Cluster NDB 7.2, see MySQL Cluster Development History.

This chapter represents a work in progress, and its contents are subject to revision as MySQL Cluster continues to evolve. Additional information regarding MySQL Cluster can be found on the MySQL Web site at `http://www.mysql.com/products/cluster/`.

Additional Resources. More information about MySQL Cluster can be found in the following places:

- For answers to some commonly asked questions about MySQL Cluster, see MySQL 5.1 FAQ: MySQL Cluster.
- The MySQL Cluster mailing list: http://lists.mysql.com/cluster.

- The MySQL Cluster Forum: http://forums.mysql.com/list.php?25.
- Many MySQL Cluster users and developers blog about their experiences with MySQL Cluster, and make feeds of these available through PlanetMySQL.

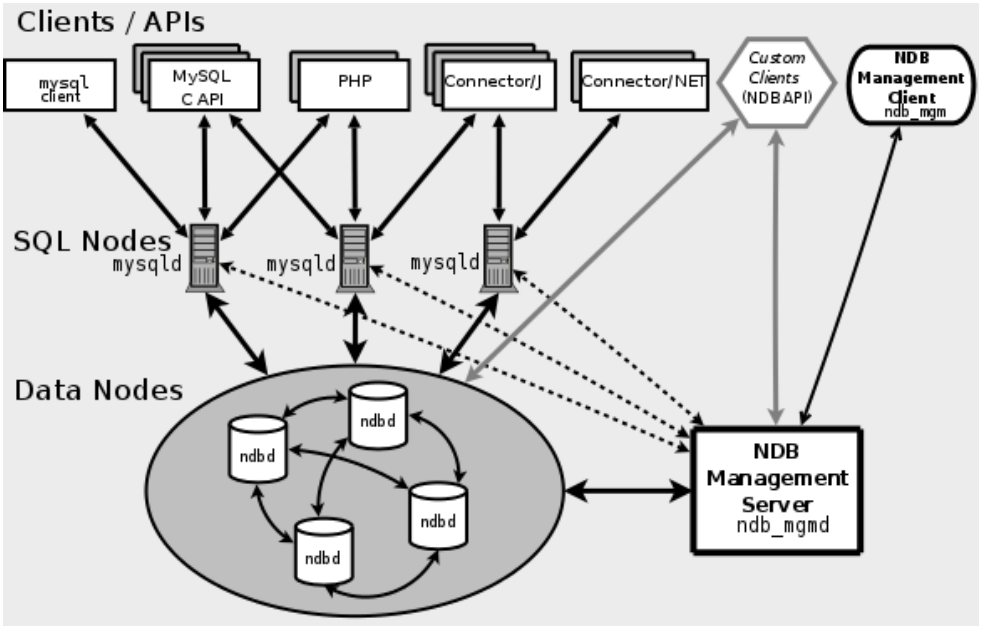
MySQL Cluster Overview

MySQL Cluster is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture enables the system to work with very inexpensive hardware, and with a minimum of specific requirements for hardware or software.

MySQL Cluster is designed not to have any single point of failure. In a shared-nothing system, each component is expected to have its own memory and disk, and the use of shared storage mechanisms such as network shares, network file systems, and SANs is not recommended or supported.

MySQL Cluster integrates the standard MySQL server with an in-memory clustered storage engine called `NDB` (which stands for "*N*etwork *D*ata*B*ase"). In our documentation, the term `NDB` refers to the part of the setup that is specific to the storage engine, whereas "MySQL Cluster" refers to the combination of one or more MySQL servers with the `NDB` storage engine.

A MySQL Cluster consists of a set of computers, known as *hosts*, each running one or more processes. These processes, known as *nodes*, may include MySQL servers (for access to NDB data), data nodes (for storage of the data), one or more management servers, and possibly other specialized data access programs. The relationship of these components in a MySQL Cluster is shown here:



All these programs work together to form a MySQL Cluster (see MySQL Cluster Programs. When data is stored by the `NDB` storage engine, the tables (and table data) are stored in the data nodes. Such tables are directly accessible from all other MySQL servers (SQL nodes) in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

Although a MySQL Cluster SQL node uses the `mysqld` server daemon, it differs in a number of critical respects from the `mysqld` binary supplied with the MySQL 5.1 distributions, and the two versions of `mysqld` are not interchangeable.

In addition, a MySQL server that is not connected to a MySQL Cluster cannot use the `NDB` storage engine and cannot access any MySQL Cluster data.

The data stored in the data nodes for MySQL Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due

to losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.

Individual nodes can be stopped and restarted, and can then rejoin the system (cluster). Rolling restarts (in which all nodes are restarted in turn) are used in making configuration changes and software upgrades (see Performing a Rolling Restart of a MySQL Cluster). In MySQL Cluster NDB 7.0 and later, rolling restarts are also used as part of the process of adding new data nodes online (see Adding MySQL Cluster Data Nodes Online). For more information about data nodes, how they are organized in a MySQL Cluster, and how they handle and store MySQL Cluster data, see MySQL Cluster Nodes, Node Groups, Replicas, and Partitions.

Backing up and restoring MySQL Cluster databases can be done using the `NDB`-native functionality found in the MySQL Cluster management client and the `ndb_restore` program included in the MySQL Cluster distribution. For more information, see Online Backup of MySQL Cluster, and `ndb_restore` — Restore a MySQL Cluster Backup. You can also use the standard MySQL functionality provided for this purpose in `mysqldump` and the MySQL server. See `mysqldump` — A Database Backup Program, for more information.

MySQL Cluster nodes can use a number of different transport mechanisms for inter-node communications, including TCP/IP using standard 100 Mbps or faster Ethernet hardware. It is also possible to use the high-speed *Scalable Coherent Interface* (SCI) protocol with MySQL Cluster, although this is not required to use MySQL Cluster. SCI requires special hardware and software; see Using High-Speed Interconnects with MySQL Cluster, for more about SCI and using it with MySQL Cluster.

MySQL Cluster Core Concepts

`NDBCLUSTER` (also known as `NDB`) is an in-memory storage engine offering high-availability and data-persistence features.

The `NDBCLUSTER` storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. MySQL Cluster's `NDB` storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The “Cluster” portion of MySQL Cluster is configured independently of the MySQL servers. In a MySQL Cluster, each part of the cluster is considered to be a *node*.

Note

In many contexts, the term “node” is used to indicate a computer, but when discussing MySQL Cluster it means a *process*. It is possible to run multiple nodes on a single computer; for a computer on which one or more cluster nodes are being run we use the term *cluster host*.

There are three types of cluster nodes, and in a minimal MySQL Cluster configuration, there will be at least three nodes, one of each of these types:

- *Management node*: The role of this type of node is to manage the other nodes within the MySQL Cluster, performing such functions as providing configuration data, starting and stopping nodes, running backup, and so forth. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. An MGM node is started with the command `ndb_mgmd`.

- *Data node*: This type of node stores cluster data. There are as many data nodes as there are replicas, times the number of fragments (see MySQL Cluster Nodes, Node Groups, Replicas, and Partitions). For example, with two replicas, each having two fragments, you need four data nodes. One replica is sufficient for data storage, but provides no redundancy; therefore, it is recommended to have 2 (or more) replicas to provide redundancy, and thus high availability. A data node is started with the command `ndbd` (see `ndbd` — The MySQL Cluster Data Node Daemon). In MySQL Cluster

NDB 7.0 and later, `ndbmtd` can also be used for the data node process; see `ndbmtd` — The MySQL Cluster Data Node Daemon (Multi-Threaded), for more information.

MySQL Cluster tables are normally stored completely in memory rather than on disk (this is why we refer to MySQL Cluster as an *in-memory* database). In MySQL 5.1, MySQL Cluster NDB 6.X, and later, some MySQL Cluster data can be stored on disk; see MySQL Cluster Disk Data Tables, for more information.

- *SQL node*: This is a node that accesses the cluster data. In the case of MySQL Cluster, an SQL node is a traditional MySQL server that uses the `NDBCLUSTER` storage engine. An SQL node is a `mysqld` process started with the `--ndbcluster` [1915] and `--ndb-connectstring` options, which are explained elsewhere in this chapter, possibly with additional MySQL server options as well.

  An SQL node is actually just a specialized type of *API node*, which designates any application which accesses MySQL Cluster data. Another example of an API node is the `ndb_restore` utility that is used to restore a cluster backup. It is possible to write such applications using the NDB API. For basic information about the NDB API, see Getting Started with the NDB API.

Important

It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; to benefit from MySQL Cluster's high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.

For a brief introduction to the relationships between nodes, node groups, replicas, and partitions in MySQL Cluster, see MySQL Cluster Nodes, Node Groups, Replicas, and Partitions.

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. MySQL Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These include standard MySQL clients, `NDB`-specific API programs, and management clients. These are described in the next few paragraphs.

Standard MySQL clients. MySQL Cluster can be used with existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on. Such client applications send SQL statements to and receive responses from MySQL servers acting as MySQL Cluster SQL nodes in much the same way that they interact with standalone MySQL servers.

MySQL clients using a MySQL Cluster as a data source can be modified to take advantage of the ability to connect with multiple MySQL servers to achieve load balancing and failover. For example, Java clients using Connector/J 5.0.6 and later can use `jdbc:mysql:loadbalance://` URLs (improved in Connector/J 5.1.7) to achieve load balancing transparently; for more information about using Connector/J with MySQL Cluster, see Using Connector/J with MySQL Cluster.

`NDB` client programs. Client programs can be written that access MySQL Cluster data directly from the `NDBCLUSTER` storage engine, bypassing any MySQL Servers that may connected to the cluster, using the *NDB API*, a high-level C++ API. Such applications may be useful for specialized purposes where an SQL interface to the data is not needed. For more information, see The NDB API.

Beginning with MySQL Cluster NDB 7.1, `NDB`-specific Java applications can also be written for MySQL Cluster, using the *MySQL Cluster Connector for Java*. This MySQL Cluster Connector includes *ClusterJ*, a high-level database API similar to object-relational mapping persistence frameworks such as Hibernate and JPA that connect directly to `NDBCLUSTER`, and so does not require access to a MySQL Server. Support is also provided in MySQL Cluster NDB 7.1 and later for *ClusterJPA*, an OpenJPA implementation for MySQL Cluster that leverages the strengths of ClusterJ and JDBC; ID lookups and other fast operations are performed using ClusterJ (bypassing the MySQL Server), while more complex queries that can benefit from MySQL's query optimizer are sent through the MySQL Server, using JDBC. See Java and MySQL Cluster, and The ClusterJ API and Data Object Model, for more information.

Management clients. These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on. An example of this type of program is the `ndb_mgm` management client supplied with MySQL Cluster (see `ndb_mgm` — The MySQL Cluster Management Client). Such applications can be written using the *MGM API*, a C-language API that communicates directly with one or more MySQL Cluster management servers. For more information, see The MGM API.

Oracle also makes available MySQL Cluster Manager, which provides an advanced command-line interface simplifying many complex MySQL Cluster management tasks, such restarting a MySQL Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as `mysqld` server options and variables relating to MySQL Cluster. MySQL Cluster Manager 1.1 provides support for adding data nodes online. See the MySQL Cluster Manager User Manual, for more information.

Event logs. MySQL Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in Event Reports Generated in MySQL Cluster. Event logs are of the two types listed here:

- *Cluster log*: Keeps a record of all desired reportable events for the cluster as a whole.
- *Node log*: A separate log which is also kept for each individual node.

Note

Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

Checkpoint. Generally speaking, when data is saved to disk, it is said that a *checkpoint* has been reached. More specific to MySQL Cluster, a checkpoint is a point in time where all committed transactions are stored on disk. With regard to the `NDB` storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster's data is maintained. These are shown in the following list:

- *Local Checkpoint (LCP)*: This is a checkpoint that is specific to a single node; however, LCP's take place for all nodes in the cluster more or less concurrently. An LCP involves saving all of a node's data to disk, and so usually occurs every few minutes. The precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.
- *Global Checkpoint (GCP)*: A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.

MySQL Cluster Nodes, Node Groups, Replicas, and Partitions

This section discusses the manner in which MySQL Cluster divides and duplicates data for storage.

A number of concepts central to an understanding of this topic are discussed in the next few paragraphs.

(Data) Node. An `ndbd` process, which stores a *replica* —that is, a copy of the *partition* (see below) assigned to the node group of which the node is a member.

Each data node should be located on a separate computer. While it is also possible to host multiple `ndbd` processes on a single computer, such a configuration is not supported.

It is common for the terms “node” and “data node” to be used interchangeably when referring to an `ndbd` process; where mentioned, management nodes (`ndb_mgmd` processes) and SQL nodes (`mysqld` processes) are specified as such in this discussion.

Node Group. A node group consists of one or more nodes, and stores partitions, or sets of *replicas* (see next item).

The number of node groups in a MySQL Cluster is not directly configurable; it is a function of the number of data nodes and of the number of replicas (`NoOfReplicas` [1815] configuration parameter), as shown here:

```
[number_of_node_groups] = number_of_data_nodes / NoOfReplicas
```

Thus, a MySQL Cluster with 4 data nodes has 4 node groups if `NoOfReplicas` [1815] is set to 1 in the `config.ini` file, 2 node groups if `NoOfReplicas` [1815] is set to 2, and 1 node group if `NoOfReplicas` [1815] is set to 4. Replicas are discussed later in this section; for more information about `NoOfReplicas` [1815], see Defining MySQL Cluster Data Nodes.

Note

All node groups in a MySQL Cluster must have the same number of data nodes.

Prior to MySQL Cluster NDB 7.0, it was not possible to add new data nodes to a MySQL Cluster without shutting down the cluster completely and reloading all of its data. In MySQL Cluster NDB 7.0 (beginning with MySQL Cluster version NDB 6.4.0), you can add new node groups (and thus new data nodes) to a running MySQL Cluster—see Adding MySQL Cluster Data Nodes Online, for information about how this can be done.

Partition. This is a portion of the data stored by the cluster. There are as many cluster partitions as nodes participating in the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one replica) available to the cluster.

A replica belongs entirely to a single node; a node can (and usually does) store several replicas.

`NDB` and user-defined partitioning. MySQL Cluster normally partitions `NDBCLUSTER` tables automatically. However, in MySQL 5.1 and later MySQL Cluster releases, it is possible to employ user-defined partitioning with `NDBCLUSTER` tables. This is subject to the following limitations:

1. Only `KEY` and `LINEAR KEY` partitioning schemes can be used with `NDBCLUSTER` tables.

2. When using `ndbd`, the maximum number of partitions that may be defined explicitly for any `NDBCLUSTER` table is `8 * [number of node groups]`. (The number of node groups in a MySQL Cluster is determined as discussed previously in this section.)

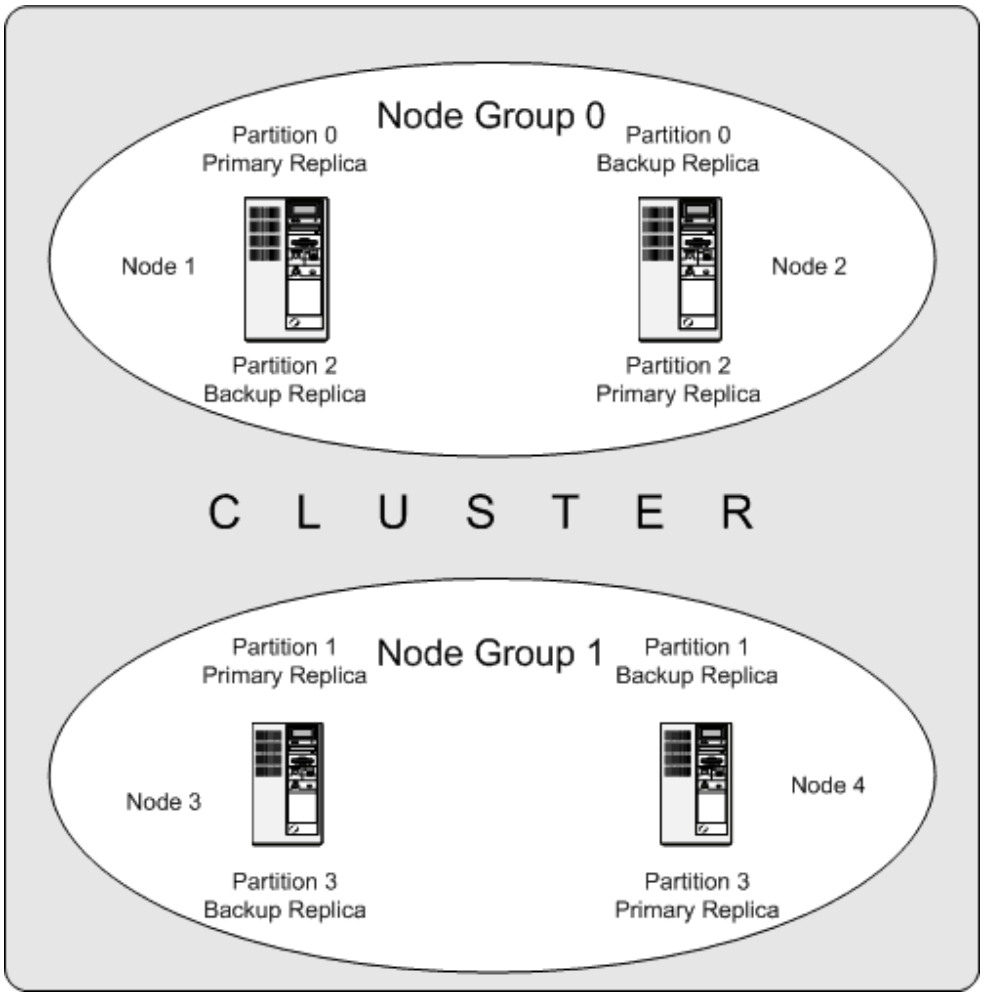
   When using `ndbmtd`, this maximum is also affected by the number of local query handler threads, which is determined by the value of the `MaxNoOfExecutionThreads` [1855] configuration parameter. In such cases, the maxmimum number of partitions that may be defined explicitly for an `NDB` table is equal to `4 * MaxNoOfExecutionThreads * [number of node groups]`.

   See `ndbmtd` — The MySQL Cluster Data Node Daemon (Multi-Threaded), for more information.

For more information relating to MySQL Cluster and user-defined partitioning, see Known Limitations of MySQL Cluster, and Partitioning Limitations Relating to Storage Engines.

Replica. This is a copy of a cluster partition. Each node in a node group stores a replica. Also sometimes known as a *partition replica*. The number of replicas is equal to the number of nodes per node group.

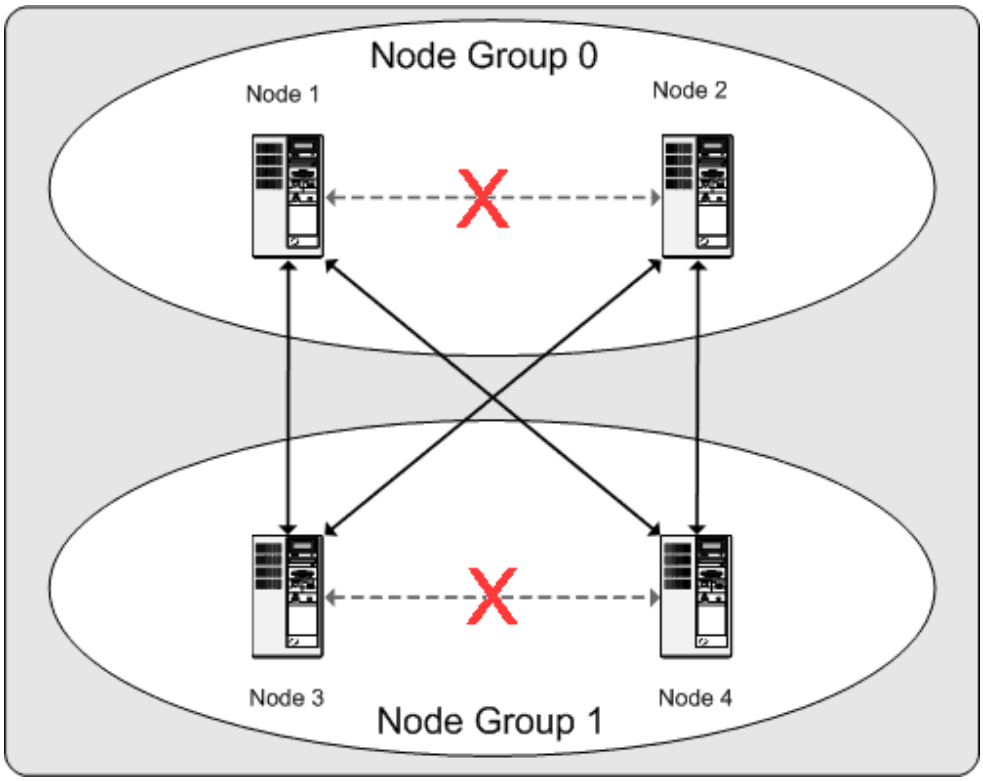
The following diagram illustrates a MySQL Cluster with four data nodes, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1. Note that only data (`ndbd`) nodes are shown here; although a working cluster requires an `ndb_mgm` process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted in the figure for clarity.



The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored—in multiple copies—on the same node group. Partitions are stored on alternate node groups as follows:

- Partition 0 is stored on node group 0; a *primary replica* (primary copy) is stored on node 1, and a *backup replica* (backup copy of the partition) is stored on node 2.
- Partition 1 is stored on the other node group (node group 1); this partition's primary replica is on node 3, and its backup replica is on node 4.
- Partition 2 is stored on node group 0. However, the placing of its two replicas is reversed from that of Partition 0; for Partition 2, the primary replica is stored on node 2, and the backup on node 1.
- Partition 3 is stored on node group 1, and the placement of its two replicas are reversed from those of partition 1. That is, its primary replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of a MySQL Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all data and remains viable. This is illustrated in the next diagram.



In this example, where the cluster consists of two node groups of two nodes each, any combination of at least one node in node group 0 and at least one node in node group 1 is sufficient to keep the cluster “alive” (indicated by arrows in the diagram). However, if *both* nodes from *either* node group fail, the remaining two nodes are not sufficient (shown by the arrows marked out with an **X**); in either case, the cluster has lost an entire partition and so can no longer provide access to a complete set of all cluster data.

MySQL Cluster Hardware, Software, and Networking Requirements

One of the strengths of MySQL Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (It is possible to reduce this requirement using Disk Data tables—see MySQL Cluster Disk Data Tables, for more information about these.) Naturally, multiple and faster CPUs can enhance performance. Memory requirements for other MySQL Cluster processes are relatively small.

The software requirements for MySQL Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support MySQL Cluster. For supported operating systems, a standard installation should be sufficient. The MySQL software requirements are simple: all that is needed is a production release of MySQL Cluster. It is not strictly necessary to compile MySQL yourself merely to be able to use MySQL Cluster. We assume that you are using the binaries appropriate to your platform, available from the MySQL Cluster software downloads page at http://dev.mysql.com/downloads/cluster/.

For communication between nodes, MySQL Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that a MySQL Cluster be run on its own subnet which is not shared with machines not forming part of the cluster for the following reasons:

- **Security.** Communications between MySQL Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within a MySQL Cluster is to run your MySQL Cluster on a protected network. If you intend to use MySQL Cluster for Web applications, the cluster

should definitely reside behind your firewall and not in your network's De-Militarized Zone (DMZ) or elsewhere.

See MySQL Cluster Security and Networking Issues, for more information.

- **Efficiency.** Setting up a MySQL Cluster on a private or protected network enables the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your MySQL Cluster not only helps protect against unauthorized access to MySQL Cluster data, it also ensures that MySQL Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

Network communication and latency. MySQL Cluster requires communication between data nodes and API nodes (including SQL nodes), as well as between data nodes and other data nodes, to execute queries and updates. Communication latency between these processes can directly affect the observed performance and latency of user queries. In addition, to maintain consistency and service despite the silent failure of nodes, MySQL Cluster uses heartbeating and timeout mechanisms which treat an extended loss of communication from a node as node failure. This can lead to reduced redundancy. Recall that, to maintain data consistency, a MySQL Cluster shuts down when the last node in a node group fails. Thus, to avoid increasing the risk of a forced shutdown, breaks in communication between nodes should be avoided wherever possible.

The failure of a data or API node results in the abort of all uncommitted transactions involving the failed node. Data node recovery requires synchronization of the failed node's data from a surviving data node, and re-establishment of disk-based redo and checkpoint logs, before the data node returns to service. This recovery can take some time, during which the Cluster operates with reduced redundancy.

Heartbeating relies on timely generation of heartbeat signals by all nodes. This may not be possible if the node is overloaded, has insufficient machine CPU due to sharing with other programs, or is experiencing delays due to swapping. If heartbeat generation is sufficiently delayed, other nodes treat the node that is slow to respond as failed.

This treatment of a slow node as a failed one may or may not be desirable in some circumstances, depending on the impact of the node's slowed operation on the rest of the cluster. When setting timeout values such as `HeartbeatIntervalDbDb` [1836] and `HeartbeatIntervalDbApi` [1837] for MySQL Cluster, care must be taken care to achieve quick detection, failover, and return to service, while avoiding potentially expensive false positives.

Where communication latencies between data nodes are expected to be higher than would be expected in a LAN environment (on the order of 100 µs), timeout parameters must be increased to ensure that any allowed periods of latency periods are well within configured timeouts. Increasing timeouts in this way has a corresponding effect on the worst-case time to detect failure and therefore time to service recovery.

LAN environments can typically be configured with stable low latency, and such that they can provide redundancy with fast failover. Individual link failures can be recovered from with minimal and controlled latency visible at the TCP level (where MySQL Cluster normally operates). WAN environments may offer a range of latencies, as well as redundancy with slower failover times. Individual link failures may require route changes to propagate before end-to-end connectivity is restored. At the TCP level this can appear as large latencies on individual channels. The worst-case observed TCP latency in these scenarios is related to the worst-case time for the IP layer to reroute around the failures.

SCI support. It is also possible to use the high-speed Scalable Coherent Interface (SCI) with MySQL Cluster, but this is not a requirement. See Using High-Speed Interconnects with MySQL Cluster, for more about this protocol and its use with MySQL Cluster.

MySQL Cluster Development History

In this section, we discuss changes in the implementation of MySQL Cluster in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x, as compared to earlier MySQL Cluster releases.

There are a number of significant changes in the implementation of the `NDBCLUSTER` storage engine in mainline MySQL 5.1 releases up to and including MySQL 5.1.23 as compared to that in MySQL 5.0; MySQL Cluster NDB 6.x and 7.x make further changes and improvements in MySQL Cluster in addition to these. The changes and features most likely to be of interest are shown in the following tables:

MySQL Cluster NDB 7.2
Distribution of MySQL users and privileges across MySQL Cluster SQL nodes
Distributed pushed-down joins, with greatly improved performance for many joins that can thus be pushed down and executed in parallel on the data nodes.
Improved default values for data node configuration parameters.

MySQL Cluster NDB 7.1
Production-level support for MySQL Cluster on Microsoft Windows platforms.
`ndbinfo` meta-information database
MySQL Cluster Connector for Java, including ClusterJ and OpenJPA (ClusterJPA) support
Native support for default column values

MySQL Cluster NDB 7.0
Multi-threaded data nodes (`ndbmtd` data node daemon)
Online addition of data nodes; online data redistribution
MySQL on Windows (alpha; source releases only)
Configuration cache
Backup snapshots (`START BACKUP ... SNAPSHOTSTART`, `START BACKUP ... SNAPSHOTEND` commands)
IPv6 support for geo-replication
Protected DDL operations
Dynamic buffering for NDB transporters
Increased flexibility in determining arbitration handling, using a new `Arbitration` [1844] data node configuration parameter
NDB API counters and associated status variables, which make it possible to observe the API-level effects of SQL statements on `NDB` tables from the `mysql` client.

MySQL Cluster NDB 6.3
Conflict detection and resolution for multi-master replication
Compressed backups and local checkpoints
Support for `OPTIMIZE TABLE`
Parallel data node recovery
Enhanced transaction coordinator selection
Improved SQL statement performance metrics
Transaction batching
`ndb_restore` attribute promotion
Support for `epoll` (Linux only)
Distribution awareness

MySQL Cluster NDB 6.3
NDB thread locks; realtime extensions for multiple CPUs

MySQL Cluster NDB 6.2
Improved backup status reporting (BackupReportFrequency [1851], REPORT BackupStatus)
Multiple connections per SQL node
Data access with NdbRecord (NDB API)
REPORT MemoryUsage command
Memory allocation improvements
Management client connection control
Micro-GCPs
Online ADD COLUMN; improved online index creation

MySQL Cluster NDB 6.1
Greater number of cluster nodes
Disabling of arbitration
Additional DUMP commands
Faster Disk Data backups
Batched slave updates

MySQL 5.1 (through 5.1.23)
MySQL Cluster Replication
Disk Data storage
Variable-size columns
User-defined partitioning
Autodiscovery of table schema changes
Online adding and dropping of indexes

MySQL Cluster Development in MySQL Cluster NDB 7.2.1

The following improvements to MySQL Cluster were made in MySQL Cluster NDB 7.2.1.

- **Distribution of MySQL users and privileges.** Automatic distribution of MySQL users and privileges across all SQL nodes in a given MySQL Cluster is now supported. To enable this support, you must first import an SQL script `share/mysql/ndb_dist_priv.sql` that is included with the MySQL Cluster NDB 7.2 distribution. This script creates several stored procedures which you can use to enable privilege distribution and perform related tasks.

  When a new MySQL Server joins a MySQL Cluster where privilege distribution is in effect, it also participates in the privilege distribution automatically.

  Once privilege distribution is enabled, all changes to the grant tables made on any `mysqld` attached to the cluster are immediately available on any other attached MySQL Servers. This is true whether the changes are made using `CREATE USER`, `GRANT`, or any of the other statements described elsewhere in this Manual (see Account Management Statements.) This includes privileges relating to stored routines and views; however, automatic distribution of the views or stored routines themselves is not currently supported.

  For more information, see Distributed MySQL Privileges for MySQL Cluster.

- **Distributed pushed-down joins.** Many joins can now be pushed down to the NDB kernel for processing on MySQL Cluster data nodes. Previously, a join was handled in MySQL Cluster by

means of repeated accesses of NDB by the SQL node; however, when pushed-down joins are enabled, a pushable join is sent in its entirety to the data nodes, where it can be distributed among the data nodes and executed in parallel on multiple copies of the data, with a single, merged result being returned to mysqld. This can reduce greatly the number of round trips between an SQL node and the data nodes required to handle such a join, leading to greatly improved performance of join processing.

It is possible to determine when joins can be pushed down to the data nodes by examining the join with EXPLAIN. A number of new system status variables (Ndb_pushed_queries_defined [1949], Ndb_pushed_queries_dropped [1949], Ndb_pushed_queries_executed [1949], and Ndb_pushed_reads [1949]) and additions to the counters table (in the ndbinfo information database) can also be helpful in determining when and how well joins are being pushed down.

More information and examples are available in the description of the ndb_join_pushdown [1925] server system variable. See also the description of the status variables referenced in the previous paragraph, as well as The ndbinfo counters Table.

- **Improved default values for data node configuration parameters.** In order to provide more resiliency to environmental issues and better handling of some potential failure scenarios, and to perform more reliably with increases in memory and other resource requirements brought about by recent improvements in join handling by NDB, the default values for a number of MySQL Cluster data node configuration parameters have been changed. The parameters and changes are described in the following list:

  - HeartbeatIntervalDbDb [1836]: Default increased from 1500 ms to 5000 ms.
  - ArbitrationTimeout [1844]: Default increased from 3000 ms to 7500 ms.
  - TimeBetweenEpochsTimeout [1840]: Now effectively disabled by default (default changed from 4000 ms to 0).
  - SharedGlobalMemory [1856]: Default increased from 20 MB to 128 MB.
  - MaxParallelScansPerFragment [1825]: Default increased from 32 to 256.

  In addition, the value computed for MaxNoOfLocalScans [1824] when this parameter is not set in config.ini has been increased by a factor of 4.

MySQL Cluster NDB 7.2.2 and later are based on MySQL Server 5.5 and are not covered here. See Chapter 17, *MySQL Cluster NDB 6.1 - 7.1*.

MySQL Cluster Development in MySQL Cluster NDB 7.1

The following improvements to MySQL Cluster have been made in MySQL Cluster NDB 7.1.

- **MySQL Cluster information database (ndbinfo).** The ndbinfo information database makes it possible to obtain real-time characteristics of a MySQL Cluster by issuing queries from the mysql client or other MySQL client applications. ndbinfo provides metadata specific to MySQL Cluster similarly to how the INFORMATION_SCHEMA database provides metadata for the standard MySQL Server. This eliminates much of the need to read log files, issue REPORT or DUMP commands in the ndb_mgm client, or parse the output of ndb_config in order to get configuration and status information from a running MySQL Cluster.

  For more information, see The ndbinfo MySQL Cluster Information Database.

- **Java connectors for MySQL Cluster.** The MySQL Cluster distribution now includes 2 new Java user APIs, ClusterJ and ClusterJPA. ClusterJ is an object-relational interface in a manner similar to that of Java persistence frameworks such as Hibernate. Cluster JPA is a reimplementation of OpenJPA. ClusterJ uses a backend library (NdbJTie) that provides access to the NDB storage engine without using a MySQL Server connection or JDBC. ClusterJPA also uses NdbJTie when it improves

performance, but can also process complex queries using JDBC and a MySQL Server connection, where it can take advantage of the MySQL query optimizer.

ClusterJ and Cluster JPA can also be made to work with recent MySQL Cluster NDB 7.0 releases although the necessary library and JAR files are included only in MySQL Cluster NDB 7.1.1 and later.

For more information about using ClusterJ and ClusterJPA, see MySQL Cluster Connector for Java.

- **New `CHANGE MASTER TO` option for circular replication.** Beginning with MySQL Cluster NDB 7.1.0, the `CHANGE MASTER TO` statement supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. (Log rotation and log deletion events are preserved.)

  See `CHANGE MASTER TO` Syntax, as well as `SHOW SLAVE STATUS` Syntax, for more information.

- **Native support for default column values.** Starting with MySQL Cluster NDB 7.1.4, default values for table columns are stored in the NDB kernel rather than by the MySQL server as was done previously. This means that inserts on tables having column value defaults can be smaller and faster than before, because less data must be sent from SQL nodes to `NDBCLUSTER`.

  Tables created using previous MySQL Cluster releases can still be used in MySQL Cluster 7.1.4 and later; however, they do not support native default values until they are upgraded. You can upgrade a table with non-native default values to support native default values using an offline `ALTER TABLE` statement.

- **MySQL Cluster on Windows (*Production*).** Beginning with MySQL Cluster NDB 7.1.3, MySQL Cluster is available for production use on Microsoft Windows operating systems; MySQL Cluster NDB 7.1 binaries for Windows can be obtained from http://dev.mysql.com/downloads/cluster/.

  Features and behavior are generally comparable to those found on previously supported platforms such as Linux and Solaris. However, you must install the binaries manually.

  Beginning with MySQL Cluster NDB 7.1.5, MySQL Cluster processes can be run as Windows services.

  If you wish to build MySQL Cluster from source on Windows, you must configure the build using the `WITH_NDBCLUSTER_STORAGE_ENGINE` option. For more information, see Installing MySQL from Source on Windows.

- **`--nowait-nodes` [1967] option for management servers.** It is now possible to configure a cluster with two management servers, but to start the cluster using only one of them by starting the management node daemon with the `--nowait-nodes` [1967] option. The other management server can then be started at a later time to join the running MySQL Cluster.

- **Improved lock handling for primary key lookups on `BLOB` tables.** A MySQL Cluster table stores all but the first 256 bytes of any `BLOB` or `TEXT` column values in a separate `BLOB` table; when executing queries against such tables, a shared lock is obtained. Prior to MySQL Cluster NDB 7.1.1, when the query used a primary key lookup and took place within a transaction, the lock was held for the duration of the transaction, even after no more data was being read from the `NDB` table. Now in such cases, the lock is released when all `BLOB` data associated with the table has been read. (Bug #49190)

  Note

  A shared lock is also taken for unique key lookups; it is still the case that this lock is held for the duration of the transaction.

- **Heartbeat thread policy and priority.** Beginning with MySQL Cluster NDB 7.1.2, a new configuration parameter `HeartbeatThreadPriority` makes it possible to set the policy and the priority for the heartbeat thread on management and API nodes.

- **Improved access to partitioning information.** The `ndb_desc` utility now provides additional information about the partitioning of data stored in MySQL Cluster. Beginning with MySQL Cluster NDB 7.1.2, the `--blob-info` [1982] option causes this program to include partition information for `BLOB` tables in its output. Also beginning with MySQL Cluster NDB 7.1.2, the `--extra-node-info` [1982] option causes `ndb_desc` to include information about data distribution (that is, which table fragments are stored on which data nodes). Each of these options also requires the use of the `--extra-partition-info` [1982] option.

  Information about partition-to-node mappings can also be obtained using the `Table::getFragmentNodes()` method, also added in MySQL Cluster NDB 7.1.2.

- **Replication attribute promotion and demotion.** Beginning with MySQL Cluster NDB 7.1.3, MySQL Cluster Replication supports attribute promotion and demotion when replicating between columns of different but similar types on the master and the slave. For example, it is possible to promote an `INT` column on the master to a `BIGINT` column on the slave, and to demote a `TEXT` column to a `VARCHAR` column.

  The implementation of type demotion distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` [1646] global server system variable.

  For more information, see Attribute promotion and demotion (MySQL Cluster).

- **Change in `ndbinfo` database.** The experimental `pools` table was removed from `ndbinfo` in MySQL Cluster NDB 7.1.3. Applications which used this table can and should be rewritten to use other `ndbinfo` tables.

- **Configuration caching control.** Beginning with MySQL Cluster NDB 7.1.4, it is possible to disable the management server's configuration cache using the `--config-cache` [1963] option, which forces `ndb_mgmd` to read its configuration data from the `config.ini` configuration file every time it starts. For more information about configuration caching and this option, see MySQL Cluster Configuration Files. See also `ndb_mgmd` — The MySQL Cluster Management Server Daemon.

- **Incompatible change in NDB API event reporting.** Beginning with MySQL Cluster NDB 7.1.4, DDL events are no longer reported on `Event` objects by default. Instead the desired level of event reporting (`EventReport` value) must be set explicitly using `Event::setReport()`.

- **Number of table attributes.** Beginning with MySQL Cluster NDB 7.1.4, the maximum number of attributes (columns plus indexes) per table has been increased from 128 to 512.

- **`InnoDB` support in commercial binaries.** Beginning with MySQL Cluster NDB 7.1.4b, all commercial binary releases of MySQL Cluster provide support for the `InnoDB` storage engine.

- **Heartbeat ordering.** Beginning with MySQL Cluster NDB 7.1.5, it is possible to set a specific order for transmission of heartbeats between data nodes, using the `HeartbeatOrder` [1837] data node configuration parameter introduced in this version. This parameter can be useful in situations where multiple data nodes are running on the same host and a temporary disruption in connectivity between hosts would otherwise cause the loss of a node group (and thus failure of the cluster).

- **Relaxed `ndb_restore` column comparison rules.** When restoring data, ndb_restore compares the attributes of a column for equality with the definition of the column in the target table. However, not all of these attributes need to be the same for `ndb_restore` to be meaningful, safe and useful. Beginning with MySQL Cluster NDB 7.1.5, `ndb_restore` automatically ignores differences in certain column attributes which do not necessarily have to match between the version of the column in a backup and the version of that column in the MySQL Cluster to which the column data is being restored. These attributes include the following:

  - `COLUMN_FORMAT` setting (`FIXED`, `DYNAMIC`, or `DEFAULT`)

  - `STORAGE` setting (`MEMORY` or `DISK`)

- The default value
- The distribution key

In such cases, `ndb_restore` reports any such differences to minimize any chance of user error.

- **Storage of user data in `anyValue`.** When writing NDB events to the binary log, MySQL Cluster uses `OperationOptions::anyValue` to store the server ID. Beginning with MySQL Cluster NDB 7.1.6, it is possible to store user data from an NDB API application in part of the `anyValue` when `mysqld` has been started with the `--server-id-bits` [1918] option set to a nondefault value. Also beginning with MySQL Cluster NDB 7.1.6, it is possible to view this data in the output of mysqlbinlog, for which its own `--server-id-bits` [353] option is added.

- **`--add-drop-trigger` [294] option for `mysqldump`.** Beginning with MySQL Cluster NDB 7.1.8, this option can be used to force all `CREATE TRIGGER` statements in `mysqldump` output to be preceded by a `DROP TRIGGER IF EXISTS` statement.

- **Forcing node shutdown and restart.** In MySQL Cluster NDB 7.1.8 and later, it is possible using the `ndb_mgm` management client or the MGM API to force a data node shutdown or restart even if this would force the shutdown or restart of the entire cluster. In the management client, this is implemented through the addition of the `-f` (force) option to the `STOP` and `RESTART` commands. For more information, see Commands in the MySQL Cluster Management Client. The MGM API also adds two new methods for forcing such a node shutdown or restart; see `ndb_mgm_stop4()`, and `ndb_mgm_restart4()`, for more information about these methods.

- **Disk Data usage statistics (`diskpagebuffer` table).** MySQL Cluster 7.1.9 introduces a new table in the `ndbinfo` information database. The `diskpagebuffer` table provides real-time data on disk page buffer usage. These statistics can be used to monitor performance of MySQL Cluster Disk Data read and write operations, and can prove useful in the tuning of Disk Data parameters such as `DiskPageBufferMemory` [1856].

- **`InnoDB` Plugin support.** Beginning with MySQL Cluster NDB 7.1.9, the MySQL Server supplied with MySQL Cluster supports the `InnoDB` Plugin. For more information about enabling the plugin if you are building MySQL Cluster from source, see MySQL Cluster Installation.

  Note

  Due to a packaging issue, the `InnoDB` plugin was not included in RPMs for MySQL Cluster NDB 7.1.9; this issue was corrected in MySQL Cluster NDB 7.1.9a. (Bug #58283)

- **`TimeBetweenEpochsTimeout` and GCP stop control.** Beginning with MySQL Cluster NDB 7.1.10, it is possible to disable GCP stops by setting `TimeBetweenEpochsTimeout` [1840] to 0. In addition, a warning is written to the cluster log whenever the time required for a GCP save exceeds 60 seconds or the time required for a GCP commit exceeds 10 seconds. This warning includes a report of the current value of `TimeBetweenEpochsTimeout` [1840]. For more information, see Disk Data and `GCP Stop` errors.

- **Skipping corrupted tables in `NDB` native backups.** Beginning with MySQL Cluster NDB 7.1.10, you can cause `ndb_restore` to ignore tables that are corrupted due to missing blob parts tables by using the the `--skip-broken-objects` [2003] option. When this option is used, such tables are skipped, and the restoration of any remaining uncorrupted tables in the backup continues.

- **`BLOB` read and write batching.** Beginning with MySQL Cluster NDB 7.1.10, it possible to control batching of `BLOB` read and write operations. For SQL nodes, this can be done using the `--ndb-blob-read-batch-bytes` [1913] and `--ndb-blob-write-batch-bytes` [1913] options for `mysqld`. In NDB API applications, you can control batching of `BLOB` reads and writes using the `NdbTransaction` methods `setMaxPendingBlobReadBytes()`, `getMaxPendingBlobReadBytes()`, `setMaxPendingBlobWriteBytes()`, and `getMaxPendingBlobWriteBytes()`.

- **Restoring from a NDB native backup to a differently-named database.** MySQL Cluster NDB 7.1.11 adds a new `--rewrite-database` [2003] option to `ndb_restore`, which makes it possible to restore to a database having a different name from that of the database in the backup. The option can be used multiple times, and it is possible to restore from more than one source database in the backup to a single target database (although no protection against table or other object name collision is provided).

  See `ndb_restore` — Restore a MySQL Cluster Backup, for more information.

- **Selective over-commit handling.** Beginning with MySQL Cluster NDB 7.1.10, it is possible to exercise more direct control over uncommitted operations from transactions aborted due to timeouts flushing redo logs to disk. This is implemented using three configuration parameters added in this version of MySQL Cluster: the data node configuration parameters `RedoOverCommitCounter` [1862] and `RedoOverCommitLimit` [1862], and the API node configuration parameter `DefaultOperationRedoProblemAction` [1867].

  When an attempt to flush a given redo log takes longer than `RedoOverCommitLimit` [1862] seconds, and this occurs `RedoOverCommitLimit` [1862] times or more, the transactions contained within the redo log are aborted. Any operations left uncommitted as a result are either aborted or re-tried, according to the value of `DefaultOperationRedoProblemAction` [1867].

  For more information, see Redo log over-commit handling

- **`INFORMATION_SCHEMA` inprovements.** Beginning with MySQL Cluster NDB 7.1.11, Beginning with MySQL Cluster NDB 7.0.22, `INFORMATION_SCHEMA` provides disk usage information for MySQL Cluster Disk Data tables. Previously, `INFORMATION_SCHEMA.TABLES` showed only the space usage for the in-memory data part of the table. Now, it also shows the space allocated for and used by the disk_part data of that table as well.

  In addition, the `INFORMATION_SCHEMA.PARTITIONS` table (which did not show any statistics for `NDB` tables) now shows correct values in this table's `TABLE_ROWS`, `AVG_ROW_LENGTH`, `DATA_LENGTH`, `MAX_DATA_LENGTH`, and `DATA_FREE` columns, for each partition.

- **`ndb_restore` attribute demotion.** Beginning with MySQL Cluster NDB 7.1.11, it is possible to enable attribute demotion when restoring a MySQL Cluster from a native backup running `ndb_restore` with a new `--lossy-conversions` [1995] option.

  In general,the rules governing demotion are the same as for MySQL replication, although there are some exceptions that you may need to take into account being employing this option. See Replication of Columns Having Different Data Types, for information about type conversions currently supported by attribute promotion and demotion in MySQL Cluster.

- **Improved multi-threaded order index building.** Previously, it was not possible to enable multi-threaded building of ordered indexes during initial restarts. In MySQL Cluster NDB 7.1.11, this can now be done, using the new `TwoPassInitialNodeRestartCopy` data node configuration parameter.

- **Configuration version information in `ndbinfo.nodes`.** You can see which version or versions of the MySQL Cluster configuration file are in effect on the data nodes by checking the `config_generation` column which is added to the `nodes` table in MySQL Cluster NDB 7.1.13.

- **Configuration version information in `ndbinfo.nodes`.** You can see which version or versions of the MySQL Cluster configuration file are in effect on the data nodes by checking the `config_generation` column which is added to the `nodes` table in MySQL Cluster NDB 7.1.13.

- **Improvements in adding data nodes online.** Begining with MySQL Cluster NDB 7.0.24, it is possible to add data nodes online to a running MySQL Cluster without performing a rolling restart of the cluster or starting data node processes with the `--nowait-nodes` [1955] option. This can be done by setting `Nodegroup = 65536` [1815] in the `config.ini` file for any data nodes that should be started at a later time, when first starting the cluster. The amount of time the cluster waits

before doing this can be controlled using the `StartNoNodeGroupTimeout` [1836] data node configuration parameter.

- **Unique key updates in replication.** It is possible in MySQL Cluster NDB 7.1.14 and later to employ operations that update unique keys when replicating `NDB` tables. Previously this could lead to duplicate key errors when trying to execute the binary log (due to the fact that row events in the binary log were ordered according to the partitioning of the base table, and could differ in order within the epoch for that in which they were executed).

  Important

  Master and slave tables must both be using the `NDB` storage engine for this to work.

- Starting with MySQL Cluster NDB 7.1.17, the NDB kernel implements a number of statistical counters relating to actions performed by or affecting `Ndb` objects. Such events include starting, closing, and aborting transactions; operations using primary keys or unique keys; table, range, and pruned scans; blocking of threads by incompleted operations; and data and events sent and received by MySQL Cluster nodes. NDB API statistics counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes. A MySQL Server running as an SQL node in the cluster can access the values of these counters as system status variables, as seen in the output of `SHOW STATUS`, or in the results of queries against the `SESSION_STATUS` or `GLOBAL_STATUS` table in the `INFORMATION_SCHEMA` database. By comparing the values of these status variables before and after the execution of statements affecting `NDB` tables, you can observe the corresponding actions taken on the NDB API level. This can be highly useful when monitoring and tuning MySQL Cluster.

  For more information, see NDB API Statistics Counters and Variables. See also MySQL Cluster Status Variables, for information about the individual status variables.

- **Version 2 binary log row events.** New versions of the `WRITE_ROW`, `UPDATE_ROW`, and `DELETE_ROW` events have been implemented in MySQL Cluster NDB 7.1.16, extending them with additional information intended to support future enhancements; these are referred to as “Version 2” binary log events.

  Version 2 log events are not backward compatible, and cannot be read by older slaves. A new `mysqld` option `--log-bin-use-v1-row-events` [1648] can be employed to force use of Version 1 events when writing the binary log. This can be used during upgrades to make a newer `mysqld` generate Version 1 binary log row events that can be read by older slaves.

- **Circular replication: “Primary wins first” conflict detection.** Two new conflict detection functions `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` can be useful in “active-active” circular replication scenarios with two MySQL Clusters. For each case, we designate one cluster as primary and one as secondary, and implement a “primary always wins” rule for determining whether to accept conflicting changes. When using `NDB$EPOCH()`, conflicting rows on the secondary are realigned with those on the primary; when using `NDB$EPOCH_TRANS()`, it is transactions containing rows in conflict (and any transactions which depend on them) on the secondary that are realigned.

  When using `NDB$EPOCH_TRANS()` as the conflict detection function, the binary log must be written using Version 2 binary logging row events; that is, the `mysqld` processes on both the primary and the secondary must be started with `--log-bin-use-v1-row-events=0` [1648]. In addition, the secondary's binary log must include transaction IDs for all rows, that is, by setting `--ndb-log-transaction-id=1` [1916].

  You can monitor conflict detection and resolution performed using these functions by reading a number of related server status variables, including `Ndb_conflict_fn_epoch` [1947], `Ndb_conflict_fn_epoch_trans` [1947], and `Ndb_conflict_trans_row_conflict_count` [1948] (among others). See MySQL Cluster Status Variables.

For more information, see MySQL Cluster Replication Conflict Resolution.

- **Fail-fast data node capability.** Beginning with MySQL Cluster NDB 7.1.17, it is possible to enable fail-fast behavior for data nodes by enabling the `CrashOnCorruptedTuple` [1833] configuration parameter introduced in this version (disabled by default). Doing so causes data nodes to fail whenever they detect a corrupted tuple.

- **Rows per partition limit removed.** Previously it was possible to store a maximum of 46137488 rows in a single MySQL Cluster partition—that is, per data node. Beginning with MySQL Cluster NDB 7.1.25, this limitation has been lifted, and there is no longer any practical upper limit to this number.

MySQL Cluster NDB 7.1 (actually, MySQL Cluster NDB 6.3 and later) is also supported by MySQL Cluster Manager, which provides an advanced command-line interface that can simplify many complex MySQL Cluster management tasks. See MySQL™ Cluster Manager 1.1.6 User Manual, for more information.

MySQL Cluster Development in MySQL Cluster NDB 7.0

The following list provides an overview of significant feature additions and changes made in MySQL Cluster NDB 7.0. For more detailed information about all feature changes and bugfixes made in MySQL Cluster NDB 7.0, see Changes in MySQL Cluster NDB 7.0.

Important

Early development versions of MySQL Cluster NDB 7.0 were known as “MySQL Cluster NDB 6.4”, and the first four releases in this series were identified as MySQL Cluster NDB 6.4.0 through 6.4.3. Any information relating to these MySQL Cluster NDB 6.4.x releases appearing in this documentation apply to MySQL Cluster NDB 7.0.

MySQL Cluster NDB 7.0.4 is the fifth MySQL Cluster NDB 7.0 release; it is the successor to MySQL Cluster NDB 6.4.3.

- **MySQL Cluster on Windows (*alpha*).** MySQL Cluster NDB 7.0 is available on an experimental basis for Windows operating systems (for production use on Windows, you should use MySQL Cluster NDB 7.1.3 or later). Features and behavior comparable to those found on platforms that are already supported—such as Linux and Solaris—are planned for MySQL Cluster on Windows. In MySQL Cluster NDB 7.0, you must build from source (Windows binaries are available for MySQL Cluster NDB 7.1 releases). To enable MySQL Cluster support on Windows when building from source, you must configure the build using the `WITH_NDBCLUSTER_STORAGE_ENGINE` option. For more information, see Installing MySQL from Source on Windows.

- **Ability to add nodes and node groups online.** Beginning with MySQL Cluster NDB 6.4.0, it is possible to add new node groups (and thus new data nodes) to a running MySQL Cluster without shutting down and reloading the cluster. As part of enabling this feature, a new command `CREATE NODEGROUP` has been added to the cluster management client and the functionality of the `ALTER ONLINE TABLE ... REORGANIZE PARTITION` SQL statement has been extended. For more information, see Adding MySQL Cluster Data Nodes Online.

- **Data node multithreading support.** Beginning with MySQL Cluster NDB 6.4.0, a multithreaded version of the data node daemon, named `ndbmtd`, is available for use on data node hosts with multiple CPU cores. This binary is built automatically when compiling with MySQL Cluster support; no additional options other than those needed to provide MySQL Cluster support are needed when configuring the build. In most respects, `ndbmtd` functions in the same way as `ndbd`, and can use the same command-line options and configuration parameters. In addition, the new `MaxNoOfExecutionThreads` [1855] configuration parameter can be used to determine the number of data node process threads for `ndbmtd`. For more information, see `ndbmtd` — The MySQL Cluster Data Node Daemon (Multi-Threaded).

Note

Disk Data tables are not yet supported for use with `ndbmtd`.

- **Configuration cache.** Formerly, MySQL Cluster configuration was stateless—that is, configuration information was reloaded from the cluster's global configuration file (usually `config.ini`) each time `ndb_mgmd` was started. Beginning with MySQL Cluster NDB 6.4.0, the cluster's configuration is cached internally, and the global configuration file is no longer automatically re-read when the management server is restarted. This behavior can be controlled using the management server options `--configdir`, `--initial`, and `--reload`. In MySQL Cluster NDB 7.0.15 and later, the configuration cache can be disabled using the `--config-cache` option. For more information about these changes, see MySQL Cluster Configuration Files. For more information about the new management server options, see `ndb_mgmd` — The MySQL Cluster Management Server Daemon.

- **Detection of NDB API client connection errors.** In MySQL Cluster NDB 7.0 (6.4.0 and later releases), the NDB API's `Ndb_cluster_connection` class adds the `get_latest_error()` and `get_latest_error_msg()` methods for catching and diagnosing problems with NDB API client connections.

- **Snapshot options for backups.** Beginning with MySQL Cluster NDB 6.4.0, you can determine when performing a cluster backup whether the backup matches the state of the data when the backup was started or when it was completed, using the new options `SNAPSHOTSTART` and `SNAPSHOTEND` for the management client's `START BACKUP` command. See Using The MySQL Cluster Management Client to Create a Backup, for more information.

- **Dynamic NDB transporter send buffer memory allocation.** Previously, the NDB kernel used a fixed-size send buffer for every data node in the cluster, which was allocated when the node started. Because the size of this buffer could not be changed after the cluster was started, it was necessary to make it large enough in advance to accommodate the maximum possible load on any transporter socket. However, this was an inefficient use of memory, since much of it often went unused. Beginning with MySQL Cluster NDB 6.4.0, send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. This change is reflected by the addition of the configuration parameters `TotalSendBufferMemory` [1861], `ReservedSendBufferMemory` [1861], and `OverLoadLimit`, as well as a change in how the existing `SendBufferMemory` [1870] configuration parameter is used. For more information, see Configuring MySQL Cluster Send Buffer Parameters.

- **Robust DDL operations.** Beginning with MySQL Cluster NDB 6.4.0, DDL operations (such as `CREATE TABLE` or `ALTER TABLE`) are protected from data node failures; in the event of a data node failure, such operations are now rolled back gracefully. Previously, if a data node failed while trying to perform a DDL operation, the MySQL Cluster data dictionary became locked and no further DDL statements could be executed without restarting the cluster.

- **IPv6 support in MySQL Cluster Replication.** Beginning with MySQL Cluster NDB 6.4.1, IPv6 networking is supported between MySQL Cluster SQL nodes, which makes it possible to replicate between instances of MySQL Cluster using IPv6 addresses. However, IPv6 is supported only for direct connections between MySQL servers; all connections *within* an individual MySQL Cluster must use IPv4. For more information, see Known Issues in MySQL Cluster Replication.

- **Restoring specific databases, tables, or columns from a MySQL Cluster backup.** It is now possible to exercise more fine-grained control when restoring a MySQL Cluster from backup using `ndb_restore`. Beginning with MySQL Cluster NDB 6.4.3, you can choose to restore only specified tables or databases, or exclude specific tables or databases from being restored, using the new `ndb_restore` options `--include-tables`, `--include-databases`, `--exclude-tables`, and `--exclude-databases`. Beginning with MySQL Cluster NDB 7.0.7, it is also possible to restore to a table having fewer columns than the original using the `--exclude-missing-columns` option.

For more information about all of these options, see ndb_restore — Restore a MySQL Cluster Backup.

- **Improved Disk Data file system configuration.** As of MySQL Cluster NDB 6.4.3, you can specify default locations for MySQL Cluster Disk Data data files and undo log files using the data node configuration parameters FileSystemPathDD [1857], FileSystemPathDataFiles [1858], and FileSystemPathUndoFiles [1858]. This eliminates the need to use symbolic links to place Disk Data files separately from other files in data node file systems to improve Disk Data performance. For more information, see Disk Data file system parameters.

- **Automatic creation of Disk Data log file groups and tablespaces.** Beginning with MySQL Cluster NDB 6.4.3, using the data node configuration parameters InitialLogFileGroup [1859] and InitialTablespace [1859], you can cause the creation of a MySQL Cluster Disk Data log file group, tablespace, or both, when the cluster is first started. When using these parameters, no SQL statements are required to create these Disk Data objects. For more information, see *Disk Data object creation parameters*.

- **Improved internal message passing and record handling.** MySQL Cluster NDB 7.0 contains 2 changes that optimize the use of network connections by addressing the size and number of messages passed between data nodes, and between data nodes and API nodes, which can increase MySQL Cluster and application performance:

  - **Packed reads.** Formerly, each read request signal contained a list of columns to be retrieved, each of these column identifiers using 4 bytes within the message. This meant that the message size increased as the number of columns being fetched increased. In addition, in the response from the data node, each column result was packed to a 4-byte boundary, which resulted in wasted space. In MySQL Cluster NDB 7.0, messaging for read operations is optimized in both directions, using a bitmap in the read request to specify the columns to be fetched. Where many fields are requested, this can result in a significant message size reduction as compared with the old method. In addition, the 4-byte packing in responses is no longer used, which means that smaller fields consume less space.

  - **Long signal transactions.** This enhancement reduces the number of messages and signals that are sent to data nodes for complex requests. Prior to MySQL Cluster NDB 7.0, there was a 100 byte limit on the size of the request signal, which meant that complex requests had to be split up between multiple messages prior to transmission, then reassembled on the receiving end. In addition to actual payload data, each message required its own operating system and protocol overhead such as header information. This often wasted network bandwidth and data node CPU. The maximum size of the message is now 32 KB, which is sufficient to accommodate most queries.

  Both of these optimizations are internal to the NDB API, and so is transparent to applications; this is true whether an application uses the NDB API directly or does so indirectly through an SQL node.

- **Configuration parameter data dumps.** Starting with MySQL Cluster NDB 7.0.6, the ndb_config utility supports a --configinfo option that causes it to dump a list of all configuration parameters supported by the cluster, along with brief descriptions, information about the parameters' default and permitted values, and the sections of the config.ini file in which the parameters apply. An additional --xml switch causes ndb_config to use XML rather than plaintext output. Using ndb_config --configinfo or ndb_config --configinfo --xml requires no access to a running MySQL Cluster, any other programs, or any files. For more information and examples, see ndb_config — Extract MySQL Cluster Configuration Information.

- **Per-table reporting of free space on disk.** The INFORMATION_SCHEMA.FILES table shows information about used and free space in MySQL Cluster Disk Data data files, but this information is not applicable to individual tables. In MySQL Cluster NDB 7.0.8 and later, the ndb_desc utility provides two additional columns in its output that show the amount of space allocated on disk for a given NDB table as well the amount of space that remains available for additional storage of disk-based column data for that table. For more information, see ndb_desc — Describe NDB Tables.

- **Improved restart times.** Optimizations in redo log handling and other file system operations introduced in MySQL Cluster NDB 7.0.9 have the potential to reduce considerably the time required for restarts. While actual performance benefits observed in production setups will naturally vary depending on database size, hardware, and other conditions, our own preliminary testing has shown that these improvements can yield startup times that are faster than those typical of previous MySQL Cluster NDB 7.0 releases by a factor of 50 or more.

- **Native support for default column values.** Starting with MySQL Cluster NDB 7.0.15, default values for table columns are stored in the NDB kernel rather than by the MySQL server as was done previously. This means that inserts on tables having column value defaults can be smaller and faster than before, because less data must be sent from SQL nodes to `NDBCLUSTER`.

  Tables created using previous MySQL Cluster releases can still be used in MySQL Cluster 7.0.15 and later; however, they do not support native default values until they are upgraded. You can upgrade a table with non-native default values to support native default values using an offline `ALTER TABLE` statement.

- **`--nowait-nodes` [1967] option for management servers.** Starting with MySQL Cluster NDB 7.0.10, it is possible to configure a cluster with two management servers, but to start the cluster using only one of them by starting the management node daemon with the `--nowait-nodes` [1967] option. The other management server can then be started at a later time to join the running MySQL Cluster.

- **Increased flexibility in online upgrade procedure.** Previously, when performing an upgrade of a running MySQL cluster, the order in which the types of cluster nodes had to be upgraded was very strict. However, beginning with MySQL Cluster NDB 7.0.10, MySQL Cluster supports online upgrading of API nodes (including MySQL servers running as SQL nodes) online upgrading management nodes, data nodes, or both.

  Important

  Before attempting to use this new upgrade functionality, see Performing a Rolling Restart of a MySQL Cluster, for additional information, especially if you are planning an online upgrade to MySQL Cluster NDB 7.0 from MySQL Cluster NDB 6.3.

- **New `CHANGE MASTER TO` option for circular replication.** Beginning with MySQL Cluster NDB 7.0.11, the `CHANGE MASTER TO` statement supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. (Log rotation and log deletion events are preserved.)

  See `CHANGE MASTER TO` Syntax, as well as `SHOW SLAVE STATUS` Syntax, for more information.

- **New replication conflict resolution strategy.** Beginning with MySQL Cluster NDB 7.0.11, the function `NDB$MAX_DELETE_WIN()` is available to implement “greatest timestamp, delete wins” conflict resolution. See `NDB$MAX_DELETE_WIN(`*`column_name`*`)`, for more information.

- **Improved lock handling for primary key lookups on `BLOB` tables.** A MySQL Cluster table stores all but the first 256 bytes of any `BLOB` or `TEXT` column values in a separate `BLOB` table; when executing queries against such tables, a shared lock is obtained. Prior to MySQL Cluster NDB 7.0.12, when the query used a primary key lookup and took place within a transaction, the lock was held for the duration of the transaction, even after no more data was being read from the `NDB` table. Now in such cases, the lock is released when all `BLOB` data associated with the table has been read. (Bug #49190)

  Note

  A shared lock is also taken for unique key lookups; it is still the case that this lock is held for the duration of the transaction.

- **Heartbeat thread policy and priority.** Beginning with MySQL Cluster NDB 7.0.13, a new configuration parameter `HeartbeatThreadPriority` makes it possible to set the policy and the priority for the heartbeat thread on management and API nodes.

- **Improved access to partitioning information.** The `ndb_desc` utility now provides additional information about the partitioning of data stored in MySQL Cluster. Beginning with MySQL Cluster NDB 7.0.13, the `--blob-info` [1982] option causes this program to include partition information for `BLOB` tables in its output. Beginning with MySQL Cluster NDB 7.0.14, the `--extra-node-info` [1982] option causes `ndb_desc` to include information about data distribution (that is, which table fragments are stored on which data nodes). Each of these options also requires the use of the `--extra-partition-info` [1982] option.

  Information about partition-to-node mappings can also be obtained using the `Table::getFragmentNodes()` method, also added in MySQL Cluster NDB 7.0.14.

- **Replication attribute promotion and demotion.** Beginning with MySQL Cluster NDB 7.0.14, MySQL Cluster Replication supports attribute promotion and demotion when replicating between columns of different but similar types on the master and the slave. For example, it is possible to promote an `INT` column on the master to a `BIGINT` column on the slave, and to demote a `TEXT` column to a `VARCHAR` column.

  The implementation of type demotion distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` [1646] global server system variable.

  For more information, see Attribute promotion and demotion (MySQL Cluster).

- **Incompatible change in NDB API event reporting.** Beginning with MySQL Cluster NDB 7.0.15, DDL events are no longer reported on `Event` objects by default. Instead such event reporting must be enabled explicitly using the `Event::setReport()` method. For more information, see `Event::setReport()`, and The `Event::EventReport` Type.

- **Number of table attributes.** Beginning with MySQL Cluster NDB 7.0.15, the maximum number of attributes (columns plus indexes) per table has been increased from 128 to 512.

- **Heartbeat ordering.** Beginning with MySQL Cluster NDB 7.0.16, it is possible to set a specific order for transmission of heartbeats between data nodes, using the `HeartbeatOrder` [1837] data node configuration parameter introduced in this version. This parameter can be useful in situations where multiple data nodes are running on the same host and a temporary disruption in connectivity between hosts would otherwise cause the loss of a node group (and thus failure of the cluster).

- **Relaxed `ndb_restore` column comparison rules.** When restoring data, ndb_restore compares the attributes of a column for equality with the definition of the column in the target table. However, not all of these attributes need to be the same for `ndb_restore` to be meaningful, safe and useful. Beginning with MySQL Cluster NDB 7.0.16, `ndb_restore` automatically ignores differences in certain column attributes which do not necessarily have to match between the version of the column in a backup and the version of that column in the MySQL Cluster to which the column data is being restored. These attributes include the following:

  - `COLUMN_FORMAT` setting (`FIXED`, `DYNAMIC`, or `DEFAULT`)
  - `STORAGE` setting (`MEMORY` or `DISK`)
  - The default value
  - The distribution key

  In such cases, `ndb_restore` reports any such differences to minimize any chance of user error.

- **Storage of user data in `anyValue`.** When writing NDB events to the binary log, MySQL Cluster uses `OperationOptions::anyValue` to store the server ID. Beginning with MySQL Cluster

NDB 7.0.17, it is possible to store user data from an NDB API application in part of the `anyValue` when `mysqld` has been started with the `--server-id-bits` [1918] option set to a nondefault value. Also beginning with MySQL Cluster NDB 7.0.17, it is possible to view this data in the output of mysqlbinlog, for which its own `--server-id-bits` [353] option is added.

- **`--add-drop-trigger` [294] option for `mysqldump`.** Beginning with MySQL Cluster NDB 7.0.19, this option can be used to force all `CREATE TRIGGER` statements in `mysqldump` output to be preceded by a `DROP TRIGGER IF EXISTS` statement.

- **Forcing node shutdown and restart.** In MySQL Cluster NDB 7.0.19 and later, it is possible using the `ndb_mgm` management client or the MGM API to force a data node shutdown or restart even if this would force the shutdown or restart of the entire cluster. In the management client, this is implemented through the addition of the `-f` (force) option to the `STOP` and `RESTART` commands. For more information, see Commands in the MySQL Cluster Management Client. The MGM API also adds two new methods for forcing such a node shutdown or restart; see `ndb_mgm_stop4()`, and `ndb_mgm_restart4()`, for more information about these methods.

- **`TimeBetweenEpochsTimeout` and GCP stop control.** Beginning with MySQL Cluster NDB 7.0.21, it is possible to disable GCP stops by setting `TimeBetweenEpochsTimeout` [1840] to 0. In addition, a warning is written to the cluster log whenever the time required for a GCP save exceeds 60 seconds or the time required for a GCP commit exceeds 10 seconds. This warning includes a report of the current value of `TimeBetweenEpochsTimeout` [1840]. For more information, see Disk Data and `GCP Stop` errors.

- **Skipping corrupted tables in `NDB` native backups.** Beginning with MySQL Cluster NDB 7.0.21, you can cause `ndb_restore` to ignore tables that are corrupted due to missing blob parts tables by using the the `--skip-broken-objects` [2003] option. When this option is used, such tables are skipped, and the restoration of any remaining uncorrupted tables in the backup continues.

- **`BLOB` read and write batching.** Beginning with MySQL Cluster NDB 7.0.21, it possible to control batching of `BLOB` read and write operations. For SQL nodes, this can be done using the `--ndb-blob-read-batch-bytes` [1913] and `--ndb-blob-write-batch-bytes` [1913] options for `mysqld`. In NDB API applications, you can control batching of `BLOB` reads and writes using the `NdbTransaction` methods `setMaxPendingBlobReadBytes()`, `getMaxPendingBlobReadBytes()`, `setMaxPendingBlobWriteBytes()`, and `getMaxPendingBlobWriteBytes()`.

- **Restoring from a NDB native backup to a differently-named database.** MySQL Cluster NDB 7.0.22 adds a new `--rewrite-database` [2003] option to `ndb_restore`, which makes it possible to restore to a database having a different name from that of the database in the backup. The option can be used multiple times, and it is possible to restore from more than one source database in the backup to a single target database (although no protection against table or other object name collision is provided).

  See `ndb_restore` — Restore a MySQL Cluster Backup, for more information.

- **`INFORMATION_SCHEMA` inprovements.** Beginning with MySQL Cluster NDB 7.0.22, `INFORMATION_SCHEMA` provides disk usage information for MySQL Cluster Disk Data tables. Previously, `INFORMATION_SCHEMA.TABLES` showed only the space usage for the in-memory data part of the table. Now, it also shows the space allocated for and used by the disk_part data of that table as well.

  In addition, the `INFORMATION_SCHEMA.PARTITIONS` table (which did not show any statistics for `NDB` tables) now shows correct values in this table's `TABLE_ROWS`, `AVG_ROW_LENGTH`, `DATA_LENGTH`, `MAX_DATA_LENGTH`, and `DATA_FREE` columns, for each partition.

- **Configuration version information in `ndbinfo.nodes`.** You can see which version or versions of the MySQL Cluster configuration file are in effect on the data nodes by checking the `config_generation` column which is added to the `nodes` table in MySQL Cluster NDB 7.0.24.

- **Improvements in adding data nodes online.** Beginning with MySQL Cluster NDB 7.0.24, it is possible to add data nodes online to a running MySQL Cluster without performing a rolling restart of the cluster or starting data node processes with the `--nowait-nodes` [1955] option. This can be done by setting `Nodegroup = 65536` [1815] in the `config.ini` file for any data nodes that should be started at a later time, when first starting the cluster. The amount of time the cluster waits before doing this can be controlled using the `StartNoNodeGroupTimeout` [1836] data node configuration parameter.

- **Unique key updates in replication.** It is possible in MySQL Cluster NDB 7.0.25 and later to employ operations that update unique keys when replicating `NDB` tables. Previously this could lead to duplicate key errors when trying to execute the binary log (due to the fact that row events in the binary log were ordered according to the partitioning of the base table, and could differ in order within the epoch for that in which they were executed).

  Important

  Master and slave tables must both be using the `NDB` storage engine for this to work.

- Starting with MySQL Cluster NDB 7.0.22, the NDB kernel implements a number of statistical counters relating to actions performed by or affecting `Ndb` objects. Such events include starting, closing, and aborting transactions; operations using primary keys or unique keys; table, range, and pruned scans; blocking of threads by incompleted operations; and data and events sent and received by MySQL Cluster nodes. NDB API statistics counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes. A MySQL Server running as an SQL node in the cluster can access the values of these counters as system status variables, as seen in the output of `SHOW STATUS`, or in the results of queries against the `SESSION_STATUS` or `GLOBAL_STATUS` table in the `INFORMATION_SCHEMA` database. By comparing the values of these status variables before and after the execution of statements affecting `NDB` tables, you can observe the corresponding actions taken on the NDB API level. This can be highly useful when monitoring and tuning MySQL Cluster.

  For more information, see NDB API Statistics Counters and Variables. See also MySQL Cluster Status Variables, for information about the individual status variables.

- **Version 2 binary log row events.** New versions of the `WRITE_ROW`, `UPDATE_ROW`, and `DELETE_ROW` events have been implemented in MySQL Cluster NDB 7.0.27, extending them with additional infromation intended to support future enhancements; these are referred to as “Version 2” binary log events.

  Version 2 log events are not backward compatible, and cannot be read by older slaves. A new `mysqld` option `--log-bin-use-v1-row-events` [1648] can be employed to force use of Version 1 events when writing the binary log. This can be used during upgrades to make a newer `mysqld` generate Version 1 binary log row events that can be read by older slaves.

- **Fail-fast data node capability.** Beginning with MySQL Cluster NDB 7.0.28, it is possible to enable fail-fast behavior for data nodes by enabling the `CrashOnCorruptedTuple` [1833] configuration parameter introduced in this version (disabled by default). Doing so causes data nodes to fail whenever they detect a corrupted tuple.

- **Rows per partition limit removed.** Previously it was possible to store a maximum of 46137488 rows in a single MySQL Cluster partition—that is, per data node. Beginning with MySQL Cluster NDB 7.0.36, this limitation has been lifted, and there is no longer any practical upper limit to this number.

MySQL Cluster NDB 6.3, MySQL Cluster NDB 7.0, and later are also supported by MySQL Cluster Manager, which provides an advanced command-line interface that can simplify many complex MySQL Cluster management tasks. See MySQL™ Cluster Manager 1.1.6 User Manual, for more information.

MySQL Cluster Development in MySQL Cluster NDB 6.3

The following list provides an overview of significant feature additions and changes first made in MySQL Cluster NDB 6.3. For more detailed information about all feature changes and bugfixes made in MySQL Cluster NDB 6.3, see Changes in MySQL Cluster NDB 6.3.

- **Conflict detection and resolution.** It is now possible to detect and resolve conflicts that arise in multi-master replication scenarios, such as circular replication, when different masters may try to update the same row on the slave with different data. Both “greatest timestamp wins” and “same timestamp wins” scenarios are supported. For more information, see MySQL Cluster Replication Conflict Resolution.

- **Recovery of “one master, many slaves” replication setups.** Recovery of multi-way replication setups (“one master, many slaves”) is now supported using the `--ndb-log-orig` server option and changes in the `mysql.ndb_binlog_index` table. See MySQL Cluster Replication Schema and Tables, for more information.

- **Enhanced selection options for transaction coordinator.** New values and behaviors are introduced for `--ndb_optimized_node_selection`, enabling greater flexibility when an SQL node chooses a transaction coordinator. For more information, see the description of `ndb_optimized_node_selection` [1928] in MySQL Cluster System Variables.

- **Replication heartbeats.** Replication heartbeats facilitate the task of monitoring and detecting failures in master-slave connections in real time. This feature is implemented using a new `MASTER_HEARTBEAT_PERIOD = value` clause for the `CHANGE MASTER TO` statement and the addition of two status variables `Slave_heartbeat_period` [1949] and `Slave_received_heartbeats` [1949]. For more information, see `CHANGE MASTER TO` Syntax.

- **`NDB` thread locks.** It is possible to lock `NDB` execution threads and maintenance threads (such as file system and other operating system threads) to specific CPUs on multiprocessor data node hosts, and to leverage real-time scheduling.

- **Improved performance of updates using primary keys or unique keys.** The number of unnecessary reads when performing a primary key or unique key update has been greatly reduced. Since it is seldom necessary to read a record prior to an update, this can yield a considerable improvement in performance. In addition, primary key columns are no longer written to when not needed during update operations.

- **Batching improvements.** Support of batched `DELETE` and `UPDATE` operations has been significantly improved. Batching of `UPDATE WHERE...` and multiple `DELETE` operations is also now implemented.

- **Improved SQL statement performance metrics.** The `Ndb_execute_count` [1948] system status variable measures the number of round trips made by SQL statements to the `NDB` kernel, providing an improved metric for determining efficiency with which statements are executed. For more information, see *MySQL Cluster Status Variables: `Ndb_execute_count` [1948]* [1948].

- **Compressed LCPs and backups.** Compressed local checkpoints and backups can save 50% or more of the disk space used by uncompressed LCPs and backups. These can be enabled using the two new data node configuration parameters `CompressedLCP` [1834] and `CompressedBackup` [1834], respectively.

- **`OPTIMIZE TABLE` support with `NDBCLUSTER` tables.** `OPTIMIZE TABLE` is supported for dynamic columns of in-memory `NDB` tables. In such cases, it is no longer necessary to drop (and possibly to re-create) a table, or to perform a rolling restart, in order to recover memory from deleted rows for general re-use by Cluster. The performance of `OPTIMIZE` on Cluster tables can be tuned by adjusting the value of the `ndb_optimization_delay` system variable, which controls the number of milliseconds to wait between processing batches of rows by `OPTIMIZE TABLE`. In addition, `OPTIMIZE TABLE` on an `NDBCLUSTER` table can be interrupted by, for example, killing the SQL thread performing the `OPTIMIZE` operation.

- **Batching of transactions.** It is possible to cause statements occurring within the same transaction to be run as a batch by setting the session variable `transaction_allow_batching` [1932] to `1` or `ON`. To use this feature, `autocommit` [461] must be set to `0` or `OFF`. Batch sizes can be controlled using the `--ndb-batch-size` option for `mysqld`. For additional information, see MySQL Server Options for MySQL Cluster, and MySQL Cluster System Variables.

- **Attribute promotion with `ndb_restore`.** It is possible using `ndb_restore` to restore data reliably from a column of a given type to a column that uses a "larger" type. This is sometimes referred to as *attribute promotion*. For example, MySQL Cluster backup data that originated in a `SMALLINT` column can be restored to a `MEDIUMINT`, `INT`, or `BIGINT` column. See `ndb_restore` — Restore a MySQL Cluster Backup, for more information.

- **Parallel data node recovery.** Recovery of multiple data nodes can now be done in parallel, rather than sequentially. In other words, several data nodes can be restored concurrently, which can often result in much faster recovery times than when they are restored one at a time.

- **Increased local checkpoint efficiency.** Only 2 local checkpoints are stored, rather than 3, lowering disk space requirements and the size and number of redo log files.

- **`NDBCLUSTER` table persistence control.** Persistence of `NDB` tables can be controlled using the session variables `ndb_table_temporary` and `ndb_table_no_logging`. `ndb_table_no_logging` causes `NDB` tables not to be checkpointed to disk; `ndb_table_temporary` does the same, and in addition, no schema files are created. See MySQL Cluster `mysqld` Option and Variable Reference.

- **Epoll support (*Linux only*).** *Epoll* is an improved method for handling file descriptors, which is more efficient than scanning to determine whether a file descriptor has data to be read. (The term *epoll* is specific to Linux and equivalent functionality is known by other names on other platforms such as Solaris and FreeBSD.) Currently, MySQL Cluster supports this functionality on Linux only.

- **Distribution awareness (SQL nodes).** In MySQL Cluster NDB 6.3, SQL nodes can take advantage of distribution awareness. Here we provide a brief example showing how to design a table to make a given class of queries distrubtion-aware. Suppose an `NDBCLUSTER` table `t1` has the following schema:

```
CREATE TABLE t1 (
    userid INT NOT NULL,
    serviceid INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    data VARCHAR(255)
)   ENGINE=NDBCLUSTER;
```

  Suppose further that most of the queries to be used in our application test values of the `userid` column of this table. The form of such a query looks something like this:

```
SELECT columns FROM t1
    WHERE userid relation value;
```

  In this query, *`relation`* represents some relational operator, such as `=`, `<`, `>`, and so on. Queries using `IN` and a list of values can also be used:

```
SELECT columns FROM t1
    WHERE userid IN value_list;
```

  To make use of distribution awareness, we need to make the `userid` column part of the table's primary key, then explicitly partition the table with this column being used as the partitioning key. (Recall that for a partitioned table having one or more unique keys, all columns of the table's partitioning key must also be part of all of the unique keys—for more information and examples, see Partitioning Keys, Primary Keys, and Unique Keys.) In other words, the table schema should be equivalent to the following `CREATE TABLE` statement:

```
CREATE TABLE t1 (
    userid INT NOT NULL,
```

```
    serviceid INT NOT NULL AUTO_INCREMENT,
    data VARCHAR(255),
    PRIMARY KEY p (userid,serviceid)
)   ENGINE=NDBCLUSTER
    PARTITION BY KEY(userid);
```

When the table is partitioned in this way, all rows having the same `userid` value are found on the same node group, and the MySQL Server can immediately select the optimal node to use as the transaction coordinator.

- **Realtime extensions for multiple CPUs.** When running MySQL Cluster data nodes on hosts with multiple processors, the realtime extensions make it possible to give priority to the data node process and control on which CPU cores it should operate. This can be done using the data node configuration parameters `RealtimeScheduler` [1853], `SchedulerExecutionTimer` [1853], and `SchedulerSpinTimer` [1853]. Doing so properly can significantly lower response times and make them much more predictable response. For more information about using these parameters, see Defining Data Nodes: Realtime Performance Parameters

- **Fully automatic database discovery.** It is no longer a requirement for database autodiscovery that an SQL node already be connected to the cluster at the time that a database is created on another SQL node, or for a `CREATE DATABASE` or `CREATE SCHEMA` statement to be issued on the new SQL node after it joins the cluster.

- **Detection of NDB API client connection errors.** Beginning with MySQL Cluster NDB 6.3.20, the NDB API's `Ndb_cluster_connection` class adds the `get_latest_error()` and `get_latest_error_msg()` methods for catching and diagnosing problems with NDB API client connections.

- **Restoring specific databases, tables, or columns from a MySQL Cluster backup.** It is now possible to exercise more fine-grained control when restoring a MySQL Cluster from backup using `ndb_restore`. Beginning with MySQL Cluster NDB 6.3.22, you can choose to restore only specified tables or databases, or exclude specific tables or databases from being restored, using the new `ndb_restore` options `--include-tables`, `--include-databases`, `--exclude-tables`, and `--exclude-databases`. Beginning with MySQL Cluster NDB 6.3.26, it is also possible to restore to a table having fewer columns than the original using the `--exclude-missing-columns` option. For more information about all of these options, see `ndb_restore` — Restore a MySQL Cluster Backup.

- **Improved Disk Data file system configuration.** As of MySQL Cluster NDB 6.3.22, you can specify default locations for MySQL Cluster Disk Data data files and undo log files using the data node configuration parameters `FileSystemPathDD` [1857], `FileSystemPathDataFiles` [1858], and `FileSystemPathUndoFiles` [1858]. This eliminates the need to use symbolic links to place Disk Data files separately from other files in data node file systems to improve Disk Data performance. For more information, see Disk Data file system parameters.

- **Automatic creation of Disk Data log file groups and tablespaces.** Beginning with MySQL Cluster NDB 6.3.22, using the data node configuration parameters `InitialLogFileGroup` [1859] and `InitialTablespace` [1859], you can cause the creation of a MySQL Cluster Disk Data log file group, tablespace, or both, when the cluster is first started. When using these parameters, no SQL statements are required to create these Disk Data objects. For more information, see *Disk Data object creation parameters*.

- **Configuration parameter data dumps.** Starting with MySQL Cluster NDB 6.3.25, the `ndb_config` utility supports a `--configinfo` option that causes it to dump a list of all configuration parameters supported by the cluster, along with brief descriptions, information about the parameters' default and permitted values, and the sections of the `config.ini` file in which the parameters apply. An additional `--xml` switch causes `ndb_config` to use XML rather than plaintext output. Using `ndb_config --configinfo` or `ndb_config --configinfo --xml` requires no access to a running MySQL Cluster, any other programs, or any files. For more information and examples, see `ndb_config` — Extract MySQL Cluster Configuration Information.

- **Per-table reporting of free space on disk.** The `INFORMATION_SCHEMA.FILES` table shows information about used and free space in MySQL Cluster Disk Data data files, but this information is not applicable to individual tables. In MySQL Cluster NDB 6.3.27 and later, the `ndb_desc` utility provides two additional columns in its output that show the amount of space allocated on disk for a given `NDB` table as well the amount of space that remains available for additional storage of disk-based column data for that table. For more information, see `ndb_desc` — Describe NDB Tables.

- **Improved restart times.** Optimizations in redo log handling and other file system operations introduced in MySQL Cluster NDB 6.3.28 have the potential to reduce considerably the time required for restarts. While actual performance benefits observed in production setups will naturally vary depending on database size, hardware, and other conditions, our own preliminary testing has shown that these improvements can yield startup times that are faster than those typical of previous MySQL Cluster NDB 6.3 releases by a factor of 50 or more.

- **Increased flexibility in online upgrade procedure.** Previously, when performing an upgrade of a running MySQL cluster, the order in which the types of cluster nodes had to be upgraded was very strict. However, beginning with MySQL Cluster NDB 6.3.29, MySQL Cluster supports online upgrading of API nodes (including MySQL servers running as SQL nodes) before upgrading management nodes, data nodes, or both.

  Important

  Before attempting to use this new upgrade functionality, see Performing a Rolling Restart of a MySQL Cluster, for additional information, especially if you are planning an online upgrade from MySQL Cluster NDB 6.3 to MySQL Cluster NDB 7.0.

- **New replication conflict resolution strategy.** Beginning with MySQL Cluster NDB 6.3.31, the function `NDB$MAX_DELETE_WIN()` is available to implement “greatest timestamp, delete wins” conflict resolution. See `NDB$MAX_DELETE_WIN(column_name)`, for more information.

- **New `CHANGE MASTER TO` option for circular replication.** Beginning with MySQL Cluster NDB 6.3.31, the `CHANGE MASTER TO` statement supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. (Log rotation and log deletion events are preserved.)

  See `CHANGE MASTER TO` Syntax, as well as `SHOW SLAVE STATUS` Syntax, for more information.

- **Heartbeat thread policy and priority.** Beginning with MySQL Cluster NDB 6.3.32, a new configuration parameter `HeartbeatThreadPriority` makes it possible to set the policy and the priority for the heartbeat thread on management and API nodes.

- **Improved access to partitioning information.** The `ndb_desc` utility now provides additional information about the partitioning of data stored in MySQL Cluster. Beginning with MySQL Cluster NDB 6.3.32, the `--blob-info` [1982] option causes this program to include partition information for `BLOB` tables in its output. Beginning with MySQL Cluster NDB 6.3.33, the `--extra-node-info` [1982] option causes `ndb_desc` to include information about data distribution (that is, which table fragments are stored on which data nodes). Each of these options also requires the use of the `--extra-partition-info` [1982] option.

  Information about partition-to-node mappings can also be obtained using the `Table::getFragmentNodes()` method, also added in MySQL Cluster NDB 6.3.33.

- **Replication attribute promotion and demotion.** Beginning with MySQL Cluster NDB 6.3.33, MySQL Cluster Replication supports attribute promotion and demotion when replicating between columns of different but similar types on the master and the slave. For example, it is possible to promote an `INT` column on the master to a `BIGINT` column on the slave, and to demote a `TEXT` column to a `VARCHAR` column.

The implementation of type demotion distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` [1646] global server system variable.

For more information, see Attribute promotion and demotion (MySQL Cluster).

- **Incompatible change in NDB API event reporting.** Beginning with MySQL Cluster NDB 6.3.34, DDL events are no longer reported on `Event` objects by default. Instead such event reporting must be enabled explicitly using the `Event::setReport()` method. For more information, see `Event::setReport()`, and The `Event::EventReport` Type.
- **Heartbeat ordering.** Beginning with MySQL Cluster NDB 6.3.35, it is possible to set a specific order for transmission of heartbeats between datat nodes, using the `HeartbeatOrder` [1837] data node configuration parameter introduced in this version. This parameter can be useful in situations where multiple data nodes are running on the same host and a temporary disruption in connectivity between hosts would otherwise cause the loss of a node group (and thus failure of the cluster).
- **Relaxed `ndb_restore` column comparison rules.** When restoring data, ndb_restore compares the attributes of a column for equality with the definition of the column in the target table. However, not all of these attributes need to be the same for `ndb_restore` to be meaningful, safe and useful. Beginning with MySQL Cluster NDB 6.3.35, `ndb_restore` automatically ignores differences in certain column attributes which do not necessarily have to match between the version of the column in a backup and the version of that column in the MySQL Cluster to which the column data is being restored. These attributes include the following:
  - `COLUMN_FORMAT` setting (`FIXED`, `DYNAMIC`, or `DEFAULT`)
  - `STORAGE` setting (`MEMORY` or `DISK`)
  - The default value
  - The distribution key

  In such cases, `ndb_restore` reports any such differences to minimize any chance of user error.
- **`--add-drop-trigger` [294] option for `mysqldump`.** Beginning with MySQL Cluster NDB 6.3.38, this option can be used to force all `CREATE TRIGGER` statements in `mysqldump` output to be preceded by a `DROP TRIGGER IF EXISTS` statement.
- **Skipping corrupted tables in `NDB` native backups.** Beginning with MySQL Cluster NDB 6.3.40, you can cause `ndb_restore` to ignore tables that are corrupted due to missing blob parts tables by using the the `--skip-broken-objects` [2003] option. When this option is used, such tables are skipped, and the restoration of any remaining uncorrupted tables in the backup continues.
- **Restoring from a NDB native backup to a differently-named database.** MySQL Cluster NDB 6.3.41 adds a new `--rewrite-database` [2003] option to `ndb_restore`, which makes it possible to restore to a database having a different name from that of the database in the backup. The option can be used multiple times, and it is possible to restore from more than one source database in the backup to a single target database (although no protection against table or other object name collision is provided).

  See `ndb_restore` — Restore a MySQL Cluster Backup, for more information.

MySQL Cluster NDB 6.3 and later is also supported by MySQL Cluster Manager, which provides an advanced command-line interface that can simplify many complex MySQL Cluster management tasks. See MySQL™ Cluster Manager 1.1.6 User Manual, for more information.

MySQL Cluster Development in MySQL Cluster NDB 6.2

The following list provides an overview of significant feature additions and changes made in MySQL Cluster NDB 6.2. All of the changes in this list are also available in MySQL Cluster NDB 6.3 . For more

detailed information about all feature changes and bugfixes made in MySQL Cluster NDB 6.2, see Changes in MySQL Cluster NDB 6.2.

- **Enhanced backup status reporting.** Backup status reporting has been improved, aided in part by the introduction of a `BackupReportFrequency` [1851] configuration parameter.
- **Multiple cluster connections per SQL node.** A single MySQL server acting as a MySQL Cluster SQL node can employ multiple connections to the cluster using the `--ndb-cluster-connection-pool` startup option for `mysqld`. This option is described in *MySQL Cluster-Related Command Options for `mysqld`: `--ndb-cluster-connection-pool` option* [1912].
- **New data access interface.** The `NdbRecord` interface provides a new and simplified data handler for use in NDB API applications.
- **New reporting commands.** The new management client `REPORT BackupStatus` and `REPORT MemoryUsage` commands provide better access to information about the status of MySQL Cluster backups and how much memory is being used by MySQL Cluster for data and index storage. See Commands in the MySQL Cluster Management Client, for more information about the `REPORT` commands. In addition, in-progress status reporting is provided by the `ndb_restore` utility; see `ndb_restore` — Restore a MySQL Cluster Backup.
- **Improved memory allocation and configuration.** Memory is now allocated by the `NDB` kernel to tables on a page-by-page basis, which significantly reduces the memory overhead required for maintaining `NDBCLUSTER` tables. In addition, the `MaxAllocate` [1825] configuration parameter now makes it possible to set the maximum size of the allocation unit used for table memory.
- **Choice of fixed-width or variable-width columns.** You can control whether fixed-width or variable-width storage is used for a given column of an `NDB` table by employing of the `COLUMN_FORMAT` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. In addition, the ability to control whether a given column of an `NDB` table is stored in memory or on disk, using the `STORAGE` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. For more information, see `CREATE TABLE` Syntax, and `ALTER TABLE` Syntax.
- **Controlling management client connections.** The `--bind-address` cluster management server startup option makes it possible to restrict management client connections to `ndb_mgmd` to a single host (IP address or host name) and port, which can make MySQL Cluster management operations more secure. For more information about this option, see `ndb_mgmd` — The MySQL Cluster Management Server Daemon.
- **Micro-GCPs.** Due to a change in the protocol for handling of global checkpoints (GCPs handled in this manner sometimes being referred to as “micro-GCPs”), it is now possible to control how often the GCI number is updated, and how often global checkpoints are written to disk, using the `TimeBetweenEpochs` [1840] and `TimeBetweenEpochsTimeout` [1840] configuration parameters. This improves the reliability and performance of MySQL Cluster Replication.
- **Core online schema change support.** Support for the online `ALTER TABLE` operations `ADD COLUMN`, `ADD INDEX`, and `DROP INDEX` is available. When the `ONLINE` keyword is used, the `ALTER TABLE` is noncopying, which means that indexes do not have to be re-created, which provides these benefits:
  - Single user mode is no longer required for `ALTER TABLE` operations that can be performed online.
  - Transactions can continue during `ALTER TABLE` operations that can be performed online.
  - Tables being altered online are not locked against access by other SQL nodes.

    However, such tables are locked against other operations on the *same* SQL node for the duration of the `ALTER TABLE`. We are working to overcome this limitation in a future MySQL Cluster release.

Online `CREATE INDEX` and `DROP INDEX` statements are also supported. Online changes can be suppressed using the `OFFLINE` key word. See `ALTER TABLE` Online Operations, `CREATE INDEX` Syntax, and `DROP INDEX` Syntax, for more detailed information.

- **`mysql.ndb_binlog_index` improvements.** More information has been added to the `mysql.ndb_binlog_index` table so that it is possible to determine which originating epochs have been applied inside an epoch. This is particularly useful for 3-way replication. See MySQL Cluster Replication Schema and Tables, for more information.

- **Epoch lag control.** The `MaxBufferedEpochs` [1840] data node configuration parameter provides a means to control the maximum number of unprocessed epochs by which a subscribing node can lag. Subscribers which exceed this number are disconnected and forced to reconnect.

- **Fully automatic database discovery.** It is no longer a requirement for database autodiscovery that an SQL node already be connected to the cluster at the time that a database is created on another SQL node, or for a `CREATE DATABASE` or `CREATE SCHEMA` statement to be issued on the new SQL node after it joins the cluster.

- **Multiple data node processes per host.**
  In earlier MySQL Cluster release series, we did not support MySQL Cluster deployments in production where more than one `ndbd` process was run on a single physical machine. However, beginning with MySQL Cluster NDB 6.2.0, you can use multiple data node processes on a single host.

  Note

  A multi-threaded version of `ndbd` tailored for use on hosts with multiple CPUs or cores was introduced in MySQL Cluster NDB 7.0. See MySQL Cluster Development in MySQL Cluster NDB 7.0, and `ndbmtd` — The MySQL Cluster Data Node Daemon (Multi-Threaded), for more information.

- **Improved Disk Data file system configuration.** As of MySQL Cluster NDB 6.2.17, you can specify default locations for MySQL Cluster Disk Data data files and undo log files using the data node configuration parameters `FileSystemPathDD` [1857], `FileSystemPathDataFiles` [1858], and `FileSystemPathUndoFiles` [1858]. This eliminates the need to use symbolic links to place Disk Data files separately from other files in data node file systems to improve Disk Data performance. For more information, see Disk Data file system parameters.

- **Automatic creation of Disk Data log file groups and tablespaces.** Beginning with MySQL Cluster NDB 6.2.17, using the data node configuration parameters `InitialLogFileGroup` [1859] and `InitialTablespace` [1859], you can cause the creation of a MySQL Cluster Disk Data log file group, tablespace, or both, when the cluster is first started. When using these parameters, no SQL statements are required to create these Disk Data objects.

- **Improved access to partitioning information.** The `ndb_desc` utility now provides additional information about the partitioning of data stored in MySQL Cluster. Beginning with MySQL Cluster NDB 6.2.19, the `--extra-node-info` [1982] option causes `ndb_desc` to include information about data distribution (that is, which table fragments are stored on which data nodes). This option also requires the use of the `--extra-partition-info` [1982] option.

  Information about partition-to-node mappings can also be obtained using the `Table::getFragmentNodes()` method, also added in MySQL Cluster NDB 6.2.19.

- **New `CHANGE MASTER TO` option for circular replication.** Beginning with MySQL Cluster NDB 6.2.19, the `CHANGE MASTER TO` statement supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. (Log rotation and log deletion events are preserved.)

  See `CHANGE MASTER TO` Syntax, as well as `SHOW SLAVE STATUS` Syntax, for more information.

MySQL Cluster Development in MySQL Cluster NDB 6.1

The following list provides an overview of significant feature additions and changes made in MySQL Cluster NDB 6.1. All of the changes in this list are also available in MySQL Cluster NDB 6.2 and 6.3 releases. For detailed information about all changes made in MySQL Cluster NDB 6.1, see Changes in MySQL Cluster NDB 6.1.

- **Increased number of cluster nodes.** The maximum number of all nodes in a MySQL Cluster has been increased to 255. For more information, see Limitations Relating to Multiple MySQL Cluster Nodes.
- **Disabling arbitration.** It is now possible to disable arbitration by setting `ArbitrationRank=0` on all cluster management and SQL nodes. For more information, see *Defining the Management Server: `ArbitrationRank`* [1811] and *Defining SQL and Other API Nodes: `ArbitrationRank`* [1865].
- **Additional `DUMP` commands.** New management client `DUMP` commands provide help with tracking transactions, scan operations, and locks. See Commands in the MySQL Cluster Management Client, and `DUMP` Commands, for more information.
- **Faster Disk Data backups.** Improvements in backups of Disk Data tables can yield a 10 to 15% increase in backup speed of Disk Data tables.
- **Batched slave updates.** Batching of updates on cluster replication slaves, enabled using the `--slave-allow-batching` option for `mysqld`, increases replication efficiency. For more information, see Starting MySQL Cluster Replication (Single Replication Channel).

Development History of MySQL Cluster in MySQL 5.1

A number of features for MySQL Cluster were implemented in MySQL 5.1 through MySQL 5.1.23, when support for MySQL Cluster was moved to MySQL Cluster NDB. All of the features in the following list are also available in all MySQL Cluster NDB (6.1 and later) releases.

- **Integration of MySQL Cluster into MySQL Replication.** MySQL Cluster Replication makes it possible to replicate from one MySQL Cluster to another. Updates on any SQL node (MySQL server) in the cluster acting as the master are replicated to the slave cluster; the state of the slave side remains consistent with the cluster acting as the master. This is sometimes referred to as *asynchronous replication* between clusters, providing *geographic redundancy*. It is also possible to replicate from a MySQL Cluster acting as the master to a standalone MySQL server acting as the slave, or from a standalone MySQL master server to to a slave cluster; in either of these cases, the standalone MySQL server uses a storage engine other than `NDBCLUSTER`. Multi-master replication setups such as circular replication are also supported.

  See MySQL Cluster Replication.
- **Support for storage of rows on disk.** Storage of `NDBCLUSTER` table data on disk is now supported. Indexed columns, including the primary key hash index, must still be stored in RAM; however, all other columns can be stored on disk.

  See MySQL Cluster Disk Data Tables.
- **Variable-size columns.** In MySQL 5.0, an `NDBCLUSTER` table column defined as `VARCHAR(255)` used 260 bytes of storage independent of what was stored in any particular record. In MySQL 5.1 Cluster tables, only the portion of the column actually taken up by the record is stored. This makes possible a significant reduction in space requirements for such columns as compared to previous release series—by a factor of up to 5 in many cases.
- **User-defined partitioning.** Users can define partitions based on columns that are part of the primary key. It is possible to partition `NDB` tables based on `KEY` and `LINEAR KEY` schemes. This feature is also available for many other MySQL storage engines, which support additional partitioning types that are not available with `NDBCLUSTER` tables.

For additional general information about user-defined partitioning in MySQL 5.1, see Chapter 18, *Partitioning*. Specifics of partitioning types are discussed in Partitioning Types.

The MySQL Server can also determine whether it is possible to “prune away” some of the partitions from the `WHERE` clause, which can greatly speed up some queries. See Partition Pruning, for information about designing tables and queries to take advantage of partition pruning.

- **Autodiscovery of table schema changes.** In MySQL 5.0, it was necessary to issue a `FLUSH TABLES` statement or a “dummy” `SELECT` for new `NDBCLUSTER` tables or changes made to schemas of existing `NDBCLUSTER` tables on one SQL node to be visible on the cluster's other SQL nodes. In MySQL 5.1, this is no longer necessary; new Cluster tables and changes in the definitions of existing `NDBCLUSTER` tables made on one SQL node are immediately visible to all SQL nodes connected to the cluster.

  Note

  When creating a new database, it is still necessary in MySQL 5.1 to issue a `CREATE DATABASE` or `CREATE SCHEMA` statement on each SQL node in the cluster.

- **Distribution awareness (NDB API).** *Distribution awareness* is a mechanism by which the best data node is automatically selected to be queried for information. (Conceptually, it is similar in some ways to partition pruning (see Partition Pruning). To take advantage of distribution awareness, you should do the following:

  1. Determine which table column is most likely to be used for finding matching records.
  2. Make this column part of the table's primary key.
  3. Explicitly partition the table by `KEY`, using this column as the table' partitioning key.

  Following these steps causes records with the same value for the partitioning column to be stored on the same partition (that is, in the same node group). When reading data, transactions are begun on the data node actually having the desired rows instead of this node being determined by the usual round-robin mechanism.

  Important

  To see a measureable impact on performance, the cluster must have at least four data nodes, since, with only two data nodes, both data nodes have exactly the same data.

  Using distribution awareness can yield performance increase of as great as 45% when using four data nodes, and possibly more when using a greater number of data nodes.

  Note

  In mainline MySQL 5.1 releases, distribution awareness was supported only when using the NDB API; support was added for SQL and API nodes in MySQL Cluster NDB 6.3 (see MySQL Cluster Development in MySQL Cluster NDB 6.3, which includes an example showing how to create a table to take advantage of distribution awareness).

- **Online adding and dropping of indexes.** For `ALTER TABLE` statements, `ADD INDEX` and `DROP INDEX` operations for dynamic (variable-width) columns on `NDB` tables are now performed as online operations (no table copying). This is also true for `CREATE INDEX` and `DROP INDEX`. As a result, these operations are now performed much more quickly than previously.

  For more information, see `ALTER TABLE` Online Operations, `CREATE INDEX` Syntax, and `DROP INDEX` Syntax.

See Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x, for more information.

MySQL Server using InnoDB Compared with MySQL Cluster

MySQL Server offers a number of choices in storage engines. Since both NDBCLUSTER and InnoDB can serve as transactional MySQL storage engines, users of MySQL Server sometimes become interested in MySQL Cluster. They see NDB as a possible alternative or upgrade to the default InnoDB storage engine in MySQL 5.5. While NDB and InnoDB share common characteristics, there are differences in architecture and implementation, so that some existing MySQL Server applications and usage scenarios can be a good fit for MySQL Cluster, but not all of them.

In this section, we discuss and compare some characteristics of the NDB storage engine used by MySQL Cluster with InnoDB used in MySQL 5.1 and MySQL 5.5. The next few sections provide a technical comparison. In many instances, decisions about when and where to use MySQL Cluster must be made on a case-by-case basis, taking all factors into consideration. While it is beyond the scope of this documentation to provide specifics for every conceivable usage scenario, we also attempt to offer some very general guidance on the relative suitability of some common types of applications for NDB as opposed to InnoDB backends.

While it is possible to use InnoDB tables with MySQL Cluster, such tables are not clustered. MySQL Cluster NDB 7.1 releases use a mysqld based on MySQL 5.1 which includes InnoDB 1.0; MySQL Cluster NDB 7.2.1 and later are based on MySQL Server 5.5, which includes support for InnoDB 1.1. It is also not possible to use programs or libraries from a MySQL Cluster NDB 6.x or MySQL Cluster NDB 7.x distribution with MySQL Server 5.1 or MySQL Server 5.5, or the reverse.

While it is also true that some types of common business applications can be run either on MySQL Cluster or on MySQL Server (most likely using the InnoDB storage engine), there are some important architectural and implementation differences. Differences Between the NDB and InnoDB Storage Engines, provides a summary of the these differences. Due to the differences, some usage scenarios are clearly more suitable for one engine or the other; see NDB and InnoDB Workloads. This in turn has an impact on the types of applications that better suited for use with NDB or InnoDB. See NDB and InnoDB Feature Usage Summary, for a comparison of the relative suitability of each for use in common types of database applications.

For information about the relative characteristics of the NDB and MEMORY storage engines, see When to Use MEMORY or MySQL Cluster.

See Chapter 14, *Storage Engines*, for additional information about MySQL storage engines.

Differences Between the NDB and InnoDB Storage Engines

The MySQL Cluster NDB storage engine is implemented using a distributed, shared-nothing architecture, which causes it to behave differently from InnoDB in a number of ways. For those unaccustomed to working with NDB, unexpected behaviors can arise due to its distributed nature with regard to transactions, foreign keys, joins, and other characteristics. These are shown in the following table:

Feature	InnoDB	MySQL Cluster
MySQL Server Version	InnoDB 1.1: 5.5 InnoDB 1.0: 5.1	MySQL Cluster NDB 6.3, 7.0, 7.1: 5.1 MySQL Cluster NDB 7.2: 5.5
InnoDB Availability	InnoDB 1.1 plugin	*NDB 6.3, 7.0*: InnoDB storage engine *NDB 7.1*: InnoDB 1.0 plugin support (MySQL Cluster NDB 7.1.9a and later)

Feature	InnoDB	MySQL Cluster
		NDB 7.2: InnoDB 1.1 (MySQL Cluster NDB 7.2.1 and later)
Storage Limits	64TB	3TB (Practical upper limit based on 48 data nodes with 64GB RAM each; can be increased with disk-based data and BLOBs)
Foreign Keys	Yes	No (Ignored, as with MyISAM) *Note*: A MySQL Cluster NDB 7.3 Early Access Release that includes a preview of foreign key support for the NDB storage engine is now available. See https://blogs.oracle.com/MySQL/entry/mysql_cluster_7_3_labs, for more information.
Transactions	All standard types	READ COMMITTED [1224]
MVCC	Yes	No
Data Compression	Yes	No (MySQL Cluster checkpoint and backup files can be compressed)
Large Row Support (> 14K)	Supported for VARBINARY, VARCHAR, BLOB, and TEXT columns	Supported for BLOB and TEXT columns only (Using these types to store very large amounts of data can lower MySQL Cluster performance)
Replication Support	Asynchronous and semi-synchronous replication using MySQL Replication	Automatic synchronous replication within a MySQL Cluster. Asynchronous replication between MySQL Clusters, using MySQL Replication
Scaleout for Read Operations	Yes (MySQL Replication)	Yes (Automatic partitioning in MySQL Cluster; MySQL Replication)
Scaleout for Write Operations	Requires application-level partitioning (sharding)	Yes (Automatic partitioning in MySQL Cluster is transparent to applications)
High Availability (HA)	Requires additional software	Yes (Designed for 99.999% uptime)
Node Failure Recovery and Failover	Requires additional software	Automatic (Key element in MySQL Cluster architecture)
Time for Node Failure Recovery	30 seconds or longer	Typically < 1 second

Feature	InnoDB	MySQL Cluster
Real-Time Performance	No	Yes (Low latency)
In-Memory Tables	No	Yes (Some data can optionally be stored on disk; both in-memory and disk data storage are durable)
NoSQL Access to Storage Engine	Native memcached interface in development (see the MySQL Dev Zone article *NoSQL to MySQL with Memcached*)	Yes Multiple APIs, including C++, HTTP/REST, Java and JPA (MySQL Cluster NDB 7.1 and later); Memcached (MySQL Cluster NDB 7.2) and later)
Concurrent and Parallel Writes	Not supported	Up to 48 writers, optimized for concurrent writes
Conflict Detection and Resolution (Multiple Replication Masters)	No	Yes
Hash Indexes	No	Yes
Online Addition of Nodes	Read-only replicas using MySQL Replication	Yes (all node types)
Online Upgrades	No	Yes
Online Schema Modifications	No	Yes
Real-Time Performance	No	Yes

NDB and InnoDB Workloads

MySQL Cluster has a range of unique attributes that make it ideal to serve applications requiring high availability, fast failover, high throughput, and low latency. Due to its distributed architecture and multi-node implementation, MySQL Cluster also has specific constraints that may keep some workloads from performing well. A number of major differences in behavior between the NDB and InnoDB storage engines with regard to some common types of database-driven application workloads are shown in the following table::

Workload	InnoDB	MySQL Cluster (NDB)
High-Volume OLTP Applications	Yes	Yes
DSS Applications (data marts, analytics)	Yes	Limited (Join operations across OLTP datasets not exceeding 3TB in size)
Custom Applications	Yes	Yes
Packaged Applications	Yes	Limited (should be mostly primary key access, without any requirement for foreign keys) *Note*: A MySQL Cluster NDB 7.3 Early Access Release that includes a preview of foreign key support for the NDB storage engine is now available. See https://blogs.oracle.com/MySQL/entry/mysql_cluster_7_3_labs, for more information.

Workload	InnoDB	MySQL Cluster (NDB)
In-Network Telecoms Applications (HLR, HSS, SDP)	No	Yes
Session Management and Caching	Yes	Yes
E-Commerce Applications	Yes	Yes
User Profile Management, AAA Protocol	Yes	Yes

NDB and InnoDB Feature Usage Summary

When comparing application feature requirements to the capabilities of InnoDB with NDB, some are clearly more compatible with one storage engine than the other. For example, since NDB does not support foreign keys, an application that requires them and cannot be re-engineered to remove this requirement is likely not to be a good match for MySQL Cluster.

Note

A MySQL Cluster NDB 7.3 Early Access Release that includes a preview of foreign key support for the NDB storage engine is now available. See https://blogs.oracle.com/MySQL/entry/mysql_cluster_7_3_labs, for more information.

The following table shows required supported features for applications according to which of these two storage engines each of them is usually better suited:

Preferred application requirements for InnoDB	Preferred application requirements for NDB
• Foreign keys **Note** A MySQL Cluster NDB 7.3 Early Access Release that includes a preview of foreign key support for the NDB storage engine is now available. See https://blogs.oracle.com/MySQL/entry/mysql_cluster_7_3_labs, for more information. • Full table scans • Very large databases, rows, or transactions • Transactions other than READ COMMITTED [1224]	• Write scaling • 99.999% uptime • Online addition of nodes and online schema operations • Multiple SQL and NoSQL APIs (see MySQL Cluster APIs: Overview and Concepts) • Real-time performance • Limited use of BLOB columns

Known Limitations of MySQL Cluster

In the sections that follow, we discuss known limitations in current releases of MySQL Cluster as compared with the features available when using the MyISAM and InnoDB storage engines. If you check the “Cluster” category in the MySQL bugs database at http://bugs.mysql.com, you can find known bugs in the following categories under “MySQL Server:” in the MySQL bugs database at http://bugs.mysql.com, which we intend to correct in upcoming releases of MySQL Cluster:

- MySQL Cluster

- Cluster Direct API (NDBAPI)
- Cluster Disk Data
- Cluster Replication
- ClusterJ

This information is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in How to Report Bugs or Problems. If we do not plan to fix the problem in MySQL Cluster NDB 6.X or 7.X, we will add it to the list.

See Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x for a list of issues in MySQL Cluster in MySQL 5.0 that have been resolved in the current version.

Note

Limitations and other issues specific to MySQL Cluster Replication are described in Known Issues in MySQL Cluster Replication.

Noncompliance with SQL Syntax in MySQL Cluster

Some SQL statements relating to certain MySQL features produce errors when used with `NDB` tables, as described in the following list:

- **Temporary tables.** Temporary tables are not supported. Trying either to create a temporary table that uses the `NDB` storage engine or to alter an existing temporary table to use `NDB` fails with the error `Table storage engine 'ndbcluster' does not support the create option 'TEMPORARY'`.
- **Indexes and keys in `NDB` tables.** Keys and indexes on MySQL Cluster tables are subject to the following limitations:
  - **Column width.** Attempting to create an index on an `NDB` table column whose width is greater than 3072 bytes succeeds, but only the first 3072 bytes are actually used for the index. In such cases, a warning `Specified key was too long; max key length is 3072 bytes` is issued, and a `SHOW CREATE TABLE` statement shows the length of the index as 3072.
  - **`TEXT` and `BLOB` columns.** You cannot create indexes on `NDB` table columns that use any of the `TEXT` or `BLOB` data types.
  - **`FULLTEXT` indexes.** The `NDB` storage engine does not support `FULLTEXT` indexes, which are possible for `MyISAM` tables only.

    However, you can create indexes on `VARCHAR` columns of `NDB` tables.
  - **`USING HASH` keys and `NULL`.** Using nullable columns in unique keys and primary keys means that queries using these columns are handled as full table scans. To work around this issue, make the column `NOT NULL`, or re-create the index without the `USING HASH` option.
  - **Prefixes.** There are no prefix indexes; only entire columns can be indexed. (The size of an `NDB` column index is always the same as the width of the column in bytes, up to and including 3072 bytes, as described earlier in this section. Also see Unsupported or Missing Features in MySQL Cluster, for additional information.)
  - **`BIT` columns.** A `BIT` column cannot be a primary key, unique key, or index, nor can it be part of a composite primary key, unique key, or index.
  - **`AUTO_INCREMENT` columns.** Like other MySQL storage engines, the `NDB` storage engine can handle a maximum of one `AUTO_INCREMENT` column per table. However, in the case of a

Cluster table with no explicit primary key, an AUTO_INCREMENT column is automatically defined and used as a “hidden” primary key. For this reason, you cannot define a table that has an explicit AUTO_INCREMENT column unless that column is also declared using the PRIMARY KEY option. Attempting to create a table with an AUTO_INCREMENT column that is not the table's primary key, and using the NDB storage engine, fails with an error.

- **MySQL Cluster and geometry data types.**
  Geometry data types (WKT and WKB) are supported in NDB tables in MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1). However, spatial indexes are not supported.

- **Character sets and binary log files.** Currently, the ndb_apply_status and ndb_binlog_index tables are created using the latin1 (ASCII) character set. Because names of binary logs are recorded in this table, binary log files named using non-Latin characters are not referenced correctly in these tables. This is a known issue, which we are working to fix. (Bug #50226)

  To work around this problem, use only Latin-1 characters when naming binary log files or setting any the --basedir [418], --log-bin [1647], or --log-bin-index [1648] options.

- **Creating NDBCLUSTER tables with user-defined partitioning.** Support for user-defined partitioning for MySQL Cluster is restricted to [LINEAR] KEY partitioning. Beginning with MySQL 5.1.12, using any other partitioning type with ENGINE=NDB or ENGINE=NDBCLUSTER in a CREATE TABLE statement results in an error.

  Default partitioning scheme. As of MySQL 5.1.6, all MySQL Cluster tables are by default partitioned by KEY using the table's primary key as the partitioning key. If no primary key is explicitly set for the table, the “hidden” primary key automatically created by the NDBCLUSTER storage engine is used instead. For additional discussion of these and related issues, see KEY Partitioning.

  Beginning with MySQL Cluster NDB 6.2.18, MySQL Cluster NDB 6.3.25, and MySQL Cluster NDB 7.0.6, CREATE TABLE and ALTER TABLE statements that would cause a user-partitioned NDBCLUSTER table not to meet either or both of the following two requirements are not permitted, and fail with an error (Bug #40709):

  1. The table must have an explicit primary key.

  2. All columns listed in the table's partitioning expression must be part of the primary key.

  Exception. If a user-partitioned NDBCLUSTER table is created using an empty column-list (that is, using PARTITION BY [LINEAR] KEY()), then no explicit primary key is required.

  Maximum number of partitions for NDBCLUSTER tables. The maximum number of partitions that can defined for a NDBCLUSTER table when employing user-defined partitioning is 8 per node group. (See MySQL Cluster Nodes, Node Groups, Replicas, and Partitions, for more information about MySQL Cluster node groups.

  DROP PARTITION not supported. It is not possible to drop partitions from NDB tables using ALTER TABLE ... DROP PARTITION. The other partitioning extensions to ALTER TABLE—ADD PARTITION, REORGANIZE PARTITION, and COALESCE PARTITION—are supported for Cluster tables, but use copying and so are not optimized. See Management of RANGE and LIST Partitions and ALTER TABLE Syntax.

- **Row-based replication.**
  When using row-based replication with MySQL Cluster, binary logging cannot be disabled. That is, the NDB storage engine ignores the value of sql_log_bin [525]. (Bug #16680)

Limits and Differences of MySQL Cluster from Standard MySQL Limits

In this section, we list limits found in MySQL Cluster that either differ from limits found in, or that are not found in, standard MySQL.

Memory usage and recovery. Memory consumed when data is inserted into an NDB table is not automatically recovered when deleted, as it is with other storage engines. Instead, the following rules hold true:

- A DELETE statement on an NDB table makes the memory formerly used by the deleted rows available for re-use by inserts on the same table only. However, this memory can be made available for general re-use by performing a rolling restart of the cluster. See Performing a Rolling Restart of a MySQL Cluster.

  Beginning with MySQL Cluster NDB 6.3.7, this limitation can be overcome using OPTIMIZE TABLE. See Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x, for more information.

- A DROP TABLE or TRUNCATE TABLE operation on an NDB table frees the memory that was used by this table for re-use by any NDB table, either by the same table or by another NDB table.

  Note

  Recall that TRUNCATE TABLE drops and re-creates the table. See TRUNCATE TABLE Syntax.

- **Limits imposed by the cluster's configuration.**
  A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in MySQL Cluster Configuration Files. Most configuration parameters can be upgraded online. These hard limits include:

  - Database memory size and index memory size (DataMemory [1817] and IndexMemory [1819], respectively).

    DataMemory [1817] is allocated as 32KB pages. As each DataMemory [1817] page is used, it is assigned to a specific table; once allocated, this memory cannot be freed except by dropping the table.

    See Defining MySQL Cluster Data Nodes, for more information.

  - The maximum number of operations that can be performed per transaction is set using the configuration parameters MaxNoOfConcurrentOperations [1821] and MaxNoOfLocalOperations [1822].

    Note

    Bulk loading, TRUNCATE TABLE, and ALTER TABLE are handled as special cases by running multiple transactions, and so are not subject to this limitation.

  - Different limits related to tables and indexes. For example, the maximum number of ordered indexes in the cluster is determined by MaxNoOfOrderedIndexes [1829], and the maximum number of ordered indexes per table is 16.

- **Node and data object maximums.** The following limits apply to numbers of cluster nodes and metadata objects:

  - The maximum number of data nodes is 48.

    A data node must have a node ID in the range of 1 to 48, inclusive. (Previous to MySQL Cluster NDB 6.1.1, management and API nodes were restricted to the range 1 to 63 inclusive as a node ID; starting with MySQL Cluster NDB 6.1.1, management and API nodes may use node IDs in the range 1 to 255, inclusive.)

  - Prior to MySQL Cluster NDB 6.1.1, the total maximum number of nodes in a MySQL Cluster was 63. Beginning with MySQL Cluster NDB 6.1.1, the total maximum number of nodes in a MySQL

Cluster is 255. In either case, this number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.

- The maximum number of metadata objects in current versions of MySQL Cluster is 20320. This limit is hard-coded.

See Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x, for more information.

Limits Relating to Transaction Handling in MySQL Cluster

A number of limitations exist in MySQL Cluster with regard to the handling of transactions. These include the following:

- **Transaction isolation level.** The NDBCLUSTER storage engine supports only the READ COMMITTED [1224] transaction isolation level. (InnoDB, for example, supports READ COMMITTED [1224], READ UNCOMMITTED [1225], REPEATABLE READ [1224], and SERIALIZABLE [1225].) See MySQL Cluster Backup Troubleshooting, for information on how this can affect backing up and restoring Cluster databases.)

- **Transactions and BLOB or TEXT columns.** NDBCLUSTER stores only part of a column value that uses any of MySQL's BLOB or TEXT data types in the table visible to MySQL; the remainder of the BLOB or TEXT is stored in a separate internal table that is not accessible to MySQL. This gives rise to two related issues of which you should be aware whenever executing SELECT statements on tables that contain columns of these types:

  1. For any SELECT from a MySQL Cluster table: If the SELECT includes a BLOB or TEXT column, the READ COMMITTED [1224] transaction isolation level is converted to a read with read lock. This is done to guarantee consistency.

  2. Prior to MySQL Cluster NDB 7.0.12, for any SELECT which used a primary key lookup or unique key lookup to retrieve any columns that used any of the BLOB or TEXT data types and that was executed within a transaction, a shared read lock was held on the table for the duration of the transaction—that is, until the transaction was either committed or aborted.

     In MySQL Cluster NDB 7.0.12 and later, for primary key lookups, the lock is released as soon as all BLOB or TEXT data has been read. (Bug #49190) However, for unique key lookups, the shared lock continues to be held for the lifetime of the transaction.

     This issue does not occur for queries that use index or table scans, even against NDB tables having BLOB or TEXT columns.

     For example, consider the table t defined by the following CREATE TABLE statement:

     ```
     CREATE TABLE t (
         a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
         b INT NOT NULL,
         c INT NOT NULL,
         d TEXT,
         INDEX i(b),
         UNIQUE KEY u(c)
     ) ENGINE = NDB,
     ```

     Either of the following queries on t causes a shared read lock, because the first query uses a primary key lookup and the second uses a unique key lookup:

     ```
     SELECT * FROM t WHERE a = 1;

     SELECT * FROM t WHERE c = 1;
     ```

     However, none of the four queries shown here causes a shared read lock:

```
SELECT * FROM t WHERE b 1;

SELECT * FROM t WHERE d = '1';

SELECT * FROM t;

SELECT b,c WHERE a = 1;
```

This is because, of these four queries, the first uses an index scan, the second and third use table scans, and the fourth, while using a primary key lookup, does not retrieve the value of any `BLOB` or `TEXT` columns.

You can help minimize issues with shared read locks by avoiding queries that use unique key lookups (or primary key lookups in MySQL Cluster NDB 7.0.11 and earlier) that retrieve `BLOB` or `TEXT` columns, or, in cases where such queries are not avoidable, by committing transactions as soon as possible afterward.

- **Rollbacks.** There are no partial transactions, and no partial rollbacks of transactions. A duplicate key or similar error causes the entire transaction to be rolled back.

  This behavior differs from that of other transactional storage engines such as `InnoDB` that may roll back individual statements.

- **Transactions and memory usage.**
  As noted elsewhere in this chapter, MySQL Cluster does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction containing a great many operations. Among other considerations, large transactions require very large amounts of memory. Because of this, the transactional behavior of a number of MySQL statements is effected as described in the following list:

  - `TRUNCATE TABLE` is not transactional when used on `NDB` tables. If a `TRUNCATE TABLE` fails to empty the table, then it must be re-run until it is successful.

  - `DELETE FROM` (even with no `WHERE` clause) *is* transactional. For tables containing a great many rows, you may find that performance is improved by using several `DELETE FROM ... LIMIT ...` statements to "chunk" the delete operation. If your objective is to empty the table, then you may wish to use `TRUNCATE TABLE` instead.

  - **`LOAD DATA` statements.** `LOAD DATA INFILE` is not transactional when used on `NDB` tables.

    Important

    When executing a `LOAD DATA INFILE` statement, the `NDB` engine performs commits at irregular intervals that enable better utilization of the communication network. It is not possible to know ahead of time when such commits take place.

    `LOAD DATA FROM MASTER` is not supported in MySQL Cluster.

  - **`ALTER TABLE` and transactions.** When copying an `NDB` table as part of an `ALTER TABLE`, the creation of the copy is nontransactional. (In any case, this operation is rolled back when the copy is deleted.)

- **Transactions and the `COUNT()` function.** When using MySQL Cluster Replication, it is not possible to guarantee the transactional consistency of the `COUNT()` function on the slave. In other words, when performing on the master a series of statements (`INSERT`, `DELETE`, or both) that changes the number of rows in a table within a single transaction, executing `SELECT COUNT(*) FROM table` queries on the slave may yield intermediate results. This is due to the fact that `SELECT COUNT(...)` may perform dirty reads, and is not a bug in the `NDB` storage engine. (See Bug #31321 for more information.)

MySQL Cluster Error Handling

Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:

- **Temporary errors.** When first starting a node, it is possible that you may see Error 1204 `Temporary failure, distribution changed` and similar temporary errors.
- **Errors due to node failure.** The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)

In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

See also Limits and Differences of MySQL Cluster from Standard MySQL Limits.

Limits Associated with Database Objects in MySQL Cluster

Some database objects such as tables and indexes have different limitations when using the `NDBCLUSTER` storage engine:

- **Table names containing special characters.** `NDB` tables whose names contain characters other than letters, numbers, dashes, and underscores and which are created on one SQL node were not always discovered correctly by other SQL nodes. (Bug #31470)

  Note

  This issue was fixed in MySQL 5.1.23, MySQL Cluster NDB 6.2.7, and MySQL Cluster NDB 6.3.4.

- **Number of database objects.** The maximum number of *all* `NDB` database objects in a single MySQL Cluster—including databases, tables, and indexes—is limited to 20320.
- **Attributes per table.** Prior to MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, the maximum number of attributes (that is, columns and indexes) per table is limited to 128.

  Beginning with MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, this limit is increased to 512.
- **Attributes per key.** The maximum number of attributes per key is 32.
- **Row size.** Prior to MySQL Cluster NDB 7.0, the maximum permitted size of any one row was 8052 bytes; in MySQL Cluster NDB 7.0 and later, this is 14000 bytes. Each `BLOB` or `TEXT` column contributes 256 + 8 = 264 bytes to this total.
- **Number of rows per partition.** The maximum number of rows that can be stored in a single MySQL Cluster partition varies with the number of replicas times the number of fragments. A single fragment can hold a maximum of approximately 45 million rows. Since the number of partitions is the same as the number of data nodes in the cluster (see MySQL Cluster Nodes, Node Groups, Replicas, and Partitions), you can increase the number of fragments—and thus the available space—by using more data nodes.

  In MySQL Cluster NDB 7.0 and later MySQL Cluster release series, you can increase the number of data nodes in the cluster while the cluster remains in operation. See Adding MySQL Cluster Data Nodes Online, for more information.

  It is also possible to increase the number of partitions for `NDB` tables by using explicit `KEY` or `LINEAR KEY` partitioning (see `KEY` Partitioning).

Unsupported or Missing Features in MySQL Cluster

A number of features supported by other storage engines are not supported for NDB tables. Trying to use any of these features in MySQL Cluster does not cause errors in or of itself; however, errors may occur in applications that expects the features to be supported or enforced:

- **Foreign key constraints.** The foreign key construct is ignored, just as it is in MyISAM tables.
- **Index prefixes.** Prefixes on indexes are not supported for NDBCLUSTER tables. If a prefix is used as part of an index specification in a statement such as CREATE TABLE, ALTER TABLE, or CREATE INDEX, the prefix is ignored.
- **OPTIMIZE operations.** OPTIMIZE operations are not supported.

  Beginning with MySQL Cluster NDB 6.3.7, this limitation has been lifted. See Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x, for more information.
- **LOAD TABLE ... FROM MASTER.** LOAD TABLE FROM MASTER is not supported.
- **Savepoints and rollbacks.** Savepoints and rollbacks to savepoints are ignored as in MyISAM.
- **Durability of commits.** There are no durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.
- **Replication.** Statement-based replication is not supported. Use --binlog-format=ROW [419] (or --binlog-format=MIXED [419]) when setting up cluster replication. See MySQL Cluster Replication, for more information.

Note

See Limits Relating to Transaction Handling in MySQL Cluster, for more information relating to limitations on transaction handling in NDB.

Limitations Relating to Performance in MySQL Cluster

The following performance issues are specific to or especially pronounced in MySQL Cluster:

- **Range scans.** There are query performance issues due to sequential access to the NDB storage engine; it is also relatively more expensive to do many range scans than it is with either MyISAM or InnoDB.
- **Reliability of Records in range.** The Records in range statistic is available but is not completely tested or officially supported. This may result in nonoptimal query plans in some cases. If necessary, you can employ USE INDEX or FORCE INDEX to alter the execution plan. See Index Hint Syntax, for more information on how to do this.
- **Unique hash indexes.** Unique hash indexes created with USING HASH cannot be used for accessing a table if NULL is given as part of the key.

Issues Exclusive to MySQL Cluster

The following are limitations specific to the NDBCLUSTER storage engine:

- **Machine architecture.** All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running mysql or other clients that may be accessing the cluster's SQL nodes.
- **Binary logging.**
  MySQL Cluster has the following limitations or restrictions with regard to binary logging:
  - sql_log_bin [525] has no effect on data operations; however, it is supported for schema operations.

- MySQL Cluster cannot produce a binary log for tables having `BLOB` columns but no primary key.
- Only the following schema operations are logged in a cluster binary log which is *not* on the `mysqld` executing the statement:
  - `CREATE TABLE`
  - `ALTER TABLE`
  - `DROP TABLE`
  - `CREATE DATABASE` / `CREATE SCHEMA`
  - `DROP DATABASE` / `DROP SCHEMA`
  - `CREATE TABLESPACE`
  - `ALTER TABLESPACE`
  - `DROP TABLESPACE`
  - `CREATE LOGFILE GROUP`
  - `ALTER LOGFILE GROUP`
  - `DROP LOGFILE GROUP`

See also Limitations Relating to Multiple MySQL Cluster Nodes.

Limitations Relating to MySQL Cluster Disk Data Storage

Disk Data object maximums and minimums. Disk data objects are subject to the following maximums and minimums:

- Maximum number of tablespaces: 2^{32} (4294967296)
- Maximum number of data files per tablespace: 2^{16} (65536)
- Maximum data file size: The theoretical limit is 64G; however, in MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1), the practical upper limit is 32G. This is equivalent to 32768 extents of 1M each.

  Since a MySQL Cluster Disk Data table can use at most 1 tablespace, this means that the theoretical upper limit to the amount of data (in bytes) that can be stored on disk by a single `NDB` table is 32G * 65536 = 2251799813685248, or approximately 2 petabytes.
- The theoretical maximum number of extents per tablespace data file is 2^{16} (65536); however, for practical purposes, the recommended maximum number of extents per data file is 2^{15} (32768).

  The minimum and maximum possible sizes of extents for tablespace data files are 32K and 2G, respectively. See `CREATE TABLESPACE` Syntax, for more information.

Disk Data tables and diskless mode. Use of Disk Data tables is not supported when running the cluster in diskless mode. Beginning with MySQL 5.1.12, it is prohibited altogether. (Bug #20008)

Limitations Relating to Multiple MySQL Cluster Nodes

Multiple SQL nodes.
The following are issues relating to the use of multiple MySQL servers as MySQL Cluster SQL nodes, and are specific to the `NDBCLUSTER` storage engine:

- **No distributed table locks.** A `LOCK TABLES` works only for the SQL node on which the lock is issued; no other SQL node in the cluster "sees" this lock. This is also true for a lock issued by any statement that locks tables as part of its operations. (See next item for an example.)

- **`ALTER TABLE` operations.** `ALTER TABLE` is not fully locking when running multiple MySQL servers (SQL nodes). (As discussed in the previous item, MySQL Cluster does not support distributed table locks.)

Multiple management nodes.
When using multiple management servers:

- You must give nodes explicit IDs in connect strings because automatic allocation of node IDs does not work across multiple management servers.

- In MySQL Cluster NDB 7.0.7 and earlier, you must take extreme care to have the same configurations for all management servers; no special checks for consistency are performed.

  Beginning with MySQL Cluster NDB 7.0.8, a management server when first starting checks for any other management server in the same MySQL Cluster, and upon successful connection to the other management server uses its configuration data. This means that the management server `--reload` [1966] and `--initial` [1965] startup options are ignored unless the management server is the only one running. It also means that, when performing a rolling restart of a MySQL Cluster with multiple management nodes, the management server reads its own configuration file if (and only if) it is the only management server running in this MySQL Cluster. See Performing a Rolling Restart of a MySQL Cluster, for more information.

Multiple network addresses. Multiple network addresses per data node are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.

Note

It is possible to use multiple network hardware *interfaces* (such as Ethernet cards) for a single data node, but these must be bound to the same address. This also means that it not possible to use more than one `[tcp]` section per connection in the `config.ini` file. See MySQL Cluster TCP/IP Connections, for more information.

Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x

A number of limitations and related issues existing in earlier versions of MySQL Cluster have been resolved:

- **Variable-length column support.** The `NDBCLUSTER` storage engine now supports variable-length column types for in-memory tables.

  Previously, for example, any Cluster table having one or more `VARCHAR` fields which contained only relatively small values, much more memory and disk space were required when using the `NDBCLUSTER` storage engine than would have been the case for the same table and data using the `MyISAM` engine. In other words, in the case of a `VARCHAR` column, such a column required the same amount of storage as a `CHAR` column of the same size. In MySQL 5.1, this is no longer the case for in-memory tables, where storage requirements for variable-length column types such as `VARCHAR` and `BINARY` are comparable to those for these column types when used in `MyISAM` tables (see Data Type Storage Requirements).

Important

For MySQL Cluster Disk Data tables, the fixed-width limitation continues to apply. See MySQL Cluster Disk Data Tables.

- **Replication with MySQL Cluster.** It is now possible to use MySQL replication with Cluster databases. For details, see MySQL Cluster Replication.

  Circular Replication. Circular replication is also supported with MySQL Cluster, beginning with MySQL 5.1.18. See MySQL Cluster Replication: Multi-Master and Circular Replication.

- **`auto_increment_increment` and `auto_increment_offset`.** The `auto_increment_increment` [1622] and `auto_increment_offset` [1624] server system variables are supported for Cluster replication beginning with MySQL 5.1.20, MySQL Cluster NDB 6.2.5, and MySQL Cluster 6.3.2.

- **Database autodiscovery and online schema changes.** Autodiscovery of databases is now supported for multiple MySQL servers accessing the same MySQL Cluster. Formerly, autodiscovery in MySQL Cluster 5.1 and MySQL Cluster NDB 6.x releases required that a given `mysqld` was already running and connected to the cluster at the time that the database was created on a different `mysqld`—in other words, when a `mysqld` process connected to the cluster after a database named *`db_name`* was created, it was necessary to issue a `CREATE DATABASE` *`db_name`* or `CREATE SCHEMA` *`db_name`* statement on the “new” MySQL server when it first accessed that MySQL Cluster. Beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.18, such a `CREATE` statement is no longer required. (Bug #39612)

  This also means that online schema changes in `NDB` tables are now possible. That is, the result of operations such as `ALTER TABLE` and `CREATE INDEX` performed on one SQL node in the cluster are now visible to the cluster's other SQL nodes without any additional action being taken.

- **Backup and restore between architectures.** Beginning with MySQL 5.1.10, it is possible to perform a Cluster backup and restore between different architectures. Previously—for example—you could not back up a cluster running on a big-endian platform and then restore from that backup to a cluster running on a little-endian system. (Bug #19255)

- **Character set directory.** Beginning with MySQL 5.1.10, it is possible to install MySQL with Cluster support to a nondefault location and change the search path for font description files using either the `--basedir` [418] or `--character-sets-dir` [421] options. (Previously, `ndbd` in MySQL 5.1 searched only the default path—typically `/usr/local/mysql/share/mysql/charsets`—for character sets.)

- **Multiple management servers.** In MySQL 5.1 (including all MySQL Cluster NDB 6.x and later versions), it is no longer necessary, when running multiple management servers, to restart all the cluster's data nodes to enable the management nodes to see one another.

  Also, when using multiple management servers and starting concurrently several API nodes (possibly including one or more SQL nodes) whose connectstrings listed the management servers in different order, it was possible for 2 API nodes to be assigned the same node ID. This issue is resolved in MySQL Cluster NDB 6.2.17, 6.3.23, and 6.4.3. (Bug #42973)

- **Multiple data node processes per host.** Beginning with MySQL Cluster NDB 6.2.0, you can use multiple data node processes on a single host. (In MySQL Cluster NDB 6.1, MySQL 5.1, and earlier release series, we did not support production MySQL Cluster deployments in which more than one `ndbd` process was run on a single physical machine.)

  In addition, MySQL Cluster NDB 7.0 introduces support for multi-threaded data nodes (`ndbmtd`). See MySQL Cluster Development in MySQL Cluster NDB 7.0, and `ndbmtd` — The MySQL Cluster Data Node Daemon (Multi-Threaded), for more information.

- **Identifiers.** Formerly (in MySQL 5.0 and earlier), database names, table names and attribute names could not be as long for `NDB` tables as tables using other storage engines, because attribute names were truncated internally. In MySQL 5.1 and later, names of MySQL Cluster databases, tables, and table columns follow the same rules regarding length as they do for any other storage engine.

- **Length of `CREATE TABLE` statements.** `CREATE TABLE` statements may be no more than 4096 characters in length. *This limitation affects MySQL 5.1.6, 5.1.7, and 5.1.8 only*. (See Bug #17813)

- **`IGNORE` and `REPLACE` functionality.** In MySQL 5.1.7 and earlier, `INSERT IGNORE`, `UPDATE IGNORE`, and `REPLACE` were supported only for primary keys, but not for unique keys. It was possible to work around this issue by removing the constraint, then dropping the unique index, performing any inserts, and then adding the unique index again.

  This limitation was removed for `INSERT IGNORE` and `REPLACE` in MySQL 5.1.8. (See Bug #17431.)

- **`AUTO_INCREMENT` columns.** In MySQL 5.1.10 and earlier versions, the maximum number of tables having `AUTO_INCREMENT` columns—including those belonging to hidden primary keys—was 2048.

  This limitation was lifted in MySQL 5.1.11.

- **Maximum number of cluster nodes.** Prior to MySQL Cluster NDB 6.1.1, the total maximum number of nodes in a MySQL Cluster was 63, including all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.

  Starting with MySQL Cluster NDB 6.1.1, the total maximum number of nodes in a MySQL Cluster is 255, including all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers. The total number of data nodes and management nodes beginning with this version is 63, of which up to 48 can be data nodes.

  Note

  The limitation that a data node cannot have a node ID greater than 49 continues to apply.

- **Recovery of memory from deleted rows.** Beginning with MySQL Cluster NDB 6.3.7, memory can be reclaimed from an `NDB` table for reuse with any `NDB` table by employing `OPTIMIZE TABLE`, subject to the following limitations:

  - Only in-memory tables are supported; the `OPTIMIZE TABLE` statement still has no effect on MySQL Cluster Disk Data tables.

  - Only variable-length columns (such as those declared as `VARCHAR`, `TEXT`, or `BLOB`) are supported.

    However, you can force columns defined using fixed-length data types (such as `CHAR`) to be dynamic using the `ROW_FORMAT` or `COLUMN_FORMAT` option with a `CREATE TABLE` or `ALTER TABLE` statement.

    See `CREATE TABLE` Syntax, and `ALTER TABLE` Syntax, for information on these options.

  You can regulate the effects of `OPTIMIZE` on performance by adjusting the value of the global system variable `ndb_optimization_delay`, which sets the number of milliseconds to wait between batches of rows being processed by `OPTIMIZE`. The default value is 10 milliseconds. It is possible to set a lower value (to a minimum of `0`), but not recommended. The maximum is 100000 milliseconds (that is, 100 seconds).

- **Implicit Rollbacks.** Prior to MySQL Cluster NDB 6.2.17 and MySQL Cluster NDB 6.3.19, MySQL Cluster did not automatically roll back a transaction that was aborted by a duplicate key or similar error, and subsequent statements raised `ERROR 1296 (HY000): Got error 4350 'Transaction already aborted' from NDBCLUSTER`. In such cases, it was necessary to issue an explicit `ROLLBACK` statement first, and then to retry the entire transaction.

  Beginning with MySQL Cluster NDB 6.2.17 and MySQL Cluster NDB 6.3.19, this limitation has been removed; now, an error which causes a transaction to be aborted generates an implicit rollback

of the entire transaction. This is logged with the warning `Storage engine NDB does not support rollback for this statement. Transaction rolled back and must be restarted`. A statement subsequent to this starts a new transaction. (Bug #32656)

Note

The `NDBCLUSTER` storage engine does not support partial transactions or partial rollbacks of transactions in any version of MySQL Cluster.

- **Number of tables.** Previously, the maximum number of `NDBCLUSTER` tables in a single MySQL Cluster was 1792, but this is no longer the case in MySQL 5.1 and later MySQL Cluster releases. However, the number of tables is still included in the total maximum number of `NDBCLUSTER` database objects (20320). (See Limits Associated with Database Objects in MySQL Cluster.)

- **DDL operations.** Beginning with MySQL Cluster NDB 6.4.0, DDL operations (such as `CREATE TABLE` or `ALTER TABLE`) are protected from data node failures. Previously, if a data node failed while trying to perform one of these, the data dictionary became locked and no further DDL statements could be executed without restarting the cluster (Bug #36718).

- **Adding and dropping of data nodes.** In MySQL Cluster NDB 6.3 and previous versions of MySQL Cluster, the online adding or dropping of data nodes was not possible; such operations required a complete shutdown and restart of the entire cluster. In MySQL Cluster NDB 7.0 (beginning with MySQL Cluster NDB 6.4.0) and later MySQL Cluster release series, it is possible to add new data nodes to a running MySQL Cluster by performing a rolling restart, so that the cluster and the data stored in it remain available to applications.

  When planning to increase the number of data nodes in the cluster online in MySQL Cluster NDB 7.0 or MySQL Cluster NDB 7.1, you should be aware of and take into account the following issues:

  - New data nodes can be added online to a MySQL Cluster only as part of a new node group.
  - New data nodes can be added online, but cannot yet be dropped online. Reducing the number of data nodes still requires a system restart of the cluster.
  - As in previous MySQL Cluster releases, it is not possible to change online either the number of replicas (`NoOfReplicas` [1815] configuration parameter) or the number of data nodes per node group. These changes require a system restart.
  - Redistribution of existing cluster data using the new data nodes is not automatic; however, this can be accomplished using simple SQL statements in the `mysql` client or other MySQL client application once the nodes have been added. During this procedure, it is not possible to perform DDL operations, although DML operations can continue as normal.

    The distribution of new cluster data (that is, data stored in the cluster *after* the new nodes have been added) uses the new nodes without manual intervention.

  For more information, see Adding MySQL Cluster Data Nodes Online.

- **Native support for default column values.** Starting with MySQL Cluster NDB 7.1.0, default values for table columns are stored by `NDBCLUSTER`, rather than by the MySQL server as was previously the case. Because less data must be sent from an SQL node to the data nodes, inserts on tables having column value defaults can be performed more efficiently than before.

  Tables created using previous MySQL Cluster releases can still be used in MySQL Cluster 7.1.0 and later, although they do not support native default values and continue to use defaults supplied by the MySQL server until they are upgraded. This can be done by means of an offline `ALTER TABLE` statement.

Important

You cannot set or change a table column's default value using an online `ALTER TABLE` operation

- **`InnoDB` plugin support.** Previously, `InnoDB` support in MySQL Cluster was limited to the version built in to the MySQl Server. Beginning with MySQL Cluster NDB 7.1.9, MySQL Cluster also provides support for the `InnoDB` Plugin. See MySQL Cluster Installation, for information about enabling `InnoDB` storage engine and plugin support with MySQL Cluster.

- **Distribution of MySQL users and privileges.** Previously, MySQL users and privileges created on one SQL node were unique to that SQL node, due to the fact that the MySQL grant tables were restricted to using the `MyISAM` storage engine. Beginning with MySQL Cluster NDB 7.2.0, it is possible, following installation of the MySQL Cluster software and setup of the desired users and privileges on one SQL node, to convert the grant tables to use `NDB` and thus to distribute the users and privileges across all SQL nodes connected to the cluster. You can do this by loading and making use of a set of stored procedures defined in an SQL script supplied with the MySQL Cluster distribution. For more information, see Distributed MySQL Privileges for MySQL Cluster.

- **Number of rows per partition.** Previously, a single MySQL Cluster partition could hold a maximum of 46137488 rows. This limitation was removed in MySQL Cluster NDB 7.0.36 and MySQL Cluster NDB 7.1.25.

  If you are still using a previous MySQL Cluster release, you can work around this limitation by taking advantage of the fact that the number of partitions is the same as the number of data nodes in the cluster (see MySQL Cluster Nodes, Node Groups, Replicas, and Partitions). This means that, by increasing the number of data nodes, you can increase the available space for storing data.

  In MySQL Cluster NDB 7.0 and later, you can increase the number of data nodes in the cluster while the cluster remains in operation. See Adding MySQL Cluster Data Nodes Online, for more information.

  It is also possible to increase the number of partitions for `NDB` tables by using explicit `KEY` or `LINEAR KEY` partitioning (see `KEY` Partitioning).

MySQL Cluster Installation

This section describes the basics for planning, installing, configuring, and running a MySQL Cluster. Whereas the examples in MySQL Cluster Configuration provide more in-depth information on a variety of clustering options and configuration, the result of following the guidelines and procedures outlined here should be a usable MySQL Cluster which meets the *minimum* requirements for availability and safeguarding of data.

For information about upgrading or downgrading a MySQL Cluster between release versions, see Upgrading and Downgrading MySQL Cluster.

This section covers hardware and software requirements; networking issues; installation of MySQL Cluster; configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.

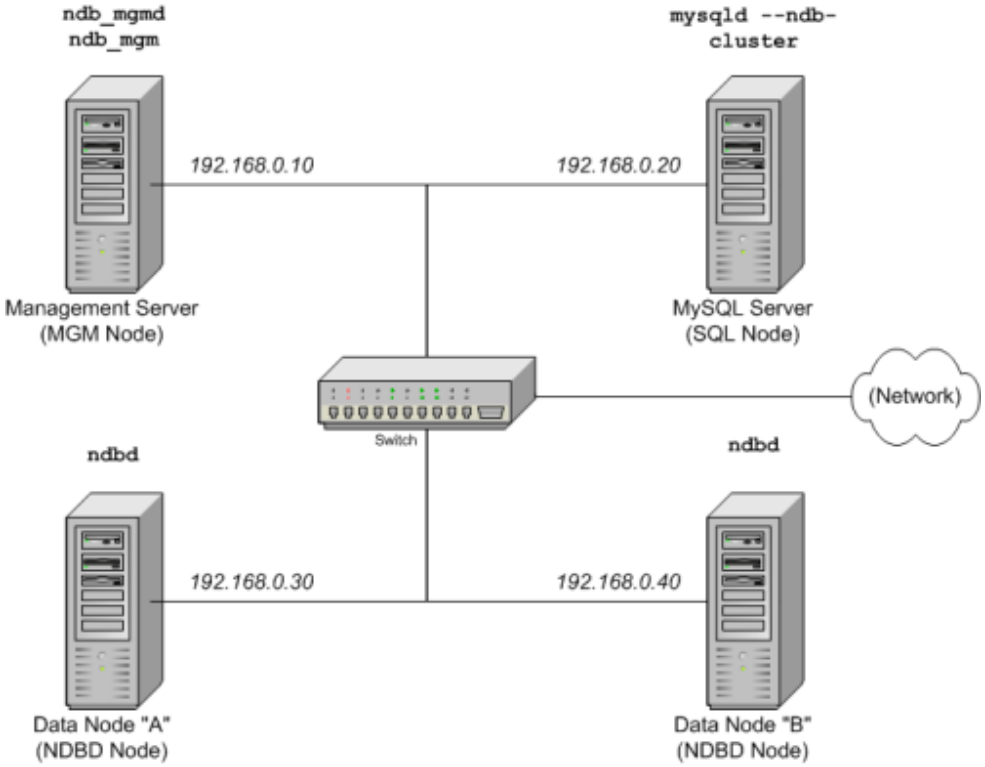
Assumptions. The following sections make a number of assumptions regarding the cluster's physical and network configuration. These assumptions are discussed in the next few paragraphs.

Cluster nodes and host computers. The cluster consists of four nodes, each on a separate host computer, and each with a fixed network address on a typical Ethernet network as shown here:

Node	IP Address
Management node (`mgmd`)	192.168.0.10

Node	IP Address
SQL node (`mysqld`)	192.168.0.20
Data node "A" (`ndbd`)	192.168.0.30
Data node "B" (`ndbd`)	192.168.0.40

This may be made clearer by the following diagram:



Network addressing. In the interest of simplicity (and reliability), this *How-To* uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use host names in lieu of IP addresses in configuring Cluster. Alternatively, you can use the `hosts` file (typically `/etc/hosts` for Linux and other Unix-like operating systems, `C:\WINDOWS\system32\drivers\etc\hosts` on Windows, or your operating system's equivalent) for providing a means to do host lookup if such is available.

Potential hosts file issues. A common problem when trying to use host names for Cluster nodes arises because of the way in which some operating systems (including some Linux distributions) set up the system's own host name in the `/etc/hosts` during installation. Consider two machines with the host names `ndb1` and `ndb2`, both in the `cluster` network domain. Red Hat Linux (including some derivatives such as CentOS and Fedora) places the following entries in these machines' `/etc/hosts` files:

```
#  ndb1 /etc/hosts:
127.0.0.1   ndb1.cluster ndb1 localhost.localdomain localhost
```

```
#  ndb2 /etc/hosts:
127.0.0.1   ndb2.cluster ndb2 localhost.localdomain localhost
```

SUSE Linux (including OpenSUSE) places these entries in the machines' `/etc/hosts` files:

```
#  ndb1 /etc/hosts:
127.0.0.1       localhost
127.0.0.2       ndb1.cluster ndb1
```

```
#  ndb2 /etc/hosts:
127.0.0.1       localhost
```

```
127.0.0.2       ndb2.cluster ndb2
```

In both instances, `ndb1` routes `ndb1.cluster` to a loopback IP address, but gets a public IP address from DNS for `ndb2.cluster`, while `ndb2` routes `ndb2.cluster` to a loopback address and obtains a public address for `ndb1.cluster`. The result is that each data node connects to the management server, but cannot tell when any other data nodes have connected, and so the data nodes appear to hang while starting.

Caution

You cannot mix `localhost` and other host names or IP addresses in `config.ini`. For these reasons, the solution in such cases (other than to use IP addresses for *all* `config.ini` `HostName` entries) is to remove the fully qualified host names from `/etc/hosts` and use these in `config.ini` for all cluster hosts.

Host computer type. Each host computer in our installation scenario is an Intel-based desktop PC running a supported operating system installed to disk in a standard configuration, and running no unnecessary services. The core operating system with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the file systems on all hosts are set up identically. In the event that they are not, you should adapt these instructions accordingly.

Network hardware. Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected through a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughout. That is, all four machines in the cluster should have 100 Mbps cards *or* all four machines should have 1 Gbps cards.) MySQL Cluster works in a 100 Mbps network; however, gigabit Ethernet provides better performance.

Important

MySQL Cluster is *not* intended for use in a network for which throughput is less than 100 Mbps or which experiences a high degree of latency. For this reason (among others), attempting to run a MySQL Cluster over a wide area network such as the Internet is not likely to be successful, and is not supported in production.

Sample data. We use the `world` database which is available for download from the MySQL Web site (see http://dev.mysql.com/doc/index-other.html). We assume that each machine has sufficient memory for running the operating system, required MySQL Cluster processes, and (on the data nodes) storing the database.

For general information about installing MySQL, see Chapter 2, *Installing and Upgrading MySQL*. For information about installation of MySQL Cluster on Linux and other Unix-like operating systems, see Installing MySQL Cluster on Linux. For information about installation of MySQL Cluster on Windows operating systems, see Installing MySQL Cluster on Windows.

For general information about MySQL Cluster hardware, software, and networking requirements, see MySQL Cluster Hardware, Software, and Networking Requirements.

Installing MySQL Cluster on Linux

This section covers installation of MySQL Cluster on Linux and other Unix-like operating systems. While the next few sections refer to a Linux operating system, the instructions and procedures given there should be easily adaptable to other supported Unix-like platforms.

Beginning with MySQL Cluster NDB 7.1.3, MySQL Cluster is also supported for production use on Windows operating systems; for installation and setup instructions specific to Windows, see Installing MySQL Cluster on Windows.

Each MySQL Cluster host computer must have the correct executable programs installed. A host running an SQL node must have installed on it a MySQL Server binary (`mysqld`). Management nodes require the management server daemon (`ndb_mgmd`); data nodes require the data node daemon (`ndbd`; in MySQL Cluster NDB 7.0 and later, you can use `ndbmtd` instead. It is not necessary to install the MySQL Server binary on management node hosts and data node hosts. It is recommended that you also install the management client (`ndb_mgm`) on the management server host.

Installation of MySQL Cluster on Linux can be done using precompiled binaries from Oracle (downloaded as a .tar.gz archive), with RPM packages (also available from Oracle), or from source code. All three of these installation methods are described in the section that follow.

Regardless of the method used, it is still necessary following installation of the MySQL Cluster binaries to create configuration files for all cluster nodes, before you can start the cluster. See Initial Configuration of MySQL Cluster.

Installing a MySQL Cluster Binary Release on Linux

This section covers the steps necessary to install the correct executables for each type of Cluster node from precompiled binaries supplied by Oracle.

For setting up a cluster using precompiled binaries, the first step in the installation process for each cluster host is to download the latest MySQL Cluster NDB 6.3, MySQL Cluster NDB 7.0, or MySQL Cluster NDB 7.1 binary archive (`mysql-cluster-gpl-6.3.50-linux-i686-glibc23.tar.gz`, `mysql-cluster-gpl-7.0.36-linux-i686-glibc23.tar.gz`, or `mysql-cluster-gpl-7.1.25-linux-i686-glibc23.tar.gz`, respectively) from the MySQL Cluster downloads area. We assume that you have placed this file in each machine's `/var/tmp` directory. (If you do require a custom binary, see Installing MySQL from a Development Source Tree.)

Note

After completing the installation, do not yet start any of the binaries. We show you how to do so following the configuration of the nodes (see Initial Configuration of MySQL Cluster).

Data nodes and SQL nodes. On each of the machines designated to host data nodes or SQL nodes, perform the following steps as the system `root` user:

1. Check your `/etc/passwd` and `/etc/group` files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a `mysql` group and `mysql` user on the system. Some OS distributions create these as part of the operating system installation process. If they are not already present, create a new `mysql` user group, and then add a `mysql` user to this group:

   ```
   shell> groupadd mysql
   shell> useradd -g mysql mysql
   ```

   The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symbolic link named `mysql` to the `mysql` directory. Note that the actual file and directory names vary according to the MySQL Cluster version number.

   ```
   shell> cd /var/tmp
   shell> tar -C /usr/local -xzvf mysql-cluster-gpl-7.1.25-linux-i686-glibc23.tar.gz
   shell> ln -s /usr/local/mysql-cluster-gpl-7.1.25-linux-i686-glibc23 /usr/local/mysql
   ```

3. Change location to the `mysql` directory and run the supplied script for creating the system databases:

   ```
   shell> cd mysql
   ```

```
shell> scripts/mysql_install_db --user=mysql
```

4. Set the necessary permissions for the MySQL server and data directories:

```
shell> chown -R root .
shell> chown -R mysql data
shell> chgrp -R mysql .
```

   Note that the data directory on each machine hosting a data node is `/usr/local/mysql/data`. This piece of information is essential when configuring the management node. (See Initial Configuration of MySQL Cluster.)

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

```
shell> cp support-files/mysql.server /etc/rc.d/init.d/
shell> chmod +x /etc/rc.d/init.d/mysql.server
shell> chkconfig --add mysql.server
```

   (The startup scripts directory may vary depending on your operating system and version—for example, in some Linux distributions, it is `/etc/init.d`.)

   Here we use Red Hat's `chkconfig` for creating links to the startup scripts; use whatever means is appropriate for this purpose on your operating system and distribution, such as `update-rc.d` on Debian.

Remember that the preceding steps must be repeated on each machine where an SQL node is to reside.

Management nodes. Installation of the management node does not require the `mysqld` binary. Only the MySQL Cluster management server (`ndb_mgmd`) is required; you most likely want to install the management client (`ndb_mgm`) as well. Both of these binaries also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root` (that is, after using `sudo`, `su root`, or your system's equivalent for temporarily assuming the system administrator account's privileges), perform the following steps to install `ndb_mgmd` and `ndb_mgm` on the Cluster management node host:

1. Change location to the `/var/tmp` directory, and extract the `ndb_mgm` and `ndb_mgmd` from the archive into a suitable directory such as `/usr/local/bin`:

```
shell> cd /var/tmp
shell> tar -zxvf mysql-5.1.63-ndb-7.1.25-linux-i686-glibc23.tar.gz
shell> cd mysql-5.1.63-ndb-7.1.25-linux-i686-glibc23
shell> cp bin/ndb_mgm* /usr/local/bin
```

   (You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndb_mgm*
```

In Initial Configuration of MySQL Cluster, we create configuration files for all of the nodes in our example MySQL Cluster.

Installing MySQL Cluster from RPM

This section covers the steps necessary to install the correct executables for each type of MySQL Cluster node using RPM packages supplied by Oracle.

RPMs are available for both 32-bit and 64-bit Linux platforms. For a MySQL Cluster, three RPMs are required:

- The **Server** RPM (for example, `MySQL-Cluster-gpl-server-6.3.50-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-server-7.0.36-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-server-7.1.25-0.sles10.i586.rpm`), which supplies the core files needed to run a MySQL Server with `NDBCLUSTER` storage engine support (that is, as a MySQL Cluster SQL node).

  If you do not have your own client application capable of administering a MySQL server, you should also obtain and install the **Client** RPM (for example, `MySQL-Cluster-gpl-client-6.3.50-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-client-7.0.36-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-client-7.1.25-0.sles10.i586.rpm`).

- The **Cluster storage engine** RPM (for example, `MySQL-Cluster-gpl-storage-6.3.50-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-storage-7.0.36-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-storage-7.1.25-0.sles10.i586.rpm`), which supplies the MySQL Cluster data node binary (`ndbd`).

- The **Cluster storage engine management RPM** (for example, `MySQL-Cluster-gpl-management-6.3.50-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-management-7.0.36-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-management-7.1.25-0.sles10.i586.rpm`) which provides the MySQL Cluster management server binary (`ndb_mgmd`).

In addition, you should also obtain the **NDB Cluster - Storage engine basic tools** RPM (for example, `MySQL-Cluster-gpl-tools-6.3.50-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-tools-7.0.36-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-tools-7.1.25-0.sles10.i586.rpm`), which supplies several useful applications for working with a MySQL Cluster. The most important of these is the MySQL Cluster management client (`ndb_mgm`). The **NDB Cluster - Storage engine extra tools** RPM (for example, `MySQL-Cluster-gpl-extra-6.3.50-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-extra-7.0.36-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-extra-7.1.25-0.sles10.i586.rpm`) contains some additional testing and monitoring programs, but is not required to install a MySQL Cluster. (For more information about these additional programs, see MySQL Cluster Programs.)

The MySQL Cluster version number in the RPM file names (shown here as `6.3.50`, `7.0.36`, or `7.1.25`) can vary according to the version which you are actually using. *It is very important that all of the Cluster RPMs to be installed have the same version number*. The `glibc` version number (if present), and architecture designation (shown here as `i586`) should be appropriate to the machine on which the RPM is to be installed.

Data nodes. On a computer that is to host a cluster data node it is necessary to install only the **NDB Cluster - Storage engine** RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL web site:

```
shell> rpm -Uhv MySQL-Cluster-gpl-storage-7.1.25-0.sles10.i586.rpm
```

The previous command installs the MySQL Cluster data node binary (`ndbd`) in the `/usr/sbin` directory.

SQL nodes. On each machine to be used for hosting a cluster SQL node, install the **Server** RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL web site:

```
shell> rpm -Uhv MySQL-Cluster-gpl-server-7.1.25-0.sles10.i586.rpm
```

This installs the MySQL server binary (`mysqld`) in the `/usr/sbin` directory, as well as all needed MySQL Server support files. It also installs the `mysql.server` and `mysqld_safe` startup scripts in

`/usr/share/mysql` and `/usr/bin`, respectively. The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.

Note

To administer the SQL node (MySQL server), you should also install the **Client** RPM, as shown here:

```
shell> rpm -Uhv MySQL-Cluster-gpl-client-7.1.25-0.sles10.i586.rpm
```

This installs the `mysql` client program.

Management nodes. To install the MySQL Cluster management server, it is necessary only to use the **NDB Cluster - Storage engine management** RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the **Storage engine management** RPM downloaded from the MySQL web site):

```
shell> rpm -Uhv MySQL-Cluster-gpl-management-7.1.25-0.sles10.i586.rpm
```

This installs the management server binary (`ndb_mgmd`) to the `/usr/sbin` directory.

You should also install the `NDB` management client, which is supplied by the **Storage engine basic tools** RPM. Copy this RPM to the same computer as the management node, and then install it by running the following command as the system root user (again, replace the name shown for the RPM as necessary to match that of the **Storage engine basic tools** RPM downloaded from the MySQL web site):

```
shell> rpm -Uhv MySQL-Cluster-gpl-tools-7.1.25-0.sles10.i586.rpm
```

The **Storage engine basic tools** RPM installs the MySQL Cluster management client (`ndb_mgm`) to the `/usr/bin` directory.

Note

You can also install the **Cluster storage engine extra tools** RPM, if you wish, as shown here:

```
shell> rpm -Uhv MySQL-Cluster-gpl-extra-7.1.25-0.sles10.i586.rpm
```

You may find the extra tools useful; however the **Cluster storage engine extra tools** RPM is *not* required to install a working MySQL Cluster.

See Installing MySQL from RPM Packages on Linux, for general information about installing MySQL using RPMs supplied by Oracle.

After installing from RPM, you still need to configure the cluster as discussed in Initial Configuration of MySQL Cluster.

Building MySQL Cluster from Source on Linux

This section provides information about compiling MySQL Cluster on Linux and other Unix-like platforms. Building MySQL Cluster from source is similar to building the standard MySQL Server, although it differs in a few key respects discussed here. For general information about building MySQL from source, see Installing MySQL from Source. Beginning with MySQL Cluster NDB 7.1.3, MySQL Cluster is also supported on Windows platforms, and can be built on Windows from source. For information about compiling MySQL Cluster on Windows platforms, see Compiling and Installing MySQL Cluster from Source on Windows.

Building MySQL Cluster requires using the MySQL Cluster sources. These are available from the MySQL Cluster downloads page at `http://dev.mysql.com/downloads/cluster/`. The archived source file should have a name similar to `mysql-cluster-gpl-6.3.50.tar.gz`, `mysql-`

`cluster-gpl-7.0.36.tar.gz`, or `mysql-cluster-gpl-7.1.25.tar.gz`. You can also obtain MySQL development sources from launchpad.net. Attempting to build MySQL Cluster from standard MySQL 5.1 sources is not supported.

In addition to any other `configure` options you wish to use, be sure to include `--with-plugins=ndbcluster` [136], `--with-plugins=max` [136], or , or `--with-plugins=max-no-innodb` [136]. Either of these options causes the binaries for the management nodes, data nodes, and other MySQL Cluster programs to be built; it also causes `mysqld` to be compiled with `NDB` storage engine support.

After you have run `make && make install` (or your system's equivalent), the result is similar to what is obtained by unpacking a precompiled binary to the same location. However, the layout can differ. These differences are covered in the next few paragraphs.

Prior to MySQL Cluster NDB 7.1.9, MySQL Cluster was not compatible with the `InnoDB` Plugin; in earlier MySQL Cluster releases, only the version of `InnoDB` supplied with the MySQL Server could be used. Beginning with MySQL Cluster NDB 7.1.9, you can build MySQL Cluster with `InnoDB` storage engine or plugin support using the appropriate `--with-plugins` [136] option for `configure`.

Management nodes. When building from source and running the default `make install`, the management server binary (`ndb_mgmd`) is placed in `/usr/local/mysql/libexec`, while the management client binary (`ndb_mgm`) can be found in `/usr/local/mysql/bin`. Only `ndb_mgmd` is required to be present on a management node host; however, it is also a good idea to have `ndb_mgm` present on the same host machine. Neither of these executables requires a specific location on the host machine's file system.

Data nodes. The only executable required on a data node host is `ndbd` (`mysqld`, for example, does not have to be present on the host machine). By default when doing a source build, this file is placed in the directory `/usr/local/mysql/libexec`. For installing on multiple data node hosts, only `ndbd` need be copied to the other host machine or machines. (This assumes that all data node hosts use the same architecture and operating system; otherwise you may need to compile separately for each different platform.) `ndbd` need not be in any particular location on the host's file system, as long as the location is known.

When compiling MySQL Cluster NDB 7.0 or later from source, no special options are required for building multi-threaded data node binaries. On Unix platforms, configuring the build with any of the options `--with-plugins=ndbcluster`, `--with-plugins=max` [136], or `--with-plugins=max-no-innodb` [136] causes `ndbmtd` to be built automatically; `make install` places the `ndbmtd` binary in the `libexec` directory along with `mysqld`, `ndbd`, and `ndb_mgm`.

SQL nodes. If you compile MySQL with clustering support, and perform the default installation (using `make install` as the system `root` user), `mysqld` is placed in `/usr/local/mysql/bin`. Follow the steps given in Installing MySQL from Source to make `mysqld` ready for use. If you want to run multiple SQL nodes, you can use a copy of the same `mysqld` executable and its associated support files on several machines. The easiest way to do this is to copy the entire `/usr/local/mysql` directory and all directories and files contained within it to the other SQL node host or hosts, then repeat the steps from Installing MySQL from Source on each machine. If you configure the build with a nondefault `--prefix` [133], you need to adjust the directory accordingly.

In Initial Configuration of MySQL Cluster, we create configuration files for all of the nodes in our example MySQL Cluster.

Installing MySQL Cluster on Windows

Experimental support for MySQL Cluster on Microsoft Windows operating systems was introduced in MySQL Cluster NDB 7.0. Beginning with MySQL Cluster NDB 7.1.3, production support is provided for MySQL Cluster on Windows, and MySQL Cluster binaries for Windows can be obtained from http://dev.mysql.com/downloads/cluster/. For information about installing MySQL Cluster on Windows from a binary release provided by Oracle, see Installing MySQL Cluster on Windows from a Binary Release.

It is also possible to compile and install MySQL Cluster from source on Windows using Microsoft Visual Studio. For more information, see Compiling and Installing MySQL Cluster from Source on Windows.

Installing MySQL Cluster on Windows from a Binary Release

This section describes a basic installation of MySQL Cluster on Windows using a binary `no-install` MySQL Cluster release provided by Oracle, using the same 4-node setup outlined in the beginning of this section (see MySQL Cluster Installation), as shown in the following table:

Node	IP Address
Management (MGMD) node	192.168.0.10
MySQL server (SQL) node	192.168.0.20
Data (NDBD) node "A"	192.168.0.30
Data (NDBD) node "B"	192.168.0.40

As on other platforms, the MySQL Cluster host computer running an SQL node must have installed on it a MySQL Server binary (`mysqld.exe`). You should also have the MySQL client (`mysql.exe`) on on this host. For management nodes and data nodes, it is not necessary to install the MySQL Server binary; however, each management node requires the management server daemon (`ndb_mgmd.exe`); each data node requires the data node daemon (`ndbd.exe` or `ndbmtd.exe`). For this example, we refer to `ndbd.exe` as the data node executable, but you can install `ndbmtd.exe`, the multi-threaded version of this program, instead, in exactly the same way. You should also install the management client (`ndb_mgm.exe`) on the management server host. This section covers the steps necessary to install the correct Windows binaries for each type of MySQL Cluster node.

`ndbmtd.exe` was not included in MySQL Cluster NDB 7.1.3 binary releases for Windows, due to a problem with `make_win_bin_dist`. This issue was corrected in MySQL Cluster NDB 7.1.5.

Note

As with other Windows programs, MySQL Cluster executables are named with the `.exe` file extension. However, it is not necessary to include the `.exe` extension when invoking these programs from the command line. Therefore, we often simply refer to these programs in this documentation as `mysqld`, `mysql`, `ndb_mgmd`, and so on. You should understand that, whether we refer (for example) to `mysqld` or `mysqld.exe`, either name means the same thing (the MySQL Server program).

For setting up a MySQL Cluster using Oracles's `no-install` binaries, the first step in the installation process is to download the latest MySQL Cluster Windows binary archive from http://dev.mysql.com/downloads/cluster/. This archive has a filename of the form `mysql-cluster-gpl-noinstall-`*`ver`*`-win`*`arch`*`.zip`, where *`ver`* is the `NDB` storage engine version (such as `7.1.3`), and *`arch`* is the architecture (`32` for 32-bit binaries, and `64` for 64-bit binaries). For example, the MySQL Cluster NDB 7.1.3 `no-install` archive for 32-bit Windows systems is named `mysql-cluster-gpl-noinstall-7.1.3-win32.zip`.

You can run 32-bit MySQL Cluster binaries on both 32-bit and 64-bit versions of Windows; however, 64-bit MySQL Cluster binaries can be used only on 64-bit versions of Windows. If you are using a 32-bit version of Windows on a computer that has a 64-bit CPU, then you must use the 32-bit MySQL Cluster binaries.

To minimize the number of files that need to be downloaded from the Internet or copied between machines, we start with the computer where you intend to run the SQL node.

SQL node. We assume that you have placed a copy of the `no-install` archive in the directory `C:\Documents and Settings\`*`username`*`\My Documents\Downloads` on the computer having the IP address 192.168.0.20, where *`username`* is the name of the current user. (You can obtain this name using `ECHO %USERNAME%` on the command line.) To install and run MySQL Cluster executables as Windows services, this user should be a member of the `Administrators` group.

Extract all the files from the archive. The Extraction Wizard integrated with Windows Explorer is adequate for this task. (If you use a different archive program, be sure that it extracts all files and directories from the archive, and that it preserves the archive's directory structure.) When you are asked for a destination directory, enter `C:\`, which causes the Extraction Wizard to extract the archive to the directory `C:\mysql-cluster-gpl-noinstall-`*`ver`*`-win`*`arch`*. Rename this directory to `C:\mysql`.

It is possible to install the MySQL Cluster binaries to directories other than `C:\mysql\bin`; however, if you do so, you must modify the paths shown in this procedure accordingly. In particular, if the MySQL Server (SQL node) binary is installed to a location other than `C:\mysql` or `C:\Program Files\MySQL\MySQL Server 5.1`, or if the SQL node's data directory is in a location other than `C:\mysql\data` or `C:\Program Files\MySQL\MySQL Server 5.1\data`, extra configuration options must be used on the command line or added to the `my.ini` or `my.cnf` file when starting the SQL node. For more information about configuring a MySQL Server to run in a nonstandard location, see Installing MySQL on Microsoft Windows Using a `noinstall` Zip Archive.

For a MySQL Server with MySQL Cluster support to run as part of a MySQL Cluster, it must be started with the options `--ndbcluster` [1915] and `--ndb-connectstring` [1914]. While you can specify these options on the command line, it is usually more convenient to place them in an option file. To do this, create a new text file in Notepad or another text editor. Enter the following configuration information into this file:

```
[mysqld]
# Options for mysqld process:
ndbcluster                      # run NDB storage engine
ndb-connectstring=192.168.0.10  # location of management server
```

You can add other options used by this MySQL Server if desired (see Creating an Option File), but the file must contain the options shown, at a minimum. Save this file as `C:\mysql\my.ini`. This completes the installation and setup for the SQL node.

Data nodes. A MySQL Cluster data node on a Windows host requires only a single executable, one of either `ndbd.exe` or `ndbmtd.exe`. For this example, we assume that you are using `ndbd.exe`, but the same instructions apply when using `ndbmtd.exe`. On each computer where you wish to run a data node (the computers having the IP addresses 192.168.0.30 and 192.168.0.40), create the directories `C:\mysql`, `C:\mysql\bin`, and `C:\mysql\cluster-data`; then, on the computer where you downloaded and extracted the `no-install` archive, locate `ndbd.exe` in the `C:\mysql\bin` directory. Copy this file to the `C:\mysql\bin` directory on each of the two data node hosts.

To function as part of a MySQL Cluster, each data node must be given the address or hostname of the management server. You can supply this information on the command line using the `--ndb-connectstring` [1972] or `-c` option when starting each data node process. However, it is usually preferable to put this information in an option file. To do this, create a new text file in Notepad or another text editor and enter the following text:

```
[mysql_cluster]
# Options for data node process:
ndb-connectstring=192.168.0.10  # location of management server
```

Save this file as `C:\mysql\my.ini` on the data node host. Create another text file containing the same information and save it on as `C:mysql\my.ini` on the other data node host, or copy the my.ini file from the first data node host to the second one, making sure to place the copy in the second data node's `C:\mysql` directory. Both data node hosts are now ready to be used in the MySQL Cluster, which leaves only the management node to be installed and configured.

Management node. The only executable program required on a computer used for hosting a MySQL Cluster management node is the management server program `ndb_mgmd.exe`. However, in order to administer the MySQL Cluster once it has been started, you should also install the MySQL Cluster management client program `ndb_mgm.exe` on the same machine as the management server. Locate these two programs on the machine where you downloaded and extracted the `no-install` archive; this should be the directory `C:\mysql\bin` on the SQL node host. Create the directory `C:`

`\mysql\bin` on the computer having the IP address 192.168.0.10, then copy both programs to this directory.

You should now create two configuration files for use by `ndb_mgmd.exe`:

1. A local configuration file to supply configuration data specific to the management node itself. Typically, this file needs only to supply the location of the MySQL Cluster global configuration file (see item 2).

   To create this file, start a new text file in Notepad or another text editor, and enter the following information:

   ```
   [mysql_cluster]
   # Options for management node process
   config-file=C:/mysql/bin/config.ini
   ```

   Save this file as the plaintext file `C:\mysql\bin\my.ini`.

2. A global configuration file from which the management node can obtain configuration information governing the MySQL Cluster as a whole. At a minimum, this file must contain a section for each node in the MySQL Cluster, and the IP addresses or hostnames for the management node and all data nodes (`HostName` configuration parameter). It is also advisable to include the following additional information:

   - The IP address or hostname of any SQL nodes
   - The data memory and index memory allocated to each data node (`DataMemory` [1817] and `IndexMemory` [1819] configuration parameters)
   - The number of replicas, using the `NoOfReplicas` [1815] configuration parameter (see MySQL Cluster Nodes, Node Groups, Replicas, and Partitions)
   - The directory where each data node stores it data and log file, and the directory where the management node keeps its log files (in both cases, the `DataDir` [1816] configuration parameter)

   Create a new text file using a text editor such as Notepad, and input the following information:

   ```
   [ndbd default]
   # Options affecting ndbd processes on all data nodes:
   NoOfReplicas=2                       # Number of replicas
   DataDir=C:/mysql/bin/cluster-data    # Directory for each data node's data files
                                        # Forward slashes used in directory path,
                                        # rather than backslashes. This is correct;
                                        # see Important note in text
   DataMemory=80M    # Memory allocated to data storage
   IndexMemory=18M   # Memory allocated to index storage
                     # For DataMemory and IndexMemory, we have used the
                     # default values. Since the "world" database takes up
                     # only about 500KB, this should be more than enough for
                     # this example Cluster setup.

   [ndb_mgmd]
   # Management process options:
   HostName=192.168.0.10               # Hostname or IP address of management node
   DataDir=C:/mysql/bin/cluster-logs   # Directory for management node log files

   [ndbd]
   # Options for data node "A":
                                  # (one [ndbd] section per data node)
   HostName=192.168.0.30          # Hostname or IP address

   [ndbd]
   # Options for data node "B":
   HostName=192.168.0.40          # Hostname or IP address

   [mysqld]
   ```

```
# SQL node options:
HostName=192.168.0.20           # Hostname or IP address
```

Save this file as the plaintext file `C:\mysql\bin\config.ini`.

Important

A single backslash character (`\`) cannot be used when specifying directory paths in program options or configuration files used by MySQL Cluster on Windows. Instead, you must either escape each backslash character with a second backslash (`\\`), or replace the backslash with a forward slash character (`/`). For example, the following line from the `[ndb_mgmd]` section of a MySQL Cluster `config.ini` file does not work:

```
DataDir=C:\mysql\bin\cluster-logs
```

Instead, you may use either of the following:

```
DataDir=C:\\mysql\\bin\\cluster-logs  # Escaped backslashes
```

```
DataDir=C:/mysql/bin/cluster-logs     # Forward slashes
```

For reasons of brevity and legibility, we recommend that you use forward slashes in directory paths used in MySQL Cluster program options and configuration files on Windows.

Compiling and Installing MySQL Cluster from Source on Windows

Oracle provides precompiled MySQL Cluster binaries for Windows which should be adequate for most users. However, if you wish, it is also possible to compile MySQL Cluster for Windows from source code. The procedure for doing this is almost identical to the procedure used to compile the standard MySQL Server binaries for Windows, and uses the same tools. However, there are two major differences:

- To build MySQL Cluster, you must use the MySQL Cluster sources, which you can obtain from http://dev.mysql.com/downloads/cluster/.

  Attempting to build MySQL Cluster from the source code for the standard MySQL Server is likely not to be successful, and is not supported by Oracle.

- You must configure the build using the `WITH_NDBCLUSTER_STORAGE_ENGINE` option in addition to any other build options you wish to use before creating the Visual Studio project files. Once you have run `configure.js` with the desired options, you can create the project files and build from them in the same manner as you do when compiling the standard MySQL Server. For more information, see Installing MySQL from Source on Windows.

Prior to MySQL Cluster NDB 7.1.9, MySQL Cluster was not compatible with the `InnoDB` Plugin; in earlier MySQL Cluster releases, only the version of `InnoDB` supplied with the MySQL Server could be used. Beginning with MySQL Cluster NDB 7.1.9, you can build MySQL Cluster with `InnoDB` storage engine or plugin support on Windows using `WITH_INNOBASE_STORAGE_ENGINE` with `configure.js`-

Once the build process is complete, you can create a Zip archive containing the compiled binaries by running `make_win_bin_dist`. The MySQL Cluster binaries can be found in the `bin` directory of the resulting archive, which is equivalent to the `no-install` archive, and which can be installed and configured in the same manner. For basic information about how to accomplish these tasks, see Installing MySQL Cluster on Windows from a Binary Release.

On Windows, beginning with MySQL Cluster NDB 7.0.11, using `WITH_NDBCLUSTER_STORAGE_ENGINE` with `configure.js` causes `ndbmtd.exe` to be built automatically, and to be found in the `bin` directory of the archive created by `make_win_bin_dist`. (It was not possible to build `ndbmtd.exe` on Windows prior to MySQL Cluster NDB 7.0.11.)

Initial Startup of MySQL Cluster on Windows

Once the MySQL Cluster executables and needed configuration files are in place, performing an initial start of the cluster is simply a matter of starting the MySQL Cluster executables for all nodes in the cluster. Each cluster node process must be started separately, and on the host computer where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes.

1. On the management node host, issue the following command from the command line to start the management node process:

```
C:\mysql\bin> ndb_mgmd
2010-06-23 07:53:34 [MgmtSrvr] INFO -- NDB Cluster Management Server. mysql-5.1.63-ndb-7.1.25
2010-06-23 07:53:34 [MgmtSrvr] INFO -- Reading cluster configuration from 'config.ini'
```

   The management node process continues to print logging output to the console. This is normal, because the management node is not running as a Windows service. (If you have used MySQL Cluster on a Unix-like platform such as Linux, you may notice that the management node's default behavior in this regard on Windows is effectively the opposite of its behavior on Unix systems, where it runs by default as a Unix daemon process. This behavior is also true of MySQL Cluster data node processes running on Windows.) For this reason, do not close the window in which `ndb_mgmd.exe` is running; doing so kills the management node process. (See Installing MySQL Cluster Processes as Windows Services, where we show how to install and run MySQL Cluster processes as Windows services.)

   The required `-f` option tells the management node where to find the global configuration file (`config.ini`). The long form of this option is `--config-file` [1964].

   Important

   A MySQL Cluster management node caches the configuration data that it reads from `config.ini`; once it has created a configuration cache, it ignores the `config.ini` file on subsequent starts unless forced to do otherwise. This means that, if the management node fails to start due to an error in this file, you must make the management node re-read `config.ini` after you have corrected any errors in it. You can do this by starting `ndb_mgmd.exe` with the `--reload` [1966] or `--initial` [1965] option on the command line. Either of these options works to refresh the configuration cache.

   It is not necessary or advisable to use either of these options in the management node's `my.ini` file.

   For additional information about options which can be used with `ndb_mgmd`, see `ndb_mgmd` — The MySQL Cluster Management Server Daemon, as well as Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs.

2. On each of the data node hosts, run the command shown here to start the data node processes:

```
C:\mysql\bin> ndbd
2010-06-23 07:53:46 [ndbd] INFO -- Configuration fetched from 'localhost:1186', generation: 1
```

   In each case, the first line of output from the data node process should resemble what is shown in the preceding example, and is followed by additional lines of logging output. As with the management node process, this is normal, because the data node is not running as a Windows service. For this reason, do not close the console window in which the data node process is running; doing so kills `ndbd.exe`. (For more information, see Installing MySQL Cluster Processes as Windows Services.)

3. Do not start the SQL node yet; it cannot connect to the cluster until the data nodes have finished starting, which may take some time. Instead, in a new console window on the management

node host, start the MySQL Cluster management client `ndb_mgm.exe`, which should be in `C:\mysql\bin` on the management node host. (Do not try to re-use the console window where `ndb_mgmd.exe` is running by typing **CTRL**+**C**, as this kills the management node.) The resulting output should look like this:

```
C:\mysql\bin> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm>
```

When the prompt `ndb_mgm>` appears, this indicates that the management client is ready to receive MySQL Cluster management commands. You can observe the status of the data nodes as they start by entering `ALL STATUS` at the management client prompt. This command causes a running report of the data nodes's startup sequence, which should look something like this:

```
ndb_mgm> ALL STATUS
Connected to Management Server at: localhost:1186
Node 2: starting (Last completed phase 3) (mysql-5.1.63-ndb-7.1.25)
Node 3: starting (Last completed phase 3) (mysql-5.1.63-ndb-7.1.25)

Node 2: starting (Last completed phase 4) (mysql-5.1.63-ndb-7.1.25)
Node 3: starting (Last completed phase 4) (mysql-5.1.63-ndb-7.1.25)

Node 2: Started (version 7.1.25)
Node 3: Started (version 7.1.25)

ndb_mgm>
```

Note

Commands issued in the management client are not case-sensitive; we use uppercase as the canonical form of these commands, but you are not required to observe this convention when inputting them into the `ndb_mgm` client. For more information, see Commands in the MySQL Cluster Management Client.

The output produced by `ALL STATUS` is likely to vary from what is shown here, according to the speed at which the data nodes are able to start, the release version number of the MySQL Cluster software you are using, and other factors. What is significant is that, when you see that both data nodes have started, you are ready to start the SQL node.

You can leave `ndb_mgm.exe` running; it has no negative impact on the performance of the MySQL Cluster, and we use it in the next step to verify that the SQL node is connected to the cluster after you have started it.

4. On the computer designated as the SQL node host, open a console window and navigate to the directory where you unpacked the MySQL Cluster binaries (if you are following our example, this is `C:\mysql\bin`).

   Start the SQL node by invoking `mysqld.exe` from the command line, as shown here:

   ```
   C:\mysql\bin> mysqld --console
   ```

   The `--console` [422] option causes logging information to be written to the console, which can be helpful in the event of problems. (Once you are satisfied that the SQL node is running in a satisfactory manner, you can stop it and restart it out without the `--console` [422] option, so that logging is performed normally.)

   In the console window where the management client (`ndb_mgm.exe`) is running on the management node host, enter the `SHOW` command, which should produce output similar to what is shown here:

   ```
   ndb_mgm> SHOW
   Connected to Management Server at: localhost:1186
   Cluster Configuration
   ```

```
--------------------
[ndbd(NDB)]     2 node(s)
id=2    @192.168.0.30  (Version: 5.1.63-ndb-7.1.25, Nodegroup: 0, Master)
id=3    @192.168.0.40  (Version: 5.1.63-ndb-7.1.25, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1    @192.168.0.10  (Version: 5.1.63-ndb-7.1.25)

[mysqld(API)]   1 node(s)
id=4    @192.168.0.20  (Version: 5.1.63-ndb-7.1.25)
```

You can also verify that the SQL node is connected to the MySQL Cluster in the `mysql` client (`mysql.exe`) using the `SHOW ENGINE NDB STATUS` [1291] statement.

You should now be ready to work with database objects and data using MySQL Cluster's `NDBCLUSTER` storage engine. See MySQL Cluster Example with Tables and Data, for more information and examples.

Beginning with MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5, you can install `ndb_mgmd.exe`, `ndbd.exe`, and `ndbmtd.exe` as Windows services. For information on how to do this, see Installing MySQL Cluster Processes as Windows Services).

Installing MySQL Cluster Processes as Windows Services

Once you are satisfied that MySQL Cluster is running as desired, you can—beginning with MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5—install the management nodes and data nodes as Windows services, so that these processes are started and stopped automatically whenever Windows is started or stopped. This also makes it possible to control these processes from the command line with the appropriate `NET START` or `NET STOP` command, or using the Windows graphical `Services` utility.

Installing programs as Windows services usually must be done using an account that has Administrator rights on the system.

To install the management node as a service on Windows, invoke `ndb_mgmd.exe` from the command line on the machine hosting the management node, using the `--install` [1969] option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install
Installing service 'MySQL Cluster Management Server'
  as '"C:\mysql\bin\ndbd.exe" "--service=ndb_mgmd"'
Service successfully installed.
```

Important

When installing a MySQL Cluster program as a Windows service, you should always specify the complete path; otherwise the service installation may fail with the error `The system cannot find the file specified`.

The `--install` [1969] option must be used first, ahead of any other options that might be specified for `ndb_mgmd.exe`. However, it is preferable to specify such options in an options file instead. If your options file is not in one of the default locations as shown in the output of `ndb_mgmd.exe --help` [2016], you can specify the location using the `--config-file` [1964] option.

Now you should be able to start and stop the management server like this:

```
C:\> NET START ndb_mgmd
The MySQL Cluster Management Server service is starting.
The MySQL Cluster Management Server service was started successfully.

C:\> NET STOP ndb_mgmd
The MySQL Cluster Management Server service is stopping..
The MySQL Cluster Management Server service was stopped successfully.
```

You can also start or stop the management server as a Windows service using the descriptive name, as shown here:

```
C:\> NET START 'MySQL Cluster Management Server'
The MySQL Cluster Management Server service is starting.
The MySQL Cluster Management Server service was started successfully.

C:\> NET STOP  'MySQL Cluster Management Server'
The MySQL Cluster Management Server service is stopping..
The MySQL Cluster Management Server service was stopped successfully.
```

However, it is usually simpler to specify a short service name or to permit the default service name to be used when installing the service, and then reference that name when starting or stopping the service. To specify a service name other than `ndb_mgmd`, append it to the `--install` [1969] option, as shown in this example:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install=mgmd1
Installing service 'MySQL Cluster Management Server'
      as '"C:\mysql\bin\ndb_mgmd.exe" "--service=mgmd1"'
Service successfully installed.
```

Now you should be able to start or stop the service using the name you have specified, like this:

```
C:\> NET START mgmd1
The MySQL Cluster Management Server service is starting.
The MySQL Cluster Management Server service was started successfully.

C:\> NET STOP mgmd1
The MySQL Cluster Management Server service is stopping..
The MySQL Cluster Management Server service was stopped successfully.
```

To remove the management node service, invoke `ndb_mgmd.exe` with the `--remove` [1969] option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove
Removing service 'MySQL Cluster Management Server'
Service successfully removed.
```

If you installed the service using a service name other than the default, you can remove the service by passing this name as the value of the `--remove` [1969] option, like this:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove=mgmd1
Removing service 'mgmd1'
Service successfully removed.
```

Installation of a MySQL Cluster data node process as a Windows service can be done in a similar fashion, using the `--install` [1956] option for `ndbd.exe` (or `ndbmtd.exe`), as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --install
Installing service 'MySQL Cluster Data Node Daemon' as '"C:\mysql\bin\ndbd.exe" "--service=ndbd"'
Service successfully installed.
```

Now you can start or stop the data node using either the default service name or the descriptive name with `net start` or `net stop`, as shown in the following example:

```
C:\> NET START ndbd
The MySQL Cluster Data Node Daemon service is starting.
The MySQL Cluster Data Node Daemon service was started successfully.

C:\> NET STOP ndbd
The MySQL Cluster Data Node Daemon service is stopping..
The MySQL Cluster Data Node Daemon service was stopped successfully.

C:\> NET START 'MySQL Cluster Data Node Daemon'
The MySQL Cluster Data Node Daemon service is starting.
The MySQL Cluster Data Node Daemon service was started successfully.

C:\> NET STOP 'MySQL Cluster Data Node Daemon'
The MySQL Cluster Data Node Daemon service is stopping..
```

```
The MySQL Cluster Data Node Daemon service was stopped successfully.
```

To remove the data node service, invoke `ndbd.exe` with the `--remove` [1956] option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove
Removing service 'MySQL Cluster Data Node Daemon'
Service successfully removed.
```

As with `ndb_mgmd.exe` (and `mysqld.exe`), when installing `ndbd.exe` as a Windows service, you can also specify a name for the service as the value of `--install` [1956], and then use it when starting or stopping the service, like this:

```
C:\> C:\mysql\bin\ndbd.exe --install=dnode1
Installing service 'dnode1' as '"C:\mysql\bin\ndbd.exe" "--service=dnode1"'
Service successfully installed.

C:\> NET START dnode1
The MySQL Cluster Data Node Daemon service is starting.
The MySQL Cluster Data Node Daemon service was started successfully.

C:\> NET STOP dnode1
The MySQL Cluster Data Node Daemon service is stopping..
The MySQL Cluster Data Node Daemon service was stopped successfully.
```

If you specified a service name when installing the data node service, you can use this name when removing it as well, by passing it as the value of the `--remove` [1956] option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove=dnode1
Removing service 'dnode1'
Service successfully removed.
```

Installation of the SQL node as a Windows service, starting the service, stopping the service, and removing the service are done in a similar fashion, using `mysqld --install`, `NET START`, `NET STOP`, and `mysqld --remove` [440]. For additional information, see Starting MySQL Server as a Microsoft Windows Service.

Initial Configuration of MySQL Cluster

For our four-node, four-host MySQL Cluster, it is necessary to write four configuration files, one per node host.

- Each data node or SQL node requires a `my.cnf` file that provides two pieces of information: a *connectstring* that tells the node where to find the management node, and a line telling the MySQL server on this host (the machine hosting the data node) to enable the `NDBCLUSTER` storage engine.

  For more information on connectstrings, see The MySQL Cluster Connectstring.

- The management node needs a `config.ini` file telling it how many replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.

Configuring the data nodes and SQL nodes. The `my.cnf` file needed for the data nodes is fairly simple. The configuration file should be located in the `/etc` directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

```
shell> vi /etc/my.cnf
```

Note

We show `vi` being used here to create the file, but any text editor should work just as well.

For each data node and SQL node in our example setup, `my.cnf` should look like this:

```
[mysqld]
```

```
# Options for mysqld process:
ndbcluster                      # run NDB storage engine
ndb-connectstring=192.168.0.10  # location of management server

[mysql_cluster]
# Options for ndbd process:
ndb-connectstring=192.168.0.10  # location of management server
```

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node “A”, data node “B”, and the SQL node.

Important

Once you have started a `mysqld` process with the `NDBCLUSTER` and `ndb-connectstring` parameters in the `[mysqld]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. *This is by design*.

Configuring the management node. The first step in configuring the management node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as `root`):

```
shell> mkdir /var/lib/mysql-cluster
shell> cd /var/lib/mysql-cluster
shell> vi config.ini
```

For our representative setup, the `config.ini` file should read as follows:

```
[ndbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2    # Number of replicas
DataMemory=80M    # How much memory to allocate for data storage
IndexMemory=18M   # How much memory to allocate for index storage
                  # For DataMemory and IndexMemory, we have used the
                  # default values. Since the "world" database takes up
                  # only about 500KB, this should be more than enough for
                  # this example Cluster setup.

[tcp default]
# TCP/IP options:
portnumber=2202   # This the default; however, you can use any
                  # port that is free for all the hosts in the cluster
                  # Note: It is recommended that you do not specify the port
                  # number at all and simply allow the default value to be used
                  # instead

[ndb_mgmd]
# Management process options:
hostname=192.168.0.10           # Hostname or IP address of MGM node
datadir=/var/lib/mysql-cluster  # Directory for MGM node log files

[ndbd]
# Options for data node "A":
                                # (one [ndbd] section per data node)
hostname=192.168.0.30           # Hostname or IP address
datadir=/usr/local/mysql/data   # Directory for this data node's data files

[ndbd]
# Options for data node "B":
hostname=192.168.0.40           # Hostname or IP address
datadir=/usr/local/mysql/data   # Directory for this data node's data files

[mysqld]
# SQL node options:
hostname=192.168.0.20           # Hostname or IP address
                                # (additional mysqld connections can be
                                # specified for this node for various
                                # purposes such as running ndb_restore)
```

Note

The `world` database can be downloaded from http://dev.mysql.com/doc/, where it can be found listed under “Examples”.

After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in Initial Startup of MySQL Cluster.

For more detailed information about the available MySQL Cluster configuration parameters and their uses, see MySQL Cluster Configuration Files, and MySQL Cluster Configuration. For configuration of MySQL Cluster as relates to making backups, see Configuration for MySQL Cluster Backups.

Note

The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. However, the cluster can automatically allocate ports for data nodes from those that are already free.

Initial Startup of MySQL Cluster

Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the management node process:

   ```
   shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
   ```

   `ndb_mgmd` must be told where to find its configuration file, using the `-f` or `--config-file` [1964] option. (See `ndb_mgmd` — The MySQL Cluster Management Server Daemon, for details.)

   For additional options which can be used with `ndb_mgmd`, see Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs.

2. On each of the data node hosts, run this command to start the `ndbd` process:

   ```
   shell> ndbd
   ```

3. If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the supplied startup script to start the MySQL server process on the SQL node.

If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the `ndb_mgm` management node client. The output should look like that shown here, although you might see some slight differences in the output depending upon the exact version of MySQL that you are using:

```
shell> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=2    @192.168.0.30  (Version: 5.1.63-ndb-7.1.25, Nodegroup: 0, Master)
id=3    @192.168.0.40  (Version: 5.1.63-ndb-7.1.25, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1    @192.168.0.10  (Version: 5.1.63-ndb-7.1.25)

[mysqld(API)]   1 node(s)
id=4    @192.168.0.20  (Version: 5.1.63-ndb-7.1.25)
```

The SQL node is referenced here as `[mysqld(API)]`, which reflects the fact that the `mysqld` process is acting as a MySQL Cluster API node.

Note

The IP address shown for a given MySQL Cluster SQL or other API node in the output of `SHOW` is the address used by the SQL or API node to connect to the cluster data nodes, and not to any management node.

You should now be ready to work with databases, tables, and data in MySQL Cluster. See MySQL Cluster Example with Tables and Data, for a brief discussion.

MySQL Cluster Example with Tables and Data

Note

The information in this section applies to MySQL Cluster running on both Unix and Windows platforms.

Working with database tables and data in MySQL Cluster is not much different from doing so in standard MySQL. There are two key points to keep in mind:

- For a table to be replicated in the cluster, it must use the `NDBCLUSTER` storage engine. To specify this, use the `ENGINE=NDBCLUSTER` or `ENGINE=NDB` option when creating the table:

  ```
  CREATE TABLE tbl_name (col_name column_definitions) ENGINE=NDBCLUSTER;
  ```

  Alternatively, for an existing table that uses a different storage engine, use `ALTER TABLE` to change the table to use `NDBCLUSTER`:

  ```
  ALTER TABLE tbl_name ENGINE=NDBCLUSTER;
  ```

- Every `NDBCLUSTER` table has a primary key. If no primary key is defined by the user when a table is created, the `NDBCLUSTER` storage engine automatically generates a hidden one. Such a key takes up space just as does any other table index. (It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)

If you are importing tables from an existing database using the output of `mysqldump`, you can open the SQL script in a text editor and add the `ENGINE` option to any table creation statements, or replace any existing `ENGINE` options. Suppose that you have the `world` sample database on another MySQL server that does not support MySQL Cluster, and you want to export the `City` table:

```
shell> mysqldump --add-drop-table world City > city_table.sql
```

The resulting `city_table.sql` file will contain this table creation statement (and the `INSERT` statements necessary to import the table data):

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY  (`ID`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);(remaining INSERT statements omitted)
```

You need to make sure that MySQL uses the `NDBCLUSTER` storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition *before* importing

it into the Cluster database. Using the `City` table as an example, modify the `ENGINE` option of the definition as follows:

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY  (`ID`)
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of `TYPE=engine_name` or `ENGINE=engine_name` with `ENGINE=NDBCLUSTER`. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use `ALTER TABLE` to change their storage engine. The particulars are given later in this section.

Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
shell> mysql world < city_table.sql
```

It is very important to keep in mind that the preceding command must be executed on the host where the SQL node is running (in this case, on the machine with the IP address `192.168.0.20`).

To create a copy of the entire `world` database on the SQL node, use `mysqldump` on the noncluster server to export the database to a file named `world.sql`; for example, in the `/tmp` directory. Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

```
shell> mysql world < /tmp/world.sql
```

If you save the file to a different location, adjust the preceding instructions accordingly.

Running `SELECT` queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the `root` password at the `Enter password:` prompt):

```
shell> mysql -u root -p
Enter password:
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.1.63-ndb-7.1.25

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

We simply use the MySQL server's `root` account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong `root` password. For more information, see Securing the Initial MySQL Accounts.

It is worth taking into account that Cluster nodes do *not* make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the `root` account) effects only applications that access the SQL node, not interaction between nodes. See MySQL Cluster and MySQL Privileges, for more information.

If you did not modify the `ENGINE` clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:

```
mysql> USE world;
mysql> ALTER TABLE City ENGINE=NDBCLUSTER;
mysql> ALTER TABLE Country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE CountryLanguage ENGINE=NDBCLUSTER;
```

Selecting a database and running a `SELECT` query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
+-----------+------------+
| Name      | Population |
+-----------+------------+
| Bombay    |   10500000 |
| Seoul     |    9981619 |
| São Paulo |    9968485 |
| Shanghai  |    9696300 |
| Jakarta   |    9604900 |
+-----------+------------+
5 rows in set (0.34 sec)

mysql> \q
Bye

shell>
```

Applications that use MySQL can employ standard APIs to access `NDB` tables. It is important to remember that your application must access the SQL node, and not the management or data nodes. This brief example shows how we might execute the `SELECT` statement just shown by using the PHP 5.X `mysqli` extension running on a Web server elsewhere on the network:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
  "http://www.w3.org/TR/html4/loose.dtd">
<html>
<head>
  <meta http-equiv="Content-Type"
          content="text/html; charset=iso-8859-1">
  <title>SIMPLE mysqli SELECT</title>
</head>
<body>
<?php
  # connect to SQL node:
  $link = new mysqli('192.168.0.20', 'root', 'root_password', 'world');
  # parameters for mysqli constructor are:
  #   host, user, password, database

  if( mysqli_connect_errno() )
    die("Connect failed: " . mysqli_connect_error());

  $query = "SELECT Name, Population
            FROM City
            ORDER BY Population DESC
            LIMIT 5";

  # if no errors...
  if( $result = $link->query($query) )
  {
?>
<table border="1" width="40%" cellpadding="4" cellspacing ="1">
  <tbody>
  <tr>
    <th width="10%">City</th>
    <th>Population</th>
  </tr>
<?
    # then display the results...
    while($row = $result->fetch_object())
      printf("<tr>\n  <td align=\"center\">%s</td><td>%d</td>\n</tr>\n",
             $row->Name, $row->Population);
?>
  </tbody
```

```
</table>
<?
  # ...and verify the number of rows that were retrieved
    printf("<p>Affected rows: %d</p>\n", $link->affected_rows);
  }
  else
    # otherwise, tell us what went wrong
    echo mysqli_error();

  # free the result set and the mysqli connection object
  $result->close();
  $link->close();
?>
</body>
</html>
```

We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.

Safe Shutdown and Restart of MySQL Cluster

To shut down the cluster, enter the following command in a shell on the machine hosting the management node:

```
shell> ndb_mgm -e shutdown
```

The `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. (See Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs, for more information about this option.) The command causes the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` or `ndbmtd` processes to terminate gracefully. Any SQL nodes can be terminated using `mysqladmin shutdown` and other means. On Windows platforms, assuming that you have installed the SQL node as a Windows service, you can use `NET STOP MYSQL`.

To restart the cluster on Unix platforms, run these commands:

- On the management host (`192.168.0.10` in our example setup):

  ```
  shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
  ```

- On each of the data node hosts (`192.168.0.30` and `192.168.0.40`):

  ```
  shell> ndbd
  ```

- Use the `ndb_mgm` client to verify that both data nodes have started successfully.

- On the SQL host (`192.168.0.20`):

  ```
  shell> mysqld_safe &
  ```

On Windows platforms, assuming that you have installed all MySQL Cluster processes as Windows services using the default service names (see Installing MySQL Cluster Processes as Windows Services), you can restart the cluster as follows:

- On the management host (`192.168.0.10` in our example setup), execute the following command:

  ```
  C:\> NET START ndb_mgmd
  ```

- On each of the data node hosts (`192.168.0.30` and `192.168.0.40`), execute the following command:

  ```
  C:\> NET START ndbd
  ```

- On the management node host, use the `ndb_mgm` client to verify that the management node and both data nodes have started successfully (see Initial Startup of MySQL Cluster on Windows).

- On the SQL node host (`192.168.0.20`), execute the following command:

```
C:\> NET START mysql
```

In a production setting, it is usually not desirable to shut down the cluster completely. In many cases, even when making configuration changes, or performing upgrades to the cluster hardware or software (or both), which require shutting down individual host machines, it is possible to do so without shutting down the cluster as a whole by performing a *rolling restart* of the cluster. For more information about doing this, see Performing a Rolling Restart of a MySQL Cluster.

Upgrading and Downgrading MySQL Cluster

This section provides information about MySQL Cluster software and table file compatibility between MySQL 5.1.23 and earlier, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x releases with regard to performing upgrades and downgrades as well as compatibility matrices and notes. You are expected already to be familiar with installing and configuring a MySQL Cluster prior to attempting an upgrade or downgrade. See MySQL Cluster Configuration.

Important

Only compatibility between MySQL versions with regard to `NDBCLUSTER` is taken into account in this section, and there are likely other issues to be considered. *As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the MySQL Cluster software*. See Upgrading MySQL.

For information about upgrades and downgrades to, from, and between different releases of MySQL Cluster NDB 7.0 and MySQL Cluster NDB 7.1, see Upgrade and downgrade compatibility: MySQL Cluster NDB 7.x.

For information about upgrades and downgrades to, from, and between different releases of MySQL Cluster NDB 6.1, MySQL Cluster NDB 6.2, and MySQL Cluster NDB 6.3, see Upgrade and Downgrade Compatibility: MySQL Cluster NDB 6.x.

For information about upgrades and downgrades to, from, and between different releases of MySQL Cluster NDB 7.2, see Upgrading and Downgrading MySQL Cluster NDB 7.2.

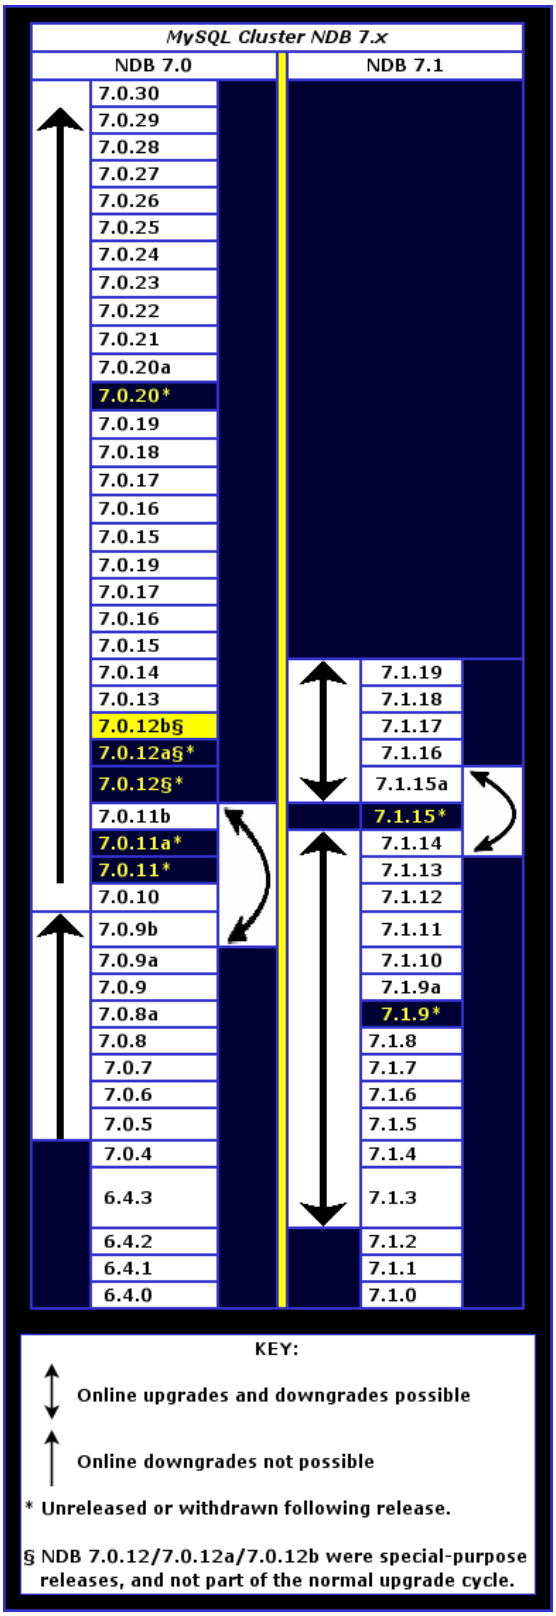
For information about upgrades and downgrades to, from, and between different editions of MySQL Cluster as found in standard MySQL 5.1.23 and earlier releases, see Upgrade and downgrade compatibility: MySQL 5.1.

Important

Only compatibility between MySQL versions with regard to `NDBCLUSTER` is taken into account in this section, and there are likely other issues to be considered. *As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the MySQL Cluster software*. See Upgrading MySQL.

Upgrade and downgrade compatibility: MySQL Cluster NDB 7.x

The table shown here provides information on MySQL Cluster upgrade and downgrade compatibility among different releases of MySQL Cluster NDB 7.0 and 7.1. Additional notes about upgrades and downgrades to, from, or within the MySQL Cluster NDB 7.x release series can be found immediately following the table.



Notes: MySQL Cluster NDB 7.x

Versions supported. Online upgrades from any MySQL Cluster NDB 7.0 release up to and including MySQL Cluster NDB 7.0.4 (as well as all early releases numbered NDB 6.4.x) to MySQL Cluster NDB 7.0.5 or later are not possible. Upgrades to MySQL Cluster NDB 7.0.6 or later from MySQL Cluster NDB 6.3.8 or a later MySQL Cluster NDB 6.3 release, or from MySQL Cluster NDB 7.0.5 or later, are supported. (Bug #44294)

Upgrading `ndbd` to `ndbmtd`. When upgrading online from a MySQL Cluster NDB 6.3 release to a MySQL Cluster NDB 7.0 (or later) release, you should not try to upgrade the data nodes from `ndbd` to `ndbmtd` at the same time. Instead, perform the upgrade using the new `ndbd` executable (from the MySQL Cluster NDB 7.0 or later distribution to which you are upgrading) to replace the one in use on the data nodes. Once the version upgrade is complete, you can perform a second (online) upgrade to replace the data node executables with `ndbmtd` from the newer distribution. Changing the data node binary type should not be an issue when upgrading from MySQL Cluster NDB 7.0 or later version.

Changes in default values. In MySQL Cluster NDB 7.0.4, the default values for a number of MySQL Cluster configuration parameters relating to memory usage and buffering changed (see Changes in MySQL Cluster NDB 7.0.4 (5.1.32-ndb-7.0.4) (2008-03-18), for a list of the parameters whose defaults changed). For this reason, you may encounter issues if you try to use a configuration that does not explicitly define each of these buffers (because it was developed for a previous version of MySQL Cluster), `SendBufferMemory` [1870] and `ReceiveBufferMemory` [1871] in particular.

Other known issues include the following:

- Prior to MySQL Cluster NDB 7.0.7, DML statements failed if executed while performing an online upgrade from a MySQL Cluster NDB 6.3 release. (Bug #45917)

- Following an upgrade from any MySQL Cluster NDB 6.3.x release to MySQL Cluster NDB 7.0.6, DDL and backup operations failed. This issue was resolved in MySQL Cluster NDB 7.0.7. (Bug #46494, Bug #46563)

- In some cases, there could be problems with online upgrades from MySQL Cluster NDB 6.3 releases to MySQL Cluster NDB 7.0 releases due to a previous change in the signalling format used between nodes. This issue was corrected in MySQL Cluster NDB 7.0.9.

- Once an `NDB` table had an `ALTER ONLINE TABLE` operation performed on it using a MySQL Cluster NDB 6.3.x release, it could not be upgraded online to MySQL Cluster NDB 7.0. This issue was resolved in MySQL Cluster NDB 7.0.8. (See Bug #47542.)

- Following an upgrade from MySQL Cluster NDB 6.3 to MySQL Cluster NDB 7.0, if there were any tables having unique indexes prior to the upgrade, attempts to create unique indexes failed. This could also occur when performing offline `ALTER TABLE` operations on tables having indexes that were not dropped as a result of the `ALTER TABLE`. This issue was due to a change in the way that `NDB` tracked unique indexes internally, and was resolved in MySQL Cluster NDB 7.0.9. (Bug #48416)

  For upgrades to MySQL Cluster NDB 7.0 releases prior to version 7.0.9, a workaround is available: Following the upgrade, execute a *second* rolling restart of the cluster before before performing any `ALTER TABLE` operations involving indexes.

- Due to an issue discovered after the release of MySQL Cluster NDB 7.0.10 (Bug #50433), it is not possible to perform an online upgrade from MySQL Cluster NDB 7.0.9b and earlier MySQL Cluster NDB 7.0 releases to MySQL Cluster NDB 7.0.10. Instead, you should upgrade your MySQL Cluster NDB 7.0 installation directly to MySQL Cluster NDB 7.0.11 or later.

  This issue did not appear to affect MySQL Cluster NDB 6.3, and it should be possible to upgrade online from MySQL Cluster NDB 6.3 to MySQL Cluster NDB 7.0.10 without any problems other than those noted previously.

- It was not possible to perform an online upgrade from a MySQL Cluster NDB 6.3 or 7.0 release to MySQL Cluster NDB 7.1.0 or 7.1.1. This issue was fixed in MySQL Cluster NDB 7.1.2 (see Bug #51429).

- Following an upgrade to MySQL Cluster NDB 7.0.15 or later (MySQL Cluster NDB 7.0), or to MySQL Cluster NDB 7.1.4 or later (MySQL Cluster NDB 7.1), a table created in a previous version of MySQL Cluster does *not* automatically support `NDB`-native default values. Such a table continues to use default values supplied by the MySQL server until it is upgraded by performing an offline `ALTER TABLE` on it.

When upgrading to a MySQL Cluster release that supports native default values from a MySQL Cluster release that does not, you should not attempt to create any new tables until all data nodes are using the new `ndbd` or `ndbmtd` binaries. This is because the older binaries do not provide support for native default values.

Important

Tables created with native default value support cannot be used with versions of MySQL Cluster that do not support native default values.

- NDB API changes in MySQL Cluster NDB 7.1.16 and MySQL Cluster NDB 7.0.27 are not backward compatible. Due to these changes the version of the included NDB client library was increased from 4.0.0 to 5.0.0; NDB API applications must be recompiled as part of any upgrade to these or later MySQL Cluster releases.

  In addition, NDB API programs should be updated as part of such an upgrade, in order to take into account changes in the default behavior and values for the `Ndb_cluster_connection::connect()` method.

- Due to issues discovered shortly after release, MySQL Cluster NDB 7.0.20 was withdrawn and replaced with MySQL Cluster NDB 7.0.20a. Users of MySQL Cluster NDB 7.0.19 and previous MySQL Cluster NDB 7.0 releases should upgrade to MySQL Cluster NDB 7.0.20a, or to a later MySQL Cluster NDB 7.0 release. See Changes in MySQL Cluster NDB 7.0.20a (5.1.51-ndb-7.0.20a) (2010-11-18), for more information.

  Due to issues discovered following release, MySQL Cluster NDB 7.1.15 was withdrawn and replaced with MySQL Cluster NDB 7.1.15a. Users of MySQL Cluster NDB 7.1.14 and previous MySQL Cluster NDB 7.1 releases should upgrade to MySQL Cluster NDB 7.1.15a, or to a later MySQL Cluster NDB 7.1 release. See Changes in MySQL Cluster NDB 7.1.15a (5.1.56-ndb-7.1.15a) (2011-08-25), for more information.

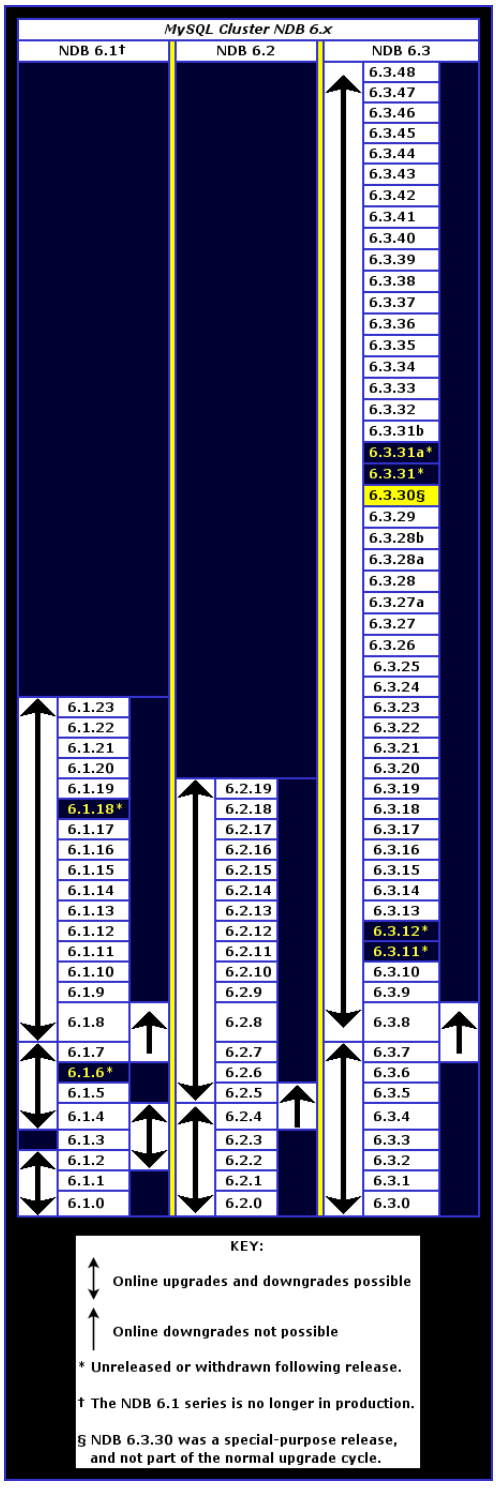
  Due to issues discovered shortly after release, MySQL Cluster NDB 7.1.9 was withdrawn and replaced with MySQL Cluster NDB 7.1.9a. Users of MySQL Cluster NDB 7.1.8 and previous MySQL Cluster NDB 7.1 releases should upgrade to MySQL Cluster NDB 7.1.14 (the last release directly upgrade-compatible with MySQL Cluster 7.1.18 and earlier) before upgrading to MySQL Cluster 7.1.15a or later. See Changes in MySQL Cluster NDB 7.1.9a (5.1.51-ndb-7.1.9a) (2010-11-18), for more information.

- When performing an online upgrade or downgrade between MySQL Cluster NDB 7.1.8 or earlier and a later release up to and including MySQL Cluster NDB 7.1.14, you must upgrade or downgrade the data nodes before upgrading or downgrading any SQL nodes; otherwise `mysql_upgrade` fails on the SQL nodes due to differences between `ndbinfo` tables used in the “old” and “new” versions of the MySQL Cluster software. You should also upgrade or downgrade the data nodes prior to the SQL nodes when performing an online upgrade or downgrade between MySQL Cluster NDB 7.1 releases where either of the versions involved is MySQL Cluster NDB 7.1.14 or earlier, and where one or more `ndbinfo` tables has more, fewer, or differing columns between the two versions.

  This issue is resolved in MySQL Cluster NDB 7.1.15. (Bug #11885602)

Upgrade and Downgrade Compatibility: MySQL Cluster NDB 6.x

The table shown here provides information on MySQL Cluster upgrade and downgrade compatibility among different releases of MySQL Cluster NDB 6.1, 6.2, and 6.3. Additional notes about upgrades and downgrades to, from, or within the MySQL Cluster NDB 6.x release series can be found immediately following the table.



Notes: MySQL Cluster NDB 6.1

Availability of older releases. MySQL Cluster NDB 6.1 is no longer in production; information about this series of releases is of historical interest only. MySQL Cluster NDB 6.2 is still available, but is no longer supported in new deployments. If you are still using a MySQL Cluster NDB 6.1 or MySQL Cluster NDB 6.2 release, you should upgrade to the most recent MySQL Cluster NDB 7.0 or MySQL Cluster NDB 7.1 release as soon as possible.

- It is not possible to upgrade from MySQL Cluster NDB 6.1.2 (or an older 6.1 release) directly to 6.1.4 or a newer NDB 6.1 release, or to downgrade from 6.1.4 (or a newer 6.1 release) directly to 6.1.2 or

an older NDB 6.1 release; in either case, you must upgrade or downgrade to MySQL Cluster NDB 6.1.3 first.

- It is not possible to perform an online downgrade from MySQL Cluster NDB 6.1.8 (or a newer 6.1 release) to MySQL Cluster NDB 6.1.7 (or an older 6.1 release).
- MySQL Cluster NDB 6.1.6 and 6.1.18 were not released.
- It is not possible to perform an online upgrade or downgrade between MySQL Cluster NDB 6.2 and any previous release series (including mainline MySQL 5.1 and MySQL Cluster NDB 6.1); it is necessary to perform a dump and reload. However, it should be possible to perform online upgrades or downgrades between any MySQL Cluster NDB 6.2 release and any MySQL Cluster NDB 6.3 release up to and including 6.3.7.

Notes: MySQL Cluster NDB 6.2 and MySQL Cluster NDB 6.3

Internal column specification changes. The internal specifications for columns in `NDB` tables changed in MySQL Cluster NDB 6.1.17 and 6.2.1 to enable compatibility with later MySQL Cluster releases implementing online adding and dropping of columns (MySQL 5.1.17 through MySQL 5.1.23; MySQL Cluster NDB 6.2.3 and later; MySQL Cluster NDB 6.3.2 and later). This change is not backward-compatible with earlier MySQL Server or MySQL Cluster releases.

To make tables created in earlier versions compatible with online adding and dropping of columns in later versions, it is necessary to force MySQL Cluster to convert the tables to the new format by following this procedure following an upgrade:

1. Upgrade the MySQL Cluster software on all data, management, and SQL nodes
2. Back up all `NDB` tables
3. Shut down the cluster (all data, management, and SQL nodes)
4. Restart the cluster, starting all data nodes with the `--initial` [1954] option (to clear and rebuild the data node file systems)
5. Restore the tables from backup

To minimize possible later difficulties, it is strongly advised that the procedure outlined above be followed as soon as possible after to upgrading between the versions indicated. The procedure is *not* necessary for `NDBCLUSTER` tables created in any of the following versions:

- MySQL Cluster NDB 6.1.8 or a later MySQL Cluster NDB 6.1 release
- MySQL Cluster 6.2.1 or a later MySQL Cluster NDB 6.2 release
- Any MySQL Cluster NDB 6.3 release (or later MySQL Cluster release series)

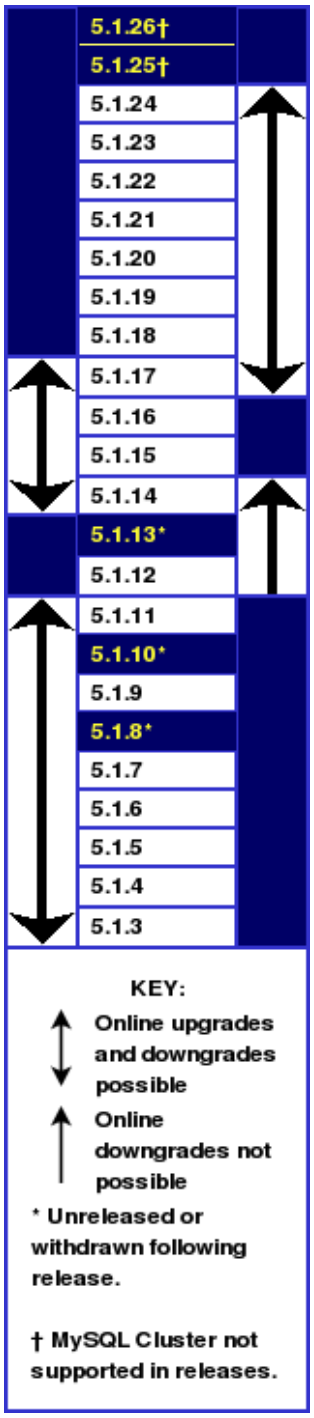
Tables created in the versions listed previously (or later versions, as indicated) are already compatible with adding and dropping of columns online (as implemented beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2).

Additional issues encountered when upgrading or downgrading to or from MySQL Cluster NDB 6.2 and MySQL Cluster NDB 6.3 releases are listed here:

- It was not possible to perform an online upgrade between any MySQL Cluster NDB 6.2 release and MySQL Cluster NDB 6.3.8 and later MySQL Cluster 6.3 releases. This issue was fixed in MySQL Cluster NDB 6.3.21. (Bug #41435)
- Online downgrades between MySQL Cluster NDB 6.2.5 and earlier releases are not supported.
- Online downgrades between MySQL Cluster NDB 6.3.8 and earlier releases are not supported.

Upgrade and downgrade compatibility: MySQL 5.1

The table shown here provides information on MySQL Cluster upgrade and downgrade compatibility among different releases of MySQL 5.1 prior to MySQL 5.1.24. Additional notes about upgrades and downgrades to, from, or within the MySQL 5.1 release series can be found immediately following the table.



Notes: MySQL 5.1

- MySQL 5.1.3 was the first public release in this series.
- Direct upgrades or downgrades between MySQL Cluster 5.0 and 5.1 are not supported; you must dump all `NDBCLUSTER` tables using `mysqldump`, install the new version of the software, and then reload the tables from the dump.

- You cannot downgrade a MySQL Cluster based on MySQL 5.1.6 or later and using Disk Data tables to MySQL 5.1.5 or earlier unless you convert all such tables to in-memory `NDB` tables first.
- MySQL 5.1.8, MySQL 5.1.10, and MySQL 5.1.13 were not released.
- Online cluster upgrades and downgrades between MySQL 5.1.11 (or an earlier version) and 5.1.12 (or a later version) are not possible due to major changes in the cluster file system. In such cases, you must perform a backup or dump, upgrade (or downgrade) the software, start each data node with `--initial` [1954], and then restore from the backup or dump. You can use native `NDB` backup and restore, or `mysqldump` and `LOAD DATA INFILE` for this purpose.
- Online downgrades from MySQL 5.1.14 or later to versions previous to 5.1.14 are not supported due to incompatible changes in the cluster system tables.

MySQL Cluster Replication: changes in `ndb_apply_status`. Online upgrades from MySQL 5.1.17 and earlier to 5.1.18 and later MySQL 5.1.x releases are not supported for clusters using replication due to incompatible changes in the `mysql.ndb_apply_status` table. (Online upgrades from MySQL 5.1 to MySQL Cluster NDB 6.2 and later are not supported, as discussed elsewhere in this section.) However, it should not be necessary to shut down the cluster entirely, if you follow this modified rolling restart procedure:

1. Stop the management server, update the management server software, then start the management server again. For multiple management servers, repeat this step for each management server in turn.
2. For each data node in turn: Stop the data node, update the data node daemon (in MySQL Cluster NDB 7.0 and later, this can be either `ndbd` or `ndbmtd`) with the new version, then restart the data node. It should not be necessary to use `--initial` when restarting any of the data nodes after updating the software.
3. Stop *all* SQL nodes. Upgrade the existing MySQL server installations to the new version on all SQL nodes, then restart them. It is not necessary to start them one at a time after upgrading the MySQL server software, but *there must be a time when none of them is running before starting any of them again using the 5.1.18 (or later)* `mysqld`. Otherwise—due to the fact that `mysql.ndb_apply_status` uses the `NDB` storage engine and is thus shared between all SQL nodes—there may be conflicts between the old and new versions of the table on different SQL nodes.

   You can find more information about the changes to `ndb_apply_status` in MySQL Cluster Replication Schema and Tables.

Note

You should upgrade the MySQL Cluster software on each node using the same method by which it was originally installed. See MySQL Cluster Installation, for more information.

As with any other MySQL Cluster version upgrade, you should also update the MySQL Cluster management client (`ndb_mgm`) and other MySQL Cluster client programs such as `ndb_config` and `ndb_error_reporter`; however, this does not have to be done in any particular order.

Internal column specification changes. The internal specifications for columns in `NDBCLUSTER` tables changed in MySQL 5.1.18 to enable compatibility with later MySQL Cluster releases that permit online adding and dropping of columns. *This change is not backward-compatible with earlier MySQL versions*.

To make tables created in MySQL 5.1.17 and earlier compatible with online adding and dropping of columns (available beginning with beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2—see `ALTER TABLE` Syntax, for more information), it is necessary to force MySQL 5.1.18 and later to convert the tables to the new format by following this procedure:

1. Back up all `NDBCLUSTER` tables.

2. Upgrade the MySQL Cluster software on all data, management, and SQL nodes.
3. Shut down the cluster completely (this includes all data, management, and API or SQL nodes).
4. Restart the cluster, starting all data nodes with the `--initial` [1954] option (to clear and rebuild the data node file systems).
5. Restore the `NDBCLUSTER` tables from backup.

It is not necessary to follow this procedure for `NDBCLUSTER` tables created in MySQL 5.1.18 and later; such tables are already compatible with online adding and dropping of columns (as implemented beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2).

To minimize possible later difficulties, it is strongly advised that the procedure outlined above be followed as soon as possible after to upgrading from MySQL 5.1.17 or earlier to MySQL 5.1.18 or later.

Information about how this change effects users of MySQL Cluster NDB 6.x and 7.x is provided later in this section.

MySQL Cluster not supported in MySQL Server 5.1.24 and later. MySQL Cluster is not supported in standard MySQL 5.1 releases beginning with MySQL 5.1.24. If you are using MySQL Cluster in a standard MySQL 5.1 release, you should upgrade to the most recent MySQL Cluster NDB 7.0 or MySQL Cluster NDB 7.1 release.

MySQL Cluster Configuration

A MySQL server that is part of a MySQL Cluster differs in one chief respect from a normal (nonclustered) MySQL server, in that it employs the `NDBCLUSTER` storage engine. This engine is also referred to simply as `NDB`, and the two forms of the name are synonymous.

To avoid unnecessary allocation of resources, the server is configured by default with the `NDB` storage engine disabled. To enable `NDB`, you must modify the server's `my.cnf` configuration file, or start the server with the `--ndbcluster` [1915] option.

For more information about `--ndbcluster` [1915] and other MySQL server options specific to MySQL Cluster, see MySQL Server Options for MySQL Cluster.

The MySQL server is a part of the cluster, so it also must know how to access an MGM node to obtain the cluster configuration data. The default behavior is to look for the MGM node on `localhost`. However, should you need to specify that its location is elsewhere, this can be done in `my.cnf` or on the MySQL server command line. Before the `NDB` storage engine can be used, at least one MGM node must be operational, as well as any desired data nodes.

`NDB`, the MySQL Cluster storage engine, is available in binary distributions for Linux, Mac OS X, Solaris. and Windows. We are working to support MySQL Cluster on all operating systems supported by the MySQL Server. For information about installing MySQL Cluster, see MySQL Cluster Installation.

Quick Test Setup of MySQL Cluster

To familiarize you with the basics, we will describe the simplest possible configuration for a functional MySQL Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as `/var/lib/mysql-cluster`, by executing the following command as the system `root` user:

```
shell> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named `config.ini` that contains the following information. Substitute appropriate values for `HostName` and `DataDir` as necessary for your system.

```
# file "config.ini" - showing minimal setup consisting of 1 data node,
# 1 management server, and 3 MySQL servers.
```

```
# The empty default sections are not required, and are shown only for
# the sake of completeness.
# Data nodes must provide a hostname but MySQL Servers are not required
# to do so.
# If you don't know the hostname for your machine, use localhost.
# The DataDir parameter also has a default value, but it is recommended to
# set it explicitly.
# Note: [db], [api], and [mgm] are aliases for [ndbd], [mysqld], and [ndb_mgmd],
# respectively. [db] is deprecated and should not be used in new installations.

[ndbd default]
NoOfReplicas= 1

[mysqld  default]
[ndb_mgmd default]
[tcp default]

[ndb_mgmd]
HostName= myhost.example.com

[ndbd]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[mysqld]
[mysqld]
[mysqld]
```

You can now start the `ndb_mgmd` management server. By default, it attempts to read the `config.ini` file in its current working directory, so change location into the directory where the file is located and then invoke `ndb_mgmd`:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single data node by running `ndbd`:

```
shell> ndbd
```

For command-line options which can be used when starting `ndbd`, see Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs.

By default, `ndbd` looks for the management server at `localhost` on port 1186.

Note

If you have installed MySQL from a binary tarball, you will need to specify the path of the `ndb_mgmd` and `ndbd` servers explicitly. (Normally, these will be found in `/usr/local/mysql/bin`.)

Finally, change location to the MySQL data directory (usually `/var/lib/mysql` or `/usr/local/mysql/data`), and make sure that the `my.cnf` file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```
shell> mysqld_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server's `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the `NDBCLUSTER` storage engine is enabled:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
```

```
Your MySQL connection id is 1 to server version: 5.1.67

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW ENGINES\G
...
*************************** 12. row ***************************
Engine: NDBCLUSTER
Support: YES
Comment: Clustered, fault-tolerant, memory-based tables
*************************** 13. row ***************************
Engine: NDB
Support: YES
Comment: Alias for NDBCLUSTER
...
```

The row numbers shown in the preceding example output may be different from those shown on your system, depending upon how your server is configured.

Try to create an `NDBCLUSTER` table:

```
shell> mysql
mysql> USE test;
Database changed

mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)

mysql> SHOW CREATE TABLE ctest \G
*************************** 1. row ***************************
       Table: ctest
Create Table: CREATE TABLE `ctest` (
  `i` int(11) default NULL
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

To check that your nodes were set up properly, start the management client:

```
shell> ndb_mgm
```

Use the `SHOW` command from within the management client to obtain a report on the cluster's status:

```
ndb_mgm> SHOW
Cluster Configuration
---------------------
[ndbd(NDB)]     1 node(s)
id=2    @127.0.0.1  (Version: 3.5.3, Nodegroup: 0, Master)

[ndb_mgmd(MGM)] 1 node(s)
id=1    @127.0.0.1  (Version: 3.5.3)

[mysqld(API)]   3 node(s)
id=3    @127.0.0.1  (Version: 3.5.3)
id=4 (not connected, accepting connect from any host)
id=5 (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working MySQL Cluster. You can now store data in the cluster by using any table created with `ENGINE=NDBCLUSTER` or its alias `ENGINE=NDB`.

MySQL Cluster Configuration Files

Configuring MySQL Cluster requires working with two files:

- `my.cnf`: Specifies options for all MySQL Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.
- `config.ini`: This file, sometimes known as the *global configuration file*, is read only by the MySQL Cluster management server, which then distributes the information contained therein to all processes

participating in the cluster. `config.ini` contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see Sections of the `config.ini` File.

Caching of configuration data. Beginning with MySQL Cluster NDB 6.4.0, MySQL Cluster uses *stateful configuration*. The global configuration file is no longer read every time the management server is restarted. Instead, the management server caches the configuration the first time it is started, and thereafter, the global configuration file is read only when one of the following items is true:

- **The management server is started using the `--initial` option.** In this case, the global configuration file is re-read, any existing cache files are deleted, and the management server creates a new configuration cache.
- **The management server is started using the `--reload` option.** In this case, the management server compares its cache with the global configuration file. If they differ, the management server creates a new configuration cache; any existing configuration cache is preserved, but not used. If the management server's cache and the global configuration file contain the same configuration data, then the existing cache is used, and no new cache is created.
- **The management server is started using a `--config-cache` option.** Beginning with MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, this option can be used to force the management server to bypass configuration caching altogether. In this case, the management server ignores any configuration files that may be present, always reading its configuration data from the `config.ini` file instead.
- **No configuration cache is found.** In this case, the management server reads the global configuration file and creates a cache containing the same configuration data as found in the file.

Configuration cache files. Beginning with MySQL Cluster 6.4.0, the management server by default creates configuration cache files in a directory named `mysql-cluster` in the MySQL installation directory. (If you build MySQL Cluster from source on a Unix system, the default location is `/usr/local/mysql-cluster`.) This can be overridden at run time by starting the management server with the `--configdir` option. Configuration cache files are binary files named according to the pattern `ndb_node_id_config.bin.seq_id`, where *`node_id`* is the management server's node ID in the cluster, and *`seq_id`* is a cache idenitifer. Cache files are numbered sequentially using *`seq_id`*, in the order in which they are created. The management server uses the latest cache file as determined by the *`seq_id`*.

Note

It is possible to roll back to a previous configuration by deleting later configuration cache files, or by renaming an earlier cache file so that it has a higher *`seq_id`*. However, since configuration cache files are written in a binary format, you should not attempt to edit their contents by hand.

For more information about the `--configdir`, `--initial`, and `--reload` options for the MySQL Cluster management server, see `ndb_mgmd` — The MySQL Cluster Management Server Daemon.

We are continuously making improvements in Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we will try to let Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in How to Report Bugs or Problems.

MySQL Cluster Configuration: Basic Example

To support MySQL Cluster, you will need to update `my.cnf` as shown in the following example. You may also specify these parameters on the command line when invoking the executables.

Note

The options shown here should not be confused with those that are used in `config.ini` global configuration files. Global configuration options are discussed later in this section.

```
# my.cnf
# example additions to my.cnf for MySQL Cluster
# (valid in MySQL 5.1)

# enable ndbcluster storage engine, and provide connectstring for
# management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

# provide connectstring for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

# provide connectstring for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

# provide location of cluster configuration file
[ndb_mgmd]
config-file=/etc/config.ini
```

(For more information on connectstrings, see The MySQL Cluster Connectstring.)

```
# my.cnf
# example additions to my.cnf for MySQL Cluster
# (will work on all versions)

# enable ndbcluster storage engine, and provide connectstring for management
# server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

Important

Once you have started a `mysqld` process with the `NDBCLUSTER` and `ndb-connectstring` parameters in the `[mysqld]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. *This is by design*.

You may also use a separate `[mysql_cluster]` section in the cluster `my.cnf` file for settings to be read and used by all executables:

```
# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

For additional `NDB` variables that can be set in the `my.cnf` file, see MySQL Cluster System Variables.

The MySQL Cluster global configuration file is named `config.ini` by default. It is read by `ndb_mgmd` at startup and can be placed anywhere. Its location and name are specified by using `--config-file=path_name` on the `ndb_mgmd` command line. If the configuration file is not specified, `ndb_mgmd` by default tries to read a file named `config.ini` located in the current working directory.

The global configuration file for MySQL Cluster uses INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon (“`:`”) as well as the equal sign (“`=`”); however, the equal sign is preferred. Another

deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in `config.ini`. (Prior to MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6, there was no default value for `NoOfReplicas` [1815], which always had to be specified explicitly in the `[ndbd default]` section. Beginning with versions just stated, the default value is 2, which is the recommended setting in most common usage scenarios.) To create a default value section, simply add the word `default` to the section name. For example, an `[ndbd]` section contains parameters that apply to a particular data node, whereas an `[ndbd default]` section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an `[ndbd default]` section that contains a `DataMemory` [1817] line to specify the data memory size.

The global configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown here:

```
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the
# management server)
# The first MySQL Server can be started from any host. The second
# can be started only on the host mysqld_5.mysql.com

[ndbd default]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[ndb_mgmd]
Hostname= ndb_mgmd.mysql.com
DataDir= /var/lib/mysql-cluster

[ndbd]
HostName= ndbd_2.mysql.com

[ndbd]
HostName= ndbd_3.mysql.com

[mysqld]
[mysqld]
HostName= mysqld_5.mysql.com
```

Note

The preceding example is intended as a minimal starting configuration for purposes of familiarization with MySQL Cluster, and is almost certain not to be sufficient for production settings. See Recommended Starting Configurations for MySQL Cluster NDB 6.2 and Later, which provides more complete example starting configurations for use with MySQL Cluster NDB 6.2 and newer versions of MySQL Cluster.

Each node has its own section in the `config.ini` file. For example, this cluster has two data nodes, so the preceding configuration file contains two `[ndbd]` sections defining these nodes.

Note

Do not place comments on the same line as a section heading in the `config.ini` file; this causes the management server not to start because it cannot parse the configuration file in such cases.

Sections of the `config.ini` File

There are six different sections that you can use in the `config.ini` configuration file, as described in the following list:

- `[computer]`: Defines cluster hosts. This is not required to configure a viable MySQL Cluster, but be may used as a convenience when setting up a large cluster. See Defining Computers in a MySQL Cluster, for more information.
- `[ndbd]`: Defines a cluster data node (`ndbd` process). See Defining MySQL Cluster Data Nodes, for details.
- `[mysqld]`: Defines the cluster's MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see Defining SQL and Other API Nodes in a MySQL Cluster.
- `[mgm]` or `[ndb_mgmd]`: Defines a cluster management server (MGM) node. For information concerning the configuration of MGM nodes, see Defining a MySQL Cluster Management Server.
- `[tcp]`: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default connection protocol. Normally, `[tcp]` or `[tcp default]` sections are not required to set up a MySQL Cluster, as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See MySQL Cluster TCP/IP Connections, for information about available TCP/IP configuration parameters and how to use them. (You may also find MySQL Cluster TCP/IP Connections Using Direct Connections to be of interest in some cases.)
- `[shm]`: Defines shared-memory connections between nodes. In MySQL 5.1, it is enabled by default, but should still be considered experimental. For a discussion of SHM interconnects, see MySQL Cluster Shared-Memory Connections.
- `[sci]`:Defines *Scalable Coherent Interface* connections between cluster data nodes. Such connections require software which, while freely available, is not part of the MySQL Cluster distribution, as well as specialized hardware. See SCI Transport Connections in MySQL Cluster for detailed information about SCI interconnects.

You can define `default` values for each section. All Cluster parameter names are case-insensitive, which differs from parameters specified in `my.cnf` or `my.ini` files.

Recommended Starting Configurations for MySQL Cluster NDB 6.2 and Later

Achieving the best performance from a MySQL Cluster depends on a number of factors including the following:

- MySQL Cluster software version
- Numbers of data nodes and SQL nodes
- Hardware
- Operating system
- Amount of data to be stored
- Size and type of load under which the cluster is to operate

Therefore, obtaining an optimum configuration is likely to be an iterative process, the outcome of which can vary widely with the specifics of each MySQL Cluster deployment. Changes in configuration are also likely to be indicated when changes are made in the platform on which the cluster is run, or in applications that use the MySQL Cluster's data. For these reasons, it is not possible to offer a single configuration that is ideal for all usage scenarios. However, in this section, we provide recommended base configurations for MySQL Cluster NDB 6.2 and 6.3 that can serve as reasonable starting points.

Starting configuration for MySQL Cluster NDB 6.2. The following is a recommended starting point for configuring a cluster running MySQL Cluster NDB 6.2.

```
# TCP PARAMETERS

[tcp default]SendBufferMemory [1870]=2M
ReceiveBufferMemory [1871]=2M
```

```
# Increasing the sizes of these 2 buffers beyond the default values
# helps prevent bottlenecks due to slow disk I/O.

# MANAGEMENT NODE PARAMETERS

[ndb_mgmd default]
DataDir [1812]=path/to/management/server/data/directory

# It is possible to use a different data directory for each management
# server, but for ease of administration it is preferable to be
# consistent.

[ndb_mgmd]
HostName [1810]=management-server-1-hostname
# NodeId [1809]=management-server-1-nodeid

[ndb_mgmd]
HostName [1810]=management-server-2-hostname

# Using 2 management servers helps guarantee that there is always an
# arbitrator in the event of network partitioning, and so is
# recommended for high availability. Each management server must be
# identified by a HostName. You may for the sake of convenience specify
# a node ID for any management server, although one will be allocated
# for it automatically; if you do so, it must be in the range 1-255
# inclusive and must be unique among all IDs specified for cluster
# nodes.

# DATA NODE PARAMETERS

[ndbd default]
NoOfReplicas [1815]=2

# Using 2 replicas is recommended to guarantee availability of data;
# using only 1 replica does not provide any redundancy, which means
# that the failure of a single data node causes the entire cluster to
# shut down. We do not recommend using more than 2 replicas, since 2 is
# sufficient to provide high availability, and we do not currently test
# with greater values for this parameter.

LockPagesInMainMemory [1832]=1

# On Linux and Solaris systems, setting this parameter locks data node
# processes into memory. Doing so prevents them from swapping to disk,
# which can severely degrade cluster performance.

DataMemory [1817]=3072M
IndexMemory [1819]=384M

# The values provided for DataMemory and IndexMemory assume 4 GB RAM
# per data node. However, for best results, you should first calculate
# the memory that would be used based on the data you actually plan to
# store (you may find the ndb_size.pl utility helpful in estimating
# this), then allow an extra 20% over the calculated values. Naturally,
# you should ensure that each data node host has at least as much
# physical memory as the sum of these two values.

# ODirect [1833]=1

# Enabling this parameter causes NDBCLUSTER to try using O_DIRECT
# writes for local checkpoints and redo logs; this can reduce load on
# CPUs. We recommend doing so when using MySQL Cluster NDB 6.2.3 or
# newer on systems running Linux kernel 2.6 or later.

NoOfFragmentLogFiles [1826]=300
DataDir [1816]=path/to/data/node/data/directory
MaxNoOfConcurrentOperations [1821]=100000
TimeBetweenGlobalCheckpoints [1839]=1000
TimeBetweenEpochs [1840]=200
DiskCheckpointSpeed [1842]=10M
DiskCheckpointSpeedInRestart [1842]=100M
RedoBuffer [1846]=32M
```

```
# MaxNoOfLocalScans [1824]=64
MaxNoOfTables [1829]=1024
MaxNoOfOrderedIndexes [1829]=256

[ndbd]
HostName [1814]=data-node-A-hostname
# NodeId [1814]=data-node-A-nodeid

[ndbd]
HostName [1814]=data-node-B-hostname
# NodeId [1814]=data-node-B-nodeid

# You must have an [ndbd] section for every data node in the cluster;
# each of these sections must include a HostName. Each section may
# optionally include an Id for convenience, but in most cases, it is
# sufficient to allow the cluster to allocate node IDs dynamically. If
# you do specify the node ID for a data node, it must be in the range 1
# to 48 inclusive and must be unique among all IDs specified for
# cluster nodes.

# SQL NODE / API NODE PARAMETERS

[mysqld]
# HostName [1865]=SQL-node-1-hostname
# NodeId [1864]=sql-node-A-nodeid

[mysqld]

[mysqld]

# Each API or SQL node that connects to the cluster requires a [mysqld]
# or [api] section of its own. Each such section defines a connection
# “slot”; you should have at least as many of these sections in the
# config.ini file as the total number of API nodes and SQL nodes that
# you wish to have connected to the cluster at any given time. There is
# no performance or other penalty for having extra slots available in
# case you find later that you want or need more API or SQL nodes to
# connect to the cluster at the same time.
# If no HostName is specified for a given [mysqld] or [api] section,
# then any API or SQL node may use that slot to connect to the
# cluster. You may wish to use an explicit HostName for one connection slot
# to guarantee that an API or SQL node from that host can always
# connect to the cluster. If you wish to prevent API or SQL nodes from
# connecting from other than a desired host or hosts, then use a
# HostName for every [mysqld] or [api] section in the config.ini file.
# You can if you wish define a node ID (Id parameter) for any API or
# SQL node, but this is not necessary; if you do so, it must be in the
# range 1 to 255 inclusive and must be unique among all IDs specified
# for cluster nodes.
```

Starting configuration for MySQL Cluster NDB 6.3. The following is a recommended starting point for configuring a cluster running MySQL Cluster NDB 6.3. It is similar to the recommendation for MySQL Cluster NDB 6.2, with the addition of parameters for better control of `NDBCLUSTER` process threads.

```
# TCP PARAMETERS

[tcp default]SendBufferMemory [1870]=2M
ReceiveBufferMemory [1871]=2M

# Increasing the sizes of these 2 buffers beyond the default values
# helps prevent bottlenecks due to slow disk I/O.

# MANAGEMENT NODE PARAMETERS

[ndb_mgmd default]
DataDir [1812]=path/to/management/server/data/directory

# It is possible to use a different data directory for each management
# server, but for ease of administration it is preferable to be
# consistent.
```

```
[ndb_mgmd]
HostName [1810]=management-server-A-hostname
# NodeId [1809]=management-server-A-nodeid

[ndb_mgmd]
HostName [1810]=management-server-B-hostname
# NodeId [1809]=management-server-B-nodeid

# Using 2 management servers helps guarantee that there is always an
# arbitrator in the event of network partitioning, and so is
# recommended for high availability. Each management server must be
# identified by a HostName. You may for the sake of convenience specify
# a NodeId for any management server, although one will be allocated
# for it automatically; if you do so, it must be in the range 1-255
# inclusive and must be unique among all IDs specified for cluster
# nodes.

# DATA NODE PARAMETERS

[ndbd default]
NoOfReplicas [1815]=2

# Using 2 replicas is recommended to guarantee availability of data;
# using only 1 replica does not provide any redundancy, which means
# that the failure of a single data node causes the entire cluster to
# shut down. We do not recommend using more than 2 replicas, since 2 is
# sufficient to provide high availability, and we do not currently test
# with greater values for this parameter.

LockPagesInMainMemory [1832]=1

# On Linux and Solaris systems, setting this parameter locks data node
# processes into memory. Doing so prevents them from swapping to disk,
# which can severely degrade cluster performance.

DataMemory [1817]=3072M
IndexMemory [1819]=384M

# The values provided for DataMemory and IndexMemory assume 4 GB RAM
# per data node. However, for best results, you should first calculate
# the memory that would be used based on the data you actually plan to
# store (you may find the ndb_size.pl utility helpful in estimating
# this), then allow an extra 20% over the calculated values. Naturally,
# you should ensure that each data node host has at least as much
# physical memory as the sum of these two values.

# ODirect [1833]=1

# Enabling this parameter causes NDBCLUSTER to try using O_DIRECT
# writes for local checkpoints and redo logs; this can reduce load on
# CPUs. We recommend doing so when using MySQL Cluster NDB 6.2.3 or
# newer on systems running Linux kernel 2.6 or later.

# NodeId [1814]=data-node-B-nodeid

LockExecuteThreadToCPU [1852]=1
LockMaintThreadsToCPU [1853]=0

# You must have an [ndbd] section for every data node in the cluster;
# each of these sections must include a HostName. Each section may
# optionally include a NodeId for convenience, but in most cases, it is
# sufficient to allow the cluster to allocate node IDs dynamically. If
# you do specify the node ID for a data node, it must be in the range 1
# to 48 inclusive and must be unique among all IDs specified for
# cluster nodes.

# SQL NODE / API NODE PARAMETERS

[mysqld]
# HostName [1865]=sql-node-A-hostname
# NodeId [1864]=sql-node-A-nodeid

[mysqld]

[mysqld]

# Each API or SQL node that connects to the cluster requires a [mysqld]
# or [api] section of its own. Each such section defines a connection
# “slot”; you should have at least as many of these sections in the
# config.ini file as the total number of API nodes and SQL nodes that
# you wish to have connected to the cluster at any given time. There is
# no performance or other penalty for having extra slots available in
# case you find later that you want or need more API or SQL nodes to
# connect to the cluster at the same time.
# If no HostName is specified for a given [mysqld] or [api] section,
# then any API or SQL node may use that slot to connect to the
# cluster. You may wish to use an explicit HostName for one connection slot
# to guarantee that an API or SQL node from that host can always
# connect to the cluster. If you wish to prevent API or SQL nodes from
# connecting from other than a desired host or hosts, then use a
# HostName for every [mysqld] or [api] section in the config.ini file.
# You can if you wish define a node ID (NodeId parameter) for any API or
# SQL node, but this is not necessary; if you do so, it must be in the
# range 1 to 255 inclusive and must be unique among all IDs specified
# for cluster nodes.
```

Recommended `my.cnf` options for SQL nodes. MySQL Servers acting as MySQL Cluster SQL nodes must always be started with the `--ndbcluster` [1915] and `--ndb-connectstring` options, either on the command line or in `my.cnf`. In addition, set the following options for all `mysqld` processes in the cluster, unless your setup requires otherwise:

- `--ndb-use-exact-count=0`
- `--ndb-index-stat-enable=0`

- `--ndb-force-send=1`
- `--engine-condition-pushdown=1`

The MySQL Cluster Connectstring

With the exception of the MySQL Cluster management server (`ndb_mgmd`), each node that is part of a MySQL Cluster requires a *connectstring* that points to the management server's location. This connectstring is used in establishing a connection to the management server as well as in performing other tasks depending on the node's role in the cluster. The syntax for a connectstring is as follows:

```
[nodeid=node_id, ]host-definition[, host-definition[, ...]]

host-definition:
    host_name[:port_number]
```

`node_id` is an integer larger than 1 which identifies a node in `config.ini`. *`host_name`* is a string representing a valid Internet host name or IP address. *`port_number`* is an integer referring to a TCP/IP port number.

```
example 1 (long):    "nodeid=2,myhost1:1100,myhost2:1100,192.168.0.3:1200"
example 2 (short):   "myhost1"
```

`localhost:1186` is used as the default connectstring value if none is provided. If *`port_num`* is omitted from the connectstring, the default port is 1186. This port should always be available on the network because it has been assigned by IANA for this purpose (see http://www.iana.org/assignments/port-numbers for details).

By listing multiple host definitions, it is possible to designate several redundant management servers. A MySQL Cluster data or API node attempts to contact successive management servers on each host in the order specified, until a successful connection has been established.

Beginning with MySQL Cluster NDB 6.3.19, it is also possible in a connectstring to specify one or more bind addresses to be used by nodes having multiple network interfaces for connecting to management servers. A bind address consists of a hostname or network address and an optional port number. This enhanced syntax for connectstrings is shown here:

```
[nodeid=node_id, ]
    [bind-address=host-definition, ]
    host-definition[; bind-address=host-definition]
    host-definition[; bind-address=host-definition]
    [, ...]]

host-definition:
    host_name[:port_number]
```

If a single bind address is used in the connectstring *prior* to specifying any management hosts, then this address is used as the default for connecting to any of them (unless overridden for a given management server; see later in this section for an example). For example, the following connectstring causes the node to use `192.168.178.242` regardless of the management server to which it connects:

```
bind-address=192.168.178.242, poseidon:1186, perch:1186
```

If a bind address is specified *following* a management host definition, then it is used only for connecting to that management node. Consider the following connectstring:

```
poseidon:1186;bind-address=localhost, perch:1186;bind-address=192.168.178.242
```

In this case, the node uses `localhost` to connect to the management server running on the host named `poseidon` and `192.168.178.242` to connect to the management server running on the host named `perch`.

You can specify a default bind address and then override this default for one or more specific management hosts. In the following example, `localhost` is used for connecting to the management server running on host `poseidon`; since `192.168.178.242` is specified first (before any management server definitions), it is the default bind address and so is used for connecting to the management servers on hosts `perch` and `orca`:

```
bind-address=192.168.178.242,poseidon:1186;bind-address=localhost,perch:1186,orca:2200
```

There are a number of different ways to specify the connectstring:

- Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)
- It is also possible to set the connectstring for all nodes in the cluster at once by placing it in a `[mysql_cluster]` section in the management server's `my.cnf` file.
- For backward compatibility, two other options are available, using the same syntax:

  1. Set the `NDB_CONNECTSTRING` environment variable to contain the connectstring.
  2. Write the connectstring for each executable into a text file named `Ndb.cfg` and place this file in the executable's startup directory.

  However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connectstring is to set it on the command line or in the `my.cnf` file for each executable.

Previous to MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, the maximum length of a connectstring was 1024 characters.

Defining Computers in a MySQL Cluster

The `[computer]` section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- `Id`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	string	[none]	...
Restart Type: IN			

This is a unique identifier, used to refer to the host computer elsewhere in the configuration file.

Important

The computer ID is *not* the same as the node ID used for a management, API, or data node. Unlike the case with node IDs, you cannot use `NodeId` in place of `Id` in the `[computer]` section of the `config.ini` file.

- `HostName`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	name or IP address	[none]	...
Restart Type: S			

This is the computer's hostname or IP address.

Defining a MySQL Cluster Management Server

The `[ndb_mgmd]` section is used to configure the behavior of the management server. `[mgm]` can be used as an alias; the two section names are equivalent. All parameters in the following list are optional and assume their default values if omitted.

Note

If neither the `ExecuteOnComputer` nor the `HostName` parameter is present, the default value `localhost` will be assumed for both.

- `Id`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	unsigned	[none]	1 - 63
NDB 6.1.1	unsigned	[none]	1 - 255
Restart Type: N			

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 63 inclusive (previous to MySQL Cluster NDB 6.1.1), or in the range 1 to 255 inclusive (MySQL Cluster NDB 6.1.1 and later). This ID is used by all internal cluster messages for addressing the node, and so must be unique for each MySQL Cluster node, regardless of the type of node.

Note

Data node IDs must be less than 49, regardless of the MySQL Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

The use of the `Id` parameter for identifying management nodes is deprecated in favor of `NodeId` [1809] beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.39, MySQL Cluster NDB 7.0.20, and MySQL Cluster NDB 7.1.9. Although `Id` continues to be supported for backward compatibility, it now generates a warning.

- `NodeId`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	unsigned	[none]	1 - 63
NDB 6.1.1	unsigned	[none]	1 - 255
Restart Type: N			

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 63 inclusive (previous to MySQL Cluster NDB 6.1.1), or in the range 1 to 255 inclusive (MySQL Cluster NDB 6.1.1 and later). This ID is used by all internal cluster messages for addressing the node, and so must be unique for each MySQL Cluster node, regardless of the type of node.

Note

Data node IDs must be less than 49, regardless of the MySQL Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

`NodeId` is the preferred parameter name to use when identifying management nodes beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.39, MySQL Cluster NDB 7.0.20, and MySQL Cluster NDB 7.1.9. Although `Id` [1809] continues to be supported for backward compatibility, it is now deprecated and generates a warning when used.

- `ExecuteOnComputer`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	name	[none]	...
Restart Type: S			

This refers to the `Id` set for one of the computers defined in a `[computer]` section of the `config.ini` file.

- `PortNumber`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	unsigned	1186	0 - 64K
Restart Type: N			

This is the port number on which the management server listens for configuration requests and management commands.

- `HostName`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	name or IP address	[none]	...
Restart Type: S			

Specifying this parameter defines the hostname of the computer on which the management node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- `LogDestination` [1810]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	{CONSOLE|SYSLOG|FILE}	[see text]	...
Restart Type: N			

This parameter specifies where to send cluster logging information. There are three options in this regard—`CONSOLE`, `SYSLOG`, and `FILE`—with `FILE` being the default:

- `CONSOLE` outputs the log to `stdout`:

```
CONSOLE
```

- `SYSLOG` sends the log to a `syslog` facility, possible values being one of `auth`, `authpriv`, `cron`, `daemon`, `ftp`, `kern`, `lpr`, `mail`, `news`, `syslog`, `user`, `uucp`, `local0`, `local1`, `local2`, `local3`, `local4`, `local5`, `local6`, or `local7`.

Note

Not every facility is necessarily supported by every operating system.

```
SYSLOG:facility=syslog
```

- `FILE` pipes the cluster log output to a regular file on the same machine. The following values can be specified:
  - `filename`: The name of the log file.

    Prior to MySQL Cluster NDB 7.0.43 and MySQL Cluster NDB 7.1.23, the log file's default name, used if `FILE` was specified without also setting `filename`, was `logger.log`. Beginning with MySQL Cluster NDB 7.0.43 and MySQL Cluster NDB 7.1.23, the default log file name used in such cases is `ndb_nodeid_cluster.log`.
  - `maxsize`: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending `.N` to the file name, where `N` is the next number not yet used with this name.
  - `maxfiles`: The maximum number of log files.

```
FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
```

The default value for the `FILE` parameter is `FILE:filename=ndb_node_id_cluster.log,maxsize=1000000,maxfiles=6`, where `node_id` is the ID of the node.

It is possible to specify multiple log destinations separated by semicolons as shown here:

```
CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
```

- `ArbitrationRank`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	0-2	1	0 - 2
Restart Type: N			

This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. `ArbitrationRank` can take one of the following values:

- `0`: The node will never be used as an arbitrator.
- `1`: The node has high priority; that is, it will be preferred as an arbitrator over low-priority nodes.
- `2`: Indicates a low-priority node which be used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its `ArbitrationRank` to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

Beginning with MySQL 5.1.16 and MySQL Cluster NDB 6.1.3, it is possible to disable arbitration completely by setting `ArbitrationRank` to 0 on all management and SQL nodes. In MySQL Cluster NDB 7.0.7 and later releases, you can also control arbitration by overriding this parameter; to do this, set the `Arbitration [1844]` parameter in the `[ndbd default]` section of the `config.ini` global configuration file.

- `ArbitrationDelay`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	milliseconds	0	0 - 4G
Restart Type: N			

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- `DataDir`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	path	.	...
Restart Type: N			

This specifies the directory where output files from the management server will be placed. These files include cluster log files, process output files, and the daemon's process ID (PID) file. (For log files, this location can be overridden by setting the `FILE` parameter for `LogDestination` [1810] as discussed previously in this section.)

The default value for this parameter is the directory in which `ndb_mgmd` is located.

- `HeartbeatThreadPriority`

Beginning with MySQL Cluster NDB 6.3.32, MySQL Cluster NDB 7.0.13, and MySQL Cluster NDB 7.1.2, it is possible to use this parameter to set the scheduling policy and priority of heartbeat threads for management and API nodes.

The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]

policy:
  {FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of `FIFO` (first in, first out) or `RR` (round robin). The policy value is followed optionally by the priority (an integer).

- `TotalSendBufferMemory`

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.4.0	bytes	256K	0 - 4G
Restart Type: N			

This parameter is available beginning with MySQL Cluster NDB 6.4.0. It is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; the maxmimum is 4294967039. For more detailed information about the behavior and use of `TotalSendBufferMemory` and configuring send buffer memory parameters in MySQL Cluster NDB 6.4.0 and later, see Configuring MySQL Cluster Send Buffer Parameters.

Note

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect.

To add new management servers to a running MySQL Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see Limitations Relating to Multiple MySQL Cluster Nodes.

Defining MySQL Cluster Data Nodes

The `[ndbd]` and `[ndbd default]` sections are used to configure the behavior of the cluster's data nodes.

`[ndbd]` and `[ndbd default]` are always used as the section names whether you are using `ndbd` or (in MySQL Cluster NDB 6.4.0 and later) `ndbmtd` binaries for the data node processes.

There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameters are:

- Either `ExecuteOnComputer` or `HostName`, which must be defined in the local `[ndbd]` section.
- The parameter `NoOfReplicas` [1815], which must be defined in the `[ndbd default]` section, as it is common to all Cluster data nodes.

Note

It is no longer strictly necessary to set `NoOfReplicas` [1815] starting with MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6, where it acquires a default value (2). However, it remains good practice to set it explicitly.

Most data node parameters are set in the `[ndbd default]` section. Only those parameters explicitly stated as being able to set local values are permitted to be changed in the `[ndbd]` section. Where present, `HostName`, `NodeId` and `ExecuteOnComputer` *must* be defined in the local `[ndbd]` section, and not in any other section of `config.ini`. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use `K`, `M`, or `G` as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, `100K` means 100 × 1024 = 102400.) Parameter names and values are currently case-sensitive.

Information about configuration parameters specific to MySQL Cluster Disk Data tables can be found later in this section.

Beginning with MySQL Cluster NDB 6.4.0, all of these parameters also apply to `ndbmtd` (the multi-threaded version of `ndbd`). An additional data node configuration parameter `MaxNoOfExecutionThreads` [1855] applies to `ndbmtd` only, and has no effect when used with `ndbd`. For more information, see `ndbmtd` — The MySQL Cluster Data Node Daemon (Multi-Threaded).

Identifying data nodes. The `NodeId` or `Id` value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

- `Id`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	unsigned	[none]	1 - 48
Restart Type: N			

A unique node ID is used as the node's address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 48 inclusive. Each node in the cluster must have a unique identifier.

`NodeId` [1814] is the preferred parameter name to use when identifying data nodes beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.39, MySQL Cluster NDB 7.0.20, and MySQL Cluster NDB 7.1.9. Although `Id` continues to be supported for backward compatibility, it is now deprecated and generates a warning when used.

- `NodeId`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	unsigned	[none]	1 - 48
Restart Type: N			

A unique node ID is used as the node's address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 48 inclusive. Each node in the cluster must have a unique identifier.

`NodeId` is the preferred parameter name to use when identifying data nodes beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.39, MySQL Cluster NDB 7.0.20, and MySQL Cluster NDB 7.1.9. Although `Id` [1813] continues to be supported for backward compatibility, it is now deprecated and generates a warning when used.

- `ExecuteOnComputer`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	name	[none]	...
Restart Type: S			

This refers to the `Id` set for one of the computers defined in a `[computer]` section.

- `HostName`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	name or IP address	localhost	...
Restart Type: S			

Specifying this parameter defines the hostname of the computer on which the data node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- `ServerPort` [1814]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	unsigned	[none]	1 - 64K
Restart Type: N			

Each node in the cluster uses a port to connect to other nodes. By default, this port is allocated dynamically in such a way as to ensure that no two nodes on the same host computer receive the same port number, so it should normally not be necessary to specify a value for this parameter.

However, if you need to be able to open specific ports in a firewall to permit communication between data nodes and API nodes (including SQL nodes), you can set this parameter to the number of the desired port in an `[ndbd]` section or (if you need to do this for multiple data nodes) the `[ndbd default]` section of the `config.ini` file, and then open the port having that number for incoming connections from SQL nodes, API nodes, or both.

Note

Connections from data nodes to management nodes is done using the `ndb_mgmd` management port (the management server's `PortNumber`; see Defining a MySQL Cluster Management Server) so outgoing connections to that port from any data nodes should always be permitted.

- `TcpBind_INADDR_ANY`

  Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE` (`0`).

  This parameter was added in MySQL Cluster NDB 6.2.0.

- `NodeGroup` [1815]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.4.0		[none]	0 - 65536
Restart Type: IS			

  This parameter can be used to assign a data node to a specific node group. It is read only when the cluster is started for the first time, and cannot be used to reassign a data node to a different node group online. It is generally not desirable to use this parameter in the `[ndbd default]` section of the `config.ini` file, and care must be taken not to assign nodes to node groups in such a way that an invalid numbers of nodes are assigned to any node groups.

  The `NodeGroup` [1815] parameter is chiefly intended for use in adding a new node group to a running MySQL Cluster without having to perform a rolling restart. For this purpose, you should set it to 65536 (the maximum value). You are not required to set a `NodeGroup` [1815] value for all cluster data nodes, only for those nodes which are to be started and added to the cluster as a new node group at a later time. For more information, see Adding MySQL Cluster Data Nodes Online: Detailed Example.

  This parameter was added in MySQL Cluster NDB 6.4.0.

- `NoOfReplicas` [1815]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	[none]	1 - 4
NDB 6.3.25	integer	2	1 - 4
NDB 7.0.6	integer	2	1 - 4
Restart Type: IS			

  This global parameter can be set only in the `[ndbd default]` section, and defines the number of replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

  Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By

way of example, assume that we have 4 data nodes and that `NoOfReplicas` [1815] is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to fail.

If no node IDs are provided, the order of the data nodes will be the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's `SHOW` command.

Prior to MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6, there was no default value for `NoOfReplicas` [1815]; beginning with these versions, the default value is 2, which is the recommended setting in most common usage scenarios. (Bug #44746)

The maximum possible value is 4; *currently, only the values 1 and 2 are actually supported*.

Important

Setting `NoOfReplicas` [1815] to 1 means that there is only a single copy of all Cluster data; in this case, the loss of a single data node causes the cluster to fail because there are no additional copies of the data stored by that node.

The value for this parameter must divide evenly into the number of data nodes in the cluster. For example, if there are two data nodes, then `NoOfReplicas` [1815] must be equal to either 1 or 2, since 2/3 and 2/4 both yield fractional values; if there are four data nodes, then `NoOfReplicas` [1815] must be equal to 1, 2, or 4.

- `DataDir`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	path	.	...
Restart Type: IN			

This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

The default is the data node process working directory.

- `FileSystemPath` [1816]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	path	DataDir	...
Restart Type: IN			

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs (for Disk Data tables), and data files are placed. The default is the directory specified by `DataDir`.

Note

This directory must exist before the `ndbd` process is initiated.

The recommended directory hierarchy for MySQL Cluster includes `/var/lib/mysql-cluster`, under which a directory for the node's file system is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named `ndb_2_fs`.

- `BackupDataDir` [1816]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	path	[see text]	...
Restart Type: IN			

This parameter specifies the directory in which backups are placed.

Important

The string '`/BACKUP`' is always appended to this value. For example, if you set the value of `BackupDataDir` [1816] to `/var/lib/cluster-data`, then all backups are stored under `/var/lib/cluster-data/BACKUP`. This also means that the *effective* default backup location is the directory named `BACKUP` under the location specified by the `FileSystemPath` [1816] parameter.

Data Memory, Index Memory, and String Memory

`DataMemory` [1817] and `IndexMemory` [1819] are `[ndbd]` parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how `DataMemory` [1817] and `IndexMemory` [1819] are used, as they usually need to be updated to reflect actual usage by the cluster:

- `DataMemory` [1817]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	bytes	80M	1M - 1024G
Restart Type: N			

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by `DataMemory` [1817] is used to store both the actual records and indexes. There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

For variable-size table attributes in MySQL 5.1, the data is stored on separate datapages, allocated from `DataMemory` [1817]. Variable-length records use a fixed-size part with an extra overhead of 4 bytes to reference the variable-size part. The variable-size part has 2 bytes overhead plus 2 bytes per attribute.

Prior to MySQL Cluster NDB 7.0, the maximum record size was 8052 bytes; in MySQL Cluster NDB 7.0 and later, it is 14000 bytes.

The memory space defined by `DataMemory` [1817] is also used to store ordered indexes, which use about 10 bytes per record. Each table row is represented in the ordered index. A common error among users is to assume that all indexes are stored in the memory allocated by `IndexMemory` [1819], but this is not the case: Only primary key and unique hash indexes use this memory; ordered indexes use the memory allocated by `DataMemory` [1817]. However, creating a primary key or unique hash index also creates an ordered index on the same keys, unless you specify `USING HASH` in the index creation statement. This can be verified by running `ndb_desc -d db_name table_name` in the management client.

Currently, MySQL Cluster can use a maximum of 512 MB for hash indexes per partition, which means in some cases it is possible to get `Table is full` errors in MySQL client applications even when `ndb_mgm -e "ALL REPORT MEMORYUSAGE"` shows significant free `DataMemory` [1817]. This can also pose a problem with data node restarts on nodes that are heavily loaded with data. You can force `NDB` to create extra partitions for MySQL Cluster tables and thus have more memory available for hash indexes by using the `MAX_ROWS` option for `CREATE TABLE`. In general, setting `MAX_ROWS` to twice the number of rows that you expect to store in the table should be sufficient. In MySQL Cluster 7.1.18 and later, you can also use the `MinFreePct` [1820] configuration parameter to help avoid problems with node restarts. (Bug #13436216)

The memory space allocated by `DataMemory` [1817] consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in `NoOfReplicas` [1815].

In addition, due to the way in which new pages are allocated when the capacity of the current page is exhausted, there is an additional overhead of approximately 18.75%. When more `DataMemory` [1817] is required, more than one new page is allocated, according to the following formula:

```
number of new pages = FLOOR(number of current pages × 0.1875) + 1
```

For example, if 15 pages are currently allocated to a given table and an insert to this table requires additional storage space, the number of new pages allocated to the table is `FLOOR(15 × 0.1875) + 1 = FLOOR(2.8125) + 1 = 2 + 1 = 3`. Now 15 + 3 = 18 memory pages are allocated to the table. When the last of these 18 pages becomes full, `FLOOR(18 × 0.1875) + 1 = FLOOR(3.3750) + 1 = 3 + 1 = 4` new pages are allocated, so the total number of pages allocated to the table is now 22.

Note

The “18.75% + 1” overhead is no longer required beginning with MySQL Cluster NDB 6.2.3 and MySQL Cluster NDB 6.3.0.

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that `DataMemory` [1817] pages, once allocated to a given table, cannot be used by other tables.) Performing a node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The `DataMemory` [1817] memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the `DataMemory` [1817]. There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones
- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

The default value for `DataMemory` [1817] is 80MB; the minimum is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process.

32-bit operating systems are generally limited to 2–4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

- `IndexMemory` [1819]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	bytes	18M	1M - 1T
Restart Type: N			

This parameter controls the amount of storage used for hash indexes in MySQL Cluster. Hash indexes are always used for primary key indexes, unique indexes, and unique constraints. Note that when defining a primary key and a unique index, two indexes will be created, one of which is a hash index used for all tuple accesses as well as lock handling. It is also used to enforce unique constraints.

The size of the hash index is 25 bytes per record, plus the size of the primary key. For primary keys larger than 32 bytes another 8 bytes is added.

The default value for `IndexMemory` [1819] is 18MB. The minimum is 1MB.

- `StringMemory` [1819]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	% or bytes	0	0 - 4G
MySQL 5.1.32	% or bytes	25	0 - 4G
MySQL 5.1.6	% or bytes	5	0 - 4G
NDB 7.2.1	% or bytes	25	0 - 4G
Restart Type: S			

This parameter determines how much memory is allocated for strings such as table names, and is specified in an `[ndbd]` or `[ndbd default]` section of the `config.ini` file. A value between `0` and `100` inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum size of `.FRM` files, `MaxNoOfTriggers` [1830], maximum column name size, and maximum default column value.

A value greater than `100` is interpreted as a number of bytes.

The default value is 25—that is, 25 percent of the default maximum. (Previously, prior to MySQL Cluster NDB 6.2.18, MySQL Cluster NDB 6.3.24, and MySQL Cluster NDB 7.0.5, the default value was 5; prior to MySQL 5.1.6, the default was 0.)

Under most circumstances, the default value should be sufficient, but when you have a great many Cluster tables (1000 or more), it is possible to get Error 773 `Out of string memory, please modify StringMemory config parameter: Permanent error: Schema error`, in which case you should increase this value. `25` (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions.

The following example illustrates how memory is used for a table. Consider this table definition:

```
CREATE TABLE example (
  a INT NOT NULL,
  b INT NOT NULL,
  c INT NOT NULL,
  PRIMARY KEY(a),
  UNIQUE(b)
```

```
) ENGINE=NDBCLUSTER;
```

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns `a` and `b` consuming roughly 10 bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with `b` as primary key and `a` as a column. This other table consumes an additional 29 bytes of index memory per record in the `example` table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in MySQL Cluster to handle uniqueness constraints.

Currently, the only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both `IndexMemory` [1819] and `DataMemory` [1817] is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two replicas, there will be two node groups. Thus, the total data memory available is 2 × `DataMemory` [1817] for each data node.

It is highly recommended that `DataMemory` [1817] and `IndexMemory` [1819] be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

`DataMemory` [1817] and `IndexMemory` [1819] can be changed, but decreasing either of these can be risky; doing so can easily lead to a node or even an entire MySQL Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

Beginning with MySQL Cluster NDB 7.0.29 and MySQL Cluster NDB 7.1.18, a proportion (5% by default) of data node resources including `DataMemory` [1817] and `IndexMemory` [1819] is kept in reserve to insure that the data node does not exhaust its memory when performing a restart. This can be adjusted using the `MinFreePct` [1820] data node configuration parameter (default 5) introduced in the same versions of MySQL Cluster.

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 7.0.29	unsigned	5	0 - 100
NDB 7.1.18	unsigned	5	0 - 100
NDB 7.2.3	unsigned	5	0 - 100
Restart Type: N			

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

Transaction parameters. The next few `[ndbd]` parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. `MaxNoOfConcurrentTransactions` [1821] sets the number of parallel transactions possible in a node. `MaxNoOfConcurrentOperations` [1821] sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially MaxNoOfConcurrentOperations [1821]) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

MaxDMLOperationsPerTransaction [1822], added in MySQL Cluster NDB 7.0.26 and MySQL Cluster NDB 7.1.15, sets the maximum number of DML operations that can be performed in a given transaction.

- MaxNoOfConcurrentTransactions [1821]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	4096	32 - 4G
Restart Type: S			

Each cluster data node requires a transaction record for each active transaction in the cluster. The task of coordinating transactions is distributed among all of the data nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Each connection to a MySQL server requires at least one transaction record, plus an additional transaction object per table accessed by that connection. This means that a reasonable minimum for this parameter is

```
MaxNoOfConcurrentTransactions =
    (maximum number of tables accessed in any single transaction + 1)
    * number of cluster SQL nodes
```

Suppose that there are 4 SQL nodes using the cluster. A single join involving 5 tables requires 6 transaction records; if there are 5 such joins in a transaction, then 5 * 6 = 30 transaction records are required for this transaction, per MySQL server, or 30 * 4 = 120 transaction records total.

This parameter must be set to the same value for all cluster data nodes. This is due to the fact that, when a data node fails, the oldest surviving node re-creates the transaction state of all transactions that were ongoing in the failed node.

Changing the value of MaxNoOfConcurrentTransactions [1821] requires a complete shutdown and restart of the cluster.

The default value is 4096.

- MaxNoOfConcurrentOperations [1821]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	32K	32 - 4G
Restart Type: N			

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions of only a few operations each and not involving a great many records, there is no need to set this parameter very high. When performing large transactions involving many records need to set this parameter higher.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes

and which is expected to handle 1,000,000 concurrent updates using transactions, you should set this value to 1000000 / 4 = 250000.

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. `MaxNoOfConcurrentOperations` [1821] will always be used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

- `MaxNoOfLocalOperations` [1822]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	UNDEFINED	32 - 4G
Restart Type: N			

By default, this parameter is calculated as 1.1 × `MaxNoOfConcurrentOperations` [1821]. This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

- `MaxDMLOperationsPerTransaction` [1822]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 7.0.26	operations (DML)	4294967295	32 - 4294967295
NDB 7.1.15	operations (DML)	4294967295	32 - 4294967295
Restart Type: N			

Added in MySQL Cluster NDB 7.0.26 and MySQL Cluster NDB 7.1.15, this parameter limits the size of a transaction. The transaction is aborted if it requires more than this many DML operations. The minimum number of operations per transaction is 32; however, you can set `MaxDMLOperationsPerTransaction` to 0 to disable any limitation on the number of DML operations per transaction. The maximum (and default) is 4294967295.

Transaction temporary storage. The next set of `[ndbd]` parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

- `MaxNoOfConcurrentIndexOperations` [1823]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	8K	0 - 4G
Restart Type: N			

For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter `MaxNoOfConcurrentOperations` [1821].

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

- `MaxNoOfFiredTriggers` [1823]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	4000	0 - 4G
Restart Type: N			

The default value of `MaxNoOfFiredTriggers` [1823] is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

- `TransactionBufferMemory` [1823]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	bytes	1M	1K - 4G
Restart Type: N			

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for `TransactionBufferMemory` [1823] is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter `ZATTRBUF_FILESIZE` (found in `ndb/src/kernel/blocks/`

Dbtc/Dbtc.hpp) set to 4000 × 128 bytes (500KB). A similar buffer for key information, ZDATABUF_FILESIZE (also in Dbtc.hpp) contains 4000 × 16 = 62.5KB of buffer space. Dbtc is the module that handles transaction coordination.

Scans and buffering. There are additional [ndbd] parameters in the Dblqh module (in ndb/src/kernel/blocks/Dblqh/Dblqh.hpp) that affect reads and updates. These include ZATTRINBUF_FILESIZE, set by default to 10000 × 128 bytes (1250KB) and ZDATABUF_FILE_SIZE, set by default to 10000*16 bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

- MaxNoOfConcurrentScans [1824]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	256	2 - 500
Restart Type: N			

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain MaxNoOfConcurrentScans [1824] scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of MaxNoOfConcurrentScans [1824] is 256. The maximum value is 500.

- MaxNoOfLocalScans [1824]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	UNDEFINED	32 - 4G
Restart Type: N			

Specifies the number of local scan records if many scans are not fully parallelized. In MySQL Cluster NDB 7.2.0 and later, when the number of local scan records is not provided, it is calculated as 4 times the product of MaxNoOfConcurrentScans [1824] and the number of data nodes in the system. (Previously, it was calculated as the product of MaxNoOfConcurrentScans [1824] and the number of data nodes.) The minimum value is 32.

- BatchSizePerLocalScan [1824]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	64	1 - 992
NDB 7.2.1	integer	256	1 - 992
Restart Type: N			

This parameter is used to calculate the number of lock records used to handle concurrent scan operations.

BatchSizePerLocalScan has a strong connection to the BatchSize [1866] defined in the SQL nodes.

- LongMessageBuffer [1825]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	bytes	1M	512K - 4G
NDB 7.0.4	bytes	4M	512K - 4G
Restart Type: N			

This is an internal buffer used for passing messages within individual nodes and between nodes. In MySQL Cluster NDB 6.4.3 and earlier, the default is 1MB; beginning with MySQL Cluster NDB 7.0.4, it is 4MB.

This parameter seldom needs to be changed from the default. However, when replicating a MySQL Cluster using ndbmtd for the data nodes, you may need to increase this value to 8MB (or possibly more) to prevent data node instability, because ndbmtd uses much more of this resource than ndbd does. Beginning with MySQL Cluster NDB 7.0.13 and MySQL Cluster NDB 7.1.2, this should no longer be necessary when using ndbmtd with MySQL Cluster Replication (Bug #46914).

- MaxParallelScansPerFragment [1825]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 7.0.23	bytes	32	1 - 1G
NDB 7.1.12	bytes	32	1 - 1G
NDB 7.2.0	bytes	256	1 - 1G
Restart Type: N			

Beginning with MySQL Cluster NDB 7.0.23 and MySQL Cluster NDB 7.1.12, it is possible to configure the maximum number of parallel scans (TUP scans and TUX scans) allowed before they begin queuing for serial handling. (Previously, the maximum number of parallel scans per fragment was fixed at 32.) You can increase this to take advantage of any unused CPU when performing large number of scans in parallel and improve their performance.

Beginning with MySQL Cluster NDB 7.2.0, the default value for this parameter is increased from 32 to 256.

Memory Allocation

MaxAllocate [1825]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.1.19	unsigned	32M	1M - 1G
NDB 6.2.3	unsigned	32M	1M - 1G
MySQL 5.1.20	unsigned	32M	1M - 1G
Restart Type: N			

This is the maximum size of the memory unit to use when allocating memory for tables. In cases where NDB gives Out of memory errors, but it is evident by examining the cluster logs or the output of DUMP 1000 (see DUMP 1000) that all available memory has not yet been used, you can increase the value of this parameter (or MaxNoOfTables [1829], or both) to cause NDB to make sufficient memory available.

This parameter was introduced in MySQL 5.1.20, MySQL Cluster NDB 6.1.12 and MySQL Cluster NDB 6.2.3.

Logging and checkpointing. The following `[ndbd]` parameters control log and checkpoint behavior.

- `NoOfFragmentLogFiles` [1826]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	8	3 - 4G
MySQL 5.1.0	integer	16	3 - 4G
Restart Type: IN			

This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the “head” and “tail” log files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A `REDO` log record is not removed until the required number of local checkpoints has been completed since that log record was inserted (prior to MySQL Cluster NDB 6.3.8, this was 3 local checkpoints; in later versions of MySQL Cluster, only 2 local checkpoints are necessary). Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

How these parameters interact and proposals for how to configure them are discussed in Configuring MySQL Cluster Parameters for Local Checkpoints.

The default parameter value is 16, which by default means 16 sets of 4 16MB files for a total of 1024MB. Beginning with MySQL Cluster NDB 6.1.1, the size of the individual log files is configurable using the `FragmentLogFileSize` [1826] parameter. In scenarios requiring a great many updates, the value for `NoOfFragmentLogFiles` [1826] may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (`Out of log file space temporarily`). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

Important

This parameter cannot be changed “on the fly”; you must restart the node using `--initial`. If you wish to change this value for all data nodes in a running cluster, you can do so using a rolling node restart (using `--initial` when starting each data node).

- `FragmentLogFileSize` [1826]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.1.11	bytes	16M	4M - 1G
Restart Type: IN			

Setting this parameter enables you to control directly the size of redo log files. This can be useful in situations when MySQL Cluster is operating under a high load and it is unable to close fragment log files quickly enough before attempting to open new ones (only 2 fragment log files can be open at one time); increasing the size of the fragment log files gives the cluster more time

before having to open each new fragment log file. The default value for this parameter is 16M. `FragmentLogFileSize` [1826] was added in MySQL Cluster NDB 6.1.11.

For more information about fragment log files, see the description for `NoOfFragmentLogFiles` [1826].

- `InitFragmentLogFiles` [1827]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.3.19	[see values]	SPARSE	SPARSE, FULL
Restart Type: IN			

By default, fragment log files are created sparsely when performing an initial start of a data node —that is, depending on the operating system and file system in use, not all bytes are necessarily written to disk. Beginning with MySQL Cluster NDB 6.3.19, it is possible to override this behavior and force all bytes to be written regardless of the platform and file system type being used by mean of this parameter.

`InitFragmentLogFiles` [1827] takes one of two values:

- `SPARSE`. Fragment log files are created sparsely. This is the default value.
- `FULL`. Force all bytes of the fragment log file to be written to disk.

Depending on your operating system and file system, setting `InitFragmentLogFiles=FULL` may help eliminate I/O errors on writes to the REDO log.

- `MaxNoOfOpenFiles` [1827]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	40	20 - 4G
MySQL 5.1.16	unsigned	0	20 - 4G
Restart Type: N			

This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug*.

The default value is 0. (Prior to MySQL 5.1.16, the default was 40.) However, the minimum value to which this parameter can be set is 20.

- `InitialNoOfOpenFiles` [1827]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1.9	files	27	20 - 4G
Restart Type: N			

This parameter sets the initial number of internal threads to allocate for open files.

The default value is 27.

- `MaxNoOfSavedMessages` [1827]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	25	0 - 4G
Restart Type: N			

This parameter sets the maximum number of trace files that are kept before overwriting old ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25 trace files.

- `MaxLCPStartDelay` [1828]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.3.23	seconds	0	0 - 600
NDB 6.4.3	seconds	0	0 - 600
Restart Type: N			

In parallel data node recovery (supported in MySQL Cluster NDB 6.3.8 and later), only table data is actually copied and synchronized in parallel; synchronization of metadata such as dictionary and checkpoint information is done in a serial fashion. In addition, recovery of dictionary and checkpoint information cannot be executed in parallel with performing of local checkpoints. This means that, when starting or restarting many data nodes concurrently, data nodes may be forced to wait while a local checkpoint is performed, which can result in longer node recovery times.

Beginning with MySQL Cluster NDB 6.3.23 and MySQL Cluster NDB 6.4.3, it is possible to force a delay in the local checkpoint to permit more (and possibly all) data nodes to complete metadata synchronization; once each data node's metadata synchronization is complete, all of the data nodes can recover table data in parallel, even while the local checkpoint is being executed.

To force such a delay, you can set `MaxLCPStartDelay` [1828], which determines the number of seconds the cluster can wait to begin a local checkpoint while data nodes continue to synchronize metadata. This parameter should be set in the `[ndbd default]` section of the `config.ini` file, so that it is the same for all data nodes. The maximum value is 600; the default is 0.

Metadata objects. The next set of `[ndbd]` parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters. Note that these act merely as “suggestions” to the cluster, and any that are not specified revert to the default values shown.

- `MaxNoOfAttributes` [1828]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	1000	32 - 4G
Restart Type: N			

This parameter sets a suggested maximum number of attributes that can be defined in the cluster; like `MaxNoOfTables` [1829], it is not intended to function as a hard upper limit.

Prior to MySQL Cluster NDB 6.3.45, MySQL Cluster NDB 7.0.26, and MySQL Cluster NDB 7.1.15, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with MySQL Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible (or not possible, depending on the circumstances) to create more than `MaxNoOfAttributes` attributes. (Bug #61684)

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting `MaxNoOfAttributes` [1828], it is important to prepare in advance for any `ALTER TABLE` statements that you might want to perform in the future. This is due to the fact, during the execution of `ALTER TABLE` on a Cluster table, 3 times the number of attributes as in the original table are used, and a good practice is to permit double this amount. For example, if the MySQL Cluster table having the greatest number of attributes (*`greatest_number_of_attributes`*) has 100 attributes, a good starting point for the value of `MaxNoOfAttributes` [1828] would be `6 * greatest_number_of_attributes = 600`.

You should also estimate the average number of attributes per table and multiply this by `MaxNoOfTables` [1829]. If this value is larger than the value obtained in the previous paragraph, you should use the larger value instead.

Assuming that you can create all desired tables without any problems, you should also verify that this number is sufficient by trying an actual `ALTER TABLE` after configuring the parameter. If this is not successful, increase `MaxNoOfAttributes` [1828] by another multiple of `MaxNoOfTables` [1829] and test it again.

- `MaxNoOfTables` [1829]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	128	8 - 20320
Restart Type: N			

A table object is allocated for each table and for each unique hash index in the cluster. This parameter sets a suggested maximum number of table objects for the cluster as a whole; like `MaxNoOfAttributes` [1828], it is not intended to function as a hard upper limit.

Prior to MySQL Cluster NDB 6.3.45, MySQL Cluster NDB 7.0.26, and MySQL Cluster NDB 7.1.15, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with MySQL Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible (or not possible, depending on the circumstances) to create more than `MaxNoOfTables` tables.

For each attribute that has a `BLOB` data type an extra table is used to store most of the `BLOB` data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 20320. Each table object consumes approximately 20KB per node.

Note

The sum of `MaxNoOfTables` [1829], `MaxNoOfOrderedIndexes` [1829], and `MaxNoOfUniqueHashIndexes` [1830] must not exceed $2^{32} - 2$ (4294967294).

- `MaxNoOfOrderedIndexes` [1829]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	128	0 - 4G
Restart Type: N			

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index. `MaxNoOfOrderedIndexes` [1829] sets the total number of ordered indexes that can be in use in the system at any one time.

The default value of this parameter is 128. Each index object consumes approximately 10KB of data per node.

Note

The sum of `MaxNoOfTables` [1829], `MaxNoOfOrderedIndexes` [1829], and `MaxNoOfUniqueHashIndexes` [1830] must not exceed $2^{32} - 2$ (4294967294).

- `MaxNoOfUniqueHashIndexes` [1830]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	64	0 - 4G
Restart Type: N			

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the `USING HASH` option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

Note

The sum of `MaxNoOfTables` [1829], `MaxNoOfOrderedIndexes` [1829], and `MaxNoOfUniqueHashIndexes` [1830] must not exceed $2^{32} - 2$ (4294967294).

- `MaxNoOfTriggers` [1830]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	768	0 - 4G
Restart Type: N			

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an *ordered* index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Replication between clusters also makes use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- `MaxNoOfIndexes` [1830]

This parameter is deprecated. You should use `MaxNoOfOrderedIndexes` [1829] and `MaxNoOfUniqueHashIndexes` [1830] instead.

This parameter is used only by unique hash indexes. There needs to be one record in this pool for each unique hash index defined in the cluster.

The default value of this parameter is 128.

- `MaxNoOfSubscriptions` [1831]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.2.10	unsigned	0	0 - 4G
NDB 6.3.7	unsigned	0	0 - 4G
Restart Type: N			

Each `NDB` table in a MySQL Cluster requires a subscription in the NDB kernel. For some NDB API applications, it may be necessary or desirable to change this parameter, which became available in MySQL Cluster NDB 6.2.10 and MySQL Cluster NDB 6.3.7. However, for normal usage with MySQL servers acting as SQL nodes, there is not any need to do so.

The default value for `MaxNoOfSubscriptions` [1831] is 0, which is treated as equal to `MaxNoOfTables` [1829]. Each subscription consumes 108 bytes.

- `MaxNoOfSubscribers` [1831]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.2.10	unsigned	0	0 - 4G
NDB 6.3.7	unsigned	0	0 - 4G
Restart Type: N			

This parameter, added in MySQL Cluster NDB 6.2.10 and MySQL Cluster NDB 6.3.7, is of interest only when using MySQL Cluster Replication. The default value is 0, which is treated as `2 * MaxNoOfTables`; that is, there is one subscription per `NDB` table for each of two MySQL servers (one acting as the replication master and the other as the slave). Each subscriber uses 16 bytes of memory.

When using circular replication, multi-master replication, and other replication setups involving more than 2 MySQL servers, you should increase this parameter to the number of `mysqld` processes included in replication (this is often, but not always, the same as the number of clusters). For example, if you have a circular replication setup using three MySQL Clusters, with one `mysqld` attached to each cluster, and each of these `mysqld` processes acts as a master and as a slave, you should set `MaxNoOfSubscribers` [1831] equal to `3 * MaxNoOfTables`.

For more information, see MySQL Cluster Replication.

- `MaxNoOfConcurrentSubOperations` [1831]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.2.10	unsigned	256	0 - 4G
NDB 6.3.7	unsigned	256	0 - 4G
Restart Type: N			

This parameter sets a ceiling on the number of operations that can be performed by all API nodes in the cluster at one time. The default value (256) is sufficient for normal operations, and might need to be adjusted only in scenarios where there are a great many API nodes each performing a high volume of operations concurrently.

This parameter was added in MySQL Cluster NDB 6.2.10 and MySQL Cluster NDB 6.3.7.

Boolean parameters. The behavior of data nodes is also affected by a set of `[ndbd]` parameters taking on boolean values. These parameters can each be specified as `TRUE` by setting them equal to `1` or `Y`, and as `FALSE` by setting them equal to `0` or `N`.

- `LockPagesInMainMemory` [1832]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	numeric	0	0 - 2
MySQL 5.1.0	true|false (1|0)	0	0 - 1
MySQL 5.1.15	numeric	0	0 - 2
Restart Type: N			

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

Beginning with MySQL 5.1.15 and MySQL Cluster NDB 6.1.1, this parameter takes one of the integer values `0`, `1`, or `2`, which act as follows:

- `0`: Disables locking. This is the default value.
- `1`: Performs the lock after allocating memory for the process.
- `2`: Performs the lock before memory for the process is allocated.

Previously, this parameter was a Boolean. `0` or `false` was the default setting, and disabled locking. `1` or `true` enabled locking of the process after its memory was allocated.

Important

Beginning with MySQL 5.1.15 and MySQL Cluster NDB 6.1.1, it is no longer possible to use `true` or `false` for the value of this parameter; when upgrading from a previous version, you must change the value to `0`, `1`, or `2`.

Prior to MySQL Cluster NDB 6.3.31 and MySQL Cluster NDB 7.0.11, setting this parameter did not cause the stated memory to be allocated when the node was started, but rather only when the memory was used by the data node process for other reasons. (Bug #37430)

Note

If the operating system is not configured to permit unprivileged users to lock pages, then the data node process making use of this parameter may have to be run as system root. (`LockPagesInMainMemory` [1832] uses the `mlockall` function. From Linux kernel 2.6.9, unprivileged users can lock memory as limited by `max locked memory`. For more information, see `ulimit -l` and http://linux.die.net/man/2/mlock).

- `StopOnError` [1832]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	boolean	true	true, false
Restart Type: N			

This parameter specifies whether an `ndbd` process should exit or perform an automatic restart when an error condition is encountered.

This feature is enabled by default.

- `CrashOnCorruptedTuple` [1833]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 7.0.28, 5.1.56-ndb-7.1.17	boolean	false	true, false
NDB 7.2.1	boolean	true	true, false
Restart Type: S			

This parameter was introduced in MySQL Cluster NDB 7.0.28 and MySQL Cluster NDB 7.1.17. When enabled, it forces a data node to shut down whenever it encounters a corrupted tuple. By default, it is disabled.

- `Diskless` [1833]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	true|false (1|0)	false	true, false
Restart Type: IS			

It is possible to specify MySQL Cluster tables as *diskless*, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run `ndbd` on a diskless computer.

Important

This feature causes the *entire* cluster to operate in diskless mode.

When this feature is enabled, Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

`Diskless` [1833] is disabled by default.

- `ODirect` [1833]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.1.11	boolean	false	true, false
NDB 6.2.3	boolean	false	true, false
NDB 6.3.0	boolean	false	true, false
Restart Type: N			

Enabling this parameter causes `NDB` to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering `kswapd` and CPU usage. When using MySQL Cluster on Linux, enable `ODirect` [1833] if you are using a 2.6 or later kernel.

This parameter was added in MySQL 5.1.20, MySQL Cluster NDB 6.1.11, MySQL Cluster NDB 6.2.3, and MySQL Cluster NDB 6.3.0.

`ODirect` [1833] is disabled by default.

- `RestartOnErrorInsert` [1833]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	error code	2	0 - 4
Restart Type: N			

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

- `CompressedBackup` [1834]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.3.7	boolean	false	true, false
Restart Type: N			

Setting this parameter to `1` causes backup files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed backup files. Compressed backups can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

Important

You cannot restore a compressed backup to a cluster running a MySQL version that does not support this feature.

The default value is `0` (disabled).

This parameter was introduced in MySQL Cluster NDB 6.3.7.

- `CompressedLCP` [1834]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.3.7	boolean	false	true, false
Restart Type: N			

Setting this parameter to `1` causes local checkpoint files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed checkpoint files. Compressed LCPs can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

Important

You cannot restore a compressed local checkpoint to a cluster running a MySQL version that does not support this feature.

The default value is `0` (disabled).

This parameter was introduced in MySQL Cluster NDB 6.3.7.

Controlling Timeouts, Intervals, and Disk Paging

There are a number of `[ndbd]` parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

- `TimeBetweenWatchDogCheck` [1835]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	milliseconds	6000	70 - 4G
Restart Type: N			

To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 6000 milliseconds (6 seconds).

- `TimeBetweenWatchDogCheckInitial` [1835]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1.20	milliseconds	6000	70 - 4G
Restart Type: N			

This is similar to the `TimeBetweenWatchDogCheck` [1835] parameter, except that `TimeBetweenWatchDogCheckInitial` [1835] controls the amount of time that passes between execution checks inside a database node in the early start phases during which memory is allocated.

The default timeout is 6000 milliseconds (6 seconds).

This parameter was added in MySQL 5.1.20.

- `StartPartialTimeout` [1835]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	milliseconds	30000	0 - 4G
Restart Type: N			

This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

- `StartPartitionedTimeout` [1835]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	milliseconds	60000	0 - 4G
Restart Type: N			

If the cluster is ready to start after waiting for `StartPartialTimeout` [1835] milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed. If `StartPartitionedTimeout` [1835] is set to 0, the cluster waits indefinitely.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default timeout is 60000 milliseconds (60 seconds).

- `StartFailureTimeout` [1836]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	milliseconds	0	0 - 4G
Restart Type: N			

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as 10–15 minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

- `StartNoNodeGroupTimeout` [1836]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 7.0.24	milliseconds	15000	0 - 4294967039
Restart Type: N			

When a data node is configured with `Nodegroup = 65536` [1815], is regarded as not being assigned to any node group. When that is done, the cluster waits `StartNoNodegroupTimeout` milliseconds, then treats such nodes as though they had been added to the list passed to the `--nowait-nodes` [1955] option, and starts. The default value is `15000` (that is, the management server waits 15 seconds). Setting this parameter equal to `0` means that the cluster waits indefinitely.

`StartNoNodegroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

This parameter was added in MySQL Cluster NDB 7.0.24 and MySQL Cluster NDB 7.1.13. See Adding MySQL Cluster Data Nodes Online, for more information.

- `HeartbeatIntervalDbDb` [1836]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	milliseconds	1500	10 - 4G
NDB 7.2.0	milliseconds	5000	10 - 4G

Effective Version	Type/Units	Default	Range or Permitted Values
Restart Type: N			

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. After missing three heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is four times the heartbeat interval.

In MySQL Cluster NDB 7.2.0 and later, the default heartbeat interval is 5000 milliseconds (5 seconds). Previously, the default was 1500 milliseconds (1.5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds, obviously the node will be declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

See also Network communication and latency.

- `HeartbeatIntervalDbApi` [1837]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	milliseconds	1500	100 - 4G
Restart Type: N			

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for `HeartbeatIntervalDbDb` [1836].

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

For more information, see Network communication and latency.

- `HeartbeatOrder` [1837]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.3.35	numeric	0	0 - 65535
NDB 7.0.16	numeric	0	0 - 65535
NDB 7.1.5	numeric	0	0 - 65535
Restart Type: S			

Data nodes send heartbeats to one another in a circular fashion whereby each data node monitors the previous one. If a heartbeat is not detected by a given data node, this node declares the previous data node in the circle “dead” (that is, no longer accessible by the cluster). The determination that a data node is dead is done globally; in other words; once a data node is declared dead, it is regarded as such by all nodes in the cluster.

It is possible for heartbeats between data nodes residing on different hosts to be too slow compared to heartbeats between other pairs of nodes (for example, due to a very low heartbeat interval or

temporary connection problem), such that a data node is declared dead, even though the node can still function as part of the cluster. .

In this type of situation, it may be that the order in which heartbeats are transmitted between data nodes makes a difference as to whether or not a particular data node is declared dead. If this declaration occurs unnecessarily, this can in turn lead to the unnecessary loss of a node group and as thus to a failure of the cluster.

Consider a setup where there are 4 data nodes A, B, C, and D running on 2 host computers `host1` and `host2`, and that these data nodes make up 2 node groups, as shown in the following table:

	`host1`	`host2`
Node Group 0:	Node A	Node B
Node Group 1:	Node C	Node D

Suppose the heartbeats are transmitted in the order A->B->C->D->A. In this case, the loss of the heartbeat between the hosts causes node B to declare node A dead and node C to declare node B dead. This results in loss of Node Group 0, and so the cluster fails. On the other hand, if the order of transmission is A->B->D->C->A (and all other conditions remain as previously stated), the loss of the heartbeat causes nodes A and D to be declared dead; in this case, each node group has one surviving node, and the cluster survives.

Priot to MySQL Cluster NDB 6.3.35, MySQL Cluster NDB 7.0.16, and MySQL Cluster NDB 7.1.5, the order of of heartbeat transmission between data nodes was always automatically determined by `NDB`. However, beginning with these versions, the `HeartbeatOrder` [1837] configuration parameter makes the order of heartbeat transmission user-configurable.

The default value for `HeartbeatOrder` [1837] is zero; allowing the default value to be used on all data nodes causes the order of heartbeat transmission to be determined by `NDB`. If this parameter is used, it must be set to a nonzero value (maximum 65535) for every data node in the cluster, and this value must be unique for each data node; this causes the heartbeat transmission to proceed from data node to data node in the order of their `HeartbeatOrder` [1837] values from lowest to highest (and then directly from the data node having the highest `HeartbeatOrder` [1837] to the data node having the lowest value, to complete the circle). The values need not be consecutive; for example, to force the heartbeat transmission order A->B->D->C->A in the scenario outlined previously, you could set the `HeartbeatOrder` [1837] values as shown here:

Node	**`HeartbeatOrder`**
A	10
B	20
C	30
D	25

To use this parameter to change the heartbeat transmission order in a running MySQL Cluster, you must first set `HeartbeatOrder` [1837] for each data node in the cluster in the global configuration (`config.ini`) file (or files). To cause the change to take effect, you must perform either of the following:

- A complete shutdown and restart of the entire cluster.
- 2 rolling restarts of the cluster in succession. *All nodes must be restarted in the same order in both rolling restarts*.

You can use `DUMP 908` to observe the effect of this parameter in the data node logs.

- `ConnectCheckIntervalDelay` [1838]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 7.1.13	string	1500	0 - 4G
NDB 7.2.1	string	0	0 - 4G
Restart Type: N			

Enables connection checking between data nodes. A data node that fails to respond within an interval of `ConnectCheckIntervalDelay` seconds is considered suspect, and is considered dead after two such intervals.

- `TimeBetweenLocalCheckpoints` [1839]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	number of 4-byte words, as a base-2 logarithm	20	0 - 31
Restart Type: N			

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB (4×2^{20}) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting `TimeBetweenLocalCheckpoints` [1839] to 6 or less means that local checkpoints will be executed continuously without pause, independent of the cluster's workload.

- `TimeBetweenGlobalCheckpoints` [1839]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	milliseconds	2000	10 - 32000
NDB 6.2.0	milliseconds	2000	20 - 32000
Restart Type: N			

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases—a complete crash of the cluster—is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- `TimeBetweenEpochs` [1840]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.2.5	milliseconds	100	0 - 32000
Restart Type: N			

This parameter defines the interval between synchronization epochs for MySQL Cluster Replication. The default value is 100 milliseconds.

`TimeBetweenEpochs` [1840] is part of the implementation of “micro-GCPs”, which can be used to improve the performance of MySQL Cluster Replication. This parameter was introduced in MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2.

- `TimeBetweenEpochsTimeout` [1840]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1.22	milliseconds	4000	0 - 32000
MySQL 5.1.51	milliseconds	4000	0 - 256000
Restart Type: N			

This parameter defines a timeout for synchronization epochs for MySQL Cluster Replication. If a node fails to participate in a global checkpoint within the time determined by this parameter, the node is shut down. In MySQL Cluster NDB 7.2.0 and later, the default value is 0; in other words, the timeout is disabled. This represents a change from previous versions of MySQL Cluster, in which the default value was 4000 milliseconds (4 seconds).

`TimeBetweenEpochsTimeout` [1840] is part of the implementation of “micro-GCPs”, which can be used to improve the performance of MySQL Cluster Replication. This parameter was introduced in MySQL Cluster NDB 6.2.7 and MySQL Cluster NDB 6.3.4.

The following changes regarding this parameter were made in MySQL Cluster NDB 7.0.21 and MySQL Cluster NDB 7.1.10:

- The maximum possible value for this parameter was increased from 32000 milliseconds to 256000 milliseconds.
- Setting this parameter to zero now has the effect of disabling GCP stops caused by save timeouts, commit timeouts, or both.
- The current value of this parameter and a warning are now written to the cluster log whenever a GCP save takes longer than 1 minute or a GCP save takes longer than 10 seconds.

- `MaxBufferedEpochs` [1840]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.2.14	epochs	100	0 - 100000
Restart Type: N			

The number of unprocessed epochs by which a subscribing node can lag behind. Exceeding this number causes a lagging subscriber to be disconnected.

The default value of 100 is sufficient for most normal operations. If a subscribing node does lag enough to cause disconnections, it is usually due to network or scheduling issues with regard to

processes or threads. (In rare circumstances, the problem may be due to a bug in the NDB client.) It may be desirable to set the value lower than the default when epochs are longer.

Disconnection prevents client issues from affecting the data node service, running out of memory to buffer data, and eventually shutting down. Instead, only the client is affected as a result of the disconnect (by, for example gap events in the binary log), forcing the client to reconnect or restart the process.

- TimeBetweenInactiveTransactionAbortCheck [1841]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	milliseconds	1000	1000 - 4G
Restart Type: N			

Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction will be checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- TransactionInactiveTimeout [1841]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	milliseconds	4G	0 - 4G
Restart Type: N			

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is 4G (also the maximum). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a relatively small value. The unit is milliseconds.

- TransactionDeadlockDetectionTimeout [1841]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	milliseconds	1200	50 - 4G
Restart Type: N			

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. A failure to respond can occur for any of the following reasons:

- The node is “dead”
- The operation has entered a lock queue
- The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection. In MySQL 5.1.10 and earlier versions, setting it too high could cause undesirable behavior in situations involving deadlocks and node failure. Beginning with MySQL 5.1.11, active transactions occurring during node failures are actively aborted by the MySQL Cluster Transaction Coordinator, and so high settings are no longer an issue with this parameter.

The default timeout value is 1200 milliseconds (1.2 seconds).

Prior to MySQL Cluster NDB versions 6.2.18, 6.3.24, and 7.0.5, the effective minimum for this parameter was 100 milliseconds. (Bug #44099) Beginning with these versions, the actual minimum is 50 milliseconds.

- `DiskSyncSize` [1842]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1.12	bytes	4M	32K - 4G
Restart Type: N			

This is the maximum number of bytes to store before flushing data to a local checkpoint file. This is done to prevent write buffering, which can impede performance significantly. This parameter is *not* intended to take the place of `TimeBetweenLocalCheckpoints` [1839].

Note

When `ODirect` [1833] is enabled, it is not necessary to set `DiskSyncSize` [1842]; in fact, in such cases its value is simply ignored.

The default value is 4M (4 megabytes).

This parameter was added in MySQL 5.1.12.

- `DiskCheckpointSpeed` [1842]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1.12	bytes	10M	1M - 4G
Restart Type: N			

The amount of data,in bytes per second, that is sent to disk during a local checkpoint. This allocation is shared by DML operations and backups (but not backup logging), which means that backups started during times of intensive DML may be impaired by flooding of the redo log buffer and may fail altogether if the contention is sufficiently severe.

The default value is 10M (10 megabytes per second).

This parameter was added in MySQL 5.1.12.

- `DiskCheckpointSpeedInRestart` [1842]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	bytes	100M	1M - 4G
Restart Type: N			

The amount of data,in bytes per second, that is sent to disk during a local checkpoint as part of a restart operation.

The default value is 100M (100 megabytes per second).

This parameter was added in MySQL 5.1.12.

- `NoOfDiskPagesToDiskAfterRestartTUP` [1842]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	8K pages/100 milliseconds	40	1 - 4G
Restart Type: N			

When executing a local checkpoint, the algorithm flushes all data pages to disk. Merely doing so as quickly as possible without any moderation is likely to impose excessive loads on processors, networks, and disks. To control the write speed, this parameter specifies how many pages per 100 milliseconds are to be written. In this context, a “page” is defined as 8KB. This parameter is specified in units of 80KB per second, so setting `NoOfDiskPagesToDiskAfterRestartTUP` [1842] to a value of `20` entails writing 1.6MB in data pages to disk each second during a local checkpoint. This value includes the writing of UNDO log records for data pages. That is, this parameter handles the limitation of writes from data memory. (See the entry for `IndexMemory` [1819] for information about index pages.)

In short, this parameter specifies how quickly to execute local checkpoints. It operates in conjunction with `NoOfFragmentLogFiles` [1826], `DataMemory` [1817], and `IndexMemory` [1819].

For more information about the interaction between these parameters and possible strategies for choosing appropriate values for them, see Configuring MySQL Cluster Parameters for Local Checkpoints.

The default value is 40 (3.2MB of data pages per second).

Note

This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use DiskCheckpointSpeed [1842] and DiskSyncSize [1842] instead.

- `NoOfDiskPagesToDiskAfterRestartACC` [1843]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	8K pages/100 milliseconds	20	1 - 4G
Restart Type: N			

This parameter uses the same units as `NoOfDiskPagesToDiskAfterRestartTUP` [1842] and acts in a similar fashion, but limits the speed of writing index pages from index memory.

The default value of this parameter is 20 (1.6MB of index memory pages per second).

Note

This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use DiskCheckpointSpeed [1842] and DiskSyncSize [1842].

- `NoOfDiskPagesToDiskDuringRestartTUP` [1843] (DEPRECATED)

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	8K pages/100 milliseconds	40	1 - 4G
Restart Type: N			

This parameter is used in a fashion similar to `NoOfDiskPagesToDiskAfterRestartTUP` [1842] and `NoOfDiskPagesToDiskAfterRestartACC` [1843], only it does so with regard to local checkpoints executed in the node when a node is restarting. A local checkpoint is always performed as part of all node restarts. During a node restart it is possible to write to disk at a higher speed than at other times, because fewer activities are being performed in the node.

This parameter covers pages written from data memory.

The default value is 40 (3.2MB per second).

Note

This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use `DiskCheckpointSpeedInRestart` [1842] and `DiskSyncSize` [1842].

- `NoOfDiskPagesToDiskDuringRestartACC` [1844] (DEPRECATED)

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	8K pages/100 milliseconds	20	1 - 4G
Restart Type: N			

Controls the number of index memory pages that can be written to disk during the local checkpoint phase of a node restart.

As with `NoOfDiskPagesToDiskAfterRestartTUP` [1842] and `NoOfDiskPagesToDiskAfterRestartACC` [1843], values for this parameter are expressed in terms of 8KB pages written per 100 milliseconds (80KB/second).

The default value is 20 (1.6MB per second).

Note

This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use DiskCheckpointSpeedInRestart [1842] and DiskSyncSize [1842].

- `ArbitrationTimeout` [1844]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	milliseconds	3000	10 - 4G
NDB 7.2.0	milliseconds	7500	10 - 4G
Restart Type: N			

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

In MySQL Cluster NDB 7.2.0 and later, the default value is 7500 milliseconds (7.5 seconds). Previously, this was 3000 milliseconds (3 seconds).

- `Arbitration` [1844]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 7.0.7	enumeration	Default	Default, Disabled, WaitExternal
Restart Type: N			

The `Arbitration` [1844] parameter, added in MySQL Cluster NDB 7.0.7, enables a choice of arbitration schemes, corresponding to one of 3 possible values for this parameter:

- **`Default`.** This enables arbitration to proceed normally, as determined by the `ArbitrationRank` settings for the management and API nodes. This is the default value.
- **`Disabled`.** Previously, it was possible to disable arbitration only by setting `ArbitrationRank` to 0 on all management and API nodes. Now, you can now use `Arbitration = Disabled` in the `[ndbd default]` section of the `config.ini` file to accomplish this task. In this case, any `ArbitrationRank` settings are ignored.
- **`WaitExternal`.** The `Arbitration` [1844] parameter also makes it possible to configure arbitration in such a way that the cluster waits until after the time determined by `ArbitrationTimeout` [1844] has passed for an external cluster manager application to perform arbitration instead of handling arbitration internally. This can be done by setting `Arbitration = WaitExternal` in the `[ndbd default]` section of the `config.ini` file. For best results with the `WaitExternal` setting, it is recommended that `ArbitrationTimeout` [1844] be 2 times as long as the interval required by the external cluster manager to perform arbitration.

Important

This parameter should be used only in the `[ndbd default]` section of the cluster configuration file. The behavior of the cluster is unspecified when `Arbitration` [1844] is set to different values for individual data nodes.

Buffering and logging. Several `[ndbd]` configuration parameters enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the `NDB` storage engine's file system abstraction layer.

- `UndoIndexBuffer` [1845]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	unsigned	2M	1M - 4G
Restart Type: N			

The UNDO index buffer, whose size is set by this parameter, is used during local checkpoints. The `NDB` storage engine uses a recovery scheme based on checkpoint consistency in conjunction with an operational REDO log. To produce a consistent checkpoint without blocking the entire system for writes, UNDO logging is done while performing the local checkpoint. UNDO logging is activated on a single table fragment at a time. This optimization is possible because tables are stored entirely in main memory.

The UNDO index buffer is used for the updates on the primary key hash index. Inserts and deletes rearrange the hash index; the NDB storage engine writes UNDO log records that map all physical changes to an index page so that they can be undone at system restart. It also logs all active insert operations for each fragment at the start of a local checkpoint.

Reads and updates set lock bits and update a header in the hash index entry. These changes are handled by the page-writing algorithm to ensure that these operations need no UNDO logging.

This buffer is 2MB by default. The minimum value is 1MB, which is sufficient for most applications. For applications doing extremely large or numerous inserts and deletes together with large transactions and large primary keys, it may be necessary to increase the size of this buffer. If this buffer is too small, the NDB storage engine issues internal error code 677 (`Index UNDO buffers overloaded`).

Important

It is not safe to decrease the value of this parameter during a rolling restart.

- `UndoDataBuffer` [1846]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	unsigned	16M	1M - 4G
Restart Type: N			

This parameter sets the size of the UNDO data buffer, which performs a function similar to that of the UNDO index buffer, except the UNDO data buffer is used with regard to data memory rather than index memory. This buffer is used during the local checkpoint phase of a fragment for inserts, deletes, and updates.

Because UNDO log entries tend to grow larger as more operations are logged, this buffer is also larger than its index memory counterpart, with a default value of 16MB.

This amount of memory may be unnecessarily large for some applications. In such cases, it is possible to decrease this size to a minimum of 1MB.

It is rarely necessary to increase the size of this buffer. If there is such a need, it is a good idea to check whether the disks can actually handle the load caused by database update activity. A lack of sufficient disk space cannot be overcome by increasing the size of this buffer.

If this buffer is too small and gets congested, the NDB storage engine issues internal error code 891 (`Data UNDO buffers overloaded`).

Important

It is not safe to decrease the value of this parameter during a rolling restart.

- `RedoBuffer` [1846]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	bytes	8M	1M - 4G
NDB 7.0.4	bytes	32M	1M - 4G
Restart Type: N			

All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

RedoBuffer [1846] sets the size of the buffer in which the REDO log is written. In MySQL Cluster NDB 6.4.3 and earlier, the default value is 8MB; beginning with MySQL Cluster NDB 7.0.4, the default is 32MB. The minimum value is 1MB.

If this buffer is too small, the NDB storage engine issues error code 1221 (REDO log buffers overloaded). For this reason, you should exercise care if you attempt to decrease the value of RedoBuffer [1846] as part of an online change in the cluster's configuration.

Controlling log messages. In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to stdout. For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to stdout; setting it to 0 means that there will be no event reports made in that category.

By default, only the startup message is sent to stdout, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server's cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

- LogLevelStartup [1847]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	1	0 - 15
Restart Type: N			

The reporting level for events generated during startup of the process.

The default level is 1.

- LogLevelShutdown [1847]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	0	0 - 15
Restart Type: N			

The reporting level for events generated as part of graceful shutdown of a node.

The default level is 0.

- LogLevelStatistic [1847]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	0	0 - 15
Restart Type: N			

The reporting level for statistical events such as number of primary key reads, number of updates, number of inserts, information relating to buffer usage, and so on.

The default level is 0.

- LogLevelCheckpoint [1847]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	log level	0	0 - 15
Restart Type: IN			

The reporting level for events generated by local and global checkpoints.

The default level is 0.

- `LogLevelNodeRestart` [1848]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	0	0 - 15
Restart Type: N			

The reporting level for events generated during node restart.

The default level is 0.

- `LogLevelConnection` [1848]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	0	0 - 15
Restart Type: N			

The reporting level for events generated by connections between cluster nodes.

The default level is 0.

- `LogLevelError` [1848]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	0	0 - 15
Restart Type: N			

The reporting level for events generated by errors and warnings by the cluster as a whole. These errors do not cause any node failure but are still considered worth reporting.

The default level is 0.

- `LogLevelCongestion` [1848]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	levelr	0	0 - 15
Restart Type: N			

The reporting level for events generated by congestion. These errors do not cause node failure but are still considered worth reporting.

The default level is 0.

- `LogLevelInfo` [1849]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	integer	0	0 - 15
Restart Type: N			

The reporting level for events generated for information about the general state of the cluster.

The default level is 0.

- `MemReportFrequency` [1849]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.1.0	unsigned	0	0 - 4G
MySQL 5.1.16	unsigned	0	0 - 4G
Restart Type: N			

This parameter controls how often data node memory usage reports are recorded in the cluster log; it is an integer value representing the number of seconds between reports.

Each data node's data memory and index memory usage is logged as both a percentage and a number of 32 KB pages of the `DataMemory` [1817] and `IndexMemory` [1819], respectively, set in the `config.ini` file. For example, if `DataMemory` [1817] is equal to 100 MB, and a given data node is using 50 MB for data memory storage, the corresponding line in the cluster log might look like this:

```
2006-12-24 01:18:16 [MgmSrvr] INFO -- Node 2: Data usage is 50%(1280 32K pages of total 2560)
```

`MemReportFrequency` [1849] is not a required parameter. If used, it can be set for all cluster data nodes in the `[ndbd default]` section of `config.ini`, and can also be set or overridden for individual data nodes in the corresponding `[ndbd]` sections of the configuration file. The minimum value—which is also the default value—is 0, in which case memory reports are logged only when memory usage reaches certain percentages (80%, 90%, and 100%), as mentioned in the discussion of statistics events in MySQL Cluster Log Events.

This parameter was added in MySQL Cluster 5.1.16 and MySQL Cluster NDB 6.1.0.

- `StartupStatusReportFrequency` [1849]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.4.0	seconds	[none]	...
Restart Type: N			

When a data node is started with the `--initial` [1954], it initializes the redo log file during Start Phase 4 (see Summary of MySQL Cluster Start Phases). When very large values are set for `NoOfFragmentLogFiles` [1826], `FragmentLogFileSize` [1826], or both, this initialization can take a long time. Previous to MySQL Cluster NDB 6.4.0, only the beginning and end of the redo log file initialization process were logged. Beginning with this version, it is possible to force reports on the progress of this process to be logged periodically, by means of the `StartupStatusReportFrequency` [1849] configuration parameter. In this case, progress is reported in the cluster log, in terms of both the number of files and the amount of space that have been initialized, as shown here:

```
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 1: Local redo log file initialization status:
```

```
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15557
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 2: Local redo log file initialization status:
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15570
```

These reports are logged each `StartupStatusReportFrequency` [1849] seconds during Start Pahe 4. If `StartupStatusReportFrequency` [1849] is 0 (the default), then reports are written to the cluster log only when at the beginning and at the completion of the redo log file initialization process.

Debugging Parameters. Beginning with MySQL Cluster NDB 6.3.36, MySQL Cluster NDB 7.0.17, and MySQL Cluster NDB 7.1.6, it is possible to cause logging of traces for events generated by creating and dropping tables using `DictTrace`. This parameter is useful only in debugging NDB kernel code. `DictTrace` takes an integer value; currently, 0 (default - no logging) and 1 (logging enabled) are the only supported values.

Backup parameters. The `[ndbd]` parameters discussed in this section define memory buffers set aside for execution of online backups.

- `BackupDataBufferSize` [1850]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	bytes	2M	0 - 4G
NDB 6.3.23	bytes	16M	0 - 4G
NDB 7.0.4	bytes	16M	0 - 4G
Restart Type: N			

In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node's tables. Once this buffer has been filled to the level specified as `BackupWriteSize` [1851], the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freed up memory so that scanning may continue.

In MySQL Cluster NDB 6.4.3 and earlier, the default value is 2MB; in MySQL Cluster NDB 7.0.4 and later, it is 16MB.

- `BackupLogBufferSize` [1850]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	bytes	2M	0 - 4G
NDB 6.3.23	bytes	16M	0 - 4G
NDB 7.0.4	bytes	16M	0 - 4G
Restart Type: N			

The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See Configuration for MySQL Cluster Backups.

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer

to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

In MySQL Cluster NDB 6.4.3 and earlier, the default value is 2MB; in MySQL Cluster NDB 7.0.4 and later, it is 16MB.

- `BackupMemory` [1851]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	bytes	4M	0 - 4G
NDB 7.0.4	bytes	32M	0 - 4G
Restart Type: N			

This parameter is simply the sum of `BackupDataBufferSize` [1850] and `BackupLogBufferSize` [1850].

In MySQL Cluster NDB 7.0.4 and later, the default value is 16MB + 16MB = 32MB. (Previously, it was 2MB + 2MB = 4MB.)

Important

If `BackupDataBufferSize` [1850] and `BackupLogBufferSize` [1850] taken together exceed the default value for `BackupMemory` [1851], then this parameter must be set explicitly in the `config.ini` file to their sum.

- `BackupReportFrequency` [1851]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.2.3	seconds	0	0 - 4G
Restart Type: N			

This parameter controls how often backup status reports are issued in the management client during a backup, as well as how often such reports are written to the cluster log (provided cluster event logging is configured to permit it—see Logging and checkpointing). `BackupReportFrequency` [1851] represents the time in seconds between backup status reports.

The default value is 0.

This parameter was added in MySQL Cluster NDB 6.2.3.

- `BackupWriteSize` [1851]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	bytes	32K	2K - 4G
NDB 7.0.4	bytes	256K	2K - 4G
Restart Type: N			

This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

In MySQL Cluster 6.4.3 and earlier, the default value for this parameter was 32KB; beginning with MySQL Cluster NDB 7.0.4, it is 256KB.

- `BackupMaxWriteSize` [1852]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	bytes	256K	2K - 4G
MySQL 5.1.32	bytes	1M	2K - 4G
NDB 7.2.1	bytes	1M	2K - 4G
Restart Type: N			

This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

In MySQL Cluster 6.4.3 and earlier, the default value for this parameter was 256KB; beginning with MySQL Cluster NDB 7.0.4, it is 1MB.

Important

When specifying these parameters, the following relationships must hold true. Otherwise, the data node will be unable to start.

- `BackupDataBufferSize >= BackupWriteSize + 188KB`
- `BackupLogBufferSize >= BackupWriteSize + 16KB`
- `BackupMaxWriteSize >= BackupWriteSize`

MySQL Cluster Realtime Performance Parameters

The `[ndbd]` parameters discussed in this section are used in scheduling and locking of threads to specific CPUs on multiprocessor data node hosts. They were introduced in MySQL Cluster NDB 6.3.4.

Note

To make use of these parameters, the data node process must be run as system root.

- `LockExecuteThreadToCPU` [1852]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.3.4	CPU ID	64K	0 - 64K
Restart Type: N			

Previous to MySQL Cluster NDB 7.0. This parameter specifies the ID of the CPU assigned to handle the `NDBCLUSTER` execution thread. The value of this parameter is an integer in the range 0 to 65535 (inclusive). The default is 65535.

MySQL Cluster NDB 7.0 and later (beginning with MySQL Cluster NDB 6.4.0). When used with `ndbd`, this parameter (now a string) specifies the ID of the CPU assigned to handle the `NDBCLUSTER` execution thread.

When used with `ndbmtd`, the value of this parameter is a comma-separated list of CPU IDs assigned to handle execution threads. Each CPU ID in the list should be an integer in the range 0 to 65535 (inclusive). The number of IDs specified should match the number of execution threads determined

by MaxNoOfExecutionThreads [1855]. However, there is no guarantee that threads are assigned to CPUs in any given order when using this parameter; beginning with in MySQL Cluster NDB 7.0.31 and MySQL Cluster NDB 7.1.20, you can obtain more finely-grained control of this type using ThreadConfig.

LockExecuteThreadToCPU [1852] has no default value.

Prior to MySQL Cluster NDB 7.0.18 and MySQL Cluster NDB 7.1.7, the effective maximum value recognized by this parameter as a valid CPU ID was 255; using a greater value caused thread locking to be disabled. (Bug #56185)

- LockMaintThreadsToCPU [1853]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.3.4	CPU ID	64K	0 - 64K
NDB 6.4.0	CPU ID	[none]	0 - 64K
Restart Type: N			

This parameter specifies the ID of the CPU assigned to handle NDBCLUSTER maintenance threads.

The value of this parameter is an integer in the range 0 to 65535 (inclusive). This parameter was added in MySQL Cluster NDB 6.3.4. Prior to MySQL Cluster NDB 6.4.0, the default is 65535; in MySQL Cluster NDB 7.0 and later MySQL Cluster release series, there is no default value.

- RealtimeScheduler [1853]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.3.4	boolean	false	true, false
Restart Type: N			

Setting this parameter to 1 enables real-time scheduling of NDBCLUSTER threads.

The default is 0 (scheduling disabled).

- SchedulerExecutionTimer [1853]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.3.4	µsec	50	0 - 11000
Restart Type: N			

This parameter specifies the time in microseconds for threads to be executed in the scheduler before being sent. Setting it to 0 minimizes the response time; to achieve higher throughput, you can increase the value at the expense of longer response times.

The default is 50 µsec, which our testing shows to increase throughput slightly in high-load cases without materially delaying requests.

This parameter was added in MySQL Cluster NDB 6.3.4.

- SchedulerSpinTimer [1853]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.3.4	µsec	0	0 - 500

Effective Version	Type/Units	Default	Range or Permitted Values
Restart Type: N			

This parameter specifies the time in microseconds for threads to be executed in the scheduler before sleeping.

The default value is 0.

- `BuildIndexThreads` [1854]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.3.30	numeric	0	0 - 128
NDB 7.0.11	numeric	0	0 - 128
Restart Type: S			

This parameter determines the number of threads to create when rebuilding indexes during a system or node start. It is supported only when there is more than one fragment for the table per data node (for example, when the `MAX_ROWS` option has been used with `CREATE TABLE`).

Setting this parameter to 0 (which is also the default value) disables multi-threaded building of ordered indexes. The maximum allowed value is 128.

This parameter was added in MySQL Cluster NDB 6.3.30 and MySQL Cluster NDB 7.0.11. Prior to MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5, it was supported only when using `ndbd`; in these and later MySQL Cluster releases, `BuildIndexThreads` [1854] is also supported for data nodes running `ndbmtd` (see Bug #54521).

Prior to MySQL Cluster NDB 7.1.11, multi-threaded building of ordered indexes was not supported during node initial restarts. Starting with MySQL Cluster NDB 7.1.11, you can enable multi-threaded builds during data node initial restarts by setting the `TwoPassInitialNodeRestartCopy` [1854] data node configuration parameter to `TRUE`.

- `TwoPassInitialNodeRestartCopy` [1854]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 7.1.11	boolean	false	true, false
Restart Type: N			

In MySQL Cluster NDB 7.1.11 and later, multi-threaded building of ordered indexes can be enabled for initial restarts of data nodes by setting this configuration parameter to `TRUE`, which enables two-pass copying of data during initial node restarts.

You must also set `BuildIndexThreads` [1854] to a nonzero value.

- `Numa` [1854]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 7.0.20	boolean	false	...
NDB 7.1.9	boolean	false	...
Restart Type: N			

NDB is extremely sensitive to Non-Uniform Memory Access settings and multi-CPU systems due to timeouts that it can cause. Due to this fact, and because most MySQL Cluster users do not employ numactl, support for NUMA is ignored by default by ndbd when running on a Linux system. If your Linux system provides NUMA support and you wish for data node memory to be subject to NUMA control, you can set this parameter equal to 0.

The Numa [1854] configuration parameter is supported only on Linux systems where libnuma.so is installed.

Multi-Threading Configuration Parameters (ndbmtd). ndbmtd runs by default as a single-threaded process and must be configured to use multiple threads, using the MaxNoOfExecutionThreads [1855] configuration parameter. The next few paragraphs provide more information about this parameter and its use with multi-threaded data nodes.

MaxNoOfExecutionThreads

Restart Type	node	
	Permitted Values	
	Type	numeric
	Default	
	Range	2 .. 8
	Permitted Values	
	Type	numeric
	Default	2
	Range	2 .. 8
	Permitted Values	
	Type	numeric
	Default	2
	Range	2 .. 36

This parameter is used to determine the number of local query handler (LQH) threads spawned by ndbmtd. Although this parameter is set in [ndbd] or [ndbd default] sections of the config.ini file, it is exclusive to ndbmtd and does not apply to ndbd.

This parameter takes an integer value from 2 to 8 inclusive. Generally, you should set this parameter equal to the number of CPU cores on the data node host, as shown in the following table:

Number of Cores	Recommended MaxNoOfExecutionThreads [1855] Value
2	2
4	4
8 or more	8

(It is possible to set this parameter to other values within the permitted range, but these are automatically rounded as shown in the **Value Used** column of the next table in this section.)

The multi-threaded data node process always spawns at least 4 threads, listed here:

- 1 local query handler (LQH) thread
- 1 transaction coordinator (TC) thread
- 1 transporter thread
- 1 subscription manager (SUMA) thread

Setting this parameter to a value between 4 and 8 inclusive causes additional LQH threads to be used by `ndbmtd` (up to a maximum of 4 LQH threads), as shown in the following table:

`config.ini` Value	Value Used	Number of LQH Threads Used
3	2	1
5 or 6	4	2
7	8	4

Setting this parameter outside the permitted range of values causes the management server to abort on startup with the error `Error line number: Illegal value value for parameter MaxNoOfExecutionThreads`.

This parameter has a default value of 2.

Currently it is not possible to cause `ndbmtd` to use more than 1 TC thread, although we plan to introduce this capability in a future MySQL Cluster release series.

Disk Data Configuration Parameters. Configuration parameters affecting Disk Data behavior include the following:

- `DiskPageBufferMemory` [1856]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1.6	bytes	64M	4M - 1T
Restart Type: N			

This determines the amount of space used for caching pages on disk, and is set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` file. It is measured in bytes. Each page takes up 32 KB. This means that Cluster Disk Data storage always uses *`N`* * 32 KB memory where *`N`* is some nonnegative integer.

The default value for this parameter is `64M` (2000 pages of 32 KB each).

This parameter was added in MySQL 5.1.6.

Beginning with MySQL Cluster NDB 7.1.9, you can query the `ndbinfo.diskpagebuffer` table to help determine whether the value for this parameter should be increased to minimize unnecessary disk seeks. See The `ndbinfo diskpagebuffer` Table, for more information.

- `SharedGlobalMemory` [1856]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 7.2.0	bytes	128M	0 - 64T
MySQL 5.1.6	bytes	20M	0 - 64T
Restart Type: N			

This parameter determines the amount of memory that is used for log buffers, disk operations (such as page requests and wait queues), and metadata for tablespaces, log file groups, `UNDO` files, and data files. The shared global memory pool also provides memory used for satisfying the memory requirements of the `INITIAL_SIZE` and `UNDO_BUFFER_SIZE` options used with `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statements, including any default value implied for these options by the setting of the `InitialLogFileGroup` [1859] data node configuration parameter. `SharedGlobalMemory` can be set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` configuration file, and is measured in bytes.

As of MySQL Cluster NDB 7.2.0, the default value is `128M`. (Previously, this was `20M`.)

This parameter was added in MySQL 5.1.6.

- `DiskIOThreadPool` [1857]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.4.3	threads	8	0 - 4G
NDB 7.0.7	threads	2	0 - 4G
NDB 7.1.0	threads	2	0 - 4G
Restart Type: N			

This parameter determines the number of unbound threads used for Disk Data file access. Before `DiskIOThreadPool` [1857] was introduced, exactly one thread was spawned for each Disk Data file, which could lead to performance issues, particularly when using very large data files. With `DiskIOThreadPool` [1857], you can—for example—access a single large data file using several threads working in parallel.

Currently, this parameter applies to Disk Data I/O threads only, but we plan in the future to make the number of such threads configurable for in-memory data as well.

The optimum value for this parameter depends on your hardware and configuration, and includes these factors:

- **Physical distribution of Disk Data files.** You can obtain better performance by placing data files, undo log files, and the data node file system on separate physical disks. If you do this with some or all of these sets of files, then you can set `DiskIOThreadPool` [1857] higher to enable separate threads to handle the files on each disk.
- **Disk performance and types.** The number of threads that can be accommodated for Disk Data file handling is also dependent on the speed and throughput of the disks. Faster disks and higher throughput allow for more disk I/O threads. Our test results indicate that solid-state disk drives can handle many more disk I/O threads than conventional disks, and thus higher values for `DiskIOThreadPool` [1857].

This parameter was added in MySQL Cluster NDB 6.4.0. Previous to MySQL Cluster NDB 6.4.3, it was named `ThreadPool`. Previous to MySQL Cluster NDB 7.0.7, the default value was 8. Beginning with MySQL Cluster NDB 7.0.7 and MySQL Cluster NDB 7.1.0, the default is 2.

- **Disk Data file system parameters.** The parameters in the following list were added in MySQL Cluster NDB 6.2.17, 6.3.22, and 6.4.3 to make it possible to place MySQL Cluster Disk Data files in specific directories without the need for using symbolic links.

  - `FileSystemPathDD` [1857]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.3.22	filename	[see text]	...
NDB 6.2.17	filename	[see text]	...
NDB 6.4.3	filename	[see text]	...
Restart Type: IN			

If this parameter is specified, then MySQL Cluster Disk Data data files and undo log files are placed in the indicated directory. This can be overridden for data files, undo log files, or both, by specifying values for `FileSystemPathDataFiles` [1858],

FileSystemPathUndoFiles [1858], or both, as explained for these parameters. It can also be overridden for data files by specifying a path in the ADD DATAFILE clause of a CREATE TABLESPACE or ALTER TABLESPACE statement, and for undo log files by specifying a path in the ADD UNDOFILE clause of a CREATE LOGFILE GROUP or ALTER LOGFILE GROUP statement. If FileSystemPathDD [1857] is not specified, then FileSystemPath [1816] is used.

If a FileSystemPathDD [1857] directory is specified for a given data node (including the case where the parameter is specified in the [ndbd default] section of the config.ini file), then starting that data node with --initial causes all files in the directory to be deleted.

- FileSystemPathDataFiles [1858]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.3.22	filename	[see text]	...
NDB 6.2.17	filename	[see text]	...
NDB 6.4.3	filename	[see text]	...
Restart Type: IN			

If this parameter is specified, then MySQL Cluster Disk Data data files are placed in the indicated directory. This overrides any value set for FileSystemPathDD [1857]. This parameter can be overridden for a given data file by specifying a path in the ADD DATAFILE clause of a CREATE TABLESPACE or ALTER TABLESPACE statement used to create that data file. If FileSystemPathDataFiles [1858] is not specified, then FileSystemPathDD [1857] is used (or FileSystemPath [1816], if FileSystemPathDD [1857] has also not been set).

If a FileSystemPathDataFiles [1858] directory is specified for a given data node (including the case where the parameter is specified in the [ndbd default] section of the config.ini file), then starting that data node with --initial causes all files in the directory to be deleted.

- FileSystemPathUndoFiles [1858]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.3.22	filename	[see text]	...
NDB 6.2.17	filename	[see text]	...
NDB 6.4.3	filename	[see text]	...
Restart Type: IN			

If this parameter is specified, then MySQL Cluster Disk Data undo log files are placed in the indicated directory. This overrides any value set for FileSystemPathDD [1857]. This parameter can be overridden for a given data file by specifying a path in the ADD UNDO clause of a CREATE LOGFILE GROUP or CREATE LOGFILE GROUP statement used to create that data file. If FileSystemPathUndoFiles [1858] is not specified, then FileSystemPathDD [1857] is used (or FileSystemPath [1816], if FileSystemPathDD [1857] has also not been set).

If a FileSystemPathUndoFiles [1858] directory is specified for a given data node (including the case where the parameter is specified in the [ndbd default] section of the config.ini file), then starting that data node with --initial causes all files in the directory to be deleted.

For more information, see MySQL Cluster Disk Data Objects.

- **Disk Data object creation parameters.** The next two parameters enable you—when starting the cluster for the first time—to cause a Disk Data log file group, tablespace, or both, to be created without the use of SQL statements.

- `InitialLogFileGroup` [1859]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.3.22	string	[see text]	...
NDB 6.2.17	string	[see text]	...
NDB 6.4.3	string	[see text]	...
Restart Type: S			

This parameter can be used to specify a log file group that is created when performing an initial start of the cluster. `InitialLogFileGroup` [1859] is specified as shown here:

```
InitialLogFileGroup = [name=name;] [undo_buffer_size=size;] file-specification-list

file-specification-list:
    file-specification[; file-specification[; ...]]

file-specification:
    filename:size
```

The `name` of the log file group is optional and defaults to `DEFAULT-LG`. The `undo_buffer_size` is also optional; if omitted, it defaults to `64M`. Each *`file-specification`* corresponds to an undo log file, and at least one must be specified in the *`file-specification-list`*. Undo log files are placed according to any values that have been set for `FileSystemPath` [1816], `FileSystemPathDD` [1857], and `FileSystemPathUndoFiles` [1858], just as if they had been created as the result of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement.

Consider the following:

```
InitialLogFileGroup = name=LG1; undo_buffer_size=128M; undo1.log:250M; undo2.log:150M
```

This is equivalent to the following SQL statements:

```
CREATE LOGFILE GROUP LG1
    ADD UNDOFILE 'undo1.log'
    INITIAL_SIZE 250M
    UNDO_BUFFER_SIZE 128M
    ENGINE NDBCLUSTER;

ALTER LOGFILE GROUP LG1
    ADD UNDOFILE 'undo2.log'
    INITIAL_SIZE 150M
    ENGINE NDBCLUSTER;
```

This logfile group is created when the data nodes are started with `--initial`.

Resources for the initial log file group are taken from the global memory pool whose size is determined by the value of the `SharedGlobalMemory` [1856] data node configuration parameter; if this parameter is set too low and the values set in `InitialLogFileGroup` for the logfile group's initial size or undo buffer size are too high, the cluster may fail to create the default log file group when starting, or fail to start altogether.

This parameter, if used, should always be set in the `[ndbd default]` section of the `config.ini` file. The behavior of a MySQL Cluster when different values are set on different data nodes is not defined.

- `InitialTablespace` [1859]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.3.22	string	[see text]	...
NDB 6.2.17	string	[see text]	...
NDB 6.4.3	string	[see text]	...
Restart Type: S			

This parameter can be used to specify a MySQL Cluster Disk Data tablespace that is created when performing an initial start of the cluster. `InitialTablespace` [1859] is specified as shown here:

```
InitialTablespace = [name=name;] [extent_size=size;] file-specification-list
```

The `name` of the tablespace is optional and defaults to `DEFAULT-TS`. The `extent_size` is also optional; it defaults to `1M`. The *`file-specification-list`* uses the same syntax as shown with the `InitialLogfileGroup` [1859] parameter, the only difference being that each *`file-specification`* used with `InitialTablespace` [1859] corresponds to a data file. At least one must be specified in the *`file-specification-list`*. Data files are placed according to any values that have been set for `FileSystemPath` [1816], `FileSystemPathDD` [1857], and `FileSystemPathDataFiles` [1858], just as if they had been created as the result of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement.

For example, consider the following line specifying `InitialTablespace` [1859] in the `[ndbd default]` section of the `config.ini` file (as with `InitialLogfileGroup` [1859], this parameter should always be set in the `[ndbd default]` section, as the behavior of a MySQL Cluster when different values are set on different data nodes is not defined):

```
InitialTablespace = name=TS1; extent_size=8M; data1.dat:2G; data2.dat:4G
```

This is equivalent to the following SQL statements:

```
CREATE TABLESPACE TS1
    ADD DATAFILE 'data1.dat'
    EXTENT_SIZE 8M
    INITIAL_SIZE 2G
    ENGINE NDBCLUSTER;

ALTER TABLESPACE TS1
    ADD UNDOFILE 'data2.dat'
    INITIAL_SIZE 4G
    ENGINE NDBCLUSTER;
```

This tablespace is created when the data nodes are started with `--initial`, and can be used whenever creating MySQL Cluster Disk Data tables thereafter.

Disk Data and `GCP Stop` errors. Errors encountered when using Disk Data tables such as `Node` *`nodeid`* `killed this node because GCP stop was detected` (error 2303) are often referred to as “GCP stop errors”. Such errors occur when the redo log is not flushed to disk quickly enough; this is usually due to slow disks and insufficient disk throughput.

You can help prevent these errors from occurring by using faster disks, and by placing Disk Data files on a separate disk from the data node file system. Reducing the value of `TimeBetweenGlobalCheckpoints` [1839] tends to decrease the amount of data to be written for each global checkpoint, and so may provide some protection against redo log buffer overflows when trying to write a global checkpoint; however, reducing this value also permits less time in which to write the GCP, so this must be done with caution.

In addition, adjusting the cluster configuration as discussed here can also help:

- **MySQL Cluster NDB 6.2 and 6.3.** When working with large amounts of data on disk under high load, the default value for `DiskPageBufferMemory` [1856] may not be large enough. In such cases, you should increase its value to include most of the memory available to the data nodes after accounting for index memory, data memory, internal buffers, and memory needed by the data node host operating system.

  You can use this formula as a guide:

  ```
  DiskPageBufferMemory
    = 0.8
      x (
          [total memory]
            - ([operating system memory] + [buffer memory] + DataMemory + IndexMemory)
        )
  ```

  Once you have established that sufficient memory is reserved for `DataMemory` [1817], `IndexMemory` [1819], NDB internal buffers, and operating system overhead, it is possible (and sometimes desirable) to allocate more than the above amount of the remainder to `DiskPageBufferMemory` [1856].

- **MySQL Cluster NDB 7.X.** In addition to the considerations given for `DiskPageBufferMemory` [1856] as explained previously, it is also very important that the `DiskIOThreadPool` [1857] configuration parameter be set correctly; having `DiskIOThreadPool` [1857] set too high is very likely to cause GCP stop errors (Bug #37227).

GCP stops can be caused by save or commit timeouts; the `TimeBetweenEpochsTimeout` [1840] data node configuration parameter determines the timeout for commits. However, beginning with MySQL Cluster NDB 7.0.21 and MySQL Cluster NDB 7.1.10, it is possible to disable both types of timeouts by setting this parameter to 0.

Parameters for configuring send buffer memory allocation (MySQL Cluster NDB 7.0 and later). Beginning with MySQL Cluster NDB 6.4.0, send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. (Previously, the NDB kernel used a fixed-size send buffer for every node in the cluster, which was allocated when the node started and could not be changed while the node was running.) The following data node configuration parameters were added in MySQL Cluster NDB 6.4.0 to permit the setting of limits on this memory allocation; this change is reflected by the addition of the configuration parameters `TotalSendBufferMemory` [1861] and `OverLoadLimit` [1869], as well as a change in how the existing `SendBufferMemory` [1870] configuration parameter is used. For more information, see Configuring MySQL Cluster Send Buffer Parameters.

- `ExtraSendBufferMemory` [1861]

  This parameter specifies the amount of transporter send buffer memory to allocate in addition to any set using `TotalSendBufferMemory` [1861], `SendBufferMemory` [1870], or both.

  This parameter was added in MySQL Cluster NDB 7.0.31 and MySQL Cluster NDB 7.1.20. (Bug #13633845, Bug #11760629, Bug #53053)

- `TotalSendBufferMemory` [1861]

  This parameter is available beginning with MySQL Cluster NDB 6.4.0. It is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

  Prior to MySQL Cluster NDB 7.0.31 and MySQL Cluster NDB 7.1.20, this parameter did not work correctly with `ndbmtd`. (Bug #13633845)

  If this parameter is set, its minimum permitted value is 256KB; the maxmimum is 4294967039.

- `ReservedSendBufferMemory` [1861]

This parameter is present in NDBCLUSTER source code beginning with MySQL Cluster NDB 6.4.0. However, it is not currently enabled.

As of MySQL Cluster NDB 7.0.31 and MySQL Cluster NDB 7.1.20, this parameter is deprecated, and is subject to removal in a future release of MySQL Cluster (Bug #11760629, Bug #53053).

For more detailed information about the behavior and use of TotalSendBufferMemory [1861] and about configuring send buffer memory parameters in MySQL Cluster NDB 6.4.0 and later, see Configuring MySQL Cluster Send Buffer Parameters.

Note

Previous to MySQL Cluster NDB 7.0, to add new data nodes to a MySQL Cluster, it was necessary to shut down the cluster completely, update the config.ini file, and then restart the cluster (that is, you had to perform a system restart). All data node processes had to be started with the --initial [1954] option.

Beginning with MySQL Cluster NDB 7.0, it is possible to add new data node groups to a running cluster online. See Adding MySQL Cluster Data Nodes Online, for more information.

Redo log over-commit handling. Beginning with MySQL Cluster NDB 7.1.10, it is possible to control the data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than RedoOverCommitLimit [1862] seconds, more than RedoOverCommitCounter [1862] times, causing any pending transactions to be aborted. When this happens, the API node that sent the transaction can handle the operations that should have been committed either by queuing the operations and re-trying them, or by aborting them, as determined by DefaultOperationRedoProblemAction [1867]. The data node configuration parameters for setting the timeout and number of times it may be exceeded before the API node takes this action are described in the following list:

- RedoOverCommitCounter [1862]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 7.1.10	numeric	3	0 - 4G
Restart Type: N			

When RedoOverCommitLimit [1862] is exceeded when trying to write a given redo log to disk this many times or more, any transactions that were not committed as a result are aborted, and an API node where any of these transactions originated handles the operations making up those transactions according to its value for DefaultOperationRedoProblemAction [1867] (by either queuing the operations to be re-tried, or aborting them).

RedoOverCommitCounter defaults to 3. Set it to 0 to disable the limit. This parameter was added in MySQL Cluster NDB 7.1.10.

- RedoOverCommitLimit [1862]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 7.1.10	seconds	20	0 - 4G
Restart Type: N			

This parameter sets an upper limit in seconds for trying to write a given redo log to disk before timing out. The number of times the data node tries to flush this redo log, but takes longer than

RedoOverCommitLimit, is kept and compared with RedoOverCommitCounter [1862], and when flushing takes too long more times than the value of that parameter, any transactions that were not committed as a result of the flush timeout are aborted. When this occurs, the API node where any of these transactions originated handles the operations making up those transactions according to its DefaultOperationRedoProblemAction [1867] setting (it either queues the operations to be retried, or aborts them).

By default, RedoOverCommitLimit is 20 seconds. Set to 0 to disable checking for redo log flush timeouts. This parameter was added in MySQL Cluster NDB 7.1.10.

Controlling restart attempts. Beginning in MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.37, MySQL Cluster NDB 7.0.18, and MySQL Cluster NDB 7.1.7, it is possible to exercise more finely-grained control over restart attempts by data nodes when they fail to start using two data node configuration parameters added in these releases. MaxStartFailRetries [1863] limits the total number of retries made before giving up on starting the data node; StartFailRetryDelay [1863] sets the number of seconds between retry attempts, as described in the following list:

- StartFailRetryDelay [1863]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.3.37	unsigned	0	0 - 4G
NDB 7.0.18	unsigned	0	0 - 4G
NDB 7.1.7	unsigned	0	0 - 4G
NDB 6.2.19	unsigned	0	0 - 4G
Restart Type: N			

Beginning in MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.37, MySQL Cluster NDB 7.0.18, and MySQL Cluster NDB 7.1.7, it is possible to set the number of seconds between restart attempts by the data node in the event on failure on startup. The default is 0 (no delay).

Note

This parameter is ignored unless StopOnError [1832] is equal to 0.

- MaxStartFailRetries [1863]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.3.37	unsigned	3	0 - 4G
NDB 7.0.18	unsigned	3	0 - 4G
NDB 7.1.7	unsigned	3	0 - 4G
NDB 6.2.19	unsigned	3	0 - 4G
Restart Type: N			

Beginning in MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.37, MySQL Cluster NDB 7.0.18, and MySQL Cluster NDB 7.1.7, it is possible to limit the number restart attempts made by the data node in the event that it fails on startup. The default is 3 attempts.

Note

This parameter is ignored unless StopOnError [1832] is equal to 0.

The [mysqld] and [api] sections in the config.ini file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a [mysqld] section is used to indicate a MySQL server providing an SQL interface to the cluster, and an [api] section is used for applications other than mysqld processes accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an [api] section.

Note

For a discussion of MySQL server options for MySQL Cluster, see MySQL Server Options for MySQL Cluster; for information about MySQL server system variables relating to MySQL Cluster, see MySQL Cluster System Variables.

- Id

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	unsigned	[none]	1 - 63
NDB 6.1.1	unsigned	[none]	1 - 255
Restart Type: N			

The Id is an integer value used to identify the node in all cluster internal messages. Prior to MySQL Cluster NDB 6.1.1, the permitted range of values for this parameter was 1 to 63 inclusive. Beginning with MySQL Cluster NDB 6.1.1, the permitted range is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

Note

Data node IDs must be less than 49, regardless of the MySQL Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 48.

NodeId [1864] is the preferred parameter name to use when identifying management nodes beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.39, MySQL Cluster NDB 7.0.20, and MySQL Cluster NDB 7.1.9. Although Id continues to be supported for backward compatibility, it is now deprecated and generates a warning when used.

- NodeId

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	unsigned	[none]	1 - 63
NDB 6.1.1	unsigned	[none]	1 - 255
Restart Type: N			

The NodeId is an integer value used to identify the node in all cluster internal messages. Prior to MySQL Cluster NDB 6.1.1, the permitted range of values for this parameter was 1 to 63 inclusive. Beginning with MySQL Cluster NDB 6.1.1, the permitted range is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

Note

Data node IDs must be less than 49, regardless of the MySQL Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to

limit the node IDs for API nodes (and management nodes) to values greater than 48.

`NodeId` [1864] is the preferred parameter name to use when identifying management nodes beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.39, MySQL Cluster NDB 7.0.20, and MySQL Cluster NDB 7.1.9. Although `Id` continues to be supported for backward compatibility, it is now deprecated and generates a warning when used.

- `ExecuteOnComputer`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	name	[none]	...
Restart Type: S			

This refers to the `Id` set for one of the computers (hosts) defined in a `[computer]` section of the configuration file.

- `HostName`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	name or IP address	[none]	...
Restart Type: S			

Specifying this parameter defines the hostname of the computer on which the SQL node (API node) is to reside. To specify a hostname, either this parameter or `ExecuteOnComputer` is required.

If no `HostName` or `ExecuteOnComputer` is specified in a given `[mysql]` or `[api]` section of the `config.ini` file, then an SQL or API node may connect using the corresponding "slot" from any host which can establish a network connection to the management server host machine. *This differs from the default behavior for data nodes, where `localhost` is assumed for `HostName` unless otherwise specified*.

- `ArbitrationRank`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	0-2	0	0 - 2
Restart Type: N			

This parameter defines which nodes can act as arbitrators. Both MGM nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its `ArbitrationRank` to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

Beginning with MySQL 5.1.16 and MySQL Cluster NDB 6.1.3, it is possible to disable arbitration completely by setting `ArbitrationRank` to 0 on all management and SQL nodes. In MySQL Cluster NDB 7.0.7 and later releases, you can also control arbitration by overriding this parameter; to do this, set the `Arbitration` [1844] parameter in the `[ndbd default]` section of the `config.ini` global configuration file.

- `ArbitrationDelay`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	milliseconds	0	0 - 4G
Restart Type: N			

Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests will be delayed by the stated number of milliseconds. It is usually not necessary to change this value.

- `BatchByteSize` [1866]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	bytes	32K	1024 - 1M
NDB 7.2.1	bytes	16K	1024 - 1M
Restart Type: N			

For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records (`BatchSize` [1866]) and in terms of bytes (`BatchByteSize` [1866]). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set. In future releases, MySQL Server will make educated guesses on how to set parameters relating to batch size, based on the query type.

This parameter is measured in bytes and by default is equal to 32KB.

- `BatchSize` [1866]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	records	64	1 - 992
NDB 7.2.1	records	256	1 - 992
Restart Type: N			

This parameter is measured in number of records and is by default set to 64. The maximum size is 992.

- `HeartbeatThreadPriority` [1866]

Beginning with MySQL Cluster NDB 6.3.32, MySQL Cluster NDB 7.0.13, and MySQL Cluster NDB 7.1.2, it is possible to use this parameter to set the scheduling policy and priority of heartbeat threads for management and API nodes.

The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]

policy:
  {FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of `FIFO` (first in, first in) or `RR` (round robin). This followed optionally by the priority (an integer).

- `MaxScanBatchSize` [1866]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	bytes	256K	32K - 16M
Restart Type: N			

The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

- `TotalSendBufferMemory`

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.4.0	bytes	256K	0 - 4G
Restart Type: N			

This parameter is available beginning with MySQL Cluster NDB 6.4.0. It is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; the maxmimum is 4294967039. For more detailed information about the behavior and use of `TotalSendBufferMemory` and configuring send buffer memory parameters in MySQL Cluster NDB 6.4.0 and later, see Configuring MySQL Cluster Send Buffer Parameters.

- `AutoReconnect` [1867]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.3.26	boolean	false	true, false
NDB 7.0.7	boolean	false	true, false
Restart Type: N			

This parameter is available beginning with MySQL Cluster NDB 6.3.26 and MySQL Cluster NDB 7.0.7. By default, its value is `false`, which forces disconnected API nodes (including MySQL Servers acting as SQL nodes) the use a new connection to the cluster rather than attempting to re-use an existing one, which can cause problems when using dynamically-allocated node IDs. (Bug #45921)

Note

This parameter can be overridden using the NDB API. For more information, see `Ndb_cluster_connection::set_auto_reconnect()`, and `Ndb_cluster_connection::get_auto_reconnect()`.

- `DefaultOperationRedoProblemAction` [1867]

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 7.1.10	enumeration	[none]	ABORT, QUEUE
Restart Type: S			

This parameter was introduced in MySQL Cluster NDB 7.1.10 (along with `RedoOverCommitLimit` [1862] and `RedoOverCommitCounter` [1862]) for controlling the data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than `RedoOverCommitLimit` [1862] seconds, more than `RedoOverCommitCounter` [1862] times, causing any pending transactions to be aborted.

When this happens, the node can respond in either of two ways, according to the value of `DefaultOperationRedoProblemAction`, listed here:

- `ABORT`: Any pending operations from aborted transactions are also aborted.
- `QUEUE`: Pending operations from transactions that were aborted are queued up to be re-tried.

You can obtain some information from a MySQL server running as a Cluster SQL node using `SHOW STATUS` in the `mysql` client, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb%';
+-----------------------------+---------------+
| Variable_name               | Value         |
+-----------------------------+---------------+
| Ndb_cluster_node_id         | 5             |
| Ndb_config_from_host        | 192.168.0.112 |
| Ndb_config_from_port        | 1186          |
| Ndb_number_of_storage_nodes | 4             |
+-----------------------------+---------------+
4 rows in set (0.02 sec)
```

For information about these Cluster system status variables, see Server Status Variables.

Note

To add new SQL or API nodes to the configuration of a running MySQL Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

MySQL Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for all connections between nodes in a MySQL Cluster. Normally it is not necessary to define TCP/IP connections; MySQL Cluster automatically sets up such connections for all data nodes, management nodes, and SQL or API nodes.

Note

For an exception to this rule, see MySQL Cluster TCP/IP Connections Using Direct Connections.

To override the default connection parameters, it is necessary to define a connection using one or more `[tcp]` sections in the `config.ini` file. Each `[tcp]` section explicitly defines a TCP/IP connection between two MySQL Cluster nodes, and must contain at a minimum the parameters `NodeId1` [1869] and `NodeId2` [1869], as well as any connection parameters to override.

It is also possible to change the default values for these parameters by setting them in the `[tcp default]` section.

Important

Any `[tcp]` sections in the `config.ini` file should be listed *last*, following all other sections in the file. However, this is not required for a `[tcp default]` section. This requirement is a known issue with the way in which the `config.ini` file is read by the MySQL Cluster management server.

Connection parameters which can be set in `[tcp]` and `[tcp default]` sections of the `config.ini` file are listed here:

- `NodeId1`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	numeric	[none]	...
Restart Type: N			

`NodeId2`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	numeric	[none]	...
Restart Type: N			

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file. These are the same unique `NodeId` (or `Id`) values for each of these nodes as described in Defining SQL and Other API Nodes in a MySQL Cluster.

- `HostName1`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	name or IP address	[none]	...
Restart Type: N			

`HostName2`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	name or IP address	[none]	...
Restart Type: N			

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be hostnames or IP addresses.

- `OverloadLimit`

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.4.0	bytes	0	0 - 4G
Restart Type: N			

Beginning in MySQL Cluster NDB 6.4.0, this parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See Configuring MySQL Cluster Send Buffer Parameters, for more information.

Prior to MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, the effective value of this parameter was limited by the size of `SendBufferMemory` [1870]; beginning with these releases, the actual value for `OverloadLimit` (up to the stated maximum of 4G) is used instead.

- `SendBufferMemory` [1870]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	unsigned	256K	64K - 4G
NDB 7.0.4	unsigned	2M	256K - 4G
Restart Type: N			

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer.

Prior to MySQL Cluster NDB 7.0, this parameter determines a fixed amount of memory allocated at startup for each configured TCP connection. Beginning with MySQL Cluster NDB 6.4.0, if this parameter is set explicitly, then the memory is not dedicated to each transporter; instead, the value used denotes the hard limit for how much memory (out of the total available memory—that is, `TotalSendBufferMemory`) that may be used by a single transporter. For more information about configuring dynamic transporter send buffer memory allocation in MySQL Cluster NDB 7.0 and later, see Configuring MySQL Cluster Send Buffer Parameters.

In MySQL Cluster NDB 6.4.3 and earlier, the default size of the send buffer was 256 KB; in MySQL Cluster NDB 7.0.4 and later, it is 2MB, which is the size recommended in most situations. The minimum size is 64 KB; the theoretical maximum is 4 GB.

- `SendSignalId`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	boolean	[see text]	true, false
Restart Type: N			

To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- `Checksum`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	boolean	false	true, false
Restart Type: N			

This parameter is a boolean parameter (enabled by setting it to `Y` or `1`, disabled by setting it to `N` or `0`). It is disabled by default. When it is enabled, checksums for all messages are calculated before they placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

- `PortNumber` (*OBSOLETE*)

  This formerly specified the port number to be used for listening for connections from other nodes. This parameter should no longer be used; use the `ServerPort` [1814] data node configuration parameter for this purpose instead.

- `ReceiveBufferMemory` [1871]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	bytes	64K	16K - 4G
NDB 7.0.4	bytes	2M	16K - 4G
Restart Type: N			

  Specifies the size of the buffer used when receiving data from the TCP/IP socket.

  In MySQL Cluster NDB 6.4.3 and earlier, the default value of this parameter was 64 KB; beginning with MySQL Cluster NDB 7.0.4, 2MB is the default. The minimum possible value is 16KB; the theoretical maximum is 4GB.

MySQL Cluster TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the `[tcp]` section of the cluster `config.ini` file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the `172.23.72.*` subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the `1.1.0.*` address range as shown:

```
# Management Server
[ndb_mgmd]
Id=1
HostName=172.23.72.20

# SQL Node
[mysqld]
Id=2
HostName=172.23.72.21

# Data Nodes
[ndbd]
Id=3
HostName=172.23.72.22

[ndbd]
Id=4
HostName=172.23.72.23

# TCP/IP Connections
[tcp]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
HostName2=1.1.0.2
```

The `HostName1` [1869] and `HostName2` [1869] parameters are used only when specifying direct connections.

The use of direct TCP connections between data nodes can improve the cluster's overall efficiency by enabling the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency. It is important to note that to take the best advantage of direct

connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.

MySQL Cluster Shared-Memory Connections

MySQL Cluster attempts to use the shared memory transporter and configure it automatically where possible. `[shm]` sections in the `config.ini` file explicitly define shared-memory connections between nodes in the cluster. When explicitly defining shared memory as the connection method, it is necessary to define at least `NodeId1` [1872], `NodeId2` [1872], and `ShmKey` [1873]. All other parameters have default values that should work well in most cases.

Important

SHM functionality is considered experimental only. It is not officially supported in any current MySQL Cluster release, and testing results indicate that SHM performance is not appreciably greater than when using TCP/IP for the transporter.

For these reasons, you must determine for yourself or by using our free resources (forums, mailing lists) whether SHM can be made to work correctly in your specific case.

- `NodeId1`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	numeric	[none]	...
Restart Type: N			

`NodeId2`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	numeric	[none]	...
Restart Type: N			

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `HostName1`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	name or IP address	[none]	...
Restart Type: N			

`HostName2`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	name or IP address	[none]	...
Restart Type: N			

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be hostnames or IP addresses.

- ShmKey [1873]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	unsigned	[none]	0 - 4G
Restart Type: N			

When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value.

- ShmSize [1873]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	bytes	1M	64K - 4G
Restart Type: N			

Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by ShmSize [1873]. The default value is 1MB.

- SendSignalId

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	boolean	false	true, false
Restart Type: N			

To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to Y causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in -debug builds.

- Checksum

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	boolean	true	true, false
Restart Type: N			

This parameter is a boolean (Y/N) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.

This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- SigNum [1873]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	unsigned	[none]	0 - 4G
Restart Type: N			

When using the shared memory transporter, a process sends an operating system signal to the other process when there is new data available in the shared memory. Should that signal conflict with with

an existing signal, this parameter can be used to change it. This is a possibility when using SHM due to the fact that different operating systems use different signal numbers.

The default value of `SigNum` [1873] is 0; therefore, it must be set to avoid errors in the cluster log when using the shared memory transporter. Typically, this parameter is set to 10 in the `[shm default]` section of the `config.ini` file.

SCI Transport Connections in MySQL Cluster

`[sci]` sections in the `config.ini` file explicitly define SCI (Scalable Coherent Interface) connections between cluster nodes. Using SCI transporters in MySQL Cluster is supported only when the MySQL binaries are built using `--with-ndb-sci=/your/path/to/SCI`. The *`path`* should point to a directory that contains at a minimum `lib` and `include` directories containing SISCI libraries and header files. (See Using High-Speed Interconnects with MySQL Cluster for more information about SCI.)

In addition, SCI requires specialized hardware.

It is strongly recommended to use SCI Transporters only for communication between `ndbd` processes. Note also that using SCI Transporters means that the `ndbd` processes never sleep. For this reason, SCI Transporters should be used only on machines having at least two CPUs dedicated for use by `ndbd` processes. There should be at least one CPU per `ndbd` process, with at least one CPU left in reserve to handle operating system activities.

- `NodeId1`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	numeric	[none]	...
Restart Type: N			

`NodeId2`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	numeric	[none]	...
Restart Type: N			

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `Host1SciId0` [1874]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	unsigned	[none]	0 - 4G
Restart Type: N			

This identifies the SCI node ID on the first Cluster node (identified by `NodeId1` [1874]).

- `Host1SciId1` [1874]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	unsigned	0	0 - 4G
Restart Type: N			

It is possible to set up SCI Transporters for failover between two SCI cards which then should use separate networks between the nodes. This identifies the node ID and the second SCI card to be used on the first node.

- `Host2SciId0` [1875]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	unsigned	[none]	0 - 4G
Restart Type: N			

This identifies the SCI node ID on the second Cluster node (identified by `NodeId2` [1874]).

- `Host2SciId1` [1875]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	unsigned	0	0 - 4G
Restart Type: N			

When using two SCI cards to provide failover, this parameter identifies the second SCI card to be used on the second node.

- `HostName1`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	name or IP address	[none]	...
Restart Type: N			

`HostName2`

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	name or IP address	[none]	...
Restart Type: N			

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given SCI connection between two nodes. The values used for these parameters can be hostnames or IP addresses.

- `SharedBufferSize` [1875]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	unsigned	10M	64K - 4G
Restart Type: N			

Each SCI transporter has a shared memory segment used for communication between the two nodes. Setting the size of this segment to the default value of 1MB should be sufficient for most applications. Using a smaller value can lead to problems when performing many parallel inserts; if the shared buffer is too small, this can also result in a crash of the `ndbd` process.

- SendLimit [1876]

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	unsigned	8K	128 - 32K
Restart Type: N			

A small buffer in front of the SCI media stores messages before transmitting them over the SCI network. By default, this is set to 8KB. Our benchmarks show that performance is best at 64KB but 16KB reaches within a few percent of this, and there was little if any advantage to increasing it beyond 8KB.

- SendSignalId

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.3.23	boolean	true	true, false
Restart Type: N			

To trace a distributed message it is necessary to identify each message uniquely. When this parameter is set to Y, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in -debug builds.

- Checksum

Effective Version	Type/Units	Default	Range or Permitted Values
MySQL 5.1	boolean	false	true, false
Restart Type: N			

This parameter is a boolean value, and is disabled by default. When Checksum is enabled, checksums are calculated for all messages before they are placed in the send buffer. This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- OverloadLimit

Effective Version	Type/Units	Default	Range or Permitted Values
NDB 6.4.0	bytes	0	0 - 4G
Restart Type: N			

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded. See Configuring MySQL Cluster Send Buffer Parameters, for more information.

Configuring MySQL Cluster Parameters for Local Checkpoints

The parameters discussed in Logging and Checkpointing and in Data Memory, Index Memory, and String Memory that are used to configure local checkpoints for a MySQL Cluster do not exist in isolation, but rather are very much interdepedent on each other. In this section, we illustrate how these parameters—including DataMemory [1817], IndexMemory [1819], NoOfDiskPagesToDiskAfterRestartTUP [1842], NoOfDiskPagesToDiskAfterRestartACC [1843], and NoOfFragmentLogFiles [1826]—relate to one another in a working Cluster.

Important

The parameters `NoOfDiskPagesToDiskAfterRestartTUP` [1842] and `NoOfDiskPagesToDiskAfterRestartACC` [1843] were deprecated in MySQL 5.1.6. From MySQL 5.1.6 through 5.1.11, disk writes during LCPs took place at the maximum speed possible. Beginning with MySQL 5.1.12, the speed and throughput for LCPs are controlled using the parameters `DiskSyncSize` [1842], `DiskCheckpointSpeed` [1842], and `DiskCheckpointSpeedInRestart` [1842]. See Defining MySQL Cluster Data Nodes.

In this example, we assume that our application performs the following numbers of types of operations per hour:

- 50000 selects
- 15000 inserts
- 15000 updates
- 15000 deletes

We also make the following assumptions about the data used in the application:

- We are working with a single table having 40 columns.
- Each column can hold up to 32 bytes of data.
- A typical `UPDATE` run by the application affects the values of 5 columns.
- No `NULL` values are inserted by the application.

A good starting point is to determine the amount of time that should elapse between local checkpoints (LCPs). It is worth noting that, in the event of a system restart, it takes 40-60 percent of this interval to execute the REDO log—for example, if the time between LCPs is 5 minutes (300 seconds), then it should take 2 to 3 minutes (120 to 180 seconds) for the REDO log to be read.

The maximum amount of data per node can be assumed to be the size of the `DataMemory` [1817] parameter. In this example, we assume that this is 2 GB. The `NoOfDiskPagesToDiskAfterRestartTUP` [1842] parameter represents the amount of data to be checkpointed per unit time—however, this parameter is actually expressed as the number of 8K memory pages to be checkpointed per 100 milliseconds. 2 GB per 300 seconds is approximately 6.8 MB per second, or 700 KB per 100 milliseconds, which works out to roughly 85 pages per 100 milliseconds.

Similarly, we can calculate `NoOfDiskPagesToDiskAfterRestartACC` [1843] in terms of the time for local checkpoints and the amount of memory required for indexes—that is, the `IndexMemory` [1819]. Assuming that we permit 512 MB for indexes, this works out to approximately 20 8-KB pages per 100 milliseconds for this parameter.

Next, we need to determine the number of REDO log files required—that is, fragment log files—the corresponding parameter being `NoOfFragmentLogFiles` [1826]. We need to make sure that there are sufficient REDO log files for keeping records for at least 3 local checkpoints (in MySQL Cluster NDB 6.3.8 and later, we need only allow for 2 local checkpoints). In a production setting, there are always uncertainties—for instance, we cannot be sure that disks always operate at top speed or with maximum throughput. For this reason, it is best to err on the side of caution, so we double our requirement and calculate a number of fragment log files which should be enough to keep records covering 6 local checkpoints (in MySQL Cluster NDB 6.3.8 and later, a number of fragment log files accommodating 4 local checkpoints should be sufficient).

It is also important to remember that the disk also handles writes to the REDO log, so if you find that the amount of data being written to disk as determined

by the values of NoOfDiskPagesToDiskAfterRestartACC [1843] and NoOfDiskPagesToDiskAfterRestartTUP [1842] is approaching the amount of disk bandwidth available, you may wish to increase the time between local checkpoints.

Given 5 minutes (300 seconds) per local checkpoint, this means that we need to support writing log records at maximum speed for 6 * 300 = 1800 seconds (*MySQL Cluster NDB 6.3.8 and later*: 4 * 300 = 1200 seconds). The size of a REDO log record is 72 bytes plus 4 bytes per updated column value plus the maximum size of the updated column, and there is one REDO log record for each table record updated in a transaction, on each node where the data reside. Using the numbers of operations set out previously in this section, we derive the following:

- 50000 select operations per hour yields 0 log records (and thus 0 bytes), since SELECT statements are not recorded in the REDO log.
- 15000 DELETE statements per hour is approximately 5 delete operations per second. (Since we wish to be conservative in our estimate, we round up here and in the following calculations.) No columns are updated by deletes, so these statements consume only 5 operations * 72 bytes per operation = 360 bytes per second.
- 15000 UPDATE statements per hour is roughly the same as 5 updates per second. Each update uses 72 bytes, plus 4 bytes per column * 5 columns updated, plus 32 bytes per column * 5 columns—this works out to 72 + 20 + 160 = 252 bytes per operation, and multiplying this by 5 operation per second yields 1260 bytes per second.
- 15000 INSERT statements per hour is equivalent to 5 insert operations per second. Each insert requires REDO log space of 72 bytes, plus 4 bytes per record * 40 columns, plus 32 bytes per column * 40 columns, which is 72 + 160 + 1280 = 1512 bytes per operation. This times 5 operations per second yields 7560 bytes per second.

So the total number of REDO log bytes being written per second is approximately 0 + 360 + 1260 + 7560 = 9180 bytes. Multiplied by 1800 seconds, this yields 16524000 bytes required for REDO logging, or approximately 15.75 MB. The unit used for NoOfFragmentLogFiles [1826] represents a set of 4 16-MB log files—that is, 64 MB. Thus, the minimum value (3) for this parameter is sufficient for the scenario envisioned in this example, since 3 times 64 = 192 MB, or about 12 times what is required; the default value of 8 (or 512 MB) is more than ample in this case.

Configuring MySQL Cluster Send Buffer Parameters

Formerly, the NDB kernel used a send buffer whose size was fixed at 2MB for every node in the cluster, which was allocated when the node started. Because the size of this buffer could not be changed after the cluster was started, it was necessary to make it large enough in advance to accommodate the maximum possible load on any transporter socket. However, this was an inefficient use of memory, since much of it often went unused, and could result in large amounts of resources being wasted when scaling up to many API nodes.

Beginning with MySQL Cluster NDB 7.0, this problem is solved by employing a unified send buffer whose memory is allocated dynamically from a pool shared by all transporters. This means that the size of the send buffer can be adjusted as necessary. Configuration of the unified send buffer can accomplished by setting the following parameters:

- **TotalSendBufferMemory.** This parameter can be set for all types of MySQL Cluster nodes—that is, it can be set in the [ndbd], [mgm], and [api] (or [mysql]) sections of the config.ini file. It represents the total amount of memory (in bytes) to be allocated by each node for which it is set for use among all configured transporters. If set, its minimum is 256KB; the maximum is 4294967039.

  To be backward-compatible with existing configurations, this parameter takes as its default value the sum of the maximum send buffer sizes of all configured transporters, plus an additional 32KB (one page) per transporter. The maximum depends on the type of transporter, as shown in the following table:

Transporter	Maxmimum Send Buffer Size (bytes)
TCP	`SendBufferMemory` [1870] (default = 2M)
SCI	`SendLimit` [1876] (default = 8K) plus 16K
SHM	20K

This enables existing configurations to function in close to the same way as they did with MySQL Cluster NDB 6.3 and earlier, with the same amount of memory and send buffer space available to each transporter. However, memory that is unused by one transporter is not available to other transporters.

- **`OverloadLimit`.** This parameter is used in the `config.ini` file `[tcp]` section, and denotes the amount of unsent data (in bytes) that must be present in the send buffer before the connection is considered overloaded. When such an overload condition occurs, transactions that affect the overloaded connection fail with NDB API Error 1218 (`Send Buffers overloaded in NDB kernel`) until the overload status passes. The default value is 0, in which case the effective overload limit is calculated as `SendBufferMemory * 0.8` for a given connection. The maximum value for this parameter is 4G.

- **`SendBufferMemory`.** In MySQL Cluster NDB 6.3 and earlier, this TCP configuration parameter represented the amount of memory allocated at startup for each configured TCP connection. Beginning with MySQL Cluster NDB 7.0, this value denotes a hard limit for the amount of memory that may be used by a single transporter out of the entire pool specified by `TotalSendBufferMemory` [1861]. However, the sum of `SendBufferMemory` for all configured transporters may be greater than the `TotalSendBufferMemory` [1861] that is set for a given node. This is a way to save memory when many nodes are in use, as long as the maximum amount of memory is never required by all transporters at the same time.

Overview of MySQL Cluster Configuration Parameters

The next four sections provide summary tables of MySQL Cluster configuration parameters used in the `config.ini` file to govern the cluster's functioning. Each table lists the parameters for one of the Cluster node process types (`ndbd`, `ndb_mgmd`, and `mysqld`), and includes the parameter's type as well as its default, minimum, and maximum values as applicable.

These tables also indicate what type of restart is required (node restart or system restart)—and whether the restart must be done with `--initial`—to change the value of a given configuration parameter.

When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a *rolling restart*). It is possible to update cluster configuration parameters marked as `node` online—that is, without shutting down the cluster—in this fashion. An initial node restart requires restarting each `ndbd` process with the `--initial` option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the cluster, wiping the cluster file system after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster's management servers must be restarted for them to read the updated configuration parameter values.

Important

Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. Many of these can be increased online, using a rolling restart.

However, decreasing the values of such parameters—whether this is done using a node restart, node initial restart, or even a complete system restart of the cluster—is not to be undertaken lightly; it is recommended that you do so only after careful planning and testing. This is especially true with regard to those parameters that relate to memory usage and disk space, such as `MaxNoOfTables` [1829], `MaxNoOfOrderedIndexes` [1829], and `MaxNoOfUniqueHashIndexes` [1830]. In addition, it is the generally the case that configuration parameters relating to memory and disk usage can be raised using a simple node restart, but they require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

Note

`4294967039` often appears as a maximum value in these tables. This value is defined in the `NDBCLUSTER` sources as `MAX_INT_RNIL` and is equal to `0xFFFFFEFF`, or $2^{32} - 2^8 - 1$.

MySQL Cluster Data Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[ndbd]` or `[ndbd default]` sections of a `config.ini` file for configuring MySQL Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see Defining MySQL Cluster Data Nodes.

Beginning with MySQL Cluster NDB 6.4.0, these parameters also apply to `ndbmtd`, which is a multi-threaded version of `ndbd`. For more information, see `ndbmtd` — The MySQL Cluster Data Node Daemon (Multi-Threaded).

Restart types. Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- `N`—Node restart: The parameter can be updated using a rolling restart (see Performing a Rolling Restart of a MySQL Cluster).
- `S`—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- `I`—Initial restart: Data nodes must be restarted using the `--initial` [1954] option.

For more information about restart types, see Overview of MySQL Cluster Configuration Parameters.

Table 17.1. Data Node Configuration Parameters

Parameter Name	Type or Units Default Value Minimum/ Maximum or Permitted Values	Restart Type	As of Version ... And Later
`Arbitration` [1844]	enumeration Default Default, Disabled, WaitExternal	N	NDB 7.0.7
`ArbitrationTimeout` [1844]	milliseconds	N	NDB 7.2.0

Parameter Name	Type or Units Default Value Minimum/ Maximum or Permitted Values	Restart Type	As of Version ... And Later
	7500 10 / 4G		
BackupDataBufferSize [1850]	bytes 16M 0 / 4G	N	NDB 7.0.4
BackupDataDir [1816]	path FileSystemPath ...	IN	all 5.1-based
BackupLogBufferSize [1850]	bytes 16M 0 / 4G	N	NDB 7.0.4
BackupMaxWriteSize [1852]	bytes 1M 2K / 4G	N	5.1.32
BackupMemory [1851]	bytes 32M 0 / 4G	N	NDB 7.0.4
BackupReportFrequency [1851]	seconds 0 0 / 4G	N	NDB 6.2.3
BackupWriteSize [1851]	bytes 256K 2K / 4G	N	NDB 7.0.4
BatchSizePerLocalScan [1824]	integer 256 1 / 992	N	NDB 7.2.1
BuildIndexThreads [1854]	numeric 0 0 / 128	S	NDB 7.0.11
CompressedBackup [1834]	boolean false true, false	N	NDB 6.3.7
CompressedLCP [1834]	boolean false true, false	N	NDB 6.3.7
ConnectCheckIntervalDelay [1838]	string 1500	N	NDB 7.1.13

Parameter Name	Type or Units Default Value Minimum/ Maximum or Permitted Values	Restart Type	As of Version ... And Later
	0 / 4G

TimeBetweenWatchDogCheckInitial [1835]	milliseconds 6000 70 / 4G	N	5.1.20
TotalSendBufferMemory [1861]	bytes 256K 0 / 4G	N	NDB 6.4.0
TransactionBufferMemory [1823]	bytes 1M 1K / 4G	N	all 5.1-based
TransactionDeadlockDetectionTimeout [1841]	milliseconds 1200 50 / 4G	N	all 5.1-based
TransactionInactiveTimeout [1841]	milliseconds 4G 0 / 4G	N	all 5.1-based
TwoPassInitialNodeRestartCopy [1854]	boolean	N	NDB 7.1.11

Parameter Name	Type or Units Default Value Minimum/ Maximum or Permitted Values	Restart Type	As of Version ... And Later
	false true, false		
UndoDataBuffer [1846]	unsigned 16M 1M / 4G	N	all 5.1-based
UndoIndexBuffer [1845]	unsigned 2M 1M / 4G	N	all 5.1-based

Table 17.2. Multi-Threaded Data Node Configuration Parameters

Parameter Name	Type or Units Default Value Minimum/ Maximum or Permitted Values	Restart Type	As of Version ... And Later
MaxNoOfExecutionThreads [1855]	integer 2 2 / 8	N	NDB 7.0.4
ThreadConfig	string '' ...	N	NDB 7.1.17

Note

Prior to MySQL Cluster NDB 7.0, to add new data nodes to a MySQL Cluster, it is necessary to shut down the cluster completely, update the `config.ini` file, and then restart the cluster, starting all data node processes using the `--initial` [1954] option—that is, you must perform a system restart.

Beginning in MySQL Cluster NDB 7.0, it is possible to add new data node groups to a running cluster online. For more information, see Adding MySQL Cluster Data Nodes Online.

MySQL Cluster Management Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[ndb_mgmd]` or `[mgm]` sections of a `config.ini` file for configuring MySQL Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see Defining a MySQL Cluster Management Server.

Restart types. Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- N—Node restart: The parameter can be updated using a rolling restart (see Performing a Rolling Restart of a MySQL Cluster).
- S—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- I—Initial restart: Data nodes must be restarted using the `--initial` [1954] option.

For more information about restart types, see Overview of MySQL Cluster Configuration Parameters.

Table 17.3. Management Node Configuration Parameters

Parameter Name	Type or Units Default Value Minimum/ Maximum or Permitted Values	Restart Type	As of Version ... And Later
ArbitrationDelay [1812]	milliseconds 0 0 / 4G	N	all 5.1-based
ArbitrationRank [1811]	0-2 1 0 / 2	N	all 5.1-based
DataDir [1812]	path	N	all 5.1-based
ExecuteOnComputer [1810]	name [none] ...	S	all 5.1-based
HeartbeatThreadPriority [1812]	string [none] ...	S	NDB 7.1.2
HostName [1810]	name or IP address [none] ...	S	all 5.1-based
Id [1809]	unsigned [none] 1 / 255	N	NDB 6.1.1
LogDestination [1810]	{CONSOLE|SYSLOG|FILE} [see text] ...	N	all 5.1-based
MaxNoOfSavedEvents	unsigned 100 0 / 4G	N	all 5.1-based

Parameter Name	Type or Units Default Value Minimum/ Maximum or Permitted Values	Restart Type	As of Version ... And Later
NodeId [1809]	unsigned [none] 1 / 255	N	NDB 6.1.1
PortNumber [1810]	unsigned 1186 0 / 64K	N	all 5.1-based
PortNumberStats	unsigned [none] 0 / 64K	N	all 5.1-based
TotalSendBufferMemory [1812]	bytes 256K 0 / 4G	N	NDB 6.4.0
wan	boolean false true, false	N	NDB 6.1.1

Note

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect. See Defining a MySQL Cluster Management Server, for more information.

To add new management servers to a running MySQL Cluster, it is also necessary perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see Limitations Relating to Multiple MySQL Cluster Nodes.

MySQL Cluster SQL Node and API Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[mysqld]` and `[api]` sections of a `config.ini` file for configuring MySQL Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see Defining SQL and Other API Nodes in a MySQL Cluster.

Note

For a discussion of MySQL server options for MySQL Cluster, see MySQL Server Options for MySQL Cluster; for information about MySQL server system variables relating to MySQL Cluster, see MySQL Cluster System Variables.

Restart types. Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- N—Node restart: The parameter can be updated using a rolling restart (see Performing a Rolling Restart of a MySQL Cluster).

- S—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- I—Initial restart: Data nodes must be restarted using the `--initial` [1954] option.

For more information about restart types, see Overview of MySQL Cluster Configuration Parameters.

Table 17.4. SQL Node / API Node Configuration Parameters

Parameter Name	Type or Units Default Value Minimum/ Maximum or Permitted Values	Restart Type	As of Version ... And Later
`ArbitrationDelay` [1865]	milliseconds 0 0 / 4G	N	all 5.1-based
`ArbitrationRank` [1865]	0-2 0 0 / 2	N	all 5.1-based
`AutoReconnect` [1867]	boolean false true, false	N	NDB 7.0.7
`BatchByteSize` [1866]	bytes 16K 1024 / 1M	N	NDB 7.2.1
`BatchSize` [1866]	records 256 1 / 992	N	NDB 7.2.1
`ConnectionMap`	string [none] ...	N	NDB 6.1.0
`DefaultOperationRedoProblemAction` [1867]	enumeration [none] ABORT, QUEUE	S	NDB 7.1.10
`ExecuteOnComputer` [1865]	name [none] ...	S	all 5.1-based
`HeartbeatThreadPriority` [1866]	string [none] ...	S	NDB 7.1.2
`HostName` [1865]	name or IP address [none] ...	S	all 5.1-based

Parameter Name	Type or Units Default Value Minimum/ Maximum or Permitted Values	Restart Type	As of Version ... And Later
Id [1864]	unsigned [none] 1 / 255	N	NDB 6.1.1
MaxScanBatchSize [1866]	bytes 256K 32K / 16M	N	all 5.1-based
NodeId [1864]	unsigned [none] 1 / 255	N	NDB 6.1.1
TotalSendBufferMemory [1867]	bytes 256K 0 / 4G	N	NDB 6.4.0
wan	boolean false true, false	N	NDB 6.1.1

Note

To add new SQL or API nodes to the configuration of a running MySQL Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

Other MySQL Cluster Configuration Parameters

The summary tables in this section provide information about parameters used in the `[computer]`, `[tcp]`, `[shm]`, and `[sci]` sections of a `config.ini` file for configuring MySQL Cluster management nodes. For detailed descriptions and other additional information about individual parameters, see MySQL Cluster TCP/IP Connections, MySQL Cluster Shared-Memory Connections, or SCI Transport Connections in MySQL Cluster, as appropriate.

Restart types. Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary tables as follows:

- `N`—Node restart: The parameter can be updated using a rolling restart (see Performing a Rolling Restart of a MySQL Cluster).
- `S`—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- `I`—Initial restart: Data nodes must be restarted using the `--initial` [1954] option.

For more information about restart types, see Overview of MySQL Cluster Configuration Parameters.

Table 17.5. Computer Configuration Parameters

Parameter Name	Type or Units Default Value Minimum/ Maximum or Permitted Values	Restart Type	As of Version ... And Later
HostName [1808]	name or IP address [none] ...	S	all 5.1-based
Id [1808]	string [none] ...	IN	all 5.1-based

Table 17.6. TCP Configuration Parameters

Parameter Name	Type or Units Default Value Minimum/ Maximum or Permitted Values	Restart Type	As of Version ... And Later

SharedBufferSize [1875]	unsigned 10M 64K / 4G	N	all 5.1-based

MySQL Server Options and Variables for MySQL Cluster

This section provides information about MySQL server options, server and status variables that are specific to MySQL Cluster. For general information on using these, and for other options and variables not specific to MySQL Cluster, see The MySQL Server.

For MySQL Cluster configuration parameters used in the cluster configuration file (usually named `config.ini`), see MySQL Cluster Configuration.

MySQL Cluster `mysqld` Option and Variable Reference

The following table provides a list of the command-line options, server and status variables applicable within `mysqld` when it is running as an SQL node in a MySQL Cluster. For a table showing *all* command-line options, server and status variables available for use with `mysqld`, see Server Option and Variable Reference.

Table 17.9. MySQL Cluster `mysqld` Options and Variables: MySQL 5.1, MySQL Cluster NDB 6.3-7.1

Option or Variable Name	Command Line Option File	System Variable Status Variable	Scope Dynamic
Notes			
Handler_discover [1936]	N N	N Y	Both N
The number of times that tables have been discovered			
Ndb_api_wait_exec_complete_count_session [1936]	N N	N Y	Session N
Number of times thread has been blocked while waiting for execution of an operation to complete in this client session.			
Ndb_api_wait_exec_complete_count_slave [1936]	N N	N Y	Global N
Number of times thread has been blocked while waiting for execution of an operation to complete by this slave.			
Ndb_api_wait_exec_complete_count [1936]	N N	N Y	Global N
Number of times thread has been blocked while waiting for execution of an operation to complete by this MySQL Server (SQL node).			
Ndb_api_wait_scan_result_count_session [1937]	N N	N Y	Session N

Option or Variable Name	Command Line	System Variable	Scope
	Option File	Status Variable	Dynamic
Notes			
Number of times thread has been blocked while waiting for a scan-based signal in this client session.			
Ndb_api_wait_scan_result_count_slave [1937]	N	N	Global
	N	Y	N
Number of times thread has been blocked while waiting for a scan-based signal by this slave.			
Ndb_api_wait_scan_result_count [1937]	N	N	Global
	N	Y	N
Number of times thread has been blocked while waiting for a scan-based signal by this MySQL Server (SQL node).			
Ndb_api_wait_meta_request_count_session [1937]	N	N	Session
	N	Y	N
Number of times thread has been blocked waiting for a metadata-based signal in this client session.			
Ndb_api_wait_meta_request_count_slave [1937]	N	N	Global
	N	Y	N
Number of times thread has been blocked waiting for a metadata-based signal by this slave.			
Ndb_api_wait_meta_request_count [1937]	N	N	Global
	N	Y	N
Number of times thread has been blocked waiting for a metadata-based signal by this MySQL Server (SQL node).			
Ndb_api_wait_nanos_count_session [1938]	N	N	Session
	N	Y	N
Total time (in nanoseconds) spent waiting for some type of signal from the data nodes in this client session.			
Ndb_api_wait_nanos_count_slave [1938]	N	N	Global
	N	Y	N
Total time (in nanoseconds) spent waiting for some type of signal from the data nodes by this slave.			
Ndb_api_wait_nanos_count [1938]	N	N	Global
	N	Y	N
Total time (in nanoseconds) spent waiting for some type of signal from the data nodes by this MySQL Server (SQL node).			
Ndb_api_bytes_sent_count_session [1938]	N	N	Session
	N	Y	N
Amount of data (in bytes) sent to the data nodes in this client session.			
Ndb_api_bytes_sent_count_slave [1938]	N	N	Global
	N	Y	N
Amount of data (in bytes) sent to the data nodes by this slave.			
Ndb_api_bytes_sent_count [1939]	N	N	Global
	N	Y	N
Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node).			

Option or Variable Name	Command Line	System Variable	Scope
	Option File	Status Variable	Dynamic
Notes			
Ndb_api_bytes_received_count_session [1939]	N	N	Session
	N	Y	N
Amount of data (in bytes) received from the data nodes in this client session.			
Ndb_api_bytes_received_count_slave [1939]	N	N	Global
	N	Y	N
Amount of data (in bytes) received from the data nodes by this slave.			
Ndb_api_bytes_received_count [1939]	N	N	Global
	N	Y	N
Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node).			
Ndb_api_trans_start_count_session [1939]	N	N	Session
	N	Y	N
Number of transactions started in this client session.			
Ndb_api_trans_start_count_slave [1939]	N	N	Global
	N	Y	N
Number of transactions started by this slave.			
Ndb_api_trans_start_count [1940]	N	N	Global
	N	Y	N
Number of transactions started by this MySQL Server (SQL node).			
Ndb_api_trans_commit_count_session [1940]	N	N	Session
	N	Y	N
Number of transactions committed in this client session.			
Ndb_api_trans_commit_count_slave [1940]	N	N	Global
	N	Y	N
Number of transactions committed by this slave.			
Ndb_api_trans_commit_count [1940]	N	N	Global
	N	Y	N
Number of transactions committed by this MySQL Server (SQL node).			
Ndb_api_trans_abort_count_session [1940]	N	N	Session
	N	Y	N
Number of transactions aborted in this client session.			
Ndb_api_trans_abort_count_slave [1940]	N	N	Global
	N	Y	N
Number of transactions aborted by this slave.			
Ndb_api_trans_abort_count [1941]	N	N	Global
	N	Y	N
Number of transactions aborted by this MySQL Server (SQL node).			
Ndb_api_trans_close_count_session [1941]	N	N	Session

Option or Variable Name	Command Line	System Variable	Scope
	Option File	Status Variable	Dynamic
Notes			
	N	Y	N
Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) in this client session.			
Ndb_api_trans_close_count_slave [1941]	N	N	Global
	N	Y	N
Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) by this slave.			
Ndb_api_trans_close_count [1941]	N	N	Global
	N	Y	N
Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) by this MySQL Server (SQL node).			
Ndb_api_pk_op_count_session [1941]	N	N	Session
	N	Y	N
Number of operations based on or using primary keys in this client session.			
Ndb_api_pk_op_count_slave [1942]	N	N	Global
	N	Y	N
Number of operations based on or using primary keys by this slave.			
Ndb_api_pk_op_count [1942]	N	N	Global
	N	Y	N
Number of operations based on or using primary keys by this MySQL Server (SQL node).			
Ndb_api_uk_op_count_session [1942]	N	N	Session
	N	Y	N
Number of operations based on or using unique keys in this client session.			
Ndb_api_uk_op_count_slave [1942]	N	N	Global
	N	Y	N
Number of operations based on or using unique keys by this slave.			
Ndb_api_uk_op_count [1942]	N	N	Global
	N	Y	N
Number of operations based on or using unique keys by this MySQL Server (SQL node).			
Ndb_api_table_scan_count_session [1942]	N	N	Session
	N	Y	N
Number of table scans that have been started, including scans of internal tables, in this client session.			
Ndb_api_table_scan_count_slave [1943]	N	N	Global
	N	Y	N
Number of table scans that have been started, including scans of internal tables, by this slave.			
Ndb_api_table_scan_count [1943]	N	N	Global
	N	Y	N

Option or Variable Name	Command Line	System Variable	Scope
	Option File	Status Variable	Dynamic
Notes			
Number of table scans that have been started, including scans of internal tables, by this MySQL Server (SQL node).			
Ndb_api_range_scan_count_session [1943]	N	N	Session
	N	Y	N
Number of range scans that have been started in this client session.			
Ndb_api_range_scan_count_slave [1943]	N	N	Global
	N	Y	N
Number of range scans that have been started by this slave.			
Ndb_api_range_scan_count [1943]	N	N	Global
	N	Y	N
Number of range scans that have been started by this MySQL Server (SQL node).			
Ndb_api_pruned_scan_count_session [1944]	N	N	Session
	N	Y	N
Number of scans that have been pruned to a single partition in this client session.			
Ndb_api_pruned_scan_count_slave [1944]	N	N	Global
	N	Y	N
Number of scans that have been pruned to a single partition by this slave.			
Ndb_api_pruned_scan_count [1944]	N	N	Global
	N	Y	N
Number of scans that have been pruned to a single partition by this MySQL Server (SQL node).			
Ndb_api_scan_batch_count_session [1944]	N	N	Session
	N	Y	N
Number of batches of rows received in this client session.			
Ndb_api_scan_batch_count_slave [1944]	N	N	Global
	N	Y	N
Number of batches of rows received by this slave.			
Ndb_api_scan_batch_count [1944]	N	N	Global
	N	Y	N
Number of batches of rows received by this MySQL Server (SQL node).			
Ndb_api_read_row_count_session [1945]	N	N	Session
	N	Y	N
Total number of rows that have been read in this client session.			
Ndb_api_read_row_count_slave [1945]	N	N	Global
	N	Y	N
Total number of rows that have been read by this slave.			
Ndb_api_read_row_count [1945]	N	N	Global
	N	Y	N
Total number of rows that have been read by this MySQL Server (SQL node).			

Option or Variable Name	Command Line	System Variable	Scope
	Option File	Status Variable	Dynamic
Notes			
Ndb_api_trans_local_read_row_count_session [1945]	N	N	Session
	N	Y	N
Total number of rows that have been read in this client session.			
Ndb_api_trans_local_read_row_count_slave [1945]	N	N	Global
	N	Y	N
Total number of rows that have been read by this slave.			
Ndb_api_trans_local_read_row_count [1946]	N	N	Global
	N	Y	N
Total number of rows that have been read by this MySQL Server (SQL node).			
Ndb_api_event_data_count_injector [1946]	N	N	Global
	N	Y	N
Number of row change events received by the NDB binlog injector thread.			
Ndb_api_event_data_count [1946]	N	N	Global
	N	Y	N
Number of row change events received by this MySQL Server (SQL node).			
Ndb_api_event_nondata_count_injector [1946]	N	N	Global
	N	Y	N
Number of events received, other than row change events, by the NDB binlog injector thread.			
Ndb_api_event_nondata_count [1946]	N	N	Global
	N	Y	N
Number of events received, other than row change events, by this MySQL Server (SQL node).			
Ndb_api_event_bytes_count_injector [1946]	N	N	Global
	N	Y	N
Number of bytes of events received by the NDB binlog injector thread.			
Ndb_api_event_bytes_count [1946]	N	N	Global
	N	Y	N
Number of bytes of events received by this MySQL Server (SQL node).			
Ndb_number_of_data_nodes [1948]	N	N	Global
	N	Y	N
If the server is part of a MySQL Cluster, the value of this variable is the number of data nodes in the cluster			
Ndb_conflict_fn_max [1947]	N	N	Global
	N	Y	N
If the server is part of a MySQL Cluster involved in cluster replication, the value of this variable indicates the number of times that conflict resolution based on "greater timestamp wins" has been applied			
Ndb_conflict_fn_old [1947]	N	N	Global
	N	Y	N

Option or Variable Name	Command Line	System Variable	Scope
	Option File	Status Variable	Dynamic
Notes			
If the server is part of a MySQL Cluster involved in cluster replication, the value of this variable indicates the number of times that "same timestamp wins" conflict resolution has been applied			
Ndb_conflict_fn_epoch [1947]	N	N	Global
	N	Y	N
Number of rows that have been found in conflict by the NDB$EPOCH() conflict detection function			
Ndb_conflict_fn_epoch_trans [1947]	N	N	Global
	N	Y	N
Number of rows that have been found in conflict by the NDB$EPOCH_TRANS() conflict detection function			
Ndb_conflict_trans_row_conflict_count [1948]	N	N	Global
	N	Y	N
Number of rows found to be in conflict by a transactional conflict function			
Ndb_conflict_trans_row_reject_count [1948]	N	N	Global
	N	Y	N
Total number of rows realigned after being found in conflict by a transactional conflict function. Includes Ndb_conflict_trans_row_conflict_count and any rows included in or dependent on conflicting transactions.			
Ndb_conflict_trans_reject_count [1948]	N	N	Global
	N	Y	N
Number of transactions rejected after being found in conflict by a transactional conflict function.			
Ndb_conflict_trans_detect_iter_count [1948]	N	N	Global
	N	Y	N
The number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to Ndb_conflict_trans_conflict_commit_count.			
Ndb_conflict_trans_conflict_commit_count [1948]	N	N	Global
	N	Y	N
The number of epoch transactions committed after requiring transactional conflict handling.			
ndb_optimization_delay [1920]	N	Y	Global
	N	N	Y
Sets the number of milliseconds to wait between processing sets of rows by OPTIMIZE TABLE on NDB tables.			
ndb_table_temporary [1931]	N	Y	Session
	N	N	Y
NDB tables are not persistent on disk: no schema files are created and the tables are not logged			
ndb_table_no_logging [1930]	N	Y	Session
	N	N	Y
NDB tables created when this setting is enabled are not checkpointed to disk (although table schema files are created). The setting in effect when the table is created with or altered to use NDBCLUSTER persists for the lifetime of the table.			
ndb_autoincrement_prefetch_sz [1921]	Y	Y	Both

Option or Variable Name	Command Line	System Variable	Scope
	Option File	Status Variable	Dynamic
Notes			
	Y	N	Y
NDB auto-increment prefetch size			
ndb-batch-size [1912]	Y	Y	Global
	Y	N	N
The size (in bytes) to use for NDB transaction batches			
ndb-blob-read-batch-bytes [1913]	Y	Y	Both
	Y	N	Y
Specifies the size in bytes that large BLOB reads should be batched into. 0 = no limit.			
ndb-blob-write-batch-bytes [1913]	Y	Y	Both
	Y	N	Y
Specifies the size in bytes that large BLOB writes should be batched into. 0 = no limit.			
ndb_cache_check_time [1922]	Y	Y	Global
	Y	N	Y
The number of milliseconds between checks of cluster SQL nodes made by the MySQL query cache			
ndb-cluster-connection-pool [1912]	Y	Y	Global
	Y	Y	N
The number of connections to the cluster used by MySQL			
ndb_join_pushdown [1925]	N	Y	Global
	N	N	N
Enables pushing down of joins to data nodes			
Ndb_execute_count [1948]	N	N	Global
	N	Y	N
Provides the number of round trips to the NDB kernel made by operations			
Ndb_scan_count [1949]	N	N	Global
	N	Y	N
The total number of scans executed by NDB since the cluster was last started			
Ndb_pruned_scan_count [1949]	N	N	Global
	N	Y	N
The number of scans executed by NDB since the cluster was last started where partition pruning could be used			
ndb-connectstring [1914]	Y	N	
	Y	N	N
The management server that distributes the cluster configuration			
ndb_extra_logging [1924]	Y	Y	Global
	Y	N	Y
Controls logging of MySQL Cluster schema, connection, and data distribution events in the MySQL error log			
ndb_force_send [1924]	Y	Y	Both

Option or Variable Name	Command Line	System Variable	Scope
	Option File	Status Variable	Dynamic
Notes			
	Y	N	Y
Forces sending of buffers to NDB immediately, without waiting for other threads			
ndb_use_exact_count [1932]	N	Y	Both
	N	N	Y
Use exact row count when planning queries			
ndb-log-apply-status [1915]	Y	Y	Global
	Y	N	N
Cause a MySQL server acting as a slave to log mysql.ndb_apply_status updates received from its immediate master in its own binary log, using its own server ID. Effective only if the server is started with the --ndbcluster option.			
ndb_log_bin [1928]	Y	Y	Both
	N	N	Y
Write updates to NDB tables in the binary log. Effective only if binary logging is enabled with --log-bin.			
ndb_log_binlog_index [1928]	Y	Y	Global
	N	N	Y
Insert mapping between epochs and binary log positions into the ndb_binlog_index table. Defaults to ON. Effective only if binary logging is enabled on the server.			
ndb_log_orig	N	Y	Global
	N	N	N
Log originating server id and epoch in mysql.ndb_binlog_index table.			
ndb-log-transaction-id [1916]	Y	Y	Global
	Y	N	N
Write NDB transaction IDs in the binary log. Requires --log-bin-v1-events=OFF.			
ndb_log_transaction_id [1935]	N	Y	Global
	N	N	N
Whether NDB transaction IDs are written into the binary log. (Read-only.)			
ndb_log_updated_only [2143]	Y	Y	Global
	Y	N	Y
Log complete rows (ON) or updates only (OFF)			
ndb-log-update-as-write [2143]	Y	Y	Global
	Y	N	Y
Toggles logging of updates on the master between updates (OFF) and writes (ON)			
ndb-log-empty-epochs [1917]	Y	Y	Global
	Y	N	Y
When enabled, causes epochs in which there were no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.			
ndb_log_empty_epochs [1935]	Y	Y	Global
	Y	N	Y

Option or Variable Name	Command Line	System Variable	Scope
	Option File	Status Variable	Dynamic
Notes			
When enabled, epochs in which there were no changes are written to the ndb_apply_status and ndb_binlog_index tables, even when log_slave_updates is enabled.			
Ndb_pushed_reads [1949]	N	N	Global
	N	Y	N
Number of reads executed on the data nodes by pushed-down joins			
Ndb_pushed_queries_defined [1949]	N	N	Global
	N	Y	N
Number of joins that API nodes have attempted to push down to the data nodes			
Ndb_pushed_queries_dropped [1949]	N	N	Global
	N	Y	N
Number of joins that API nodes have tried to push down, but failed			
Ndb_pushed_queries_executed [1949]	N	N	Global
	N	Y	N
Number of joins successfully pushed down and executed on the data nodes			
ndb-nodeid [1916]	Y	N	Global
	Y	Y	N
MySQL Cluster node ID for this MySQL server			
ndb-mgmd-host [1915]	Y	N	
	Y	N	N
Set the host (and port, if desired) for connecting to the management server			
ndb-wait-connected [1919]	Y	Y	Global
	Y	N	N
Time (in seconds) for the MySQL server to wait for connection to cluster management and data nodes before accepting MySQL client connections.			
ndb-wait-setup [1919]	Y	Y	Global
	Y	N	N
Time (in seconds) for the MySQL server to wait for NDB engine setup to complete.			
ndbcluster [1915]	Y	N	
	Y	N	N
Enable NDB Cluster (if this version of MySQL supports it)			
ndbinfo_database [1933]	N	Y	Global
	N	N	N
The name used for the NDB information database; read only.			
ndbinfo_max_bytes [1933]	Y	Y	Both
	N	N	Y
Used for debugging only.			
ndbinfo_max_rows [1933]	Y	Y	Both
	N	N	Y

Option or Variable Name	Command Line	System Variable	Scope
	Option File	Status Variable	Dynamic
Notes			
Used for debugging only.			
ndbinfo_show_hidden [1934]	Y	Y	Both
	N	N	Y
Whether to show ndbinfo internal base tables in the mysql client. The default is OFF.			
ndbinfo_table_prefix [1934]	Y	Y	Both
	N	N	Y
The prefix to use for naming ndbinfo internal base tables. Defaults to 'ndb$'.			
ndbinfo_version [1934]	N	Y	Global
	N	N	N
The version of the ndbinfo engine; read only.			
server-id-bits [1918]	Y	Y	Global
	Y	N	N
Sets the number of least significant bits in the server_id actually used for identifying the server, permitting NDB API applications to store application data in the most significant bits. server_id must be less than 2 to the power of this value.			
slave_allow_batching [1930]	Y	Y	Global
	Y	N	Y
Turns update batching on and off for a replication slave			
transaction_allow_batching [1932]	N	Y	Session
	N	N	Y
Allows batching of statements within a transaction. Disable AUTOCOMMIT to use.			
have_ndbcluster [1920]	N	Y	Global
	N	N	N
Whether mysqld supports NDB Cluster tables (set by --ndbcluster option)			
ndb-deferred-constraints [1914]	Y	Y	Both
	Y	N	Y
Specifies that constraint checks on unique indexes (where these are supported) should be deferred until commit time. Not normally needed or used; for testing purposes only.			
ndb_deferred_constraints [1923]	Y	Y	Both
	Y	N	Y
Specifies that constraint checks should be deferred (where these are supported). Not normally needed or used; for testing purposes only.			
ndb-distribution [1915]	Y	Y	Both
	Y	N	Y
Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH)			
ndb_distribution [1923]	Y	Y	Both
	Y	N	Y
Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH)			

Option or Variable Name	Command Line	System Variable	Scope
	Option File	Status Variable	Dynamic
Notes			
ndb_index_stat_cache_entries [1924]	Y	N	
	Y	N	N
Sets the granularity of the statistics by determining the number of starting and ending keys			
ndb_index_stat_enable [1925]	Y	N	
	Y	N	N
Use NDB index statistics in query optimization			
ndb_index_stat_update_freq [1925]	Y	N	
	Y	N	N
How often to query data nodes instead of the statistics cache			
ndb_optimized_node_selection [1928]	Y	N	
	Y	N	N
Determines how an SQL node chooses a cluster data node to use as transaction coordinator			
ndb_report_thresh_binlog_epoch_slip [1929]	Y	N	
	Y	N	N
This is a threshold on the number of epochs to be behind before reporting binlog status			
ndb_report_thresh_binlog_mem_usage [1930]	Y	N	
	Y	N	N
This is a threshold on the percentage of free memory remaining before reporting binlog status			
ndb_use_transactions [1932]	Y	Y	Both
	Y	N	Y
Forces NDB to use a count of records during SELECT COUNT(*) query planning to speed up this type of query			
Ndb_cluster_node_id [1947]	N	N	Both
	N	Y	N
If the server is acting as a MySQL Cluster node, then the value of this variable its node ID in the cluster			
Ndb_config_from_host [1947]	N	N	Both
	N	Y	N
The host name or IP address of the Cluster management server. Formerly Ndb_connected_host			
Ndb_config_from_port [1947]	N	N	Both
	N	Y	N
The port for connecting to the Cluster management server. Formerly Ndb_connected_port			
Com_show_ndb_status [559]	N	N	Both
	N	Y	N
Count of SHOW NDB STATUS statements			

MySQL Server Options for MySQL Cluster

This section provides descriptions of `mysqld` server options relating to MySQL Cluster. For information about `mysqld` options not specific to MySQL Cluster, and for general information about the use of options with `mysqld`, see Server Command Options.

For information about command-line options used with other MySQL Cluster processes (`ndbd`, `ndb_mgmd`, and `ndb_mgm`), see Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs. For information about command-line options used with `NDB` utility programs (such as `ndb_desc`, `ndb_size.pl`, and `ndb_show_tables`), see MySQL Cluster Programs.

- `--ndb-batch-size=#`

Version Introduced	5.1.23-ndb-6.3.8	
Command-Line Format	`--ndb-batch-size`	
Option-File Format	`ndb-batch-size`	
Variable Name	`ndb_batch_size`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`numeric`
	Default	`32768`
	Range	`0 .. 31536000`

This sets the size in bytes that is used for NDB transaction batches.

- `--ndb-cluster-connection-pool=#`

Version Introduced	5.1.19-ndb-6.2.2	
Command-Line Format	`--ndb-cluster-connection-pool`	
Option-File Format	`ndb-cluster-connection-pool`	
Variable Name	`ndb_cluster_connection_pool`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`numeric`
	Default	`1`
	Range	`1 .. 63`

By setting this option to a value greater than 1 (the default), a `mysqld` process can use multiple connections to the cluster, effectively mimicking several SQL nodes. Each connection requires its own `[api]` or `[mysqld]` section in the cluster configuration (`config.ini`) file, and counts against the maximum number of API connections supported by the cluster.

Suppose that you have 2 cluster host computers, each running an SQL node whose `mysqld` process was started with `--ndb-cluster-connection-pool=4`; this means that the cluster must have 8 API slots available for these connections (instead of 2). All of these connections are set up when the SQL node connects to the cluster, and are allocated to threads in a round-robin fashion.

This option is useful only when running `mysqld` on host machines having multiple CPUs, multiple cores, or both. For best results, the value should be smaller than the total number of cores available on the host machine. Setting it to a value greater than this is likely to degrade performance severely.

Important

Because each SQL node using connection pooling occupies multiple API node slots—each slot having its own node ID in the cluster—you must *not* use a node ID as part of the cluster connectstring when starting any `mysqld` process that employs connection pooling.

Setting a node ID in the connectstring when using the `--ndb-cluster-connection-pool` option causes node ID allocation errors when the SQL node attempts to connect to the cluster.

This option was introduced in MySQL Cluster NDB 6.2.2. Beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.13, the value used for this option is available as a system variable (Bug #35573).

Prior to MySQL Cluster NDB 7.0.23 and MySQL Cluster NDB 7.1.12, there was also a status variable corresponding to this option; however, the status variable was removed as redundant as of these versions. (Bug #60119)

- `--ndb-blob-read-batch-bytes=`*`bytes`*

Version Introduced	5.1.51-ndb-7.0.21, 5.1.51-ndb-7.1.10	
Command-Line Format	`--ndb-blob-read-batch-bytes`	
Option-File Format	`ndb-blob-read-batch-bytes`	
Variable Name	`ndb_blob_read_batch_bytes`	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`numeric`
	Default	`65535`
	Range	`0 .. 4294967295`

This option can be used to set the size (in bytes) for batching of `BLOB` data reads in MySQL Cluster applications. When this batch size is exceeded by the amount of `BLOB` data to be read within the current transaction, any pending `BLOB` read operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65535. Setting it to 0 has the effect of disabling `BLOB` read batching.

Note

In NDB API applications, you can control `BLOB` write batching with the `setMaxPendingBlobReadBytes()` and `getMaxPendingBlobReadBytes()` methods.

This option was introduced in MySQL Cluster NDB 7.0.21 and MySQL Cluster NDB 7.1.10.

- `--ndb-blob-write-batch-bytes=`*`bytes`*

Version Introduced	5.1.51-ndb-7.0.21, 5.1.51-ndb-7.1.10
Command-Line Format	`--ndb-blob-write-batch-bytes`
Option-File Format	`ndb-blob-write-batch-bytes`
Variable Name	`ndb_blob_write_batch_bytes`
Variable Scope	Global, Session

Dynamic Variable	Yes	
	Permitted Values	
	Type	`numeric`
	Default	`65535`
	Range	`0 .. 4294967295`

This option can be used to set the size (in bytes) for batching of `BLOB` data writes in MySQL Cluster applications. When this batch size is exceeded by the amount of `BLOB` data to be written within the current transaction, any pending `BLOB` write operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65535. Setting it to 0 has the effect of disabling `BLOB` write batching.

Note

In NDB API applications, you can control `BLOB` write batching with the `setMaxPendingBlobWriteBytes()` and `getMaxPendingBlobWriteBytes()` methods.

This option was introduced in MySQL Cluster NDB 7.0.21 and MySQL Cluster NDB 7.1.10.

- `--ndb-connectstring=`*`connect_string`*

Command-Line Format	`--ndb-connectstring`	
Option-File Format	`ndb-connectstring`	
	Permitted Values	
	Type	`string`

When using the `NDBCLUSTER` storage engine, this option specifies the management server that distributes cluster configuration data. See The MySQL Cluster Connectstring, for syntax.

- `--ndb-deferred-constraints=[TRUE|FALSE]`

Version Introduced	5.1.56-ndb-7.0.28, 5.1.56-ndb-7.1.14	
Command-Line Format	`--ndb-deferred-constraints`	
Option-File Format	`ndb-deferred-constraints`	
Option Sets Variable	Yes, `ndb_deferred_constraints` [1923]	
Variable Name	`ndb-deferred-constraints`	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`boolean`
	Default	`false`
	Range	`false .. true`

Controls whether or not constraint checks on unique indexes are deferred until commit time, where such checks are supported. `OFF` is the default.

This option is not normally needed for operation of MySQL Cluster or MySQL Cluster Replication, and is intended primarily for use in testing.

This option was added in MySQL Cluster NDB 7.0.28 and MySQL Cluster NDB 7.1.14.

- `--ndb-distribution=[KEYHASH|LINHASH]`

Version Introduced	5.1.32-ndb-7.0.4	
Command-Line Format	`--ndb-distribution={KEYHASH|LINHASH}`	
Option-File Format	`ndb-distribution`	
Option Sets Variable	Yes, `ndb_distribution` [1923]	
Variable Name	`ndb-distribution`	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`enumeration`
	Default	`KEYHASH`
	Valid Values	`LINHASH` `KEYHASH`

Controls the default distribution method for `NDB` tables. Can be set to either of `KEYHASH` (key hashing) or `LINHASH` (linear hashing). `KEYHASH` is the default.

- `--ndb-mgmd-host=host[:port]`

Command-Line Format	`--ndb-mgmd-host=host[:port]`	
Option-File Format	`ndb-mgmd-host`	
	Permitted Values	
	Type	`string`
	Default	`localhost:1186`

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` [1914] option instead.

- `--ndbcluster` [1915]

Command-Line Format	`--ndbcluster`	
Option-File Format	`ndbcluster`	
Option Sets Variable	Yes, `have_ndbcluster` [1920]	
Disabled by	`skip-ndbcluster`	
	Permitted Values	
	Type	`boolean`
	Default	`FALSE`

The `NDBCLUSTER` storage engine is necessary for using MySQL Cluster. If a `mysqld` binary includes support for the `NDBCLUSTER` storage engine, the engine is disabled by default. Use the `--ndbcluster` [1915] option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

- `--ndb-log-apply-status`

Version Introduced	5.1.51-ndb-7.0.21, 5.1.51-ndb-7.1.10
Command-Line Format	`--ndb-log-apply-status`
Option-File Format	`ndb-log-apply-status`

Option Sets Variable	Yes, `ndb_log_apply_status` [1927]	
Variable Name	`ndb_log_apply_status`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`boolean`
	Default	`OFF`

Causes a slave `mysqld` to log any updates received from its immediate master to the `mysql.ndb_apply_status` table in its own binary log using its own server ID rather than the server ID of the master. In a circular or chain replication setting, this allows such updates to propagate to the `mysql.ndb_apply_status` tables of any MySQL servers configured as slaves of the current `mysqld`.

In a chain replication setup, using this option allows downstream (slave) clusters to be aware of their positions relative to all of their upstream contributors (masters).

In a circular replication setup, this option causes changes to `ndb_apply_status` tables to complete the entire circuit, eventually propagating back to the originating MySQL Cluster. This also allows a cluster acting as a master to see when its changes (epochs) have been applied to the other clusters in the circle.

This option was added in MySQL Cluster NDB 7.0.21 and MySQL Cluster NDB 7.1.10. It has no effect unless the MySQL server is started with the `--ndbcluster` [1915] option.

- `--ndb-log-transaction-id`

Version Introduced	5.1.56-ndb-7.1.16	
Command-Line Format	`--ndb-log-transaction-id[={0|1}]`	
Option-File Format	`ndb-log-transaction-id`	
Option Sets Variable	Yes, `ndb_log_transaction_id` [1935]	
Variable Name	`ndb_log_transaction_id`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`boolean`
	Default	`OFF`

Causes a slave `mysqld` to write the NDB transaction ID in each row of the binary log. Such logging requires the use of the Version 2 event format for the binary log; thus, `--log-bin-use-v1-row-events` [1648] must be set to `FALSE` in order to use this option.

This option is available beginning with MySQL Cluster NDB 7.1.16 (and is not supported in mainline MySQL Server 5.1). It is required to enable MySQL Cluster Replication conflict detection and resolution using the `NDB$EPOCH_TRANS()` function introduced in the same MySQL Cluster release.

The default value is `FALSE`.

For more information, see MySQL Cluster Replication Conflict Resolution.

- `--ndb-nodeid=#`

Version Introduced	5.1.15

Command-Line Format	`--ndb-nodeid=#`	
Option-File Format	`ndb-nodeid`	
Variable Name	`Ndb_cluster_node_id`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values (>= 5.1.5)	
	Type	`numeric`
	Range	`1 .. 255`

Set this MySQL server's node ID in a MySQL Cluster.

Prior to MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, this option can be used *instead* of specifying the node ID as part of the connectstring or in the `config.ini` file, or permitting the cluster to determine an arbitrary node ID. If you use this option, then `--ndb-nodeid` must be specified *before* `--ndb-connectstring` [1914]. If `--ndb-nodeid` is used *and* a node ID is specified in the connectstring, then the MySQL server cannot connect to the cluster.

Beginning with MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, the `--ndb-nodeid` option *overrides* any node ID set with `--ndb-connectstring` [1914], regardless of the order in which the two options are used.

In addition (regardless of the MySQL Cluster version), if `--ndb-nodeid` is used, then either a matching node ID must be found in a `[mysqld]` or `[api]` section of `config.ini`, or there must be an “open” `[mysqld]` or `[api]` section in the file (that is, a section without a `NodeId` or `Id` parameter specified). This is also true if the node ID is specified as part of the connectstring.

Regardless of how the node ID is determined, its is shown as the value of the global status variable `Ndb_cluster_node_id` in the output of `SHOW STATUS`, and as `cluster_node_id` in the `connection` row of the output of `SHOW ENGINE NDBCLUSTER STATUS`.

For more information about node IDs for MySQL Cluster SQL nodes, see Defining SQL and Other API Nodes in a MySQL Cluster.

- `--ndb-log-empty-epochs=[0|1]`

Version Introduced	5.1.31-ndb-6.3.21, 5.1.31-ndb-6.4.1	
Command-Line Format	`--ndb-log-empty-epochs`	
Option-File Format	`ndb-log-empty-epochs`	
Variable Name	`ndb_log_empty_epochs`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`boolean`
	Default	`OFF`

Causes epochs during which there were no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `--log-slave-updates` is enabled.

By default this option is disabled. Disabling `--ndb-log-empty-epochs` causes epoch transactions with no changes not to be written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index` (Bug #49559, Bug #11757505).

Because `--ndb-log-empty-epochs=1` causes the size of `ndb_binlog_index` table to increase independently of the size of the binary log, users should be prepared to manage the growth of this table, even if they expect the cluster to be idle a large part of the time.

This option was introduced in MySQL Cluster NDB 6.3.21 and MySQL Cluster NDB 6.4.1. Prior to MySQL Cluster NDB 6.3.33, MySQL Cluster NDB 7.0.14, and MySQL Cluster NDB 7.1.3, setting `--ndb-log-empty-epochs=0` also caused no row to be written in `ndb_binlog_index` for an empty epoch.

- `--server-id-bits=#`

Version Introduced	5.1.47-ndb-7.0.17, 5.1.47-ndb-7.1.6	
Command-Line Format	`--server-id-bits=#`	
Option-File Format	`server-id-bits`	
Option Sets Variable	Yes, `server_id_bits` [1935]	
Variable Name	`server_id_bits`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`numeric`
	Default	`32`
	Range	`7 .. 32`

This option indicates the number of least significant bits within the 32-bit `server_id` [521] which actually identify the server. Indicating that the server is actually identified by fewer than 32 bits makes it possible for some of the remaining bits to be used for other purposes, such as storing user data generated by applications using the NDB API's Event API within the `AnyValue` of an `OperationOptions` structure (MySQL Cluster uses the `AnyValue` to store the server ID).

When extracting the effective server ID from `server_id` [521] for purposes such as detection of replication loops, the server ignores the remaining bits. The `--server-id-bits` option is used to mask out any irrelevant bits of `server_id` [521] in the IO and SQL threads when deciding whether an event should be ignored based on the server ID.

This data can be read from the binary log by `mysqlbinlog`, provided that it is run with its own `--server-id-bits` [353] option set to 32 (the default).

The value of `server_id` [521] must be less than 2 ^ `server_id_bits` [1935]; otherwise, `mysqld` refuses to start.

This system variable was added in MySQL Cluster NDB 7.0.17 and MySQL Cluster NDB 7.1.6; it is supported only in these and later releases of MySQL Cluster. It is not supported by the standard MySQL Server.

- `--skip-ndbcluster`

Command-Line Format	`--skip-ndbcluster`
Option-File Format	`skip-ndbcluster`

Disable the `NDBCLUSTER` storage engine. This is the default for binaries that were built with `NDBCLUSTER` storage engine support; the server allocates memory and other resources for this storage engine only if the `--ndbcluster` [1915] option is given explicitly. See Quick Test Setup of MySQL Cluster, for an example.

- `--ndb-wait-connected=seconds`

Version Introduced	5.1.16-ndb-6.2.0	
Command-Line Format	`--ndb-wait-connected=#`	
Option-File Format	`ndb-wait-connected`	
Variable Name	`ndb-wait-connected`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`numeric`
	Default	`0`
	Range	`0 .. 31536000`
	Permitted Values	
	Type	`numeric`
	Default	`0`
	Range	`0 .. 31536000`
	Permitted Values	
	Type	`numeric`
	Default	`30`
	Range	`0 .. 31536000`
	Permitted Values	
	Type	`numeric`
	Default	`30`
	Range	`0 .. 31536000`

This option sets the period of time that the MySQL server waits for connections to MySQL Cluster management and data nodes to be established before accepting MySQL client connections. The time is specified in seconds.

Prior to MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, there existed a hard-coded 30-second timeout (which was removed in these versions), and the default value for this option was `0`. Starting with these releases, the default value is `30`, and user-supplied values are handled correctly. (Bug #12543299)

- `--ndb-wait-setup=seconds`

Version Introduced	5.1.39-ndb-6.2.19, 5.1.39-ndb-6.3.28, 5.1.39-ndb-7.0.9	
Command-Line Format	`--ndb-wait-setup=#`	
Option-File Format	`ndb-wait-setup`	
Variable Name	`ndb-wait-setup`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`numeric`
	Default	`15`
	Range	`0 .. 31536000`

	Permitted Values	
	Type	`numeric`
	Default	`15`
	Range	`0 .. 31536000`
	Permitted Values	
	Type	`numeric`
	Default	`30`
	Range	`0 .. 31536000`
	Permitted Values	
	Type	`numeric`
	Default	`30`
	Range	`0 .. 31536000`

This variable shows the period of time that the MySQL server waits for the `NDB` storage engine to complete setup before timing out and treating `NDB` as unavailable. The time is specified in seconds.

Prior to MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, the default value for this option was `15`. In these and later releases, the default value is `30`. (Bug #12543299)

- `--ndb_optimization_delay=`*`milliseconds`*

Version Introduced	5.1.23-ndb-6.3.7	
Variable Name	`ndb_optimization_delay`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`numeric`
	Default	`10`
	Range	`0 .. 100000`

Set the number of milliseconds to wait between sets of rows by `OPTIMIZE TABLE` statements on `NDB` tables. The default is 15.

MySQL Cluster System Variables

This section provides detailed information about MySQL server system variables that are specific to MySQL Cluster and the `NDB` storage engine. For system variables not specific to MySQL Cluster, see Server System Variables. For general information on using system variables, see Using System Variables.

- `have_ndbcluster` [1920]

Variable Name	`have_ndbcluster`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`boolean`

`YES` if `mysqld` supports `NDBCLUSTER` tables. `DISABLED` if `--skip-ndbcluster` is used.

This variable is deprecated and is removed in MySQL 5.6. Use `SHOW ENGINES` instead.

- `multi_range_count`

Command-Line Format	`--multi_range_count=#`	
Option-File Format	`multi_range_count`	
Option Sets Variable	Yes, `multi_range_count` [1921]	
Variable Name	`multi_range_count`	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`numeric`
	Default	`256`
	Range	`1 .. 4294967295`

The maximum number of ranges to send to a table handler at once during range selects. The default value is 256. Sending multiple ranges to a handler at once can improve the performance of certain selects dramatically. This is especially true for the `NDBCLUSTER` table handler, which needs to send the range requests to all nodes. Sending a batch of those requests at once reduces communication costs significantly.

This variable is deprecated in MySQL 5.1, and is no longer supported in MySQL 5.5, in which arbitrarily long lists of ranges can be processed.

- `ndb_autoincrement_prefetch_sz` [1921]

Command-Line Format	`--ndb_autoincrement_prefetch_sz`	
Option-File Format	`ndb_autoincrement_prefetch_sz`	
Option Sets Variable	Yes, `ndb_autoincrement_prefetch_sz` [1921]	
Variable Name	`ndb_autoincrement_prefetch_sz`	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values (>= 5.1.1, <= 5.1.22)	
	Type	`numeric`
	Default	`32`
	Range	`1 .. 256`
	Permitted Values (>= 5.1.23, <= 5.1.24)	
	Type	`numeric`
	Default	`1`
	Range	`1 .. 256`
	Permitted Values (>= NDB 6.2.0, <= NDB 6.2.9)	
	Type	`numeric`
	Default	`32`
	Range	`1 .. 256`
	Permitted Values (>= NDB 6.2.10)	
	Type	`numeric`
	Default	`32`
	Range	`1 .. 256`

	Permitted Values (>= NDB 6.3.0, <= 6.3.6)	
	Type	numeric
	Default	32
	Range	1 .. 256
	Permitted Values (>= NDB 6.3.7, <= 6.3.30)	
	Type	numeric
	Default	1
	Range	1 .. 256
	Permitted Values (>= NDB 6.3.31)	
	Type	numeric
	Default	1
	Range	1 .. 65536
	Permitted Values (>= NDB 6.4.0, <= 7.0.10)	
	Type	numeric
	Default	32
	Range	1 .. 256
	Permitted Values (>= NDB 7.0.11)	
	Type	numeric
	Default	1
	Range	1 .. 65536
	Permitted Values (>= NDB 7.1.1)	
	Type	numeric
	Default	1
	Range	1 .. 65536

Determines the probability of gaps in an autoincremented column. Set it to 1 to minimize this. Setting it to a high value for optimization makes inserts faster, but decreases the likelihood that consecutive autoincrement numbers will be used in a batch of inserts. The minimum value is 1. Prior to MySQL 5.1.23, MySQL Cluster NDB 6.2.9, and MySQL Cluster NDB 6.3.7, the default value was 32; in these and all later versions, the default is 1. Prior to MySQL Cluster NDB 6.3.31 and MySQL Cluster NDB 7.0.11, the maximum value was 256; in these and all later versions of MySQL Cluster (including all MySQL Cluster NDB 7.1 releases), the maximum is 65536 (Bug #50621).

Beginning with MySQL Cluster NDB 6.2.10, MySQL Cluster NDB 6.3.7, and MySQL 5.1.23, this variable affects the number of AUTO_INCREMENT IDs that are fetched between statements only. Within a statement, at least 32 IDs are now obtained at a time. The default value for ndb_autoincrement_prefetch_sz [1921] is now 1, to increase the speed of statements inserting single rows. (Bug #31956)

Important

This variable does not affect inserts performed using INSERT ... SELECT.

- ndb_cache_check_time [1922]

Command-Line Format	--ndb_cache_check_time
Option-File Format	ndb_cache_check_time
Option Sets Variable	Yes, ndb_cache_check_time [1922]

Variable Name	ndb_cache_check_time	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric
	Default	0

The number of milliseconds that elapse between checks of MySQL Cluster SQL nodes by the MySQL query cache. Setting this to 0 (the default and minimum value) means that the query cache checks for validation on every query.

The recommended maximum value for this variable is 1000, which means that the check is performed once per second. A larger value means that the check is performed and possibly invalidated due to updates on different SQL nodes less often. It is generally not desirable to set this to a value greater than 2000.

- ndb_deferred_constraints [1923]

Version Introduced	5.1.56-ndb-7.0.28, 5.1.56-ndb-7.1.14	
Command-Line Format	--ndb-deferred-constraints	
Option-File Format	ndb_deferred_constraints	
Option Sets Variable	Yes, ndb_deferred_constraints [1923]	
Variable Name	ndb_deferred_constraints	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	boolean
	Default	false
	Range	false .. true

Controls whether or not constraint checks are deferred, where these are supported. OFF is the default.

This variable was added in MySQL Cluster NDB 7.0.28 and MySQL Cluster NDB 7.1.14.

This variable is not normally needed for operation of MySQL Cluster or MySQL Cluster Replication, and is intended primarily for use in testing.

- ndb_distribution [1923]

Version Introduced	5.1.32-ndb-7.0.4	
Command-Line Format	--ndb-distribution={KEYHASH|LINHASH}	
Option-File Format	ndb_distribution	
Variable Name	ndb_distribution={KEYHASH|LINHASH}	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	enumeration
	Default	KEYHASH

	Valid Values	`LINHASH` `KEYHASH`

Controls the default distribution method for `NDB` tables. Can be set to either of `KEYHASH` (key hashing) or `LINHASH` (linear hashing). `KEYHASH` is the default.

- `ndb_extra_logging` [1924]

Version Introduced	5.1.6	
Command-Line Format	`ndb_extra_logging=#`	
Option-File Format	`ndb_extra_logging`	
Variable Name	`ndb_extra_logging`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`numeric`
	Default	`0`

This variable can be used to enable recording in the MySQL error log of information specific to the `NDB` storage engine. It is normally of interest only when debugging `NDB` storage engine code.

The default value is 0, which means that the only `NDB`-specific information written to the MySQL error log relates to transaction handling. If the value is greater than 0 but less than 10, `NDB` table schema and connection events are also logged, as well as whether or not conflict resolution is in use, and other `NDB` errors and information. If the value is set to 10 or more, information about `NDB` internals, such as the progress of data distribution among cluster nodes, is also written to the MySQL error log.

This variable was added in MySQL 5.1.6.

- `ndb_force_send` [1924]

Command-Line Format	`--ndb-force-send`	
Option-File Format	`ndb_force_send`	
Option Sets Variable	Yes, `ndb_force_send` [1924]	
Variable Name	`ndb_force_send`	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`boolean`
	Default	`TRUE`

Forces sending of buffers to `NDB` immediately, without waiting for other threads. Defaults to `ON`.

- `ndb_index_stat_cache_entries` [1924]

Version Removed	5.1.14	
Command-Line Format	`--ndb_index_stat_cache_entries`	
Option-File Format	`ndb_index_stat_cache_entries`	
	Permitted Values	
	Type	`numeric`

	Default	`32`
	Range	`0 .. 4294967295`

Sets the granularity of the statistics by determining the number of starting and ending keys to store in the statistics memory cache. Zero means no caching takes place; in this case, the data nodes are always queried directly. Default value: `32`.

Note

If `ndb_index_stat_enable` [1925] is `OFF`, then setting this variable has no effect.

- `ndb_index_stat_enable` [1925]

Version Removed	5.1.19	
Command-Line Format	`--ndb_index_stat_enable`	
Option-File Format	`ndb_index_stat_enable`	
	Permitted Values	
	Type	`boolean`
	Default	`ON`

Use `NDB` index statistics in query optimization. Defaults to `ON`.

- `ndb_index_stat_update_freq` [1925]

Version Removed	5.1.14	
Command-Line Format	`--ndb_index_stat_update_freq`	
Option-File Format	`ndb_index_stat_update_freq`	
	Permitted Values	
	Type	`numeric`
	Default	`20`
	Range	`0 .. 4294967295`

How often to query data nodes instead of the statistics cache. For example, a value of `20` (the default) means to direct every 20th query to the data nodes.

Note

If `ndb_index_stat_cache_entries` [1924] is `0`, then setting this variable has no effect; in this case, every query is sent directly to the data nodes.

- `ndb_join_pushdown` [1925]

Version Introduced	5.1.51-ndb-7.2.0	
Variable Name	`ndb_join_pushdown`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`boolean`
	Default	`TRUE`

Added in MySQL Cluster NDB 7.2.0, this variable controls whether joins on `NDB` tables are pushed down to the NDB kernel (data nodes). Previously, a join was handled using multiple accesses of `NDB` by the SQL node; however, when `ndb_join_pushdown` [1925] is enabled, a pushable join is sent in its entirety to the data nodes, where it can be distributed among the data nodes and executed in parallel on multiple copies of the data, with a single, merged result being returned to `mysqld`. This can reduce greatly the number of round trips between an SQL node and the data nodes required to handle such a join.

By default, `ndb_join_pushdown` [1925] is enabled.

In order for a join to be pushable, it must meet the following conditions:

1. Only columns can be compared, and all columns to be joined must use *exactly* the same data type.

   This means that expressions such as `t1.a = t2.a + constant` cannot be pushed down, and that (for example) a join on an `INT` column and a `BIGINT` column also cannot be pushed down.

2. Queries referencing `BLOB` or `TEXT` columns are not supported.

3. Explicit locking is not supported; however, the `NDB` storage engine's characteristic implicit row-based locking is enforced.

   This means that a join using `FOR UPDATE` cannot be pushed down.

4. In order for a join to be pushed down, child tables in the join must be accessed using one of the `ref` [697], `eq_ref` [697], or `const` [696] access methods, or some combination of these methods.

   Outer joined child tables can only be pushed using `eq_ref` [697].

   If the root of the pushed join is an `eq_ref` [697] or `const` [696], only child tables joined by `eq_ref` [697] can be appended. (A table joined by `ref` [697] is likely to become the root of another pushed join.)

   If the query optimizer decides on `Using join cache` for a candidate child table, that table cannot be pushed as a child. However, it may be the root of another set of pushed tables.

5. Joins referencing tables explicitly partitioned by `[LINEAR] HASH`, `LIST`, or `RANGE` currently cannot be pushed down.

You can see whether a given join can be pushed down by checking it with `EXPLAIN`; when the join can be pushed down, you can see references to the `pushed join` in the `Extra` column of the output, as shown in this example:

```
mysql> EXPLAIN
    ->     SELECT e.first_name, e.last_name, t.title, d.dept_name
    ->         FROM employees e
    ->         JOIN dept_emp de ON e.emp_no=de.emp_no
    ->         JOIN departments d ON d.dept_no=de.dept_no
    ->         JOIN titles t ON e.emp_no=t.emp_no\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: d
         type: ALL
possible_keys: PRIMARY
          key: NULL
      key_len: NULL
          ref: NULL
         rows: 9
        Extra: Parent of 4 pushed join@1
*************************** 2. row ***************************
```

```
           id: 1
  select_type: SIMPLE
        table: de
         type: ref
possible_keys: PRIMARY,emp_no,dept_no
          key: dept_no
      key_len: 4
          ref: employees.d.dept_no
         rows: 5305
        Extra: Child of 'd' in pushed join@1
*************************** 3. row ***************************
           id: 1
  select_type: SIMPLE
        table: e
         type: eq_ref
possible_keys: PRIMARY
          key: PRIMARY
      key_len: 4
          ref: employees.de.emp_no
         rows: 1
        Extra: Child of 'de' in pushed join@1
*************************** 4. row ***************************
           id: 1
  select_type: SIMPLE
        table: t
         type: ref
possible_keys: PRIMARY,emp_no
          key: emp_no
      key_len: 4
          ref: employees.de.emp_no
         rows: 19
        Extra: Child of 'e' in pushed join@1
4 rows in set (0.00 sec)
```

Note

If inner joined child tables are joined by `ref` [697], *and* the result is ordered or grouped by a sorted index, this index cannot provide sorted rows, which forces writing to a sorted tempfile.

Two additional sources of information about pushed join performance are available:

1. The status variables `Ndb_pushed_queries_defined` [1949], `Ndb_pushed_queries_dropped` [1949], `Ndb_pushed_queries_executed` [1949], and `Ndb_pushed_reads` [1949] (all introduced in MySQL Cluster NDB 7.2.0).

2. The counters in the `ndbinfo.counters` table that belong to the `DBSPJ` kernel block. (These counters and the `DBSPJ` block were also introduced in MySQL Cluster NDB 7.2.0). See The `ndbinfo counters` Table, for information about these counters. See also The `DBSPJ` Block, in the *MySQL Cluster API Developer Guide*.

- `ndb_log_apply_status` [1927]

Version Introduced	5.1.51-ndb-7.0.21, 5.1.51-ndb-7.1.10
Command-Line Format	`--ndb-log-apply-status`
Option-File Format	`ndb-log-apply-status`
Option Sets Variable	Yes, `ndb_log_apply_status` [1927]
Variable Name	`ndb_log_apply_status`
Variable Scope	Global
Dynamic Variable	No
	Permitted Values
	Type `boolean`

	Default	`OFF`

A read-only variable which shows whether the server was started with the `--ndb-log-apply-status` [1915] option.

This variable was added in MySQL Cluster NDB 7.0.21 and MySQL Cluster NDB 7.1.10.

- `ndb_log_bin` [1928]

Version Introduced	5.1.6	
Command-Line Format	`--ndb-log-bin={1|0}`	
Option Sets Variable	Yes, `ndb_log_bin` [1928]	
Variable Name	`ndb_log_bin`	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`boolean`
	Default	`ON`

Causes updates to `NDB` tables to be written to the binary log. Setting this variable has no effect if binary logging is not already enabled for the server using `log_bin` [488]. `ndb_log_bin` defaults to 1 (ON); normally, there is never any need to change this value in a production environment.

This variable was added in MySQL 5.1.6.

- `ndb_log_binlog_index` [1928]

Version Introduced	5.1.6	
Command-Line Format	`--ndb-log-binlog-index={1|0}`	
Option Sets Variable	Yes, `ndb_log_binlog_index` [1928]	
Variable Name	`ndb_log_binlog_index`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`boolean`
	Default	`ON`

Causes a mapping of epochs to positions in the binary log to be inserted into the `ndb_binlog_index` table. Setting this variable has no effect if binary logging is not already enabled for the server using `log_bin` [488]. (In addition, `ndb_log_bin` [1928] must not be disabled.) `ndb_log_binlog_index` defaults to `1` (`ON`); normally, there is never any need to change this value in a production environment.

This variable was added in MySQL 5.1.6.

- `ndb_optimized_node_selection` [1928]

Command-Line Format	`--ndb-optimized-node-selection=#`	
Option-File Format	`ndb_optimized_node_selection`	
	Permitted Values	
	Type	`boolean`

	Default	`ON`
	Permitted Values	
	Type	`numeric`
	Default	`3`
	Range	`0 .. 3`

Prior to MySQL Cluster NDB 6.3.4. Causes an SQL node to use the "closest" data node as transaction coordinator. Enabled by default. Set to `0` or `OFF` to disable, in which case the SQL node uses each data node in the cluster in succession. When this option is disabled each SQL thread attempts to use a given data node 8 times before proceeding to the next one.

Beginning with MySQL Cluster NDB 6.3.4. There are two forms of optimized node selection, described here:

1. The SQL node uses *promixity* to determine the transaction coordinator; that is, the "closest" data node to the SQL node is chosen as the transaction coordinator. For this purpose, a data node having a shared memory connection with the SQL node is considered to be "closest" to the SQL node; the next closest (in order of decreasing proximity) are: TCP connection to `localhost`; SCI connection; TCP connection from a host other than `localhost`.

2. The SQL thread uses *distribution awareness* to select the data node. That is, the data node housing the cluster partition accessed by the first statement of a given transaction is used as the transaction coordinator for the entire transaction. (This is effective only if the first statement of the transaction accesses no more than one cluster partition.)

This option takes one of the integer values `0`, `1`, `2`, or `3`. `3` is the default. These values affect node selection as follows:

- `0`: Node selection is not optimized. Each data node is employed as the transaction coordinator 8 times before the SQL thread proceeds to the next data node. (This is the same "round-robin" behavior as caused by setting this option to `0` or `OFF` in previous versions of MySQL Cluster.)

- `1`: Proximity to the SQL node is used to determine the transaction coordinator. (This is the same behavior as caused by setting this option to `1` or `ON` in previous MySQL versions.)

- `2`: Distribution awareness is used to select the transaction coordinator. However, if the first statement of the transaction accesses more than one cluster partition, the SQL node reverts to the round-robin behavior seen when this option is set to `0`.

- `3`: If distribution awareness can be employed to determine the transaction coordinator, then it is used; otherwise proximity is used to select the transaction coordinator. (This is the default behavior in MySQL Cluster NDB 6.3.4 and later.)

Important

Beginning with MySQL Cluster NDB 6.3.4, it is no longer possible to set `--ndb_optimized_node_selection` to `ON` or `OFF`; attempting to do so causes `mysqld` to abort with an error.

- `ndb_report_thresh_binlog_epoch_slip` [1929]

Command-Line Format	`--ndb_report_thresh_binlog_epoch_slip`	
Option-File Format	`ndb_report_thresh_binlog_epoch_slip`	
	Permitted Values	
	Type	`numeric`
	Default	`3`

	Range	`0 .. 256`

This is a threshold on the number of epochs to be behind before reporting binary log status. For example, a value of `3` (the default) means that if the difference between which epoch has been received from the storage nodes and which epoch has been applied to the binary log is 3 or more, a status message will be sent to the cluster log.

- `ndb_report_thresh_binlog_mem_usage` [1930]

Command-Line Format	`--ndb_report_thresh_binlog_mem_usage`	
Option-File Format	`ndb_report_thresh_binlog_mem_usage`	
	Permitted Values	
	Type	`numeric`
	Default	`10`
	Range	`0 .. 10`

This is a threshold on the percentage of free memory remaining before reporting binary log status. For example, a value of `10` (the default) means that if the amount of available memory for receiving binary log data from the data nodes falls below 10%, a status message will be sent to the cluster log.

- `slave_allow_batching` [1930]

Version Introduced	5.1.19-ndb-6.2.3	
Command-Line Format	`--slave-allow-batching`	
Option-File Format	`slave_allow_batching`	
Option Sets Variable	Yes, `slave_allow_batching` [1930]	
Variable Name	`slave_allow_batching`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`boolean`
	Default	`off`

Whether or not batched updates are enabled on MySQL Cluster replication slaves.

This variable is available beginning with MySQL Cluster NDB 6.2.3. Currently, it is available for `mysqld` only as supplied with MySQL Cluster or built from the MySQL Cluster sources. For more information, see Starting MySQL Cluster Replication (Single Replication Channel).

- `ndb_table_no_logging` [1930]

Version Introduced	5.1.23-ndb-6.3.8	
Variable Name	`ndb_table_no_logging`	
Variable Scope	Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`boolean`
	Default	`FALSE`

When this variable is set to `ON` or `1`, it causes `NDB` tables not to be checkpointed to disk. More specifically, this setting applies to tables which are created or altered using `ENGINE NDB` when

ndb_table_no_logging [1930] is enabled, and continues to apply for the lifetime of the table, even if ndb_table_no_logging [1930] is later changed. Suppose that A, B, C, and D are tables that we create (and perhaps also alter), and that we also change the setting for ndb_table_no_logging [1930] as shown here:

```
SET @@ndb_table_no_logging = 1;

CREATE TABLE A ... ENGINE NDB;

CREATE TABLE B ... ENGINE MYISAM;
CREATE TABLE C ... ENGINE MYISAM;

ALTER TABLE B ENGINE NDB;

SET @@ndb_table_no_logging = 0;

CREATE TABLE D ... ENGINE NDB;
ALTER TABLE C ENGINE NDB;

SET @@ndb_table_no_logging = 1;
```

After the previous sequence of events, tables A and B are not checkpointed; A was created with ENGINE NDB and B was altered to use NDB, both while ndb_table_no_logging was enabled. However, tables C and D are logged; C was altered to use NDB and D was created using ENGINE NDB, both while ndb_table_no_logging [1930] was disabled. Setting ndb_table_no_logging [1930] back to 1 or ON does *not* cause table C or D to be checkpointed.

Note

ndb_table_no_logging [1930] has no effect on the creation of NDB table schema files; to suppress these, use ndb_table_temporary [1931] instead.

- ndb_table_temporary [1931]

Version Introduced	5.1.23-ndb-6.3.8	
Variable Name	ndb_table_temporary	
Variable Scope	Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	boolean
	Default	FALSE

When set to ON or 1, this variable causes NDB tables not to be written to disk: This means that no table schema files are created, and that the tables are not logged.

Note

Setting this variable currently has no effect in MySQL Cluster NDB 7.0 and later. This is a known issue; see BUG#34036.

- ndb_use_copying_alter_table [1931]

Version Introduced	5.1.12
Variable Name	ndb_use_copying_alter_table
Variable Scope	Global, Session
Dynamic Variable	No

Forces NDB to use copying of tables in the event of problems with online ALTER TABLE operations. The default value is OFF.

This variable was added in MySQL 5.1.12.

- ndb_use_exact_count [1932]

Variable Name	ndb_use_exact_count	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	boolean
	Default	ON

Forces NDB to use a count of records during SELECT COUNT(*) query planning to speed up this type of query. The default value is ON. For faster queries overall, disable this feature by setting the value of ndb_use_exact_count [1932] to OFF.

- ndb_use_transactions [1932]

Command-Line Format	--ndb_use_transactions	
Option-File Format	ndb_use_transactions	
Variable Name	ndb_use_transactions	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	boolean
	Default	ON

You can disable NDB transaction support by setting this variable's values to OFF (not recommended). The default is ON.

Note

The setting for this variable was not honored in MySQL Cluster NDB 6.4.3 and MySQL Cluster NDB 7.0.4. (Bug #43236)

- transaction_allow_batching [1932]

Version Introduced	5.1.23-ndb-6.3.7	
Variable Name	transaction_allow_batching	
Variable Scope	Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	boolean
	Default	FALSE

When set to 1 or ON, this variable enables batching of statements within the same transaction. To use this variable, autocommit [461] must first be disabled by setting it to 0 or OFF; otherwise, setting transaction_allow_batching [1932] has no effect.

It is safe to use this variable with transactions that performs writes only, as having it enabled can lead to reads from the “before” image. You should ensure that any pending transactions are committed (using an explicit `COMMIT` if desired) before issuing a `SELECT`.

Important

`transaction_allow_batching` [1932] should not be used whenever there is the possibility that the effects of a given statement depend on the outcome of a previous statement within the same transaction.

This variable was added in MySQL Cluster NDB 6.3.7, and is currently supported in MySQL Cluster only.

The system variables in the following list all relate to the `ndbinfo` information database. They were added in MySQL Cluster NDB 7.1.1.

- `ndbinfo_database` [1933]

Version Introduced	5.1.41-ndb-7.1.1	
Variable Name	`ndbinfo_database`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`string`
	Default	`ndbinfo`

Shows the name used for the `NDB` information database; the default is `ndbinfo`. This is a read-only variable whose value is determined at compile time; you can set it by starting the server using `--ndbinfo-database=`*`name`*, which sets the value shown for this variable but does not actually change the name used for the NDB information database.

- `ndbinfo_max_bytes` [1933]

Version Introduced	5.1.41-ndb-7.1.1	
Command-Line Format	`--ndbinfo-max-bytes=#`	
Option Sets Variable	Yes, `ndbinfo_max_bytes` [1933]	
Variable Name	`ndbinfo_max_bytes`	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`numeric`
	Default	`0`

Used in testing and debugging only.

- `ndbinfo_max_rows` [1933]

Version Introduced	5.1.41-ndb-7.1.1
Command-Line Format	`--ndbinfo-max-rows=#`
Option Sets Variable	Yes, `ndbinfo_max_rows` [1933]
Variable Name	`ndbinfo_max_rows`
Variable Scope	Global, Session

Dynamic Variable	Yes	
	Permitted Values	
	Type	`numeric`
	Default	`10`

Used in testing and debugging only.

- `ndbinfo_show_hidden` [1934]

Version Introduced	5.1.41-ndb-7.1.1	
Command-Line Format	`--ndbinfo-show-hidden={0|1}`	
Option Sets Variable	Yes, `ndbinfo_show_hidden` [1934]	
Variable Name	`ndbinfo_show_hidden`	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`boolean`
	Default	`OFF`

Whether or not the `ndbinfo` database's underlying internal tables are shown in the `mysql` client. The default is `OFF`.

- `ndbinfo_table_prefix` [1934]

Version Introduced	5.1.41-ndb-7.1.1	
Command-Line Format	`--ndbinfo-table-prefix=name`	
Option Sets Variable	Yes, `ndbinfo_table_prefix` [1934]	
Variable Name	`ndbinfo_table_prefix`	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`string`
	Default	`ndb$`

The prefix used in naming the ndbinfo database's base tables (normally hidden, unless exposed by setting `ndbinfo_show_hidden` [1934]). This is a read-only variable whose default value is "`ndb$`". You can start the server with the `--ndbinfo-table-prefix` option, but this merely sets the variable and does not change the actual prefix used to name the hidden base tables; the prefix itself is determined at compile time.

- `ndbinfo_version` [1934]

Version Introduced	5.1.41-ndb-7.1.1	
Variable Name	`ndbinfo_version`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`string`
	Default	

Shows the version of the `ndbinfo` engine in use; read-only.

- `ndb_log_transaction_id` [1935]

Version Introduced	5.1.56-ndb-7.1.16	
Variable Name	`ndb_log_transaction_id`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`boolean`
	Default	`OFF`

This read-only, Boolean system variable shows whether a slave `mysqld` writes NDB transaction IDs in the binary log (required to use "active-active" MySQL Cluster Replication with `NDB $EPOCH_TRANS()` conflict detection). To change the setting, use the `--ndb-log-transaction-id` [1916] option.

`ndb_log_transaction_id` [1935] is available in MySQL Cluster NDB 7.1.16 and later. It is not supported in mainline MySQL Server 5.1.

For more information, see MySQL Cluster Replication Conflict Resolution.

- `ndb_log_empty_epochs` [1935]

Version Introduced	5.1.31-ndb-6.3.21, 5.1.31-ndb-6.4.1	
Command-Line Format	`--ndb-log-empty-epochs`	
Option-File Format	`ndb_log_empty_epochs`	
Variable Name	`ndb_log_empty_epochs`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`boolean`
	Default	`OFF`

When this variable is set to 0, epoch transactions with no changes are not written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index` (Bug #49559, Bug #11757505).

- `server_id_bits` [1935]

Version Introduced	5.1.47-ndb-7.0.17, 5.1.47-ndb-7.1.6	
Command-Line Format	`--server-id-bits=#`	
Option-File Format	`server-id-bits`	
Option Sets Variable	Yes, `server_id_bits` [1935]	
Variable Name	`server_id_bits`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`numeric`

	Default	32
	Range	7 .. 32

The effective value of server_id if the server was started with the --server-id-bits [1918] option set to a nondefault value.

If the value of server_id [521] greater than or equal to 2 to the power of server_id_bits [1935], mysqld refuses to start.

This system variable was added in MySQL Cluster NDB 7.0.17 and MySQL Cluster NDB 7.1.6; it is supported only in these and later releases of MySQL Cluster. server_id_bits [1935] is not supported by the standard MySQL Server.

MySQL Cluster Status Variables

This section provides detailed information about MySQL server status variables that relate to MySQL Cluster and the NDB storage engine. For status variables not specific to MySQL Cluster, and for general information on using status variables, see Server Status Variables.

- Handler_discover [1936]

  The MySQL server can ask the NDBCLUSTER storage engine if it knows about a table with a given name. This is called discovery. Handler_discover [1936] indicates the number of times that tables have been discovered using this mechanism.

- Ndb_api_wait_exec_complete_count_session [1936]

  The number of times a thread has been blocked in this client session while waiting for execution of an operation to complete. This includes all execute() calls as well as implicit implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it relates to the current session only, and is not affected by any other clients of this mysqld.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- Ndb_api_wait_exec_complete_count_slave [1936]

  The number of times a thread has been blocked by this slave while waiting for execution of an operation to complete. This includes all execute() calls as well as implicit implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- Ndb_api_wait_exec_complete_count [1936]

  The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for execution of an operation to complete. This includes all execute() calls as well as implicit implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_wait_scan_result_count_session` [1937]

  The number of times a thread has been blocked in this client session while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_wait_scan_result_count_slave` [1937]

  The number of times a thread has been blocked by this slave while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_wait_scan_result_count` [1937]

  The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_wait_meta_request_count_session` [1937]

  The number of times a thread has been blocked in this client session waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_wait_meta_request_count_slave` [1937]

  The number of times a thread has been blocked by this slave waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_wait_meta_request_count` [1937]

The number of times a thread has been blocked by this MySQL Server (SQL node) waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_wait_nanos_count_session` [1938]

  Total time (in nanoseconds) spent in this client session waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_wait_nanos_count_slave` [1938]

  Total time (in nanoseconds) spent by this slave waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_wait_nanos_count` [1938]

  Total time (in nanoseconds) spent by this MySQL Server (SQL node) waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_bytes_sent_count_session` [1938]

  Amount of data (in bytes) sent to the data nodes in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_bytes_sent_count_slave` [1938]

  Amount of data (in bytes) sent to the data nodes by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_bytes_sent_count` [1939]

  Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_bytes_received_count_session` [1939]

  Amount of data (in bytes) received from the data nodes in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_bytes_received_count_slave` [1939]

  Amount of data (in bytes) received from the data nodes by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_bytes_received_count` [1939]

  Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_trans_start_count_session` [1939]

  The number of transactions started in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_trans_start_count_slave` [1939]

  The number of transactions started by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_trans_start_count` [1940]

  The number of transactions started by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_trans_commit_count_session` [1940]

  The number of transactions committed in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_trans_commit_count_slave` [1940]

  The number of transactions committed by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_trans_commit_count` [1940]

  The number of transactions committed by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_trans_abort_count_session` [1940]

  The number of transactions aborted in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_trans_abort_count_slave` [1940]

  The number of transactions aborted by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_trans_abort_count` [1941]

  The number of transactions aborted by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_trans_close_count_session` [1941]

  The number of transactions closed in this client session. This value may be greater than the sum of `Ndb_api_trans_commit_count_session` [1940] and `Ndb_api_trans_abort_count_session` [1940], since some transactions may have been rolled back.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_trans_close_count_slave` [1941]

  The number of transactions closed by this slave. This value may be greater than the sum of `Ndb_api_trans_commit_count_slave` [1940] and `Ndb_api_trans_abort_count_slave` [1940], since some transactions may have been rolled back.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_trans_close_count` [1941]

  The number of transactions closed by this MySQL Server (SQL node). This value may be greater than the sum of `Ndb_api_trans_commit_count` [1940] and `Ndb_api_trans_abort_count` [1941], since some transactions may have been rolled back.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_pk_op_count_session` [1941]

  The number of operations in this client session based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_pk_op_count_slave` [1942]

  The number of operations by this slave based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_pk_op_count` [1942]

  The number of operations by this MySQL Server (SQL node) based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_uk_op_count_session` [1942]

  The number of operations in this client session based on or using unique keys.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_uk_op_count_slave` [1942]

  The number of operations by this slave based on or using unique keys.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_uk_op_count` [1942]

  The number of operations by this MySQL Server (SQL node) based on or using unique keys.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_table_scan_count_session` [1942]

The number of table scans that have been started in this client session, including scans of internal tables,.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_table_scan_count_slave` [1943]

  The number of table scans that have been started by this slave, including scans of internal tables,.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_table_scan_count` [1943]

  The number of table scans that have been started by this MySQL Server (SQL node), including scans of internal tables,.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_range_scan_count_session` [1943]

  The number of range scans that have been started in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_range_scan_count_slave` [1943]

  The number of range scans that have been started by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_range_scan_count` [1943]

  The number of range scans that have been started by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_pruned_scan_count_session` [1944]

  The number of scans in this client session that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_pruned_scan_count_slave` [1944]

  The number of scans by this slave that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_pruned_scan_count` [1944]

  The number of scans by this MySQL Server (SQL node) that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_scan_batch_count_session` [1944]

  The number of batches of rows received in this client session. 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_scan_batch_count_slave` [1944]

  The number of batches of rows received by this slave. 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_scan_batch_count` [1944]

  The number of batches of rows received by this MySQL Server (SQL node). 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_read_row_count_session` [1945]

  The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_read_row_count_slave` [1945]

  The total number of rows that have been read by this slave. This includes all rows read by any primary key, unique key, or scan operation made by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_read_row_count` [1945]

  The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_trans_local_read_row_count_session` [1945]

  The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_trans_local_read_row_count_slave` [1945]

  The total number of rows that have been read by this slave. This includes all rows read by any primary key, unique key, or scan operation made by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_trans_local_read_row_count` [1946]

  The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_event_data_count_injector` [1946]

  The number of row change events received by the NDB binlog injector thread.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_event_data_count` [1946]

  The number of row change events received by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_event_nondata_count_injector` [1946]

  The number of events received, other than row change events, by the NDB binlog injector thread.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_event_nondata_count` [1946]

  The number of events received, other than row change events, by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_event_bytes_count_injector` [1946]

  The number of bytes of events received by the NDB binlog injector thread.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_api_event_bytes_count` [1946]

The number of bytes of events received by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see NDB API Statistics Counters and Variables.

- `Ndb_cluster_node_id` [1947]

  If the server is acting as a MySQL Cluster node, then the value of this variable its node ID in the cluster.

  If the server is not part of a MySQL Cluster, then the value of this variable is 0.

- `Ndb_config_from_host` [1947]

  If the server is part of a MySQL Cluster, the value of this variable is the host name or IP address of the Cluster management server from which it gets its configuration data.

  If the server is not part of a MySQL Cluster, then the value of this variable is an empty string.

  Prior to MySQL 5.1.12, this variable was named `Ndb_connected_host`.

- `Ndb_config_from_port` [1947]

  If the server is part of a MySQL Cluster, the value of this variable is the number of the port through which it is connected to the Cluster management server from which it gets its configuration data.

  If the server is not part of a MySQL Cluster, then the value of this variable is 0.

  Prior to MySQL 5.1.12, this variable was named `Ndb_connected_port`.

- `Ndb_conflict_fn_max`

  Used in MySQL Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that this `mysqld` was started.

  This variable was added in MySQL Cluster NDB 6.3.3. For more information, see MySQL Cluster Replication Conflict Resolution.

- `Ndb_conflict_fn_old`

  Used in MySQL Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given `mysqld` since the last time it was restarted.

  This variable was added in MySQL Cluster NDB 6.3.4. For more information, see MySQL Cluster Replication Conflict Resolution.

- `Ndb_conflict_fn_epoch`

  Used in MySQL Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH()` conflict resolution on a given `mysqld` since the last time it was restarted.

  This variable was added in MySQL Cluster NDB 7.1.16. For more information, see MySQL Cluster Replication Conflict Resolution.

- `Ndb_conflict_fn_epoch_trans`

Used in MySQL Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS()` conflict resolution on a given `mysqld` since the last time it was restarted.

This variable was added in MySQL Cluster NDB 7.1.16. For more information, see MySQL Cluster Replication Conflict Resolution.

- `Ndb_conflict_trans_row_conflict_count`

  Used in MySQL Cluster Replication conflict resolution, this status variable shows the number of rows found to be directly in-conflict by a transactional conflict function on a given `mysqld` since the last time it was restarted.

  Currently, the only transactional conflict detection function supported by MySQL Cluster is NDB$EPOCH_TRANS(), so this status variable is effectively the same as `Ndb_conflict_fn_epoch_trans` [1947].

  This variable was added in MySQL Cluster NDB 7.1.16. For more information, see MySQL Cluster Replication Conflict Resolution.

- `Ndb_conflict_trans_row_reject_count`

  Used in MySQL Cluster Replication conflict resolution, this status variable shows the total number of rows realigned due to being determined as conflicting by a transactional conflict detection function. This includes not only `Ndb_conflict_trans_row_conflict_count` [1948], but any rows in or dependent on conflicting transactions.

  This variable was added in MySQL Cluster NDB 7.1.16. For more information, see MySQL Cluster Replication Conflict Resolution.

- `Ndb_conflict_trans_reject_count`

  Used in MySQL Cluster Replication conflict resolution, this status variable shows the number of transactions found to be in conflict by a transactional conflict detection function.

  This variable was added in MySQL Cluster NDB 7.1.16. For more information, see MySQL Cluster Replication Conflict Resolution.

- `Ndb_conflict_trans_detect_iter_count`

  Used in MySQL Cluster Replication conflict resolution, this shows the number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to `Ndb_conflict_trans_conflict_commit_count` [1948].

  This variable was added in MySQL Cluster NDB 7.1.16. For more information, see MySQL Cluster Replication Conflict Resolution.

- `Ndb_conflict_trans_conflict_commit_count`

  Used in MySQL Cluster Replication conflict resolution, this shows the number of epoch transactions committed after they required transactional conflict handling.

  This variable was added in MySQL Cluster NDB 7.1.16. For more information, see MySQL Cluster Replication Conflict Resolution.

- `Ndb_execute_count` [1948]

  Provides the number of round trips to the `NDB` kernel made by operations. Added in MySQL Cluster NDB 6.3.6.

- `Ndb_number_of_data_nodes` [1948]

If the server is part of a MySQL Cluster, the value of this variable is the number of data nodes in the cluster.

If the server is not part of a MySQL Cluster, then the value of this variable is 0.

Prior to MySQL 5.1.12, this variable was named `Ndb_number_of_storage_nodes`.

- `Ndb_pushed_queries_defined` [1949]

  The total number of joins pushed down to the NDB kernel for distributed handling on the data nodes. Note that joins tested using `EXPLAIN` that can be pushed down contribute to this number. Added in MySQL Cluster NDB 7.2.0.

- `Ndb_pushed_queries_dropped` [1949]

  The number of joins that were pushed down to the NDB kernel but that could not be handled there. Added in MySQL Cluster NDB 7.2.0.

- `Ndb_pushed_queries_executed` [1949]

  The number of joins successfully pushed down to `NDB` and executed there. Added in MySQL Cluster NDB 7.2.0.

- `Ndb_pushed_reads` [1949]

  The number of rows returned to `mysqld` from the NDB kernel by joins that were pushed down. Note that executing `EXPLAIN` on joins that can be pushed down to `NDB` does not add to this number. Added in MySQL Cluster NDB 7.2.0.

- `Slave_heartbeat_period` [1949]

  Shows the replication heartbeat interval (in seconds) on a replication slave.

  This variable was added in MySQL Cluster NDB 6.3.4.

- `Slave_received_heartbeats` [1949]

  This counter increments with each replication heartbeat received by a replication slave since the last time that the slave was restarted or reset, or a `CHANGE MASTER TO` statement was issued.

  This variable was added in MySQL Cluster NDB 6.3.4.

- `Ndb_pruned_scan_count` [1949]

  This variable holds a count of the number of scans executed by `NDBCLUSTER` since the MySQL Cluster was last started where `NDBCLUSTER` was able to use partition pruning.

  Using this variable together with `Ndb_scan_count` [1949] can be helpful in schema design to maximize the ability of the server to prune scans to a single table partition, thereby involving only a single data node.

  This variable was added in MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.5.

- `Ndb_scan_count` [1949]

  This variable holds a count of the total number of scans executed by `NDBCLUSTER` since the MySQL Cluster was last started.

  This variable was added in MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.5.

Using High-Speed Interconnects with MySQL Cluster

Even before design of `NDBCLUSTER` began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, `NDBCLUSTER` was designed from the very beginning to permit the use of a number of different data transport mechanisms. In this Manual, we use the term *transporter* for these.

The MySQL Cluster codebase provides for four different transporters:

- *TCP/IP using 100 Mbps or gigabit Ethernet*, as discussed in MySQL Cluster TCP/IP Connections.
- *Direct (machine-to-machine) TCP/IP*; although this transporter uses the same TCP/IP protocol as mentioned in the previous item, it requires setting up the hardware differently and is configured differently as well. For this reason, it is considered a separate transport mechanism for MySQL Cluster. See MySQL Cluster TCP/IP Connections Using Direct Connections, for details.
- *Shared memory (SHM)*. For more information about SHM, see MySQL Cluster Shared-Memory Connections.

Note

SHM is considered experimental only, and is not officially supported.

- *Scalable Coherent Interface (SCI)*, as described in the next section of this chapter, SCI Transport Connections in MySQL Cluster.

Most users today employ TCP/IP over Ethernet because it is ubiquitous. TCP/IP is also by far the best-tested transporter for use with MySQL Cluster.

We are working to make sure that communication with the `ndbd` process is made in “chunks” that are as large as possible because this benefits all types of data transmission.

For users who desire it, it is also possible to use cluster interconnects to enhance performance even further. There are two ways to achieve this: Either a custom transporter can be designed to handle this case, or you can use socket implementations that bypass the TCP/IP stack to one extent or another. We have experimented with both of these techniques using the SCI (Scalable Coherent Interface) technology developed by Dolphin Interconnect Solutions.

Configuring MySQL Cluster to use SCI Sockets

It is possible employing Scalable Coherent Interface (SCI) technology to achieve a significant increase in connection speeds and throughput between MySQL Cluster data and SQL nodes. To use SCI, it is necessary to obtain and install Dolphin SCI network cards and to use the drivers and other software supplied by Dolphin. You can get information on obtaining these, from Dolphin Interconnect Solutions. SCI SuperSocket or SCI Transporter support is available for 32-bit and 64-bit Linux, Solaris, Windows, and other platforms. See the Dolphin documentation referenced later in this section for more detailed information regarding platforms supported for SCI.

Note

Prior to MySQL 5.1.20, there were issues with building MySQL Cluster with SCI support (see Bug #25470), but these have been resolved due to work contributed by Dolphin. SCI Sockets are now correctly supported for MySQL Cluster hosts running recent versions of Linux using the `-max` builds, and versions of MySQL Cluster with SCI Transporter support can be built using either of `compile-amd64-max-sci` or `compile-pentium64-max-sci`. Both of these build scripts can be found in the `BUILD` directory of the MySQL Cluster source trees; it should not be difficult to adapt them for other platforms. Generally, all that is necessary is to compile MySQL Cluster with SCI Transporter support is to configure the MySQL Cluster build using `--with-ndb-sci=/opt/DIS`.

Once you have acquired the required Dolphin hardware and software, you can obtain detailed information on how to adapt a MySQL Cluster configured for normal TCP/IP communication to use SCI from the from the Dolphin SCI online documentation.

MySQL Cluster Interconnects and Performance

The ndbd process has a number of simple constructs which are used to access the data in a MySQL Cluster. We have created a very simple benchmark to check the performance of each of these and the effects which various interconnects have on their performance.

There are four access methods:

- **Primary key access.** This is access of a record through its primary key. In the simplest case, only one record is accessed at a time, which means that the full cost of setting up a number of TCP/IP messages and a number of costs for context switching are borne by this single request. In the case where multiple primary key accesses are sent in one batch, those accesses share the cost of setting up the necessary TCP/IP messages and context switches. If the TCP/IP messages are for different destinations, additional TCP/IP messages need to be set up.
- **Unique key access.** Unique key accesses are similar to primary key accesses, except that a unique key access is executed as a read on an index table followed by a primary key access on the table. However, only one request is sent from the MySQL Server, and the read of the index table is handled by ndbd. Such requests also benefit from batching.
- **Full table scan.** When no indexes exist for a lookup on a table, a full table scan is performed. This is sent as a single request to the ndbd process, which then divides the table scan into a set of parallel scans on all cluster ndbd processes. In future versions of MySQL Cluster, an SQL node will be able to filter some of these scans.
- **Range scan using ordered index.** When an ordered index is used, it performs a scan in the same manner as the full table scan, except that it scans only those records which are in the range used by the query transmitted by the MySQL server (SQL node). All partitions are scanned in parallel when all bound index attributes include all attributes in the partitioning key.

With benchmarks developed internally by MySQL for testing simple and batched primary and unique key accesses, we have found that using SCI sockets improves performance by approximately 100% over TCP/IP, except in rare instances when communication performance is not an issue. This can occur when scan filters make up most of processing time or when very large batches of primary key accesses are achieved. In that case, the CPU processing in the ndbd processes becomes a fairly large part of the overhead.

Using the SCI transporter instead of SCI Sockets is only of interest in communicating between ndbd processes. Using the SCI transporter is also only of interest if a CPU can be dedicated to the ndbd process because the SCI transporter ensures that this process will never go to sleep. It is also important to ensure that the ndbd process priority is set in such a way that the process does not lose priority due to running for an extended period of time, as can be done by locking processes to CPUs in Linux 2.6. If such a configuration is possible, the ndbd process will benefit by 10–70% as compared with using SCI sockets. (The larger figures will be seen when performing updates and probably on parallel scan operations as well.)

There are several other optimized socket implementations for computer clusters, including Myrinet, Gigabit Ethernet, Infiniband and the VIA interface. However, we have tested MySQL Cluster so far only with SCI sockets. See Configuring MySQL Cluster to use SCI Sockets, for information on how to set up SCI sockets using ordinary TCP/IP for MySQL Cluster.

MySQL Cluster Programs

Using and managing a MySQL Cluster requires several specialized programs, which we describe in this chapter. We discuss the purposes of these programs in a MySQL Cluster, how to use the programs, and what startup options are available for each of them.

These programs include the MySQL Cluster data, management, and SQL node processes (ndbd, ndbmtd, ndb_mgmd, and mysqld) and the management client (ndb_mgm).

For information about using mysqld as a MySQL Cluster process, see MySQL Server Usage for MySQL Cluster.

Other NDB utility, diagnostic, and example programs are included with the MySQL Cluster distribution. These include ndb_restore, ndb_show_tables, and ndb_config. These programs are also covered in this section.

The final portion of this section contains tables of options that are common to all the various MySQL Cluster programs.

ndbd — The MySQL Cluster Data Node Daemon

ndbd is the process that is used to handle all the data in tables using the NDB Cluster storage engine. This is the process that empowers a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks.

In a MySQL Cluster, a set of ndbd processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

The following table includes command options specific to the MySQL Cluster data node program ndbd. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including ndbd), see Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs.

Table 17.10. ndbd Options and Variables: MySQL 5.1, MySQL Cluster NDB 6.3-7.1

Format	Description	Added / Removed
--initial [1954]	Perform initial start of ndbd, including cleaning the file system. Consult the documentation before using this option	All MySQL 5.1 based releases
--nostart [1955], -n [1955]	Don't start ndbd immediately; ndbd waits for command to start from ndb_mgmd	All MySQL 5.1 based releases
--daemon [1953], -d [1953]	Start ndbd as daemon (default); override with --nodaemon	All MySQL 5.1 based releases
--nodaemon [1953]	Do not start ndbd as daemon; provided for testing purposes	All MySQL 5.1 based releases
--foreground [1954]	Run ndbd in foreground, provided for debugging purposes (implies --nodaemon)	All MySQL 5.1 based releases
--nowait-nodes=list [1955]	Do not wait for these data nodes to start (takes comma-separated list of node IDs). Also requires --ndb-nodeid to be used.	ADDED: 5.1.9
--initial-start [1955]	Perform partial initial start (requires --nowait-nodes)	ADDED: 5.1.11
--bind-address=name [1953]	Local bind address	ADDED: 5.1.12
--install[=name] [1956]	Used to install the data node process as a Windows service. Does not apply on non-Windows platforms.	ADDED: NDB 7.0.16, NDB 7.1.5

Format	Description	Added / Removed
--remove[=name] [1956]	Used to remove a data node process that was previously installed as a Windows service. Does not apply on non-Windows platforms.	ADDED: NDB 7.0.16, NDB 7.1.5
--connect-retries=# [1956]	Number of times to try contacting the management server; set to -1 to keep trying indefinitely	ADDED: NDB 7.0.36, NDB 7.1.25
--connect-delay=# [1957]	Time to wait between attempts to contact a management server, in seconds	ADDED: NDB 7.0.36, NDB 7.1.25

Note

All of these options also apply to the multi-threaded version of this program (ndbmtd, available in MySQL Cluster NDB 7.0 and later) and you may substitute "ndbmtd" for "ndbd" wherever the latter occurs in this section.

- --bind-address

Version Introduced	5.1.12	
Command-Line Format	--bind-address=name	
	Permitted Values	
	Type	string
	Default	

Causes ndbd to bind to a specific network interface (host name or IP address). This option has no default value.

This option was added in MySQL 5.1.12.

- --daemon, -d

Command-Line Format	--daemon	
	-d	
	Permitted Values	
	Type	boolean
	Default	TRUE

Instructs ndbd or ndbmtd to execute as a daemon process. This is the default behavior. --nodaemon [1953] can be used to prevent the process from running as a daemon.

This option has no effect when running ndbd or ndbmtd on Windows platforms.

- --nodaemon

Command-Line Format	--nodaemon	
	Permitted Values	
	Type	boolean
	Default	FALSE

Prevents ndbd or ndbmtd from executing as a daemon process. This option overrides the --daemon [1953] option. This is useful for redirecting output to the screen when debugging the binary.

As of MySQL Cluster NDB 7.0.8, the default behavior for ndbd and ndbmtd on Windows is to run in the foreground, making this option unnecessary on Windows platforms, where it has no effect. (Bug #45588)

- --foreground

Command-Line Format	--foreground	
	Permitted Values	
	Type	boolean
	Default	FALSE

Causes ndbd or ndbmtd to execute as a foreground process, primarily for debugging purposes. This option implies the --nodaemon [1953] option.

This option has no effect when running ndbd or ndbmtd on Windows platforms.

- --initial

Command-Line Format	--initial	
	Permitted Values	
	Type	boolean
	Default	FALSE

Instructs ndbd to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of ndbd. It also re-creates recovery log files. Note that on some operating systems this process can take a substantial amount of time.

An --initial [1954] start is to be used *only* when starting the ndbd process under very special circumstances; this is because this option causes all files to be removed from the MySQL Cluster file system and all redo log files to be re-created. These circumstances are listed here:

- When performing a software upgrade which has changed the contents of any files.
- When restarting the node with a new version of ndbd.
- As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware that this node can no longer be used to restore data due to the destruction of the data files.

Use of this option prevents the StartPartialTimeout [1835] and StartPartitionedTimeout [1835] configuration parameters from having any effect.

Important

This option does *not* affect either of the following types of files:

- Backup files that have already been created by the affected node
- MySQL Cluster Disk Data files (see MySQL Cluster Disk Data Tables).

This option also has no effect on recovery of data by a data node that is just starting (or restarting) from data nodes that are already running. This recovery of data occurs automatically, and requires no user intervention in a MySQL Cluster that is running normally.

It is permissible to use this option when starting the cluster for the very first time (that is, before any data node files have been created); however, it is *not* necessary to do so.

- `--initial-start`

Version Introduced	5.1.11	
Command-Line Format	`--initial-start`	
	Permitted Values	
	Type	`boolean`
	Default	`FALSE`

This option is used when performing a partial initial start of the cluster. Each node should be started with this option, as well as `--nowait-nodes` [1955].

Suppose that you have a 4-node cluster whose data nodes have the IDs 2, 3, 4, and 5, and you wish to perform a partial initial start using only nodes 2, 4, and 5—that is, omitting node 3:

```
shell> ndbd --ndb-nodeid=2 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=4 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=5 --nowait-nodes=3 --initial-start
```

Prior to MySQL 5.1.19, it was not possible to perform DDL operations involving Disk Data tables on a partially started cluster. (See Bug #24631.)

When using this option, you must also specify the node ID for the data node being started with the `--ndb-nodeid` [2017] option.

This option was added in MySQL 5.1.11.

Important

Do not confuse this option with the `--nowait-nodes` [1967] option added for `ndb_mgmd` in MySQL Cluster NDB 7.0.10, which can be used to enable a cluster configured with multiple management servers to be started without all management servers being online.

- `--nowait-nodes=`*`node_id_1`*`[, `*`node_id_2`*`[, ...]]`

Version Introduced	5.1.9	
Command-Line Format	`--nowait-nodes=list`	
	Permitted Values	
	Type	`string`
	Default	

This option takes a list of data nodes which for which the cluster will not wait for before starting.

This can be used to start the cluster in a partitioned state. For example, to start the cluster with only half of the data nodes (nodes 2, 3, 4, and 5) running in a 4-node cluster, you can start each `ndbd` process with `--nowait-nodes=3,5`. In this case, the cluster starts as soon as nodes 2 and 4 connect, and does *not* wait `StartPartitionedTimeout` [1835] milliseconds for nodes 3 and 5 to connect as it would otherwise.

If you wanted to start up the same cluster as in the previous example without one `ndbd` (say, for example, that the host machine for node 3 has suffered a hardware failure) then start nodes 2, 4, and 5 with `--nowait-nodes=3`. Then the cluster will start as soon as nodes 2, 4, and 5 connect and will not wait for node 3 to start.

This option was added in MySQL 5.1.9.

- `--nostart`, `-n`

Command-Line Format	--nostart	
	-n	
	Permitted Values	
	Type	boolean
	Default	FALSE

Instructs ndbd not to start automatically. When this option is used, ndbd connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper START command in the management client (see Commands in the MySQL Cluster Management Client).

- --install[=*name*]

Version Introduced	5.1.47-ndb-7.1.5	
Command-Line Format	--install[=name]	
	Permitted Values	
	Type	string
	Default	ndbd

Causes ndbd to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to ndbd. Although it is preferable to specify other ndbd program options in a my.ini or my.cnf configuration file, it is possible to use together with --install. However, in such cases, the --install option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the --initial [1954] option, since this causes the data node file system to be wiped and rebuilt every time the service is stopped and started. Extreme care should also be taken if you intend to use any of the other ndbd options that affect the starting of data nodes—including --initial-start [1955], --nostart [1955], and --nowait-nodes [1955]—together with --install [1956], and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The --install [1956] option has no effect on non-Windows platforms.

This option became available in MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5.

- --remove[=*name*] [1956]

Version Introduced	5.1.47-ndb-7.1.5	
Command-Line Format	--remove[=name]	
	Permitted Values	
	Type	string
	Default	ndbd

Causes an ndbd process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to ndbd.

The --remove [1956] option has no effect on non-Windows platforms.

This option became available in MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5.

- --connect-retries=#

Version Introduced	5.1.63-ndb-7.1.25	
Command-Line Format	--connect-retries=#	
	Permitted Values	
	Type	numeric
	Default	12
	Range	-1 .. 65535

Determines the number of times that the data node attempts to contact a management server when starting. Setting this option to -1 causes the data node to keep trying to make contact indefinitely. The default is 12 attempts. The time to wait between attempts is controlled by the --connect-delay [1957] option.

This option was added in MySQL Cluster NDB 7.0.36 and MySQL Cluster 7.1.25.

- --connect-delay=#

Version Introduced	5.1.63-ndb-7.1.25	
Command-Line Format	--connect-delay=#	
	Permitted Values	
	Type	numeric
	Default	5
	Range	0 .. 3600

Determines the time to wait between attempts to contact a management server when starting (the time between attempts is controlled by the --connect-retries [1956] option). The default is 5 attempts.

This option was added in MySQL Cluster NDB 7.0.36 and MySQL Cluster 7.1.25.

ndbd generates a set of log files which are placed in the directory specified by DataDir [1816] in the config.ini configuration file.

These log files are listed below. *node_id* is the node's unique identifier. Note that *node_id* represents the node's unique identifier. For example, ndb_2_error.log is the error log generated by the data node whose node ID is 2.

- ndb_*node_id*_error.log is a file containing records of all crashes which the referenced ndbd process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

```
Date/Time: Saturday 30 July 2004 - 00:20:01
Type of error: error
Message: Internal program error (failed ndbrequire)
Fault ID: 2341
Problem data: DbtupFixAlloc.cpp
Object of reference: DBTUP (Line: 173)
ProgramName: NDB Kernel
ProcessID: 14909
TraceFile: ndb_2_trace.log.2
***EOM***
```

Listings of possible ndbd exit codes and messages generated when a data node process shuts down prematurely can be found in ndbd Error Messages.

Important

The last entry in the error log file is not necessarily the newest one (nor is it likely to be). Entries in the error log are *not* listed in chronological order; rather, they correspond to the order of the trace files as determined in the `ndb_node_id_trace.log.next` file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.

- `ndb_node_id_trace.log.trace_id` is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the MySQL Cluster development team.

  It is possible to configure the number of these trace files that will be created before old files are overwritten. *`trace_id`* is a number which is incremented for each successive trace file.

- `ndb_node_id_trace.log.next` is the file that keeps track of the next trace file number to be assigned.

- `ndb_node_id_out.log` is a file containing any data output by the `ndbd` process. This file is created only if `ndbd` is started as a daemon, which is the default behavior.

- `ndb_node_id.pid` is a file containing the process ID of the `ndbd` process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.

- `ndb_node_id_signal.log` is a file used only in debug versions of `ndbd`, where it is possible to trace all incoming, outgoing, and internal messages with their data in the `ndbd` process.

It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the `.pid` file remains in effect even after the process has terminated.

To start `ndbd`, it may also be necessary to specify the host name of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

See The MySQL Cluster Connectstring, for additional information about this issue. `ndbd` — The MySQL Cluster Data Node Daemon, describes other options for `ndbd`.

When `ndbd` starts, it actually initiates two processes. The first of these is called the “angel process”; its only job is to discover when the execution process has been completed, and then to restart the `ndbd` process if it is configured to do so. Thus, if you attempt to kill `ndbd` using the Unix `kill` command, it is necessary to kill both processes, beginning with the angel process. The preferred method of terminating an `ndbd` process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent actions. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the `ndbd` process. In a multi-processor system performing a large number of operations (including updates), the `ndbd` process can consume up to 2 CPUs if permitted to do so.

For a machine with many CPUs it is possible to use several `ndbd` processes which belong to different node groups; however, such a configuration is still considered experimental and is not supported for MySQL 5.1 in a production setting. See Known Limitations of MySQL Cluster.

`ndbinfo_select_all` — Select From ndbinfo Tables

`ndbinfo_select_all` is a client program that selects all rows and columns from one or more tables in the `ndbinfo` database. It is included with the MySQL Cluster NDB 7.1 and later distributions, starting with MySQL Cluster NDB 7.1.17.

Not all ndbinfo tables can be accessed by this program. ndbinfo_select_all can access the counters, diskpagebuffer, logbuffers, logspaces, nodes, resources, threadblocks, threadstat, and transporters tables.

To select from one or more ndbinfo tables using ndbinfo_select_all, it is necessary to supply the names of the tables when invoking the program as shown here:

```
shell> ndbinfo_select_all table_name1  [table_name2] [...]
```

For example:

```
shell> ndbinfo_select_all logbuffers logspaces
== logbuffers ==
node_id log_type        log_id  log_part        total   used    high
5       0       0       0       33554432        262144  0
6       0       0       0       33554432        262144  0
7       0       0       0       33554432        262144  0
8       0       0       0       33554432        262144  0
== logspaces ==
node_id log_type        log_id  log_part        total   used    high
5       0       0       0       268435456       0       0
5       0       0       1       268435456       0       0
5       0       0       2       268435456       0       0
5       0       0       3       268435456       0       0
6       0       0       0       268435456       0       0
6       0       0       1       268435456       0       0
6       0       0       2       268435456       0       0
6       0       0       3       268435456       0       0
7       0       0       0       268435456       0       0
7       0       0       1       268435456       0       0
7       0       0       2       268435456       0       0
7       0       0       3       268435456       0       0
8       0       0       0       268435456       0       0
8       0       0       1       268435456       0       0
8       0       0       2       268435456       0       0
8       0       0       3       268435456       0       0
shell>
```

The following table includes options that are specific to ndbinfo_select_all. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including ndbinfo_select_all), see Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs.

Table 17.11. ndbinfo_select_all Options and Variables: MySQL 5.1, MySQL Cluster NDB 6.3-7.1

Format	Description	Added / Removed
--delay=# [1959]	Set the delay in seconds between loops. Default is 5.	All MySQL 5.1 based releases
--loops=# [1960], -l [1960]	Set the number of times to perform the select. Default is 1.	All MySQL 5.1 based releases
--database=db_name [2005], -d [2005]	Name of the database where the table located.	All MySQL 5.1 based releases
--parallelism=# [2005], -p [2005]	Set the degree of parallelism.	All MySQL 5.1 based releases

- --delay=seconds

Command-Line Format	--delay=#
	Permitted Values

	Type	numeric
	Default	5
	Range	0 .. MAX_INT

This option sets the number of seconds to wait between executing loops. Has no effect if --loops [1960] is set to 0 or 1.

- --loops=number, -l *number*

Command-Line Format	--loops=#	
	-l	
	Permitted Values	
	Type	numeric
	Default	1
	Range	0 .. MAX_INT

This option sets the number of times to execute the select. Use --delay [1959] to set the time between loops.

ndbmtd — The MySQL Cluster Data Node Daemon (Multi-Threaded)

ndbmtd is a multi-threaded version of ndbd, the process that is used to handle all the data in tables using the NDBCLUSTER storage engine. ndbmtd is intended for use on host computers having multiple CPU cores. Except where otherwise noted, ndbmtd functions in the same way as ndbd; therefore, in this section, we concentrate on the ways in which ndbmtd differs from ndbd, and you should consult ndbd — The MySQL Cluster Data Node Daemon, for additional information about running MySQL Cluster data nodes that apply to both the single-threaded and multi-threaded versions of the data node process.

Command-line options and configuration parameters used with ndbd also apply to ndbmtd. For more information about these options and parameters, see ndbd — The MySQL Cluster Data Node Daemon, and Defining MySQL Cluster Data Nodes, respectively.

ndbmtd is also file system-compatible with ndbd. In other words, a data node running ndbd can be stopped, the binary replaced with ndbmtd, and then restarted without any loss of data. (However, when doing this, you must make sure that MaxNoOfExecutionThreads [1855] is set to an apppriate value before restarting the node if you wish for ndbmtd to run in multi-threaded fashion.) Similarly, an ndbmtd binary can be replaced with ndbd simply by stopping the node and then starting ndbd in place of the multi-threaded binary. It is not necessary when switching between the two to start the data node binary using --initial [1954].

Prior to MySQL Cluster NDB 7.0.6, there were known issues when using ndbmtd with MySQL Cluster Disk Data tables. If you wish to use multi-threaded data nodes with disk-based NDB tables, you should ensure that you are running MySQL Cluster NDB 7.0.6 or later (see Bug #41915 and Bug #44915)

Using ndbmtd differs from using ndbd in two key respects:

1. Because ndbmtd runs by default in single-threaded mode (that is, it behaves like ndbd), you must configure it to use multiple threads. This can be done by setting an appropriate value in the config.ini file for the MaxNoOfExecutionThreads [1855] configuration parameter. For more information about this parameter and its use, see Multi-Threading Configuration Parameters (ndbmtd).

2. Trace files are generated by critical errors in ndbmtd processes in a somewhat different fashion from how these are generated by ndbd failures. These differences are discussed in more detail in the next few paragraphs.

Like ndbd, ndbmtd generates a set of log files which are placed in the directory specified by DataDir [1816] in the config.ini configuration file. Except for trace files, these are generated in the same way and have the same names as those generated by ndbd.

In the event of a critical error, ndbmtd generates trace files describing what happened just prior to the error' occurrence. These files, which can be found in the data node's DataDir [1816], are useful for analysis of problems by the MySQL Cluster Development and Support teams. One trace file is generated for each ndbmtd thread. The names of these files have the following pattern:

```
ndb_node_id_trace.log.trace_id_tthread_id,
```

In this pattern, *node_id* stands for the data node's unique node ID in the cluster, *trace_id* is a trace sequence number, and *thread_id* is the thread ID. For example, in the event of the failure of an ndbmtd process running as a MySQL Cluster data node having the node ID 3 and with MaxNoOfExecutionThreads [1855] equal to 4, four trace files are generated in the data node's data directory. If the is the first time this node has failed, then these files are named ndb_3_trace.log.1_t1, ndb_3_trace.log.1_t2, ndb_3_trace.log.1_t3, and ndb_3_trace.log.1_t4. Internally, these trace files follow the same format as ndbd trace files.

The ndbd exit codes and messages that are generated when a data node process shuts down prematurely are also used by ndbmtd. See ndbd Error Messages, for a listing of these.

Note

It is possible to use ndbd and ndbmtd concurrently on different data nodes in the same MySQL Cluster. However, such configurations have not been tested extensively; thus, we cannot recommend doing so in a production setting at this time.

ndb_mgmd — The MySQL Cluster Management Server Daemon

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

The following table includes options that are specific to the MySQL Cluster management server program ndb_mgmd. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including ndb_mgmd), see Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs.

Table 17.12. ndb_mgmd Options and Variables: MySQL 5.1, MySQL Cluster NDB 6.3-7.1

Format	Description	Added / Removed
--config-file=file [1964], -f [1964], -c [1964]	Specify the cluster configuration file; in NDB-6.4.0 and later, needs --reload or --initial to override configuration cache if present	All MySQL 5.1 based releases
--configdir=directory [1963]	Specify the cluster management server's configuration cache directory	ADDED: NDB 6.4.0
--bind-address=ip_address [1962]	Local bind address	ADDED: NDB 6.2.5, NDB 6.3.2
--print-full-config [1966], -P [1966]	Print full configuration and exit	All MySQL 5.1 based releases
--daemon [1964], -d [1964]	Run ndb_mgmd in daemon mode (default)	All MySQL 5.1 based releases

Format	Description	Added / Removed
--nodaemon [1965]	Do not run ndb_mgmd as a daemon	ADDED: NDB 7.0.8
--interactive [1965]	Run ndb_mgmd in interactive mode (not officially supported in production; for testing purposes only)	All MySQL 5.1 based releases
--log-name=name [1965]	A name to use when writing messages applying to this node in the cluster log.	ADDED: NDB 7.0.8
--no-nodeid-checks [1963]	Do not provide any node id checks	All MySQL 5.1 based releases
--mycnf [1964]	Read cluster configuration data from the my.cnf file	All MySQL 5.1 based releases
--reload [1966]	Causes the management server to compare the configuration file with its configuration cache	ADDED: NDB 6.4.0
--initial [1965]	Causes the management server reload its configuration data from the configuration file, bypassing the configuration cache	ADDED: NDB 6.4.0
--nowait-nodes=list [1967]	Do not wait for these management nodes when starting this management server. Also requires --ndb-nodeid to be used.	ADDED: NDB 7.0.10, NDB 7.1.0
--config-cache=value [1963]	Enable the management server configuration cache; ON by default.	ADDED: NDB 7.0.15, NDB 7.1.4
--install[=name] [1969]	Used to install the management server process as a Windows service. Does not apply on non-Windows platforms.	ADDED: NDB 7.0.16, NDB 7.1.5
--remove[=name] [1969]	Used to remove a management server process that was previously installed as a Windows service, optionally specifying the name of the service to be removed. Does not apply on non-Windows platforms.	ADDED: NDB 7.0.16, NDB 7.1.5

- `--bind-address=host[:port]`

Version Introduced	5.1.22-ndb-6.3.2	
Command-Line Format	`--bind-address=ip_address`	
	Permitted Values	
	Type	`string`
	Default	`[none]`

When specified, this option limits management server connections by management clients to clients at the specified host name or IP address (and possibly port, if this is also specified). In such cases, a management client attempting to connect to the management server from any other address fails with the error `Unable to setup port: host:port!`

If the *port* is not specified, the management client attempts to use port 1186.

This option was added in MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2.

- --no-nodeid-checks

Command-Line Format	--no-nodeid-checks	
	Permitted Values	
	Type	boolean
	Default	FALSE

Do not perform any checks of node IDs.

- --configdir=*path*

Version Introduced	5.1.30-ndb-6.4.0	
Command-Line Format	--configdir=directory	
	Permitted Values	
	Type	file name
	Default	$INSTALLDIR/mysql-cluster

In MySQL Cluster NDB 7.0 and later, specifies the cluster management server's configuration cache directory. Starting with MySQL Cluster NDB 7.0.8, --config-dir is accepted as an alias for this option.

- This option, whose default value is 1 (or TRUE, or ON), can be used to disable the management server's configuration cache, so that it reads its configuration from config.ini every time it starts (see MySQL Cluster Configuration Files). You can do this by starting the ndb_mgmd process with any one of the following options:

  - --config-cache=0
  - --config-cache=FALSE
  - --config-cache=OFF
  - --skip-config-cache

  Using one of the options just listed is effective only if the management server has no stored configuration at the time it is started. If the management server finds any configuration cache files, then the --config-cache option or the --skip-config-cache option is ignored. Therefore, to disable configuration caching, the option should be used the *first* time that the management server is started. Otherwise—that is, if you wish to disable configuration caching for a management server that has *already* created a configuration cache—you must stop the management server, delete any existing configuration cache files manually, then restart the management server with --skip-config-cache (or with --config-cache set equal to 0, OFF, or FALSE).

  Configuration cache files are normally created in a directory named mysql-cluster under the installation directory (unless this location has been overridden using the --configdir [1963] option). Each time the management server updates its configuration data, it writes a new cache file. The files are named sequentially in order of creation using the following format:

```
ndb_node-id_config.bin.seq-number
```

  node-id is the management server's node ID; *seq-number* is a sequence number, beginning with 1. For example, if the management server's node ID is 5, then the first three configuration cache files

would, when they are created, be named `ndb_5_config.bin.1`, `ndb_5_config.bin.2`, and `ndb_5_config.bin.3`.

If your intent is to purge or reload the configuration cache without actually disabling caching, you should start `ndb_mgmd` with one of the options `--reload` [1966] or `--initial` [1965] instead of `--skip-config-cache`.

To re-enable the configuration cache, simply restart the management server, but without the `--config-cache` or `--skip-config-cache` option that was used previously to disable the configuration cache.

This option was added in MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4.

Beginning with MySQL Cluster NDB 7.0.31 and MySQL Cluster NDB 7.1.20, `ndb_mgmd` no longer checks for the configuration directory (`--configdir` [1963]) or attempts to create one when `--skip-config-cache` is used. (Bug #13428853)

- `--config-file=filename`, `-f filename`

Command-Line Format	`--config-file=file`	
	`-f`	
	`-c`	
	Permitted Values	
	Type	`file name`
	Default	`./config.ini`

Instructs the management server as to which file it should use for its configuration file. By default, the management server looks for a file named `config.ini` in the same directory as the `ndb_mgmd` executable; otherwise the file name and location must be specified explicitly.

Beginning with MySQL Cluster NDB 6.4.0, this option is ignored unless the management server is forced to read the configuration file, either because `ndb_mgmd` was started with the `--reload` [1966] or `--initial` [1965] option, or because the management server could not find any configuration cache. Beginning with MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, this option is also read if `ndb_mgmd` was started with `--config-cache=OFF` [1963]. See MySQL Cluster Configuration Files, for more information.

- `--mycnf`

Command-Line Format	`--mycnf`	
	Permitted Values	
	Type	`boolean`
	Default	`FALSE`

Read configuration data from the `my.cnf` file.

- `--daemon`, `-d`

Command-Line Format	`--daemon`	
	`-d`	
	Permitted Values	
	Type	`boolean`
	Default	`TRUE`

Instructs `ndb_mgmd` to start as a daemon process. This is the default behavior.

This option has no effect when running ndb_mgmd on Windows platforms.

- --interactive

Command-Line Format	--interactive	
	Permitted Values	
	Type	boolean
	Default	FALSE

Starts ndb_mgmd in interactive mode; that is, an ndb_mgm client session is started as soon as the management server is running. This option does not start any other MySQL Cluster nodes.

- --initial

Version Introduced	5.1.30-ndb-6.4.0	
Command-Line Format	--initial	
	Permitted Values	
	Type	boolean
	Default	FALSE

Beginning with MySQL Cluster NDB 6.4.0, configuration data is cached internally rather than being read from the cluster global configuration file each time the management server is started (see MySQL Cluster Configuration Files). Using this option overrides this behavior, by forcing the management server to delete any existing cache files, and then to re-read the configuration data from the cluster configuration file and to build a new cache.

This differs in two ways from the --reload [1966] option. First, --reload forces the server to check the configuration file against the cache and reload its data only if the contents of the file are different from the cache. Second, --reload does not delete any existing cache files.

If ndb_mgmd is invoked with --initial but cannot find a global configuration file, the management server cannot start.

In MySQL Cluster NDB 7.0.8 and later, when starting, the management server checks for another management server in the same MySQL Cluster and tries to use its configuration data. In other words, ndb_mgmd ignores --initial [1965] unless it is the only management server running. This behavior has implications when performing a rolling restart of a MySQL Cluster with multiple management nodes. See Performing a Rolling Restart of a MySQL Cluster, for more information.

This option was introduced in MySQL Cluster NDB 6.4.0.

- --log-name=*name*

Version Introduced	5.1.37-ndb-7.0.8	
Command-Line Format	--log-name=name	
	Permitted Values	
	Type	string
	Default	MgmtSrvr

Provides a name to be used for this node in the cluster log.

This option was added in MySQL Cluster NDB 7.0.8.

- --nodaemon

Version Introduced	5.1.37-ndb-7.0.8	
Command-Line Format	--nodaemon	
	Permitted Values	
	Type	boolean
	Default	FALSE

Instructs ndb_mgmd not to start as a daemon process.

As of MySQL Cluster NDB 7.0.8, the default behavior for ndb_mgmd on Windows is to run in the foreground, making this option unnecessary on Windows platforms. (Bug #45588)

- --print-full-config, -P

Command-Line Format	--print-full-config	
	-P	
	Permitted Values	
	Type	boolean
	Default	FALSE

Shows extended information regarding the configuration of the cluster. With this option on the command line the ndb_mgmd process prints information about the cluster setup including an extensive list of the cluster configuration sections as well as parameters and their values. Normally used together with the --config-file [1964] (-f) option.

- --reload

Version Introduced	5.1.30-ndb-6.4.0	
Command-Line Format	--reload	
	Permitted Values	
	Type	boolean
	Default	FALSE

Beginning with MySQL Cluster NDB 6.4.0, configuration data is stored internally rather than being read from the cluster global configuration file each time the management server is started (see MySQL Cluster Configuration Files). Using this option forces the management server to check its internal data store against the cluster configuration file and to reload the configuration if it finds that the configuration file does not match the cache. Existing configuration cache files are preserved, but not used.

This differs in two ways from the --initial [1965] option. First, --initial causes all cache files to be deleted. Second, --initial forces the management server to re-read the global configuration file and construct a new cache.

If the management server cannot find a global configuration file, then the --reload option is ignored.

In MySQL Cluster NDB 7.0.8 and later, when starting, the management server checks for another management server in the same MySQL Cluster and tries to use its configuration data. In other words, ndb_mgmd ignores --reload [1966] unless it is the only management server running. This behavior has implications when performing a rolling restart of a MySQL Cluster with multiple management nodes. See Performing a Rolling Restart of a MySQL Cluster, for more information.

This option was introduced in MySQL Cluster NDB 6.4.0.

- `--nowait-nodes`

Version Introduced	5.1.39-ndb-7.1.0	
Command-Line Format	`--nowait-nodes=list`	
	Permitted Values	
	Type	`numeric`
	Default	
	Range	`1 .. 255`

When starting a MySQL Cluster is configured with two management nodes and running MySQL Cluster NDB 7.0 and later, each management server normally checks to see whether the other `ndb_mgmd` is also operational and whether the other management server's configuration is identical to its own. However, it is sometimes desirable to start the cluster with only one management node (and perhaps to allow the other `ndb_mgmd` to be started later). This option causes the management node to bypass any checks for any other management nodes whose node IDs are passed to this option, permitting the cluster to start as though configured to use only the management node that was started.

For purposes of illustration, consider the following portion of a `config.ini` file (where we have omitted most of the configuration parameters that are not relevant to this example):

```
[ndbd]
NodeId = 1
HostName = 192.168.0.101

[ndbd]
NodeId = 2
HostName = 192.168.0.102

[ndbd]
NodeId = 3
HostName = 192.168.0.103

[ndbd]
NodeId = 4
HostName = 192.168.0.104

[ndb_mgmd]
NodeId = 10
HostName = 192.168.0.150

[ndb_mgmd]
NodeId = 11
HostName = 192.168.0.151

[api]
NodeId = 20
HostName = 192.168.0.200

[api]
NodeId = 21
HostName = 192.168.0.201
```

Assume that you wish to start this cluster using only the management server having node ID `10` and running on the host having the IP address 192.168.0.150. (Suppose, for example, that the host computer on which you intend to the other management server is temporarily unavailable due to a hardware failure, and you are waiting for it to be repaired.) To start the cluster in this way, use a command line on the machine at 192.168.0.150 to enter the following command:

```
shell> ndb_mgmd --ndb-nodeid=10 --nowait-nodes=11
```

As shown in the preceding example, when using `--nowait-nodes` [1967], you must also use the `--ndb-nodeid` [2017] option to specify the node ID of this `ndb_mgmd` process.

You can then start each of the cluster's data nodes in the usual way. If you wish to start and use the second management server in addition to the first management server at a later time without restarting the data nodes, you must start each data node with a connectstring that references both management servers, like this:

```
shell> ndbd -c 192.168.0.150,192.168.0.151
```

The same is true with regard to the connectstring used with any mysqld processes that you wish to start as MySQL Cluster SQL nodes connected to this cluster. See The MySQL Cluster Connectstring, for more information.

When used with ndb_mgmd, this option affects the behavior of the management node with regard to other management nodes only. Do not confuse it with the --nowait-nodes [1955] option used with ndbd (or ndbmtd in MySQL Cluster NDB 7.0 and later) to permit a cluster to start with fewer than its full complement of data nodes; when used with data nodes, this option affects their behavior only with regard to other data nodes.

Multiple management node IDs may be passed to this option as a comma-separated list. Each node ID must be no less than 1 and no greater than 255. In practice, it is quite rare to use more than two management servers for the same MySQL Cluster (or to have any need for doing so); in most cases you need to pass to this option only the single node ID for the one management server that you do not wish to use when starting the cluster.

Note

When you later start the “missing” management server, its configuration must match that of the management server that is already in use by the cluster. Otherwise, it fails the configuration check performed by the existing management server, and does not start.

This option was introduced in MySQL Cluster NDB 7.0.10 and MySQL Cluster NDB 7.1.0.

It is not strictly necessary to specify a connectstring when starting the management server. However, if you are using more than one management server, a connectstring should be provided and each node in the cluster should specify its node ID explicitly.

See The MySQL Cluster Connectstring, for information about using connectstrings. ndb_mgmd — The MySQL Cluster Management Server Daemon, describes other options for ndb_mgmd.

The following files are created or used by ndb_mgmd in its starting directory, and are placed in the DataDir [1816] as specified in the config.ini configuration file. In the list that follows, *node_id* is the unique node identifier.

- config.ini is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. MySQL Cluster Configuration, discusses how to set up this file.
- ndb_*node_id*_cluster.log is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in Management of MySQL Cluster.

  When the size of the cluster log reaches one million bytes, the file is renamed to ndb_*node_id*_cluster.log.*seq_id*, where *seq_id* is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.)
- ndb_*node_id*_out.log is the file used for stdout and stderr when running the management server as a daemon.
- ndb_*node_id*.pid is the process ID file used when running the management server as a daemon.

- `--install[=name]`

Version Introduced	5.1.47-ndb-7.1.5	
Command-Line Format	`--install[=name]`	
	Permitted Values	
	Type	`string`
	Default	`ndb_mgmd`

Causes `ndb_mgmd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndb_mgmd`. Although it is preferable to specify other `ndb_mgmd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use them together with `--install` [1969]. However, in such cases, the `--install` [1969] option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` [1954] option, since this causes the configuration cache to be wiped and rebuilt every time the service is stopped and started. Care should also be taken if you intend to use any other `ndb_mgmd` options that affect the starting of the management server, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` [1969] option has no effect on non-Windows platforms.

This option became available in MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5.

- `--remove[=name]` [1969]

Version Introduced	5.1.47-ndb-7.1.5	
Command-Line Format	`--remove[=name]`	
	Permitted Values	
	Type	`string`
	Default	`ndb_mgmd`

Causes an `ndb_mgmd` process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to `ndb_mgmd`.

The `--remove` [1969] option has no effect on non-Windows platforms.

This option became available in MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5.

ndb_mgm — The MySQL Cluster Management Client

The `ndb_mgm` management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster's status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by `ndb_mgm`.

To start the management client, it is necessary to supply the host name and port number of the management server:

```
shell> ndb_mgm [host_name [port_num]]
```

For example:

```
shell> ndb_mgm ndb_mgmd.mysql.com 1186
```

The default host name and port number are `localhost` and 1186, respectively.

The following table includes options that are specific to the MySQL Cluster management client program ndb_mgm. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including ndb_mgm), see Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs.

Table 17.13. ndb_mgm Options and Variables: MySQL 5.1, MySQL Cluster NDB 6.3-7.1

Format	Description	Added / Removed
--try-reconnect=# [1970], -t [1970]	Specify number of tries for connecting to ndb_mgmd (0 = infinite)	All MySQL 5.1 based releases
--execute=name [1970], -e [1970]	Execute command and exit	All MySQL 5.1 based releases

- --execute=command, -e command

Command-Line Format	--execute=name
	-e

This option can be used to send a command to the MySQL Cluster management client from the system shell. For example, either of the following is equivalent to executing SHOW in the management client:

```
shell> ndb_mgm -e "SHOW"

shell> ndb_mgm --execute="SHOW"
```

This is analogous to how the --execute [262] or -e option works with the mysql command-line client. See Using Options on the Command Line.

Note

If the management client command to be passed using this option contains any space characters, then the command *must* be enclosed in quotation marks. Either single or double quotation marks may be used. If the management client command contains no space characters, the quotation marks are optional.

- --try-reconnect=*number*

Command-Line Format	--try-reconnect=#	
	-t	
	Permitted Values	
	Type	boolean
	Default	TRUE

If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to *number* before giving up and reporting an error instead.

Additional information about using ndb_mgm can be found in Commands in the MySQL Cluster Management Client.

ndb_config — Extract MySQL Cluster Configuration Information

This tool extracts current configuration information for data nodes, SQL nodes, and API nodes from one of a number of sources: a MySQL Cluster management node, or its config.ini or my.cnf file. By default, the management node is the source for the configuration data; to override the default,

execute ndb_config with the --config-file [1972] or --mycnf [1973] option. Beginning with MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, it is also possible to use a data node as the source by specifying its node ID using --config_from_node=*node_id* [1972]-

Beginning with MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6, ndb_config can also provide an offline dump of all configuration parameters which can be used, along with their default, maximum, and minimum values and other information. The dump can be produced in either text or XML format; for more information, see the discussion of the --configinfo [1975] and --xml [1976] options later in this section).

Beginning with MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, you can filter the results by section (DB, SYSTEM, or CONNECTIONS) using one of the options --nodes [1974], --system [1974], or --connections [1974].

The following table includes options that are specific to ndb_config. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including ndb_config), see Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs.

Table 17.14. ndb_config Options and Variables: MySQL 5.1, MySQL Cluster NDB 6.3-7.1

Format	Description	Added / Removed
--nodes [1974]	Print node information (DB section) only.	All MySQL 5.1 based releases
--connections [1974]	Print CONNECTIONS section information only. Cannot be used with --nodes or --system option.	All MySQL 5.1 based releases
--query=string [1973], -q [1973]	One or more query options (attributes)	All MySQL 5.1 based releases
--host=name [1973]	Specify host	All MySQL 5.1 based releases
--type=name [1974]	Specify node type	All MySQL 5.1 based releases
--nodeid [1974], --id [1974]	Get configuration of node with this ID	All MySQL 5.1 based releases
--fields=string [1975], -f [1975]	Field separator	All MySQL 5.1 based releases
--rows=string [1975], -r [1975]	Row separator	All MySQL 5.1 based releases
--config-file=path [1972]	Set the path to config.ini file	All MySQL 5.1 based releases
--mycnf [1973]	Read configuration data from my.cnf file	All MySQL 5.1 based releases
-c [2016]	Short form for --ndb-connectstring	ADDED: 5.1.12
--configinfo [1975]	Dumps information about all NDB configuration parameters in text format with default, maximum, and minimum values. Use with --xml to obtain XML output.	ADDED: NDB 6.3.25, NDB 7.0.6
--configinfo --xml [1976]	Use --xml with --configinfo to obtain a dump of all NDB configuration parameters in XML	ADDED: NDB 6.3.25, NDB 7.0.6

Format	Description	Added / Removed
	format with default, maximum, and minimum values.	
--system [1974]	Print SYSTEM section information only. Cannot be used with --nodes or --connections option.	ADDED: NDB 7.0.27, NDB 7.1.16
--config_from_node=# [1972]	Obtain configuration data from the node having this ID (must be a data node).	ADDED: NDB 7.0.27, NDB 7.1.16

- --usage, --help, or -?

Command-Line Format	--help
	--usage
	-?

Causes ndb_config to print a list of available options, and then exit.

- --config_from_node=#

Version Introduced	5.1.56-ndb-7.1.16	
Command-Line Format	--config_from_node=#	
	Permitted Values	
	Type	numeric
	Default	none
	Range	1 .. 48

Obtain the cluster's configuration data from the data node that has this ID.

If the node having this ID is not a data node, ndb_config fails with an error. (To obtain configuration data from the management node instead, simply omit this option.)

--config_from_node was added in MySQL Cluster NDB 7.0.27 and MySQL NDB 7.1.16.

- --version, -V

Command-Line Format	--version
	-V

Causes ndb_config to print a version information string, and then exit.

- --ndb-connectstring=*connect_string*

Specifies the connectstring to use in connecting to the management server. The format for the connectstring is the same as described in The MySQL Cluster Connectstring, and defaults to localhost:1186.

The use of -c as a short version for this option is supported for ndb_config beginning with MySQL 5.1.12.

- --config-file=*path-to-file*

Command-Line Format	--config-file=path	
	Permitted Values	
	Type	file name

	Default	

Gives the path to the management server's configuration file (`config.ini`). This may be a relative or absolute path. If the management node resides on a different host from the one on which `ndb_config` is invoked, then an absolute path must be used.

- `--mycnf`

Command-Line Format	`--mycnf`	
	Permitted Values	
	Type	`boolean`
	Default	`FALSE`

Read configuration data from the `my.cnf` file.

- `--query=`*`query-options`*, `-q` *`query-options`*

Command-Line Format	`--query=string`	
	`-q`	
	Permitted Values	
	Type	`string`
	Default	

This is a comma-delimited list of *query options*—that is, a list of one or more node attributes to be returned. These include `id` (node ID), type (node type—that is, `ndbd`, `mysqld`, or `ndb_mgmd`), and any configuration parameters whose values are to be obtained.

For example, `--query=id,type,indexmemory,datamemory` returns the node ID, node type, `DataMemory` [1817], and `IndexMemory` [1819] for each node.

Note

If a given parameter is not applicable to a certain type of node, than an empty string is returned for the corresponding value. See the examples later in this section for more information.

- `--host=`*`hostname`*

Command-Line Format	`--host=name`	
	Permitted Values	
	Type	`string`
	Default	

Specifies the host name of the node for which configuration information is to be obtained.

Note

While the hostname `localhost` usually resolves to the IP address `127.0.0.1`, this may not necessarily be true for all operating platforms and configurations. This means that it is possible, when `localhost` is used in `config.ini`, for `ndb_config --host=localhost` to fail if `ndb_config` is run on a different host where `localhost` resolves to a different address (for example, on some versions of SUSE Linux, this is `127.0.0.2`). In general, for best results, you should use numeric IP addresses for all MySQL

Cluster configuration values relating to hosts, or verify that all MySQL Cluster hosts handle `localhost` in the same fashion.

- `--id=node_id`

  `--nodeid=node_id`

  Either of these options can be used to specify the node ID of the node for which configuration information is to be obtained. `--nodeid` is the preferred form.

- `--nodes`

Command-Line Format	`--nodes`	
	Permitted Values	
	Type	`boolean`
	Default	`FALSE`

  Tells `ndb_config` to print information from parameters defined in `DB` sections only. Prior to MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, this option had no affect. This option cannot be used together with `--connections` [1974] or `--system` [1974].

- `--connections`

Command-Line Format	`--connections`	
	Permitted Values	
	Type	`boolean`
	Default	`FALSE`

  Tells `ndb_config` to print `CONNECTIONS` information only. This option existed prior to MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, but had no affect before then. This option cannot be used together with `--nodes` [1974] or `--system` [1974].

- `--system`

Version Introduced	5.1.56-ndb-7.1.16	
Command-Line Format	`--system`	
	Permitted Values	
	Type	`boolean`
	Default	`FALSE`

  Tells `ndb_config` to print `SYSTEM` information only.

  This option was introduced in MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16. It cannot be used together with the `--nodes` [1974] or `--system` [1974] options.

- `--type=node_type`

Command-Line Format	`--type=name`	
	Permitted Values	
	Type	`enumeration`
	Default	
	Valid Values	`ndbd` `mysqld`

		ndb_mgmd

Filters results so that only configuration values applying to nodes of the specified *node_type* (ndbd, mysqld, or ndb_mgmd) are returned.

- --fields=*delimiter*, -f *delimiter*

Command-Line Format	--fields=string	
	-f	
	Permitted Values	
	Type	string
	Default	

Specifies a *delimiter* string used to separate the fields in the result. The default is "," (the comma character).

Note

If the *delimiter* contains spaces or escapes (such as \n for the linefeed character), then it must be quoted.

- --rows=*separator*, -r *separator*

Command-Line Format	--rows=string	
	-r	
	Permitted Values	
	Type	string
	Default	

Specifies a *separator* string used to separate the rows in the result. The default is a space character.

Note

If the *separator* contains spaces or escapes (such as \n for the linefeed character), then it must be quoted.

- --configinfo

The --configinfo option, added in MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6, causes ndb_config to dump a list of each MySQL Cluster configuration parameter supported by the MySQL Cluster distribution of which ndb_config is a part, including the following information:

- A brief description of each parameter's purpose, effects, and usage
- The section of the config.ini file where the parameter may be used
- The parameter's data type or unit of measurement
- Where applicable, the parameter's default, minimum, and maximum values
- A brief description of the parameter's purpose, effects, and usage
- MySQL Cluster release version and build information

By default, this output is in text format. Part of this output is shown here:

```
shell> ndb_config --configinfo

****** SYSTEM ******

Name (String)
Name of system (NDB Cluster)
MANDATORY

PrimaryMGMNode (Non-negative Integer)
Node id of Primary ndb_mgmd(MGM) node
Default: 0 (Min: 0, Max: 4294967039)

ConfigGenerationNumber (Non-negative Integer)
Configuration generation number
Default: 0 (Min: 0, Max: 4294967039)

****** DB ******

MaxNoOfSubscriptions (Non-negative Integer)
Max no of subscriptions (default 0 == MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

MaxNoOfSubscribers (Non-negative Integer)
Max no of subscribers (default 0 == 2 * MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

…
```

--configinfo --xml

Version Introduced	5.1.34-ndb-7.0.6	
Command-Line Format	`--configinfo --xml`	
	Permitted Values	
	Type	`boolean`
	Default	`false`

You can obtain the output of `ndb_config --configinfo` [1975] as XML by adding the `--xml` option (like the `--configinfo` option, available beginning with MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6). A portion of the resulting output is shown in this example:

```
shell> ndb_config --configinfo --xml

<configvariables protocolversion="1" ndbversionstring="5.1.63-ndb-7.1.25"
                   ndbversion="458758" ndbversionmajor="7" ndbversionminor="0"
                   ndbversionbuild="6">
  <section name="SYSTEM">
    <param name="Name" comment="Name of system (NDB Cluster)" type="string"
              mandatory="true"/>
    <param name="PrimaryMGMNode" comment="Node id of Primary ndb_mgmd(MGM) node"
              type="unsigned" default="0" min="0" max="4294967039"/>
    <param name="ConfigGenerationNumber" comment="Configuration generation number"
              type="unsigned" default="0" min="0" max="4294967039"/>
  </section>
  <section name="NDBD">
    <param name="MaxNoOfSubscriptions"
              comment="Max no of subscriptions (default 0 == MaxNoOfTables)"
              type="unsigned" default="0" min="0" max="4294967039"/>
    <param name="MaxNoOfSubscribers"
              comment="Max no of subscribers (default 0 == 2 * MaxNoOfTables)"
              type="unsigned" default="0" min="0" max="4294967039"/>

    …

  </section>

  …
```

```
</configvariables>
```

Note

Normally, the XML output produced by `ndb_config --configinfo --xml` is formatted using one line per element; we have added extra whitespace in the previous example, as well as the next one, for reasons of legibility. This should not make any difference to applications using this output, since most XML processors either ignore nonessential whitespace as a matter of course, or can be instructed to do so.

Beginning with MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, the XML output also indicates when changing a given parameter requires that data nodes be restarted using the `--initial` [1954] option. This is shown by the presence of an `initial="true"` attribute in the corresponding `<param>` element. In addition (also beginning with MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10), the restart type (`system` or `node`) is also shown; if a given parameter requires a system restart, this is indicated by the presence of a `restart="system"` attribute in the corresponding `<param>` element. For example, changing the value set for the `Diskless` [1833] parameter requires a system initial restart, as shown here (with the `restart` and `initial` attributes highlighted for visibility):

```
<param name="Diskless" comment="Run wo/ disk" type="bool" default="false"
         restart="system" initial="true"/>
```

Currently, no `initial` attribute is included in the XML output for `<param>` elements corresponding to parameters which do not require initial restarts; in other words, `initial="false"` is the default, and the value `false` should be assumed if the attribute is not present. Similarly, the default restart type is `node` (that is, an online or “rolling” restart of the cluster), but the `restart` attribute is included only if the restart type is `system` (meaning that all cluster nodes must be shut down at the same time, then restarted).

Important

The `--xml` option can be used only with the `--configinfo` option. Using `--xml` without `--configinfo` fails with an error.

Unlike the options used with this program to obtain current configuration data, `--configinfo` and `--xml` use information obtained from the MySQL Cluster sources when `ndb_config` was compiled. For this reason, no connection to a running MySQL Cluster or access to a `config.ini` or `my.cnf` file is required for these two options.

Combining other `ndb_config` options (such as `--query` [1973] or `--type` [1974]) with `--configinfo` or `--xml` is not supported. Currently, if you attempt to do so, the usual result is that all other options besides `--configinfo` or `--xml` are simply ignored. *However, this behavior is not guaranteed and is subject to change at any time*. In addition, since `ndb_config`, when used with the `--configinfo` option, does not access the MySQL Cluster or read any files, trying to specify additional options such as `--ndb-connectstring` or `--config-file` with `--configinfo` serves no purpose.

Examples

1. To obtain the node ID and type of each node in the cluster:

```
shell> ./ndb_config --query=id,type --fields=':' --rows='\n'
1:ndbd
2:ndbd
3:ndbd
4:ndbd
5:ndb_mgmd
6:mysqld
7:mysqld
```

```
8:mysqld
9:mysqld
```

In this example, we used the `--fields` [1975] options to separate the ID and type of each node with a colon character (`:`), and the `--rows` [1975] options to place the values for each node on a new line in the output.

2. To produce a connectstring that can be used by data, SQL, and API nodes to connect to the management server:

```
shell> ./ndb_config --config-file=usr/local/mysql/cluster-data/config.ini \
--query=hostname,portnumber --fields=: --rows=, --type=ndb_mgmd
192.168.0.179:1186
```

3. This invocation of `ndb_config` checks only data nodes (using the `--type` [1974] option), and shows the values for each node's ID and host name, as well as the values set for its `DataMemory` [1817], `IndexMemory` [1819], and `DataDir` [1816] parameters:

```
shell> ./ndb_config --type=ndbd --query=id,host,datamemory,indexmemory,datadir -f ' : ' -r '\n'
1 : 192.168.0.193 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
2 : 192.168.0.112 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
3 : 192.168.0.176 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
4 : 192.168.0.119 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
```

In this example, we used the short options `-f` and `-r` for setting the field delimiter and row separator, respectively.

4. To exclude results from any host except one in particular, use the `--host` [1973] option:

```
shell> ./ndb_config --host=192.168.0.176 -f : -r '\n' -q id,type
3:ndbd
5:ndb_mgmd
```

In this example, we also used the short form `-q` to determine the attributes to be queried.

Similarly, you can limit results to a node with a specific ID using the `--id` [1974] or `--nodeid` [1974] option.

ndb_cpcd — Automate Testing for NDB Development

This utility is found in the `libexec` directory. It is part of an internal automated test framework used in testing and debugging MySQL Cluster. Because it can control processes on remote systems, it is not advisable to use `ndb_cpcd` in a production cluster.

The source files for `ndb_cpcd` may be found in the directory `storage/ndb/src/cw/cpcd`, in the MySQL Cluster source tree.

Deprecated feature. As of MySQL Cluster NDB 7.0, this program is deprecated and no longer actively maintained. It is subject to removal in a future MySQL Cluster version.

ndb_delete_all — Delete All Rows from an NDB Table

`ndb_delete_all` deletes all rows from the given `NDB` table. In some cases, this can be much faster than `DELETE` or even `TRUNCATE TABLE`.

Usage

```
ndb_delete_all -c connect_string tbl_name -d db_name
```

This deletes all rows from the table named *`tbl_name`* in the database named *`db_name`*. It is exactly equivalent to executing `TRUNCATE db_name.tbl_name` in MySQL.

The following table includes options that are specific to `ndb_delete_all`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_delete_all`), see Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs.

Table 17.15. ndb_delete_all Options and Variables: MySQL 5.1, MySQL Cluster NDB 6.3-7.1

Format	Description	Added / Removed
--database=dbname, -d	Name of the database in which the table is found	All MySQL 5.1 based releases
--transactional [1979], -t [1979]	Perform the delete in a single transaction (may run out of operations)	All MySQL 5.1 based releases
--tupscan	Run tup scan	All MySQL 5.1 based releases
--diskscan	Run disk scan	All MySQL 5.1 based releases

- --transactional, -t

  Use of this option causes the delete operation to be performed as a single transaction.

Warning

With very large tables, using this option may cause the number of operations available to the cluster to be exceeded.

ndb_desc — Describe NDB Tables

ndb_desc provides a detailed description of one or more NDB tables.

Usage

```
ndb_desc -c connect_string tbl_name -d db_name [-p]
```

Sample Output

MySQL table creation and population statements:

```
USE test;

CREATE TABLE fish (
    id INT(11) NOT NULL AUTO_INCREMENT,
    name VARCHAR(20) NOT NULL,
    length_mm INT(11) NOT NULL,
    weight_gm INT(11) NOT NULL,

    PRIMARY KEY pk (id),
    UNIQUE KEY uk (name)
) ENGINE=NDB;

INSERT INTO fish VALUES
    ('','guppy', 35, 2), ('','tuna', 2500, 150000),
    ('','shark', 3000, 110000), ('','manta ray', 1500, 50000),
    ('','grouper', 900, 125000), ('','puffer', 250, 2500);
```

Output from ndb_desc:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --

NDBT_ProgramExit: 0 - OK
```

Information about multiple tables can be obtained in a single invocation of `ndb_desc` by using their names, separated by spaces. All of the tables must be in the same database.

The `Extent_space` and `Free extent_space` columns were added in MySQL Cluster NDB 6.3.27 and MySQL Cluster NDB 7.0.8. They are applicable only to `NDB` tables having columns on disk; for tables having only in-memory columns, these columns always contain the value `0`.

To illustrate their use, we modify the previous example. First, we must create the necessary Disk Data objects, as shown here:

```
CREATE LOGFILE GROUP lg_1
    ADD UNDOFILE 'undo_1.log'
    INITIAL_SIZE 16M
    UNDO_BUFFER_SIZE 2M
    ENGINE NDB;

ALTER LOGFILE GROUP lg_1
    ADD UNDOFILE 'undo_2.log'
    INITIAL_SIZE 12M
    ENGINE NDB;

CREATE TABLESPACE ts_1
    ADD DATAFILE 'data_1.dat'
    USE LOGFILE GROUP lg_1
    INITIAL_SIZE 32M
    ENGINE NDB;

ALTER TABLESPACE ts_1
    ADD DATAFILE 'data_2.dat'
    INITIAL_SIZE 48M
    ENGINE NDB;
```

(For more information on the statements just shown and the objects created by them, see MySQL Cluster Disk Data Objects, as well as `CREATE LOGFILE GROUP` Syntax, and `CREATE TABLESPACE` Syntax.)

Now we can create and populate a version of the `fish` table that stores 2 of its columns on disk (deleting the previous version of the table first, if it already exists):

```
CREATE TABLE fish (
    id INT(11) NOT NULL AUTO_INCREMENT,
    name VARCHAR(20) NOT NULL,
    length_mm INT(11) NOT NULL,
    weight_gm INT(11) NOT NULL,

    PRIMARY KEY pk (id),
    UNIQUE KEY uk (name)
) TABLESPACE ts_1 STORAGE DISK
ENGINE=NDB;

INSERT INTO fish VALUES
    ('','guppy', 35, 2), ('','tuna', 2500, 150000),
    ('','shark', 3000, 110000), ('','manta ray', 1500, 50000),
    ('','grouper', 900, 125000), ('','puffer', 250, 2500);
```

When run against this version of the table, `ndb_desc` displays the following output:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 3
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 321
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
length_mm Int NOT NULL AT=FIXED ST=DISK

... 32768                 0             0

NDBT_ProgramExit: 0 - OK
```

This means that 1048576 bytes are allocated from the tablespace for this table on each partition, of which 1044440 bytes remain free for additional storage. In other words, 1048576 - 1044440 = 4136 bytes per partition is currently being used to store the data from this table's disk-based columns. The number of bytes shown as `Free extent_space` is available for storing on-disk column data from the `fish` table only; for this reason, it is not visible when selecting from the `INFORMATION_SCHEMA.FILES` table.

The following table includes options that are specific to `ndb_desc`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_desc`), see Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs.

Table 17.16. ndb_desc Options and Variables: MySQL 5.1, MySQL Cluster NDB 6.3-7.1

Format	Description	Added / Removed
--database=dbname, -d	Name of database containing table	All MySQL 5.1 based releases
--unqualified, -u	Use unqualified table names	All MySQL 5.1 based releases
--extra-partition-info [1982], -p [1982]	Display information about partitions	All MySQL 5.1 based releases
--retries=#, -r	Number of times to retry the connection (once per second)	All MySQL 5.1 based releases
--blob-info [1982], -b [1982]	Include partition information for BLOB tables in output. Requires that the -p option also be used	ADDED: NDB 6.3.32, NDB 7.0.13, NDB 7.1.2
--extra-node-info [1982], -n [1982]	Include partition-to-data-node mappings in output. Requires that the -p option also be used	ADDED: NDB 6.2.19, NDB 6.3.33, NDB 7.0.14, NDB 7.1.2

- --extra-partition-info, -p

  Print additional information about the table's partitions.

- --blob-info, -b

  Include information about subordinate BLOB and TEXT columns.

  Use of this option also requires the use of the --extra-partition-info [1982] (-p) option.

  This option was added in MySQL Cluster NDB 6.3.32, MySQL Cluster NDB 7.0.13, and MySQL Cluster NDB 7.1.2.

- --extra-node-info, -n

  Include information about the mappings between table partitions and the data nodes upon which they reside. This information can be useful for verifying distribution awareness mechanisms and supporting more efficient application access to the data stored in MySQL Cluster.

  Use of this option also requires the use of the --extra-partition-info [1982] (-p) option.

  This option was added in MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.33, MySQL Cluster NDB 7.0.14, and MySQL Cluster NDB 7.1.2.

ndb_drop_index — Drop Index from an NDB Table

ndb_drop_index drops the specified index from an NDB table. *It is recommended that you use this utility only as an example for writing NDB API applications*—see the Warning later in this section for details.

Usage

```
ndb_drop_index -c connect_string table_name index -d db_name
```

The statement shown above drops the index named *index* from the *table* in the *database*.

The following table includes options that are specific to ndb_drop_index. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including ndb_drop_index), see Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs.

Table 17.17. ndb_drop_index Options and Variables: MySQL 5.1, MySQL Cluster NDB 6.3-7.1

Format	Description	Added / Removed
--database=dbname, -d	Name of the database in which the table is found	All MySQL 5.1 based releases

Warning

Operations performed on Cluster table indexes using the NDB API are not visible to MySQL and make the table unusable by a MySQL server. If you use this program to drop an index, then try to access the table from an SQL node, an error results, as shown here:

```
shell> ./ndb_drop_index -c localhost dogs ix -d ctest1
Dropping index dogs/idx...OK

NDBT_ProgramExit: 0 - OK

shell> ./mysql -u jon -p ctest1
Enter password: *******
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 7 to server version: 5.1.63-ndb-7.1.25

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW TABLES;
+------------------+
| Tables_in_ctest1 |
+------------------+
| a                |
| bt1              |
| bt2              |
| dogs             |
| employees        |
| fish             |
+------------------+
6 rows in set (0.00 sec)

mysql> SELECT * FROM dogs;
ERROR 1296 (HY000): Got error 4243 'Index not found' from NDBCLUSTER
```

In such a case, your *only* option for making the table available to MySQL again is to drop the table and re-create it. You can use either the SQL statementDROP TABLE or the ndb_drop_table utility (see ndb_drop_table — Drop an NDB Table) to drop the table.

ndb_drop_table — Drop an NDB Table

ndb_drop_table drops the specified NDB table. (If you try to use this on a table created with a storage engine other than NDB, the attempt fails with the error 723: No such table exists.) This operation is extremely fast; in some cases, it can be an order of magnitude faster than using a MySQL DROP TABLE statement on an NDB table.

Usage

```
ndb_drop_table -c connect_string tbl_name -d db_name
```

The following table includes options that are specific to ndb_drop_table. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including ndb_drop_table), see Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs.

Table 17.18. ndb_drop_table Options and Variables: MySQL 5.1, MySQL Cluster NDB 6.3-7.1

Format	Description	Added / Removed
--database=dbname, -d	Name of the database in which the table is found	All MySQL 5.1 based releases

ndb_error_reporter — NDB Error-Reporting Utility

ndb_error_reporter creates an archive from data node and management node log files that can be used to help diagnose bugs or other problems with a cluster. *It is highly recommended that you make use of this utility when filing reports of bugs in MySQL Cluster*.

The following table includes command options specific to the MySQL Cluster program ndb_error_reporter. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including ndb_error_reporter), see Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs.

Table 17.19. ndb_error_reporter Options and Variables: MySQL 5.1, MySQL Cluster NDB 6.3-7.1

Format	Description	Added / Removed
--fs [1984]	Include file system data in error report; can use a large amount of disk space	All MySQL 5.1 based releases

Usage

```
ndb_error_reporter path/to/config-file [username] [--fs]
```

This utility is intended for use on a management node host, and requires the path to the management host configuration file (config.ini). Optionally, you can supply the name of a user that is able to access the cluster's data nodes using SSH, to copy the data node log files. ndb_error_reporter then includes all of these files in archive that is created in the same directory in which it is run. The archive is named ndb_error_report_*YYYYMMDDHHMMSS*.tar.bz2, where *YYYYMMDDHHMMSS* is a datetime string.

If the --fs is used, then the data node file systems are also copied to the management host and included in the archive that is produced by this script. As data node file systems can be extremely large even after being compressed, we ask that you please do *not* send archives created using this option to Oracle unless you are specifically requested to do so.

Command-Line Format	--fs	
	Permitted Values	
	Type	boolean
	Default	FALSE

ndb_index_stat — NDB Index Statistics Utility

ndb_index_stat ...

Usage

To obtain basic index statistics about a given NDB table, invoke ndb_index_stat as shown here, with the name of the table as the first argument and the name of the database containing this table specified immediately following it, using the --database [1986] (-d) option:

```
ndb_index_stat table -d database
```

In this example, we use ndb_index_stat to obtain such information about an NDB table named mytable in the test database:

```
shell> ndb_index_stat -d test mytable
table:mytable index:PRIMARY fragCount:4
sampleVersion:2 loadTime:1336751773 sampleCount:0 keyBytes:0
query cache: valid:1 sampleCount:0 totalBytes:0
times in ms: save: 12.380 sort: 0.001

NDBT_ProgramExit: 0 - OK
```

The `--verbose` [1988] option provides some additional output, as shown here:

```
shell> ndb_index_stat -d test mytable --verbose
random seed 1337010518
connected
loop 1 of 1
table:mytable index:PRIMARY fragCount:4
sampleVersion:2 loadTime:1336751773 sampleCount:0 keyBytes:0
read stats
query cache created
query cache: valid:1 sampleCount:0 totalBytes:0
times in ms: save: 20.766 sort: 0.001
disconnected

NDBT_ProgramExit: 0 - OK

shell>
```

Options

The following table includes options that are specific to the MySQL Cluster `ndb_index_stat` utility. Additional descriptions are listed following the table. For options common to most MySQL Cluster programs (including `ndb_index_stat`), see Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs.

Table 17.20. `ndb_index_stat` Options and Variables: MySQL 5.1, MySQL Cluster NDB 6.3-7.1

Format	Description	Added / Removed
`--database=name`, `-d`	Name of the database containing the table.	All MySQL 5.1 based releases
`--delete`	Delete index statistics for the given table, stopping any auto-update previously configured.	All MySQL 5.1 based releases
`--update`	Update index statistics for the given table, restarting any auto-update previously configured.	All MySQL 5.1 based releases
`--dump`	Print the query cache.	All MySQL 5.1 based releases
`--query=#`	Perform a number of random range queries on first key attr (must be int unsigned).	All MySQL 5.1 based releases
`--sys-drop`	Drop any statistics tables and events in NDB kernel (all statistics are lost)	All MySQL 5.1 based releases
`--sys-create`	Create all statistics tables and events in NDB kernel, if none of them already exist	All MySQL 5.1 based releases
`--sys-create-if-not-exist`	Create any statistics tables and events in NDB kernel that do not already exist.	All MySQL 5.1 based releases

Format	Description	Added / Removed
--sys-create-if-not-valid	Create any statistics tables or events that do not already exist in the NDB kernel. after dropping any that are invalid.	All MySQL 5.1 based releases
--sys-check	Verify that NDB system index statistics and event tables exist.	All MySQL 5.1 based releases
--sys-skip-tables	Do not apply sys-* options to tables.	All MySQL 5.1 based releases
--sys-skip-events	Do not apply sys-* options to events.	All MySQL 5.1 based releases
--verbose, -v	Turn on verbose output	All MySQL 5.1 based releases
--loops=#	Set the number of times to perform a given command. Default is 0.	All MySQL 5.1 based releases

ndb_index_stat statistics options. The following options are used to generate index statistics. They work with a given table and database. They cannot be mixed with ndb_index_stat system options.

- --database=*name*, -d *name*

Command-Line Format	--database=name	
	-d	
	Permitted Values	
	Type	string
	Default	[none]
	Range	..

The name of the database that contains the table being queried.

- --delete

Command-Line Format	--delete	
	Permitted Values	
	Type	boolean
	Default	true
	Range	..

Delete the index statistics for the given table, stopping any auto-update that was previously configured.

- --update

Command-Line Format	--update	
	Permitted Values	
	Type	boolean
	Default	true
	Range	..

Update the index statistics for the given table, and restart any auto-update that previously configured.

- `--dump`

Command-Line Format	`--dump`	
	Permitted Values	
	Type	`boolean`
	Default	`true`
	Range	`..`

Dump the contents of the query cache.

- `--query=#`

Command-Line Format	`--query=#`	
	Permitted Values	
	Type	`numeric`
	Default	`0`
	Range	`0 .. MAX_INT`

Perform random range queries on first key attribute (must be int unsigned).

`ndb_index_stat` system options. The following options are used to generate and update the statistics tables in the NDB kernel. They cannot be mixed with `ndb_index_stat` statistics options.

- `--sys-drop`

Command-Line Format	`--sys-drop`	
	Permitted Values	
	Type	`boolean`
	Default	`true`
	Range	`..`

Drop all statistics tables and events in the NDB kernel. *This causes all statistics to be lost*.

- `--sys-create`

Command-Line Format	`--sys-create`	
	Permitted Values	
	Type	`boolean`
	Default	`true`
	Range	`..`

Create all statistics tables and events in the NDB kernel. This works only if none of them exist previously.

- `sys-create-if-not-exist`

Command-Line Format	`--sys-create-if-not-exist`	
	Permitted Values	
	Type	`boolean`
	Default	`true`
	Range	`..`

Create any NDB system statistics tables or events (or both) that do not already exist when the program is invoked.

- `--sys-create-if-not-valid`

Command-Line Format	`--sys-create-if-not-valid`	
	Permitted Values	
	Type	`boolean`
	Default	`true`
	Range	`..`

Create any NDB system statistics tables or events that do not already exist, after dropping any that are invalid.

- `--sys-check`

Command-Line Format	`--sys-check`	
	Permitted Values	
	Type	`boolean`
	Default	`true`
	Range	`..`

Verify that all required system statistics tables and events exist in the NDB kernel.

- `--sys-skip-tables`

Command-Line Format	`--sys-skip-tables`	
	Permitted Values	
	Type	`boolean`
	Default	`true`
	Range	`..`

Do not apply any `--sys-*` options to any statistics tables.

- `--sys-skip-events`

Command-Line Format	`--sys-skip-events`	
	Permitted Values	
	Type	`boolean`
	Default	`true`
	Range	`..`

Do not apply any `--sys-*` options to any events.

- `--verbose`

Command-Line Format	`--verbose`	
	`-v`	
	Permitted Values	
	Type	`boolean`
	Default	`true`

	Range	`..`

Turn on verbose output.

- `--loops=#`

Command-Line Format	`--loops=#`	
	Permitted Values	
	Type	`numeric`
	Default	`0`
	Range	`0 .. MAX_INT`

Repeat commands this number of times (for use in testing).

ndb_print_backup_file — Print NDB Backup File Contents

`ndb_print_backup_file` obtains diagnostic information from a cluster backup file.

Usage

```
ndb_print_backup_file file_name
```

`file_name` is the name of a cluster backup file. This can be any of the files (`.Data`, `.ctl`, or `.log` file) found in a cluster backup directory. These files are found in the data node's backup directory under the subdirectory `BACKUP-#`, where `#` is the sequence number for the backup. For more information about cluster backup files and their contents, see MySQL Cluster Backup Concepts.

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other `NDB` utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

ndb_print_schema_file — Print NDB Schema File Contents

`ndb_print_schema_file` obtains diagnostic information from a cluster schema file.

Usage

```
ndb_print_schema_file file_name
```

`file_name` is the name of a cluster schema file. For more information about cluster schema files, see MySQL Cluster Data Node `FileSystemDir` Files.

Like `ndb_print_backup_file` and `ndb_print_sys_file` (and unlike most of the other `NDB` utilities that are intended to be run on a management server host or to connect to a management server) `ndb_schema_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

ndb_print_sys_file — Print NDB System File Contents

ndb_print_sys_file obtains diagnostic information from a MySQL Cluster system file.

Usage

```
ndb_print_sys_file file_name
```

file_name is the name of a cluster system file (sysfile). Cluster system files are located in a data node's data directory (DataDir [1816]); the path under this directory to system files matches the pattern ndb_#_fs/D#/DBDIH/P#.sysfile. In each case, the # represents a number (not necessarily the same number). For more information, see MySQL Cluster Data Node FileSystemDir Files.

Like ndb_print_backup_file and ndb_print_schema_file (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) ndb_print_backup_file must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

ndbd_redo_log_reader — Check and Print Content of Cluster Redo Log

Reads a redo log file, checking it for errors, printing its contents in a human-readable format, or both. ndbd_redo_log_reader is intended for use primarily by MySQL Cluster developers and Support personnel in debugging and diagnosing problems.

This utility was made available as part of default builds beginning with MySQL Cluster NDB 6.1.3. It remains under development, and its syntax and behavior are subject to change in future releases. For this reason, it should be considered experimental at this time.

The C++ source files for ndbd_redo_log_reader can be found in the directory /storage/ndb/src/kernel/blocks/dblqh/redoLogReader.

The following table includes options that are specific to the MySQL Cluster program ndbd_redo_log_reader. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including ndbd_redo_log_reader), see Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs.

Table 17.21. ndbd_redo_log_reader Options and Variables: MySQL 5.1, MySQL Cluster NDB 6.3-7.1

Format	Description	Added / Removed
-noprint [1991]	Do not print records	All MySQL 5.1 based releases
-nocheck [1991]	Do not check records for errors	All MySQL 5.1 based releases

Usage

```
ndbd_redo_log_reader file_name [options]
```

file_name is the name of a cluster redo log file. redo log files are located in the numbered directories under the data node's data directory (DataDir [1816]); the path under this directory to the redo log files matches the pattern ndb_#_fs/D#/LCP/#/T#F#.Data. In each case, the # represents a number (not necessarily the same number). For more information, see MySQL Cluster Data Node FileSystemDir Files.

The name of the file to be read may be followed by one or more of the options listed here:

Command-Line Format	-noprint	
	Permitted Values	
	Type	boolean
	Default	FALSE

  -noprint: Do not print the contents of the log file.

Command-Line Format	-nocheck	
	Permitted Values	
	Type	boolean
	Default	FALSE

  -nocheck: Do not check the log file for errors.

Like ndb_print_backup_file and ndb_print_schema_file (and unlike most of the NDB utilities that are intended to be run on a management server host or to connect to a management server) ndbd_redo_log_reader must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

ndb_restore — Restore a MySQL Cluster Backup

The cluster restoration program is implemented as a separate command-line utility ndb_restore, which can normally be found in the MySQL bin directory. This program reads the files created as a result of the backup and inserts the stored information into the database.

ndb_restore must be executed once for each of the backup files that were created by the START BACKUP command used to create the backup (see Using The MySQL Cluster Management Client to Create a Backup). This is equal to the number of data nodes in the cluster at the time that the backup was created.

Note

Before using ndb_restore, it is recommended that the cluster be running in single user mode, unless you are restoring multiple data nodes in parallel. See MySQL Cluster Single User Mode, for more information.

The following table includes options that are specific to the MySQL Cluster native backup restoration program ndb_restore. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including ndb_restore), see Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs.

Table 17.22. ndb_restore Options and Variables: MySQL 5.1, MySQL Cluster NDB 6.3-7.1

Format	Description	Added / Removed
--connect [1994], -c [1994]	Same as connectstring	All MySQL 5.1 based releases
--nodeid=# [1994], -n [1994]	Back up files from node with this ID	All MySQL 5.1 based releases
--backupid=# [1996], -b [1996]	Restore from the backup with the given ID	All MySQL 5.1 based releases

Format	Description	Added / Removed
--restore_data [1996]	Restore table data and logs into NDB Cluster using the NDB API	All MySQL 5.1 based releases
--restore_meta [1996], -m [1996]	Restore metadata to NDB Cluster using the NDB API	All MySQL 5.1 based releases
--no-upgrade [1997], -u [1997]	Do not upgrade array type for varsize attributes which do not already resize VAR data, and do not change column attributes	ADDED: 5.1.19
--promote-attributes [1995], -A [1995]	Allow attributes to be promoted when restoring data from backup	ADDED: NDB 6.3.8
--preserve-trailing-spaces [1995], -P [1995]	Allow preservation of trailing spaces (including padding) when promoting fixed-width string types to variable-width types	ADDED: NDB 6.3.8
--no-restore-disk-objects [1999], -d [1999]	Do not restore objects relating to Disk Data	ADDED: 5.1.6
--restore_epoch [1996], -e [1996]	Restore epoch info into the status table. Convenient on a MySQL Cluster replication slave for starting replication. The row in mysql.ndb_apply_status with id 0 will be updated/inserted.	All MySQL 5.1 based releases
--skip-table-check [1994], -s [1994]	Skip table structure check during restoring of data	ADDED: 5.1.17
--parallelism=# [1999], -p [1999]	Number of parallel transactions to use while restoring data	All MySQL 5.1 based releases
--print [1999]	Print metadata, data and log to stdout (equivalent to --print_meta --print_data --print_log)	All MySQL 5.1 based releases
--print_meta [1998]	Print metadata to stdout	All MySQL 5.1 based releases
--print_data [1997]	Print data to stdout	All MySQL 5.1 based releases
--print_log [1998]	Print to stdout	All MySQL 5.1 based releases
--backup_path=path [1996]	Path to backup files directory	ADDED: 5.1.17, NDB 6.1.5
--dont_ignore_systab_0 [1999], -f [1999]	Do not ignore system table during restore. Experimental only; not for production use	All MySQL 5.1 based releases
--ndb-nodegroup-map=map [1999], -z [1999]	Nodegroup map for NDBCLUSTER storage engine. Syntax: list of (source_nodegroup, destination_nodegroup)	All MySQL 5.1 based releases
--fields-enclosed-by=char [1997]	Fields are enclosed with the indicated character	ADDED: 5.1.18

Format	Description	Added / Removed
--fields-terminated-by=char [1998]	Fields are terminated by the indicated character	ADDED: 5.1.18
--fields-optionally-enclosed-by [1997]	Fields are optionally enclosed with the indicated character	ADDED: 5.1.18
--lines-terminated-by=char [1998]	Lines are terminated by the indicated character	ADDED: 5.1.18
--hex [1998]	Print binary types in hexadecimal format	ADDED: 5.1.18
--tab=path [1997], -T [1997]	Creates a tab-separated .txt file for each table in the given path	ADDED: 5.1.18
--append [1998]	Append data to a tab-delimited file	ADDED: 5.1.18
--progress-frequency=# [1999]	Print status of restoration each given number of seconds	All MySQL 5.1 based releases
--no-binlog [1999]	If a mysqld is connected and using binary logging, do not log the restored data	ADDED: NDB 6.2.16, NDB 6.3.16
--verbose=# [1999]	Level of verbosity in output	All MySQL 5.1 based releases
--include-databases=db-list [1999]	List of one or more databases to restore (excludes those not named)	ADDED: NDB 6.3.22, NDB 6.4.3
--exclude-databases=db-list [2001]	List of one or more databases to exclude (includes those not named)	ADDED: NDB 6.3.22, NDB 6.4.3
--include-tables=table-list [2000]	List of one or more tables to restore (excludes those in same database that are not named); each table reference must include the database name	ADDED: NDB 6.3.22, NDB 6.4.3
--exclude-tables=table-list [2001]	List of one or more tables to exclude (includes those in same database that are not not named); each table reference must include the database name	ADDED: NDB 6.3.22, NDB 6.4.3
--exclude-missing-columns [2002]	Causes columns from the backup version of a table that are missing from the version of the table in the database to be ignored.	ADDED: NDB 6.3.26, NDB 7.0.7
--disable-indexes [2002]	Causes indexes from a backup to be ignored; may decrease time needed to restore data.	ADDED: NDB 6.3.31, NDB 7.0.11, NDB 7.1.2
--rebuild-indexes [2002]	Causes multi-threaded ordered index rebuilding of indexes found in the backup.	ADDED: NDB 6.3.31, NDB 7.0.11, NDB 7.1.2
--skip-broken-objects [2003]	Causes missing blob tables in the backup file to be ignored.	ADDED: NDB 6.3.40, NDB 7.0.21, NDB 7.1.10

Format	Description	Added / Removed
--skip-unknown-objects [2003]	Causes schema objects not recognized by ndb_restore to be ignored when restoring a backup made from a newer MySQL Cluster version to an older version.	ADDED: NDB 6.3.34, NDB 7.0.15, NDB 7.1.4
--rewrite-database=olddb,newdb [2003]	Restores to a database with a different name than the original	ADDED: NDB 6.3.41, NDB 7.0.22, NDB 7.1.11
--lossy-conversions [1995], -L [1995]	Allow lossy conversions of column values (type demotions or changes in sign) when restoring data from backup	ADDED: NDB 7.1.11
--restore-privilege-tables [1996]	Restore MySQL privilege tables that were previously moved to NDB.	ADDED: NDB 7.2.0

Typical options for this utility are shown here:

```
ndb_restore [-c connectstring] -n node_id [-m] -b backup_id \
    -r --backup_path=/path/to/backup/files
```

The -c option is used to specify a connectstring which tells ndb_restore where to locate the cluster management server. (See The MySQL Cluster Connectstring, for information on connectstrings.) If this option is not used, then ndb_restore attempts to connect to a management server on localhost:1186. This utility acts as a cluster API node, and so requires a free connection "slot" to connect to the cluster management server. This means that there must be at least one [api] or [mysqld] section that can be used by it in the cluster config.ini file. It is a good idea to keep at least one empty [api] or [mysqld] section in config.ini that is not being used for a MySQL server or other application for this reason (see Defining SQL and Other API Nodes in a MySQL Cluster).

You can verify that ndb_restore is connected to the cluster by using the SHOW command in the ndb_mgm management client. You can also accomplish this from a system shell, as shown here:

```
shell> ndb_mgm -e "SHOW"
```

-n is used to specify the node ID of the data node on which the backups were taken.

The first time you run the ndb_restore restoration program, you also need to restore the metadata. In other words, you must re-create the database tables—this can be done by running it with the -m option. Note that the cluster should have an empty database when starting to restore a backup. (In other words, you should start ndbd with --initial [1954] prior to performing the restore. You should also remove manually any Disk Data files present in the data node's DataDir [1816].)

It is possible to restore data without restoring table metadata. Prior to MySQL 5.1.17, ndb_restore did not perform any checks of table schemas; if a table was altered between the time the backup was taken and when ndb_restore was run, ndb_restore would still attempt to restore the data to the altered table.

Beginning with MySQL 5.1.17, the default behavior is for ndb_restore to fail with an error if table data do not match the table schema; this can be overridden using the --skip-table-check or -s option. Prior to MySQL 5.1.21, if this option is used, then ndb_restore attempts to fit data into the existing table schema, but the result of restoring a backup to a table schema that does not match the original is unspecified.

Beginning with MySQL Cluster NDB 6.3.35, MySQL Cluster NDB 7.0.16, and MySQL Cluster NDB 7.1.5, some of the restrictions on mismatches in column definitions when restoring data using

ndb_restore are relaxed; when one of these types of mismatches is encountered, ndb_restore does not stop with an error as it did previously, but rather accepts the data and inserts it into the target table while issuing a warning to the user that this is being done. This behavior occurs whether or not either of the options --skip-table-check or --promote-attributes [1995] is in use. These differences in column definitions are of the following types:

- Different COLUMN_FORMAT settings (FIXED, DYNAMIC, DEFAULT)
- Different STORAGE settings (MEMORY, DISK)
- Different default values
- Different distribution key settings

Beginning with MySQL Cluster NDB 6.3.8, ndb_restore supports limited *attribute promotion* in much the same way that it is supported by MySQL replication; that is, data backed up from a column of a given type can generally be restored to a column using a “larger, similar” type. For example, data from a CHAR(20) column can be restored to a column declared as VARCHAR(20), VARCHAR(30), or CHAR(30); data from a MEDIUMINT column can be restored to a column of type INT or BIGINT. See Replication of Columns Having Different Data Types, for a table of type conversions currently supported by attribute promotion.

Attribute promotion by ndb_restore must be enabled explicitly, as follows:

1. Prepare the table to which the backup is to be restored. ndb_restore cannot be used to re-create the table with a different definition from the original; this means that you must either create the table manually, or alter the columns which you wish to promote using ALTER TABLE after restoring the table metadata but before restoring the data.
2. Invoke ndb_restore with the --promote-attributes [1995] option (short form -A) when restoring the table data. Attribute promotion does not occur if this option is not used; instead, the restore operation fails with an error.

--lossy-conversions, -L

Version Introduced	5.1.51-ndb-7.1.11	
Command-Line Format	--lossy-conversions	
	-L	
	Permitted Values	
	Type	boolean
	Default	FALSE

This option is intended to complement the --promote-attributes [1995] option. Using --lossy-conversions allows lossy conversions of column values (type demotions or changes in sign) when restoring data from backup. With some exceptions, the rules governing demotion are the same as for MySQL replication; see Replication of Columns Having Different Data Types, for information about specific type conversions currently supported by attribute demotion.

ndb_restore reports any truncation of data that it performs during lossy conversions once per attribute and column.

This option was added in MySQL Cluster NDB 7.1.11.

The --preserve-trailing-spaces option is also available beginning with MySQL Cluster NDB 6.3.8. This option (short form -R) causes trailing spaces to be preserved when promoting a fixed-width character data type to its variable-width equivalent—that is, when promoting a CHAR column value to VARCHAR or a BINARY column value to VARBINARY. Otherwise, any trailing spaces are dropped from such column values when they are inserted into the new columns.

Note

Although you can promote CHAR columns to VARCHAR and BINARY columns to VARBINARY, you cannot promote VARCHAR columns to CHAR or VARBINARY columns to BINARY.

The -b option is used to specify the ID or sequence number of the backup, and is the same number shown by the management client in the Backup *backup_id* completed message displayed upon completion of a backup. (See Using The MySQL Cluster Management Client to Create a Backup.)

Important

When restoring cluster backups, you must be sure to restore all data nodes from backups having the same backup ID. Using files from different backups will at best result in restoring the cluster to an inconsistent state, and may fail altogether.

--restore_epoch (short form: -e) adds (or restores) epoch information to the cluster replication status table. This is useful for starting replication on a MySQL Cluster replication slave. When this option is used, the row in the mysql.ndb_apply_status having 0 in the id column is updated if it already exists; such a row is inserted if it does not already exist. (See MySQL Cluster Backups With MySQL Cluster Replication.)

--restore_data causes ndb_restore to output NDB table data and logs.

This option causes ndb_restore to print NDB table metadata.

ndb_restore does not by default restore distributed MySQL privilege tables (MySQL Cluster NDB 7.2.0 and later). This option causes ndb_restore to restore the privilege tables.

This works only if the privilege tables were converted to NDB before the backup was taken. For more information, see Distributed MySQL Privileges for MySQL Cluster.

The path to the backup directory is required; this is supplied to ndb_restore using the --backup_path option, and must include the subdirectory corresponding to the ID backup of the backup to be restored. For example, if the data node's DataDir [1816] is /var/lib/mysql-cluster, then the backup directory is /var/lib/mysql-cluster/BACKUP, and the backup files for the backup with the ID 3 can be found in /var/lib/mysql-cluster/BACKUP/BACKUP-3. The path may be absolute or relative to the directory in which the ndb_restore executable is located, and may be optionally prefixed with backup_path=.

Note

Previous to MySQL 5.1.17 and MySQL Cluster NDB 6.1.5, the path to the backup directory was specified as shown here, with backup_path= being optional:

```
[backup_path=]/path/to/backup/files
```

Beginning with MySQL 5.1.17 and MySQL Cluster NDB 6.1.5, this syntax changed to --backup_path=*/path/to/backup/files*, to conform more closely with options used by other MySQL programs; --backupid [1996] is required, and there is no short form for this option.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID 12, created in a cluster with two database nodes having the node IDs 2 and 3, is to be restored to a cluster with four nodes. Then ndb_restore must be run twice—once for each database node in the cluster where the backup was taken. However, ndb_restore cannot always restore backups made from a cluster running one version of MySQL to a cluster running a different MySQL version. See Upgrading and Downgrading MySQL Cluster, for more information.

Important

It is not possible to restore a backup made from a newer version of MySQL Cluster using an older version of ndb_restore. You can restore a backup made from a newer version of MySQL to an older cluster, but you must use a copy of ndb_restore from the newer MySQL Cluster version to do so.

For example, to restore a cluster backup taken from a cluster running MySQL Cluster NDB 7.1.8 to a cluster running MySQL Cluster NDB 7.0.16, you must use the ndb_restore that comes with the MySQL Cluster NDB 7.1.8 distribution.

For more rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. That is, when restoring to multiple nodes in parallel, you must have an [api] or [mysqld] section in the cluster config.ini file available for each concurrent ndb_restore process. However, the data files must always be applied before the logs.

Formerly, when using ndb_restore to restore a backup made from a MySQL 5.0 cluster to a 5.1 cluster, VARCHAR columns were not resized and were recreated using the 5.0 fixed format. Beginning with MySQL 5.1.19, ndb_restore recreates such VARCHAR columns using MySQL Cluster 5.1's variable-width format. Also beginning with MySQL 5.1.19, this behavior can be overridden using the --no-upgrade [1997] option (short form: -u) when running ndb_restore.

--print_data

The --print_data option causes ndb_restore to direct its output to stdout.

TEXT and BLOB column values are always truncated to the first 256 bytes in the output; this cannot currently be overridden when using --print_data.

Beginning with MySQL 5.1.18, several additional options are available for use with the --print_data option in generating data dumps, either to stdout, or to a file. These are similar to some of the options used with mysqldump, and are shown in the following list:

- --tab, -T

Version Introduced	5.1.18
Command-Line Format	--tab=path
	-T

This option causes --print_data [1997] to create dump files, one per table, each named *tbl_name*.txt. It requires as its argument the path to the directory where the files should be saved; use . for the current directory.

- --fields-enclosed-by=*string*

Version Introduced	5.1.18	
Command-Line Format	--fields-enclosed-by=char	
	Permitted Values	
	Type	string
	Default	

Each column values are enclosed by the string passed to this option (regardless of data type; see next item).

- --fields-optionally-enclosed-by=*string*

Version Introduced	5.1.18

Command-Line Format	--fields-optionally-enclosed-by	
	Permitted Values	
	Type	string
	Default	

The string passed to this option is used to enclose column values containing character data (such as CHAR, VARCHAR, BINARY, TEXT, or ENUM).

- --fields-terminated-by=*string*

Version Introduced	5.1.18	
Command-Line Format	--fields-terminated-by=char	
	Permitted Values	
	Type	string
	Default	\t (tab)

The string passed to this option is used to separate column values. The default value is a tab character (\t).

- --hex

Version Introduced	5.1.18
Command-Line Format	--hex

If this option is used, all binary values are output in hexadecimal format.

- --fields-terminated-by=*string*

Version Introduced	5.1.18	
Command-Line Format	--fields-terminated-by=char	
	Permitted Values	
	Type	string
	Default	\t (tab)

This option specifies the string used to end each line of output. The default is a linefeed character (\n).

- --append

Version Introduced	5.1.18
Command-Line Format	--append

When used with the --tab [1997] and --print_data [1997] options, this causes the data to be appended to any existing files having the same names.

Note

If a table has no explicit primary key, then the output generated when using the --print_data [1997] option includes the table's hidden primary key.

--print_meta

This option causes ndb_restore to print all metadata to stdout.

--print_log

The --print_log option causes ndb_restore to output its log to stdout.

--print

Causes ndb_restore to print all data, metadata, and logs to stdout. Equivalent to using the --print_data [1997], --print_meta [1998], and --print_log [1998] options together.

Note

Use of --print or any of the --print_* options is in effect performing a dry run. Including one or more of these options causes any output to be redirected to stdout; in such cases, ndb_restore makes no attempt to restore data or metadata to a MySQL Cluster.

--dont_ignore_systab_0

Normally, when restoring table data and metadata, ndb_restore ignores the copy of the NDB system table that is present in the backup. --dont_ignore_systab_0 causes the system table to be restored. *This option is intended for experimental and development use only, and is not recommended in a production environment*.

--ndb-nodegroup-map, -z

This option can be used to restore a backup taken from one node group to a different node group. Its argument is a list of the form *source_node_group, target_node_group*.

--no-binlog

This option prevents any connected SQL nodes from writing data restored by ndb_restore to their binary logs. Available beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.16.

--no-restore-disk-objects, -d

This option stops ndb_restore from restoring any MySQL Cluster Disk Data objects, such as tablespaces and log file groups; see MySQL Cluster Disk Data Tables, for more information about these. Added in MySQL 5.1.6.

--parallelism=#, -p

Determines the maximum number of parallel transactions that ndb_restore tries to use. By default, this is 128; the minimum is 1, and the maximum is 1024.

--progress-frequency=*N*

Print a status report each *N* seconds while the backup is in progress. 0 (the default) causes no status reports to be printed. The maximum is 65535.

--verbose=#

Sets the level for the verbosity of the output. The minimum is 0; the maximum is 255. The default value is 1.

Beginning with MySQL 5.1.18, it is possible to restore only selected databases, or selected tables from a single database, using the syntax shown here:

```
ndb_restore other_options db_name,[db_name[,...] | tbl_name[,tbl_name][,...]]
```

In other words, you can specify either of the following to be restored:

- All tables from one or more databases
- One or more tables from a single database

--include-databases=*db_name*[,*db_name*][,...]

Version Introduced	5.1.32-ndb-6.4.3	
Command-Line Format	--include-databases=db-list	
	Permitted Values	
	Type	string
	Default	

--include-tables=*db_name.tbl_name*[,*db_name.tbl_name*][,...]

Version Introduced	5.1.32-ndb-6.4.3	
Command-Line Format	--include-tables=table-list	
	Permitted Values	
	Type	string
	Default	

Beginning with MySQL Cluster NDB 6.3.22 and MySQL Cluster NDB 6.4.3, you can (and should) use instead the --include-databases [1999] option or the --include-tables option for restoring only specific databases or tables, respectively. --include-databases takes a comma-delimited list of databases to be restored. --include-tables takes a comma-delimited list of tables (in *database.table* format) to be restored.

When --include-databases or --include-tables is used, only those databases or tables named by the option are restored; all other databases and tables are excluded by ndb_restore, and are not restored.

The following table shows several invocations of ndb_restore using --include-* options (other options possibly required have been omitted for clarity), and the effects these have on restoring from a MySQL Cluster backup:

Option Used	Result
--include-databases=db1	Only tables in database db1 are restored; all tables in all other databases are ignored
--include-databases=db1,db2 (or --include-databases=db1 --include-databases=db2)	Only tables in databases db1 and db2 are restored; all tables in all other databases are ignored
--include-tables=db1.t1	Only table t1 in database db1 is restored; no other tables in db1 or in any other database are restored
--include-tables=db1.t2,db2.t1 (or --include-tables=db1.t2 --include-tables=db2.t1)	Only the table t2 in database db1 and the table t1 in database db2 are restored; no other tables in db1, db2, or any other database are restored

Beginning with MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, you can use these two options together. For example, the following causes all tables in databases db1 and db2, together with the tables t1 and t2 in database db3, to be restored (and no other databases or tables):

```
shell> ndb_restore [...] --include-databases=db1,db2 --include-tables=db3.t1,db3.t2
```

(Again we have omitted other, possibly required, options in the example just shown.)

Note

Prior to MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, multiple --include-* options were not handled correctly, and the result of the options shown in the previous example was that only the tables db3.t1 and db3.t2 were actually restored. (Bug #48907)

--exclude-databases=*db_name*[,*db_name*][,...]

Version Introduced	5.1.32-ndb-6.4.3	
Command-Line Format	--exclude-databases=db-list	
	Permitted Values	
	Type	string
	Default	

--exclude-tables=*db_name.tbl_name*[,*db_name.tbl_name*][,...]

Version Introduced	5.1.32-ndb-6.4.3	
Command-Line Format	--exclude-tables=table-list	
	Permitted Values	
	Type	string
	Default	

Beginning with MySQL Cluster NDB 6.3.22 and MySQL Cluster NDB 6.4.3, it is possible to prevent one or more databases or tables from being restored using the ndb_restore options --exclude-databases and --exclude-tables. --exclude-databases takes a comma-delimited list of one or more databases which should not be restored. --exclude-tables takes a comma-delimited list of one or more tables (using *database.table* format) which should not be restored.

When --exclude-databases or --exclude-tables is used, only those databases or tables named by the option are excluded; all other databases and tables are restored by ndb_restore.

This table shows several invocations of ndb_restore usng --exclude-* options (other options possibly required have been omitted for clarity), and the effects these options have on restoring from a MySQL Cluster backup:

Option Used	Result
--exclude-databases=db1	All tables in all databases except db1 are restored; no tables in db1 are restored
--exclude-databases=db1,db2 (or --exclude-databases=db1 --exclude-databases=db2)	All tables in all databases except db1 and db2 are restored; no tables in db1 or db2 are restored
--exclude-tables=db1.t1	All tables except t1 in database db1 are restored; all other tables in db1 are restored; all tables in all other databases are restored
--exclude-tables=db1.t2,db2.t1 (or --exclude-tables=db1.t2 --exclude-tables=db2.t1)	All tables in database db1 except for t2 and all tables in database db2 except for table t1 are restored; no other tables in db1 or db2 are restored; all tables in all other databases are restored

Beginning with MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, you can use these two options together. For example, the following causes all tables in all databases *except for* databases db1 and db2, along with the tables t1 and t2 in database db3, *not* to be restored:

```
shell> ndb_restore [...] --exclude-databases=db1,db2 --exclude-tables=db3.t1,db3.t2
```

(Again, we have omitted other possibly necessary options in the interest of clarity and brevity from the example just shown.)

Note

Prior to MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, multiple --exclude-* options were not handled correctly, with the result that the

options shown in the previous example caused ndb_restore to exclude only the tables db3.t1 and db3.t2. (Bug #48907)

Beginning with MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, you can use --include-* and --exclude-* options together, subject to the following rules:

- The actions of all --include-* and --exclude-* options are cumulative.
- All --include-* and --exclude-* options are evaluated in the order passed to ndb_restore, from right to left.
- In the event of conflicting options, the first (rightmost) option takes precedence. In other words, the first option (going from right to left) that matches against a given database or table "wins".

For example, the following set of options causes ndb_restore to restore all tables from database db1 except db1.t1, while restoring no other tables from any other databases:

```
--include-databases=db1 --exclude-tables=db1.t1
```

However, reversing the order of the options just given simply causes all tables from database db1 to be restored (including db1.t1, but no tables from any other database), because the --include-databases [1999] option, being farthest to the right, is the first match against database db1 and thus takes precedence over any other option that matches db1 or any tables in db1:

```
--exclude-tables=db1.t1 --include-databases=db1
```

Note

Prior to MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, it was not possible to use --include-databases or --include-tables together with --exclude-databases or --exclude-tables, as these combinations were evaluated inconsistently. (Bug #48907)

--exclude-missing-columns

Version Introduced	5.1.35-ndb-7.0.7
Command-Line Format	--exclude-missing-columns

Beginning with MySQL Cluster NDB 6.3.26 and MySQL Cluster NDB 7.0.7, it is also possible to restore only selected table columns using the --exclude-missing-columns option. When this option is used, ndb_restore ignores any columns missing from tables being restored as compared to the versions of those tables found in the backup. This option applies to all tables being restored. If you wish to apply this option only to selected tables or databases, you can use it in combination with one or more of the options described in the previous paragraph to do so, then restore data to the remaining tables using a complementary set of these options.

--disable-indexes

Version Introduced	5.1.41-ndb-7.1.2
Command-Line Format	--disable-indexes

Beginning with MySQL Cluster NDB 6.3.31, MySQL Cluster NDB 7.0.11, and MySQL CLuster NDB 7.1.2, you can use this option with ndb_restore to disable restoration of indexes during restoration of the data from a native NDB backup. Afterwards, you can restore indexes for all tables at once with multi-threaded building of indexes using --rebuild-indexes [2002], which should be faster than rebuilding indexes concurrently for very large tables.

--rebuild-indexes

Version Introduced	5.1.41-ndb-7.1.2

Command-Line Format	--rebuild-indexes

Beginning with MySQL Cluster NDB 6.3.31, MySQL Cluster NDB 7.0.11, and MySQL CLuster NDB 7.1.2, you can use this option with ndb_restore to cause multi-threaded rebuilding of the ordered indexes while restoring a native NDB backup.

--skip-broken-objects

Version Introduced	5.1.51-ndb-7.1.10
Command-Line Format	--skip-broken-objects

This option causes ndb_restore to ignore corrupt tables while reading a native NDB backup, and to continue restoring any remaining tables (that are not also corrupted). Currently, the --skip-broken-objects option works only in the case of missing blob parts tables.

This option was added in MySQL Cluster NDB 6.3.40, MySQL Cluster NDB 7.0.21, and MySQL CLuster NDB 7.1.10.

--skip-unknown-objects

Version Introduced	5.1.41-ndb-7.1.4
Command-Line Format	--skip-unknown-objects

This option causes ndb_restore to ignore any schema objects it does not recognize while reading a native NDB backup. This can be used for restoring a backup made from a cluster running MySQL Cluster NDB 7.0 to a cluster running MySQL Cluster NDB 6.3.

This option was added in MySQL Cluster NDB 6.3.34, MySQL Cluster NDB 7.0.15, and MySQL CLuster NDB 7.1.4.

--rewrite-database=*old_dbname*,*new_dbname*

Version Introduced	5.1.51-ndb-7.1.11	
Command-Line Format	--rewrite-database=olddb,newdb	
	Permitted Values	
	Type	string
	Default	none

This option makes it possible to restore to a database having a different name from that used in the backup. For example, if a backup is made of a database named products, you can restore the data it contains to a database named inventory, use this option as shown here (omitting any other options that might be required):

```
shell> ndb_restore --rewrite-database=product,inventory
```

The option can be employed multiple times in a single invocation of ndb_restore. Thus it is possible to restore simultaneously from a database named db1 to a database named db2 and from a database named db3 to one named db4 using --rewrite-database=db1,db2 --rewrite-database=db3,db4. Other ndb_restore options may be used between multiple occurrences of --rewrite-database.

In the event of conflicts between multiple --rewrite-database options, the last --rewrite-database option used, reading from left to right, is the one that takes effect. For example, if --rewrite-database=db1,db2 --rewrite-database=db1,db3 is used, only --rewrite-database=db1,db3 is honored, and --rewrite-database=db1,db2 is ignored. It is also possible to restore from multiple databases to a single database, so that --rewrite-database=db1,db3 --rewrite-database=db2,db3 restores all tables and data from databases db1 and db2 into database db3.

Important

When restoring from multiple backup databases into a single target database using `--rewrite-database`, no check is made for collisions between table or other object names, and the order in which rows are restored is not guaranteed. This means that it is possible in such cases for rows to be overwritten and updates to be lost.

This option was added in MySQL Cluster NDB 6.3.41, MySQL Cluster NDB 7.0.22, and MySQL Cluster NDB 7.1.11.

Error reporting.
`ndb_restore` reports both temporary and permanent errors. In the case of temporary errors, it may able to recover from them. Beginning with MySQL 5.1.12, it reports `Restore successful, but encountered temporary error, please look at configuration` in such cases.

Important

After using `ndb_restore` to initialize a MySQL Cluster for use in circular replication, binary logs on the SQL node acting as the replication slave are not automatically created, and you must cause them to be created manually. To cause the binary logs to be created, issue a `SHOW TABLES` statement on that SQL node before running `START SLAVE`. This is a known issue in MySQL Cluster.

ndb_select_all — Print Rows from an NDB Table

`ndb_select_all` prints all rows from an `NDB` table to `stdout`.

Usage

```
ndb_select_all -c connect_string tbl_name -d db_name [> file_name]
```

The following table includes options that are specific to the MySQL Cluster native backup restoration program `ndb_select_all`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_select_all`), see Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs.

Table 17.23. `ndb_select_all` Options and Variables: MySQL 5.1, MySQL Cluster NDB 6.3-7.1

Format	Description	Added / Removed
`--database=dbname [2005]`, `-d [2005]`	Name of the database in which the table is found	All MySQL 5.1 based releases
`--parallelism=# [2005]`, `-p [2005]`	Degree of parallelism	All MySQL 5.1 based releases
`--lock=# [2005]`, `-l [2005]`	Lock type	All MySQL 5.1 based releases
`--order=index [2005]`, `-o [2005]`	Sort resultset according to index whose name is supplied	All MySQL 5.1 based releases
`--descending [2005]`, `-z [2005]`	Sort resultset in descending order (requires order flag)	All MySQL 5.1 based releases
`--header [2005]`,	Print header (set to 0|FALSE to disable headers in output)	All MySQL 5.1 based releases

Format	Description	Added / Removed
-h [2005]		
--useHexFormat [2005], -x [2005]	Output numbers in hexadecimal format	All MySQL 5.1 based releases
--delimiter=char [2006], -D [2006]	Set a column delimiter	All MySQL 5.1 based releases
--disk [2006]	Print disk references (useful only for Disk Data tables having nonindexed columns)	All MySQL 5.1 based releases
--rowid [2006]	Print rowid	All MySQL 5.1 based releases
--gci [2006]	Include GCI in output	All MySQL 5.1 based releases
--tup [2006], -t [2006]	Scan in tup order	All MySQL 5.1 based releases
--nodata [2006]	Do not print table column data	All MySQL 5.1 based releases

- --database=*dbname*, -d *dbname*

  Name of the database in which the table is found. The default value is TEST_DB.

- parallelism=#, -p #

  Specifies the degree of parallelism.

- --lock=*lock_type*, -l *lock_type*

  Employs a lock when reading the table. Possible values for *lock_type* are:

  - 0: Read lock
  - 1: Read lock with hold
  - 2: Exclusive read lock

  There is no default value for this option.

- --order=*index_name*, -o *index_name*

  Orders the output according to the index named *index_name*. Note that this is the name of an index, not of a column, and that the index must have been explicitly named when created.

- --descending, -z

  Sorts the output in descending order. This option can be used only in conjunction with the -o (--order [2005]) option.

- --header=FALSE

  Excludes column headers from the output.

- --useHexFormat -x

  Causes all numeric values to be displayed in hexadecimal format. This does not affect the output of numerals contained in strings or datetime values.

- `--delimiter=character`, `-D character`

  Causes the *`character`* to be used as a column delimiter. Only table data columns are separated by this delimiter.

  The default delimiter is the tab character.

- `--disk`

  Adds a disk reference column to the output. The column is nonempty only for Disk Data tables having nonindexed columns.

- `--rowid`

  Adds a `ROWID` column providing information about the fragments in which rows are stored.

- `--gci`

  Adds a column to the output showing the global checkpoint at which each row was last updated. See MySQL Cluster Overview, and MySQL Cluster Log Events, for more information about checkpoints.

- `--tupscan`, `-t`

  Scan the table in the order of the tuples.

- `--nodata`

  Causes any table data to be omitted.

Sample Output

Output from a MySQL `SELECT` statement:

```
mysql> SELECT * FROM ctest1.fish;
+----+-----------+
| id | name      |
+----+-----------+
|  3 | shark     |
|  6 | puffer    |
|  2 | tuna      |
|  4 | manta ray |
|  5 | grouper   |
|  1 | guppy     |
+----+-----------+
6 rows in set (0.04 sec)
```

Output from the equivalent invocation of `ndb_select_all`:

```
shell> ./ndb_select_all -c localhost fish -d ctest1
id      name
3       [shark]
6       [puffer]
2       [tuna]
4       [manta ray]
5       [grouper]
1       [guppy]
6 rows returned

NDBT_ProgramExit: 0 - OK
```

Note that all string values are enclosed by square brackets (“`[...]`”) in the output of `ndb_select_all`. For a further example, consider the table created and populated as shown here:

```
CREATE TABLE dogs (
    id INT(11) NOT NULL AUTO_INCREMENT,
    name VARCHAR(25) NOT NULL,
    breed VARCHAR(50) NOT NULL,
    PRIMARY KEY pk (id),
```

```
    KEY ix (name)
)
TABLESPACE ts STORAGE DISK
ENGINE=NDBCLUSTER;

INSERT INTO dogs VALUES
    ('', 'Lassie', 'collie'),
    ('', 'Scooby-Doo', 'Great Dane'),
    ('', 'Rin-Tin-Tin', 'Alsatian'),
    ('', 'Rosscoe', 'Mutt');
```

This demonstrates the use of several additional `ndb_select_all` options:

```
shell> ./ndb_select_all -d ctest1 dogs -o ix -z --gci --disk
GCI     id name          breed        DISK_REF
834461  2  [Scooby-Doo]  [Great Dane] [ m_file_no: 0 m_page: 98 m_page_idx: 0 ]
834878  4  [Rosscoe]     [Mutt]       [ m_file_no: 0 m_page: 98 m_page_idx: 16 ]
834463  3  [Rin-Tin-Tin] [Alsatian]   [ m_file_no: 0 m_page: 34 m_page_idx: 0 ]
835657  1  [Lassie]      [Collie]     [ m_file_no: 0 m_page: 66 m_page_idx: 0 ]
4 rows returned

NDBT_ProgramExit: 0 - OK
```

Note

In earlier MySQL Cluster NDB 7.0 and 7.1 releases, `ndb_select_all` did not print any output for `NULL` values as it did in MySQL Cluster NDB 6.3 and earlier release series. This issue was fixed in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. (Bug #60045)

ndb_select_count — Print Row Counts for NDB Tables

`ndb_select_count` prints the number of rows in one or more `NDB` tables. With a single table, the result is equivalent to that obtained by using the MySQL statement `SELECT COUNT(*) FROM tbl_name`.

Usage

```
ndb_select_count [-c connect_string] -ddb_name tbl_name[, tbl_name2[, ...]]
```

The following table includes options that are specific to the MySQL Cluster native backup restoration program `ndb_select_count`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_select_count`), see Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs.

Table 17.24. `ndb_select_count` Options and Variables: MySQL 5.1, MySQL Cluster NDB 6.3-7.1

Format	Description	Added / Removed
`--database=dbname`, `-d`	Name of the database in which the table is found	All MySQL 5.1 based releases
`--parallelism=#`, `-p`	Degree of parallelism	All MySQL 5.1 based releases
`--lock=#`, `-l`	Lock type	All MySQL 5.1 based releases

You can obtain row counts from multiple tables in the same database by listing the table names separated by spaces when invoking this command, as shown under **Sample Output**.

Sample Output

```
shell> ./ndb_select_count -c localhost -d ctest1 fish dogs
6 records in table fish
```

```
4 records in table dogs

NDBT_ProgramExit: 0 - OK
```

ndb_show_tables — Display List of NDB Tables

ndb_show_tables displays a list of all NDB database objects in the cluster. By default, this includes not only both user-created tables and NDB system tables, but NDB-specific indexes, internal triggers, and MySQL Cluster Disk Data objects as well.

The following table includes options that are specific to the MySQL Cluster native backup restoration program ndb_show_tables. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including ndb_show_tables), see Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs.

Table 17.25. ndb_show_tables Options and Variables: MySQL 5.1, MySQL Cluster NDB 6.3-7.1

Format	Description	Added / Removed
--database=string [2008], -d [2008]	Specifies the database in which the table is found	All MySQL 5.1 based releases
--loops=# [2008], -l [2008]	Number of times to repeat output	All MySQL 5.1 based releases
--type=# [2008], -t [2008]	Limit output to objects of this type	All MySQL 5.1 based releases
--unqualified [2009], -u [2009]	Do not qualify table names	All MySQL 5.1 based releases
--parsable [2008], -p [2008]	Return output suitable for MySQL LOAD DATA INFILE statement	All MySQL 5.1 based releases
--show-temp-status [2008]	Show table temporary flag	All MySQL 5.1 based releases

Usage

```
ndb_show_tables [-c connect_string]
```

- --database, -d

  Specifies the name of the database in which the tables are found.

- --loops, -l

  Specifies the number of times the utility should execute. This is 1 when this option is not specified, but if you do use the option, you must supply an integer argument for it.

- --parsable, -p

  Using this option causes the output to be in a format suitable for use with LOAD DATA INFILE.

- --show-temp-status

  If specified, this causes temporary tables to be displayed.

- --type, -t

  Can be used to restrict the output to one type of object, specified by an integer type code as shown here:

- 1: System table
- 2: User-created table
- 3: Unique hash index

Any other value causes all NDB database objects to be listed (the default).

- --unqualified, -u

If specified, this causes unqualified object names to be displayed.

Note

Only user-created MySQL Cluster tables may be accessed from MySQL; system tables such as SYSTAB_0 are not visible to mysqld. However, you can examine the contents of system tables using NDB API applications such as ndb_select_all (see ndb_select_all — Print Rows from an NDB Table).

ndb_size.pl — NDBCLUSTER Size Requirement Estimator

This is a Perl script that can be used to estimate the amount of space that would be required by a MySQL database if it were converted to use the NDBCLUSTER storage engine. Unlike the other utilities discussed in this section, it does not require access to a MySQL Cluster (in fact, there is no reason for it to do so). However, it does need to access the MySQL server on which the database to be tested resides.

Requirements

- A running MySQL server. The server instance does not have to provide support for MySQL Cluster.
- A working installation of Perl.
- The DBI module, which can be obtained from CPAN if it is not already part of your Perl installation. (Many Linux and other operating system distributions provide their own packages for this library.)
- Previous to MySQL 5.1.18, ndb_size.pl also required the HTML::Template module and an associated template file share/mysql/ndb_size.tmpl. Beginning with MySQL 5.1.18, ndb_size.tmpl is no longer needed (or included).
- A MySQL user account having the necessary privileges. If you do not wish to use an existing account, then creating one using GRANT USAGE ON *db_name*.*—where *db_name* is the name of the database to be examined—is sufficient for this purpose.

ndb_size.pl can also be found in the MySQL sources in storage/ndb/tools.

The following table includes options that are specific to the MySQL Cluster program ndb_size.pl. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including ndb_size.pl), see Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs.

Table 17.26. ndb_size.pl Options and Variables: MySQL 5.1, MySQL Cluster NDB 6.3-7.1

Format	Description	Added / Removed
--database=dbname [2010]	The database or databases to examine; accepts a comma-delimited list; the default is ALL (use all databases found on the server)	All MySQL 5.1 based releases

Format	Description	Added / Removed
--hostname[:port] [2010]	Specify host and optional port as host[:port]	All MySQL 5.1 based releases
--socket=file [2010]	Specify a socket to connect to	ADDED: NDB 6.2.5
--user=string [2010]	Specify a MySQL user name	All MySQL 5.1 based releases
--password=string [2010]	Specify a MySQL user password	All MySQL 5.1 based releases
--format=string [2011]	Set output format (text or HTML)	All MySQL 5.1 based releases
--excludetables=tbl_list [2010]	Skip any tables in a comma-separated list of tables	All MySQL 5.1 based releases
--excludedbs=db_list [2010]	Skip any databases in a comma-separated list of databases	All MySQL 5.1 based releases
--savequeries=file [2011]	Saves all queries to the database into the file specified	All MySQL 5.1 based releases
--loadqueries=file [2011]	Loads all queries from the file specified; does not connect to a database	All MySQL 5.1 based releases
--real_table_name=table [2010]	Designates a table to handle unique index size calculations	ADDED: NDB 6.2.5

Usage

```
perl ndb_size.pl [--database={db_name|ALL}] [--hostname=host[:port]] [--socket=socket] \
      [--user=user] [--password=password]  \
      [--help|-h] [--format={html|text}] \
      [--loadqueries=file_name] [--savequeries=file_name]
```

By default, this utility attempts to analyze all databases on the server. You can specify a single database using the `--database` option; the default behavior can be made explicit by using `ALL` for the name of the database. You can also exclude one or more databases by using the `--excludedbs` option with a comma-separated list of the names of the databases to be skipped. Similarly, you can cause specific tables to be skipped by listing their names, separated by commas, following the optional `--excludetables` option. A host name (and possibly a port as well) can be specified using `--hostname`; the default is `localhost`. Beginning with MySQL Cluster NDB 6.3.49, MySQL Cluster NDB 7.0.32, and MySQL Cluster NDB 7.1.21, you can specify a port in addition to the host using *`host`*:*`port`* format for the value of `--hostname`. The default port number is 3306. If necessary, you can also specify a socket; the default is `/var/lib/mysql.sock`. A MySQL user name and password can be specified the corresponding options shown. It also possible to control the format of the output using the `--format` option; this can take either of the values `html` or `text`, with `text` being the default. An example of the text output is shown here:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock
ndb_size.pl report for database: 'test' (1 tables)
----------------------------------------------------
Connected to: DBI:mysql:host=localhost;mysql_socket=/tmp/mysql.sock

Including information for versions: 4.1, 5.0, 5.1

test.t1
-------

DataMemory for Columns (* means varsized DataMemory):
         Column Name            Type  Varsized   Key  4.1  5.0   5.1

   Varsize Columns DM/Row                         0    0     4

DataMemory for Indexes:
   Index Name                Type        4.1        5.0        5.1
      PRIMARY               BTREE         16         16         16
                                          --         --         --
       Total Index DM/Row                 16         16         16

IndexMemory for Indexes:
               Index Name        4.1        5.0        5.1
                  PRIMARY         33         16         16
                                  --         --         --
           Indexes IM/Row         33         16         16

Summary (for THIS table):
                                 4.1        5.0        5.1
    Fixed Overhead DM/Row         12         12         16
           NULL Bytes/Row          4          4          4
           DataMemory/Row         96         96         48
                    (Includes overhead, bitmap and indexes)

  Varsize Overhead DM/Row          0          0          8
   Varsize NULL Bytes/Row          0          0          4
       Avg Varside DM/Row          0          0         16

                 No. Rows          0          0          0

        Rows/32kb DM Page        340        340        680
Fixedsize DataMemory (KB)          0          0          0

Rows/32kb Varsize DM Page          0          0       2040
  Varsize DataMemory (KB)          0          0          0

         Rows/8kb IM Page        248        512        512
         IndexMemory (KB)          0          0          0

Parameter Minimum Requirements
------------------------------
* indicates greater than default

               Parameter     Default        4.1         5.0         5.1
          DataMemory (KB)       81920          0           0           0
       NoOfOrderedIndexes         128          1           1           1
                NoOfTables         128          1           1           1
         IndexMemory (KB)       18432          0           0           0
    NoOfUniqueHashIndexes          64          0           0           0
           NoOfAttributes        1000          3           3           3
             NoOfTriggers         768          5           5           5
```

For debugging purposes, the Perl arrays containing the queries run by this script can be read from the file specified using can be saved to a file using `--savequeries`; a file containing such arrays to be read in during script execution can be specified using `--loadqueries`. Neither of these options has a default value.

To produce output in HTML format, use the `--format` option and redirect the output to a file, as shown here:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock --format=html > ndb_size.html
```

(Without the redirection, the output is sent to `stdout`.)

The output from this script includes the following information:

- Minimum values for the `DataMemory` [1817], `IndexMemory` [1819], `MaxNoOfTables` [1829], `MaxNoOfAttributes` [1828], `MaxNoOfOrderedIndexes` [1829], `MaxNoOfUniqueHashIndexes` [1830], and `MaxNoOfTriggers` [1830] configuration parameters required to accommodate the tables analyzed.

- Memory requirements for all of the tables, attributes, ordered indexes, and unique hash indexes defined in the database.
- The IndexMemory [1819] and DataMemory [1817] required per table and table row.

Note

Prior to MySQL 5.1.23, MySQL Cluster NDB 6.2.5, and MySQL Cluster NDB 6.3.7, ndb_size.pl was invoked as shown here:

```
perl ndb_size.pl db_name hostname username password > file_name.html
```

For more information about this change, see Bug #28683 and Bug #28253.

ndb_waiter — Wait for MySQL Cluster to Reach a Given Status

ndb_waiter repeatedly (each 100 milliseconds) prints out the status of all cluster data nodes until either the cluster reaches a given status or the --timeout [2013] limit is exceeded, then exits. By default, it waits for the cluster to achieve STARTED status, in which all nodes have started and connected to the cluster. This can be overridden using the --no-contact [2013] and --not-started [2013] options.

The node states reported by this utility are as follows:

- NO_CONTACT: The node cannot be contacted.
- UNKNOWN: The node can be contacted, but its status is not yet known. Usually, this means that the node has received a START or RESTART command from the management server, but has not yet acted on it.
- NOT_STARTED: The node has stopped, but remains in contact with the cluster. This is seen when restarting the node using the management client's RESTART command.
- STARTING: The node's ndbd process has started, but the node has not yet joined the cluster.
- STARTED: The node is operational, and has joined the cluster.
- SHUTTING_DOWN: The node is shutting down.
- SINGLE USER MODE: This is shown for all cluster data nodes when the cluster is in single user mode.

The following table includes options that are specific to the MySQL Cluster native backup restoration program ndb_waiter. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including ndb_waiter), see Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs.

Table 17.27. ndb_waiter Options and Variables: MySQL 5.1, MySQL Cluster NDB 6.3-7.1

Format	Description	Added / Removed
--no-contact [2013], -n [2013]	Wait for cluster to reach NO CONTACT state	All MySQL 5.1 based releases
--not-started [2013]	Wait for cluster to reach NOT STARTED state	All MySQL 5.1 based releases
--single-user [2013]	Wait for cluster to enter single user mode	All MySQL 5.1 based releases
--timeout=# [2013], -t [2013]	Wait this many seconds, then exit whether or not cluster has reached desired state; default is 2 minutes (120 seconds)	All MySQL 5.1 based releases

Format	Description	Added / Removed
--nowait-nodes=list [2013]	List of nodes not to be waited for.	ADDED: NDB 6.2.1
--wait-nodes=list [2013], -w [2013]	List of nodes to be waited for.	ADDED: NDB 6.3.34, NDB 7.0.15, NDB 7.1.4

Usage

```
ndb_waiter [-c connect_string]
```

Additional Options

- --no-contact, -n

  Instead of waiting for the STARTED state, ndb_waiter continues running until the cluster reaches NO_CONTACT status before exiting.

- --not-started

  Instead of waiting for the STARTED state, ndb_waiter continues running until the cluster reaches NOT_STARTED status before exiting.

- --timeout=*seconds*, -t *seconds*

  Time to wait. The program exits if the desired state is not achieved within this number of seconds. The default is 120 seconds (1200 reporting cycles).

- --single-user

  The program waits for the cluster to enter single user mode.

- --nowait-nodes=*list*

  When this option is used, ndb_waiter does not wait for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

  ```
  shell> ndb_waiter --nowait-nodes=1,3,7-9
  ```

  Important

  Do *not* use this option together with the --wait-nodes [2013] option.

  This option was added in MySQL Cluster NDB 6.2.1.

- --wait-nodes=*list*, -w *list*

  When this option is used, ndb_waiter waits only for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

  ```
  shell> ndb_waiter --wait-nodes=2,4-6,10
  ```

  Important

  Do *not* use this option together with the --nowait-nodes [2013] option.

  This option was added in MySQL Cluster NDB 6.3.34, 7.0.15, and 7.1.4.

Sample Output. Shown here is the output from ndb_waiter when run against a 4-node cluster in which two nodes have been shut down and then started again manually. Duplicate reports (indicated by "...") are omitted.

```
shell> ./ndb_waiter -c localhost

Connecting to mgmsrv at (localhost)
State node 1 STARTED
State node 2 NO_CONTACT
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 UNKNOWN
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 UNKNOWN
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTED
Waiting for cluster enter state STARTED

NDBT_ProgramExit: 0 - OK
```

Note

If no connectstring is specified, then `ndb_waiter` tries to connect to a management on `localhost`, and reports `Connecting to mgmsrv at (null)`.

Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs

All MySQL Cluster programs accept the options described in this section, with the following exceptions:

- mysqld
- ndb_print_backup_file
- ndb_print_schema_file
- ndb_print_sys_file

Users of earlier MySQL Cluster versions should note that some of these options have been changed to make them consistent with one another as well as with mysqld. You can use the --help option with any MySQL Cluster program—with the exception of ndb_print_backup_file, ndb_print_schema_file, and ndb_print_sys_file—to view a list of the options which the program supports.

The options in the following table are common to all MySQL Cluster executables (except those noted previously in this section).

Table 17.28. Common MySQL Cluster Program Options and Variables: MySQL 5.1, MySQL Cluster NDB 6.3-7.1

Format	Description	Added / Removed
--help [2016], --usage [2016], -? [2016]	Display help message and exit	All MySQL 5.1 based releases
--ndb-connectstring=connectstring [2016], --connect-string=connectstring [2016], -c [2016]	Set connectstring for connecting to ndb_mgmd. Syntax: [nodeid=<id>;] [host=]<hostname>[:<port>]. Overrides entries specified in NDB_CONNECTSTRING or my.cnf.	All MySQL 5.1 based releases
--ndb-mgmd-host=host[:port] [2017]	Set the host (and port, if desired) for connecting to the management server	All MySQL 5.1 based releases
--ndb-nodeid=# [2017]	Set node id for this node	All MySQL 5.1 based releases
--ndb-shm [2017]	Allow for optimization using shared memory connections where available (was EXPERIMENTAL, later REMOVED)	REMOVED: NDB 7.0.16, NDB 7.1.5
--ndb-optimized-node-selection [2017]	Select nodes for transactions in a more optimal way	All MySQL 5.1 based releases
--character-sets-dir=path [2016]	Directory where character sets are	All MySQL 5.1 based releases
--debug=options [2016]	Enable output from debug calls. Can be used only for versions compiled with debugging enabled	All MySQL 5.1 based releases
--core-file [2016]	Write core on errors (defaults to TRUE in debug builds)	All MySQL 5.1 based releases
--version [2017], -V [2017]	Output version information and exit	All MySQL 5.1 based releases

For options specific to individual MySQL Cluster programs, see MySQL Cluster Programs.

See MySQL Server Options for MySQL Cluster, for `mysqld` options relating to MySQL Cluster.

- `--help`, `--usage`, `-?`

Command-Line Format	`--help`	
	`--usage`	
	`-?`	

Prints a short list with descriptions of the available command options.

- `--character-sets-dir=`*`name`*

Command-Line Format	`--character-sets-dir=path`	
	Permitted Values	
	Type	`file name`
	Default	

Tells the program where to find character set information.

- `--ndb-connectstring=`*`connect_string`*, `--connect-string=`*`connect_string`*, `-c` *`connect_string`*

Command-Line Format	`--ndb-connectstring=connectstring`	
	`--connect-string=connectstring`	
	`-c`	
	Permitted Values	
	Type	`string`
	Default	`localhost:1186`

This option takes a MySQL Cluster connectstring that specifies the management server for the application to connect to, as shown here:

```
shell> ndbd --ndb-connectstring="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

For more information, see The MySQL Cluster Connectstring.

- `--core-file`

Command-Line Format	`--core-file`	
	Permitted Values	
	Type	`boolean`
	Default	`FALSE`

Write a core file if the program dies. The name and location of the core file are system-dependent. (For MySQL Cluster programs nodes running on Linux, the default location is the program's working directory—for a data node, this is the node's `DataDir` [1816].) For some systems, there may be restrictions or limitations; for example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation for detailed information.

If MySQL Cluster was built using the `--debug` option for `configure`, then `--core-file` is enabled by default. For regular builds, `--core-file` is disabled by default.

- `--debug[=`*`options`*`]`

Command-Line Format	`--debug=options`

	Permitted Values	
	Type	`string`
	Default	`d:t:O,/tmp/ndb_restore.trace`

This option can be used only for versions compiled with debugging enabled. It is used to enable output from debug calls in the same manner as for the `mysqld` process.

- `--ndb-mgmd-host=host[:port]`

Command-Line Format	`--ndb-mgmd-host=host[:port]`	
Option-File Format	`ndb-mgmd-host`	
	Permitted Values	
	Type	`string`
	Default	`localhost:1186`

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` [2016] option instead.

- `--ndb-nodeid=#`

Command-Line Format	`--ndb-nodeid=#`	
	Permitted Values	
	Type	`numeric`
	Default	`0`

Sets this node's MySQL Cluster node ID. *The range of permitted values depends on the node's type (data, management, or API) and the MySQL Cluster software version*. See Limits and Differences of MySQL Cluster from Standard MySQL Limits, for more information.

- `--ndb-optimized-node-selection`

Command-Line Format	`--ndb-optimized-node-selection`	
	Permitted Values	
	Type	`boolean`
	Default	`TRUE`

Optimize selection of nodes for transactions. Enabled by default.

- `--version`, `-V`

Command-Line Format	`--version`
	`-V`

Prints the MySQL Cluster version number of the executable. The version number is relevant because not all versions can be used together, and the MySQL Cluster startup process verifies that the versions of the binaries being used can co-exist in the same cluster. This is also important when performing an online (rolling) software upgrade or downgrade of MySQL Cluster.

See Performing a Rolling Restart of a MySQL Cluster), for more information.

- `--ndb-shm`

Version Removed	5.1.47-ndb-7.1.5

Command-Line Format	--ndb-shm	
	Permitted Values	
	Type	boolean
	Default	FALSE

In older versions of MySQL Cluster, this experimental option allowed the application to use shared memory for optimization when available. --ndb-shm was removed from all MySQL Cluster programs beginning with MySQL Cluster NDB 7.0.16 and MySQL Cluster 7.1.5.

Management of MySQL Cluster

Managing a MySQL Cluster involves a number of tasks, the first of which is to configure and start MySQL Cluster. This is covered in MySQL Cluster Configuration, and MySQL Cluster Programs.

The next few sections cover the management of a running MySQL Cluster.

For information about security issues relating to management and deployment of a MySQL Cluster, see MySQL Cluster Security Issues.

There are essentially two methods of actively managing a running MySQL Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be checked, log levels changed, backups started and stopped, and nodes stopped and started. The second method involves studying the contents of the cluster log ndb_*node_id*_cluster.log; this is usually found in the management server's DataDir [1812] directory, but this location can be overridden using the LogDestination [1810] option. (Recall that *node_id* represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by ndbd. It is also possible to send cluster log entries to a Unix system log.

Some aspects of the cluster's operation can be also be monitored from an SQL node using the SHOW ENGINE NDB STATUS statement.

In MySQL Cluster NDB 7.1.1 and later, detailed information about cluster operations is available in real time through an SQL interface using the ndbinfo database. For more information, see The ndbinfo MySQL Cluster Information Database.

Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, NDB statistics counters provide improved monitoring using the mysql client. These counters, implemented in the NDB kernel, relate to operations performed by or affecting Ndb objects, such as starting, closing, and aborting transactions; primary key and unique key operations; table, range, and pruned scans; blocked threads waiting for various operations to complete; and data and events sent and received by MySQL Cluster. The counters are incremented by the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes.

mysqld exposes the NDB API statistics counters as system status variables, which can be identified from the prefix common to all of their names (Ndb_api_). The values of these variables can be read in the mysql client from the output of a SHOW STATUS statement, or by querying either the SESSION_STATUS table or the GLOBAL_STATUS table (in the INFORMATION_SCHEMA database). By comparing the values of the status variables before and after the execution of an SQL statement that acts on NDB tables, you can observe the actions taken on the NDB API level that correspond to this statement, which can be beneficial for monitoring and performance tuning of MySQL Cluster.

MySQL Enterprise Monitor can also be used to monitor MySQL Servers that are part of a MySQL Cluster deployment. MySQL Enterprise Monitor 2.3, added a MySQL Cluster advisor, including a set of graphs providing information on MySQL Cluster resources, and defining rules for alerts on key information from data nodes such as DataMemory [1817] usage. This information is made available to MySQL Enterprise Monitor 2.3 or later by any MySQL Server which is connected to the MySQL Cluster, using ndbinfo. The advisor could be run against a single MySQL Server in the Cluster, or

against a pair in order to provide a higher level of availability for the monitoring service. For more information, see the *MySQL Enterprise Monitor 2.3 Manual*.

MySQL Cluster Manager provides an advanced command-line interface that simplifies many otherwise complex MySQL Cluster management tasks, such as starting, stopping, or restarting a MySQL Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as `mysqld` server options and variables relating to MySQL Cluster. MySQL Cluster Manager 1.1 provides support for adding data nodes online. See the *MySQL Cluster Manager 1.1 User Manual*, for more information.

Summary of MySQL Cluster Start Phases

This section provides a simplified outline of the steps involved when MySQL Cluster data nodes are started. More complete information can be found in MySQL Cluster Start Phases, in the *NDB Internals Guide*.

These phases are the same as those reported in the output from the *node_id* `STATUS` command in the management client (see Commands in the MySQL Cluster Management Client). In MySQL Cluster NDB 7.1.1 and later, these start phases are also reported in the `start_phase` column of the `ndbinfo.nodes` table.

Start types. There are several different startup types and modes, as shown in the following list:

- **Initial start.** The cluster starts with a clean file system on all data nodes. This occurs either when the cluster started for the very first time, or when all data nodes are restarted using the `--initial` [1954] option.

  Note

  Disk Data files are not removed when restarting a node using `--initial` [1954].

- **System restart.** The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster to resume operations from the point where it left off.

- **Node restart.** This is the online restart of a cluster node while the cluster itself is running.

- **Initial node restart.** This is the same as a node restart, except that the node is reinitialized and started with a clean file system.

Setup and initialization (phase -1). Prior to startup, each data node (`ndbd` process) must be initialized. Initialization consists of the following steps:

1. Obtain a node ID
2. Fetch configuration data
3. Allocate ports to be used for inter-node communications
4. Allocate memory according to settings obtained from the configuration file

When a data node or SQL node first connects to the management node, it reserves a cluster node ID. To make sure that no other node allocates the same node ID, this ID is retained until the node has managed to connect to the cluster and at least one `ndbd` reports that this node is connected. This retention of the node ID is guarded by the connection between the node in question and `ndb_mgmd`.

Normally, in the event of a problem with the node, the node disconnects from the management server, the socket used for the connection is closed, and the reserved node ID is freed. However, if a node is disconnected abruptly—for example, due to a hardware failure in one of the cluster hosts, or because of network issues—the normal closing of the socket by the operating system may not take place. In

this case, the node ID continues to be reserved and not released until a TCP timeout occurs 10 or so minutes later.

To take care of this problem, you can use `PURGE STALE SESSIONS`. Running this statement forces all reserved node IDs to be checked; any that are not being used by nodes actually connected to the cluster are then freed.

Beginning with MySQL 5.1.11, timeout handling of node ID assignments is implemented. This performs the ID usage checks automatically after approximately 20 seconds, so that `PURGE STALE SESSIONS` should no longer be necessary in a normal Cluster start.

After each data node has been initialized, the cluster startup process can proceed. The stages which the cluster goes through during this process are listed here:

- **Phase 0.** The `NDBFS` and `NDBCNTR` blocks start (see `NDB` Kernel Blocks). Data node file systems are cleared on those data nodes that were started with `--initial` [1954] option.
- **Phase 1.** In this stage, all remaining `NDB` kernel blocks are started. MySQL Cluster connections are set up, inter-block communications are established, and heartbeats are started. In the case of a node restart, API node connections are also checked.

  Note

  When one or more nodes hang in Phase 1 while the remaining node or nodes hang in Phase 2, this often indicates network problems. One possible cause of such issues is one or more cluster hosts having multiple network interfaces. Another common source of problems causing this condition is the blocking of TCP/IP ports needed for communications between cluster nodes. In the latter case, this is often due to a misconfigured firewall.
- **Phase 2.** The `NDBCNTR` kernel block checks the states of all existing nodes. The master node is chosen, and the cluster schema file is initialized.
- **Phase 3.** The `DBLQH` and `DBTC` kernel blocks set up communications between them. The startup type is determined; if this is a restart, the `DBDIH` block obtains permission to perform the restart.
- **Phase 4.** For an initial start or initial node restart, the redo log files are created. The number of these files is equal to `NoOfFragmentLogFiles` [1826].

  For a system restart:

  - Read schema or schemas.
  - Read data from the local checkpoint.
  - Apply all redo information until the latest restorable global checkpoint has been reached.

  For a node restart, find the tail of the redo log.
- **Phase 5.** Most of the database-related portion of a data node start is performed during this phase. For an initial start or system restart, a local checkpoint is executed, followed by a global checkpoint. Periodic checks of memory usage begin during this phase, and any required node takeovers are performed.
- **Phase 6.** In this phase, node groups are defined and set up.
- **Phase 7.** The arbitrator node is selected and begins to function. The next backup ID is set, as is the backup disk write speed. Nodes reaching this start phase are marked as `Started`. It is now possible for API nodes (including SQL nodes) to connect to the cluster.
- **Phase 8.** If this is a system restart, all indexes are rebuilt (by `DBDIH`).
- **Phase 9.** The node internal startup variables are reset.

- **Phase 100 (*OBSOLETE*).** Formerly, it was at this point during a node restart or initial node restart that API nodes could connect to the node and begin to receive events. Currently, this phase is empty.
- **Phase 101.** At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly-joined node takes over responsibility for delivering its primary data to subscribers. This phase is also referred to as *`SUMA` handover phase*.

After this process is completed for an initial start or system restart, transaction handling is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.

Commands in the MySQL Cluster Management Client

In addition to the central configuration file, a cluster may also be controlled through a command-line interface available through the management client `ndb_mgm`. This is the primary administrative interface to a running cluster.

Commands for the event logs are given in Event Reports Generated in MySQL Cluster; commands for creating backups and restoring from them are provided in Online Backup of MySQL Cluster.

The management client has the following basic commands. In the listing that follows, *`node_id`* denotes either a database node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- `HELP`

  Displays information on all available commands.

- `SHOW`

  Displays information on the cluster's status. Possible node status values include `UNKNOWN`, `NO_CONTACT`, `NOT_STARTED`, `STARTING`, `STARTED`, `SHUTTING_DOWN`, and `RESTARTING`.

  Beginning with MySQL Cluster NDB 6.2.8 and MySQL Cluster NDB 6.3.6, the output from this command indicates when the cluster is in single user mode (status `SINGLE USER MODE`).

  Prior to MySQL Cluster NDB 7.0.26 and MySQL Cluster NDB 7.1.5, in a cluster having multiple management nodes, this command displayed information only for data nodes that were actually connected to the current management server; in addition, management servers could not find each other until all nodes had been started. Beginning with these versions, such issues are fixed (see Bug #12352191), and management nodes can be additionally be reported with status `RESUME` or `CONNECTED`.

- *`node_id`* `START`

  Brings online the data node identified by *`node_id`* (or all data nodes).

  `ALL START` works on all data nodes only, and does not affect management nodes.

  Important

  To use this command to bring a data node online, the data node must have been started using `ndbd --nostart [1955]` or `ndbd -n`.

- *`node_id`* `STOP [-a] [-f]`

  Stops the data or management node identified by *`node_id`*. Note that `ALL STOP` works to stop all data nodes only, and does not affect management nodes.

  A node affected by this command disconnects from the cluster, and its associated `ndbd` or `ndb_mgmd` process terminates.

The `-a` option causes the node to be stopped immediately, without waiting for the completion of any pending transactions.

Normally, `STOP` fails if the result would cause an incomplete cluster. The `-f` option, added in MySQL Cluster NDB 7.0.19 and MySQL Cluster NDB 7.1.8, forces the node to shut down without checking for this. If this option is used and the result is an incomplete cluster, the cluster immediately shuts down.

Warning

Use of the `-a` option also disables the safety check otherwise performed when `STOP` is invoked to insure that stopping the node does not cause an incomplete cluster. In other words, you should exercise extreme care when using the `-a` option with the `STOP` command, due to the fact that this option makes it possible for the cluster to undergo a forced shutdown because it no longer has a complete copy of all data stored in `NDB`.

- *`node_id`* `RESTART [-n] [-i] [-a] [-f]`

  Restarts the data node identified by *`node_id`* (or all data nodes).

  Using the `-i` option with `RESTART` causes the data node to perform an initial restart; that is, the node's file system is deleted and recreated. The effect is the same as that obtained from stopping the data node process and then starting it again using `ndbd --initial [1954]` from the system shell. Note that backup files and Disk Data files are not removed when this option is used.

  Using the `-n` option causes the data node process to be restarted, but the data node is not actually brought online until the appropriate `START` command is issued. The effect of this option is the same as that obtained from stopping the data node and then starting it again using `ndbd --nostart [1955]` or `ndbd -n` from the system shell.

  Using the `-a` causes all current transactions relying on this node to be aborted. No GCP check is done when the node rejoins the cluster.

  Normally, `RESTART` fails if taking the node offline would result in an incomplete cluster. The `-f` option, added in MySQL Cluster NDB 7.0.19 and MySQL Cluster NDB 7.1.8, forces the node to restart without checking for this. If this option is used and the result is an incomplete cluster, the entire cluster is restarted.

- *`node_id`* `STATUS`

  Displays status information for the data node identified by *`node_id`* (or for all data nodes).

  Beginning with MySQL Cluster NDB 6.2.8 and MySQL Cluster NDB 6.3.6, the output from this command indicates when the cluster is in single user mode.

- *`node_id`* `REPORT` *`report-type`*

  Displays a report of type *`report-type`* for the data node identified by *`node_id`*, or for all data nodes using `ALL`.

  Currently, there are two accepted values for *`report-type`*:

  - `BackupStatus` provides a status report on a cluster backup in progress
  - `MemoryUsage` displays how much data memory and index memory is being used by each data node as shown in this example:

    ```
    ndb_mgm> ALL REPORT MEMORY

    Node 1: Data usage is 5%(177 32K pages of total 3200)
    ```

```
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
```

In MySQL Cluster NDB 7.1.1 and later, this information is also available from the `ndbinfo.memoryusage` table.

`report-type` is case-insensitive and “fuzzy”; for `MemoryUsage`, you can use `MEMORY` (as shown in the prior example), `memory`, or even simply `MEM` (or `mem`). You can abbreviate `BackupStatus` in a similar fashion.

The `REPORT` command was introduced in MySQL Cluster NDB 6.2.3 and MySQL Cluster NDB 6.3.0.

- `ENTER SINGLE USER MODE` *`node_id`*

  Enters single user mode, whereby only the MySQL server identified by the node ID *`node_id`* is permitted to access the database.

  Currently, it is not possible for data nodes to join a MySQL Cluster while it is running in single user mode. (Bug #20395)

- `EXIT SINGLE USER MODE`

  Exits single user mode, enabling all SQL nodes (that is, all running `mysqld` processes) to access the database.

  Note

  It is possible to use `EXIT SINGLE USER MODE` even when not in single user mode, although the command has no effect in this case.

- `QUIT`, `EXIT`

  Terminates the management client.

  This command does not affect any nodes connected to the cluster.

- `SHUTDOWN`

  Shuts down all cluster data nodes and management nodes. To exit the management client after this has been done, use `EXIT` or `QUIT`.

  This command does *not* shut down any SQL nodes or API nodes that are connected to the cluster.

- `CREATE NODEGROUP` *`nodeid`*`[, nodeid, ...]`

  Creates a new MySQL Cluster node group and causes data nodes to join it.

  This command is used after adding new data nodes online to a MySQL Cluster, and causes them to join a new node group and thus to begin participating fully in the cluster. The command takes as its sole parameter a comma-separated list of node IDs—these are the IDs of the nodes just added and started that are to join the new node group. The number of nodes must be the same as the number of nodes in each node group that is already part of the cluster (each MySQL Cluster node group must have the same number of nodes). In other words, if the MySQL Cluster has 2 node groups of 2 data nodes each, then the new node group must also have 2 data nodes.

  The node group ID of the new node group created by this command is determined automatically, and always the next highest unused node group ID in the cluster; it is not possible to set it manually.

  This command was introduced in MySQL Cluster NDB 6.4.0. For more information, see Adding MySQL Cluster Data Nodes Online.

- `DROP NODEGROUP` *`nodegroup_id`*

Drops the MySQL Cluster node group with the given *`nodegroup_id`*.

This command can be used to drop a node group from a MySQL Cluster. `DROP NODEGROUP` takes as its sole argument the node group ID of the node group to be dropped.

`DROP NODEGROUP` acts only to remove the data nodes in the effected node group from that node group. It does not stop data nodes, assign them to a different node group, or remove them from the cluster's configuration. A data node that does not belong to a node group is indicated in the output of the management client `SHOW` command with `no nodegroup` in place of the node group ID, like this (indicated using bold text):

```
id=3    @10.100.2.67  (5.1.63-ndb-7.1.25, no nodegroup)
```

Prior to MySQL Cluster NDB 7.0.4, the `SHOW` output was not updated correctly following `DROP NODEGROUP`. (Bug #43413)

`DROP NODEGROUP` works only when all data nodes in the node group to be dropped are completely empty of any table data and table definitions. Since there is currently no way using `ndb_mgm` or the `mysql` client to remove all data from a specific data node or node group, this means that the command succeeds only in the two following cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.
2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

   `TRUNCATE TABLE` does not work for this purpose because this removes only the table data; the data nodes continue to store an `NDBCLUSTER` table's definition until a `DROP TABLE` statement is issued that causes the table metadata to be dropped.

`DROP NODEGROUP` was introduced in MySQL Cluster NDB 6.4.0. For more information, see Adding MySQL Cluster Data Nodes Online.

Online Backup of MySQL Cluster

The next few sections describe how to prepare for and then to create a MySQL Cluster backup using the functionality for this purpose found in the `ndb_mgm` management client. To distinguish this type of backup from a backup made using `mysqldump`, we sometimes refer to it as a “native” MySQL Cluster backup. (For information about the creation of backups with `mysqldump`, see `mysqldump` — A Database Backup Program.) Restoration of MySQL Cluster backups is done using the `ndb_restore` utility provided with the MySQL Cluster distribution; for information about `ndb_restore` and its use in restoring MySQL Cluster backups, see `ndb_restore` — Restore a MySQL Cluster Backup.

MySQL Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

- **Metadata.** The names and definitions of all database tables
- **Table records.** The data actually stored in the database tables at the time that the backup was made
- **Transaction log.** A sequential record telling how and when data was stored in the database

Each of these parts is saved on all nodes participating in the backup. During backup, each node saves these three parts into three files on disk:

- `BACKUP-`*`backup_id`*`.`*`node_id`*`.ctl`

  A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

- `BACKUP-backup_id-0.node_id.data`

  A data file containing the table records, which are saved on a per-fragment basis. That is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states the tables to which the records belong. Following the list of records there is a footer containing a checksum for all records.

- `BACKUP-backup_id.node_id.log`

  A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records because different nodes host different database fragments.

In the listing above, *`backup_id`* stands for the backup identifier and *`node_id`* is the unique identifier for the node creating the file.

Using The MySQL Cluster Management Client to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See Configuration for MySQL Cluster Backups.)

The `START BACKUP` command is used to create a backup:

```
START BACKUP [backup_id] [wait_option] [snapshot_option]

wait_option:
WAIT {STARTED | COMPLETED} | NOWAIT

snapshot_option:
SNAPSHOTSTART | SNAPSHOTEND
```

Successive backups are automatically identified sequentially, so the *`backup_id`*, an integer greater than or equal to 1, is optional; if it is omitted, the next available value is used. If an existing *`backup_id`* value is used, the backup fails with the error `Backup failed: file already exists`. If used, the *`backup_id`* must follow `START BACKUP` immediately, before any other options are used.

Prior to MySQL Cluster NDB 6.2.17, 6.3.23, and 6.4.3, backup IDs greater than 2147483648 (2^{31}) were not supported correctly. (Bug #43042) Beginning with these versions, the maximum possible backup ID is 4294967296 (2^{32}).

Note

Prior to MySQL Cluster NDB 7.0.5, when starting a backup using `ndb_mgm -e "START BACKUP"`, the *`backup_id`* was required. (Bug #31754)

The *`wait_option`* can be used to determine when control is returned to the management client after a `START BACKUP` command is issued, as shown in the following list:

- If `NOWAIT` is specified, the management client displays a prompt immediately, as seen here:

  ```
  ndb_mgm> START BACKUP NOWAIT
  ndb_mgm>
  ```

  In this case, the management client can be used even while it prints progress information from the backup process.

- With `WAIT STARTED` the management client waits until the backup has started before returning control to the user, as shown here:

  ```
  ndb_mgm> START BACKUP WAIT STARTED
  Waiting for started, this may take several minutes
  Node 2: Backup 3 started from node 1
  ```

```
ndb_mgm>
```

- **WAIT COMPLETED** causes the management client to wait until the backup process is complete before returning control to the user.

WAIT COMPLETED is the default.

Beginning with MySQL Cluster NDB 6.4.0, a *snapshot_option* can be used to determine whether the backup matches the state of the cluster when START BACKUP was issued, or when it was completed. SNAPSHOTSTART causes the backup to match the state of the cluster when the backup began; SNAPSHOTEND causes the backup to reflect the state of the cluster when the backup was finished. SNAPSHOTEND is the default, and matches the behavior found in previous MySQL Cluster releases.

Note

If you use the SNAPSHOTSTART option with START BACKUP, and the CompressedBackup [1834] parameter is enabled, only the data and control files are compressed—the log file is not compressed.

If both a *wait_option* and a *snapshot_option* are used, they may be specified in either order. For example, all of the following commands are valid, assuming that there is no existing backup having 4 as its ID:

```
START BACKUP WAIT STARTED SNAPSHOTSTART
START BACKUP SNAPSHOTSTART WAIT STARTED
START BACKUP 4 WAIT COMPLETED SNAPSHOTSTART
START BACKUP SNAPSHOTEND WAIT COMPLETED
START BACKUP 4 NOWAIT SNAPSHOTSTART
```

The procedure for creating a backup consists of the following steps:

1. Start the management client (ndb_mgm), if it not running already.
2. Execute the **START BACKUP** command. This produces several lines of output indicating the progress of the backup, as shown here:

   ```
   ndb_mgm> START BACKUP
   Waiting for completed, this may take several minutes
   Node 2: Backup 1 started from node 1
   Node 2: Backup 1 started from node 1 completed
    StartGCP: 177 StopGCP: 180
    #Records: 7362 #LogRecords: 0
    Data: 453648 bytes Log: 0 bytes
   ndb_mgm>
   ```

3. When the backup has started the management client displays this message:

   ```
   Backup backup_id started from node node_id
   ```

   backup_id is the unique identifier for this particular backup. This identifier is saved in the cluster log, if it has not been configured otherwise. *node_id* is the identifier of the management server that is coordinating the backup with the data nodes. At this point in the backup process the cluster has received and processed the backup request. It does not mean that the backup has finished. An example of this statement is shown here:

   ```
   Node 2: Backup 1 started from node 1
   ```

4. The management client indicates with a message like this one that the backup has started:

   ```
   Backup backup_id started from node node_id completed
   ```

   As is the case for the notification that the backup has started, *backup_id* is the unique identifier for this particular backup, and *node_id* is the node ID of the management server that is coordinating the backup with the data nodes. This output is accompanied by additional information

including relevant global checkpoints, the number of records backed up, and the size of the data, as shown here:

```
Node 2: Backup 1 started from node 1 completed
 StartGCP: 177 StopGCP: 180
 #Records: 7362 #LogRecords: 0
 Data: 453648 bytes Log: 0 bytes
```

It is also possible to perform a backup from the system shell by invoking `ndb_mgm` with the `-e` or `--execute` [1970] option, as shown in this example:

```
shell> ndb_mgm -e "START BACKUP 6 WAIT COMPLETED SNAPSHOTSTART"
```

When using `START BACKUP` in this way, you must specify the backup ID.

Cluster backups are created by default in the `BACKUP` subdirectory of the `DataDir` [1816] on each data node. This can be overridden for one or more data nodes individually, or for all cluster data nodes in the `config.ini` file using the `BackupDataDir` [1816] configuration parameter. The backup files created for a backup with a given *`backup_id`* are stored in a subdirectory named `BACKUP-`*`backup_id`* in the backup directory.

To abort a backup that is already in progress:

1. Start the management client.
2. Execute this command:

   ```
   ndb_mgm> ABORT BACKUP backup_id
   ```

   The number *`backup_id`* is the identifier of the backup that was included in the response of the management client when the backup was started (in the message `Backup` *`backup_id`* `started from node` *`management_node_id`*).
3. The management client will acknowledge the abort request with `Abort of backup` *`backup_id`* `ordered`.

   Note

   At this point, the management client has not yet received a response from the cluster data nodes to this request, and the backup has not yet actually been aborted.
4. After the backup has been aborted, the management client will report this fact in a manner similar to what is shown here:

   ```
   Node 1: Backup 3 started from 5 has been aborted.
     Error: 1321 - Backup aborted by user request: Permanent error: User defined error
   Node 3: Backup 3 started from 5 has been aborted.
     Error: 1323 - 1323: Permanent error: Internal error
   Node 2: Backup 3 started from 5 has been aborted.
     Error: 1323 - 1323: Permanent error: Internal error
   Node 4: Backup 3 started from 5 has been aborted.
     Error: 1323 - 1323: Permanent error: Internal error
   ```

   In this example, we have shown sample output for a cluster with 4 data nodes, where the sequence number of the backup to be aborted is 3, and the management node to which the cluster management client is connected has the node ID 5. The first node to complete its part in aborting the backup reports that the reason for the abort was due to a request by the user. (The remaining nodes report that the backup was aborted due to an unspecified internal error.)

   Note

   There is no guarantee that the cluster nodes respond to an `ABORT BACKUP` command in any particular order.

The `Backup backup_id started from node management_node_id has been aborted` messages mean that the backup has been terminated and that all files relating to this backup have been removed from the cluster file system.

It is also possible to abort a backup in progress from a system shell using this command:

```
shell> ndb_mgm -e "ABORT BACKUP backup_id"
```

Note

If there is no backup having the ID *backup_id* running when an ABORT BACKUP is issued, the management client makes no response, nor is it indicated in the cluster log that an invalid abort command was sent.

Configuration for MySQL Cluster Backups

Five configuration parameters are essential for backup:

- BackupDataBufferSize [1850]

  The amount of memory used to buffer data before it is written to disk.

- BackupLogBufferSize [1850]

  The amount of memory used to buffer log records before these are written to disk.

- BackupMemory [1851]

  The total memory allocated in a data node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.

- BackupWriteSize [1851]

  The default size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

- BackupMaxWriteSize [1852]

  The maximum size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

More detailed information about these parameters can be found in Backup Parameters.

MySQL Cluster Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or disk space. You should check that there is enough memory allocated for the backup.

Important

If you have set BackupDataBufferSize [1850] and BackupLogBufferSize [1850] and their sum is greater than 4MB, then you must also set BackupMemory [1851] as well.

You should also make sure that there is sufficient space on the hard drive partition of the backup target.

NDB does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is “hot”, restoring a MySQL Cluster from backup is not a 100% “hot” process. This is due to the fact that, for the duration of the restore process, running transactions get

nonrepeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

MySQL Server Usage for MySQL Cluster

`mysqld` is the traditional MySQL server process. To be used with MySQL Cluster, `mysqld` needs to be built with support for the `NDBCLUSTER` storage engine, as it is in the precompiled binaries available from http://dev.mysql.com/downloads/. If you build MySQL from source, you must invoke `configure` with one of the options to enable `NDBCLUSTER` storage engine support:

- `--with-plugins=ndbcluster` [136]
- `--with-plugins=max` [136]
- `--with-plugins=max-no-innodb` [136]

(`--with-ndbcluster` also works to enable `NDBCLUSTER` support, but is deprecated and so produces a `configure` warning as of MySQL 5.1.9.)

For information about other MySQL server options and variables relevant to MySQL Cluster in addition to those discussed in this section, see MySQL Server Options and Variables for MySQL Cluster.

If the `mysqld` binary has been built with Cluster support, the `NDBCLUSTER` storage engine is still disabled by default. You can use either of two possible options to enable this engine:

- Use `--ndbcluster` [1915] as a startup option on the command line when starting `mysqld`.
- Insert a line containing `ndbcluster` in the `[mysqld]` section of your `my.cnf` file.

An easy way to verify that your server is running with the `NDBCLUSTER` storage engine enabled is to issue the `SHOW ENGINES` statement in the MySQL Monitor (`mysql`). You should see the value `YES` as the `Support` value in the row for `NDBCLUSTER`. If you see `NO` in this row or if there is no such row displayed in the output, you are not running an `NDB`-enabled version of MySQL. If you see `DISABLED` in this row, you need to enable it in either one of the two ways just described.

To read cluster configuration data, the MySQL server requires at a minimum three pieces of information:

- The MySQL server's own cluster node ID
- The host name or IP address for the management server (MGM node)
- The number of the TCP/IP port on which it can connect to the management server

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The `mysqld` parameter `ndb-connectstring` is used to specify the connectstring either on the command line when starting `mysqld` or in `my.cnf`. The connectstring contains the host name or IP address where the management server can be found, as well as the TCP/IP port it uses.

In the following example, `ndb_mgmd.mysql.com` is the host where the management server resides, and the management server listens for cluster messages on port 1186:

```
shell> mysqld --ndbcluster --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See The MySQL Cluster Connectstring, for more information on connectstrings.

Given this information, the MySQL server will be a full participant in the cluster. (We often refer to a `mysqld` process running in this manner as an SQL node.) It will be fully aware of all cluster data nodes as well as their status, and will establish connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to read and update node data.

You can see in the `mysql` client whether a MySQL server is connected to the cluster using `SHOW PROCESSLIST`. If the MySQL server is connected to the cluster, and you have the `PROCESS` [627] privilege, then the first row of the output is as shown here:

```
mysql> SHOW PROCESSLIST \G
*************************** 1. row ***************************
     Id: 1
   User: system user
   Host:
     db:
Command: Daemon
   Time: 1
  State: Waiting for event from ndbcluster
   Info: NULL
```

Important

To participate in a MySQL Cluster, the `mysqld` process must be started with *both* the options `--ndbcluster` [1915] and `--ndb-connectstring` [1914] (or their equivalents in `my.cnf`). If `mysqld` is started with only the `--ndbcluster` [1915] option, or if it is unable to contact the cluster, it is not possible to work with `NDB` tables, *nor is it possible to create any new tables regardless of storage engine*. The latter restriction is a safety measure intended to prevent the creation of tables having the same names as `NDB` tables while the SQL node is not connected to the cluster. If you wish to create tables using a different storage engine while the `mysqld` process is not participating in a MySQL Cluster, you must restart the server *without* the `--ndbcluster` [1915] option.

Performing a Rolling Restart of a MySQL Cluster

This section discusses how to perform a *rolling restart* of a MySQL Cluster installation, so called because it involves stopping and starting (or restarting) each node in turn, so that the cluster itself remains operational. This is often done as part of a *rolling upgrade* or *rolling downgrade*, where high availability of the cluster is mandatory and no downtime of the cluster as a whole is permissible. Where we refer to upgrades, the information provided here also generally applies to downgrades as well.

There are a number of reasons why a rolling restart might be desirable. These are described in the next few paragraphs.

Configuration change.
To make a change in the cluster's configuration, such as adding an SQL node to the cluster, or setting a configuration parameter to a new value.

MySQL Cluster software upgrade or downgrade. To upgrade the cluster to a newer version of the MySQL Cluster software (or to downgrade it to an older version). This is usually referred to as a “rolling upgrade” (or “rolling downgrade”, when reverting to an older version of MySQL Cluster).

Change on node host. To make changes in the hardware or operating system on which one or more MySQL Cluster node processes are running.

System reset (cluster reset).
To reset the cluster because it has reached an undesirable state. In such cases it is often desirable to reload the data and metadata of one or more data nodes. This can be done in any of three ways:

- Start each data node process (`ndbd`, or possibly `ndbmtd` in MySQL Cluster NDB 7.0 and later) with the `--initial` [1954] option, which forces the data node to clear its file system and to reload all MySQL Cluster data and metadata from the other data nodes.
- Create a backup using the `ndb_mgm` client `BACKUP` command prior to performing the restart. Following the upgrade, restore the node or nodes using `ndb_restore`.

See Online Backup of MySQL Cluster, and `ndb_restore` — Restore a MySQL Cluster Backup, for more information.

- Use `mysqldump` to create a backup prior to the upgrade; afterward, restore the dump using `LOAD DATA INFILE`.

Resource Recovery.
To free memory previously allocated to a table by successive `INSERT` and `DELETE` operations, for re-use by other MySQL Cluster tables.

The process for performing a rolling restart may be generalized as follows:

1. Stop all cluster management nodes (`ndb_mgmd` processes), reconfigure them, then restart them.

   (If there are multiple management servers and you are using MySQL Cluster NDB 7.0.8 or later, see Rolling restarts with multiple management servers (MySQL Cluster NDB 7.0.8 and later).)

2. Stop, reconfigure, then restart each cluster data node (`ndbd` process) in turn.

3. Stop, reconfigure, then restart each cluster SQL node (`mysqld` process) in turn.

The specifics for implementing a given rolling upgrade depend upon the changes being made. A more detailed view of the process is presented here:

<table>
<tr><th colspan="6">RESTART TYPE:</th></tr>
<tr><th>Cluster Configuration Change</th><th>Cluster Software Upgrade or Downgrade</th><th>Change on Node Host</th><th colspan="3">Cluster Reset</th></tr>
<tr><td colspan="6">A. Management node (<code>ndb_mgmd</code>) processes...</td></tr>
<tr><td rowspan="2">1. Stop all <code>ndb_mgmd</code> processes

2. Make changes in global configuration file(s)

3. Start all <code>ndb_mgmd</code> processes</td><td rowspan="2">1. Stop all <code>ndb_mgmd</code> processes

2. Replace each <code>ndb_mgmd</code> binary with new version

3. Start <code>ndb_mgmd</code> processes</td><td rowspan="2">1. Stop all <code>ndb_mgmd</code> processes

2. Make desired changes in hardware, operating system, or both

3. Start all <code>ndb_mgmd</code> processes</td><td colspan="2">(OR)</td></tr>
<tr><td>1. Stop all <code>ndb_mgmd</code> processes

2. Start all <code>ndb_mgmd</code> processes</td><td>Restart all <code>ndb_mgmd</code> processes (optional)</td></tr>
<tr><td colspan="6">B. For each data node (<code>ndbd</code>) process...</td></tr>
<tr><td colspan="2">(OR)</td><td rowspan="2">1. Stop <code>ndbd</code>

2. Replace <code>ndbd</code> binary with new version

3. Start <code>ndbd</code></td><td rowspan="2">1. Stop <code>ndbd</code>

2. Make desired changes in hardware, operating system, or both

3. Start <code>ndbd</code></td><td colspan="2">(OR)</td></tr>
<tr><td>1. Stop <code>ndbd</code>

2. Start <code>ndbd</code></td><td>Restart <code>ndbd</code></td><td>1. Stop <code>ndbd</code>

2. Start <code>ndbd</code></td><td>Restart <code>ndbd</code></td></tr>
<tr><td colspan="6">C. For each SQL node (<code>mysqld</code>) process...</td></tr>
<tr><td colspan="2">(OR)</td><td rowspan="2">1. Stop <code>mysqld</code>

2. Replace <code>mysqld</code> binary with new version

3. Start <code>mysqld</code></td><td rowspan="2">1. Stop <code>mysqld</code>

2. Make desired changes in hardware, operating system, or both

3. Start <code>mysqld</code></td><td colspan="2">(OR)</td></tr>
<tr><td>1. Stop <code>mysqld</code>

2. Start <code>mysqld</code></td><td>Restart <code>mysqld</code></td><td>1. Stop <code>mysqld</code>

2. Start <code>mysqld</code></td><td>Restart <code>mysqld</code></td></tr>
</table>

In the previous diagram, the **Stop** and **Start** steps indicate that the process must be stopped completely using a shell command (such as `kill` on most Unix systems) or the management client `STOP` command, then started again from a system shell by invoking the `ndbd` or `ndb_mgmd` executable as appropriate. On Windows (MySQL Cluster NDB 7.1.3 and later), you can also use the system `NET START` and `NET STOP` commands or the Windows Service Manager to start and stop nodes which have been installed as Windows services (see Installing MySQL Cluster Processes as Windows Services).

Restart indicates that the process may be restarted using the `ndb_mgm` management client `RESTART` command (see Commands in the MySQL Cluster Management Client).

Prior to MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10. When performing an upgrade or downgrade of the cluster software, you must upgrade or downgrade the management nodes first, then the data nodes, and finally the SQL nodes. Doing so in any other order may leave the cluster in an unusable state.

MySQL Cluster NDB 6.3.29 and later; MySQL Cluster NDB 7.0.10 and later. MySQL Cluster supports a more flexible order for upgrading the cluster nodes. When upgrading a cluster running MySQL Cluster NDB 6.3.29 or later, or a cluster that is running MySQL Cluster NDB 7.0.10 or later, you may upgrade API nodes (including SQL nodes) before upgrading the management nodes, data nodes, or both. In other words, you are permitted to upgrade the API and SQL nodes in any order. This is subject to the following provisions:

- This functionality is intended for use as part of an online upgrade only. A mix of node binaries from different MySQL Cluster releases is neither intended nor supported for constant, long-term use in a production setting.
- All management nodes must be upgraded before any data nodes are upgraded. This remains true regardless of the order in which you upgrade the cluster's API and SQL nodes.
- For MySQL Cluster NDB 6.3, the ability to upgrade API nodes in any order relative to upgrading management nodes and data nodes is supported only for MySQL Cluster NDB 6.3.29 and later; for MySQL Cluster NDB 7.0, it supported only for MySQL Cluster NDB 7.0.10 and later. This means that, if you are upgrading from a MySQL Cluster NDB 6.3 release to a MySQL Cluster NDB 7.0 release, the “old” `NDB` engine version must be 6.3.29 or later, and the “new” `NDB` engine version must be 7.0.10 or later.
- When upgrading the cluster from a MySQL Cluster NDB 6.3 release to a MySQL Cluster NDB 7.0 release: Once you have started upgrading the API nodes, you should not perform DDL operations until all management nodes and data nodes have been upgraded. DML operations should be unaffected, and can continue while the upgrade is in progress.

  However, it is possible to perform DDL from an “old” (NDB 6.3 version) API node as long as the master data node is also running the “old” version of MySQL Cluster. You should keep in mind that a data node restart could result in the master node running a “new” (NDB 7.0 version) binary while one or more data nodes are still using the “old” (NDB 6.3) version; in this situation, no DDL can be performed from *any* API node, because the master data node is no longer using an NDB 6.3 binary, but the cluster still contains nodes which are not yet using NDB 7.0. For this reason, we recommend that you avoid performing DDL at any time while the upgrade is in progress.
- Features specific to the “new” version must not be used until all management nodes and data nodes have been upgraded.

  This also applies to any MySQL Server version change that may apply, in addition to the NDB engine version change, so do not forget to take this into account when planning the upgrade. (This is true for online upgrades of MySQL Cluster in general.)

See also Bug #48528 and Bug #49163.

Rolling restarts with multiple management servers (MySQL Cluster NDB 7.0.8 and later). A change in MySQL Cluster NDB 7.0.8 in the way in which management nodes obtain configuration data makes it necessary to alter the procedure previously outlined, when performing a rolling restart of a MySQL Cluster with multiple management nodes. (Previously, a management node checked only its own configuration cache, but in MySQL Cluster NDB 7.0.8 and later, `ndb_mgmd` also checks to see if any other management node is running, and, if so, tries to use that node's configuration data.) To keep this from occurring, and to force `ndb_mgmd` to reread its configuration file, perform the following steps:

1. Stop all MySQL Cluster `ndb_mgmd` processes.
2. Update all `config.ini` files.
3. Start a single `ndb_mgmd` with `--reload` [1966], `--initial` [1965], or both options as desired.

4. Start any remaining `ndb_mgmd` processes *without using either of the `--reload` [1966] or `--initial` [1965] options*.

5. Complete the rolling restarts of the data nodes and API nodes as normal.

See also Bug #45495 and Bug #46488.

MySQL Cluster NDB 7.0.24 and later; MySQL Cluster NDB 7.1.13 and later. When performing a rolling restart to update the cluster's configuration, you can use the `config_generation` column of the `ndbinfo.nodes` table to keep track of which data nodes have been successfully restarted with the new configuration. See The `ndbinfo nodes` Table.

Event Reports Generated in MySQL Cluster

In this section, we discuss the types of event logs provided by MySQL Cluster, and the types of events that are logged.

MySQL Cluster provides two types of event log:

- The *cluster log*, which includes events generated by all cluster nodes. The cluster log is the log recommended for most uses because it provides logging information for an entire cluster in a single location.

  By default, the cluster log is saved to a file named `ndb_node_id_cluster.log`, (where *`node_id`* is the node ID of the management server) in the same directory where the `ndb_mgm` binary resides.

  Cluster logging information can also be sent to `stdout` or a `syslog` facility in addition to or instead of being saved to a file, as determined by the values set for the `DataDir` [1812] and `LogDestination` [1810] configuration parameters. See Defining a MySQL Cluster Management Server, for more information about these parameters.

- *Node logs* are local to each node.

  Output generated by node event logging is written to the file `ndb_node_id_out.log` (where *`node_id`* is the node's node ID) in the node's `DataDir` [1816]. Node event logs are generated for both management nodes and data nodes.

  Node logs are intended to be used only during application development, or for debugging application code.

Both types of event logs can be set to log different subsets of events.

Each reportable event can be distinguished according to three different criteria:

- *Category*: This can be any one of the following values: `STARTUP`, `SHUTDOWN`, `STATISTICS`, `CHECKPOINT`, `NODERESTART`, `CONNECTION`, `ERROR`, or `INFO`.

- *Priority*: This is represented by one of the numbers from 1 to 15 inclusive, where 1 indicates “most important” and 15 “least important.”

- *Severity Level*: This can be any one of the following values: `ALERT`, `CRITICAL`, `ERROR`, `WARNING`, `INFO`, or `DEBUG`.

Both the cluster log and the node log can be filtered on these properties.

The format used in the cluster log is as shown here:

```
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 1: Data usage is 2%(60 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 1: Index usage is 1%(24 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 1: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 2: Data usage is 2%(76 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 2: Index usage is 1%(24 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 2: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 3: Data usage is 2%(58 32K pages of total 2560)
```

```
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 3: Index usage is 1%(25 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 3: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 4: Data usage is 2%(74 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 4: Index usage is 1%(25 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 4: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 4: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 1: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 1: Node 9: API 5.1.63-ndb-7.1.25

2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 2: Node 9: API 5.1.63-ndb-7.1.25
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 3: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 3: Node 9: API 5.1.63-ndb-7.1.25
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 4: Node 9: API 5.1.63-ndb-7.1.25
2007-01-26 19:59:22 [MgmSrvr] ALERT    -- Node 2: Node 7 Disconnected
2007-01-26 19:59:22 [MgmSrvr] ALERT    -- Node 2: Node 7 Disconnected
```

Each line in the cluster log contains the following information:

- A timestamp in *`YYYY-MM-DD HH:MM:SS`* format.
- The type of node which is performing the logging. In the cluster log, this is always `[MgmSrvr]`.
- The severity of the event.
- The ID of the node reporting the event.
- A description of the event. The most common types of events to appear in the log are connections and disconnections between different nodes in the cluster, and when checkpoints occur. In some cases, the description may contain status information.

MySQL Cluster Logging Management Commands

The following management commands are related to the cluster log:

- `CLUSTERLOG ON`

  Turns the cluster log on.

- `CLUSTERLOG OFF`

  Turns the cluster log off.

- `CLUSTERLOG INFO`

  Provides information about cluster log settings.

- *`node_id`* `CLUSTERLOG` *`category=threshold`*

  Logs *`category`* events with priority less than or equal to *`threshold`* in the cluster log.

- `CLUSTERLOG FILTER` *`severity_level`*

  Toggles cluster logging of events of the specified *`severity_level`*.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, it is reported in the cluster log.

Note that events are reported per data node, and that the threshold can be set to different values on different nodes.

Category	Default threshold (All data nodes)
`STARTUP`	**7**
`SHUTDOWN`	**7**
`STATISTICS`	**7**

Category	Default threshold (All data nodes)
CHECKPOINT	7
NODERESTART	7
CONNECTION	7
ERROR	15
INFO	7

The STATISTICS category can provide a great deal of useful data. See Using CLUSTERLOG STATISTICS in the MySQL Cluster Management Client, for more information.

Thresholds are used to filter events within each category. For example, a STARTUP event with a priority of 3 is not logged unless the threshold for STARTUP is set to 3 or higher. Only events with priority 3 or lower are sent if the threshold is 3.

The following table shows the event severity levels.

Note

These correspond to Unix syslog levels, except for LOG_EMERG and LOG_NOTICE, which are not used or mapped.

1	ALERT	A condition that should be corrected immediately, such as a corrupted system database
2	CRITICAL	Critical conditions, such as device errors or insufficient resources
3	ERROR	Conditions that should be corrected, such as configuration errors
4	WARNING	Conditions that are not errors, but that might require special handling
5	INFO	Informational messages
6	DEBUG	Debugging messages used for NDBCLUSTER development

Event severity levels can be turned on or off (using CLUSTERLOG FILTER—see above). If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.

Important

Cluster log levels are set on a per ndb_mgmd, per subscriber basis. This means that, in a MySQL Cluster with multiple management servers, using a CLUSTERLOG command in an instance of ndb_mgm connected to one management server affects only logs generated by that management server but not by any of the others. This also means that, should one of the management servers be restarted, only logs generated by that management server are affected by the resetting of log levels caused by the restart.

MySQL Cluster Log Events

An event report reported in the event logs has the following format:

```
datetime [string] severity -- message
```

For example:

```
09:19:30 2005-07-24 [NDB] INFO -- Node 4 Start phase 4 completed
```

This section discusses all reportable events, ordered by category and severity level within each category.

In the event descriptions, GCP and LCP mean “Global Checkpoint” and “Local Checkpoint”, respectively.

`CONNECTION` Events

These events are associated with connections between Cluster nodes.

Event	Priority	Severity Level	Description
data nodes connected	8	`INFO`	Data nodes connected
data nodes disconnected	8	`INFO`	Data nodes disconnected
Communication closed	8	`INFO`	SQL node or data node connection closed
Communication opened	8	`INFO`	SQL node or data node connection opened

`CHECKPOINT` Events

The logging messages shown here are associated with checkpoints.

Event	Priority	Severity Level	Description
LCP stopped in calc keep GCI	0	`ALERT`	LCP stopped
Local checkpoint fragment completed	11	`INFO`	LCP on a fragment has been completed
Global checkpoint completed	10	`INFO`	GCP finished
Global checkpoint started	9	`INFO`	Start of GCP: REDO log is written to disk
Local checkpoint completed	8	`INFO`	LCP completed normally
Local checkpoint started	7	`INFO`	Start of LCP: data written to disk

`STARTUP` Events

The following events are generated in response to the startup of a node or of the cluster and of its success or failure. They also provide information relating to the progress of the startup process, including information concerning logging activities.

Event	Priority	Severity Level	Description
Internal start signal received STTORRY	15	`INFO`	Blocks received after completion of restart
New REDO log started	10	`INFO`	GCI keep *X*, newest restorable GCI *Y*
New log started	10	`INFO`	Log part *X*, start MB *Y*, stop MB *Z*
Node has been refused for inclusion in the cluster	8	`INFO`	Node cannot be included in cluster due to misconfiguration, inability to establish communication, or other problem
data node neighbors	8	`INFO`	Shows neighboring data nodes
data node start phase *X* completed	4	`INFO`	A data node start phase has been completed
Node has been successfully included into the cluster	3	`INFO`	Displays the node, managing node, and dynamic ID
data node start phases initiated	1	`INFO`	NDB Cluster nodes starting
data node all start phases completed	1	`INFO`	NDB Cluster nodes started
data node shutdown initiated	1	`INFO`	Shutdown of data node has commenced
data node shutdown aborted	1	`INFO`	Unable to shut down data node normally

`NODERESTART` Events

The following events are generated when restarting a node and relate to the success or failure of the node restart process.

Event	Priority	Severity Level	Description
Node failure phase completed	8	ALERT	Reports completion of node failure phases
Node has failed, node state was *X*	8	ALERT	Reports that a node has failed
Report arbitrator results	2	ALERT	There are eight different possible results for arbitration attempts: • Arbitration check failed—less than 1/2 nodes left • Arbitration check succeeded—node group majority • Arbitration check failed—missing node group • Network partitioning—arbitration required • Arbitration succeeded—affirmative response from node *X* • Arbitration failed - negative response from node *X* • Network partitioning - no arbitrator available • Network partitioning - no arbitrator configured
Completed copying a fragment	10	INFO	
Completed copying of dictionary information	8	INFO	
Completed copying distribution information	8	INFO	
Starting to copy fragments	8	INFO	
Completed copying all fragments	8	INFO	
GCP takeover started	7	INFO	
GCP takeover completed	7	INFO	
LCP takeover started	7	INFO	
LCP takeover completed (state = *X*)	7	INFO	
Report whether an arbitrator is found or not	6	INFO	There are seven different possible outcomes when seeking an arbitrator: • Management server restarts arbitration thread [state=*X*] • Prepare arbitrator node *X* [ticket=*Y*] • Receive arbitrator node *X* [ticket=*Y*] • Started arbitrator node *X* [ticket=*Y*]

Event	Priority	Severity Level	Description
			• Lost arbitrator node *X* - process failure [state=*Y*] • Lost arbitrator node *X* - process exit [state=*Y*] • Lost arbitrator node *X* <error msg> [state=*Y*]

`STATISTICS` Events

The following events are of a statistical nature. They provide information such as numbers of transactions and other operations, amount of data sent or received by individual nodes, and memory usage.

Event	Priority	Severity Level	Description
Report job scheduling statistics	9	`INFO`	Mean internal job scheduling statistics
Sent number of bytes	9	`INFO`	Mean number of bytes sent to node *X*
Received # of bytes	9	`INFO`	Mean number of bytes received from node *X*
Report transaction statistics	8	`INFO`	Numbers of: transactions, commits, reads, simple reads, writes, concurrent operations, attribute information, and aborts
Report operations	8	`INFO`	Number of operations
Report table create	7	`INFO`	
Memory usage	5	`INFO`	Data and index memory usage (80%, 90%, and 100%)

`ERROR` Events

These events relate to Cluster errors and warnings. The presence of one or more of these generally indicates that a major malfunction or failure has occurred.

Event	Priority	Severity	Description
Dead due to missed heartbeat	8	`ALERT`	Node *X* declared “dead” due to missed heartbeat
Transporter errors	2	ERROR	
Transporter warnings	8	`WARNING`	
Missed heartbeats	8	`WARNING`	Node *X* missed heartbeat #*Y*
General warning events	2	`WARNING`	

`INFO` Events

These events provide general information about the state of the cluster and activities associated with Cluster maintenance, such as logging and heartbeat transmission.

Event	Priority	Severity	Description
Sent heartbeat	12	`INFO`	Heartbeat sent to node *X*
Create log bytes	11	`INFO`	Log part, log file, MB
General information events	2	`INFO`	

Using `CLUSTERLOG STATISTICS` in the MySQL Cluster Management Client

The NDB management client's CLUSTERLOG STATISTICS command can provide a number of useful statistics in its output. Counters providing information about the state of the cluster are updated at 5-second reporting intervals by the transaction coordinator (TC) and the local query handler (LQH), and written to the cluster log.

Transaction coordinator statistics. Each transaction has one transaction coordinator, which is chosen by one of the following methods:

- In a round-robin fashion
- By communication proximity
- (*Beginning with MySQL Cluster NDB 6.3.4*:) By supplying a data placement hint when the transaction is started

Note

You can determine which TC selection method is used for transactions started from a given SQL node using the ndb_optimized_node_selection [1928] system variable.

All operations within the same transaction use the same transaction coordinator, which reports the following statistics:

- **Trans count.** This is the number transactions started in the last interval using this TC as the transaction coordinator. Any of these transactions may have committed, have been aborted, or remain uncommitted at the end of the reporting interval.

  Note

  Transactions do not migrate between TCs.

- **Commit count.** This is the number of transactions using this TC as the transaction coordinator that were committed in the last reporting interval. Because some transactions committed in this reporting interval may have started in a previous reporting interval, it is possible for Commit count to be greater than Trans count.

- **Read count.** This is the number of primary key read operations using this TC as the transaction coordinator that were started in the last reporting interval, including simple reads. This count also includes reads performed as part of unique index operations. A unique index read operation generates 2 primary key read operations—1 for the hidden unique index table, and 1 for the table on which the read takes place.

- **Simple read count.** This is the number of simple read operations using this TC as the transaction coordinator that were started in the last reporting interval. This is a subset of Read count. Because the value of Simple read count is incremented at a different point in time from Read count, it can lag behind Read count slightly, so it is conceivable that Simple read count is not equal to Read count for a given reporting interval, even if all reads made during that time were in fact simple reads.

- **Write count.** This is the number of primary key write operations using this TC as the transaction coordinator that were started in the last reporting interval. This includes all inserts, updates, writes and deletes, as well as writes performed as part of unique index operations.

  Note

  A unique index update operation can generate multiple PK read and write operations on the index table and on the base table.

- **AttrInfoCount.** This is the number of 32-bit data words received in the last reporting interval for primary key operations using this TC as the transaction coordinator. For reads, this is proportional

to the number of columns requested. For inserts and updates, this is proportional to the number of columns written, and the size of their data. For delete operations, this is usually zero.

Unique index operations generate multiple PK operations and so increase this count. However, data words sent to describe the PK operation itself, and the key information sent, are *not* counted here. Attribute information sent to describe columns to read for scans, or to describe ScanFilters, is also not counted in `AttrInfoCount`.

- **`Concurrent Operations`.** This is the number of primary key or scan operations using this TC as the transaction coordinator that were started during the last reporting interval but that were not completed. Operations increment this counter when they are started and decrement it when they are completed; this occurs after the transaction commits. Dirty reads and writes—as well as failed operations—decrement this counter.

  The maximum value that `Concurrent Operations` can have is the maximum number of operations that a TC block can support; currently, this is `(2 * MaxNoOfConcurrentOperations) + 16 + MaxNoOfConcurrentTransactions`. (For more information about these configuration parameters, see the *Transaction Parameters* section of Defining MySQL Cluster Data Nodes.)

- **`Abort count`.** This is the number of transactions using this TC as the transaction coordinator that were aborted during the last reporting interval. Because some transactions that were aborted in the last reporting interval may have started in a previous reporting interval, `Abort count` can sometimes be greater than `Trans count`.

- **`Scans`.** This is the number of table scans using this TC as the transaction coordinator that were started during the last reporting interval. This does not include range scans (that is, ordered index scans).

- **`Range scans`.** This is the number of ordered index scans using this TC as the transaction coordinator that were started in the last reporting interval.

Local query handler statistics (`Operations`). There is 1 cluster event per local query handler block (that is, 1 per data node process). Operations are recorded in the LQH where the data they are operating on resides.

Note

A single transaction may operate on data stored in multiple LQH blocks.

The `Operations` statistic provides the number of local operations performed by this LQH block in the last reporting interval, and includes all types of read and write operations (insert, update, write, and delete operations). This also includes operations used to replicate writes. For example, in a 2-replica cluster, the write to the primary replica is recorded in the primary LQH, and the write to the backup will be recorded in the backup LQH. Unique key operations may result in multiple local operations; however, this does *not* include local operations generated as a result of a table scan or ordered index scan, which are not counted.

Process scheduler statistics. In addition to the statistics reported by the transaction coordinator and local query handler, each `ndbd` process has a scheduler which also provides useful metrics relating to the performance of a MySQL Cluster. This scheduler runs in an infinite loop; during each loop the scheduler performs the following tasks:

1. Read any incoming messages from sockets into a job buffer.
2. Check whether there are any timed messages to be executed; if so, put these into the job buffer as well.
3. Execute (in a loop) any messages in the job buffer.
4. Send any distributed messages that were generated by executing the messages in the job buffer.

5. Wait for any new incoming messages.

Process scheduler statistics include the following:

- **`Mean Loop Counter`.** This is the number of loops executed in the third step from the preceding list. This statistic increases in size as the utilization of the TCP/IP buffer improves. You can use this to monitor changes in performance as you add new data node processes.
- **`Mean send size` and `Mean receive size`.** These statistics enable you to gauge the efficiency of, respectively writes and reads between nodes. The values are given in bytes. Higher values mean a lower cost per byte sent or received; the maximum value is 64K.

To cause all cluster log statistics to be logged, you can use the following command in the `NDB` management client:

```
ndb_mgm> ALL CLUSTERLOG STATISTICS=15
```

Note

Setting the threshold for `STATISTICS` to 15 causes the cluster log to become very verbose, and to grow quite rapidly in size, in direct proportion to the number of cluster nodes and the amount of activity in the MySQL Cluster.

For more information about MySQL Cluster management client commands relating to logging and reporting, see MySQL Cluster Logging Management Commands.

MySQL Cluster Log Messages

This section contains information about the messages written to the cluster log in response to different cluster log events. It provides additional, more specific information on `NDB` transporter errors.

MySQL Cluster: Messages in the Cluster Log

The following table lists the most common `NDB` cluster log messages. For information about the cluster log, log events, and event types, see Event Reports Generated in MySQL Cluster. These log messages also correspond to log event types in the MGM API; see The `Ndb_logevent_type` Type, for related information of interest to Cluster API developers.

Log Message. `Node mgm_node_id: Node data_node_id Connected` **Description.** The data node having node ID *`node_id`* has connected to the management server (node *`mgm_node_id`*).	**Event Name.** `Connected` **Event Type.** `Connection` **Priority.** 8 **Severity.** `INFO`
Log Message. `Node mgm_node_id: Node data_node_id Disconnected` **Description.** The data node having node ID *`data_node_id`* has disconnected from the management server (node *`mgm_node_id`*).	**Event Name.** `Disconnected` **Event Type.** `Connection` **Priority.** 8 **Severity.** `ALERT`
Log Message. `Node data_node_id: Communication to Node api_node_id closed` **Description.** The API node or SQL node having node ID *`api_node_id`* is no longer communicating with data node *`data_node_id`*.	**Event Name.** `CommunicationClosed` **Event Type.** `Connection` **Priority.** 8 **Severity.** `INFO`
Log Message. `Node data_node_id: Communication to Node api_node_id opened`	**Event Name.** `CommunicationOpened`

Description. The API node or SQL node having node ID *api_node_id* is now communicating with data node *data_node_id*.	**Event Type.** Connection **Priority.** 8 **Severity.** INFO
Log Message. Node *mgm_node_id*: Node *api_node_id*: API *version* **Description.** The API node having node ID *api_node_id* has connected to management node *mgm_node_id* using NDB API version *version* (generally the same as the MySQL version number).	**Event Name.** ConnectedApiVersion **Event Type.** Connection **Priority.** 8 **Severity.** INFO
Log Message. Node *node_id*: Global checkpoint *gci* started **Description.** A global checkpoint with the ID *gci* has been started; node *node_id* is the master responsible for this global checkpoint.	**Event Name.** GlobalCheckpointStarted **Event Type.** Checkpoint **Priority.** 9 **Severity.** INFO
Log Message. Node *node_id*: Global checkpoint *gci* completed **Description.** The global checkpoint having the ID *gci* has been completed; node *node_id* was the master responsible for this global checkpoint.	**Event Name.** GlobalCheckpointCompleted **Event Type.** Checkpoint **Priority.** 10 **Severity.** INFO
Log Message. Node *node_id*: Local checkpoint *lcp* started. Keep GCI = *current_gci* oldest restorable GCI = *old_gci* **Description.** The local checkpoint having sequence ID *lcp* has been started on node *node_id*. The most recent GCI that can be used has the index *current_gci*, and the oldest GCI from which the cluster can be restored has the index *old_gci*.	**Event Name.** LocalCheckpointStarted **Event Type.** Checkpoint **Priority.** 7 **Severity.** INFO
Log Message. Node *node_id*: Local checkpoint *lcp* completed **Description.** The local checkpoint having sequence ID *lcp* on node *node_id* has been completed.	**Event Name.** LocalCheckpointCompleted **Event Type.** Checkpoint **Priority.** 8 **Severity.** INFO
Log Message. Node *node_id*: Local Checkpoint stopped in CALCULATED_KEEP_GCI **Description.** The node was unable to determine the most recent usable GCI.	**Event Name.** LCPStoppedInCalcKeepGci **Event Type.** Checkpoint **Priority.** 0 **Severity.** ALERT
Log Message. Node *node_id*: Table ID = *table_id*, fragment *ID* = *fragment_id* has completed LCP on Node *node_id* maxGciStarted: *started_gci* maxGciCompleted: *completed_gci*	**Event Name.** LCPFragmentCompleted **Event Type.** Checkpoint

Description. A table fragment has been checkpointed to disk on node *node_id*. The GCI in progress has the index *started_gci*, and the most recent GCI to have been completed has the index *completed_gci*.	**Priority.** 11 **Severity.** INFO
Log Message. Node *node_id*: ACC Blocked *num_1* and TUP Blocked *num_2* times last second **Description.** Undo logging is blocked because the log buffer is close to overflowing.	**Event Name.** UndoLogBlocked **Event Type.** Checkpoint **Priority.** 7 **Severity.** INFO
Log Message. Node *node_id*: Start initiated *version* **Description.** Data node *node_id*, running NDB version *version*, is beginning its startup process.	**Event Name.** NDBStartStarted **Event Type.** StartUp **Priority.** 1 **Severity.** INFO
Log Message. Node *node_id*: Started *version* **Description.** Data node *node_id*, running NDB version *version*, has started successfully.	**Event Name.** NDBStartCompleted **Event Type.** StartUp **Priority.** 1 **Severity.** INFO
Log Message. Node *node_id*: STTORRY received after restart finished **Description.** The node has received a signal indicating that a cluster restart has completed.	**Event Name.** STTORRYRecieved **Event Type.** StartUp **Priority.** 15 **Severity.** INFO
Log Message. Node *node_id*: Start phase *phase* completed (*type*) **Description.** The node has completed start phase *phase* of a *type* start. For a listing of start phases, see Summary of MySQL Cluster Start Phases. (*type* is one of initial, system, node, initial node, or <Unknown>.)	**Event Name.** StartPhaseCompleted **Event Type.** StartUp **Priority.** 4 **Severity.** INFO
Log Message. Node *node_id*: CM_REGCONF president = *president_id*, own Node = *own_id*, our dynamic id = *dynamic_id* **Description.** Node *president_id* has been selected as "president". *own_id* and *dynamic_id* should always be the same as the ID (*node_id*) of the reporting node.	**Event Name.** CM_REGCONF **Event Type.** StartUp **Priority.** 3 **Severity.** INFO
Log Message. Node *node_id*: CM_REGREF from Node *president_id* to our Node *node_id*. Cause = *cause* **Description.** The reporting node (ID *node_id*) was unable to accept node *president_id* as president. The *cause* of the problem is given as one of Busy, Election with wait = false, Not president, Election without selecting new candidate, or No such cause.	**Event Name.** CM_REGREF **Event Type.** StartUp **Priority.** 8 **Severity.** INFO

Log Message. `Node node_id: We are Node own_id with dynamic ID dynamic_id, our left neighbor is Node id_1, our right is Node id_2` **Description.** The node has discovered its neighboring nodes in the cluster (node `id_1` and node `id_2`). `node_id`, `own_id`, and `dynamic_id` should always be the same; if they are not, this indicates a serious misconfiguration of the cluster nodes.	**Event Name.** `FIND_NEIGHBOURS` **Event Type.** `StartUp` **Priority.** 8 **Severity.** `INFO`
Log Message. `Node node_id: type shutdown initiated` **Description.** The node has received a shutdown signal. The `type` of shutdown is either `Cluster` or `Node`.	**Event Name.** `NDBStopStarted` **Event Type.** `StartUp` **Priority.** 1 **Severity.** `INFO`
Log Message. `Node node_id: Node shutdown completed [, action] [Initiated by signal signal.]` **Description.** The node has been shut down. This report may include an `action`, which if present is one of `restarting`, `no start`, or `initial`. The report may also include a reference to an `NDB` Protocol `signal`; for possible signals, refer to Operations and Signals.	**Event Name.** `NDBStopCompleted` **Event Type.** `StartUp` **Priority.** 1 **Severity.** `INFO`
Log Message. `Node node_id: Forced node shutdown completed [, action]. [Occured during startphase start_phase.] [ Initiated by signal.] [Caused by error error_code: 'error_message(error_classification). error_status'. [(extra info extra_code)]]` **Description.** The node has been forcibly shut down. The `action` (one of `restarting`, `no start`, or `initial`) subsequently being taken, if any, is also reported. If the shutdown occurred while the node was starting, the report includes the `start_phase` during which the node failed. If this was a result of a `signal` sent to the node, this information is also provided (see Operations and Signals, for more information). If the error causing the failure is known, this is also included; for more information about `NDB` error messages and classifications, see MySQL Cluster API Errors.	**Event Name.** `NDBStopForced` **Event Type.** `StartUp` **Priority.** 1 **Severity.** `ALERT`
Log Message. `Node node_id: Node shutdown aborted` **Description.** The node shutdown process was aborted by the user.	**Event Name.** `NDBStopAborted` **Event Type.** `StartUp` **Priority.** 1 **Severity.** `INFO`
Log Message. `Node node_id: StartLog: [GCI Keep: keep_pos LastCompleted: last_pos NewestRestorable: restore_pos]` **Description.** This reports global checkpoints referenced during a node start. The redo log prior to `keep_pos` is	**Event Name.** `StartREDOLog` **Event Type.** `StartUp` **Priority.** 4 **Severity.** `INFO`

dropped. *`last_pos`* is the last global checkpoint in which data node the participated; *`restore_pos`* is the global checkpoint which is actually used to restore all data nodes.	
Log Message. *`startup_message`* [*Listed separately; see below.*] **Description.** There are a number of possible startup messages that can be logged under different circumstances.	**Event Name.** `StartReport` **Event Type.** `StartUp` **Priority.** 4 **Severity.** `INFO`
Log Message. `Node` *`node_id`*`: Node restart completed copy of dictionary information` **Description.** Copying of data dictionary information to the restarted node has been completed.	**Event Name.** `NR_CopyDict` **Event Type.** `NodeRestart` **Priority.** 8 **Severity.** `INFO`
Log Message. `Node` *`node_id`*`: Node restart completed copy of distribution information` **Description.** Copying of data distribution information to the restarted node has been completed.	**Event Name.** `NR_CopyDistr` **Event Type.** `NodeRestart` **Priority.** 8 **Severity.** `INFO`
Log Message. `Node` *`node_id`*`: Node restart starting to copy the fragments to Node` *`node_id`* **Description.** Copy of fragments to starting data node *`node_id`* has begun	**Event Name.** `NR_CopyFragsStarted` **Event Type.** `NodeRestart` **Priority.** 8 **Severity.** `INFO`
Log Message. `Node` *`node_id`*`: Table ID =` *`table_id`*`, fragment ID =` *`fragment_id`* `have been copied to Node` *`node_id`* **Description.** Fragment *`fragment_id`* from table *`table_id`* has been copied to data node *`node_id`*	**Event Name.** `NR_CopyFragDone` **Event Type.** `NodeRestart` **Priority.** 10 **Severity.** `INFO`
Log Message. `Node` *`node_id`*`: Node restart completed copying the fragments to Node` *`node_id`* **Description.** Copying of all table fragments to restarting data node *`node_id`* has been completed	**Event Name.** `NR_CopyFragsCompleted` **Event Type.** `NodeRestart` **Priority.** 8 **Severity.** `INFO`
Log Message. Any of the following: 1. `Node` *`node_id`*`: Node` *`node1_id`* `completed failure of Node` *`node2_id`* 2. `All nodes completed failure of Node` *`node_id`* 3. `Node failure of` *`node_idblock`* `completed` **Description.** One of the following (each corresponding to the same-numbered message listed above):	**Event Name.** `NodeFailCompleted` **Event Type.** `NodeRestart` **Priority.** 8 **Severity.** `ALERT`

1. Data node *node1_id* has detected the failure of data node *node2_id* 2. All (remaining) data nodes have detected the failure of data node *node_id* 3. The failure of data node *node_id* has been detected in the *block*NDB kernel block, where block is 1 of DBTC, DBDICT, DBDIH, or DBLQH; for more information, see NDB Kernel Blocks	
Log Message. Node *mgm_node_id*: Node *data_node_id* has failed. The Node state at failure was *state_code* **Description.** A data node has failed. Its state at the time of failure is described by an arbitration state code *state_code*: possible state code values can be found in the file include/kernel/signaldata/ArbitSignalData.hpp.	**Event Name.** NODE_FAILREP **Event Type.** NodeRestart **Priority.** 8 **Severity.** ALERT
Log Message. President restarts arbitration thread [state=*state_code*] or Prepare arbitrator node *node_id* [ticket=*ticket_id*] or Receive arbitrator node *node_id* [ticket=*ticket_id*] or Started arbitrator node *node_id* [ticket=*ticket_id*] or Lost arbitrator node *node_id* - process failure [state=*state_code*] or Lost arbitrator node *node_id* - process exit [state=*state_code*] or Lost arbitrator node *node_id* - *error_message* [state=*state_code*] **Description.** This is a report on the current state and progress of arbitration in the cluster. *node_id* is the node ID of the management node or SQL node selected as the arbitrator. *state_code* is an arbitration state code, as found in include/kernel/signaldata/ArbitSignalData.hpp. When an error has occurred, an *error_message*, also defined in ArbitSignalData.hpp, is provided. *ticket_id* is a unique identifier handed out by the arbitrator when it is selected to all the nodes that participated in its selection; this is used to ensure that each node requesting arbitration was one of the nodes that took part in the selection process.	**Event Name.** ArbitState **Event Type.** NodeRestart **Priority.** 6 **Severity.** INFO
Log Message. Arbitration check lost - less than 1/2 nodes left or Arbitration check won - all node groups and more than 1/2 nodes left or Arbitration check won - node group majority or Arbitration check lost - missing node group or Network partitioning - arbitration required or Arbitration won - positive reply from node *node_id* or Arbitration lost - negative reply from node *node_id* or Network partitioning - no arbitrator available or Network partitioning - no arbitrator configured or Arbitration failure - *error_message* [state=*state_code*]	**Event Name.** ArbitResult **Event Type.** NodeRestart **Priority.** 2 **Severity.** ALERT

Description. This message reports on the result of arbitration. In the event of arbitration failure, an *error_message* and an arbitration *state_code* are provided; definitions for both of these are found in include/kernel/signaldata/ArbitSignalData.hpp.	
Log Message. Node *node_id*: GCP Take over started **Description.** This node is attempting to assume responsibility for the next global checkpoint (that is, it is becoming the master node)	**Event Name.** GCP_TakeoverStarted **Event Type.** NodeRestart **Priority.** 7 **Severity.** INFO
Log Message. Node *node_id*: GCP Take over completed **Description.** This node has become the master, and has assumed responsibility for the next global checkpoint	**Event Name.** GCP_TakeoverCompleted **Event Type.** NodeRestart **Priority.** 7 **Severity.** INFO
Log Message. Node *node_id*: LCP Take over started **Description.** This node is attempting to assume responsibility for the next set of local checkpoints (that is, it is becoming the master node)	**Event Name.** LCP_TakeoverStarted **Event Type.** NodeRestart **Priority.** 7 **Severity.** INFO
Log Message. Node *node_id*: LCP Take over completed **Description.** This node has become the master, and has assumed responsibility for the next set of local checkpoints	**Event Name.** LCP_TakeoverCompleted **Event Type.** NodeRestart **Priority.** 7 **Severity.** INFO
Log Message. Node *node_id*: Trans. Count = *transactions*, Commit Count = *commits*, Read Count = *reads*, Simple Read Count = *simple_reads*, Write Count = *writes*, AttrInfo Count = *AttrInfo_objects*, Concurrent Operations = *concurrent_operations*, Abort Count = *aborts*, Scans = *scans*, Range scans = *range_scans* **Description.** This report of transaction activity is given approximately once every 10 seconds	**Event Name.** TransReportCounters **Event Type.** Statistic **Priority.** 8 **Severity.** INFO
Log Message. Node *node_id*: Operations=*operations* **Description.** Number of operations performed by this node, provided approximately once every 10 seconds	**Event Name.** OperationReportCounters **Event Type.** Statistic **Priority.** 8 **Severity.** INFO

Log Message. `Node node_id: Table with ID = table_id created` **Description.** A table having the table ID shown has been created	**Event Name.** `TableCreated` **Event Type.** `Statistic` **Priority.** 7 **Severity.** `INFO`
Log Message. `Node node_id: Mean loop Counter in doJob last 8192 times = count` **Description.**	**Event Name.** `JobStatistic` **Event Type.** `Statistic` **Priority.** 9 **Severity.** `INFO`
Log Message. `Mean send size to Node = node_id last 4096 sends = bytes bytes` **Description.** This node is sending an average of *bytes* bytes per send to node *node_id*	**Event Name.** `SendBytesStatistic` **Event Type.** `Statistic` **Priority.** 9 **Severity.** `INFO`
Log Message. `Mean receive size to Node = node_id last 4096 sends = bytes bytes` **Description.** This node is receiving an average of *bytes* of data each time it receives data from node *node_id*	**Event Name.** `ReceiveBytesStatistic` **Event Type.** `Statistic` **Priority.** 9 **Severity.** `INFO`
Log Message. `Node node_id: Data usage is data_memory_percentage% (data_pages_used 32K pages of total data_pages_total)` / `Node node_id: Index usage is index_memory_percentage% (index_pages_used 8K pages of total index_pages_total)` **Description.** This report is generated when a `DUMP 1000` command is issued in the cluster management client; for more information, see `DUMP 1000`, in MySQL Cluster Internals	**Event Name.** `MemoryUsage` **Event Type.** `Statistic` **Priority.** 5 **Severity.** `INFO`
Log Message. `Node node1_id: Transporter to node node2_id reported error error_code: error_message` **Description.** A transporter error occurred while communicating with node *node2_id*; for a listing of transporter error codes and messages, see NDB Transporter Errors, in MySQL Cluster Internals	**Event Name.** `TransporterError` **Event Type.** `Error` **Priority.** 2 **Severity.** `ERROR`
Log Message. `Node node1_id: Transporter to node node2_id reported error error_code: error_message` **Description.** A warning of a potential transporter problem while communicating with node *node2_id*; for a listing of transporter error codes and messages, see NDB Transporter Errors, for more information	**Event Name.** `TransporterWarning` **Event Type.** `Error` **Priority.** 8 **Severity.** `WARNING`

Log Message. `Node node1_id: Node node2_id missed heartbeat heartbeat_id` **Description.** This node missed a heartbeat from node `node2_id`	**Event Name.** `MissedHeartbeat` **Event Type.** `Error` **Priority.** 8 **Severity.** `WARNING`
Log Message. `Node node1_id: Node node2_id declared dead due to missed heartbeat` **Description.** This node has missed at least 3 heartbeats from node `node2_id`, and so has declared that node "dead"	**Event Name.** `DeadDueToHeartbeat` **Event Type.** `Error` **Priority.** 8 **Severity.** `ALERT`
Log Message. `Node node1_id: Node Sent Heartbeat to node = node2_id` **Description.** This node has sent a heartbeat to node `node2_id`	**Event Name.** `SentHeartbeat` **Event Type.** `Info` **Priority.** 12 **Severity.** `INFO`
Log Message. `Node node_id: Event buffer status: used=bytes_used (percent_used%) alloc=bytes_allocated (percent_available%) max=bytes_available apply_gci=latest_restorable_GCI latest_gci=latest_GCI` **Description.** This report is seen during heavy event buffer usage, for example, when many updates are being applied in a relatively short period of time; the report shows the number of bytes and the percentage of event buffer memory used, the bytes allocated and percentage still available, and the latest and latest restorable global checkpoints	**Event Name.** `EventBufferStatus` **Event Type.** `Info` **Priority.** 7 **Severity.** `INFO`
Log Message. `Node node_id: Entering single user mode`, `Node node_id: Entered single user mode Node API_node_id has exclusive access`, `Node node_id: Entering single user mode` **Description.** These reports are written to the cluster log when entering and exiting single user mode; `API_node_id` is the node ID of the API or SQL having exclusive access to the cluster (for more information, see MySQL Cluster Single User Mode); the message `Unknown single user report API_node_id` indicates an error has taken place and should never be seen in normal operation	**Event Name.** `SingleUser` **Event Type.** `Info` **Priority.** 7 **Severity.** `INFO`
Log Message. `Node node_id: Backup backup_id started from node mgm_node_id` **Description.** A backup has been started using the management node having `mgm_node_id`; this message is also displayed in the cluster management client when the `START BACKUP` command is issued; for more information, see Using The MySQL Cluster Management Client to Create a Backup	**Event Name.** `BackupStarted` **Event Type.** `Backup` **Priority.** 7 **Severity.** `INFO`

Log Message. `Node node_id: Backup backup_id started from node mgm_node_id completed. StartGCP: start_gcp StopGCP: stop_gcp #Records: records #LogRecords: log_records Data: data_bytes bytes Log: log_bytes bytes` **Description.** The backup having the ID `backup_id` has been completed; for more information, see Using The MySQL Cluster Management Client to Create a Backup	**Event Name.** `BackupCompleted` **Event Type.** `Backup` **Priority.** 7 **Severity.** `INFO`
Log Message. `Node node_id: Backup request from mgm_node_id failed to start. Error: error_code` **Description.** The backup failed to start; for error codes, see MGM API Errors	**Event Name.** `BackupFailedToStart` **Event Type.** `Backup` **Priority.** 7 **Severity.** `ALERT`
Log Message. `Node node_id: Backup backup_id started from mgm_node_id has been aborted. Error: error_code` **Description.** The backup was terminated after starting, possibly due to user intervention	**Event Name.** `BackupAborted` **Event Type.** `Backup` **Priority.** 7 **Severity.** `ALERT`

MySQL Cluster: NDB Transporter Errors

This section lists error codes, names, and messages that are written to the cluster log in the event of transporter errors.

Error Code	Error Name	Error Text
0x00	**TE_NO_ERROR**	No error
0x01	**TE_ERROR_CLOSING_SOCKET**	Error found during closing of socket
0x02	**TE_ERROR_IN_SELECT_BEFORE_ACCEPT**	Error found before accept. The transporter will retry
0x03	**TE_INVALID_MESSAGE_LENGTH**	Error found in message (invalid message length)
0x04	**TE_INVALID_CHECKSUM**	Error found in message (checksum)
0x05	**TE_COULD_NOT_CREATE_SOCKET**	Error found while creating socket(can't create socket)
0x06	**TE_COULD_NOT_BIND_SOCKET**	Error found while binding server socket
0x07	**TE_LISTEN_FAILED**	Error found while listening to server socket
0x08	**TE_ACCEPT_RETURN_ERROR**	Error found during accept(accept return error)

Error Code	Error Name	Error Text
0x0b	**TE_SHM_DISCONNECT**	The remote node has disconnected
0x0c	**TE_SHM_IPC_STAT**	Unable to check shm segment
0x0d	**TE_SHM_UNABLE_TO_CREATE_SEGMENT**	Unable to create shm segment
0x0e	**TE_SHM_UNABLE_TO_ATTACH_SEGMENT**	Unable to attach shm segment
0x0f	**TE_SHM_UNABLE_TO_REMOVE_SEGMENT**	Unable to remove shm segment
0x10	**TE_TOO_SMALL_SIGID**	Sig ID too small
0x11	**TE_TOO_LARGE_SIGID**	Sig ID too large
0x12	**TE_WAIT_STACK_FULL**	Wait stack was full
0x13	**TE_RECEIVE_BUFFER_FULL**	Receive buffer was full
0x14	**TE_SIGNAL_LOST_SEND_BUFFER_FULL**	Send buffer was full,and trying to force send fails
0x15	**TE_SIGNAL_LOST**	Send failed for unknown reason(signal lost)
0x16	**TE_SEND_BUFFER_FULL**	The send buffer was full, but sleeping for a while solved
0x0017	**TE_SCI_LINK_ERROR**	There is no link from this node to the switch
0x18	**TE_SCI_UNABLE_TO_START_SEQUENCE**	Could not start a sequence, because system resources are exumed or no sequence has been created
0x19	**TE_SCI_UNABLE_TO_REMOVE_SEQUENCE**	Could not remove a sequence
0x1a	**TE_SCI_UNABLE_TO_CREATE_SEQUENCE**	Could not create a sequence, because system resources are exempted. Must reboot
0x1b	**TE_SCI_UNRECOVERABLE_DATA_TFX_ERROR**	Tried to send data on redundant link but failed
0x1c	**TE_SCI_CANNOT_INIT_LOCALSEGMENT**	Cannot initialize local segment
0x1d	**TE_SCI_CANNOT_MAP_REMOTESEGMENT**	Cannot map remote segment
0x1e	**TE_SCI_UNABLE_TO_UNMAP_SEGMENT**	Cannot free the resources used by this segment (step 1)

Error Code	Error Name	Error Text
0x1f	TE_SCI_UNABLE_TO_REMOVE_SEGMENT	Cannot free the resources used by this segment (step 2)
0x20	TE_SCI_UNABLE_TO_DISCONNECT_SEGMENT	Cannot disconnect from a remote segment
0x21	TE_SHM_IPC_PERMANENT	Shm ipc Permanent error
0x22	TE_SCI_UNABLE_TO_CLOSE_CHANNEL	Unable to close the sci channel and the resources allocated

MySQL Cluster Single User Mode

Single user mode enables the database administrator to restrict access to the database system to a single API node, such as a MySQL server (SQL node) or an instance of `ndb_restore`. When entering single user mode, connections to all other API nodes are closed gracefully and all running transactions are aborted. No new transactions are permitted to start.

Once the cluster has entered single user mode, only the designated API node is granted access to the database.

You can use the `ALL STATUS` command in the `ndb_mgm` client to see when the cluster has entered single user mode. Beginning with MySQL Cluster NDB 7.1.1, you can also check the `status` column of the `ndbinfo.nodes` table (see The `ndbinfo nodes` Table, for more information).

Example:

```
ndb_mgm> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the API node whose node ID is `5` becomes the cluster's only permitted user.

The node specified in the preceding command must be an API node; attempting to specify any other type of node will be rejected.

Note

When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command `EXIT SINGLE USER MODE` changes the state of the cluster's data nodes from single user mode to normal mode. API nodes—such as MySQL Servers—waiting for a connection (that is, waiting for the cluster to become ready and available), are again permitted to connect. The API node denoted as the single-user node continues to run (if still connected) during and after the state change.

Example:

```
ndb_mgm> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single user mode:

- Method 1:

  1. Finish all single user mode transactions

2. Issue the `EXIT SINGLE USER MODE` command
3. Restart the cluster's data nodes

- Method 2:

  Restart database nodes prior to entering single user mode.

Quick Reference: MySQL Cluster SQL Statements

This section discusses several SQL statements that can prove useful in managing and monitoring a MySQL server that is connected to a MySQL Cluster, and in some cases provide information about the cluster itself.

- `SHOW ENGINE NDB STATUS`, `SHOW ENGINE NDBCLUSTER STATUS`

  The output of this statement contains information about the server's connection to the cluster, creation and usage of MySQL Cluster objects, and binary logging for MySQL Cluster replication.

  See `SHOW ENGINE` Syntax, for a usage example and more detailed information.

- `SHOW ENGINES`

  This statement can be used to determine whether or not clustering support is enabled in the MySQL server, and if so, whether it is active.

  See `SHOW ENGINES` Syntax, for more detailed information.

  Note

  In MySQL 5.1 and later, this statement does not support a `LIKE` [959] clause. However, you can use `LIKE` [959] to filter queries against the `INFORMATION_SCHEMA.ENGINES`, as discussed in the next item.

- `SELECT * FROM INFORMATION_SCHEMA.ENGINES [WHERE ENGINE LIKE 'NDB%']`

  This is the equivalent of `SHOW ENGINES`, but uses the `ENGINES` table of the `INFORMATION_SCHEMA` database (available beginning with MySQL 5.1.5). Unlike the case with the `SHOW ENGINES` statement, it is possible to filter the results using a `LIKE` [959] clause, and to select specific columns to obtain information that may be of use in scripts. For example, the following query shows whether the server was built with `NDB` support and, if so, whether it is enabled:

```
mysql> SELECT SUPPORT FROM INFORMATION_SCHEMA.ENGINES
    ->   WHERE ENGINE LIKE 'NDB%';
+---------+
| support |
+---------+
| ENABLED |
+---------+
```

  See The `INFORMATION_SCHEMA ENGINES` Table, for more information.

- `SHOW VARIABLES LIKE 'NDB%'`

  This statement provides a list of most server system variables relating to the `NDB` storage engine, and their values, as shown here:

```
mysql> SHOW VARIABLES LIKE 'NDB%';
+-----------------------------------+-------+
| Variable_name                     | Value |
+-----------------------------------+-------+
| ndb_autoincrement_prefetch_sz     | 32    |
| ndb_cache_check_time              | 0     |
```

```
| ndb_extra_logging                    | 0     |
| ndb_force_send                       | ON    |
| ndb_index_stat_cache_entries         | 32    |
| ndb_index_stat_enable                | OFF   |
| ndb_index_stat_update_freq           | 20    |
| ndb_report_thresh_binlog_epoch_slip | 3     |
| ndb_report_thresh_binlog_mem_usage   | 10    |
| ndb_use_copying_alter_table          | OFF   |
| ndb_use_exact_count                  | ON    |
| ndb_use_transactions                 | ON    |
+--------------------------------------+-------+
```

See Server System Variables, for more information.

- `SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES WHERE VARIABLE_NAME LIKE 'NDB%';`

  This statement is the equivalent of the `SHOW` command described in the previous item, and provides almost identical output, as shown here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
    ->   WHERE VARIABLE_NAME LIKE 'NDB%';
+--------------------------------------+----------------+
| VARIABLE_NAME                        | VARIABLE_VALUE |
+--------------------------------------+----------------+
| NDB_AUTOINCREMENT_PREFETCH_SZ        | 32             |
| NDB_CACHE_CHECK_TIME                 | 0              |
| NDB_EXTRA_LOGGING                    | 0              |
| NDB_FORCE_SEND                       | ON             |
| NDB_INDEX_STAT_CACHE_ENTRIES         | 32             |
| NDB_INDEX_STAT_ENABLE                | OFF            |
| NDB_INDEX_STAT_UPDATE_FREQ           | 20             |
| NDB_REPORT_THRESH_BINLOG_EPOCH_SLIP | 3              |
| NDB_REPORT_THRESH_BINLOG_MEM_USAGE   | 10             |
| NDB_USE_COPYING_ALTER_TABLE          | OFF            |
| NDB_USE_EXACT_COUNT                  | ON             |
| NDB_USE_TRANSACTIONS                 | ON             |
+--------------------------------------+----------------+
```

  Unlike the case with the `SHOW` command, it is possible to select individual columns. For example:

```
mysql> SELECT VARIABLE_VALUE
    ->   FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
    ->   WHERE VARIABLE_NAME = 'ndb_force_send';
+----------------+
| VARIABLE_VALUE |
+----------------+
| ON             |
+----------------+
```

  See The `INFORMATION_SCHEMA GLOBAL_VARIABLES` and `SESSION_VARIABLES` Tables, and Server System Variables, for more information.

- `SHOW STATUS LIKE 'NDB%'`

  This statement shows at a glance whether or not the MySQL server is acting as a cluster SQL node, and if so, it provides the MySQL server's cluster node ID, the host name and port for the cluster management server to which it is connected, and the number of data nodes in the cluster, as shown here:

```
mysql> SHOW STATUS LIKE 'NDB%';
+--------------------------+---------------+
| Variable_name            | Value         |
+--------------------------+---------------+
| Ndb_cluster_node_id      | 10            |
| Ndb_config_from_host     | 192.168.0.103 |
| Ndb_config_from_port     | 1186          |
| Ndb_number_of_data_nodes | 4             |
+--------------------------+---------------+
```

If the MySQL server was built with clustering support, but it is not connected to a cluster, all rows in the output of this statement contain a zero or an empty string:

```
mysql> SHOW STATUS LIKE 'NDB%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| Ndb_cluster_node_id      | 0     |
| Ndb_config_from_host     |       |
| Ndb_config_from_port     | 0     |
| Ndb_number_of_data_nodes | 0     |
+--------------------------+-------+
```

See also SHOW STATUS Syntax.

- SELECT * FROM INFORMATION_SCHEMA.GLOBAL_STATUS WHERE VARIABLE_NAME LIKE 'NDB%';

  Beginning with MySQL 5.1.12, this statement provides similar output to the SHOW command discussed in the previous item. However, unlike the case with SHOW STATUS, it is possible using the SELECT to extract values in SQL for use in scripts for monitoring and automation purposes.

  See The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables, for more information.

Beginning with MySQL Cluster NDB 7.1.1, you can also query the tables in the ndbinfo information database for real-time data about many MySQL Cluster operations. See The ndbinfo MySQL Cluster Information Database.

The ndbinfo MySQL Cluster Information Database

ndbinfo is a database storing containing information specific to MySQL Cluster, available beginning with MySQL Cluster NDB 7.1.1.

This database contains a number of tables, each providing a different sort of data about MySQL Cluster node status, resource usage, and operations. You can find more detailed information about each of these tables in the next several sections.

ndbinfo is included with MySQL Cluster support in the MySQL Server; no special compilation or configuration steps are required; the tables are created by the MySQL Server when it connects to the cluster. You can verify that ndbinfo support is active in a given MySQL Server instance using SHOW PLUGINS; if ndbinfo support is enabled, you should see a row containing ndbinfo in the Name column and ACTIVE in the Status column, as shown here (emphasized text):

```
mysql> SHOW PLUGINS;
+------------+----------+----------------+---------+---------+
| Name       | Status   | Type           | Library | License |
+------------+----------+----------------+---------+---------+
| binlog     | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| partition  | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| ARCHIVE    | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| BLACKHOLE  | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| CSV        | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| FEDERATED  | DISABLED | STORAGE ENGINE | NULL    | GPL     |
| MEMORY     | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| InnoDB     | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| MyISAM     | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| MRG_MYISAM | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| ndbcluster | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| ndbinfo    | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
+------------+----------+----------------+---------+---------+
12 rows in set (0.00 sec)
```

You can also do this by checking the output of SHOW ENGINES for a row that has ndbinfo for Engine and YES for Support, as shown here (emphasized text):

```
mysql> SHOW ENGINES\G
*************************** 1. row ***************************
      Engine: ndbcluster
     Support: YES
     Comment: Clustered, fault-tolerant tables
Transactions: YES

10 rows in set (0.00 sec)
```

If ndbinfo support is enabled, then you can access ndbinfo using SQL statements in mysql or another MySQL client. For example, you can see ndbinfo listed in the output of SHOW DATABASES, as shown here:

```
mysql> SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| information_schema |
| mysql              |
| ndbinfo            |
| test               |
+--------------------+
4 rows in set (0.00 sec)
```

If the mysqld process was not started with the --ndbcluster [1915] option, ndbinfo is not available and is not displayed by SHOW DATABASES. If mysqld was formerly connected to a MySQL Cluster but the cluster becomes unavailable (due to events such as cluster shutdown, loss of network connectivity, and so forth), ndbinfo and its tables remain visible, but an attempt to access any tables (other than blocks or config_params) fails with Got error 157 'Connection to NDB failed' from NDBINFO.

With the exception of the blocks and config_params tables, what we refer to as ndbinfo "tables" are actually views generated from internal NDB tables not normally visible to the MySQL Server.

All ndbinfo tables are read-only, and are generated on demand when queried. Because many of them are generated in parallel by the data nodes while other are specific to a given SQL node, they are not guaranteed to provide a consistent snapshot.

In addition, pushing down of joins is not supported on ndbinfo tables; so joining large ndbinfo tables can require transfer of a large amount of data to the requesting API node, even when the query makes use of a WHERE clause.

Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, ndbinfo tables are not included in the query cache. (Bug #59831)

You can select the ndbinfo database with a USE statement, and then issue a SHOW TABLES statement to obtain a list of tables, just as for any other database, like this:

```
mysql> USE ndbinfo;
Database changed

mysql> SHOW TABLES;
+----------------------+
| Tables_in_ndbinfo    |
+----------------------+
| blocks               |
| cluster_operations   |
| cluster_transactions |
| config_params        |
| counters             |
| diskpagebuffer       |
| logbuffers           |
| logspaces            |
| memoryusage          |
| nodes                |
| resources            |
| server_operations    |
| server_transactions  |
| threadblocks         |
| threadstat           |
| transporters         |
+----------------------+
16 rows in set (0.04 sec)
```

The diskpagebuffer table was added in MySQL Cluster NDB 7.1.9.

The cluster_operations, cluster_transactions, server_operations, server_transactions, threadblocks, and threadstat tables were added in MySQL Cluster NDB 7.1.17.

In early versions of MySQL Cluster NDB 7.1, there was an additional pools table in the ndbinfo database; however, this table was removed in MySQL Cluster NDB 7.1.3.

You can execute SELECT statements against these tables, just as you would normally expect:

```
mysql> SELECT * FROM memoryusage;
+---------+--------------+------+-------+
| node_id | DATA_MEMORY  | used | max   |
+---------+--------------+------+-------+
|       1 | DATA_MEMORY  | 3230 |  6408 |
|       2 | DATA_MEMORY  | 3230 |  6408 |
|       1 | INDEX_MEMORY |   16 | 12832 |
|       2 | INDEX_MEMORY |   16 | 12832 |
+---------+--------------+------+-------+
4 rows in set (0.37 sec)
```

More complex queries, such as the two following SELECT statements using the memoryusage table, are possible:

```
mysql> SELECT SUM(used) as 'Data Memory Used, All Nodes'
    >     FROM memoryusage
    >     WHERE DATA_MEMORY = 'DATA_MEMORY';
+-----------------------------+
| Data Memory Used, All Nodes |
+-----------------------------+
|                        6460 |
+-----------------------------+
1 row in set (0.37 sec)

mysql> SELECT SUM(max) as 'Total IndexMemory Available'
    >     FROM memoryusage
    >     WHERE DATA_MEMORY = 'INDEX_MEMORY';
+-----------------------------+
| Total IndexMemory Available |
+-----------------------------+
|                       25664 |
+-----------------------------+
1 row in set (0.33 sec)
```

ndbinfo table and column names are case sensitive (as is the name of the ndbinfo database itself). These identifiers are in lowercase. Trying to use the wrong lettercase results in an error, as shown in this example:

```
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+
| node_id | uptime | status  | start_phase |
+---------+--------+---------+-------------+
|       1 |  13602 | STARTED |           0 |
|       2 |     16 | STARTED |           0 |
+---------+--------+---------+-------------+
2 rows in set (0.04 sec)

mysql> SELECT * FROM Nodes;
ERROR 1146 (42S02): Table 'ndbinfo.Nodes' doesn't exist
```

Beginning with MySQL Cluster NDB 7.1.7, mysqldump ignores ndbinfo entirely, and excludes it from any output. This is true even when using the --databases [295] or --all-databases [294] option.

MySQL Cluster also maintains tables in the INFORMATION_SCHEMA information database, including the FILES table which contains information about files used for MySQL Cluster Disk Data storage. For more information, see INFORMATION_SCHEMA Tables for MySQL Cluster.

The ndbinfo blocks Table

The blocks table is a static table which simply contains the names and internal IDs of all NDB kernel blocks (see NDB Kernel Blocks). It is for use by the other ndbinfo tables (most of which are actually views) in mapping block numbers to block names for producing human-readable output.

The following table provides information about the columns in the blocks table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
block_number	integer	Block number
block_name	string	Block name

To obtain a list of all block names, simply execute SELECT block_name FROM ndbinfo.blocks. Although this is a static table, its content can vary between different MySQL Cluster releases.

The ndbinfo cluster_operations Table

The cluster_operations table provides a per-operation (stateful primary key op) view of all activity in the MySQL Cluster from the point of view of the local data management (LQH) blocks (see The DBLQH Block).

The following table provides information about the columns in the cluster_operations table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
node_id	integer	Node ID of reporting LQH block
block_instance	integer	LQH block instance
transid	integer	Transaction ID
operation_type	string	Operation type (see text for possible values)
state	string	Operation state (see text for possible values)
tableid	integer	Table ID
fragmentid	integer	Fragment ID
client_node_id	integer	Client node ID
client_block_ref	integer	Client block reference
tc_node_id	integer	Transaction coordinator node ID
tc_block_no	integer	Transaction coordinator block number
tc_block_instance	integer	Transaction coordinator block instance

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's getTransactionId() method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The operation_type column can take any one of the values READ, READ-SH, READ-EX, INSERT, UPDATE, DELETE, WRITE, UNLOCK, REFRESH, SCAN, SCAN-SH, SCAN-EX, or <unknown>.

The state column can have any one of the values ABORT_QUEUED, ABORT_STOPPED, COMMITTED, COMMIT_QUEUED, COMMIT_STOPPED, COPY_CLOSE_STOPPED, COPY_FIRST_STOPPED, COPY_STOPPED, COPY_TUPKEY, IDLE, LOG_ABORT_QUEUED, LOG_COMMIT_QUEUED, LOG_COMMIT_QUEUED_WAIT_SIGNAL, LOG_COMMIT_WRITTEN, LOG_COMMIT_WRITTEN_WAIT_SIGNAL, LOG_QUEUED, PREPARED, PREPARED_RECEIVED_COMMIT, SCAN_CHECK_STOPPED, SCAN_CLOSE_STOPPED, SCAN_FIRST_STOPPED, SCAN_RELEASE_STOPPED, SCAN_STATE_USED, SCAN_STOPPED, SCAN_TUPKEY, STOPPED, TC_NOT_CONNECTED, WAIT_ACC, WAIT_ACC_ABORT, WAIT_AI_AFTER_ABORT, WAIT_ATTR, WAIT_SCAN_AI, WAIT_TUP, WAIT_TUPKEYINFO, WAIT_TUP_COMMIT, or WAIT_TUP_TO_ABORT. (If

the MySQL Server is running with ndbinfo_show_hidden [1934] enabled, you can view this list of states by selecting from the ndb$dblqh_tcconnect_state table, which is normally hidden.)

You can obtain the name of an NDB table from its table ID by checking the output of ndb_show_tables.

The fragid is the same as the partition number seen in the output of ndb_desc --extra-partition-info [1982] (short form -p).

In client_node_id and client_block_ref, client refers to a MySQL Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

This table was added in MySQL Cluster NDB 7.1.17.

The ndbinfo cluster_transactions Table

The cluster_transactions table shows information about all ongoing transactions in a MySQL Cluster.

The following table provides information about the columns in the cluster_transactions table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
node_id	integer	Node ID of transaction coordinator
block_instance	integer	TC block instance
transid	integer	Transaction ID
state	string	Operation state (see text for possible values)
count_operations	integer	Number of stateful primary key operations in transaction (includes reads with locks, as well as DML operations)
outstanding_operations	integer	Operations still being executed in local data management blocks
inactive_seconds	integer	Time spent waiting for API
client_node_id	integer	Client node ID
client_block_ref	integer	Client block reference

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's getTransactionId() method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The state column can have any one of the values CS_ABORTING, CS_COMMITTING, CS_COMMIT_SENT, CS_COMPLETE_SENT, CS_COMPLETING, CS_CONNECTED, CS_DISCONNECTED, CS_FAIL_ABORTED, CS_FAIL_ABORTING, CS_FAIL_COMMITTED, CS_FAIL_COMMITTING, CS_FAIL_COMPLETED, CS_FAIL_PREPARED, CS_PREPARE_TO_COMMIT, CS_RECEIVING, CS_REC_COMMITTING, CS_RESTART, CS_SEND_FIRE_TRIG_REQ, CS_STARTED, CS_START_COMMITTING, CS_START_SCAN, CS_WAIT_ABORT_CONF, CS_WAIT_COMMIT_CONF, CS_WAIT_COMPLETE_CONF, CS_WAIT_FIRE_TRIG_REQ. (If the MySQL Server is running with ndbinfo_show_hidden [1934] enabled, you can view this list of states by selecting from the ndb$dbtc_apiconnect_state table, which is normally hidden.)

In client_node_id and client_block_ref, client refers to a MySQL Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

This table was added in MySQL Cluster NDB 7.1.17.

The ndbinfo config_params Table

The config_params table is a static table which provides the names and internal ID numbers of all MySQL Cluster configuration parameters.

The following table provides information about the columns in the config_params table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
param_number	integer	The parameter's internal ID number
param_name	string	The name of the parameter

Although this is a static table, its content can vary between MySQL Cluster installations, since supported parameters can vary due to differences between software releases, cluster hardware configurations, and other factors.

The ndbinfo counters Table

The counters table provides running totals of events such as reads and writes for specific kernel blocks and data nodes. Counts are kept from the most recent node start or restart; a node start or restart resets all counters on that node. Not all kernel blocks have all types of counters.

The following table provides information about the columns in the counters table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
node_id	integer	The data node ID
block_name	string	Name of the associated NDB kernel block (see NDB Kernel Blocks).
block_instance	integer	Block instance
counter_id	integer	The counter's internal ID number; normally an integer between 1 and 10, inclusive.
counter_name	string	The name of the counter. See text for names of individual counters and the NDB kernel block with which each counter is associated.
val	integer	The counter's value

Each counter is associated with a particular NDB kernel block. Prior to MySQL Cluster NDB 7.2.0, this was limited to either the DBLQH kernel block or the DBTC kernel block.

The OPERATIONS counter is associated with the DBLQH (local query handler) kernel block (see The DBLQH Block).

The ATTRINFO, TRANSACTIONS, COMMITS, READS, SIMPLE_READS, WRITES, ABORTS, TABLE_SCANS, and RANGE_SCANS counters are associated with the DBTC (transaction co-ordinator) kernel block (see The DBTC Block).

MySQL Cluster NDB 7.2.0, as part of its implementation of distributed pushed-down joins, adds the LOCAL_TABLE_SCANS_SENT, READS_RECEIVED, PRUNED_RANGE_SCANS_RECEIVED, RANGE_SCANS_RECEIVED, LOCAL_READS_SENT, CONST_PRUNED_RANGE_SCANS_RECEIVED, LOCAL_RANGE_SCANS_SENT, REMOTE_READS_SENT, REMOTE_RANGE_SCANS_SENT, READS_NOT_FOUND, SCAN_BATCHES_RETURNED, TABLE_SCANS_RECEIVED, and SCAN_ROWS_RETURNED counters. These counters are associated with the DBSPJ (select push-down join) kernel block (see The DBSPJ Block).

The ndbinfo diskpagebuffer Table

The diskpagebuffer table provides statistics about disk page buffer usage by MySQL Cluster Disk Data tables.

The following table provides information about the columns in the diskpagebuffer table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
node_id	integer	The data node ID
block_instance	integer	Block instance
pages_written	integer	Number of pages written to disk.
pages_written_lcp	integer	Number of pages written by local checkpoints.
pages_read	integer	Number of pages read from disk
log_waits	integer	Number of page writes waiting for log to be written to disk
page_requests_direct_return	integer	Number of requests for pages that were available in buffer
page_requests_wait_queue	integer	Number of requests that had to wait for pages to become available in buffer
page_requests_wait_io	integer	Number of requests that had to be read from pages on disk (pages were unavailable in buffer)

You can use this table with MySQL Cluster Disk Data tables to determine whether DiskPageBufferMemory [1856] is sufficiently large to allow data to be read from the buffer rather from disk; minimizing disk seeks can help improve performance of such tables.

You can determine the proportion of reads from DiskPageBufferMemory [1856] to the total number of reads using a query such as this one, which obtains this ratio as a percentage:

```
SELECT
  node_id,
  100 * page_requests_direct_return /
    (page_requests_direct_return + page_requests_wait_io)
      AS hit_ratio
FROM ndbinfo.diskpagebuffer;
```

The result from this query should be similar to what is shown here, with one row for each data node in the cluster (in this example, the cluster has 4 data nodes):

```
+---------+-----------+
| node_id | hit_ratio |
+---------+-----------+
|       5 |   97.6744 |
|       6 |   97.6879 |
|       7 |   98.1776 |
|       8 |   98.1343 |
+---------+-----------+
4 rows in set (0.00 sec)
```

hit_ratio values approaching 100% indicate that only a very small number of reads are being made from disk rather than from the buffer, which means that Disk Data read performance is approaching an optimum level. If any of these values are less than 95%, this is a strong indicator that the setting for DiskPageBufferMemory [1856] needs to be increased in the config.ini file.

Note

A change in DiskPageBufferMemory [1856] requires a rolling restart of all of the cluster's data nodes before it takes effect.

The ndbinfo logbuffers Table

The logbuffer table provides information on MySQL Cluster log buffer usage.

The following table provides information about the columns in the logbuffers table. For each column, the table shows the name, data type, and a brief description.

Column Name	Type	Remarks
node_id	integer	The ID of this data node.
log_type	string	Type of log; one of: REDO or DD-UNDO.
log_id	integer	The log ID.
log_part	integer	The log part number.
total	integer	Total space available for this log.
used	integer	Space used by this log.

The ndbinfo logspaces Table

This table provides information about MySQL Cluster log space usage.

The following table provides information about the columns in the logspaces table. For each column, the table shows the name, data type, and a brief description.

Column Name	Type	Remarks
node_id	integer	The ID of this data node.
log_type	string	Type of log; one of: REDO or DD-UNDO.
log_id	integer	The log ID.
log_part	integer	The log part number.
total	integer	Total space available for this log.
used	integer	Space used by this log.

The ndbinfo memoryusage Table

Querying this table provides information similar to that provided by the ALL REPORT MemoryUsage command in the ndb_mgm client, or logged by ALL DUMP 1000.

The following table provides information about the columns in the memoryusage table in MySQL Cluster NDB 7.1.3 and later. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
node_id	integer	The node ID of this data node.
memory_type	string	One of DATA_MEMORY or INDEX_MEMORY.
used	integer	Number of bytes currently used for data memory or index memory by this data node.
used_pages	integer	Number of pages currently used for data memory or index memory by this data node; see text.
total	integer	Total number of bytes of data memory or index memory available for this data node; see text.
total_pages	integer	Total number of memory pages available for data memory or index memory on this data node; see text.

The total column represents the total amount of memory in bytes available for the given resource (data memory or index memory) on a particular data node. This number should be approximately equal to the setting of the corresponding configuration parameter in the config.ini file.

Suppose that the cluster has 2 data nodes having node IDs 1 and 2, and the config.ini file contains the following:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
```

The following query shows approximately the same values:

```
mysql> SELECT node_id, memory_type, total
     > FROM ndbinfo.memoryusage;
+---------+--------------+-----------+
| node_id | memory_type  | total     |
+---------+--------------+-----------+
|       1 | Data memory  | 104857600 |
|       1 | Index memory | 105119744 |
|       2 | Data memory  | 104857600 |
|       2 | Index memory | 105119744 |
+---------+--------------+-----------+
4 rows in set (0.30 sec)
```

In this case, the total column values for index memory are slightly higher than the value set of IndexMemory [1819] due to internal rounding.

For the used_pages and total_pages columns, resources are measured in pages, which are 32K in size for DataMemory [1817] and 8K for IndexMemory [1819].

MySQL Cluster NDB 7.1.2 and earlier. The the remainder of this section provides information about the memoryusage table as implemented prior to MySQL Cluster NDB 7.1.3. (If you are using MySQL Cluster NDB 7.1.3 or later, refer to the beginning of this section.) For each column, the table shown here provides the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
node_id	integer	The node ID of this data node.
memory_type	string	One of DATA_MEMORY or INDEX_MEMORY
used	integer	Number of memory pages used; see text.
max	integer	Total number of memory pages available; see text.

For the used and max columns, resources are measured in pages, which (in MySQL Cluster NDB 7.1.2 and earlier) are 16K in size for DataMemory [1817] and 8K for IndexMemory [1819].
This example shows how to use this information in obtaining totals for DataMemory [1817], IndexMemory [1819], or both, which you can do by summing across data nodes and table columns, like this:

```
mysql> USE ndbinfo;
Database changed
mysql> SET @IPAGE := 8 * 1024;
Query OK, 0 rows affected (0.03 sec)

mysql> SET @DPAGE := 2 * @IPAGE;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT
    ->     @DPAGE * SUM(used) as 'Total DataMemory Used',
    ->     @DPAGE * SUM(max) as 'Total DataMemory Available',
    ->     @DPAGE * SUM(used) DIV COUNT(*) as 'Average DataMemory Used Per Node',
    ->     @DPAGE * SUM(max) DIV COUNT(*) as 'Average DataMemory Available Per Node'
```

```
    ->         FROM memoryusage WHERE memory_type = 'DATA_MEMORY'\G
*************************** 1. row ***************************
                 Total DataMemory Used: 106102784
           Total DataMemory Available: 209977344
     Average DataMemory Used Per Node: 53051392
Average DataMemory Available Per Node: 104988672
1 row in set (0.34 sec)

mysql> SELECT
    ->     @IPAGE * SUM(used) as 'Total IndexMemory Used',
    ->     @IPAGE * SUM(max) as 'Total IndexMemory Available',
    ->     @IPAGE * SUM(used) DIV COUNT(*) as 'Average IndexMemory Used Per Node',
    ->     @IPAGE * SUM(max) DIV COUNT(*) as 'Average IndexMemory Available Per Node'
    ->     FROM memoryusage WHERE memory_type = 'INDEX_MEMORY'\G
*************************** 1. row ***************************
                 Total IndexMemory Used: 376832
           Total IndexMemory Available: 210239488
     Average IndexMemory Used Per Node: 188416
Average IndexMemory Available Per Node: 105119744
1 row in set (0.33 sec)
```

(We use `DIV` rather than `/` in both queries so that the results in all of the output columns are integers.)

Prior to MySQL Cluster NDB 7.1.2, the `memory_type` column was named `DATA_MEMORY`. (Bug #50926)

The `ndbinfo nodes` Table

This table contains information on the status of data nodes. For each data node that is running in the cluster, a corresponding row in this table provides the node's node ID, status, and uptime. For nodes that are starting, it also shows the current start phase.

The following table provides information about the columns in the `nodes` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
`node_id`	integer	The data node's unique node ID in the cluster.
`uptime`	integer	Time since the node was last started, in seconds.
`status`	string	Current status of the data node; see text for possible values.
`start_phase`	integer	If the data node is starting, the current start phase.
`config_generation`	integer	The version of the cluster configuration file in use on this data node.

The `uptime` column shows the time in seconds that this node has been running since it was last started or restarted. This is a `BIGINT` value. This figure includes the time actually needed to start the node; in other words, this counter starts running the moment that `ndbd` or `ndbmtd` is first invoked; thus, even for a node that has not yet finished starting, `uptime` may show a non-zero value.

The `status` column shows the node's current status. This is one of: `NOTHING`, `CMVMI`, `STARTING`, `STARTED`, `SINGLEUSER`, `STOPPING_1`, `STOPPING_2`, `STOPPING_3`, or `STOPPING_4`. When the status is `STARTING`, you can see the current start phase in the `start_phase` column (see later in this section). `SINGLEUSER` is displayed in the `status` column for all data nodes when the cluster is in single user mode (see MySQL Cluster Single User Mode). Seeing one of the `STOPPING` states does not necessarily mean that the node is shutting down but can mean rather that it is entering a new state; for example, if you put the cluster in single user mode, you can sometimes see data nodes report their state briefly as `STOPPING_2` before the status changes to `SINGLEUSER`.

The start_phase column uses the same range of values as those used in the output of the ndb_mgm client *node_id* STATUS command (see Commands in the MySQL Cluster Management Client). If the node is not currently starting, then this column shows 0. For a listing of MySQL Cluster start phases with descriptions, see Summary of MySQL Cluster Start Phases.

The config_generation column was added in MySQL Cluster NDB 7.0.24 and MySQL Cluster NDB 7.1.13. This column shows which version of the cluster configuration is in effect on each data node. This can be useful when performing a rolling restart of the cluster in order to make changes in configuration parameters. For example, from the output of the following SELECT statement, you can see that node 3 is not yet using the latest version of the cluster configuration (6) although nodes 1, 2, and 4 are doing so:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+
|       1 |  10462 | STARTED |           0 |                 6 |
|       2 |  10460 | STARTED |           0 |                 6 |
|       3 |  10457 | STARTED |           0 |                 5 |
|       4 |  10455 | STARTED |           0 |                 6 |
+---------+--------+---------+-------------+-------------------+
2 rows in set (0.04 sec)
```

Therefore, for the case just shown, you should restart node 3 to complete the rolling restart of the cluster.

Note

When upgrading to MySQL Cluster NDB 7.0.24 or MySQL Cluster NDB 7.1.13 from a previous version of MySQL Cluster, you should run mysql_upgrade on all MySQL Servers that should connect to the cluster, in order to enable support for the new config_generation column. Otherwise, when you attempt to access this table, you get the warning `Table 'ndb$nodes' is defined differently in NDB, there are more columns available...`

Nodes that are stopped are not accounted for in this table. Suppose that you have a MySQL Cluster with 4 data nodes (node IDs 1, 2, 3 and 4), and all nodes are running normally, then this table contains 4 rows, 1 for each data node:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+
|       1 |  11776 | STARTED |           0 |                 6 |
|       2 |  11774 | STARTED |           0 |                 6 |
|       3 |  11771 | STARTED |           0 |                 6 |
|       4 |  11769 | STARTED |           0 |                 6 |
+---------+--------+---------+-------------+-------------------+
4 rows in set (0.04 sec)
```

If you shut down one of the nodes, only the nodes that are still running are represented in the output of this SELECT statement, as shown here:

```
ndb_mgm> 2 STOP
Node 2: Node shutdown initiated
Node 2: Node shutdown completed.
Node 2 has shutdown.
```

```
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+
|       1 |  11807 | STARTED |           0 |                 6 |
```

```
|       3 |  11802 | STARTED |           0 |                 6 |
|       4 |  11800 | STARTED |           0 |                 6 |
+---------+--------+---------+-------------+-------------------+
3 rows in set (0.02 sec)
```

The ndbinfo pools Table

Important

This table was part of the original ndbinfo implementation, but was later removed (in MySQL Cluster NDB 7.1.3). The information in this section is now obsolete, and subject to removal in a future version of the documentation.

The pools table was originally intended to provide information about NDB memory pool usage, but was later removed.

For each column, this table shows the name, data type, and a brief description of each ndbinfo.pools column (as it appeared prior to MySQL Cluster NDB 7.1.3). Additional information can be found in the notes afterward.

Column Name	Type	Remarks
node_id	integer	The data node's node ID.
block_name	string	Name of the NDB kernel block using this pool.
block_instance	integer	Kernel block instance ID.
pool_name	string	The name of the pool.
used	integer	Amount of the pool in use.
total	integer	Total size of the pool.
high	integer	The maximum used from this pool (since the node was last started).
entry_size	integer	The size of each object, in bytes.
param_name1	string	Name of a configuration parameter associated with this pool (or NULL); see text.
param_name2	string	Name of a configuration parameter associated with this pool (or NULL); see text.
param_name3	string	Name of a configuration parameter associated with this pool (or NULL); see text.
param_name4	string	Name of a configuration parameter associated with this pool (or NULL); see text.

The columns param_name1, param_name2, param_name3, and param_name4 contain names of configuration parameters that are associated with a given pool. If no parameters are associated with the pool, then all 4 of these columns are NULL. For pools that are associated with configuration parameters, these columns are filled with non-NULL values, but not in any particular order.

You can use a query such as the one shown here to generate a table showing the associations of pools, NDB kernel blocks, and (where applicable) configuration parameters:

```
SELECT
    DISTINCT(pool_name) as 'Pool',
    block_name as 'Block',
    IF(
        (param_name1 && param_name2 && param_name3 && param_name4) IS NULL,
        '[NONE]',
        REPLACE(
            TRIM(
                CONCAT(
                    IFNULL(param_name1, ''),
```

```
                    IFNULL(CONCAT(' ', param_name2), ''),
                    IFNULL(CONCAT(' ', param_name3), ''),
                    IFNULL(CONCAT(' ', param_name4), '')
                )
            ), ' ', ', '
        )
    ) as 'Parameter(s)'
FROM pools ORDER BY pool_name;
```

You may also find the following stored procedure useful. It returns a list of pools associated with a given configuration parameter, along with the kernel blocks to which these pools belong. You can see here the statement used to create this stored procedure along with sample output for some typical parameters:

```
mysql> DELIMITER |
mysql> CREATE PROCEDURE get_pools (p VARCHAR(50))
    -> BEGIN
    ->     SELECT
    ->         DISTINCT(pool_name) as Pool,
    ->         block_name as Block
    ->     FROM ndbinfo.pools
    ->     WHERE p
    ->           IN (param_name1, param_name2, param_name3, param_name4)
    .>     ORDER BY Pool;
    -> END
    -> |
Query OK, 0 rows affected (0.02 sec)

mysql> DELIMITER ;

The ndbinfo resources Table

This table provides information about data node resource availability and usage.

These resources are sometimes known as *super-pools*.

The following table provides information about the columns in the resources table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
node_id	integer	The unique node ID of this data node.
resource_name	string	Name of the resource; see text.
reserved	integer	The amount reserved for this resource.
used	integer	The amount actually used by this resource.
max	integer	The maximum amount of this resource used, since the node was last started.

The resource_name can be one of RESERVED, DISK_OPERATIONS, DISK_RECORDS, DATA_MEMORY, JOBBUFFER, FILE_BUFFERS, or TRANSPORTER_BUFFERS.

The ndbinfo server_operations Table

The server_operations table contains entries for all ongoing NDB operations that the current SQL node (MySQL Server) is currently involved in. It effectively is a subset of the the cluster_operations table, in which operations for other SQL and API nodes are not shown.

The following table provides information about the columns in the server_operations table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
mysql_connection_id	integer	MySQL Server connection ID
node_id	integer	Node ID
block_instance	integer	Block instance
transid	integer	Transaction ID
operation_type	string	Operation type (see text for possible values)
state	string	Operation state (see text for possible values)
tableid	integer	Table ID
fragmentid	integer	Fragment ID
client_node_id	integer	Client node ID
client_block_ref	integer	Client block reference
tc_node_id	integer	Transaction coordinator node ID
tc_block_no	integer	Transaction coordinator block number
tc_block_instance	integer	Transaction coordinator block instance

The mysql_connection_id is the same as the connection or session ID shown in the output of SHOW PROCESSLIST. It is obtained from the INFORMATION_SCHEMA table NDB_TRANSID_MYSQL_CONNECTION_MAP.

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's getTransactionId() method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The operation_type column can take any one of the values READ, READ-SH, READ-EX, INSERT, UPDATE, DELETE, WRITE, UNLOCK, REFRESH, SCAN, SCAN-SH, SCAN-EX, or <unknown>.

The state column can have any one of the values ABORT_QUEUED, ABORT_STOPPED, COMMITTED, COMMIT_QUEUED, COMMIT_STOPPED, COPY_CLOSE_STOPPED,

COPY_FIRST_STOPPED, COPY_STOPPED, COPY_TUPKEY, IDLE, LOG_ABORT_QUEUED, LOG_COMMIT_QUEUED, LOG_COMMIT_QUEUED_WAIT_SIGNAL, LOG_COMMIT_WRITTEN, LOG_COMMIT_WRITTEN_WAIT_SIGNAL, LOG_QUEUED, PREPARED, PREPARED_RECEIVED_COMMIT, SCAN_CHECK_STOPPED, SCAN_CLOSE_STOPPED, SCAN_FIRST_STOPPED, SCAN_RELEASE_STOPPED, SCAN_STATE_USED, SCAN_STOPPED, SCAN_TUPKEY, STOPPED, TC_NOT_CONNECTED, WAIT_ACC, WAIT_ACC_ABORT, WAIT_AI_AFTER_ABORT, WAIT_ATTR, WAIT_SCAN_AI, WAIT_TUP, WAIT_TUPKEYINFO, WAIT_TUP_COMMIT, or WAIT_TUP_TO_ABORT. (If the MySQL Server is running with ndbinfo_show_hidden [1934] enabled, you can view this list of states by selecting from the ndb$dblqh_tcconnect_state table, which is normally hidden.)

You can obtain the name of an NDB table from its table ID by checking the output of ndb_show_tables.

The fragid is the same as the partition number seen in the output of ndb_desc --extra-partition-info [1982] (short form -p).

In client_node_id and client_block_ref, client refers to a MySQL Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

This table was added in MySQL Cluster NDB 7.1.17.

The ndbinfo server_transactions Table

The server_transactions table is subset of the cluster_transactions table, but includes only those transactions in which the current SQL node (MySQL Server) is a participant, while including the relevant connection IDs.

The following table provides information about the columns in the server_transactions table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
mysql_connection_id	integer	MySQL Server connection ID
node_id	integer	Transaction coordinator node ID
block_instance	integer	Transaction coordinator block instance
transid	integer	Transaction ID
state	string	Operation state (see text for possible values)
count_operations	integer	Number of stateful operations in the transaction
outstanding_operations	integer	Operations still being executed by local data management layer (LQH blocks)
inactive_seconds	integer	Time spent waiting for API
client_node_id	integer	Client node ID
client_block_ref	integer	Client block reference

The mysql_connection_id is the same as the connection or session ID shown in the output of SHOW PROCESSLIST. It is obtained from the INFORMATION_SCHEMA table NDB_TRANSID_MYSQL_CONNECTION_MAP.

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's getTransactionId() method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The state column can have any one of the values CS_ABORTING, CS_COMMITTING, CS_COMMIT_SENT, CS_COMPLETE_SENT, CS_COMPLETING, CS_CONNECTED, CS_DISCONNECTED, CS_FAIL_ABORTED, CS_FAIL_ABORTING, CS_FAIL_COMMITTED, CS_FAIL_COMMITTING, CS_FAIL_COMPLETED, CS_FAIL_PREPARED, CS_PREPARE_TO_COMMIT, CS_RECEIVING,

CS_REC_COMMITTING, CS_RESTART, CS_SEND_FIRE_TRIG_REQ, CS_STARTED, CS_START_COMMITTING, CS_START_SCAN, CS_WAIT_ABORT_CONF, CS_WAIT_COMMIT_CONF, CS_WAIT_COMPLETE_CONF, CS_WAIT_FIRE_TRIG_REQ. (If the MySQL Server is running with ndbinfo_show_hidden [1934] enabled, you can view this list of states by selecting from the ndb$dbtc_apiconnect_state table, which is normally hidden.)

In client_node_id and client_block_ref, client refers to a MySQL Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

This table was added in MySQL Cluster NDB 7.1.17.

The ndbinfo threadblocks Table

The threadblocks table associates data nodes, threads, and instances of NDB kernel blocks.

The following table provides information about the columns in the threadblocks table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
node_id	integer	Node ID
thr_no	integer	Thread ID
block_name	string	Block name
block_instance	integer	Block instance number

The block_name is one of the values found in the block_name column when selecting from the ndbinfo.blocks table. Although the list of possible values is static for a given MySQL Cluster release, the list may vary between releases.

This table was added in MySQL Cluster NDB 7.1.17.

The ndbinfo threadstat Table

The threadstat table provides a rough snapshot of statistics for threads running in the NDB kernel.

The following table provides information about the columns in the threadstat table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
node_id	integer	Node ID
thr_no	integer	Thread ID
thr_nm	string	Thread name
c_loop	string	Number of loops in main loop
c_exec	string	Number of signals executed
c_wait	string	Number of times waiting for additional input
c_l_sent_prioa	integer	Number of priority A signals sent to own node
c_l_sent_priob	integer	Number of priority B signals sent to own node
c_r_sent_prioa	integer	Number of priority A signals sent to remote node
c_r_sent_priob	integer	Number of priority B signals sent to remote node
os_tid	integer	OS thread ID

Column Name	Type	Remarks
os_now	integer	OS time (ms)
os_ru_utime	integer	OS user CPU time (µs)
os_ru_stime	integer	OS system CPU time (µs)
os_ru_minflt	integer	OS page reclaims (soft page faults)
os_ru_majflt	integer	OS page faults (hard page faults)
os_ru_nvcsw	integer	OS voluntary context switches
os_ru_nivcsw	integer	OS involuntary context switches

os_time uses the system gettimeofday() call.

The values of the os_ru_utime, os_ru_stime, os_ru_minflt, os_ru_majflt, os_ru_nvcsw, and os_ru_nivcsw columns are obtained using the system getrusage() call, or the equivalent.

Since this table contains counts taken at a given point in time, for best results it is necessary to query this table periodically and store the results in an intermediate table or tables. The MySQL Server's Event Scheduler can be employed to automate such monitoring. For more information, see Using the Event Scheduler.

This table was added in MySQL Cluster NDB 7.1.17.

The ndbinfo transporters Table

This table contains information about NDB transporters.

The following table provides information about the columns in the transporters table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
node_id	integer	This data node's unique node ID in the cluster.
remote_node_id	integer	The remote data node's node ID.
status	string	Status of the connection.
remote_address	string	Name or IP address of the remote host
bytes_sent	integer	Number of bytes sent using this connection
bytes_received		Number of bytes received using this connection

For each running data node in the cluster, the transporters table displays a row showing the status of each of that node's connections with all nodes in the cluster, *including itself*. This information is shown in the table's *status* column, which can have any one of the following values: CONNECTING, CONNECTED, DISCONNECTING, or DISCONNECTED.

Connections to API and management nodes which are configured but not currently connected to the cluster are shown with status DISCONNECTED. Rows where the node_id is that of a data nodes which is not currently connected are not shown in this table. (This is similar omission of disconnected nodes in the ndbinfo.nodes table.

The remote_address, bytes_sent, and bytes_received columns were added in MySQL Cluster NDB 7.0.36 and MySQL Cluster NDB 7.1.25. The remote_address is the the host name or address for the node whose ID is shown in the remote_node_id column. The bytes_sent from this node and bytes_received by this node are the numbers, respectively, of bytes sent and received by the node using this connection since it was established; for nodes whose status is CONNECTING or DISCONNECTED, these columns always display 0.

Assume you have a 5-node cluster consisting of 2 data nodes, 2 SQL nodes, and 1 management node, as shown in the output of the SHOW command in the ndb_mgm client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @10.100.10.1  (5.1.63-ndb-7.1.25, Nodegroup: 0, Master)
id=2    @10.100.10.2  (5.1.63-ndb-7.1.25, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10   @10.100.10.10  (5.1.63-ndb-7.1.25)

[mysqld(API)]   2 node(s)
id=20   @10.100.10.20  (5.1.63-ndb-7.1.25)
id=21   @10.100.10.21  (5.1.63-ndb-7.1.25)
```

There are 10 rows in the transporters table—5 for the first data node, and 5 for the second—assuming that all data nodes are running, as shown here:

```
mysql> SELECT * FROM transporters\G
*************************** 1. row ***************************
       node_id: 1
remote_node_id: 1
        status: CONNECTED
remote_address: -
    bytes_sent: 73152808
bytes_received: 20483274
*************************** 2. row ***************************
       node_id: 1
remote_node_id: 2
        status: CONNECTED
remote_address: 10.100.10.2
    bytes_sent: 78542086
bytes_received: 52199244
*************************** 3. row ***************************
       node_id: 1
remote_node_id: 10
        status: CONNECTED
remote_address: 10.100.10.10
    bytes_sent: 414291808
bytes_received: 123137928
*************************** 4. row ***************************
       node_id: 1
remote_node_id: 20
        status: CONNECTED
remote_address: 10.100.10.20
    bytes_sent: 11506400
bytes_received: 94987842
*************************** 5. row ***************************
       node_id: 1
remote_node_id: 21
        status: CONNECTED
remote_address: 10.100.10.21
    bytes_sent: 114691452
bytes_received: 95030012
*************************** 6. row ***************************
       node_id: 2
remote_node_id: 1
        status: CONNECTED
remote_address: 10.100.10.1
    bytes_sent: 30298240
bytes_received: 28990996

*************************** 7. row ***************************
       node_id: 2
remote_node_id: 2
        status: CONNECTED
remote_address: -
    bytes_sent: 78521888
bytes_received: 21986470
```

```
*************************** 8. row ***************************
       node_id: 2
remote_node_id: 10
        status: CONNECTED
remote_address: 10.100.10.10
    bytes_sent: 123176964
bytes_received: 142915844
*************************** 9. row ***************************
       node_id: 5
remote_node_id: 20
        status: CONNECTED
remote_address: 10.100.10.20
bytes_received: 142941844
    bytes_sent: 78507368
*************************** 10. row ***************************
       node_id: 2
remote_node_id: 21
        status: CONNECTED
remote_address: 10.100.10.21
bytes_received: 21982304
    bytes_sent: 94198784
10 rows in set (0.04 sec)
```

If you shut down one of the data nodes in this cluster using the `ndb_mgm` client `STOP` command, then repeat the query, this table now shows only 5 rows—1 row for each connection from the remaining management node to another node, including both itself and the data node that is currently offline, as shown here:

```
mysql> SELECT node_id, remote_mode_id, status
    -> FROM transporters;

*************************** 1. row ***************************
       node_id: 1
remote_node_id: 1
        status: CONNECTED
remote_address: -
*************************** 2. row ***************************
       node_id: 1
remote_node_id: 2
        status: CONNECTED
remote_address: 10.100.10.2
*************************** 3. row ***************************
       node_id: 1
remote_node_id: 10
        status: CONNECTED
remote_address: 10.100.10.10
*************************** 4. row ***************************
       node_id: 1
remote_node_id: 20
        status: DISCONNECTED
remote_address: 10.100.10.20
*************************** 5. row ***************************
       node_id: 1
remote_node_id: 21
        status: CONNECTED
remote_address: 10.100.10.21
5 rows in set (0.02 sec)
```

MySQL Cluster Security Issues

This section discusses security considerations to take into account when setting up and running MySQL Cluster.

Topics covered in this section include the following:

- MySQL Cluster and network security issues
- Configuration issues relating to running MySQL Cluster securely
- MySQL Cluster and the MySQL privilege system

- MySQL standard security procedures as applicable to MySQL Cluster

MySQL Cluster Security and Networking Issues

In this section, we discuss basic network security issues as they relate to MySQL Cluster. It is extremely important to remember that MySQL Cluster “out of the box” is not secure; you or your network administrator must take the proper steps to ensure that your cluster cannot be compromised over the network.

Cluster communication protocols are inherently insecure, and no encryption or similar security measures are used in communications between nodes in the cluster. Because network speed and latency have a direct impact on the cluster's efficiency, it is also not advisable to employ SSL or other encryption to network connections between nodes, as such schemes will effectively slow communications.

It is also true that no authentication is used for controlling API node access to a MySQL Cluster. As with encryption, the overhead of imposing authentication requirements would have an adverse impact on Cluster performance.

In addition, there is no checking of the source IP address for either of the following when accessing the cluster:

- SQL or API nodes using “free slots” created by empty `[mysqld]` or `[api]` sections in the `config.ini` file

  This means that, if there are any empty `[mysqld]` or `[api]` sections in the `config.ini` file, then any API nodes (including SQL nodes) that know the management server's host name (or IP address) and port can connect to the cluster and access its data without restriction. (See MySQL Cluster and MySQL Privileges, for more information about this and related issues.)

  Note

  You can exercise some control over SQL and API node access to the cluster by specifying a `HostName` parameter for all `[mysqld]` and `[api]` sections in the `config.ini` file. However, this also means that, should you wish to connect an API node to the cluster from a previously unused host, you need to add an `[api]` section containing its host name to the `config.ini` file.

  More information is available elsewhere in this chapter [1865] about the `HostName` parameter. Also see Quick Test Setup of MySQL Cluster, for configuration examples using `HostName` with API nodes.

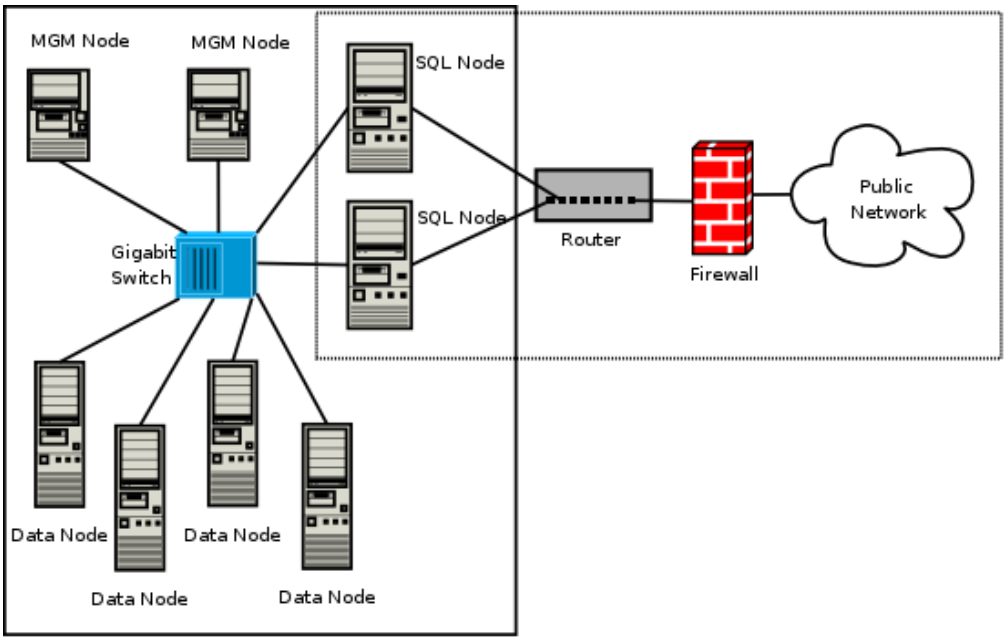
- Any `ndb_mgm` client

  This means that any cluster management client that is given the management server's host name (or IP address) and port (if not the standard port) can connect to the cluster and execute any management client command. This includes commands such as `ALL STOP` and `SHUTDOWN`.

For these reasons, it is necessary to protect the cluster on the network level. The safest network configuration for Cluster is one which isolates connections between Cluster nodes from any other network communications. This can be accomplished by any of the following methods:

1. Keeping Cluster nodes on a network that is physically separate from any public networks. This option is the most dependable; however, it is the most expensive to implement.

   We show an example of a MySQL Cluster setup using such a physically segregated network here:



This setup has two networks, one private (solid box) for the Cluster management servers and data nodes, and one public (dotted box) where the SQL nodes reside. (We show the management and data nodes connected using a gigabit switch since this provides the best performance.) Both networks are protected from the outside by a hardware firewall, sometimes also known as a *network-based firewall*.

This network setup is safest because no packets can reach the cluster's management or data nodes from outside the network—and none of the cluster's internal communications can reach the outside—without going through the SQL nodes, as long as the SQL nodes do not permit any packets to be forwarded. This means, of course, that all SQL nodes must be secured against hacking attempts.

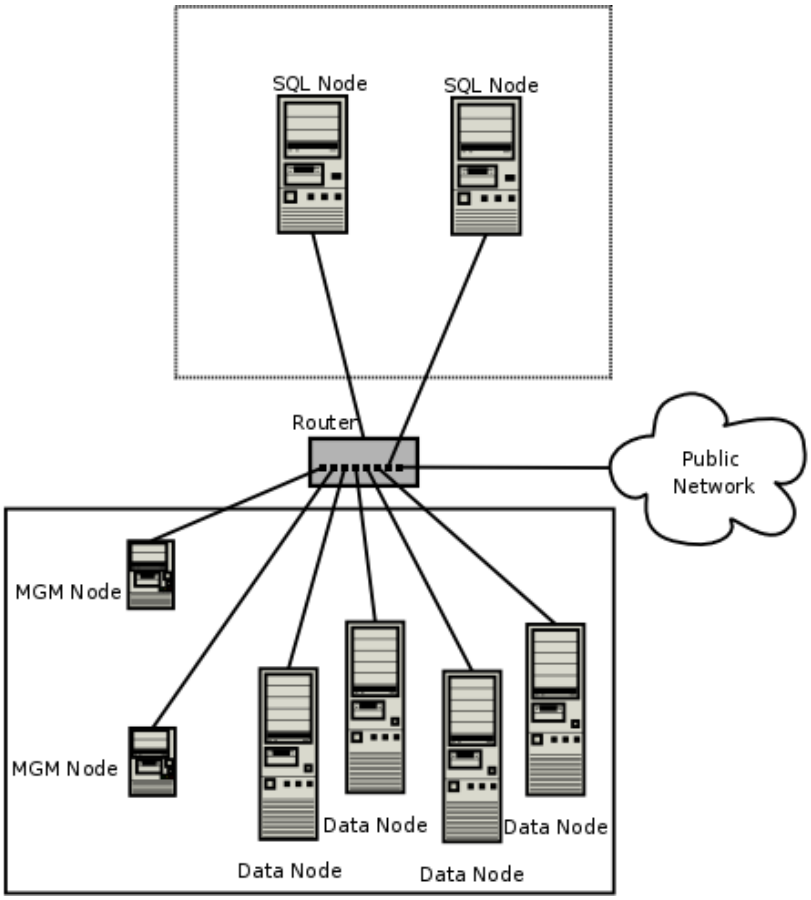
Important

With regard to potential security vulnerabilities, an SQL node is no different from any other MySQL server. See Making MySQL Secure Against Attackers, for a description of techniques you can use to secure MySQL servers.

2. Using one or more software firewalls (also known as *host-based firewalls*) to control which packets pass through to the cluster from portions of the network that do not require access to it. In this type of setup, a software firewall must be installed on every host in the cluster which might otherwise be accessible from outside the local network.

   The host-based option is the least expensive to implement, but relies purely on software to provide protection and so is the most difficult to keep secure.

   This type of network setup for MySQL Cluster is illustrated here:



Using this type of network setup means that there are two zones of MySQL Cluster hosts. Each cluster host must be able to communicate with all of the other machines in the cluster, but only those hosting SQL nodes (dotted box) can be permitted to have any contact with the outside, while those in the zone containing the data nodes and management nodes (solid box) must be isolated from any machines that are not part of the cluster. Applications using the cluster and user of those applications must *not* be permitted to have direct access to the management and data node hosts.

To accomplish this, you must set up software firewalls that limit the traffic to the type or types shown in the following table, according to the type of node that is running on each cluster host computer:

Type of Node to be Accessed	**Traffic to Permit**
SQL or API node	• It originates from the IP address of a management or data node (using any TCP or UDP port). • It originates from within the network in which the cluster resides and is on the port that your application is using.
Data node or Management node	• It originates from the IP address of a management or data node (using any TCP or UDP port). • It originates from the IP address of an SQL or API node.

Any traffic other than that shown in the table for a given node type should be denied.

The specifics of configuring a firewall vary from firewall application to firewall application, and are beyond the scope of this Manual. `iptables` is a very common and reliable firewall application, which is often used with APF as a front end to make configuration easier. You can (and should) consult the documentation for the software firewall that you employ, should you choose to

implement a MySQL Cluster network setup of this type, or of a “mixed” type as discussed under the next item.

3. It is also possible to employ a combination of the first two methods, using both hardware and software to secure the cluster—that is, using both network-based and host-based firewalls. This is between the first two schemes in terms of both security level and cost. This type of network setup keeps the cluster behind the hardware firewall, but permits incoming packets to travel beyond the router connecting all cluster hosts to reach the SQL nodes.

   One possible network deployment of a MySQL Cluster using hardware and software firewalls in combination is shown here:

   In this case, you can set the rules in the hardware firewall to deny any external traffic except to SQL nodes and API nodes, and then permit traffic to them only on the ports required by your application.

Whatever network configuration you use, remember that your objective from the viewpoint of keeping the cluster secure remains the same—to prevent any unessential traffic from reaching the cluster while ensuring the most efficient communication between the nodes in the cluster.

Because MySQL Cluster requires large numbers of ports to be open for communications between nodes, the recommended option is to use a segregated network. This represents the simplest way to prevent unwanted traffic from reaching the cluster.

Note

If you wish to administer a MySQL Cluster remotely (that is, from outside the local network), the recommended way to do this is to use `ssh` or another secure login shell to access an SQL node host. From this host, you can then run the management client to access the management server safely, from within the Cluster's own local network.

Even though it is possible to do so in theory, it is *not* recommended to use `ndb_mgm` to manage a Cluster directly from outside the local network on which the Cluster is running. Since neither authentication nor encryption takes place between the management client and the management server, this represents an

extremely insecure means of managing the cluster, and is almost certain to be compromised sooner or later.

MySQL Cluster and MySQL Privileges

In this section, we discuss how the MySQL privilege system works in relation to MySQL Cluster and the implications of this for keeping a MySQL Cluster secure.

Standard MySQL privileges apply to MySQL Cluster tables. This includes all MySQL privilege types (`SELECT` [627] privilege, `UPDATE` [628] privilege, `DELETE` [626] privilege, and so on) granted on the database, table, and column level. As with any other MySQL Server, user and privilege information is stored in the `mysql` system database. The SQL statements used to grant and revoke privileges on `NDB` tables, databases containing such tables, and columns within such tables are identical in all respects with the `GRANT` and `REVOKE` statements used in connection with database objects involving any (other) MySQL storage engine. The same thing is true with respect to the `CREATE USER` and `DROP USER` statements.

It is important to keep in mind that, by default, the MySQL grant tables use the `MyISAM` storage engine. Because of this, those tables are not duplicated or shared among MySQL servers acting as SQL nodes in a MySQL Cluster. By way of example, suppose that two SQL nodes **A** and **B** are connected to the same MySQL Cluster, which has an `NDB` table named `mytable` in a database named `mydb`, and that you execute an SQL statement on server **A** that creates a new user `jon@localhost` and grants this user the `SELECT` [627] privilege on that table:

```
mysql> GRANT SELECT ON mydb.mytable
    ->   TO jon@localhost IDENTIFIED BY 'mypass';
```

This user is *not* created on server **B**. For this to take place, the statement must also be run on server **B**. Similarly, statements run on server **A** and affecting the privileges of existing users on server **A** do not affect users on server **B** unless those statements are actually run on server **B** as well.

In other words, *changes in users and their privileges do not automatically propagate between SQL nodes by default*. Prior to MySQL Cluster NDB 7.2, any synchronization of privileges between SQL nodes must be done either manually or by scripting an application that periodically synchronizes the privilege tables on all SQL nodes in the cluster. In MySQL Cluster NDB 7.2 and later, you can enable automatic distribution of MySQL users and privileges across MySQL Cluster SQL nodes; see Distributed MySQL Privileges for MySQL Cluster, for details.

Conversely, because there is no way in MySQL to deny privileges (privileges can either be revoked or not granted in the first place, but not denied as such), there is no special protection for `NDB` tables on one SQL node from users that have privileges on another SQL node. (This is true even if you are not using the automatic distribution of user privileges available in MySQl Cluster NDB 7.2 and later.) The most far-reaching example of this is the MySQL `root` account, which can perform any action on any database object. In combination with empty `[mysqld]` or `[api]` sections of the `config.ini` file, this account can be especially dangerous. To understand why, consider the following scenario:

- The `config.ini` file contains at least one empty `[mysqld]` or `[api]` section. This means that the MySQL Cluster management server performs no checking of the host from which a MySQL Server (or other API node) accesses the MySQL Cluster.
- There is no firewall, or the firewall fails to protect against access to the MySQL Cluster from hosts external to the network.
- The host name or IP address of the MySQL Cluster's management server is known or can be determined from outside the network.

If these conditions are true, then anyone, anywhere can start a MySQL Server with `--ndbcluster` [1915] `--ndb-connectstring=`*`management_host`* [1914] and access this MySQL Cluster. Using the MySQL `root` account, this person can then perform the following actions:

- Execute a `SHOW DATABASES` statement to obtain a list of all `NDB` databases

- Execute a `SHOW TABLES FROM some_database` statement to obtain a list of all `NDB` tables in a given database
- Run any legal MySQL statements on any of those tables, such as:
  - `SELECT * FROM some_table` to read all the data from any table
  - `DELETE FROM some_table` to delete all the data from a table
  - `DESCRIBE some_table` or `SHOW CREATE TABLE some_table` to determine the table schema
  - `UPDATE some_table SET column1 = some_value` to fill a table column with “garbage” data; this could actually cause much greater damage than simply deleting all the data

    More insidious variations might include statements like these:

    ```
    UPDATE some_table SET an_int_column = an_int_column + 1
    ```

    or

    ```
    UPDATE some_table SET a_varchar_column = REVERSE(a_varchar_column)
    ```

    Such malicious statements are limited only by the imagination of the attacker.

The only tables that would be safe from this sort of mayhem would be those tables that were created using storage engines other than `NDB`, and so not visible to a “rogue” SQL node.

Note

A user who can log in as `root` can also access the `INFORMATION_SCHEMA` database and its tables, and so obtain information about databases, tables, stored routines, scheduled events, and any other database objects for which metadata is stored in `INFORMATION_SCHEMA`.

It is also a very good idea to use different passwords for the `root` accounts on different cluster SQL nodes (unless you are using distributed privileges as supported in MySQL Cluster NDB 7.2 and later).

In sum, you cannot have a safe MySQL Cluster if it is directly accessible from outside your local network.

Important

Never leave the MySQL root account password empty. This is just as true when running MySQL as a MySQL Cluster SQL node as it is when running it as a standalone (non-Cluster) MySQL Server, and should be done as part of the MySQL installation process before configuring the MySQL Server as an SQL node in a MySQL Cluster.

Prior to MySQL Cluster NDB 7.2, you should never convert the system tables in the `mysql` database to use the `NDB` storage engine. There are a number of reasons why you should not do this, but the most important reason is this: *Many of the SQL statements that affect `mysql` tables storing information about user privileges, stored routines, scheduled events, and other database objects cease to function if these tables are changed to use any storage engine other than `MyISAM`*. This is a consequence of various MySQL Server internals. Beginning with MySQL Cluster NDB 7.2, you can use a stored procedure provided for this purpose (see Distributed MySQL Privileges for MySQL Cluster), but you are strongly advised not to attempt convert the system tables manually.

Otherwise, if you need to synchronize `mysql` system tables between SQL nodes, you can use standard MySQL replication to do so, or employ a script to copy table entries between the MySQL servers.

Summary. The two most important points to remember regarding the MySQL privilege system with regard to MySQL Cluster are:

1. **Prior to MySQL Cluster NDB 7.2.** Users and privileges established on one SQL node do not automatically exist or take effect on other SQL nodes in the cluster. Conversely, removing a user or privilege on one SQL node in the cluster does not remove the user or privilege from any other SQL nodes.

   In MySQL Cluster NDB 7.2 and later. You can distribute MySQL users and privileges among SQL nodes using the SQL script, and the stored procedures it contains, that are supplied for this purpose in the MySQL Cluster distribution.

2. Once a MySQL user is granted privileges on an `NDB` table from one SQL node in a MySQL Cluster, that user can "see" any data in that table regardless of the SQL node from which the data originated. (This is true even if you are not using the privilege distribution support available in MySQl Cluster NDB 7.2 or later.)

MySQL Cluster and MySQL Security Procedures

In this section, we discuss MySQL standard security procedures as they apply to running MySQL Cluster.

In general, any standard procedure for running MySQL securely also applies to running a MySQL Server as part of a MySQL Cluster. First and foremost, you should always run a MySQL Server as the `mysql` system user; this is no different from running MySQL in a standard (non-Cluster) environment. The `mysql` system account should be uniquely and clearly defined. Fortunately, this is the default behavior for a new MySQL installation. You can verify that the `mysqld` process is running as the system user `mysql` by using the system command such as the one shown here:

```
shell> ps aux | grep mysql
root     10467  0.0  0.1   3616  1380 pts/3    S    11:53   0:00 \
  /bin/sh ./mysqld_safe --ndbcluster --ndb-connectstring=localhost:1186
mysql    10512  0.2  2.5  58528 26636 pts/3    Sl   11:53   0:00 \
  /usr/local/mysql/libexec/mysqld --basedir=/usr/local/mysql \
  --datadir=/usr/local/mysql/var --user=mysql --ndbcluster \
  --ndb-connectstring=localhost:1186 --pid-file=/usr/local/mysql/var/mothra.pid \
  --log-error=/usr/local/mysql/var/mothra.err
jon      10579  0.0  0.0   2736   688 pts/0    S+   11:54   0:00 grep mysql
```

If the `mysqld` process is running as any other user than `mysql`, you should immediately shut it down and restart it as the `mysql` user. If this user does not exist on the system, the `mysql` user account should be created, and this user should be part of the `mysql` user group; in this case, you should also make sure that the MySQL data directory on this system (as set using the `--datadir` [423] option for `mysqld`) is owned by the `mysql` user, and that the SQL node's `my.cnf` file includes `user=mysql` in the `[mysqld]` section. Alternatively, you can start the MySQL server process with `--user=mysql` [448] on the command line, but it is preferable to use the `my.cnf` option, since you might forget to use the command-line option and so have `mysqld` running as another user unintentionally. The `mysqld_safe` startup script forces MySQL to run as the `mysql` user.

Important

Never run `mysqld` as the system root user. Doing so means that potentially any file on the system can be read by MySQL, and thus—should MySQL be compromised—by an attacker.

As mentioned in the previous section (see MySQL Cluster and MySQL Privileges), you should always set a root password for the MySQL Server as soon as you have it running. You should also delete the anonymous user account that is installed by default. You can accomplish these tasks using the following statements:

```
shell> mysql -u root

mysql> UPDATE mysql.user
```

```
    ->     SET Password=PASSWORD('secure_password')
    ->     WHERE User='root';

mysql> DELETE FROM mysql.user
    ->     WHERE User='';

mysql> FLUSH PRIVILEGES;
```

Be very careful when executing the `DELETE` statement not to omit the `WHERE` clause, or you risk deleting *all* MySQL users. Be sure to run the `FLUSH PRIVILEGES` statement as soon as you have modified the `mysql.user` table, so that the changes take immediate effect. Without `FLUSH PRIVILEGES`, the changes do not take effect until the next time that the server is restarted.

Note

Many of the MySQL Cluster utilities such as `ndb_show_tables`, `ndb_desc`, and `ndb_select_all` also work without authentication and can reveal table names, schemas, and data. By default these are installed on Unix-style systems with the permissions `wxr-xr-x` (755), which means they can be executed by any user that can access the `mysql/bin` directory.

See MySQL Cluster Programs, for more information about these utilities.

MySQL Cluster Disk Data Tables

Beginning with MySQL 5.1.6, it is possible to store the nonindexed columns of `NDB` tables on disk, rather than in RAM as with previous versions of MySQL Cluster.

As part of implementing MySQL Cluster Disk Data work, a number of improvements were made in MySQL Cluster for the efficient handling of very large amounts (terabytes) of data during node recovery and restart. These include a “no-steal” algorithm for synchronizing a starting node with very large data sets. For more information, see the paper *Recovery Principles of MySQL Cluster 5.1*, by MySQL Cluster developers Mikael Ronström and Jonas Oreland.

MySQL Cluster Disk Data performance can be influenced by a number of configuration parameters. For information about these parameters and their effects, see *MySQL Cluster Disk Data configuration parameters* and *MySQL Cluster Disk Data storage and `GCP Stop` errors*

The performance of a MySQL Cluster that uses Disk Data storage can also be greatly improved by separating data node file systems from undo log files and tablespace data files, which can be done using symbolic links. For more information, see Using Symbolic Links with Disk Data Objects.

MySQL Cluster Disk Data Objects

MySQL Cluster Disk Data storage is implemented using a number of *Disk Data objects*. These include the following:

- *Tablespaces* act as containers for other Disk Data objects.
- *Undo log files* undo information required for rolling back transactions.
- One or more undo log files are assigned to a *log file group*, which is then assigned to a tablespace.
- *Data files* store Disk Data table data. A data file is assigned directly to a tablespace.

Undo log files and data files are actual files in the file system of each data node; by default they are placed in `ndb_node_id_fs` in the `DataDir` specified in the MySQL Cluster `config.ini` file, and where `node_id` is the data node's node ID. It is possible to place these elsewhere by specifying either an absolute or relative path as part of the filename when creating the undo log or data file. Statements that create these files are shown later in this section.

MySQL Cluster tablespaces and log file groups are not implemented as files.

Important

Although not all Disk Data objects are implemented as files, they all share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group both named `dd1`.

Assuming that you have already set up a MySQL Cluster with all nodes (including management and SQL nodes) running MySQL 5.1.6 or newer, the basic steps for creating a Cluster table on disk are as follows:

1. Create a log file group, and assign one or more undo log files to it (an undo log file is also sometimes referred to as an *undofile*).

   Note

   In MySQL 5.1 and later, undo log files are necessary only for Disk Data tables. They are no longer used for `NDBCLUSTER` tables that are stored only in memory.

2. Create a tablespace; assign the log file group, as well as one or more data files, to the tablespace.

3. Create a Disk Data table that uses this tablespace for data storage.

Each of these tasks can be accomplished using SQL statements in the `mysql` client or other MySQL client application, as shown in the example that follows.

1. We create a log file group named `lg_1` using `CREATE LOGFILE GROUP`. This log file group is to be made up of two undo log files, which we name `undo_1.log` and `undo_2.log`, whose initial sizes are 16 MB and 12 MB, respectively. (The default initial size for an undo log file is 128 MB.) Optionally, you can also specify a size for the log file group's undo buffer, or permit it to assume the default value of 8 MB. In this example, we set the UNDO buffer's size at 2 MB. A log file group must be created with an undo log file; so we add `undo_1.log` to `lg_1` in this `CREATE LOGFILE GROUP` statement:

   ```
   CREATE LOGFILE GROUP lg_1
       ADD UNDOFILE 'undo_1.log'
       INITIAL_SIZE 16M
       UNDO_BUFFER_SIZE 2M
       ENGINE NDBCLUSTER;
   ```

   To add `undo_2.log` to the log file group, use the following `ALTER LOGFILE GROUP` statement:

   ```
   ALTER LOGFILE GROUP lg_1
       ADD UNDOFILE 'undo_2.log'
       INITIAL_SIZE 12M
       ENGINE NDBCLUSTER;
   ```

   Some items of note:

   - The `.log` file extension used here is not required. We use it merely to make the log files easily recognizable.
   - Every `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statement must include an `ENGINE` clause. In MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1), the permitted values for this clause are `NDBCLUSTER` and `NDB`.

     Important

     In MySQL 5.1.8 and later, there can exist only one log file group in the same MySQL Cluster at any given time.

- When you add an undo log file to a log file group using `ADD UNDOFILE 'filename'`, a file with the name *`filename`* is created in the `ndb_node_id_fs` directory within the `DataDir` [1816] of each data node in the cluster, where *`node_id`* is the node ID of the data node. Each undo log file is of the size specified in the SQL statement. For example, if a MySQL Cluster has 4 data nodes, then the `ALTER LOGFILE GROUP` statement just shown creates 4 undo log files, 1 each on in the data directory of each of the 4 data nodes; each of these files is named `undo_2.log` and each file is 12 MB in size.

- `UNDO_BUFFER_SIZE` is limited by the amount of system memory available.

- For more information about the `CREATE LOGFILE GROUP` statement, see `CREATE LOGFILE GROUP` Syntax. For more information about `ALTER LOGFILE GROUP`, see `ALTER LOGFILE GROUP` Syntax.

2. Now we can create a tablespace, which contains files to be used by MySQL Cluster Disk Data tables for storing their data. A tablespace is also associated with a particular log file group. When creating a new tablespace, you must specify the log file group which it is to use for undo logging; you must also specify a data file. You can add more data files to the tablespace after the tablespace is created; it is also possible to drop data files from a tablespace (an example of dropping data files is provided later in this section).

   Assume that we wish to create a tablespace named `ts_1` which uses `lg_1` as its log file group. This tablespace is to contain two data files named `data_1.dat` and `data_2.dat`, whose initial sizes are 32 MB and 48 MB, respectively. (The default value for `INITIAL_SIZE` is 128 MB.) We can do this using two SQL statements, as shown here:

```
CREATE TABLESPACE ts_1
    ADD DATAFILE 'data_1.dat'
    USE LOGFILE GROUP lg_1
    INITIAL_SIZE 32M
    ENGINE NDBCLUSTER;

ALTER TABLESPACE ts_1
    ADD DATAFILE 'data_2.dat'
    INITIAL_SIZE 48M
    ENGINE NDBCLUSTER;
```

   The `CREATE TABLESPACE` statement creates a tablespace `ts_1` with the data file `data_1.dat`, and associates `ts_1` with log file group `lg_1`. The `ALTER TABLESPACE` adds the second data file (`data_2.dat`).

   Some items of note:

   - As is the case with the `.log` file extension used in this example for undo log files, there is no special significance for the `.dat` file extension; it is used merely for easy recognition of data files.

   - When you add a data file to a tablespace using `ADD DATAFILE 'filename'`, a file with the name *`filename`* is created in the `ndb_node_id_fs` directory within the `DataDir` [1816] of each data node in the cluster, where *`node_id`* is the node ID of the data node. Each undo log file is of the size specified in the SQL statement. For example, if a MySQL Cluster has 4 data nodes, then the `ALTER TABLESPACE` statement just shown creates 4 undo log files, 1 each on in the data directory of each of the 4 data nodes; each of these files is named `data_2.dat` and each file is 48 MB in size.

   - All `CREATE TABLESPACE` and `ALTER TABLESPACE` statements must contain an `ENGINE` clause; only tables using the same storage engine as the tablespace can be created in the tablespace. In MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1), the only permitted values for this clause are `NDBCLUSTER` and `NDB`.

   - For more information about the `CREATE TABLESPACE` and `ALTER TABLESPACE` statements, see `CREATE TABLESPACE` Syntax, and `ALTER TABLESPACE` Syntax.

3. Now it is possible to create a table whose nonindexed columns are stored on disk in the tablespace `ts_1`:

```
CREATE TABLE dt_1 (
    member_id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
    last_name VARCHAR(50) NOT NULL,
    first_name VARCHAR(50) NOT NULL,
    dob DATE NOT NULL,
    joined DATE NOT NULL,
    INDEX(last_name, first_name)
    )
    TABLESPACE ts_1 STORAGE DISK
    ENGINE NDBCLUSTER;
```

The `TABLESPACE ... STORAGE DISK` option tells the `NDBCLUSTER` storage engine to use tablespace `ts_1` for disk data storage.

Note

Beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2, it is also possible to specify whether an individual column is stored on disk or in memory by using a `STORAGE` clause as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. `STORAGE DISK` causes the column to be stored on disk, and `STORAGE MEMORY` causes in-memory storage to be used. See `CREATE TABLE` Syntax, for more information.

Once table `ts_1` has been created as shown, you can perform `INSERT`, `SELECT`, `UPDATE`, and `DELETE` statements on it just as you would with any other MySQL table.

For table `dt_1` as it has been defined here, only the `dob` and `joined` columns are stored on disk. This is because there are indexes on the `id`, `last_name`, and `first_name` columns, and so data belonging to these columns is stored in RAM. In MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1), only nonindexed columns can be held on disk; indexes and indexed column data continue to be stored in memory. This tradeoff between the use of indexes and conservation of RAM is something you must keep in mind as you design Disk Data tables.

Performance note. The performance of a cluster using Disk Data storage is greatly improved if Disk Data files are kept on a separate physical disk from the data node file system. This must be done for each data node in the cluster to derive any noticeable benefit.

You may use absolute and relative file system paths with `ADD UNDOFILE` and `ADD DATAFILE`. Relative paths are calculated relative to the data node's data directory. You may also use symbolic links; see Using Symbolic Links with Disk Data Objects, for more information and examples.

A log file group, a tablespace, and any Disk Data tables using these must be created in a particular order. The same is true for dropping any of these objects:

- A log file group cannot be dropped as long as any tablespaces are using it.
- A tablespace cannot be dropped as long as it contains any data files.
- You cannot drop any data files from a tablespace as long as there remain any tables which are using the tablespace.
- Beginning with MySQL 5.1.12, it is no longer possible to drop files created in association with a different tablespace than the one with which the files were created. (Bug #20053)

For example, to drop all the objects created so far in this section, you would use the following statements:

```
mysql> DROP TABLE dt_1;

mysql> ALTER TABLESPACE ts_1
    -> DROP DATAFILE 'data_2.dat'
    -> ENGINE NDBCLUSTER;
```

```
mysql> ALTER TABLESPACE ts_1
    -> DROP DATAFILE 'data_1.dat'
    -> ENGINE NDBCLUSTER;

mysql> DROP TABLESPACE ts_1
    -> ENGINE NDBCLUSTER;

mysql> DROP LOGFILE GROUP lg_1
    -> ENGINE NDBCLUSTER;
```

These statements must be performed in the order shown, except that the two `ALTER TABLESPACE ... DROP DATAFILE` statements may be executed in either order.

You can obtain information about data files used by Disk Data tables by querying the `FILES` table in the `INFORMATION_SCHEMA` database. An extra "`NULL` row" was added to this table in MySQL 5.1.14 for providing additional information about undo log files. For more information and examples of use, see The `INFORMATION_SCHEMA FILES` Table.

Beginning with MySQL Cluster NDB 6.3.27 and MySQL Cluster NDB 7.0.8, it is also possible to view information about allocated and free disk space for each Disk Data table or table partition using the `ndb_desc` utility. For more information, see `ndb_desc` — Describe NDB Tables.

Using Symbolic Links with Disk Data Objects

The performance of a MySQL Cluster that uses Disk Data storage can be greatly improved by separating data node file systems from undo log files and tablespace data files and placing these on different disks. Previous to MySQL Cluster NDB 6.2.17, MySQL Cluster NDB 6.3.22, and MySQL Cluster NDB 6.4.3, there was no direct support for this in MySQL Cluster, but it was possible to achieve this separation using symbolic links as described in this section.

Beginning with MySQL Cluster NDB 6.2.17, MySQL Cluster NDB 6.3.22, and MySQL Cluster NDB 6.4.3, the data node configuration parameters `FileSystemPathDD` [1857], `FileSystemPathDataFiles` [1858], and `FileSystemPathUndoFiles` [1858] make the use of symbolic links for this purpose unnecessary. For information about these parameters, see Disk Data file system parameters.

Each data node in the cluster creates a file system in the directory named `ndb_node_id_fs` under the data node's `DataDir [1816]` as defined in the `config.ini` file. In this example, we assume that each data node host has 3 disks, aliased as `/data0`, `/data1`, and `/data2`, and that the cluster's `config.ini` includes the following:

```
[ndbd default]
DataDir= /data0
```

Our objective is to place all Disk Data log files in `/data1`, and all Disk Data data files in `/data2`, on each data node host.

Note

In this example, we assume that the cluster's data node hosts are all using Linux operating systems. For other platforms, you may need to substitute you operating system's commands for those shown here.

To accomplish this, perform the following steps:

- Under the data node file system create symbolic links pointing to the other drives:

```
shell> cd /data0/ndb_2_fs
shell> ls
D1  D10  D11  D2  D8  D9  LCP
shell> ln -s /data0 dnlogs
shell> ln -s /data1 dndata
```

  You should now have two symbolic links:

```
shell> ls -l --hide=D*
lrwxrwxrwx 1 user group   30 2007-03-19 13:58 dndata -> /data1
lrwxrwxrwx 1 user group   30 2007-03-19 13:59 dnlogs -> /data2
```

We show this only for the data node with node ID 2; however, you must do this for *each* data node.

- Now, in the `mysql` client, create a log file group and tablespace using the symbolic links, as shown here:

```
mysql> CREATE LOGFILE GROUP lg1
    ->    ADD UNDOFILE 'dnlogs/undo1.log'
    ->    INITIAL_SIZE 150M
    ->    UNDO_BUFFER_SIZE = 1M
    ->    ENGINE=NDBCLUSTER;

mysql> CREATE TABLESPACE ts1
    ->    ADD DATAFILE 'dndata/data1.log'
    ->    USE LOGFILE GROUP lg1
    ->    INITIAL_SIZE 1G
    ->    ENGINE=NDBCLUSTER;
```

Verify that the files were created and placed correctly as shown here:

```
shell> cd /data1
shell> ls -l
total 2099304
-rw-rw-r--  1 user group 157286400 2007-03-19 14:02 undo1.dat

shell> cd /data2
shell> ls -l
total 2099304
-rw-rw-r--  1 user group 1073741824 2007-03-19 14:02 data1.dat
```

- If you are running multiple data nodes on one host, you must take care to avoid having them try to use the same space for Disk Data files. You can make this easier by creating a symbolic link in each data node file system. Suppose you are using `/data0` for both data node file systems, but you wish to have the Disk Data files for both nodes on `/data1`. In this case, you can do something similar to what is shown here:

```
shell> cd /data0
shell> ln -s /data1/dn2 ndb_2_fs/dd
shell> ln -s /data1/dn3 ndb_3_fs/dd
shell> ls -l --hide=D* ndb_2_fs
lrwxrwxrwx 1 user group   30 2007-03-19 14:22 dd -> /data1/dn2
shell> ls -l --hide=D* ndb_3_fs
lrwxrwxrwx 1 user group   30 2007-03-19 14:22 dd -> /data1/dn3
```

- Now you can create a logfile group and tablespace using the symbolic link, like this:

```
mysql> CREATE LOGFILE GROUP lg1
    ->    ADD UNDOFILE 'dd/undo1.log'
    ->    INITIAL_SIZE 150M
    ->    UNDO_BUFFER_SIZE = 1M
    ->    ENGINE=NDBCLUSTER;

mysql> CREATE TABLESPACE ts1
    ->    ADD DATAFILE 'dd/data1.log'
    ->    USE LOGFILE GROUP lg1
    ->    INITIAL_SIZE 1G
    ->    ENGINE=NDBCLUSTER;
```

Verify that the files were created and placed correctly as shown here:

```
shell> cd /data1
shell> ls
dn2        dn3
shell> ls dn2
undo1.log        data1.log
shell> ls dn3
```

```
undo1.log        data1.log
```

MySQL Cluster Disk Data Storage Requirements

The following items apply to Disk Data storage requirements:

- Variable-length columns of Disk Data tables take up a fixed amount of space. For each row, this is equal to the space required to store the largest possible value for that column.

  For general information about calculating these values, see Data Type Storage Requirements.

  You can obtain an estimate the amount of space available in data files and undo log files by querying the `INFORMATION_SCHEMA.FILES` table. For more information and examples, see The `INFORMATION_SCHEMA FILES` Table.

  Note

  The `OPTIMIZE TABLE` statement does not have any effect on Disk Data tables.

- In a Disk Data table, the first 256 bytes of a `TEXT` or `BLOB` column are stored in memory; only the remainder is stored on disk.

- Each row in a Disk Data table uses 8 bytes in memory to point to the data stored on disk. This means that, in some cases, converting an in-memory column to the disk-based format can actually result in greater memory usage. For example, converting a `CHAR(4)` column from memory-based to disk-based format increases the amount of `DataMemory` [1817] used per row from 4 to 8 bytes.

  Important

  Starting the cluster with the `--initial` option does *not* remove Disk Data files. You must remove these manually prior to performing an initial restart of the cluster.

Performance of Disk Data tables can be improved by minimizing the number of disk seeks by making sure that `DiskPageBufferMemory` [1856] is of sufficient size. You can query the `diskpagebuffer` table to help determine whether the value for this parameter needs to be increased.

Adding MySQL Cluster Data Nodes Online

This section describes how to add MySQL Cluster data nodes “online”—that is, without needing to shut down the cluster completely and restart it as part of the process. This capability is available in MySQL Cluster NDB 7.0 (beginning with MySQL Cluster NDB 6.4.0) and later MySQL Cluster release series.

Important

Currently, you must add new data nodes to a MySQL Cluster as part of a new node group. In addition, it is not possible to change the number of replicas (or the number of nodes per node group) online.

Adding MySQL Cluster Data Nodes Online: General Issues

This section provides general information about the behavior of and current limitations in adding MySQL Cluster nodes online.

Redistribution of Data. The ability to add new nodes online includes a means to reorganize `NDBCLUSTER` table data and indexes so that they are distributed across all data nodes, including the new ones. Table reorganization of both in-memory and Disk Data tables is supported. This redistribution does not currently include unique indexes (only ordered indexes are redistributed) or `BLOB` table data.

The redistribution for NDBCLUSTER tables already existing before the new data nodes were added is not automatic, but can be accomplished using simple SQL statements in mysql or another MySQL client application. However, all data and indexes added to tables created after a new node group has been added are distributed automatically among all cluster data nodes, including those added as part of the new node group.

Partial starts. It is possible to add a new node group without all of the new data nodes being started. It is also possible to add a new node group to a degraded cluster—that is, a cluster that is only partially started, or where one or more data nodes are not running. In the latter case, the cluster must have enough nodes running to be viable before the new node group can be added.

Effects on ongoing operations. Normal DML operations using MySQL Cluster data are not prevented by the creation or addition of a new node group, or by table reorganization. However, it is not possible to perform DDL concurrently with table reorganization—that is, no other DDL statements can be issued while an ALTER TABLE ... REORGANIZE PARTITION statement is executing. In addition, during the execution of ALTER TABLE ... REORGANIZE PARTITION (or the execution of any other DDL statement), it is not possible to restart cluster data nodes.

Failure handling. Failures of data nodes during node group creation and table reorganization are handled as hown in the following table:

Failure occurs during:	**Failure occurs in:**		
	“Old” data nodes	**“New” data nodes**	**System**

Node group creation	• **If a node other than the master fails:** The creation of the node group is always rolled forward.
	• **If the master fails:**
	  • **If the internal commit point has been reached:** The creation of the node group is rolled forward.
	  • **If the internal commit point has not yet been reached.** The creation of the node group is rolled back
		• **If a node other than the master fails:** The creation of the node group is always rolled forward.
		• **If the master fails:**
		  • **If the internal commit point has been reached:** The creation of the node group is rolled forward.
		  • **If the internal commit point has not yet been reached.** The creation of the node group is rolled back
			• **If the execution of CREATE NODEGROUP has reached the internal commit point:** When restarted, the cluster includes the new node group. Otherwise it without.
			• **If the execution of CREATE NODEGROUP has not yet reached the internal commit point:** When restarted, the cluster does not include the new node group.

Table reorganization	• **If a node other than the master fails:** The table reorganization is always rolled forward.
	• **If the master fails:**
	  • **If the internal commit point has been reached:** The table reorganization is rolled forward.
		• **If a node other than the master fails:** The table reorganization is always rolled forward.
		• **If the master fails:**
		  • **If the internal commit point has been reached:** The table reorganization is rolled forward.
			• **If the execution of an ALTER ONLINE TABLE *table* REORGANIZE PARTITION statement has reached the internal commit point:** When the cluster is restarted, the data and indexes belonging to *table* are distributed using the “new” data nodes.

Failure occurs during:	Failure occurs in:		
	"Old" data nodes	"New" data nodes	System
	• **If the internal commit point has not yet been reached.** The table reorganization is rolled back.	• **If the internal commit point has not yet been reached.** The table reorganization is rolled back.	• **If the execution of an `ALTER ONLINE TABLE table REORGANIZE PARTITION` statement has not yet reached the internal commit point:** When the cluster is restarted, the data and indexes belonging to *`table`* are distributed using only the "old" data nodes.

Dropping node groups. The `ndb_mgm` client supports a `DROP NODEGROUP` command, but it is possible to drop a node group only when no data nodes in the node group contain any data. Since there is currently no way to "empty" a specific data node or node group, this command works only the following two cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.
2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

   `TRUNCATE TABLE` does not work for this purpose because the data nodes continue to store the table definitions.

Adding MySQL Cluster Data Nodes Online: Basic procedure

In this section, we list the basic steps required to add new data nodes to a MySQL Cluster. For a detailed example, see Adding MySQL Cluster Data Nodes Online: Detailed Example.

Note

Beginning with MySQL Cluster NDB 7.0.4, this procedure applies whether you are using `ndbd` or `ndbmtd` binaries for the data node processes. Previously, this did not work with multi-threaded data nodes. (Bug #43108)

Assuming that you already have a running MySQL Cluster, adding data nodes online requires the following steps:

1. Edit the cluster configuration `config.ini` file, adding new `[ndbd]` sections corresponding to the nodes to be added. In the case where the cluster uses multiple management servers, these changes need to be made to all `config.ini` files used by the management servers.

   You must be careful that node IDs for any new data nodes added in the `config.ini` file do not overlap node IDs used by existing nodes. In the event that you have API nodes using dynamically allocated node IDs and these IDs match node IDs that you want to use for new data nodes, it is possible to force any such API nodes to "migrate", as described later in this procedure.
2. Perform a rolling restart of all MySQL Cluster management servers.

Important

All management servers must be restarted with the `--reload` [1966] or `--initial` [1965] option to force the reading of the new configuration.

3. Perform a rolling restart of all existing MySQL Cluster data nodes. It is not necessary (or usually even desirable) to use `--initial` [1954] when restarting the existing data nodes.

   If you are using API nodes with dynamically allocated IDs matching any node IDs that you wish to assign to new data nodes, you must restart all API nodes (including SQL nodes) before restarting any of the data nodes processes in this step. This causes any API nodes with node IDs that were previously not explicitly assigned to relinquish those node IDs and acquire new ones.

4. Perform a rolling restart of any SQL or API nodes connected to the MySQL Cluster.

5. Start the new data nodes.

   The new data nodes may be started in any order. They can also be started concurrently, as long as they are started after the rolling restarts of all existing data nodes have been completed, and before proceeding to the next step.

6. Execute one or more `CREATE NODEGROUP` commands in the MySQL Cluster management client to create the new node group or node groups to which the new data nodes will belong.

7. Redistribute the cluster's data among all data nodes (including the new ones) by issuing an `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement in the `mysql` client for each `NDBCLUSTER` table.

   Note

   This needs to be done only for tables already existing at the time the new node group is added. Data in tables created after the new node group is added is distributed automatically; however, data added to any given table `tbl` that existed before the new nodes were added is not distributed using the new nodes until that table has been reorganized using `ALTER ONLINE TABLE tbl REORGANIZE PARTITION`.

8. Reclaim the space freed on the “old” nodes by issuing, for each `NDBCLUSTER` table, an `OPTIMIZE TABLE` statement in the `mysql` client.

You can add all the nodes desired, then issue several `CREATE NODEGROUP` commands in succession to add the new node groups to the cluster. Prior to MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5, when adding multiple new node groups to a MySQL Cluster, it was necessary to add only the nodes to be assigned to a given new node group, create that node group using `CREATE NODEGROUP`, then repeat this process for each new node group to be added to the cluster. (Bug #54497)

Adding MySQL Cluster Data Nodes Online: Detailed Example

In this section we provide a detailed example illustrating how to add new MySQL Cluster data nodes online, starting with a MySQL Cluster having 2 data nodes in a single node group and concluding with a cluster having 4 data nodes in 2 node groups.

Starting configuration. For purposes of illustration, we assume a minimal configuration, and that the cluster uses a `config.ini` file containing only the following information:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 192.168.0.1

[ndbd]
Id = 2
HostName = 192.168.0.2
```

```
[mgm]
HostName = 192.168.0.10
Id = 10

[api]
Id=20
HostName = 192.168.0.20

[api]
Id=21
HostName = 192.168.0.21
```

Note

We have left a gap in the sequence between data node IDs and other nodes. This make it easier later to assign node IDs that are not already in use to data nodes which are newly added.

We also assume that you have already started the cluster using the appropriate command line or `my.cnf` options, and that running `SHOW` in the management client produces output similar to what is shown here:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @192.168.0.1  (5.1.63-ndb-7.1.25, Nodegroup: 0, Master)
id=2    @192.168.0.2  (5.1.63-ndb-7.1.25, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10   @192.168.0.10  (5.1.63-ndb-7.1.25)

[mysqld(API)]   2 node(s)
id=20   @192.168.0.20  (5.1.63-ndb-7.1.25)
id=21   @192.168.0.21  (5.1.63-ndb-7.1.25)
```

Finally, we assume that the cluster contains a single `NDBCLUSTER` table created as shown here:

```
USE n;

CREATE TABLE ips (
    id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    country_code CHAR(2) NOT NULL,
    type CHAR(4) NOT NULL,
    ip_address varchar(15) NOT NULL,
    addresses BIGINT UNSIGNED DEFAULT NULL,
    date BIGINT UNSIGNED DEFAULT NULL
)   ENGINE NDBCLUSTER;
```

The memory usage and related information shown later in this section was generated after inserting approximately 50000 rows into this table.

Note

In this example, we show the single-threaded `ndbd` being used for the data node processes. However—beginning with MySQL Cluster NDB 7.0.4—you can also apply this example, if you are using the multi-threaded `ndbmtd` by substituting `ndbmtd` for `ndbd` wherever it appears in the steps that follow. (Bug #43108)

Step 1: Update configuration file. Open the cluster global configuration file in a text editor and add `[ndbd]` sections corresponding to the 2 new data nodes. (We give these data nodes IDs 3 and 4, and assume that they are to be run on host machines at addresses 192.168.0.3 and 192.168.0.4, respectively.) After you have added the new sections, the contents of the `config.ini` file should look like what is shown here, where the additions to the file are shown in bold type:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 192.168.0.1

[ndbd]
Id = 2
HostName = 192.168.0.2
[ndbd]
Id = 3
HostName = 192.168.0.3

[ndbd]
Id = 4
HostName = 192.168.0.4

[mgm]
HostName = 192.168.0.10
Id = 10

[api]
Id=20
HostName = 192.168.0.20

[api]
Id=21
HostName = 192.168.0.21
```

Once you have made the necessary changes, save the file.

Step 2: Restart the management server. Restarting the cluster management server requires that you issue separate commands to stop the management server and then to start it again, as follows:

1. Stop the management server using the management client `STOP` command, as shown here:

   ```
   ndb_mgm> 10 STOP
   Node 10 has shut down.
   Disconnecting to allow Management Server to shutdown

   shell>
   ```

2. Because shutting down the management server causes the management client to terminate, you must start the management server from the system shell. For simplicity, we assume that `config.ini` is in the same directory as the management server binary, but in practice, you must supply the correct path to the configuration file. You must also supply the `--reload` [1966] or `--initial` [1965] option so that the management server reads the new configuration from the file rather than its configuration cache. If your shell's current directory is also the same as the directory where the management server binary is located, then you can invoke the management server as shown here:

   ```
   shell> ndb_mgmd -f config.ini --reload
   2008-12-08 17:29:23 [MgmSrvr] INFO     -- NDB Cluster Management Server. 5.1.63-ndb-7.1.25
   2008-12-08 17:29:23 [MgmSrvr] INFO     -- Reading cluster configuration from 'config.ini'
   ```

If you check the output of `SHOW` in the management client after restarting the `ndb_mgm` process, you should now see something like this:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @192.168.0.1  (5.1.63-ndb-7.1.25, Nodegroup: 0, Master)
```

```
id=2    @192.168.0.2  (5.1.63-ndb-7.1.25, Nodegroup: 0)
id=3 (not connected, accepting connect from 192.168.0.3)
id=4 (not connected, accepting connect from 192.168.0.4)

[ndb_mgmd(MGM)] 1 node(s)
id=10   @192.168.0.10  (5.1.63-ndb-7.1.25)

[mysqld(API)]   2 node(s)
id=20   @192.168.0.20  (5.1.63-ndb-7.1.25)
id=21   @192.168.0.21  (5.1.63-ndb-7.1.25)
```

Step 3: Perform a rolling restart of the existing data nodes. This step can be accomplished entirely within the cluster management client using the `RESTART` command, as shown here:

```
ndb_mgm> 1 RESTART
Node 1: Node shutdown initiated
Node 1: Node shutdown completed, restarting, no start.
Node 1 is being restarted

ndb_mgm> Node 1: Start initiated (version 7.1.25)
Node 1: Started (version 7.1.25)

ndb_mgm> 2 RESTART
Node 2: Node shutdown initiated
Node 2: Node shutdown completed, restarting, no start.
Node 2 is being restarted

ndb_mgm> Node 2: Start initiated (version 7.1.25)

ndb_mgm> Node 2: Started (version 7.1.25)
```

Important

After issuing each *`X`* `RESTART` command, wait until the management client reports `Node` *`X`*`: Started (version ...)` *before* proceeding any further.

Beginning with MySQL Cluster NDB 7.0.24 and MySQL Cluster NDB 7.1.13, you can verify that all existing data nodes were restarted using the updated configuration by checking the `ndbinfo.nodes` table in the `mysql` client.

Step 4: Perform a rolling restart of all cluster API nodes. Shut down and restart each MySQL server acting as an SQL node in the cluster using `mysqladmin shutdown` followed by `mysqld_safe` (or another startup script). This should be similar to what is shown here, where *`password`* is the MySQL `root` password for a given MySQL server instance:

```
shell> mysqladmin -uroot -ppassword shutdown
081208 20:19:56 mysqld_safe mysqld from pid file
/usr/local/mysql/var/tonfisk.pid ended
shell> mysqld_safe --ndbcluster --ndb-connectstring=192.168.0.10 &
081208 20:20:06 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
081208 20:20:06 mysqld_safe Starting mysqld daemon with databases
from /usr/local/mysql/var
```

Of course, the exact input and output depend on how and where MySQL is installed on the system, as well as which options you choose to start it (and whether or not some or all of these options are specified in a `my.cnf` file).

Step 5: Perform an initial start of the new data nodes. From a system shell on each of the hosts for the new data nodes, start the data nodes as shown here, using the `--initial` [1954] option:

```
shell> ndbd -c 192.168.0.10 --initial
```

Note

Unlike the case with restarting the existing data nodes, you can start the new data nodes concurrently; you do not need to wait for one to finish starting before starting the other.

Wait until both of the new data nodes have started before proceeding with the next step. Once the new data nodes have started, you can see in the output of the management client `SHOW` command that they do not yet belong to any node group (as indicated with bold type here):

```
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @192.168.0.1  (5.1.63-ndb-7.1.25, Nodegroup: 0, Master)
id=2    @192.168.0.2  (5.1.63-ndb-7.1.25, Nodegroup: 0)
id=3    @192.168.0.3  (5.1.63-ndb-7.1.25, no nodegroup)
id=4    @192.168.0.4  (5.1.63-ndb-7.1.25, no nodegroup)

[ndb_mgmd(MGM)] 1 node(s)
id=10   @192.168.0.10  (5.1.63-ndb-7.1.25)

[mysqld(API)]   2 node(s)
id=20   @192.168.0.20  (5.1.63-ndb-7.1.25)
id=21   @192.168.0.21  (5.1.63-ndb-7.1.25)
```

Step 6: Create a new node group. You can do this by issuing a `CREATE NODEGROUP` command in the cluster management client. This command takes as its argument a comma-separated list of the node IDs of the data nodes to be included in the new node group, as shown here:

```
ndb_mgm> CREATE NODEGROUP 3,4
Nodegroup 1 created
```

By issuing `SHOW` again, you can verify that data nodes 3 and 4 have joined the new node group (again indicated in bold type):

```
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @192.168.0.1  (5.1.63-ndb-7.1.25, Nodegroup: 0, Master)
id=2    @192.168.0.2  (5.1.63-ndb-7.1.25, Nodegroup: 0)
id=3    @192.168.0.3  (5.1.63-ndb-7.1.25, Nodegroup: 1)
id=4    @192.168.0.4  (5.1.63-ndb-7.1.25, Nodegroup: 1)

[ndb_mgmd(MGM)] 1 node(s)
id=10   @192.168.0.10  (5.1.63-ndb-7.1.25)

[mysqld(API)]   2 node(s)
id=20   @192.168.0.20  (5.1.63-ndb-7.1.25)
id=21   @192.168.0.21  (5.1.63-ndb-7.1.25)
```

Step 7: Redistribute cluster data. When a node group is created, existing data and indexes are not automatically distributed to the new node group's data nodes, as you can see by issuing the appropriate `REPORT` command in the management client:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
Node 3: Data usage is 0%(0 32K pages of total 3200)
Node 3: Index usage is 0%(0 8K pages of total 12832)
Node 4: Data usage is 0%(0 32K pages of total 3200)
Node 4: Index usage is 0%(0 8K pages of total 12832)
```

By using `ndb_desc` with the `-p` option, which causes the output to include partitioning information, you can see that the table still uses only 2 partitions (in the `Per partition info` section of the output, shown here in bold text):

```
shell> ndb_desc -c 192.168.0.10 -d n ips -p
-- ips --
Version: 1
```

```
Fragment type: 9
K Value: 6

1           26329       26329         1605632             557056

NDBT_ProgramExit: 0 - OK
```

You can cause the data to be redistributed among all of the data nodes by performing, for each `NDBCLUSTER` table, an `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement in the `mysql` client. After issuing the statement `ALTER ONLINE TABLE ips REORGANIZE PARTITION`, you can see using `ndb_desc` that the data for this table is now stored using 4 partitions, as shown here (with the relevant portions of the output in bold type):

```
shell> ndb_desc -c 192.168.0.10 -d n ips -p

Note

Normally, `ALTER [ONLINE] TABLE table_name REORGANIZE PARTITION` is used with a list of partition identifiers and a set of partition definitions to create a new partitioning scheme for a table that has already been explicitly partitioned. Its use here to redistribute data onto a new MySQL Cluster node group is an exception in this regard; when used in this way, only the name of the table is used following the `TABLE` keyword, and no other keywords or identifiers follow `REORGANIZE PARTITION`.

Prior to MySQL Cluster NDB 6.4.3, `ALTER ONLINE TABLE ... REORGANIZE PARTITION` with no `partition_names INTO (partition_definitions)` option did not work correctly with Disk Data tables or with in-memory `NDBCLUSTER` tables having one or more disk-based columns. (Bug #42549)

For more information, see `ALTER TABLE` Syntax.

In addition, for each table, the `ALTER ONLINE TABLE` statement should be followed by an `OPTIMIZE TABLE` to reclaim wasted space. You can obtain a list of all `NDBCLUSTER` tables using the following query against the `INFORMATION_SCHEMA.TABLES` table:

```
SELECT TABLE_SCHEMA, TABLE_NAME
    FROM INFORMATION_SCHEMA.TABLES
    WHERE ENGINE = 'NDBCLUSTER';
```

Note

The `INFORMATION_SCHEMA.TABLES.ENGINE` value for a MySQL Cluster table is always `NDBCLUSTER`, regardless of whether the `CREATE TABLE` statement used to create the table (or `ALTER TABLE` statement used to convert an existing table from a different storage engine) used `NDB` or `NDBCLUSTER` in its `ENGINE` option.

You can see after performing these statements in the output of `ALL REPORT MEMORY` that the data and indexes are now redistributed between all cluster data nodes, as shown here:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(176 32K pages of total 3200)
Node 1: Index usage is 0%(76 8K pages of total 12832)
Node 2: Data usage is 5%(176 32K pages of total 3200)
Node 2: Index usage is 0%(76 8K pages of total 12832)
Node 3: Data usage is 2%(80 32K pages of total 3200)
Node 3: Index usage is 0%(51 8K pages of total 12832)
Node 4: Data usage is 2%(80 32K pages of total 3200)
Node 4: Index usage is 0%(50 8K pages of total 12832)
```

Note

Since only one DDL operation on `NDBCLUSTER` tables can be executed at a time, you must wait for each `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement to finish before issuing the next one.

It is not necessary to issue `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statements for `NDBCLUSTER` tables created *after* the new data nodes have been added; data added to such tables is distributed among all data nodes automatically. However, in `NDBCLUSTER` tables that existed *prior to* the addition of the new nodes, neither existing nor new data is distributed using the new nodes until these tables have been reorganized using `ALTER ONLINE TABLE ... REORGANIZE PARTITION`.

Alternative procedure, without rolling restart. It is possible to avoid the need for a rolling restart by configuring the extra data nodes, but not starting them, when first starting the cluster. We assume, as before, that you wish to start with two data nodes—nodes 1 and 2—in one node group and later to expand the cluster to four data nodes, by adding a second node group consisting of nodes 3 and 4:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 192.168.0.1

[ndbd]
Id = 2
HostName = 192.168.0.2

[ndbd]
Id = 3
HostName = 192.168.0.3
Nodegroup = 65536   # MySQL Cluster NDB 7.0.24 and later;
                    # MySQL Cluster NDB 7.1.13 and later

[ndbd]
Id = 4
HostName = 192.168.0.4
Nodegroup = 65536   # MySQL Cluster NDB 7.0.24 and later;
                    # MySQL Cluster NDB 7.1.13 and later

[mgm]
HostName = 192.168.0.10
Id = 10

[api]
Id=20
HostName = 192.168.0.20

[api]
Id=21
HostName = 192.168.0.21
```

Prior to MySQL Cluster NDB 7.0.24 and MySQL Cluster NDB 7.1.13, you must perform the initial start of the cluster using the `--nowait-nodes` [1955] option with `ndbd` (or `ndbmtd` in MySQL Cluster NDB 7.0.4 and later) for each of the data nodes that you wish to have online immediately, so that the cluster does not wait for the remaining nodes to start:

```
shell> ndbd -c 192.168.0.10 --initial --nowait-nodes=3,4
```

Beginning with MySQL Cluster NDB 7.0.24 and MySQL Cluster NDB 7.1.13, the data nodes to be brought online at a later time (nodes 3 and 4) can be configured with `NodeGroup = 65536` [1815], in which case it is not necessary to start the nodes to be started immediately (nodes 1 and 2) with the `--nowait-nodes` [1955] option, so nodes 1 and 2 can each be started as shown here:

```
shell> ndbd -c 192.168.0.10 --initial
```

The data nodes configured with `NodeGroup = 65536` [1815] are treated by the management server as though you had started nodes 1 and 2 using `--nowait-nodes=3,4` [1955] after waiting for a period of time determined by the setting for the `StartNoNodeGroupTimeout` [1836] data node configuration parameter (also introduced in MySQL Cluster NDB 7.0.24 and MySQL Cluster NDB 7.1.13). By default, this is 15 seconds (15000 milliseconds).

Note

`StartNoNodegroupTimeout` [1836] must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

When you are ready to add the second node group, you need only perform the following additional steps:

1. Start data nodes 3 and 4, invoking the data node process once for each new node:

```
shell> ndbd -c 192.168.0.10 --initial
```

2. Issue the appropriate `CREATE NODEGROUP` command in the management client:

```
ndb_mgm> CREATE NODEGROUP 3,4
```

3. In the `mysql` client, issue `ALTER ONLINE TABLE ... REORGANIZE PARTITION` and `OPTIMIZE TABLE` statements for each existing `NDBCLUSTER` table. (As noted elsewhere in this section, existing MySQL Cluster tables cannot use the new nodes for data distribution until this has been done.)

Distributed MySQL Privileges for MySQL Cluster

MySQL Cluster NDB 7.2 introduces support for distributing MySQL users and privileges across all SQL nodes in a MySQL Cluster. This support is not enabled by default; you should follow the procedure outlined in this section in order to do so.

Normally, each MySQL server's user privilege tables in the `mysql` database must use the `MyISAM` storage engine, which means that a user account and its associated privileges created on one SQL node are not available on the cluster's other SQL nodes. In MySQL Cluster NDB 7.2 and later, an SQL file `ndb_dist_priv.sql` is provided with the MySQL Cluster distribution. This file can be found in the `share/mysql` directory in the MySQL installation directory.

The first step in enabling distributed privileges is to load this script into a MySQL Server that functions as an SQL node (which we refer to after this as the *target* SQL node or MySQL Server). You can do this by executing the following command from the system shell on the target SQL node after changing to its MySQL installation directory (where *`options`* stands for any additional options needed to connect to this SQL node):

```
shell> mysql options -uroot < share/mysql/ndb_dist_priv.sql
```

Importing `ndb_dist_priv.sql` creates a number of stored routines (six stored procedures and one stored function) in the `mysql` database on the target SQL node. After connecting to the SQL node in the `mysql` client (as the MySQL `root` user), you can verify that these were created as shown here:

```
mysql> SELECT ROUTINE_NAME, ROUTINE_SCHEMA, ROUTINE_TYPE
    ->     FROM INFORMATION_SCHEMA.ROUTINES
    ->     WHERE ROUTINE_NAME LIKE 'mysql_cluster%'
    ->     ORDER BY ROUTINE_TYPE;
+-----------------------------------------+----------------+--------------+
| ROUTINE_NAME                            | ROUTINE_SCHEMA | ROUTINE_TYPE |
+-----------------------------------------+----------------+--------------+
| mysql_cluster_privileges_are_distributed | mysql          | FUNCTION     |
| mysql_cluster_backup_privileges         | mysql          | PROCEDURE    |
| mysql_cluster_move_grant_tables         | mysql          | PROCEDURE    |
| mysql_cluster_move_privileges           | mysql          | PROCEDURE    |
| mysql_cluster_restore_local_privileges  | mysql          | PROCEDURE    |
| mysql_cluster_restore_privileges        | mysql          | PROCEDURE    |
| mysql_cluster_restore_privileges_from_local | mysql          | PROCEDURE    |
+-----------------------------------------+----------------+--------------+

7 rows in set (0.01 sec)
```

The stored procedure named `mysql_cluster_move_privileges` creates backup copies of the existing privilege tables, then converts them to `NDB`. Two sets of copies are created in the `mysql` database:

- A set of local copies that use the `MyISAM` storage engine, and named by adding the suffix `_backup` to the original privilege table names.

- A set of distributed copies (using `NDBCLUSTER`). These tables are named by prefixing `ndb_` and appending `_backup` to the names of the original tables.

Although the original privilege tables are backed up automatically, it is always a good idea to create backups manually of the existing privilege tables on all affected SQL nodes before proceeding. You can do this using `mysqldump` in a manner similar to what is shown here:

```
shell> mysqldump options -uroot \
    mysql host user db tables_priv columns_priv procs_priv proxies_priv > backup_file
```

To perform the conversion, you must be connected to the target SQL node using the `mysql` client (again, as the MySQL `root` user). Invoke the stored procedure like this:

```
mysql> CALL mysql.mysql_cluster_move_privileges();
Query OK, 0 rows affected (22.32 sec)
```

Depending on the number of rows in the privilege tables, this procedure may take some time to execute. If some of the privilege tables are empty, you may see one or more `No data - zero rows fetched, selected, or processed` warnings when `mysql_cluster_move_privileges` returns. In such cases, the warnings may be safely ignored. To verify that the conversion was successful, you can use the stored function `mysql_cluster_privileges_are_distributed` as shown here:

```
mysql> SELECT CONCAT(
    ->    'Conversion ',
    ->    IF(mysql.mysql_cluster_privileges_are_distributed(), 'succeeded', 'failed'),
    ->    '.')
    ->    AS Result;
+----------------------+
| Result               |
+----------------------+
| Conversion succeeded. |
+----------------------+
1 row in set (0.00 sec)
```

`mysql_cluster_privileges_are_distributed` checks for the existence of the distributed privilege tables and returns `1` if all of the privilege tables are distributed; otherwise, it returns `0`.

You can verify that the backups have been created using a query such as this one:

```
mysql> SELECT TABLE_NAME, ENGINE FROM INFORMATION_SCHEMA.TABLES
    ->     WHERE TABLE_SCHEMA = 'mysql' AND TABLE_NAME LIKE '%backup'
    ->     ORDER BY ENGINE;
+-------------------------+------------+
| TABLE_NAME              | ENGINE     |
+-------------------------+------------+
| host_backup             | MyISAM     |
| db_backup               | MyISAM     |
| columns_priv_backup     | MyISAM     |
| user_backup             | MyISAM     |
| tables_priv_backup      | MyISAM     |
| proxies_priv_backup     | MyISAM     |
| procs_priv_backup       | MyISAM     |
| ndb_user_backup         | ndbcluster |
| ndb_tables_priv_backup  | ndbcluster |
| ndb_proxies_priv_backup | ndbcluster |
| ndb_procs_priv_backup   | ndbcluster |
| ndb_host_backup         | ndbcluster |
| ndb_db_backup           | ndbcluster |
| ndb_columns_priv_backup | ndbcluster |
+-------------------------+------------+
14 rows in set (0.00 sec)
```

Once the conversion to distributed privileges has been made, any time a MySQL user account is created, dropped, or has its privileges updated on any SQL node, the changes take effect immediately

on all other MySQL servers attached to the cluster. Once privileges are distributed, any new MySQL Servers that connect to the cluster automatically participate in the distribution.

Note

For clients connected to SQL nodes at the time that `mysql_cluster_move_privileges` is executed, you may need to execute `FLUSH PRIVILEGES` on those SQL nodes, or to disconnect and then reconnect the clients, in order for those clients to be able to see the changes in privileges.

All MySQL user privileges are distributed across all connected MySQL Servers. This includes privileges associated with views and stored routines. While automatic distribution of views and stored routines is not currently supported, you can attempt to distribute stored routines by issuing a statement such as `ALTER TABLE mysql.proc ENGINE = NDB`, but you must verify manually that any tables referenced by the stored routines exist on all SQL nodes, since MySQL Cluster has no support at the present time for doing this automatically. There is currently no way to distribute views among MySQL Cluster SQL nodes, other than by creating them manually on each SQL node. If you do this, you must make certain that all base tables referenced by the views use the `NDB` storage engine; otherwise, the views are likely to diverge very quickly.

In the event that an SQL node becomes disconnected from the cluster while `mysql_cluster_move_privileges` is running, you must drop its privilege tables after reconnecting to the cluster, using a statement such as `DROP TABLE IF EXISTS mysql.user mysql.db mysql.tables_priv mysql.columns_priv mysql.procs_priv`. This causes the SQL node to use the shared privilege tables rather than its own local versions of them. This is not needed when connecting a new SQL node to the cluster for the first time.

In the event of an initial restart of the entire cluster (all data nodes shut down, then started again with `--initial` [1954]), the shared privilege tables are lost. If this happens, you can restore them using the original target SQL node either from the backups made by `mysql_cluster_move_privileges` or from a dump file created with `mysqldump`. If you need to use a new MySQL Server to perform the restoration, you should start it with `--skip-grant-tables` [443] when connecting to the cluster for the first time; after this, you can restore the privilege tables locally, then distribute them again using `mysql_cluster_move_privileges`. After restoring and distributing the tables, you should restart this MySQL Server without the `--skip-grant-tables` [443] option.

You can also restore the distributed tables using `ndb_restore --restore-privilege-tables` [1996] from a backup made using `START BACKUP` in the `ndb_mgm` client. (The `MyISAM` tables created by `mysql_cluster_move_privileges` are not backed up by the `START BACKUP` command.) `ndb_restore` does not restore the privilege tables by default; the `--restore-privilege-tables` [1996] option causes it to do so.

Important

Applications that access MySQL Cluster data directly, including NDB API and ClusterJ applications, are not subject to the MySQL privilege system. This means that, once you have distributed the grant tables, they can be freely accessed by such applications, just as they can any other `NDB` tables. In particular, you should keep in mind that *NDB API and ClusterJ applications can read and write user names, host names, password hashes, and any other contents of the distributed grant tables without any restrictions*.

NDB API Statistics Counters and Variables

Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, a number of types of statistical counters relating to actions performed by or affecting `Ndb` objects are added. Such actions include starting and closing (or aborting) transactions; primary key and unique key operations; table, range, and pruned scans; threads blocked while waiting for the completion of various operations; and data and events sent and received by `NDBCLUSTER`. The counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data

nodes. `mysqld` exposes these counters as system status variables; their values can be read in the output of `SHOW STATUS`, or by querying the `INFORMATION_SCHEMA.SESSION_STATUS` or `INFORMATION_SCHEMA.GLOBAL_STATUS` table. By comparing the values before and after statements operating on `NDB` tables, you can observe the corresponding actions taken on the API level, and thus the cost of performing the statement.

You can list all of these status variables using the following `SHOW STATUS` statement:

```
mysql> SHOW STATUS LIKE 'ndb_api%';
+-----------------------------------------------+----------+
| Variable_name                                 | Value    |
+-----------------------------------------------+----------+
| Ndb_api_wait_exec_complete_count_session      | 0        |
| Ndb_api_wait_scan_result_count_session        | 0        |
| Ndb_api_wait_meta_request_count_session       | 0        |
| Ndb_api_wait_nanos_count_session              | 0        |
| Ndb_api_bytes_sent_count_session              | 0        |
| Ndb_api_bytes_received_count_session          | 0        |
| Ndb_api_trans_start_count_session             | 0        |
| Ndb_api_trans_commit_count_session            | 0        |
| Ndb_api_trans_abort_count_session             | 0        |
| Ndb_api_trans_close_count_session             | 0        |
| Ndb_api_pk_op_count_session                   | 0        |
| Ndb_api_uk_op_count_session                   | 0        |
| Ndb_api_table_scan_count_session              | 0        |
| Ndb_api_range_scan_count_session              | 0        |
| Ndb_api_pruned_scan_count_session             | 0        |
| Ndb_api_scan_batch_count_session              | 0        |
| Ndb_api_read_row_count_session                | 0        |
| Ndb_api_trans_local_read_row_count_session    | 0        |
| Ndb_api_event_data_count_injector             | 0        |
| Ndb_api_event_nondata_count_injector          | 0        |
| Ndb_api_event_bytes_count_injector            | 0        |
| Ndb_api_wait_exec_complete_count_slave        | 0        |
| Ndb_api_wait_scan_result_count_slave          | 0        |
| Ndb_api_wait_meta_request_count_slave         | 0        |
| Ndb_api_wait_nanos_count_slave                | 0        |
| Ndb_api_bytes_sent_count_slave                | 0        |
| Ndb_api_bytes_received_count_slave            | 0        |
| Ndb_api_trans_start_count_slave               | 0        |
| Ndb_api_trans_commit_count_slave              | 0        |
| Ndb_api_trans_abort_count_slave               | 0        |
| Ndb_api_trans_close_count_slave               | 0        |
| Ndb_api_pk_op_count_slave                     | 0        |
| Ndb_api_uk_op_count_slave                     | 0        |
| Ndb_api_table_scan_count_slave                | 0        |
| Ndb_api_range_scan_count_slave                | 0        |
| Ndb_api_pruned_scan_count_slave               | 0        |
| Ndb_api_scan_batch_count_slave                | 0        |
| Ndb_api_read_row_count_slave                  | 0        |
| Ndb_api_trans_local_read_row_count_slave      | 0        |
| Ndb_api_wait_exec_complete_count              | 2        |
| Ndb_api_wait_scan_result_count                | 3        |
| Ndb_api_wait_meta_request_count               | 27       |
| Ndb_api_wait_nanos_count                      | 45612023 |
| Ndb_api_bytes_sent_count                      | 992      |
| Ndb_api_bytes_received_count                  | 9640     |
| Ndb_api_trans_start_count                     | 2        |
| Ndb_api_trans_commit_count                    | 1        |
| Ndb_api_trans_abort_count                     | 0        |
| Ndb_api_trans_close_count                     | 2        |
| Ndb_api_pk_op_count                           | 1        |
| Ndb_api_uk_op_count                           | 0        |
| Ndb_api_table_scan_count                      | 1        |
| Ndb_api_range_scan_count                      | 0        |
| Ndb_api_pruned_scan_count                     | 0        |
| Ndb_api_scan_batch_count                      | 0        |
| Ndb_api_read_row_count                        | 1        |
| Ndb_api_trans_local_read_row_count            | 1        |
| Ndb_api_event_data_count                      | 0        |
| Ndb_api_event_nondata_count                   | 0        |
```

```
| Ndb_api_event_bytes_count                  | 0        |
+--------------------------------------------+----------+
60 rows in set (0.02 sec)
```

These status variables are also available from the `SESSION_STATUS` and `GLOBAL_STATUS` tables of the `INFORMATION_SCHEMA` database, as shown here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.SESSION_STATUS
    ->   WHERE VARIABLE_NAME LIKE 'ndb_api%';
+--------------------------------------------+----------------+
| VARIABLE_NAME                              | VARIABLE_VALUE |
+--------------------------------------------+----------------+

+--------------------------------------------+----------------+
60 rows in set (0.00 sec)
```

Each `Ndb` object has its own counters. NDB API applications can read the values of the counters for use in optimization or monitoring. For multithreaded clients which use more than one `Ndb` object concurrently, it is also possible to obtain a summed view of counters from all `Ndb` objects belonging to a given `Ndb_cluster_connection`.

Four sets of these counters are exposed. One set applies to the current session only; the other 3 are global. *This is in spite of the fact that their values can be obtained as either session or global status variables in the `mysql` client*. This means that specifying the `SESSION` or `GLOBAL` keyword with `SHOW STATUS` has no effect on the values reported for NDB API statistics status variables, and the value for each of these variables is the same whether the value is obtained from the equivalent column of the `SESSION_STATUS` or the `GLOBAL_STATUS` table.

- *Session counters (session specific)*

  Session counters relate to the `Ndb` objects in use by (only) the current session. Use of such objects by other MySQL clients does not influence these counts.

  In order to minimize confusion with standard MySQL session variables, we refer to the variables that correspond to these NDB API session counters as "`_session` variables", with a leading underscore.

- *Slave counters (global)*

  This set of counters relates to the `Ndb` objects used by the replication slave SQL thread, if any. If this `mysqld` does not act as a replication slave, or does not use `NDB` tables, then all of these counts are 0.

  We refer to the related status variables as "`_slave` variables" (with a leading underscore).

- *Injector counters (global)*

  Injector counters relate to the `Ndb` object used to listen to cluster events by the binlog injector thread. Even when not writing a binary log, `mysqld` processes attached to a MySQL Cluster continue to listen for some events, such as schema changes.

  We refer to the status variables that correspond to NDB API injector counters as "`_injector` variables" (with a leading underscore).

- *Server (Global) counters (global)*

  This set of counters relates to all `Ndb` objects currently used by this `mysqld`. This includes all MySQL client applications, the slave SQL thread (if any), the binlog injector, and the `NDB` utility thread.

  We refer to the status variables that correspond to these counters as "global variables" or "`mysqld`-level variables".

You can obtain values for a particular set of variables by additionally filtering for the substring `session`, `slave`, or `injector` in the variable name (along with the common prefix `Ndb_api`). For `_session` variables, this can be done as shown here:

```
mysql> SHOW STATUS LIKE 'ndb_api%session';
+-----------------------------------------+---------+
| Variable_name                           | Value   |
+-----------------------------------------+---------+
| Ndb_api_wait_exec_complete_count_session | 2       |
| Ndb_api_wait_scan_result_count_session   | 0       |
| Ndb_api_wait_meta_request_count_session  | 1       |
| Ndb_api_wait_nanos_count_session         | 8144375 |
| Ndb_api_bytes_sent_count_session         | 68      |
| Ndb_api_bytes_received_count_session     | 84      |
| Ndb_api_trans_start_count_session        | 1       |
| Ndb_api_trans_commit_count_session       | 1       |
| Ndb_api_trans_abort_count_session        | 0       |
| Ndb_api_trans_close_count_session        | 1       |
```

```
| Ndb_api_pk_op_count_session                | 1       |
| Ndb_api_uk_op_count_session                | 0       |
| Ndb_api_table_scan_count_session           | 0       |
| Ndb_api_range_scan_count_session           | 0       |
| Ndb_api_pruned_scan_count_session          | 0       |
| Ndb_api_scan_batch_count_session           | 0       |
| Ndb_api_read_row_count_session             | 1       |
| Ndb_api_trans_local_read_row_count_session | 1       |
+--------------------------------------------+---------+
18 rows in set (0.50 sec)
```

To obtain a listing of the NDB API `mysqld`-level status variables, filter for variable names beginning with `ndb_api` and ending in `_count`, like this:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.SESSION_STATUS
    ->     WHERE VARIABLE_NAME LIKE 'ndb_api%count';
+-----------------------------------+----------------+
| VARIABLE_NAME                     | VARIABLE_VALUE |
+-----------------------------------+----------------+
| NDB_API_WAIT_EXEC_COMPLETE_COUNT  | 4              |
| NDB_API_WAIT_SCAN_RESULT_COUNT    | 3              |
| NDB_API_WAIT_META_REQUEST_COUNT   | 28             |
| NDB_API_WAIT_NANOS_COUNT          | 53756398       |
| NDB_API_BYTES_SENT_COUNT          | 1060           |
| NDB_API_BYTES_RECEIVED_COUNT      | 9724           |
| NDB_API_TRANS_START_COUNT         | 3              |
| NDB_API_TRANS_COMMIT_COUNT        | 2              |
| NDB_API_TRANS_ABORT_COUNT         | 0              |
| NDB_API_TRANS_CLOSE_COUNT         | 3              |
| NDB_API_PK_OP_COUNT               | 2              |
| NDB_API_UK_OP_COUNT               | 0              |
| NDB_API_TABLE_SCAN_COUNT          | 1              |
| NDB_API_RANGE_SCAN_COUNT          | 0              |
| NDB_API_PRUNED_SCAN_COUNT         | 0              |
| NDB_API_SCAN_BATCH_COUNT          | 0              |
| NDB_API_READ_ROW_COUNT            | 2              |
| NDB_API_TRANS_LOCAL_READ_ROW_COUNT | 2             |
| NDB_API_EVENT_DATA_COUNT          | 0              |
| NDB_API_EVENT_NONDATA_COUNT       | 0              |
| NDB_API_EVENT_BYTES_COUNT         | 0              |
+-----------------------------------+----------------+
21 rows in set (0.09 sec)
```

Not all counters are reflected in all 4 sets of status variables. For the event counters `DataEventsRecvdCount`, `NondataEventsRecvdCount`, and `EventBytesRecvdCount`, only `_injector` and `mysqld`-level NDB API status variables are available:

```
mysql> SHOW STATUS LIKE 'ndb_api%event%';
+-------------------------------------+-------+
| Variable_name                       | Value |
+-------------------------------------+-------+
| Ndb_api_event_data_count_injector   | 0     |
| Ndb_api_event_nondata_count_injector | 0     |
| Ndb_api_event_bytes_count_injector  | 0     |
| Ndb_api_event_data_count            | 0     |
| Ndb_api_event_nondata_count         | 0     |
| Ndb_api_event_bytes_count           | 0     |
+-------------------------------------+-------+
6 rows in set (0.00 sec)
```

`_injector` status variables are not implemented for any other NDB API counters, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb_api%injector%';
+-------------------------------------+-------+
| Variable_name                       | Value |
+-------------------------------------+-------+
| Ndb_api_event_data_count_injector   | 0     |
| Ndb_api_event_nondata_count_injector | 0     |
| Ndb_api_event_bytes_count_injector  | 0     |
+-------------------------------------+-------+
3 rows in set (0.00 sec)
```

The names of the status variables can easily be associated with the names of the corresponding counters. Each NDB API statistics counter is listed in the following table with a description as well as the names of any MySQL server status variables corresponding to this counter.

Counter Name	Description
	Status Variables (by statistic type): • **Session** • **Slave** • **Injector** • **Server**
`WaitExecCompleteCount`	Number of times thread has been blocked while waiting for execution of an operation to complete. Includes all `execute()` calls as well as implicit executes for blob operations and auto-increment not visible to clients.
	• `Ndb_api_wait_exec_complete_count_session` [1936] • `Ndb_api_wait_exec_complete_count_slave` [1936] • [none] • `Ndb_api_wait_exec_complete_count` [1936]
`WaitScanResultCount`	Number of times thread has been blocked while waiting for a scan-based signal, such waiting for additional results, or for a scan to close.
	• `Ndb_api_wait_scan_result_count_session` [1937] • `Ndb_api_wait_scan_result_count_slave` [1937] • [none] • `Ndb_api_wait_scan_result_count` [1937]
`WaitMetaRequestCount`	Number of times thread has been blocked waiting for a metadata-based signal; this can occur when waiting for a DDL operation or for an epoch to be started (or ended).
	• `Ndb_api_wait_meta_request_count_session` [1937] • `Ndb_api_wait_meta_request_count_slave` [1937] • [none] • `Ndb_api_wait_meta_request_count` [1937]
`WaitNanosCount`	Total time (in nanoseconds) spent waiting for some type of signal from the data nodes.
	• `Ndb_api_wait_nanos_count_session` [1938] • `Ndb_api_wait_nanos_count_slave` [1938] • [none] • `Ndb_api_wait_nanos_count` [1938]
`BytesSentCount`	Amount of data (in bytes) sent to the data nodes
	• `Ndb_api_bytes_sent_count_session` [1938]

Counter Name	Description
	Status Variables (by statistic type): • **Session** • **Slave** • **Injector** • **Server**
	• Ndb_api_bytes_sent_count_slave [1938] • [none] • Ndb_api_bytes_sent_count [1939]
BytesRecvdCount	Amount of data (in bytes) received from the data nodes
	• Ndb_api_bytes_received_count_session [1939] • Ndb_api_bytes_received_count_slave [1939] • [none] • Ndb_api_bytes_received_count [1939]
TransStartCount	Number of transactions started.
	• Ndb_api_trans_start_count_session [1939] • Ndb_api_trans_start_count_slave [1939] • [none] • Ndb_api_trans_start_count [1940]
TransCommitCount	Number of transactions committed.
	• Ndb_api_trans_commit_count_session [1940] • Ndb_api_trans_commit_count_slave [1940] • [none] • Ndb_api_trans_commit_count [1940]
TransAbortCount	Number of transactions aborted.
	• Ndb_api_trans_abort_count_session [1940] • Ndb_api_trans_abort_count_slave [1940] • [none] • Ndb_api_trans_abort_count [1941]
TransCloseCount	Number of transactions aborted. (This value may be greater than the sum of TransCommitCount and TransAbortCount.)
	• Ndb_api_trans_close_count_session [1941] • Ndb_api_trans_close_count_slave [1941] • [none] • Ndb_api_trans_close_count [1941]

Counter Name	Description
	Status Variables (by statistic type): • **Session** • **Slave** • **Injector** • **Server**
PkOpCount	Number of operations based on or using primary keys. This count includes blob-part table operations, implicit unlocking operations, and auto-increment operations, as well as primary key operations normally visible to MySQL clients.
	• Ndb_api_pk_op_count_session [1941] • Ndb_api_pk_op_count_slave [1942] • [none] • Ndb_api_pk_op_count [1942]
UkOpCount	Number of operations based on or using unique keys.
	• Ndb_api_uk_op_count_session [1942] • Ndb_api_uk_op_count_slave [1942] • [none] • Ndb_api_uk_op_count [1942]
TableScanCount	Number of table scans that have been started. This includes scans of internal tables.
	• Ndb_api_table_scan_count_session [1942] • Ndb_api_table_scan_count_slave [1943] • [none] • Ndb_api_table_scan_count [1943]
RangeScanCount	Number of range scans that have been started.
	• Ndb_api_range_scan_count_session [1943] • Ndb_api_range_scan_count_slave [1943] • [none] • Ndb_api_range_scan_count [1943]
PrunedScanCount	Number of scans that have been pruned to a single partition.
	• Ndb_api_pruned_scan_count_session [1944] • Ndb_api_pruned_scan_count_slave [1944] • [none] • Ndb_api_pruned_scan_count [1944]
ScanBatchCount	Number of batches of rows received. (A *batch* in this context is a set of scan results from a single fragment.)

Counter Name	Description
	Status Variables (by statistic type): • **Session** • **Slave** • **Injector** • **Server**
	• `Ndb_api_scan_batch_count_session` [1944] • `Ndb_api_scan_batch_count_slave` [1944] • [none] • `Ndb_api_scan_batch_count` [1944]
`ReadRowCount`	Total number of rows that have been read. Includes rows read using primary key, unique key, and scan operations.
	• `Ndb_api_read_row_count_session` [1945] • `Ndb_api_read_row_count_slave` [1945] • [none] • `Ndb_api_read_row_count` [1945]
`TransLocalReadRowCount`	Number of rows read from the data same node on which the transaction was being run.
	• `Ndb_api_trans_local_read_row_count_session` [1945] • `Ndb_api_trans_local_read_row_count_slave` [1945] • [none] • `Ndb_api_trans_local_read_row_count` [1946]
`DataEventsRecvdCount`	Number of row change events received.
	• [none] • [none] • `Ndb_api_event_data_count_injector` [1946] • `Ndb_api_event_data_count` [1946]
`NondataEventsRecvdCount`	Number of events received, other than row change events.
	• [none] • [none] • `Ndb_api_event_nondata_count_injector` [1946] • `Ndb_api_event_nondata_count` [1946]
`EventBytesRecvdCount`	Number of bytes of events received.
	• [none] • [none]

Counter Name	Description
	Status Variables (by statistic type): • **Session** • **Slave** • **Injector** • **Server**
	• Ndb_api_event_bytes_count_injector [1946] • Ndb_api_event_bytes_count [1946]

To see all counts of committed transactions—that is, all TransCommitCount counter status variables—you can filter the results of SHOW STATUS for the substring trans_commit_count, like this:

```
mysql> SHOW STATUS LIKE '%trans_commit_count%';
+-----------------------------------+-------+
| Variable_name                     | Value |
+-----------------------------------+-------+
| Ndb_api_trans_commit_count_session | 1     |
| Ndb_api_trans_commit_count_slave   | 0     |
| Ndb_api_trans_commit_count         | 2     |
+-----------------------------------+-------+
3 rows in set (0.00 sec)
```

From this you can determine that 1 transaction has been committed in the current mysql client session, and 2 transactions have been committed on this mysqld since it was last restarted.

You can see how various NDB API counters are incremented by a given SQL statement by comparing the values of the corresponding _session status variables immediately before and after performing the statement. In this example, after getting the initial values from SHOW STATUS, we create in the test database an NDB table, named t, that has a single column:

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
+-------------------------------------------+--------+
| Variable_name                             | Value  |
+-------------------------------------------+--------+
| Ndb_api_wait_exec_complete_count_session   | 2      |
| Ndb_api_wait_scan_result_count_session     | 0      |
| Ndb_api_wait_meta_request_count_session    | 3      |
| Ndb_api_wait_nanos_count_session           | 820705 |
| Ndb_api_bytes_sent_count_session           | 132    |
| Ndb_api_bytes_received_count_session       | 372    |
| Ndb_api_trans_start_count_session          | 1      |
| Ndb_api_trans_commit_count_session         | 1      |
| Ndb_api_trans_abort_count_session          | 0      |
| Ndb_api_trans_close_count_session          | 1      |
| Ndb_api_pk_op_count_session                | 1      |
| Ndb_api_uk_op_count_session                | 0      |
| Ndb_api_table_scan_count_session           | 0      |
| Ndb_api_range_scan_count_session           | 0      |
| Ndb_api_pruned_scan_count_session          | 0      |
| Ndb_api_scan_batch_count_session           | 0      |
| Ndb_api_read_row_count_session             | 1      |
| Ndb_api_trans_local_read_row_count_session | 1      |
+-------------------------------------------+--------+
18 rows in set (0.00 sec)

mysql> USE test;
Database changed
mysql> CREATE TABLE t (c INT) ENGINE NDBCLUSTER;
Query OK, 0 rows affected (0.85 sec)
```

Now you can execute a new SHOW STATUS statement and observe the changes, as shown here (with the changed rows highlighted in the output):

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
+-----------------------------------------+-----------+
| Variable_name                           | Value     |
+-----------------------------------------+-----------+
| Ndb_api_wait_exec_complete_count_session | 8         |
| Ndb_api_wait_scan_result_count_session   | 0         |
| Ndb_api_wait_meta_request_count_session  | 17        |
| Ndb_api_wait_nanos_count_session         | 706871709 |
| Ndb_api_bytes_sent_count_session         | 2376      |
| Ndb_api_bytes_received_count_session     | 3844      |
| Ndb_api_trans_start_count_session        | 4         |
| Ndb_api_trans_commit_count_session       | 4         |
| Ndb_api_trans_abort_count_session        | 0         |
| Ndb_api_trans_close_count_session        | 4         |
| Ndb_api_pk_op_count_session              | 6         |
| Ndb_api_uk_op_count_session              | 0         |
| Ndb_api_table_scan_count_session         | 0         |
| Ndb_api_range_scan_count_session         | 0         |
| Ndb_api_pruned_scan_count_session        | 0         |
| Ndb_api_scan_batch_count_session         | 0         |
| Ndb_api_read_row_count_session           | 2         |
| Ndb_api_trans_local_read_row_count_session | 1       |
+-----------------------------------------+-----------+
18 rows in set (0.00 sec)
```

Similarly, you can see the changes in the NDB API statistics counters caused by inserting a row into `t`: Insert the row, then run the same `SHOW STATUS` statement used in the previous example, as shown here:

```
mysql> INSERT INTO t VALUES (100);
Query OK, 1 row affected (0.00 sec)

mysql> SHOW STATUS LIKE 'ndb_api%session%';
+-----------------------------------------+-----------+
| Variable_name                           | Value     |
+-----------------------------------------+-----------+
| Ndb_api_wait_exec_complete_count_session | 11        |
| Ndb_api_wait_scan_result_count_session   | 6         |
| Ndb_api_wait_meta_request_count_session  | 20        |
| Ndb_api_wait_nanos_count_session         | 707370418 |
| Ndb_api_bytes_sent_count_session         | 2724      |
| Ndb_api_bytes_received_count_session     | 4116      |
| Ndb_api_trans_start_count_session        | 7         |
| Ndb_api_trans_commit_count_session       | 6         |
| Ndb_api_trans_abort_count_session        | 0         |
| Ndb_api_trans_close_count_session        | 7         |
| Ndb_api_pk_op_count_session              | 8         |
| Ndb_api_uk_op_count_session              | 0         |
| Ndb_api_table_scan_count_session         | 1         |
| Ndb_api_range_scan_count_session         | 0         |
| Ndb_api_pruned_scan_count_session        | 0         |
| Ndb_api_scan_batch_count_session         | 0         |
| Ndb_api_read_row_count_session           | 3         |
| Ndb_api_trans_local_read_row_count_session | 2       |
+-----------------------------------------+-----------+
18 rows in set (0.00 sec)
```

We can make a number of observations from these results:

- Although we created `t` with no explicit primary key, 5 primary key operations were performed in doing so (the difference in the “before” and “after” values of `Ndb_api_pk_op_count_session` [1941], or 6 minus 1). This reflects the creation of the hidden primary key that is a feature of all tables using the `NDB` storage engine.

- By comparing successive values for `Ndb_api_wait_nanos_count_session` [1938], we can see that the NDB API operations implementing the `CREATE TABLE` statement waited much longer (706871709 - 820705 = 706051004 nanoseconds, or approximately 0.7 second) for responses from the data nodes than those executed by the `INSERT` (707370418 - 706871709 = 498709 ns

or roughly .0005 second). The execution times reported for these statements in the `mysql` client correlate roughly with these figures.

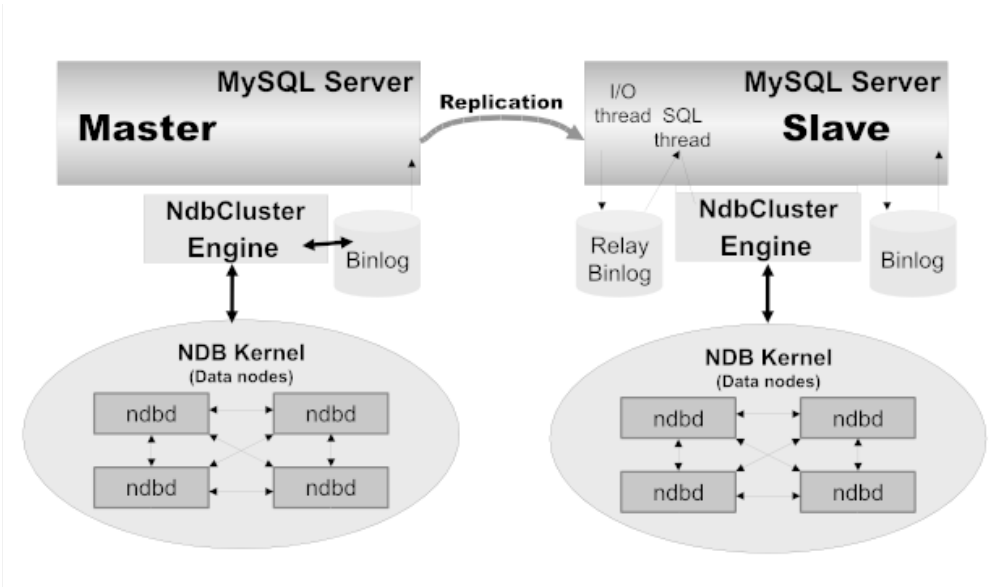
On platforms with without sufficient (nanosecond) time resolution, small changes in the value of the `WaitNanosCount` NDB API counter due to SQL statements that execute very quickly may not always be visible in the values of `Ndb_api_wait_nanos_count_session` [1938], `Ndb_api_wait_nanos_count_slave` [1938], or `Ndb_api_wait_nanos_count` [1938].

- The `INSERT` statement incremented both the `ReadRowCount` and `TransLocalReadRowCount` NDB API statistics counters, as reflected by the increased values of `Ndb_api_read_row_count_session` [1945] and `Ndb_api_trans_local_read_row_count_session` [1945].

MySQL Cluster Replication

Previous to MySQL 5.1.6, *asynchronous replication*, more usually referred to simply as “replication”, was not available when using MySQL Cluster. MySQL 5.1.6 introduces master-slave replication of this type for MySQL Cluster databases. This section explains how to set up and manage a configuration wherein one group of computers operating as a MySQL Cluster replicates to a second computer or group of computers. We assume some familiarity on the part of the reader with standard MySQL replication as discussed elsewhere in this Manual. (See Chapter 16, *Replication*).

Normal (non-clustered) replication involves a “master” server and a “slave” server, the master being the source of the operations and data to be replicated and the slave being the recipient of these. In MySQL Cluster, replication is conceptually very similar but can be more complex in practice, as it may be extended to cover a number of different configurations including replicating between two complete clusters. Although a MySQL Cluster itself depends on the `NDB` storage engine for clustering functionality, it is not necessary to use `NDB` as the storage engine for the slave's copies of the replicated tables (see Replication from `NDB` to non-`NDB` tables). However, for maximum availability, it is possible (and preferable) to replicate from one MySQL Cluster to another, and it is this scenario that we discuss, as shown in the following figure:



In this scenario, the replication process is one in which successive states of a master cluster are logged and saved to a slave cluster. This process is accomplished by a special thread known as the NDB binlog injector thread, which runs on each MySQL server and produces a binary log (`binlog`). This thread ensures that all changes in the cluster producing the binary log—and not just those changes that are effected through the MySQL Server—are inserted into the binary log with the correct serialization order. We refer to the MySQL replication master and replication slave servers as replication servers or replication nodes, and the data flow or line of communication between them as a *replication channel*.

For information about performing point-in-time recovery with MySQL Cluster and MySQL Cluster Replication, see Point-In-Time Recovery Using MySQL Cluster Replication.

NDB API `_slave` status variables. Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, NDB API counters provide enhanced monitoring capabilities on MySQL Cluster replication slaves. These are implelemented as NDB statistics `_slave` status variables, as seen in the output of `SHOW STATUS`, or in the results of queries against the `SESSION_STATUS` or `GLOBAL_STATUS` table in a `mysql` client session connected to a MySQL Server that is acting as a slave in MySQL Cluster Replication. By comparing the values of these status variables before and after the execution of statements affecting replicated `NDB` tables, you can observe the corresponding actions taken on the NDB API level by the slave, which can be useful when monitoring or troubleshooting MySQL Cluster Replication. NDB API Statistics Counters and Variables, provides additional information.

Replication from `NDB` to non-`NDB` tables. It is possible to replicate `NDB` tables from a MySQL Cluster acting as the master to tables using other MySQL storage engines such as `InnoDB` or `MyISAM` on a slave `mysqld`. However, because of differences between the version of `mysqld` provided with MySQL Cluster and that included with MySQL Server 5.1, the slave server must also use a `mysqld` binary from the MySQL Cluster distribution. See General Requirements for MySQL Cluster Replication.

MySQL Cluster Replication: Abbreviations and Symbols

Throughout this section, we use the following abbreviations or symbols for referring to the master and slave clusters, and to processes and commands run on the clusters or cluster nodes:

Symbol or Abbreviation	Description (Refers to...)
M	The cluster serving as the (primary) replication master
S	The cluster acting as the (primary) replication slave
shell*M*>	Shell command to be issued on the master cluster
mysql*M*>	MySQL client command issued on a single MySQL server running as an SQL node on the master cluster
mysql*M**>	MySQL client command to be issued on all SQL nodes participating in the replication master cluster
shell*S*>	Shell command to be issued on the slave cluster
mysql*S*>	MySQL client command issued on a single MySQL server running as an SQL node on the slave cluster
mysql*S**>	MySQL client command to be issued on all SQL nodes participating in the replication slave cluster
C	Primary replication channel
C'	Secondary replication channel
M'	Secondary replication master
S'	Secondary replication slave

General Requirements for MySQL Cluster Replication

A replication channel requires two MySQL servers acting as replication servers (one each for the master and slave). For example, this means that in the case of a replication setup with two replication channels (to provide an extra channel for redundancy), there will be a total of four replication nodes, two per cluster.

Replication of a MySQL Cluster as described in this section and those following is dependent on row-based replication. This means that the replication master MySQL server must be started with `--binlog-format=ROW` [419] or `--binlog-format=MIXED` [419], as described in Starting MySQL Cluster Replication (Single Replication Channel). For general information about row-based replication, see Replication Formats.

Important

If you attempt to use MySQL Cluster Replication with `--binlog-format=STATEMENT` [419], replication fails to work properly because the `ndb_binlog_index` table on the master and the `epoch` column of the `ndb_apply_status` table on the slave are not updated (see MySQL Cluster Replication Schema and Tables). Instead, only updates on the MySQL server acting as the replication master propagate to the slave, and no updates from any other SQL nodes on the master cluster are replicated.

In all MySQL Cluster NDB 6.x and 7.x releases, the default value for the `--binlog-format` [419] option is `MIXED`.

Each MySQL server used for replication in either cluster must be uniquely identified among all the MySQL replication servers participating in either cluster (you cannot have replication servers on both the master and slave clusters sharing the same ID). This can be done by starting each SQL node using the `--server-id=`*`id`* option, where *`id`* is a unique integer. Although it is not strictly necessary, we will assume for purposes of this discussion that all MySQL Cluster binaries are of the same release version.

It is generally true in MySQL Replication that both MySQL servers (`mysqld` processes) involved must be compatible with one another with respect to both the version of the replication protocol used and the SQL feature sets which they support (see Replication Compatibility Between MySQL Versions). It is due to such differences between the binaries in the MySQL Cluster and MySQL Server 5.1 distributions that MySQL Cluster Replication has the additional requirement that both `mysqld` binaries come from a MySQL Cluster distribution. The simplest and easiest way to assure that the `mysqld` servers are compatible is to use the same MySQL Cluster distribution for all master and slave `mysqld` binaries.

We assume that the slave server or cluster is dedicated to replication of the master, and that no other data is being stored on it.

Note

It is possible to replicate a MySQL Cluster using statement-based replication. However, in this case, the following restrictions apply:

- All updates to data rows on the cluster acting as the master must be directed to a single MySQL server.
- It is not possible to replicate a cluster using multiple simultaneous MySQL replication processes.
- Only changes made at the SQL level are replicated.

These are in addition to the other limitations of statement-based replication as opposed to row-based replication; see Advantages and Disadvantages of Statement-Based and Row-Based Replication, for more specific information concerning the differences between the two replication formats.

Known Issues in MySQL Cluster Replication

This section discusses known problems or issues when using replication with MySQL Cluster in MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1).

Loss of master-slave connection. A loss of connection can occur either between the replication master SQL node and the replication slave SQL node, or between the replication master SQL node and the data nodes in the master cluster. In the latter case, this can occur not only as a result of loss of physical connection (for example, a broken network cable), but due to the overflow of data node event buffers; if the SQL node is too slow to respond, it may be dropped by the cluster (this is controllable to some degree by adjusting the `MaxBufferedEpochs` [1840] and `TimeBetweenEpochs` [1840] configuration parameters). If this occurs, *it is entirely possible for new data to be inserted into the*

master cluster without being recorded in the replication master's binary log. For this reason, to guarantee high availability, it is extremely important to maintain a backup replication channel, to monitor the primary channel, and to fail over to the secondary replication channel when necessary to keep the slave cluster synchronized with the master. MySQL Cluster is not designed to perform such monitoring on its own; for this, an external application is required.

Prior to MySQL 5.1.18, a MySQL Cluster replication slave `mysqld` had no way of detecting that the connection from the master had been interrupted. For this reason, it was possible for the slave to become inconsistent with the master.

Beginning with MySQL 5.1.18, the replication master issues a “gap” event when connecting or reconnecting to the master cluster. (A gap event is a type of “incident event,” which indicates an incident that occurs that affects the contents of the database but that cannot easily be represented as a set of changes. Examples of incidents are server crashes, database resynchronization, (some) software updates, and (some) hardware changes.) When the slave encounters a gap in the replication log, it stops with an error message. This message is available in the output of `SHOW SLAVE STATUS`, and indicates that the SQL thread has stopped due to an incident registered in the replication stream, and that manual intervention is required. See Implementing Failover with MySQL Cluster Replication, for more information about what to do in such circumstances.

Important

Because MySQL Cluster is not designed on its own to monitor replication status or provide failover, if high availability is a requirement for the slave server or cluster, then you must set up multiple replication lines, monitor the master `mysqld` on the primary replication line, and be prepared fail over to a secondary line if and as necessary. This must be done manually, or possibly by means of a third-party application. For information about implementing this type of setup, see Using Two Replication Channels for MySQL Cluster Replication, and Implementing Failover with MySQL Cluster Replication.

However, if you are replicating from a standalone MySQL server to a MySQL Cluster, one channel is usually sufficient.

Multi-byte character sets. Previously, there were several known issues with regard to the use of multi-byte characters sets with MySQL Cluster Replication. These were resolved in MySQL 5.1.21, MySQL Cluster NDB 6.2.14, and MySQL Cluster NDB 6.3.11. (See Bug #27404 and Bug #29562.)

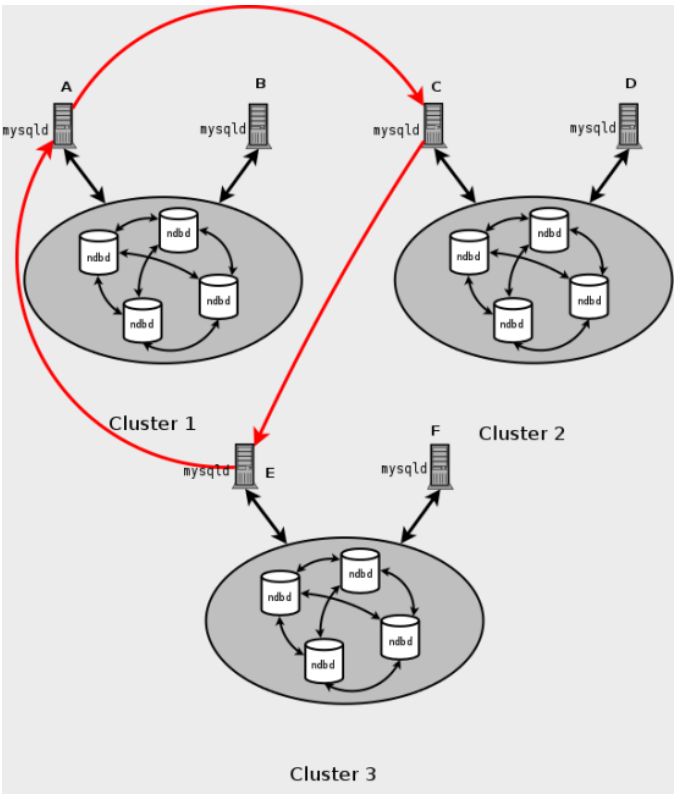
Circular replication. Prior to MySQL 5.1.18, circular replication was not supported with MySQL Cluster replication, due to the fact that all log events created in a particular MySQL Cluster were wrongly tagged with the server ID of the MySQL server used as master and not with the server ID of the originating server.

Beginning with MySQL 5.1.18, this limitation is lifted, as discussed in the next few paragraphs, in which we consider the example of a replication setup involving three MySQL Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication master for Cluster 2, Cluster 2 acts as the master for Cluster 3, and Cluster 3 acts as the master for Cluster 1. Each cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

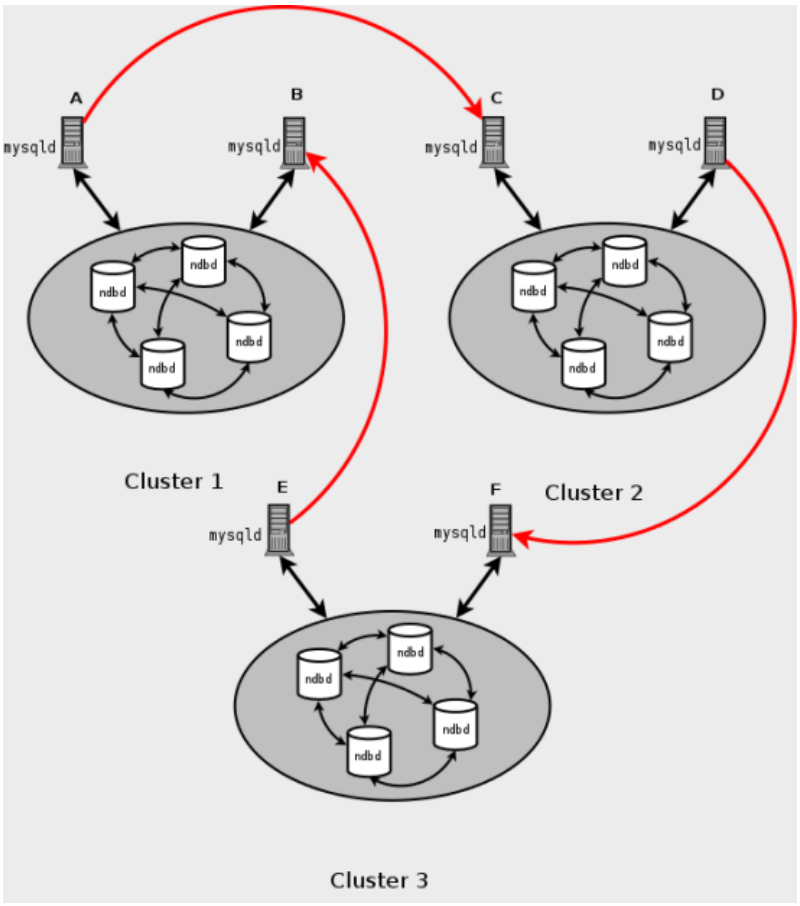
- The SQL nodes on all masters and slaves are the same
- All SQL nodes acting as replication masters and slaves are started using the `--log-slave-updates` [1628] option

This type of circular replication setup is shown in the following diagram:



In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the red arrows in the diagram) directly connects all SQL nodes used as replication masters and slaves.

It should also be possible to set up circular replication in which not all master SQL nodes are also slaves, as shown here:



In this case, different SQL nodes in each cluster are used as replication masters and slaves. However, you must *not* start any of the SQL nodes using `--log-slave-updates` [1628]). This type of circular replication scheme for MySQL Cluster, in which the line of replication (again indicated by the red arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

Note

Beginning with MySQL 5.1.24, the `NDB` storage engine uses *idempotent execution mode*, which suppresses duplicate-key and other errors that otherwise break circular replication of MySQL Cluster. This is equivalent to setting the global `slave_exec_mode` [1644] system variable to `IDEMPOTENT`. This is also required for multi-master replication when using MySQL Cluster. (Bug #31609)

It is not necessary to set `slave_exec_mode` [1644] in MySQL Cluster replication; MySQL Cluster does this automatically for all `NDB` tables and ignores any attempts to set this variable explicitly.

MySQL Cluster replication and primary keys. In MySQL 5.1.6, only those `NDB` tables having explicit primary keys could be replicated. This limitation was lifted in MySQL 5.1.7. However, in the event of a node failure, errors in replication of `NDB` tables without primary keys can still occur, due to the possibility of duplicate rows being inserted in such cases. For this reason, it is highly recommended that all `NDB` tables being replicated have primary keys.

MySQL Cluster Replication and Unique Keys. Prior to MySQL Cluster NDB 7.0.25 and MySQL Cluster NDB 7.1.14, operations that updated values of unique key columns of `NDB` tables could result in duplicate-key errors when replicated. This was due to the ordering of row events in the binary log according to the partitioning of the base table, which meant that they could appear in a different order from that in which they were originally executed. (Bug #11756082)

In MySQL Cluster NDB 7.0.25, MySQL Cluster NDB 7.1.14, and later, this issue is solved for replication between NDB tables by deferring unique key checks until after all table row updates have been performed.

Deferring constraints in this way is currently supported only by NDB. Thus, updates of unique keys when replicating from NDB to a different storage engine such as MyISAM or InnoDB are still not supported.

The problem encountered when replicating without deferred checking of unique key updates can be illustrated using NDB table such as t, is created and populated on the master (and replicated to a slave that does not support deferred unique key updates) as shown here:

```
CREATE TABLE t (
    p INT PRIMARY KEY,
    c INT,
    UNIQUE KEY u (c)
)   ENGINE NDB;

INSERT INTO t
    VALUES (1,1), (2,2), (3,3), (4,4), (5,5);
```

The following UPDATE statement on t succeeded on the master, since the rows affected are processed in the order determined by the ORDER BY option, performed over the entire table:

```
UPDATE t SET c = c - 1 ORDER BY p;
```

However, the same statement failed with a duplicate key error or other constraint violation on the slave, because the ordering of the row updates was done for one partition at a time, rather than for the table as a whole.

Note

In MySQL 5.1.6 and later, every NDB table is implicitly partitioned by key when it is created. This also applies to all MySQL Cluster NDB 6.x and MySQL Cluster NDB 7.x releases. See KEY Partitioning, for more information.

Restarting with `--initial`. Restarting the cluster with the `--initial` [1954] option causes the sequence of GCI and epoch numbers to start over from 0. (This is generally true of MySQL Cluster and not limited to replication scenarios involving Cluster.) The MySQL servers involved in replication should in this case be restarted. After this, you should use the RESET MASTER and RESET SLAVE statements to clear the invalid ndb_binlog_index and ndb_apply_status tables, respectively.

`auto_increment_offset` and `auto_increment_increment` variables. The use of the `auto_increment_offset` [1624] and `auto_increment_increment` [1622] server system variables is supported beginning with MySQL 5.1.20. Previously, these produced unpredictable results when used with NDB tables or MySQL Cluster replication.

Replication from NDB to other storage engines. It is possible to replicate an NDB table on the master to a table using a different storage engine on the slave, taking into account the restrictions listed here:

- Multi-master and circular replication are not supported (tables on both the master and the slave must use the NDB storage engine for this to work).
- Using a storage engine does not perform binary logging for slave tables requires special handling.
- Use of a non-transactional storage engine for slave tables also requires special handling.

The next few paragraphs provide additional information about each of the issues just described.

Multiple masters not supported when replicating NDB to other storage engines. For replication from NDB to a different storage engine, the relationship between the two databases must be a simple

master-slave one. This means that circular or master-master replication is not supported between MySQL Cluster and other storage engines.

In addition, it is not possible to configure more than one replication channel when replicating between NDB and a different storage engine. (However, a MySQL Cluster database *can* simultaneously replicate to multiple slave MySQL Cluster databases.) If the master uses NDB tables, it is still possible to have more than one MySQL Server maintain a binary log of all changes; however, for the slave to change masters (fail over), the new master-slave relationship must be explicitly defined on the slave.

Replicating NDB to a slave storage engine that does not perform binary logging. If you attempt to replicate from a MySQL Cluster to a slave that uses a storage engine that does not handle its own binary logging, the replication process aborts with the error `Binary logging not possible ... Statement cannot be written atomically since more than one engine involved and at least one engine is self-logging` (Error 1595). It is possible to work around this issue in one of the following ways:

- **Turn off binary logging on the slave.** This can be accomplished by setting `sql_log_bin = 0` [525].
- **Change the storage engine used for the `mysql.ndb_apply_status` table.** Causing this table to use an engine that does not handle its own binary logging can also eliminate the conflict. This can be done by issuing a statement such as `ALTER TABLE mysql.ndb_apply_status ENGINE=MyISAM` on the slave. It is safe to do this when using a non-NDB storage engine on the slave, since you do not then need to worry about keeping multiple slave SQL nodes synchronized.
- **Filter out changes to the `mysql.ndb_apply_status` table on the slave.** This can be done by starting the slave SQL node with `--replicate-ignore-table=mysql.ndb_apply_status` [1636]. If you need for other tables to be ignored by replication, you might wish to use an appropriate `--replicate-wild-ignore-table` [1638] option instead.

Important

You should *not* disable replication or binary logging of `mysql.ndb_apply_status` or change the storage engine used for this table when replicating from one MySQL Cluster to another. See Replication and binary log filtering rules with replication between MySQL Clusters, for details.

Replication from NDB to a nontransactional storage engine. When replicating from NDB to a nontransactional storage engine such as MyISAM, you may encounter unnecessary duplicate key errors when replicating `INSERT ... ON DUPLICATE KEY UPDATE` statements. You can suppress these in MySQL Cluster NDB 6.2 and later MySQL Cluster releases by using `--ndb-log-update-as-write=0` [2143], which forces updates to be logged as writes (rather than as updates).

In addition, when replicating from NDB to a storage engine that does not implement transactions, if the slave fails to apply any row changes from a given transaction, it does not roll back the rest of the transaction. (This is true when replicating tables using any transactional storage engine—not only NDB—to a nontransactional storage engine.) Because of this, it cannot be guaranteed that transactional consistency will be maintained on the slave in such cases.

Replication and binary log filtering rules with replication between MySQL Clusters. If you are using any of the options `--replicate-do-*`, `--replicate-ignore-*`, `--binlog-do-db` [1649], or `--binlog-ignore-db` [1651] to filter databases or tables being replicated, care must be taken not to block replication or binary logging of the `mysql.ndb_apply_status`, which is required for replication between MySQL Clusters to operate properly. In particular, you must keep in mind the following:

1. Using `--replicate-do-db=`*`db_name`* [1634] (and no other `--replicate-do-*` or `--replicate-ignore-*` options) means that *only* tables in database *`db_name`* are replicated.

In this case, you should also use `--replicate-do-db=mysql` [1634], `--binlog-do-db=mysql` [1649], or `--replicate-do-table=mysql.ndb_apply_status` [1636] to ensure that `mysql.ndb_apply_status` is populated on slaves.

Using `--binlog-do-db=db_name` [1649] (and no other `--binlog-do-db` [1649] options) means that changes *only* to tables in database *db_name* are written to the binary log. In this case, you should also use `--replicate-do-db=mysql` [1634], `--binlog-do-db=mysql` [1649], or `--replicate-do-table=mysql.ndb_apply_status` [1636] to ensure that `mysql.ndb_apply_status` is populated on slaves.

2. Using `--replicate-ignore-db=mysql` [1635] means that no tables in the `mysql` database are replicated. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` [1636] to ensure that `mysql.ndb_apply_status` is replicated.

   Using `--binlog-ignore-db=mysql` [1651] means that no changes to tables in the `mysql` database are written to the binary log. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` [1636] to ensure that `mysql.ndb_apply_status` is replicated.

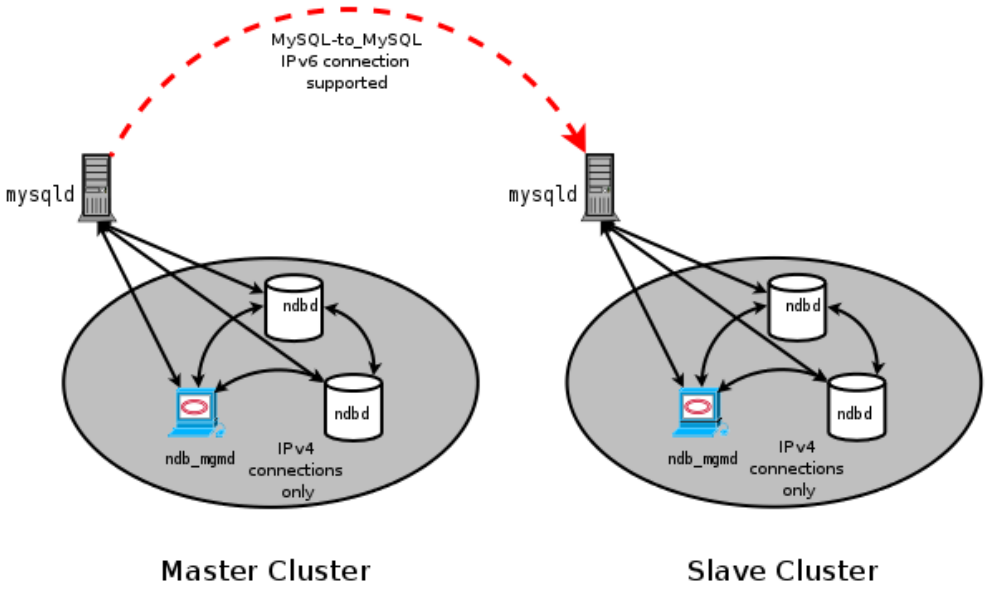
You should also remember that each replication rule requires the following:

1. Its own `--replicate-do-*` or `--replicate-ignore-*` option, and that multiple rules cannot be expressed in a single replication filtering option. For information about these rules, see Replication and Binary Logging Options and Variables.

2. Its own `--binlog-do-db` [1649] or `--binlog-ignore-db` [1651] option, and that multiple rules cannot be expressed in a single binary log filtering option. For information about these rules, see The Binary Log.

If you are replicating a MySQL Cluster to a slave that uses a storage engine other than `NDB`, the considerations just given previously may not apply, as discussed elsewhere in this section.

MySQL Cluster Replication and IPv6. Currently, the NDB API and MGM API do not support IPv6. However, beginning with MySQL Cluster NDB 6.4.1, MySQL Servers—including those acting as SQL nodes in a MySQL Cluster—can use IPv6 to contact other MySQL Servers. This means that you can replicate between MySQL Clusters using IPv6 to connect the master and slave SQL nodes as shown by the dotted arrow in the following diagram:



However, all connections originating *within* the MySQL Cluster—represented in the preceding diagram by solid arrows—must use IPv4. In other words, all MySQL Cluster data nodes, management servers, and management clients must be accessible from one another using IPv4. In addition, SQL nodes must use IPv4 to communicate with the cluster.

Since there is currently no support in the NDB and MGM APIs for IPv6, any applications written using these APIs must also make all connections using IPv4.

Attribute promotion and demotion. Formerly, support in MySQL Cluster for type conversions between columns of similar but different types on the master and the slave was extremely limited. However, starting with MySQL Cluster NDB 6.3.33, 7.0.14, and 7.1.3, MySQL Cluster Replication includes support for attribute promotion and demotion. The implementation of the latter distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` [1646] global server system variable.

For more information about attribute promotion and demotion in MySQL Cluster, see Attribute promotion and demotion (MySQL Cluster).

MySQL Cluster Replication Schema and Tables

Replication in MySQL Cluster makes use of a number of dedicated tables in the `mysql` database on each MySQL Server instance acting as an SQL node in both the cluster being replicated and the replication slave (whether the slave is a single server or a cluster). These tables are created during the MySQL installation process by the `mysql_install_db` script, and include a table for storing the binary log's indexing data. Since the `ndb_binlog_index` table is local to each MySQL server and does not participate in clustering, it uses the `MyISAM` storage engine. This means that it must be created separately on each `mysqld` participating in the master cluster. (However, the binary log itself contains updates from all MySQL servers in the cluster to be replicated.) This table is defined as follows:

```
CREATE TABLE `ndb_binlog_index` (
    `Position`  BIGINT(20) UNSIGNED NOT NULL,
    `File`      VARCHAR(255) NOT NULL,
    `epoch`     BIGINT(20) UNSIGNED NOT NULL,
    `inserts`   BIGINT(20) UNSIGNED NOT NULL,
    `updates`   BIGINT(20) UNSIGNED NOT NULL,
    `deletes`   BIGINT(20) UNSIGNED NOT NULL,
    `schemaops` BIGINT(20) UNSIGNED NOT NULL,
    `next_position` bigint(20) unsigned NOT NULL,
    `next_file` varchar(255) NOT NULL,
    PRIMARY KEY (`epoch`)
) ENGINE=MYISAM  DEFAULT CHARSET=latin1;
```

The `next_position` and `next_file` columns were added in MySQL Cluster NDB 7.2.6; see Implementing Failover with MySQL Cluster Replication, for more information about using these columns.

Important

Prior to MySQL 5.1.14, the `ndb_binlog_index` table was known as `binlog_index`, and was kept in a separate `cluster` database, which in MySQL 5.1.7 and earlier was known as the `cluster_replication` database. Similarly, the `ndb_apply_status` and `ndb_schema` tables were known as `apply_status` and `schema`, and were also found in the `cluster` (earlier `cluster_replication`) database. However, beginning with MySQL 5.1.14, all MySQL Cluster replication tables reside in the `mysql` system database.

Information about how this change affects upgrades from MySQL Cluster 5.1.13 and earlier to 5.1.14 and later versions can be found in Changes in MySQL 5.1.14 (2006-12-05).

Beginning with MySQL Cluster NDB 6.3.2, this table has been changed to facilitate 3-way replication recovery. Two columns `orig_server_id` and `orig_epoch` have been added to this table; when

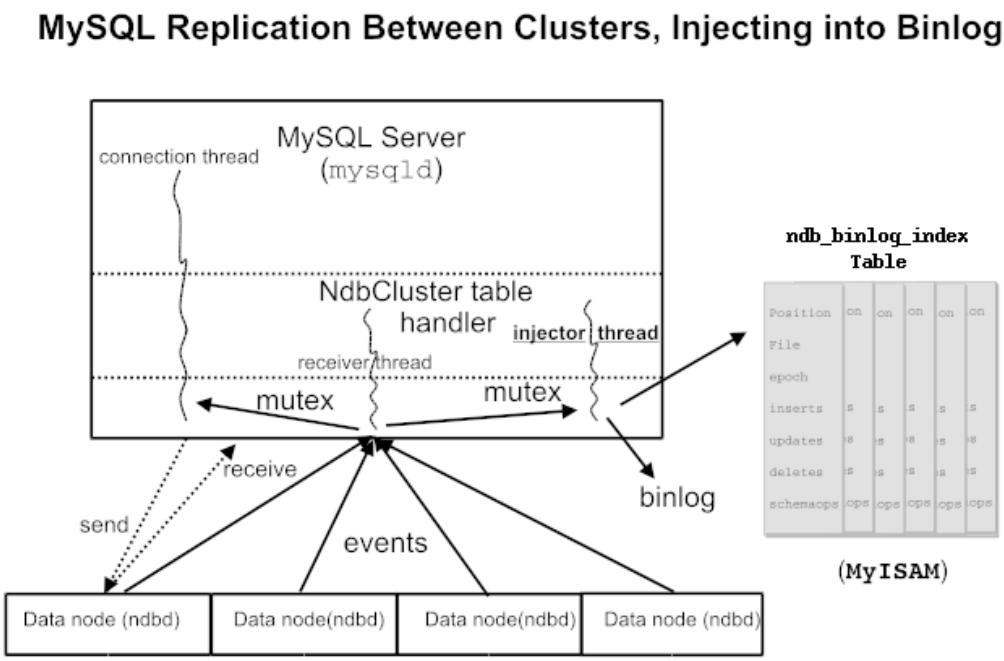
`mysqld` is started with the `--ndb-log-orig` option, these columns store, respectively, the ID of the server on which the event originated and the epoch in which the event took place on the originating server. In addition, the table's primary key now includes these two columns. The modified table definition is shown here:

```
CREATE TABLE `ndb_binlog_index` (
    `Position` BIGINT(20) UNSIGNED NOT NULL,
    `File` VARCHAR(255) NOT NULL,
    `epoch` BIGINT(20) UNSIGNED NOT NULL,
    `inserts` INT(10) UNSIGNED NOT NULL,
    `updates` INT(10) UNSIGNED NOT NULL,
    `deletes` INT(10) UNSIGNED NOT NULL,
    `schemaops` INT(10) UNSIGNED NOT NULL,
    `orig_server_id` INT(10) UNSIGNED NOT NULL,
    `orig_epoch` BIGINT(20) UNSIGNED NOT NULL,
    `gci` INT(10) UNSIGNED NOT NULL,
    `next_position` bigint(20) unsigned NOT NULL,
    `next_file` varchar(255) NOT NULL,
    PRIMARY KEY (`epoch`,`orig_server_id`,`orig_epoch`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;
```

The `gci` column was added in MySQL Cluster NDB 6.2.6 and MySQL Cluster NDB 6.3.2.

The `next_position` and `next_file` columns were added in MySQL Cluster NDB 7.0.33 and MySQL Cluster NDB 7.1.22; see Implementing Failover with MySQL Cluster Replication, for more information about using these columns.

The following figure shows the relationship of the MySQL Cluster replication master server, its binlog injector thread, and the `mysql.ndb_binlog_index` table.



An additional table, named `ndb_apply_status`, is used to keep a record of the operations that have been replicated from the master to the slave. Unlike the case with `ndb_binlog_index`, the data in this table is not specific to any one SQL node in the (slave) cluster, and so `ndb_apply_status` can use the `NDBCLUSTER` storage engine, as shown here:

```
CREATE TABLE `ndb_apply_status` (
    `server_id`   INT(10) UNSIGNED NOT NULL,
    `epoch`       BIGINT(20) UNSIGNED NOT NULL,
```

```
    `log_name`    VARCHAR(255) CHARACTER SET latin1 COLLATE latin1_bin NOT NULL,
    `start_pos`   BIGINT(20) UNSIGNED NOT NULL,
    `end_pos`     BIGINT(20) UNSIGNED NOT NULL,
    PRIMARY KEY (`server_id`) USING HASH
) ENGINE=NDBCLUSTER   DEFAULT CHARSET=latin1;
```

This table is populated only on slaves; on the master, no `DataMemory` [1817] is allocated to it. Since this table is populated from data originating on the master, it should be allowed to replicate; any replication filtering or binary log filtering rules that inadvertently prevent the slave from updating `ndb_apply_status` or the master from writing into the binary log may prevent replication between clusters from operating properly. For more information about potential problems arising from such filtering rules, see Replication and binary log filtering rules with replication between MySQL Clusters.

The `log_name`, `start_pos`, and `end_pos` columns were added in MySQL 5.1.18.

Important

If you are using MySQL Cluster replication, see Upgrade and downgrade compatibility: MySQL 5.1 before upgrading to MySQL 5.1.18 or later from an earlier version.

The `ndb_binlog_index` and `ndb_apply_status` tables are created in the `mysql` database because they should not be explicitly replicated by the user. User intervention is normally not required to create or maintain either of these tables, since both `ndb_binlog_index` and the `ndb_apply_status` are maintained by the `NDB` binary log (binlog) injector thread. This keeps the master `mysqld` process updated to changes performed by the `NDB` storage engine. The `NDB` *binlog injector thread* receives events directly from the `NDB` storage engine. The `NDB` injector is responsible for capturing all the data events within the cluster, and ensures that all events which change, insert, or delete data are recorded in the `ndb_binlog_index` table. The slave I/O thread transfers the events from the master's binary log to the slave's relay log.

However, it is advisable to check for the existence and integrity of these tables as an initial step in preparing a MySQL Cluster for replication. It is possible to view event data recorded in the binary log by querying the `mysql.ndb_binlog_index` table directly on the master. This can be also be accomplished using the `SHOW BINLOG EVENTS` statement on either the replication master or slave MySQL servers. (See `SHOW BINLOG EVENTS` Syntax.)

You can also obtain useful information from the output of `SHOW ENGINE NDB STATUS`.

The `ndb_schema` table is used to track schema changes made to `NDB` tables. It is defined as shown here:

```
CREATE TABLE ndb_schema (
    `db` VARBINARY(63) NOT NULL,
    `name` VARBINARY(63) NOT NULL,
    `slock` BINARY(32) NOT NULL,
    `query` BLOB NOT NULL,
    `node_id` INT UNSIGNED NOT NULL,
    `epoch` BIGINT UNSIGNED NOT NULL,
    `id` INT UNSIGNED NOT NULL,
    `version` INT UNSIGNED NOT NULL,
    `type` INT UNSIGNED NOT NULL,
    PRIMARY KEY USING HASH (db,name)
) ENGINE=NDB   DEFAULT CHARSET=latin1;
```

Unlike the two tables previously mentioned in this section, the `ndb_schema` table is not visible either to MySQL `SHOW` statements, or in any `INFORMATION_SCHEMA` tables; however, it can be seen in the output of `ndb_show_tables`, as shown here:

```
shell> ndb_show_tables -t 2
id    type                state    logging database     schema   name
4     UserTable           Online   Yes     mysql        def      ndb_apply_status
```

```
5     UserTable            Online   Yes     ndbworld     def      City
6     UserTable            Online   Yes     ndbworld     def      Country
3     UserTable            Online   Yes     mysql        def      NDB$BLOB_2_3
7     UserTable            Online   Yes     ndbworld     def      CountryLanguage
2     UserTable            Online   Yes     mysql        def      ndb_schema

NDBT_ProgramExit: 0 - OK
```

It is also possible to `SELECT` from this table in `mysql` and other MySQL client applications, as shown here:

```
mysql> SELECT * FROM mysql.ndb_schema WHERE name='City' \G
*************************** 1. row ***************************
     db: ndbworld
   name: City
  slock:
  query: alter table City engine=ndb
node_id: 4
  epoch: 0
     id: 0
version: 0
   type: 7
1 row in set (0.00 sec)
```

This can sometimes be useful when debugging applications.

Note

When performing schema changes on `NDB` tables, applications should wait until the `ALTER TABLE` statement has returned in the MySQL client connection that issued the statement before attempting to use the updated definition of the table.

The `ndb_schema` table was added in MySQL 5.1.8.

Beginning with MySQL 5.1.14, if the `ndb_apply_status` table or the `ndb_schema` table does not exist on the slave, `ndb_restore` re-creates the missing table or tables (Bug #14612).

Conflict resolution for MySQL Cluster Replication requires the presence of an additional `mysql.ndb_replication` table. Currently, this table must be created manually. For information about how to do this, see MySQL Cluster Replication Conflict Resolution.

Preparing the MySQL Cluster for Replication

Preparing the MySQL Cluster for replication consists of the following steps:

1. Check all MySQL servers for version compatibility (see General Requirements for MySQL Cluster Replication).

2. Create a slave account on the master Cluster with the appropriate privileges:

   ```
   mysqlM> GRANT REPLICATION SLAVE
        -> ON *.* TO 'slave_user'@'slave_host'
        -> IDENTIFIED BY 'slave_password';
   ```

   In the previous statement, *`slave_user`* is the slave account user name, *`slave_host`* is the host name or IP address of the replication slave, and *`slave_password`* is the password to assign to this account.

   For example, to create a slave user account with the name “`myslave`,” logging in from the host named “`rep-slave`,” and using the password “`53cr37`,” use the following `GRANT` statement:

   ```
   mysqlM> GRANT REPLICATION SLAVE
        -> ON *.* TO 'myslave'@'rep-slave'
        -> IDENTIFIED BY '53cr37';
   ```

For security reasons, it is preferable to use a unique user account—not employed for any other purpose—for the replication slave account.

3. Configure the slave to use the master. Using the MySQL Monitor, this can be accomplished with the `CHANGE MASTER TO` statement:

```
mysqlS> CHANGE MASTER TO
     -> MASTER_HOST='master_host',
     -> MASTER_PORT=master_port,
     -> MASTER_USER='slave_user',
     -> MASTER_PASSWORD='slave_password';
```

In the previous statement, *`master_host`* is the host name or IP address of the replication master, *`master_port`* is the port for the slave to use for connecting to the master, *`slave_user`* is the user name set up for the slave on the master, and *`slave_password`* is the password set for that user account in the previous step.

For example, to tell the slave to replicate from the MySQL server whose host name is "`rep-master`," using the replication slave account created in the previous step, use the following statement:

```
mysqlS> CHANGE MASTER TO
     -> MASTER_HOST='rep-master',
     -> MASTER_PORT=3306,
     -> MASTER_USER='myslave',
     -> MASTER_PASSWORD='53cr37';
```

For a complete list of options that can be used with this statement, see `CHANGE MASTER TO` Syntax.

To provide replication backup capability, you also need to add an `ndb-connectstring` option to the slave's `my.cnf` file prior to starting the replication process. See MySQL Cluster Backups With MySQL Cluster Replication, for details.

For additional options that can be set in `my.cnf` for replication slaves, see Replication and Binary Logging Options and Variables.

4. If the master cluster is already in use, you can create a backup of the master and load this onto the slave to cut down on the amount of time required for the slave to synchronize itself with the master. If the slave is also running MySQL Cluster, this can be accomplished using the backup and restore procedure described in MySQL Cluster Backups With MySQL Cluster Replication.

```
ndb-connectstring=management_host[:port]
```

In the event that you are *not* using MySQL Cluster on the replication slave, you can create a backup with this command on the replication master:

```
shellM> mysqldump --master-data=1
```

Then import the resulting data dump onto the slave by copying the dump file over to the slave. After this, you can use the `mysql` client to import the data from the dumpfile into the slave database as shown here, where *`dump_file`* is the name of the file that was generated using `mysqldump` on the master, and *`db_name`* is the name of the database to be replicated:

```
shellS> mysql -u root -p db_name < dump_file
```

For a complete list of options to use with `mysqldump`, see `mysqldump` — A Database Backup Program.

Note

If you copy the data to the slave in this fashion, you should make sure that the slave is started with the `--skip-slave-start` option on the command

line, or else include `skip-slave-start` in the slave's `my.cnf` file to keep it from trying to connect to the master to begin replicating before all the data has been loaded. Once the data loading has completed, follow the additional steps outlined in the next two sections.

5. Ensure that each MySQL server acting as a replication master is configured with a unique server ID, and with binary logging enabled, using the row format. (See Replication Formats.) These options can be set either in the master server's `my.cnf` file, or on the command line when starting the master `mysqld` process. See Starting MySQL Cluster Replication (Single Replication Channel), for information regarding the latter option.

Starting MySQL Cluster Replication (Single Replication Channel)

This section outlines the procedure for starting MySQL Cluster replication using a single replication channel.

1. Start the MySQL replication master server by issuing this command:

```
shellM> mysqld --ndbcluster --server-id=id \
        --log-bin --binlog-format=ROW &
```

In the previous statement, *`id`* is this server's unique ID (see General Requirements for MySQL Cluster Replication). This starts the server's `mysqld` process with binary logging enabled using the proper logging format.

Note

You can also start the master with `--binlog-format=MIXED` [419], in which case row-based replication is used automatically when replicating between clusters.

2. Start the MySQL replication slave server as shown here:

```
shellS> mysqld --ndbcluster --server-id=id &
```

In the command just shown, *`id`* is the slave server's unique ID. It is not necessary to enable logging on the replication slave.

Note

You should use the `--skip-slave-start` option with this command or else you should include `skip-slave-start` in the slave server's `my.cnf` file, unless you want replication to begin immediately. With the use of this option, the start of replication is delayed until the appropriate `START SLAVE` statement has been issued, as explained in Step 4 below.

3. It is necessary to synchronize the slave server with the master server's replication binary log. If binary logging has not previously been running on the master, run the following statement on the slave:

```
mysqlS> CHANGE MASTER TO
     -> MASTER_LOG_FILE='',
     -> MASTER_LOG_POS=4;
```

This instructs the slave to begin reading the master's binary log from the log's starting point. Otherwise—that is, if you are loading data from the master using a backup—see Implementing Failover with MySQL Cluster Replication, for information on how to obtain the correct values to use for `MASTER_LOG_FILE` and `MASTER_LOG_POS` in such cases.

4. Finally, you must instruct the slave to begin applying replication by issuing this command from the `mysql` client on the replication slave:

```
mysqlS> START SLAVE;
```

This also initiates the transmission of replication data from the master to the slave.

It is also possible to use two replication channels, in a manner similar to the procedure described in the next section; the differences between this and using a single replication channel are covered in Using Two Replication Channels for MySQL Cluster Replication.

Beginning with MySQL Cluster NDB 6.2.3, it is possible to improve cluster replication performance by enabling *batched updates*. This can be accomplished by setting the `slave_allow_batching` [1930] system variable on the slave `mysqld` processes. Normally, updates are applied as soon as they are received. However, the use of batching causes updates to be applied in 32 KB batches, which can result in higher throughput and less CPU usage, particularly where individual updates are relatively small.

Note

Slave batching works on a per-epoch basis; updates belonging to more than one transaction can be sent as part of the same batch.

All outstanding updates are applied when the end of an epoch is reached, even if the updates total less than 32 KB.

Batching can be turned on and off at runtime. To activate it at runtime, you can use either of these two statements:

```
SET GLOBAL slave_allow_batching = 1;
SET GLOBAL slave_allow_batching = ON;
```

If a particular batch causes problems (such as a statement whose effects do not appear to be replicated correctly), slave batching can be deactivated using either of the following statements:

```
SET GLOBAL slave_allow_batching = 0;
SET GLOBAL slave_allow_batching = OFF;
```

You can check whether slave batching is currently being used by means of an appropriate `SHOW VARIABLES` statement, like this one:

```
mysql> SHOW VARIABLES LIKE 'slave%';
+---------------------------+-------+
| Variable_name             | Value |
+---------------------------+-------+
| slave_allow_batching      | ON    |
| slave_compressed_protocol | OFF   |
| slave_load_tmpdir         | /tmp  |
| slave_net_timeout         | 3600  |
| slave_skip_errors         | OFF   |
| slave_transaction_retries | 10    |
+---------------------------+-------+
6 rows in set (0.00 sec)
```

Using Two Replication Channels for MySQL Cluster Replication

In a more complete example scenario, we envision two replication channels to provide redundancy and thereby guard against possible failure of a single replication channel. This requires a total of four replication servers, two masters for the master cluster and two slave servers for the slave cluster. For purposes of the discussion that follows, we assume that unique identifiers are assigned as shown here:

Server ID	Description
1	Master - primary replication channel (*M*)
2	Master - secondary replication channel (*M'*)
3	Slave - primary replication channel (*S*)
4	Slave - secondary replication channel (*S'*)

Setting up replication with two channels is not radically different from setting up a single replication channel. First, the `mysqld` processes for the primary and secondary replication masters must be started, followed by those for the primary and secondary slaves. Then the replication processes may be initiated by issuing the `START SLAVE` statement on each of the slaves. The commands and the order in which they need to be issued are shown here:

1. Start the primary replication master:

```
shellM> mysqld --ndbcluster --server-id=1 \
               --log-bin --binlog-format=ROW &
```

2. Start the secondary replication master:

```
shellM'> mysqld --ndbcluster --server-id=2 \
               --log-bin --binlog-format=ROW &
```

3. Start the primary replication slave server:

```
shellS> mysqld --ndbcluster --server-id=3 \
               --skip-slave-start &
```

4. Start the secondary replication slave:

```
shellS'> mysqld --ndbcluster --server-id=4 \
                --skip-slave-start &
```

5. Finally, initiate replication on the primary channel by executing the `START SLAVE` statement on the primary slave as shown here:

```
mysqlS> START SLAVE;
```

Warning

Only the primary channel is to be started at this point. The secondary replication channel is to be started only in the event that the primary replication channel fails, as described in Implementing Failover with MySQL Cluster Replication. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replication slaves.

As mentioned previously, it is not necessary to enable binary logging on replication slaves.

Implementing Failover with MySQL Cluster Replication

In the event that the primary Cluster replication process fails, it is possible to switch over to the secondary replication channel. The following procedure describes the steps required to accomplish this.

1. Obtain the time of the most recent global checkpoint (GCP). That is, you need to determine the most recent epoch from the `ndb_apply_status` table on the slave cluster, which can be found using the following query:

```
mysqlS'> SELECT @latest:=MAX(epoch)
      ->        FROM mysql.ndb_apply_status;
```

2. Using the information obtained from the query shown in Step 1, obtain the corresponding records from the `ndb_binlog_index` table on the master cluster.

   Prior to MySQL Cluster NDB 7.0.33 and MySQL Cluster 7.1.22, you should use the following query to accomplish this task:

```
mysqlM'> SELECT
      ->     @file:=SUBSTRING_INDEX(File, '/', -1),
      ->     @pos:=Position
      -> FROM mysql.ndb_binlog_index
      -> WHERE epoch > @latest
```

```
      -> ORDER BY epoch ASC LIMIT 1;
```

Beginning with MySQL Cluster NDB 7.0.33 and MySQL Cluster NDB 7.1.22, you can take advantage of the improved binary logging of DDL statements implemented in those and later versions by using the following query to obtain the needed records from the master's `ndb_binlog_index` table:

```
mysqlM'> SELECT
      ->     @file:=SUBSTRING_INDEX(next_file, '/', -1),
      ->     @pos:=next_position
      -> FROM mysql.ndb_binlog_index
      -> WHERE epoch = @latest
      -> ORDER BY epoch ASC LIMIT 1;
```

In either case, these are the records saved on the master since the failure of the primary replication channel. We have employed a user variable `@latest` here to represent the value obtained in Step 1. Of course, it is not possible for one `mysqld` instance to access user variables set on another server instance directly. These values must be “plugged in” to the second query manually or in application code.

Important

If (and only if) you use the second of the two queries just shown against `ndb_binlog_index` (that is, the query that employs the `next_position` and `next_file` columns), you must ensure that the slave `mysqld` is started with `--slave-skip-errors=ddl_exist_errors` [1641] before executing `START SLAVE`. Otherwise, replication may stop with duplicate DDL errors.

3. Now it is possible to synchronize the secondary channel by running the following query on the secondary slave server:

```
mysqlS'> CHANGE MASTER TO
      ->     MASTER_LOG_FILE='@file',
      ->     MASTER_LOG_POS=@pos;
```

Again we have employed user variables (in this case `@file` and `@pos`) to represent the values obtained in Step 2 and applied in Step 3; in practice these values must be inserted manually or using application code that can access both of the servers involved.

Note

`@file` is a string value such as `'/var/log/mysql/replication-master-bin.00001'`, and so must be quoted when used in SQL or application code. However, the value represented by `@pos` must *not* be quoted. Although MySQL normally attempts to convert strings to numbers, this case is an exception.

4. You can now initiate replication on the secondary channel by issuing the appropriate command on the secondary slave `mysqld`:

```
mysqlS'> START SLAVE;
```

Once the secondary replication channel is active, you can investigate the failure of the primary and effect repairs. The precise actions required to do this will depend upon the reasons for which the primary channel failed.

Warning

The secondary replication channel is to be started only if and when the primary replication channel has failed. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replication slaves.

If the failure is limited to a single server, it should (in theory) be possible to replicate from *M* to *S'*, or from *M'* to *S*; however, this has not yet been tested.

MySQL Cluster Backups With MySQL Cluster Replication

This section discusses making backups and restoring from them using MySQL Cluster replication. We assume that the replication servers have already been configured as covered previously (see Preparing the MySQL Cluster for Replication, and the sections immediately following). This having been done, the procedure for making a backup and then restoring from it is as follows:

1. There are two different methods by which the backup may be started.

   - **Method A.** This method requires that the cluster backup process was previously enabled on the master server, prior to starting the replication process. This can be done by including the following line in a `[mysql_cluster]` section in the `my.cnf file`, where *`management_host`* is the IP address or host name of the `NDB` management server for the master cluster, and *`port`* is the management server's port number:

     ```
     ndb-connectstring=management_host[:port]
     ```

     Note

     The port number needs to be specified only if the default port (1186) is not being used. See Initial Configuration of MySQL Cluster, for more information about ports and port allocation in MySQL Cluster.

     In this case, the backup can be started by executing this statement on the replication master:

     ```
     shellM> ndb_mgm -e "START BACKUP"
     ```

   - **Method B.** If the `my.cnf` file does not specify where to find the management host, you can start the backup process by passing this information to the `NDB` management client as part of the `START BACKUP` command. This can be done as shown here, where *`management_host`* and *`port`* are the host name and port number of the management server:

     ```
     shellM> ndb_mgm management_host:port -e "START BACKUP"
     ```

     In our scenario as outlined earlier (see Preparing the MySQL Cluster for Replication), this would be executed as follows:

     ```
     shellM> ndb_mgm rep-master:1186 -e "START BACKUP"
     ```

2. Copy the cluster backup files to the slave that is being brought on line. Each system running an `ndbd` process for the master cluster will have cluster backup files located on it, and *all* of these files must be copied to the slave to ensure a successful restore. The backup files can be copied into any directory on the computer where the slave management host resides, so long as the MySQL and NDB binaries have read permissions in that directory. In this case, we will assume that these files have been copied into the directory `/var/BACKUPS/BACKUP-1`.

   It is not necessary that the slave cluster have the same number of `ndbd` processes (data nodes) as the master; however, it is highly recommended this number be the same. It *is* necessary that the slave be started with the `--skip-slave-start` option, to prevent premature startup of the replication process.

3. Create any databases on the slave cluster that are present on the master cluster that are to be replicated to the slave.

   Important

   A `CREATE DATABASE` (or `CREATE SCHEMA`) statement corresponding to each database to be replicated must be executed on each SQL node in the slave cluster.

4. Reset the slave cluster using this statement in the MySQL Monitor:

```
mysqlS> RESET SLAVE;
```

   It is important to make sure that the slave's `apply_status` table does not contain any records prior to running the restore process. You can accomplish this by running this SQL statement on the slave:

```
mysqlS> DELETE FROM mysql.ndb_apply_status;
```

5. You can now start the cluster restoration process on the replication slave using the `ndb_restore` command for each backup file in turn. For the first of these, it is necessary to include the `-m` option to restore the cluster metadata:

```
shellS> ndb_restore -c slave_host:port -n node-id \
        -b backup-id -m -r dir
```

   `dir` is the path to the directory where the backup files have been placed on the replication slave. For the `ndb_restore` commands corresponding to the remaining backup files, the `-m` option should *not* be used.

   For restoring from a master cluster with four data nodes (as shown in the figure in MySQL Cluster Replication) where the backup files have been copied to the directory `/var/BACKUPS/BACKUP-1`, the proper sequence of commands to be executed on the slave might look like this:

```
shellS> ndb_restore -c rep-slave:1186 -n 2 -b 1 -m \
        -r ./var/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 3 -b 1 \
        -r ./var/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 4 -b 1 \
        -r ./var/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 5 -b 1 -e \
        -r ./var/BACKUPS/BACKUP-1
```

Important

The `-e` (or `--restore-epoch`) option in the final invocation of `ndb_restore` in this example is required in order that the epoch is written to the slave `mysql.ndb_apply_status`. Without this information, the slave will not be able to synchronize properly with the master. (See `ndb_restore` — Restore a MySQL Cluster Backup.)

6. Now you need to obtain the most recent epoch from the `ndb_apply_status` table on the slave (as discussed in Implementing Failover with MySQL Cluster Replication):

```
mysqlS> SELECT @latest:=MAX(epoch)
        FROM mysql.ndb_apply_status;
```

7. Using `@latest` as the epoch value obtained in the previous step, you can obtain the correct starting position `@pos` in the correct binary log file `@file` from the master's `mysql.ndb_binlog_index` table using the query shown here:

```
mysqlM> SELECT
     ->     @file:=SUBSTRING_INDEX(File, '/', -1),
     ->     @pos:=Position
     -> FROM mysql.ndb_binlog_index
     -> WHERE epoch > @latest
     -> ORDER BY epoch ASC LIMIT 1;
```

   In the event that there is currently no replication traffic, you can get this information by running `SHOW MASTER STATUS` on the master and using the value in the `Position` column for the file whose name has the suffix with the greatest value for all files shown in the `File` column. However, in this case, you must determine this and supply it in the next step manually or by parsing the output with a script.

8. Using the values obtained in the previous step, you can now issue the appropriate `CHANGE MASTER TO` statement in the slave's `mysql` client:

```
mysqlS> CHANGE MASTER TO
     ->     MASTER_LOG_FILE='@file',
     ->     MASTER_LOG_POS=@pos;
```

9. Now that the slave “knows” from what point in which `binlog` file to start reading data from the master, you can cause the slave to begin replicating with this standard MySQL statement:

```
mysqlS> START SLAVE;
```

To perform a backup and restore on a second replication channel, it is necessary only to repeat these steps, substituting the host names and IDs of the secondary master and slave for those of the primary master and slave replication servers where appropriate, and running the preceding statements on them.

For additional information on performing Cluster backups and restoring Cluster from backups, see Online Backup of MySQL Cluster.

MySQL Cluster Replication: Automating Synchronization of the Replication Slave to the Master Binary Log

It is possible to automate much of the process described in the previous section (see MySQL Cluster Backups With MySQL Cluster Replication). The following Perl script `reset-slave.pl` serves as an example of how you can do this.

```
#!/user/bin/perl -w

#  file: reset-slave.pl

Point-In-Time Recovery Using MySQL Cluster Replication

Point-in-time recovery—that is, recovery of data changes made since a given point in time—is performed after restoring a full backup that returns the server to its state when the backup was made. Performing point-in-time recovery of MySQL Cluster tables with MySQL Cluster and MySQL

Cluster Replication can be accomplished using a native `NDB` data backup (taken by issuing `CREATE BACKUP` in the `ndb_mgm` client) and restoring the `ndb_binlog_index` table (from a dump made using `mysqldump`).

To perform point-in-time recovery of MySQL Cluster, it is necessary to follow the steps shown here:

1. Back up all `NDB` databases in the cluster, using the `START BACKUP` command in the `ndb_mgm` client (see Online Backup of MySQL Cluster).
2. At some later point, prior to restoring the cluster, make a backup of the `mysql.ndb_binlog_index` table. It is probably simplest to use `mysqldump` for this task. Also back up the binary log files at this time.

   This backup should be updated regularly—perhaps even hourly—depending on your needs.
3. (*Catastrophic failure or error occurs*.)
4. Locate the last known good backup.
5. Clear the data node file systems (using `ndbd --initial` [1954] or, in MySQL Cluster NDB 7.0 and later, `ndbmtd --initial` [1954]).

   Note

   MySQL Cluster Disk Data tablespace and log files are not removed by `--initial` [1954]. You must delete these manually.
6. Use `DROP TABLE` or `TRUNCATE TABLE` with the `mysql.ndb_binlog_index` table.
7. Execute `ndb_restore`, restoring all data. You must include the `--restore_epoch` [1996] option when you run `ndb_restore`, so that the `ndb_apply_status` table is populated correctly. (See `ndb_restore` — Restore a MySQL Cluster Backup, for more information.)
8. Restore the `ndb_binlog_index` table from the output of `mysqldump` and restore the binary log files from backup, if necessary.
9. Find the epoch applied most recently—that is, the maximum `epoch` column value in the `ndb_apply_status` table—as the user variable `@LATEST_EPOCH` (emphasized):

   ```
   SELECT @LAST_EPOCH:=MAX(epoch)
       FROM mysql.ndb_apply_status;
   ```
10. Find the latest binary log file (`@FIRST_FILE`) and position (`Position` column value) within this file that correspond to `@LATEST_EPOCH` in the `ndb_binlog_index` table:

    ```
    SELECT Position, @FIRST_FILE:=File
        FROM mysql.ndb_binlog_index
        WHERE epoch > @LAST_EPOCH ORDER BY epoch ASC LIMIT 1;
    ```
11. Using `mysqlbinlog`, replay the binary log events from the given file and position up to the point of the failure. (See `mysqlbinlog` — Utility for Processing Binary Log Files.)

See also Point-in-Time (Incremental) Recovery Using the Binary Log, for more information about the binary log, replication, and incremental recovery.

MySQL Cluster Replication: Multi-Master and Circular Replication

Beginning with MySQL 5.1.18, it is possible to use MySQL Cluster in multi-master replication, including circular replication between a number of MySQL Clusters.

Note

Prior to MySQL 5.1.18, multi-master replication including circular replication was not supported with MySQL Cluster replication. This was because log events

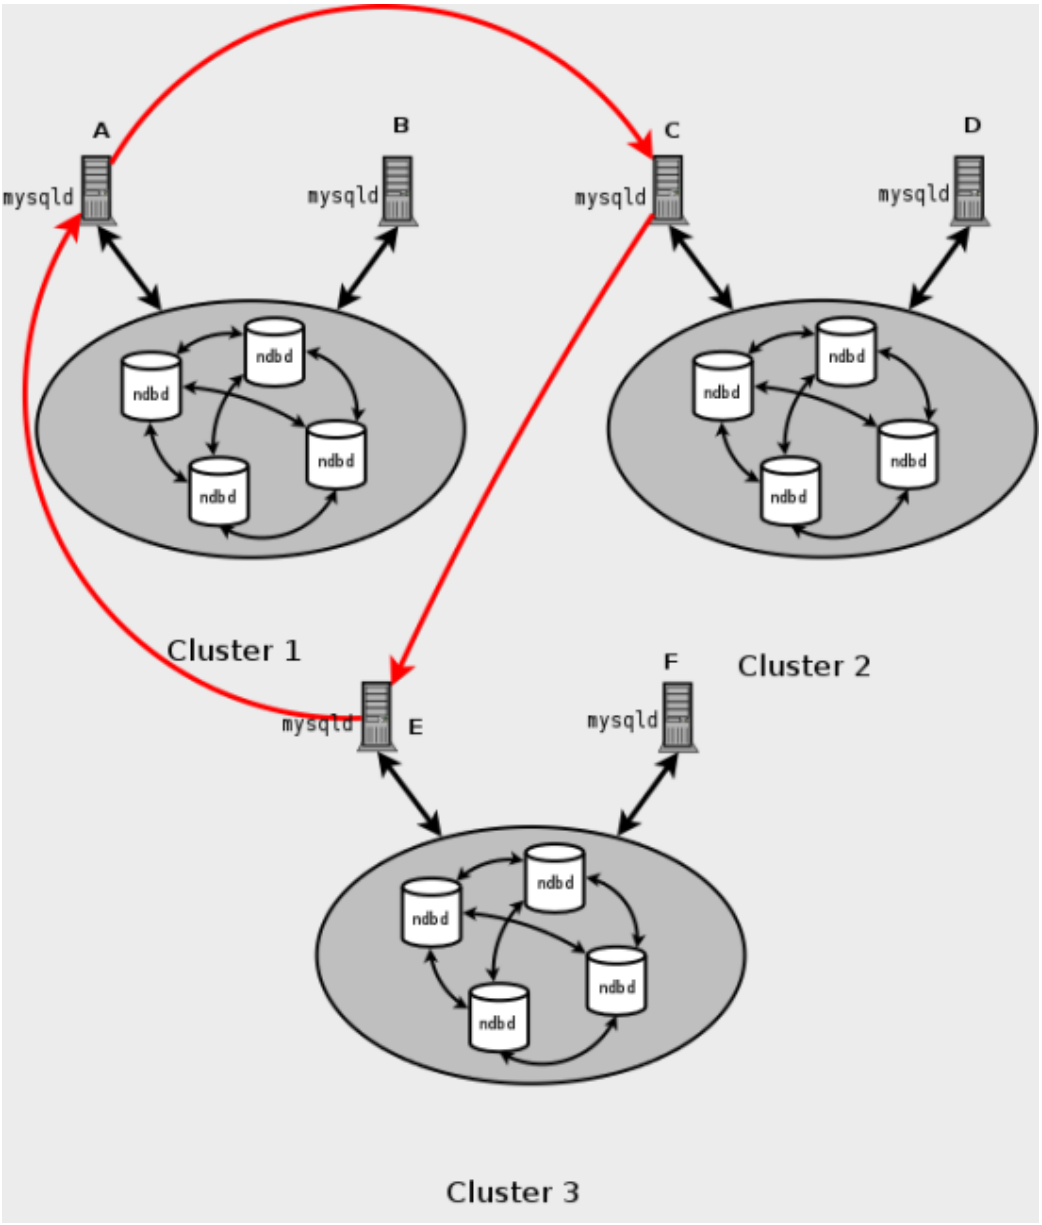
created in a particular MySQL Cluster were wrongly tagged with the server ID of the master rather than the server ID of the originating server.

Circular replication example. In the next few paragraphs we consider the example of a replication setup involving three MySQL Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication master for Cluster 2, Cluster 2 acts as the master for Cluster 3, and Cluster 3 acts as the master for Cluster 1. Each cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all masters and slaves are the same
- All SQL nodes acting as replication masters and slaves are started using the `--log-slave-updates` option

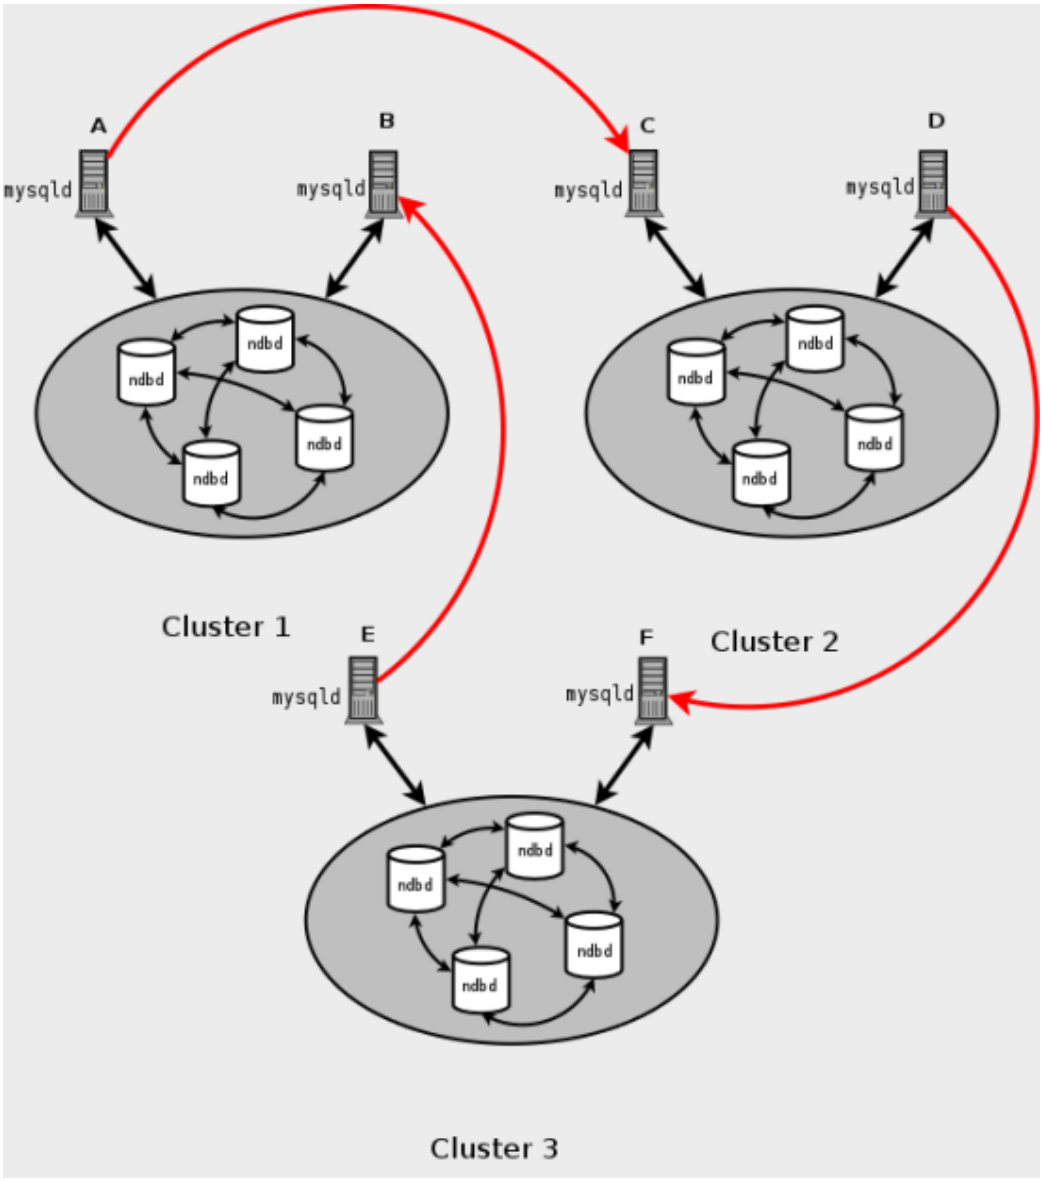
This type of circular replication setup is shown in the following diagram:



In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication

line (indicated by the red arrows in the diagram) directly connects all SQL nodes used as replication masters and slaves.

It is also possible to set up circular replication in such a way that not all master SQL nodes are also slaves, as shown here:



In this case, different SQL nodes in each cluster are used as replication masters and slaves. However, you must *not* start any of the SQL nodes using `--log-slave-updates`. This type of circular replication scheme for MySQL Cluster, in which the line of replication (again indicated by the red arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

Important

Beginning with MySQL 5.1.24, you should execute the following statement before starting circular replication:

```
mysql> SET GLOBAL SLAVE_EXEC_MODE = 'IDEMPOTENT';
```

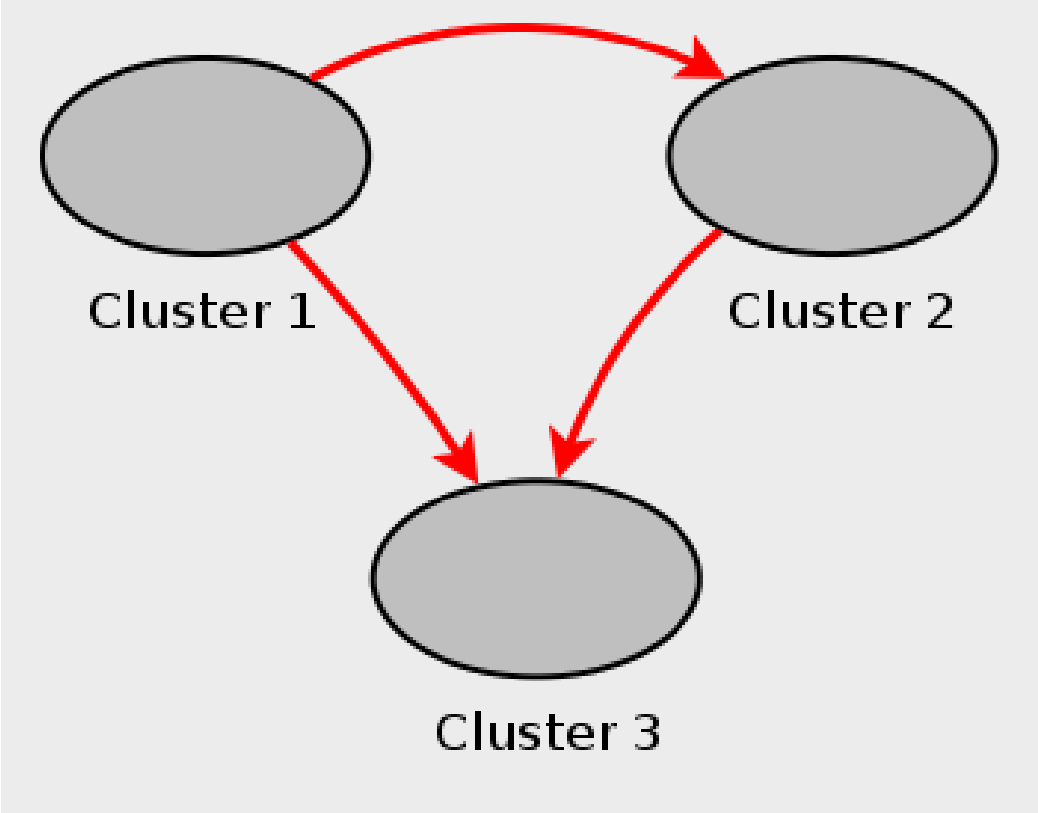
This is necessary to suppress duplicate-key and other errors that otherwise break circular replication in MySQL Cluster. `IDEMPOTENT` mode is also required for multi-master replication when using MySQL Cluster. (Bug #31609)

See `slave_exec_mode` [1644], for more information.

Using NDB-native backup and restore to initialize a slave MySQL Cluster. When setting up circular replication, it is possible to initialize the slave cluster by using the management client `BACKUP` command on one MySQL Cluster to create a backup and then applying this backup on another MySQL Cluster using `ndb_restore`. However, this does not automatically create binary logs on the second MySQL Cluster's SQL node acting as the replication slave. In order to cause the binary logs to be created, you must issue a `SHOW TABLES` statement on that SQL node; this should be done prior to running `START SLAVE`.

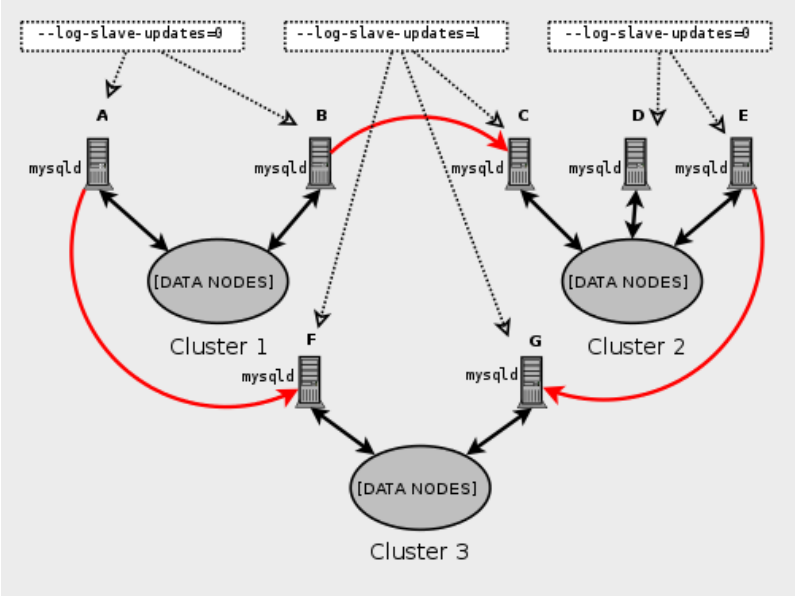
This is a known issue which we intend to address in a future release.

Multi-master failover example. In this section, we discuss failover in a multi-master MySQL Cluster replication setup with three MySQL Clusters having server IDs 1, 2, and 3. In this scenario, Cluster 1 replicates to Clusters 2 and 3; Cluster 2 also replicates to Cluster 3. This relationship is shown here:



In other words, data replicates from Cluster 1 to Cluster 3 through 2 different routes: directly, and by way of Cluster 2.

Not all MySQL servers taking part in multi-master replication must act as both master and slave, and a given MySQL Cluster might use different SQL nodes for different replication channels. Such a case is shown here:



MySQL servers acting as replication slaves must be run with the `--log-slave-updates` [1628] option. Which `mysqld` processes require this option is also shown in the preceding diagram.

Note

Using the `--log-slave-updates` [1628] option has no effect on servers not being run as replication slaves.

The need for failover arises when one of the replicating clusters goes down. In this example, we consider the case where Cluster 1 is lost to service, and so Cluster 3 loses 2 sources of updates from Cluster 1. Because replication between MySQL Clusters is asynchronous, there is no guarantee that Cluster 3's updates originating directly from Cluster 1 are more recent than those received through Cluster 2. You can handle this by ensuring that Cluster 3 catches up to Cluster 2 with regard to updates from Cluster 1. In terms of MySQL servers, this means that you need to replicate any outstanding updates from MySQL server C to server F.

On server C, perform the following queries:

```
mysqlC> SELECT @latest:=MAX(epoch)
     ->     FROM mysql.ndb_apply_status
     ->     WHERE server_id=1;

mysqlC> SELECT
     ->     @file:=SUBSTRING_INDEX(File, '/', -1),
     ->     @pos:=Position
     ->     FROM mysql.ndb_binlog_index
     ->     WHERE orig_epoch >= @latest
     ->     AND orig_server_id = 1
     ->     ORDER BY epoch ASC LIMIT 1;
```

Copy over the values for *`@file`* and *`@pos`* manually from server C to server F (or have your application perform the equivalent). Then, on server F, execute the following `CHANGE MASTER TO` statement:

```
mysqlF> CHANGE MASTER TO
     ->     MASTER_HOST = 'serverC'
     ->     MASTER_LOG_FILE='@file',
     ->     MASTER_LOG_POS=@pos;
```

Once this has been done, you can issue a `START SLAVE` statement on MySQL server F, and any missing updates originating from server B will be replicated to server F.

Beginning with MySQL Cluster MySQL Cluster NDB 6.1.29, MySQL Cluster NDB 6.3.31, MySQL Cluster NDB 7.0.11, and MySQL Cluster NDB 7.1.0, the `CHANGE MASTER TO` statement also supports

an IGNORE_SERVER_IDS option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. For more information, see CHANGE MASTER TO Syntax, and SHOW SLAVE STATUS Syntax.

MySQL Cluster Replication Conflict Resolution

When using a replication setup involving multiple masters (including circular replication), it is possible that different masters may try to update the same row on the slave with different data. Conflict resolution in MySQL Cluster Replication provides a means of resolving such conflicts by permitting a user-defined resolution column to be used to determine whether or not an update to the row on a given master should be applied on the slave.

When using one of the timestamp-based conflict resolution functions supported by MySQL Cluster ((NDB$OLD(), NDB$MAX(), NDB$MAX_DELETE_WIN()), we sometimes refer to this column as a "timestamp" column (although its type cannot be TIMESTAMP, as explained later in this section). Different methods can be used to compare resolution column values on the slave when conflicts occur, as explained later in this section; the method used can be set on a per-table basis.

Important

Conflict resolution as described in this section is always applied on a row-by-row basis rather than a transactional basis. In addition, it is the application's responsibility to ensure that the resolution column is correctly populated with relevant values, so that the resolution function can make the appropriate choice when determining whether to apply an update.

Requirements. Preparations for conflict resolution must be made on both the master and the slave. These tasks are described in the following list:

- On the master writing the binary logs, you must determine which columns are sent (all columns or only those that have been updated). This is done for the MySQL Server as a whole by applying the mysqld startup option --ndb-log-updated-only [2143] (described later in this section) or on a per-table basis by entries in the mysql.ndb_replication table (see The ndb_replication system table).

Note

If you are replicating tables with very large columns (such as TEXT or BLOB columns), --ndb-log-updated-only can also be useful for reducing the size of the master and slave binary logs and avoiding possible replication failures due to exceeding max_allowed_packet [493].

See Replication and max_allowed_packet, for more information about this issue.

- On the slave, you must determine which type of conflict resolution to apply ("latest timestamp wins", "same timestamp wins", or none). This is done using the mysql.ndb_replication system table, on a per-table basis (see The ndb_replication system table).

- Prior to MySQL Cluster NDB 7.0.31 and MySQL Cluster NDB 7.1.20, conflict detection and resolution did not always work properly unless set up for NDB tables created on the same server only (Bug #13578660).

When using the functions NDB$OLD(), NDB$MAX(), and NDB$MAX_DELETE_WIN() for timestamp-based conflict resolution, we often refer to the column used for determining updates as a "timestamp" column, but the data type of this column is never TIMESTAMP; rather, its data type should be INT (INTEGER) or BIGINT. The "timestamp" column should also be UNSIGNED and NOT NULL.

Master column control. We can see update operations in terms of "before" and "after" images—that is, the states of the table before and after the update is applied. Normally, when updating a table

with a primary key, the “before” image is not of great interest; however, when we need to determine on a per-update basis whether or not to use the updated values on a replication slave, we need to make sure that both images are written to the master's binary log. This is done with the `--ndb-log-update-as-write` [2143] option for `mysqld`, as described later in this section.

Important

Whether logging of complete rows or of updated columns only is done is decided when the MySQL server is started, and cannot be changed online; you must either restart `mysqld`, or start a new `mysqld` instance with different logging options.

Logging Full or Partial Rows (`--ndb-log-updated-only` Option)

Version Introduced	5.1.19-ndb-6.3.0	
Command-Line Format	`--ndb-log-updated-only`	
Option-File Format	`ndb_log_updated_only`	
Variable Name	`ndb_log_updated_only`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`boolean`
	Default	`ON`

For purposes of conflict resolution, there are two basic methods of logging rows, as determined by the setting of the `--ndb-log-updated-only` option for `mysqld`:

- Log complete rows
- Log only column data that has been updated—that is, column data whose value has been set, regardless of whether or not this value was actually changed. This is the default behavior.

It is usually sufficient—and more efficient—to log updated columns only; however, if you need to log full rows, you can do so by setting `--ndb-log-updated-only` to `0` or `OFF`.

`--ndb-log-update-as-write` [2143] Option: Logging Changed Data as Updates

Version Introduced	5.1.19-ndb-6.3.0, 5.1.22-ndb-6.2.5	
Command-Line Format	`--ndb-log-update-as-write`	
Option-File Format	`ndb-log-update-as-write`	
Variable Name	`ndb_log_update_as_write`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`boolean`
	Default	`ON`

The setting of the MySQL Server's `--ndb-log-update-as-write` [2143] option determines whether logging is performed with or without the “before” image. Because conflict resolution is done in the MySQL Server's update handler, it is necessary to control logging on the master such that updates are updates and not writes; that is, such that updates are treated as changes in existing rows

rather than the writing of new rows (even though these replace existing rows). This option is turned on by default; in other words, updates are treated as writes. (That is, updates are by default written as `write_row` events in the binary log, rather than as `update_row` events.) To turn off the option, start the master `mysqld` with `--ndb-log-update-as-write=0` or `--ndb-log-update-as-write=OFF`.

Conflict resolution control. Conflict resolution is usually enabled on the server where conflicts can occur. Like logging method selection, it is enabled by entries in the `mysql.ndb_replication` table.

The `ndb_replication` system table. To enable conflict resolution, it is necessary to create an `ndb_replication` table in the `mysql` system database on the master, the slave, or both, depending on the conflict resolution type and method to be employed. This table is used to control logging and conflict resolution functions on a per-table basis, and has one row per table involved in replication. `ndb_replication` is created and filled with control information on the server where the conflict is to be resolved. In a simple master-slave setup where data can also be changed locally on the slave this will typically be the slave. In a more complex master-master (2-way) replication schema this will usually be all of the masters involved. Each row in `mysql.ndb_replication` corresponds to a table being replicated, and specifies how to log and resolve conflicts (that is, which conflict resolution function, if any, to use) for that table. The definition of the `mysql.ndb_replication` table is shown here:

```
CREATE TABLE mysql.ndb_replication  (
    db VARBINARY(63),
    table_name VARBINARY(63),
    server_id INT UNSIGNED,
    binlog_type INT UNSIGNED,
    conflict_fn VARBINARY(128),
    PRIMARY KEY USING HASH (db, table_name, server_id)
)   ENGINE=NDB
PARTITION BY KEY(db,table_name);
```

The columns in this table are described in the next few paragraphs.

`db`. The name of the database containing the table to be replicated.

`table_name`. The name of the table to be replicated.

`server_id`. The unique server ID of the MySQL instance (SQL node) where the table resides.

`binlog_type`. The type of binary logging to be employed. This is determined as shown in the following table:

Value	Internal Value	Description
0	`NBT_DEFAULT`	Use server default
1	`NBT_NO_LOGGING`	Do not log this table in the binary log
2	`NBT_UPDATED_ONLY`	Only updated attributes are logged
3	`NBT_FULL`	Log full row, even if not updated (MySQL server default behavior)
4	`NBT_USE_UPDATE`	(For generating `NBT_UPDATED_ONLY_USE_UPDATE` and `NBT_FULL_USE_UPDATE` values only—not intended for separate use)
5	[*Not used*]	---
6	`NBT_UPDATED_ONLY_USE_UPDATE` (equal to `NBT_UPDATED_ONLY | NBT_USE_UPDATE`)	Use updated attributes, even if values are unchanged
7	`NBT_FULL_USE_UPDATE` (equal to `NBT_FULL | NBT_USE_UPDATE`)	Use full row, even if values are unchanged

`conflict_fn`. The conflict resolution function to be applied. This function must be specified as one of those shown in the following list:

- `NDB$OLD(column_name)`
- `NDB$MAX(column_name)`
- `NDB$MAX_DELETE_WIN(column_name)`
- `NDB$EPOCH()` (MySQL Cluster NDB 7.1.16 and later)
- `NDB$EPOCH_TRANS()` (MySQL Cluster NDB 7.1.16 and later)
- `NULL`

These functions are described in the next few paragraphs.

`NDB$OLD(column_name)`. If the value of `column_name` is the same on both the master and the slave, then the update is applied; otherwise, the update is not applied on the slave and an exception is written to the log. This is illustrated by the following pseudocode:

```
if (master_old_column_value == slave_current_column_value)
  perform_update();
else
  log_exception();
```

This function can be used for “same value wins” conflict resolution. This type of conflict resolution ensures that updates are not applied on the slave from the wrong master.

Important

The column value from the master's “before” image is used by this function.

`NDB$MAX(column_name)`. If the “timestamp” column value for a given row coming from the master is higher than that on the slave, it is applied; otherwise it is not applied on the slave. This is illustrated by the following pseudocode:

```
if (master_new_column_value > slave_current_column_value)
  perform_update();
```

This function can be used for “greatest timestamp wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was most recently updated is the version that persists.

Important

The column value from the master's “after” image is used by this function.

`NDB$MAX_DELETE_WIN(column_name)`. This is a variation on `NDB$MAX()`. Due to the fact that no timestamp is available for a delete operation, a delete using `NDB$MAX()` is in fact processed as `NDB$OLD`. However, for some use cases, this is not optimal. For `NDB$MAX_DELETE_WIN()`, if the “timestamp” column value for a given row adding or updating an existing row coming from the master is higher than that on the slave, it is applied. However, delete operations are treated as always having the higher value. This is illustrated in the following pseudocode:

```
if ( (master_new_column_value > slave_current_column_value)
        ||
     operation.type == "delete")
  perform_update();
```

This function can be used for “greatest timestamp, delete wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was deleted or (otherwise) most recently updated is the version that persists.

Note

As with `NDB$MAX()`, the column value from the master's “after” image is the value used by this function.

`NDB$EPOCH()`. The `NDB$EPOCH()` function, available beginning with MySQL Cluster NDB 7.1.16, tracks the order in which replicated epochs are applied on a slave MySQL Cluster relative to changes originating on the slave. This relative ordering is used to determine whether changes originating on the slave are concurrent with any changes that originate locally, and are therefore potentially in conflict.

Most of what follows in the description of `NDB$EPOCH()` also applies to `NDB$EPOCH_TRANS()`. Any exceptions are noted in the text.

`NDB$EPOCH()` is asymmetric, operating on one MySQL Cluster in a two-cluster circular replication configuration (sometimes referred to as “active-active” replication). We refer here to cluster on which it operates as the primary, and the other as the secondary. The slave on the primary is responsible for detecting and handling conflicts, while the slave on the secondaryis not involved in any conflict detection or handling.

When the slave on the primary detects conflicts, it injects events into its own binary log to compensate for these; this ensures that the secondary MySQL Cluster eventually realigns itself with the primary and so keeps the primary and secondary from diverging. This compensation and realignment mechanism requires that the primary MySQL Cluster always wins any conflicts with the secondary—that is, that the primary's changes are always used rather than those from the secondary in event of a conflict. This “primary always wins” rule has the following implications:

- Operations that change data, once committed on the primary, are fully persistent and will not be undone or rolled back by conflict detection and resolution.
- Data read from the primary is fully consistent. Any changes committed on the Primary (locally or from the slave) will not be reverted later.
- Operations that change data on the secondary may later be reverted if the primary determines that they are in conflict.
- Individual rows read on the secondary are self-consistent at all times, each row always reflecting either a state committed by the secondary, or one committed by the primary.
- Sets of rows read on the secondary may not necessarily be consistent at a given single point in time. For `NDB$EPOCH_TRANS()`, this is a transient state; for `NDB$EPOCH()`, it can be a persistent state.
- Assuming a period of sufficient length without any conflicts, all data on the secondary MySQL Cluster (eventually) becomes consistent with the primary's data.

`NDB$EPOCH()` and `NDB$EPOCH_TRANS()` do not require any user schema modifications, or application changes to provide conflict detection. However, careful thought must be given to the schema used, and the access patterns used, to verify that the complete system behaves within specified limits.

Each of the `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions can take an optional parameter; this is the number of bits to use to represent the lower 32 bits of the epoch, and should be set to no less than

```
CEIL( LOG2( TimeBetweenGlobalCheckpoints [1839] / TimeBetweenEpochs [1840] ), 1)
```

For the default values of these configuration parameters (2000 and 100 milliseconds, respectively), this gives a value of 5 bits, so the default value (6) should be sufficient, unless other values are used for `TimeBetweenGlobalCheckpoints` [1839], `TimeBetweenEpochs` [1840], or both. A value that is too small can result in false positives, while one that is too large could lead to excessive wasted space in the database.

Both `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` insert entries for conflicting rows into the relevant exceptions tables, provided that these tables have been defined according to the same exception table

schema rules as described elsewhere in this section (see NDB$OLD(*column_name*)). Note that you need to create any exception table before creating the table with which it is to be used.

As with the other conflict detection functions discussed in this section, NDB$EPOCH() and NDB$EPOCH_TRANS() are activated by including relevant entries in the mysql.ndb_replication table (see The ndb_replication system table). The roles of the primary and secondary MySQL Clusters in this scenario are fully determined by mysql.ndb_replication table entries.

Note

Because the conflict detection algorithms employed by NDB$EPOCH() and NDB$EPOCH_TRANS() are asymmetric, you must use different values for the primary slave's and secondary slave's server_id entries.

NDB$EPOCH() and NDB$EPOCH_TRANS() status variables. MySQL Cluster NDB 7.1.16 introduces several status variables that can be used to monitor NDB$EPOCH() and NDB$EPOCH_TRANS() conflict detection. You can see how many rows have been found in conflict by NDB$EPOCH() since this slave was last restarted from the current value of the Ndb_conflict_fn_epoch [1947] system status variable.

Ndb_conflict_fn_epoch_trans [1947] provides the number of rows that have been found directly in conflict by NDB$EPOCH_TRANS(); the number of rows actually realigned, including those affected due to their membership in or dependency on the same transactions as other conflicting rows, is given by Ndb_conflict_trans_row_reject_count [1948].

For more information, see MySQL Cluster Status Variables.

Limitations on NDB$EPOCH(). The following limitations currently apply when using NDB$EPOCH() to perform conflict detection:

- Conflicts are detected using MySQL Cluster epoch boundaries, with granularity proportional to TimeBetweenEpochs [1840] (default: 100 milliseconds). The minimum conflict window is the minimum time during which concurrent updates to the same data on both clusters always report a conflict. This is always a nonzero length of time, and is roughly proportional to 2 * (latency + queueing + TimeBetweenEpochs). This implies that—assuming the default for TimeBetweenEpochs [1840] and ignoring any latency between clusters (as well as any queuing delays)—the minimum conflict window size is approximately 200 milliseconds. This minimum window should be considered when looking at expected application “race” patterns.

- Additional storage is required for tables using the NDB$EPOCH() and NDB$EPOCH_TRANS() functions; from 1 to 32 bits extra space per row is required, depending on the value passed to the function.

- Conflicts between delete operations may result in divergence between the primary and secondary. When a row is deleted on both clusters concurrently, the conflict can be detected, but is not recorded, since the row is deleted. This means that further conflicts during the propagation of any subsequent realignment operations will not be detected, which can lead to divergence.

  Deletes should be externally serialized, or routed to one cluster only. Alternatively, a separate row should be updated transactionally with such deletes and any inserts that follow them, so that conflicts can be tracked across row deletes. This may require changes in applications.

- Only two MySQL Clusters in a circular “active-active” configuration are currently supported when using NDB$EPOCH() or NDB$EPOCH_TRANS() for conflict detection.

- Tables having BLOB or TEXT columns are not currently supported with NDB$EPOCH() or NDB$EPOCH_TRANS().

NDB$EPOCH_TRANS(). NDB$EPOCH_TRANS() extends the NDB$EPOCH() function, and, like NDB$EPOCH(), is available beginning with MySQL Cluster NDB 7.1.16. Conflicts are detected and handled

in the same way using the “primary wins all” rule (see NDB$EPOCH()) but with the extra condition that any other rows updated in the same transaction in which the conflict occurred are also regarded as being in conflict. In other words, where NDB$EPOCH() realigns individual conflicting rows on the secondary, NDB$EPOCH_TRANS() realigns conflicting transactions.

In addition, any transactions which are detectably dependent on a conflicting transaction are also regarded as being in conflict, these dependencies being determined by the contents of the secondary cluster's binary log. Since the binary log contains only data modification operations (inserts, updates, and deletes), only overlapping data modifications are used to determine dependencies between transactions.

NDB$EPOCH_TRANS() is subject to the same conditions and limitations as NDB$EPOCH(), and in addition requires that Version 2 binary log row events are used (--log-bin-use-v1-row-events [1648] equal to 0), which adds a storage overhead of 2 bytes per event in the binary log. In addition, all transaction IDs must be recorded in the secondary's binary log (--ndb-log-transaction-id [1916] option), which adds a further variable overhead (up to 13 bytes per row).

See NDB$EPOCH().

NULL. Indicates that conflict resolution is not to be used for the corresponding table.

Status information. Beginning with MySQL Cluster NDB 6.3.3, a server status variable Ndb_conflict_fn_max [1947] provides a count of the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that mysqld was started.

Beginning with MySQL Cluster NDB 6.3.4, the number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given mysqld since the last time it was restarted is given by the global status variable Ndb_conflict_fn_old [1947]. In addition to incrementing Ndb_conflict_fn_old [1947], the primary key of the row that was not used is inserted into an *exceptions table*, as explained later in this section.

Exceptions table. To use the NDB$OLD() conflict resolution function, it is also necessary to create an exceptions table corresponding to each NDB table for which this type of conflict resolution is to be employed. This is also true when using NDB$EPOCH() or NDB$EPOCH_TRANS() in MySQL Cluster NDB 7.1.16 and later. The name of this table is that of the table for which conflict resolution is to be applied, with the string $EX appended. (For example, if the name of the original table is mytable, the name of the corresponding exception table name should be mytable$EX.) This table is created as follows:

```
CREATE TABLE original_table$EX  (
    server_id INT UNSIGNED,
    master_server_id INT UNSIGNED,
    master_epoch BIGINT UNSIGNED,
    count INT UNSIGNED,
    original_table_pk_columns,
    [additional_columns,]
    PRIMARY KEY(server_id, master_server_id, master_epoch, count)
) ENGINE=NDB;
```

The first four columns are required. Following these columns, the columns making up the original table's primary key should be copied in the order in which they are used to define the primary key of the original table.

Note

The names of the first four columns and the columns matching the original table's primary key columns are not critical; however, we suggest for reasons of clarity and consistency, that you use the names shown here for the server_id [521], master_server_id, master_epoch, and count columns, and that you use the same names as in the original table for the columns matching those in the original table's primary key.

The data types for the columns duplicating the primary key columns of the original table should be the same as for (or larger than) the original columns.

Additional columns may optionally be defined following these columns, but not before any of them; any such extra columns cannot be `NOT NULL`. The exception table's primary key must be defined as shown. The exception table must use the `NDB` storage engine. An example that uses `NDB$OLD()` with an exceptions table is shown later in this section.

Important

The `mysql.ndb_replication` table is read when a data table is set up for replication, so the row corresponding to a table to be replicated must be inserted into `mysql.ndb_replication` *before* the table to be replicated is created.

Examples. The following examples assume that you have already a working MySQL Cluster replication setup, as described in Preparing the MySQL Cluster for Replication, and Starting MySQL Cluster Replication (Single Replication Channel).

- **`NDB$MAX()` example.** Suppose you wish to enable “greatest timestamp wins” conflict resolution on table `test.t1`, using column `mycol` as the “timestamp”. This can be done using the following steps:

  1. Make sure that you have started the master `mysqld` with `--ndb-log-update-as-write=OFF`.

  2. On the master, perform this `INSERT` statement:

     ```
     INSERT INTO mysql.ndb_replication
         VALUES ('test', 't1', 0, NULL, 'NDB$MAX(mycol)');
     ```

     Inserting a 0 into the `server_id` [521] indicates that all SQL nodes accessing this table should use conflict resolution. If you want to use conflict resolution on a specific `mysqld` only, use the actual server ID.

     Inserting `NULL` into the `binlog_type` column has the same effect as inserting 0 (`NBT_DEFAULT`); the server default is used.

  3. Create the `test.t1` table:

     ```
     CREATE TABLE test.t1 (
         columns
         mycol INT UNSIGNED,
         columns
     ) ENGINE=NDB;
     ```

     Now, when updates are done on this table, conflict resolution is applied, and the version of the row having the greatest value for `mycol` is written to the slave.

Note

Other `binlog_type` options—such as `NBT_UPDATED_ONLY_USE_UPDATE` should be used to control logging on the master using the `ndb_replication` table rather than by using command-line options.

- **`NDB$OLD()` example.** Suppose an `NDB` table such as the one defined here is being replicated, and you wish to enable “same timestamp wins” conflict resolution for updates to this table:

  ```
  CREATE TABLE test.t2  (
      a INT UNSIGNED NOT NULL,
      b CHAR(25) NOT NULL,
      columns,
      mycol INT UNSIGNED NOT NULL,
  ```

```
    columns,
    PRIMARY KEY pk (a, b)
)   ENGINE=NDB;
```

The following steps are required, in the order shown:

1. First—and *prior* to creating `test.t2`—you must insert a row into the `mysql.ndb_replication` table, as shown here:

   ```
   INSERT INTO mysql.ndb_replication
       VALUES ('test', 't2', 0, NULL, 'NDB$OLD(mycol)');
   ```

   Possible values for the `binlog_type` column are shown earlier in this section. The value `'NDB$OLD(mycol)'` should be inserted into the `conflict_fn` column.

2. Create an appropriate exceptions table for `test.t2`. The table creation statement shown here includes all required columns; any additional columns must be declared following these columns, and before the definition of the table's primary key.

   ```
   CREATE TABLE test.t2$EX  (
       server_id SMALLINT UNSIGNED,
       master_server_id INT UNSIGNED,
       master_epoch BIGINT UNSIGNED,
       count BIGINT UNSIGNED,
       a INT UNSIGNED NOT NULL,
       b CHAR(25) NOT NULL,
       [additional_columns,]
       PRIMARY KEY(server_id, master_server_id, master_epoch, count)
   )   ENGINE=NDB;
   ```

3. Create the table `test.t2` as shown previously.

These steps must be followed for every table for which you wish to perform conflict resolution using `NDB$OLD()`. For each such table, there must be a corresponding row in `mysql.ndb_replication`, and there must be an exceptions table in the same database as the table being replicated.

Changes in MySQL Cluster NDB 6.1 - 7.1

This section contains changelog information for MySQL Cluster releases that use versions 6.1, 6.2, 6.3, 7.0, and 7.1 of the `NDBCLUSTER` storage engine.

Note

Version 7.0 of the `NDBCLUSTER` storage engine was previously known as “NDB 6.4”. For more information, see Changes in MySQL Cluster NDB 7.0.

Each MySQL Cluster release is based on a mainline MySQL 5.1 release and a particular version of the `NDBCLUSTER` storage engine, as shown in the version string returned by executing `SELECT VERSION()` in the `mysql` client, or by executing the `ndb_mgm` client `SHOW` or `STATUS` command; for more information, see Chapter 17, *MySQL Cluster NDB 6.1 - 7.1*.

For general information about features added in MySQL Cluster, see MySQL Cluster Development History. For a complete list of all bugfixes and feature changes in MySQL Cluster, please refer to the changelog section for each individual MySQL Cluster release.

An overview of features added in MySQL 5.1 not specific to MySQL Cluster can be found here: What Is New in MySQL 5.1. For a complete list of all bugfixes and features changes made in MySQL 5.1 that are not specific to MySQL Cluster, see Changes in Release 5.1.x (Production).

This section contains changelogs for individual MySQL Cluster NDB 6.X and 7.X releases.

For long-format changelogs covering each MySQL Cluster NDB 6.X and 7.X series, see Release Series Changelogs: MySQL Cluster NDB 6.X and 7.X.

Changes in MySQL Cluster NDB 7.2

This section contains change history information for MySQL Cluster releases based on version 7.2 of the NDBCLUSTER storage engine, currently in development.

For an overview of new features added in MySQL Cluster NDB 7.2, see MySQL Cluster Development in MySQL Cluster NDB 7.2.1.

Note

MySQL Cluster NDB 7.2 releases following MySQL Cluster NDB 7.2.0 are based on MySQL 5.5. For information about MySQL Cluster NDB 7.2.1 and later, see Changes in MySQL Cluster, in the *MySQL 5.5 Manual*.

Changes in MySQL Cluster NDB 7.2.0 (5.1.51-ndb-7.2.0) (2011-04-11, Development Milestone)

MySQL Cluster NDB 7.2.0 is a new development preview release of MySQL Cluster, incorporating several new features in the NDBCLUSTER storage engine for testing and user feedback.

Obtaining MySQL Cluster NDB 7.2. MySQL Cluster NDB 7.2.0 source code and binaries can be obtained from http://dev.mysql.com/downloads/cluster/.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.51 (see Changes in MySQL 5.1.51 (2010-09-10)).

Functionality Added or Changed

- **Performance**: Added support for pushing down joins to the NDB kernel for parallel execution across the data nodes, which can speed up execution of joins across NDB tables by a factor of 20 or more in some cases. Some restrictions apply on the types of joins that can be optimized in this way; in particular, columns to be joined must use exactly the same data type, and cannot be any of the BLOB or TEXT types. In addition, columns to be joined must be part of a table index or primary key. Support for this feature can be enabled or disabled using the ndb_join_pushdown [1925] server system variable (enabled by default); see the description of this variable for more information and examples.

  As part of this improvement, the status variables Ndb_pushed_queries_defined [1949], Ndb_pushed_queries_dropped [1949], Ndb_pushed_queries_executed [1949], and Ndb_pushed_reads [1949] also been introduced for monitoring purposes. You can also see whether a given join is pushed down using EXPLAIN. In addition, several new counters relating to push-down join performance have been added to the counters table in the ndbinfo database. For more information, see the descriptions of the status variables previously mentioned.

- **Important Change**: MySQL user privileges can now be distributed automatically across all MySQL servers (SQL nodes) connected to the same MySQL Cluster. Previously, each MySQL Server's user privilege tables were required to use the MyISAM storage engine, which meant that a user account and its associated privileges created on one SQL node were not available on any other SQL node without manual intervention. MySQL Cluster now provides an SQL script file ndb_dist_priv.sql that can be found in share/mysql under the MySQL installation directory; loading this script creates a stored procedure mysql_cluster_move_privileges that can be used following initial installation to convert the privilege tables to the NDB storage engine, so that any time a MySQL user account is created, dropped, or has its privileges updated on any SQL node, the changes take effect immediately on all other MySQL servers attached to the cluster. Note that you may need to execute FLUSH PRIVILEGES on any SQL nodes with connected MySQL clients (or to disconnect and then reconnect the clients) in order for those clients to be able to see the changes in privileges.

  Once mysql_cluster_move_privileges has been executed successfully, all MySQL user privileges are distributed across all connected MySQL Servers. MySQL Servers that join the cluster after this automatically participate in the privilege distribution.

`ndb_dist_priv.sql` also provides stored routines that can be used to verify that the privilege tables have been distributed successfully, and to perform other tasks.

For more information, see Distributed MySQL Privileges for MySQL Cluster.

- **Important Change**: The default values for a number of MySQL Cluster data node configuration parameters have changed, to provide more resiliency to environmental issues and better handling of some potential failure scenarios, and to perform more reliably with increases in memory and other resource requirements brought about by recent improvements in join handling by `NDB`. The affected parameters are listed here:

  - `HeartbeatIntervalDbDb` [1836]: Default increased from 1500 ms to 5000 ms.
  - `ArbitrationTimeout` [1844]: Default increased from 3000 ms to 7500 ms.
  - `TimeBetweenEpochsTimeout` [1840]: Now effectively disabled by default (default changed from 4000 ms to 0).
  - `SharedGlobalMemory` [1856]: Default increased from 20MB to 128MB.
  - `MaxParallelScansPerFragment` [1825]: Default increased from 32 to 256.

  In addition, when `MaxNoOfLocalScans` [1824] is not specified, the value computed for it automatically has been increased by a factor of 4 (that is, to 4 times `MaxNoOfConcurrentScans` [1824], times the number of data nodes in the cluster).

Changes in MySQL Cluster NDB 7.1

This section contains change history information for MySQL Cluster releases based on version 7.1 of the `NDBCLUSTER` storage engine.

For an overview of new features added in MySQL Cluster NDB 7.1, see MySQL Cluster Development in MySQL Cluster NDB 7.1.

Changes in MySQL Cluster NDB 7.1.25 (5.1.63-ndb-7.1.25) (Not yet released)

MySQL Cluster NDB 7.1.25 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in previous MySQL Cluster NDB 7.1 releases.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.63 (see Changes in MySQL 5.1.63 (2012-05-07)).

Version 5.1.63-ndb-7.1.25 has no changelog entries.

Changes in MySQL Cluster NDB 7.1.24 (5.1.63-ndb-7.1.24) (Not yet released)

MySQL Cluster NDB 7.1.24 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in previous MySQL Cluster NDB 7.1 releases.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest

MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.63 (see Changes in MySQL 5.1.63 (2012-05-07)).

Version 5.1.63-ndb-7.1.24 has no changelog entries.

Changes in MySQL Cluster NDB 7.1.23 (5.1.63-ndb-7.1.23) (2012-07-17)

MySQL Cluster NDB 7.1.23 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in previous MySQL Cluster NDB 7.1 releases.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.63 (see Changes in MySQL 5.1.63 (2012-05-07)).

Bugs Fixed

- If the Transaction Coordinator aborted a transaction in the “prepared” state, this could cause a resource leak. (Bug #14208924)
- When attempting to connect using a socket with a timeout, it was possible (if the timeout was exceeded) for the socket not to be set back to blocking. (Bug #14107173)
- In some circumstances, transactions could be lost during an online upgrade. (Bug #13834481)
- When an `NDB` table was created during a data node restart, the operation was rolled back in the `NDB` engine, but not on the SQL node where it was executed. This was due to the table `.FRM` files not being cleaned up following the operation that was rolled back by `NDB`. Now in such cases these files are removed. (Bug #13824846)
- Attempting to add both a column and an index on that column in the same online `ALTER TABLE` statement caused `mysqld` to fail. Although this issue affected only the `mysqld` shipped with MySQL Cluster, the table named in the `ALTER TABLE` could use any storage engine for which online operations are supported. (Bug #12755722)
- **Cluster API**: When an NDB API application called `NdbScanOperation::nextResult()` again after the previous call had returned end-of-file (return code 1), a transaction object was leaked. Now when this happens, NDB returns error code 4210 (`Ndb sent more info than length specified`); previouslyu in such cases, -1 was returned. In addition, the extra transaction object associated with the scan is freed, by returning it to the transaction coordinator's idle list. (Bug #11748194)

Changes in MySQL Cluster NDB 7.1.22 (5.1.61-ndb-7.1.22) (2012-05-24)

MySQL Cluster NDB 7.1.22 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in previous MySQL Cluster NDB 7.1 releases.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest

MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.61 (see Changes in MySQL 5.1.61 (2012-01-10)).

Bugs Fixed

- `DUMP 2303` in the `ndb_mgm` client now includes the status of the single fragment scan record reserved for a local checkpoint. (Bug #13986128)
- A shortage of scan fragment records in `DBTC` resulted in a leak of concurrent scan table records and key operation records. (Bug #13966723)
- **Cluster Replication**: DDL statements could sometimes be missed during replication channel cutover, due to the fact that there may not be any epochs following the last applied epoch when the slave is up to date and no new epoch has been finalized on the master. Because epochs are not consecutively numbered, there may be a gap between the last applied epoch and the next epoch; thus it is not possible to determine the number assigned to the next epoch. This meant that, if the new master did not have all epochs, it was possible for those epochs containing only DDL statements to be skipped over.

  The fix for this problem includes modifications to mysqld binary logging code so that the next position in the binary log following the `COMMIT` event at the end of an epoch transaction, as well as the addition of two new columns `next_file` and `next_position` to the `mysql.ndb_binlog_index` table. In addition, a new replication channel cutover mechanism is defined that employs these new columns. To make use of the new cutover mechanism, it is necessary to modify the query used to obtain the start point; in addition, to simplify prevention of possible errors caused by duplication of DDL statements, a new shorthand value `ddl_exist_errors` is implemented for use with the `mysqld` option `--slave-skip-errors` [1641]. It is highly recommended that you use this option and value on the new replication slave when using the modified query.

  For more information, see Implementing Failover with MySQL Cluster Replication.

  Note that the existing replication channel cutover mechanism continues to function as before, including the same limitations described previously. (Bug #11762277, Bug #54854)

Changes in MySQL Cluster NDB 7.1.21 (5.1.61-ndb-7.1.21) (2012-04-17)

MySQL Cluster NDB 7.1.21 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in previous MySQL Cluster NDB 7.1 releases.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.61 (see Changes in MySQL 5.1.61 (2012-01-10)).

Bugs Fixed

- **Important Change**: The `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement can be used to create new table partitions after new empty nodes have been added to a MySQL Cluster. Usually, the number of partitions to create is determined automatically, such that, if no new partitions are required, then none are created. This behavior can be overridden by creating the

original table using the MAX_ROWS option, which indicates that extra partitions should be created to store a large number of rows. However, in this case ALTER ONLINE TABLE ... REORGANIZE PARTITION simply uses the MAX_ROWS value specified in the original CREATE TABLE statement to determine the number of partitions required; since this value remains constant, so does the number of partitions, and so no new ones are created. This means that the table is not rebalanced, and the new data nodes remain empty.

To solve this problem, support is added for ALTER ONLINE TABLE ... MAX_ROWS=*newvalue*, where *newvalue* is greater than the value used with MAX_ROWS in the original CREATE TABLE statement. This larger MAX_ROWS value implies that more partitions are required; these are allocated on the new data nodes, which restores the balanced distribution of the table data.

For more information, see ALTER TABLE Syntax, and Adding MySQL Cluster Data Nodes Online. (Bug #13714648)

- When the --skip-config-cache [1963] and --initial [1965] options were used together, ndb_mgmd failed to start. (Bug #13857301)
- ALTER ONLINE TABLE failed when a DEFAULT option was used. (Bug #13830980)
- In some cases, restarting data nodes spent a very long time in Start Phase 101, when API nodes must connect to the starting node (using NdbEventOperation), when the API nodes trying to connect failed in a live-lock scenario. This connection process uses a handshake during which a small number of messages are exchanged, with a timeout used to detect failures during the handshake.

  Prior to this fix, this timeout was set such that, if one API node encountered the timeout, all other nodes connecting would do the same. The fix also decreases this timeout. This issue (and the effects of the fix) are most likely to be observed on relatively large configurations having 10 or more data nodes and 200 or more API nodes. (Bug #13825163)
- ndbmtd failed to restart when the size of a table definition exceeded 32K.

  (The size of a table definition is dependent upon a number of factors, but in general the 32K limit is encountered when a table has 250 to 300 columns.) (Bug #13824773)
- An initial start using ndbmtd could sometimes hang. This was due to a state which occurred when several threads tried to flush a socket buffer to a remote node. In such cases, to minimize flushing of socket buffers, only one thread actually performs the send, on behalf of all threads. However, it was possible in certain cases for there to be data in the socket buffer waiting to be sent with no thread ever being chosen to perform the send. (Bug #13809781)
- When trying to use ndb_size.pl --hostname=*host*:*port* to connect to a MySQL server running on a nonstandard port, the *port* argument was ignored. (Bug #13364905, Bug #62635)
- **Cluster Replication**: Error handling in conflict detection and resolution has been improved to include errors generated for reasons other than operation execution errors, and to distinguish better between permanent errors and transient errors. Transactions failing due to transient problems are now retried rather than leading to SQL node shutdown as occurred in some cases. (Bug #13428909)

Changes in MySQL Cluster NDB 7.1.20 (5.1.61-ndb-7.1.20) (2012-03-29)

MySQL Cluster NDB 7.1.20 is a new release of MySQL Cluster, incorporating new features in the NDBCLUSTER storage engine and fixing recently discovered bugs in previous MySQL Cluster NDB 7.1 releases.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.61 (see Changes in MySQL 5.1.61 (2012-01-10)).

Bugs Fixed

- **Important Change**: A number of changes have been made in the configuration of transporter send buffers.

  1. The data node configuration parameter `ReservedSendBufferMemory` [1861] is now deprecated, and thus subject to removal in a future MySQL Cluster release. `ReservedSendBufferMemory` has been non-functional since it was introduced and remains so.

  2. `TotalSendBufferMemory` now works correctly with data nodes using `ndbmtd`.

  3. `SendBufferMemory` [1870] can now over-allocate into `SharedGlobalMemory` [1856] for `ndbmtd` data nodes (only).

  4. A new data node configuration parameter `ExtraSendBufferMemory` [1861] is introduced. Its purpose is to control how much additional memory can be allocated to the send buffer over and above that specified by `TotalSendBufferMemory` or `SendBufferMemory`. The default setting (0) allows up to 16MB to be allocated automatically.

  (Bug #13633845, Bug #11760629, Bug #53053)

- **Cluster Replication**: **Important Change**: The master limited the number of operations per transaction to 10000 (based on `TimeBetweenEpochs` [1840]). This could result in a larger number of data-modification operations in a single epoch than could be applied at one time, due to the limit imposed on the slave by its (own) setting for `MaxDMLOperationsPerTransaction` [1822].

  The fix for this issue is to allow a replication slave cluster to exceed the configured value of `MaxDMLOperationsPerTransaction` [1822] when necessary, so that it can apply all DML operations received from the master in the same transaction. (Bug #12825405)

- Setting `insert_id` [482] had no effect on the auto-increment counter for `NDB` tables. (Bug #13731134)

- A data node crashed when more than 16G fixed-size memory was allocated by `DBTUP` to one fragment (because the `DBACC` kernel block was not prepared to accept values greater than 32 bits from it, leading to an overflow). Now in such cases, the data node returns Error 889 `Table fragment fixed data reference has reached maximum possible value...`. When this happens, you can work around the problem by increasing the number of partitions used by the table (such as by using the `MAXROWS` option with `CREATE TABLE`). (Bug #13637411)

  References: See also Bug #11747870, Bug #34348.

- Several instances in the NDB code affecting the operation of multi-threaded data nodes, where `SendBufferMemory` was associated with a specific thread for an unnecessarily long time, have been identified and fixed, by minimizing the time that any of these buffers can be held exclusively by a given thread (send buffer memory being critical to operation of the entire node). (Bug #13618181)

- A very large value for `BackupWriteSize` [1851], as compared to `BackupMaxWriteSize` [1852], `BackupDataBufferSize` [1850], or `BackupLogBufferSize` [1850], could cause a local checkpoint or backup to hang. (Bug #13613344)

- Queries using `LIKE ... ESCAPE` on `NDB` tables failed when pushed down to the data nodes. Such queries are no longer pushed down, regardless of the value of `engine_condition_pushdown` [473]. (Bug #13604447, Bug #61064)

- To avoid TCP transporter overload, an overload flag is kept in the NDB kernel for each data node; this flag is used to abort key requests if needed, yielding error 1218 `Send Buffers overloaded`

`in NDB kernel` in such cases. Scans can also put significant pressure on transporters, especially where scans with a high degree of parallelism are executed in a configuration with relatively small send buffers. However, in these cases, overload flags were not checked, which could lead to node failures due to send buffer exhaustion. Now, overload flags are checked by scans, and in cases where returning sufficient rows to match the batch size (`--ndb-batch-size` [1912] server option) would cause an overload, the number of rows is limited to what can be accommodated by the send buffer.

See also Configuring MySQL Cluster Send Buffer Parameters. (Bug #13602508)

- A `SELECT` from an `NDB` table using `LIKE` with a multi-byte column (such as `utf8`) did not return the correct result when `engine_condition_pushdown` [473] was enabled. (Bug #13579318, Bug #64039)

  References: See also Bug #13608135.

- A node failure and recovery while performing a scan on more than 32 partitions led to additional node failures during node takeover. (Bug #13528976)

- The `--skip-config-cache` [1963] option now causes `ndb_mgmd` to skip checking for the configuration directory, and thus to skip creating it in the event that it does not exist. (Bug #13428853)

- **Cluster Replication**: Conflict detection and resolution for statements updating a given table could be employed only on the same server where the table was created. When an `NDB` table is created by executing DDL on an SQL node, the binary log setup portion of the processing for the `CREATE TABLE` statement reads the table's conflict detection function from the ndb_replication table and sets up that function for the table. However, when the created table was discovered by other SQL nodes attached to the same MySQL Cluster due to schema distribution, the conflict detection function was not correctly set up. The same problem occurred when an `NDB` table was discovered as a result of selecting a database for the first time (such as when executing a `USE` statement), and when a table was discovered as a result of scanning all files at server startup.

  Both of these issues were due to a dependency of the conflict detection and resolution code on table objects, even in cases where checking for such objects might not be appropriate. With this fix, conflict detection and resolution for any `NDB` table works whether the table was created on the same SQL node, or on a different one. (Bug #13578660)

Changes in MySQL Cluster NDB 7.1.19 (5.1.56-ndb-7.1.19) (2012-01-30)

MySQL Cluster NDB 7.1.19 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in previous MySQL Cluster NDB 7.1 releases.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.56 (see Changes in MySQL 5.1.56 (2011-03-01)).

Bugs Fixed

- Accessing a table having a `BLOB` column but no primary key following a restart of the SQL node failed with Error 1 (`Unknown error code`). (Bug #13563280)

- At the beginning of a local checkpoint, each data node marks its local tables with a “to be checkpointed” flag. A failure of the master node during this process could cause either the LCP to hang, or one or more data nodes to be forcibly shut down. (Bug #13436481)

- A node failure while a `ANALYZE TABLE` statement was executing resulted in a hung connection (and the user was not informed of any error that would cause this to happen). (Bug #13416603)

  References: See also Bug #13407848.

- **Cluster Replication**: Under certain circumstances, the `Rows` count in the output of `SHOW TABLE STATUS` for a replicated slave `NDB` table could be misreported as many times larger than the result of `SELECT COUNT(*)` on the same table. (Bug #13440282)

Changes in MySQL Cluster NDB 7.1.18 (5.1.56-ndb-7.1.18) (2011-12-13)

MySQL Cluster NDB 7.1.18 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in previous MySQL Cluster NDB 7.1 releases.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.56 (see Changes in MySQL 5.1.56 (2011-03-01)).

Bugs Fixed

- Added the `MinFreePct` [1820] data node configuration parameter, which specifies a percentage of data node resources to hold in reserve for restarts. The resources monitored are `DataMemory` [1817], `IndexMemory` [1819], and any per-table `MAX_ROWS` settings (see `CREATE TABLE` Syntax). The default value of `MinFreePct` [1820] is 5, which means that 5% from each these resources is now set aside for restarts. (Bug #13436216)

- Because the log event buffer used internally by data nodes was circular, periodic events such as statistics events caused it to be overwritten too quickly. Now the buffer is partitioned by log event category, and its default size has been increased from 4K to 8K. (Bug #13394771)

- The `BatchSize` [1866] and `BatchByteSize` [1866] configuration parameters, used to control the maximum sizes of result batches, are defined as integers. However, the values used to store these were incorrectly interpreted as numbers of bytes in the NDB kernel. This caused the `DBLQH` kernel block to fail to detect when the specified `BatchByteSize` [1866] was consumed.

  In addition, the `DBSPJ` kernel block could miscalculate statistics for adaptive parallelism. (Bug #13355055)

- Previously, forcing simultaneously the shutdown of multiple data nodes using `SHUTDOWN -F` in the `ndb_mgm` management client could cause the entire cluster to fail. Now in such cases, any such nodes are forced to abort immediately. (Bug #12928429)

- A **`SubscriberNodeIdUndefined`** error was previously unhandled, resulting in a data node crash, but is now handled by NDB Error 1429, `Subscriber node undefined in SubStartReq`. (Bug #12598496)

- `SELECT` statements using `LIKE CONCAT(...)` [951] `OR LIKE CONCAT(...)` in the `WHERE` clause returned incorrect results when run against `NDB` tables. (Bug #11765142, Bug #58073)

- **Cluster Replication**: With many SQL nodes, all writing binary logs, connected to a MySQL Cluster, `RENAME TABLE` could cause data node processes (`ndbmtd`) to fail. (Bug #13447705)

- **Cluster Replication**: It was possible for `PURGE MASTER LOGS` and `SHOW BINARY LOGS` to deadlock when run concurrently. (Bug #13400021)

Changes in MySQL Cluster NDB 7.1.17 (5.1.56-ndb-7.1.17) (2011-11-15)

MySQL Cluster NDB 7.1.17 is a new release of MySQL Cluster, incorporating new features in the NDBCLUSTER storage engine and fixing recently discovered bugs in previous MySQL Cluster NDB 7.1 releases.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.56 (see Changes in MySQL 5.1.56 (2011-03-01)).

Functionality Added or Changed

- Introduced the CrashOnCorruptedTuple [1833] data node configuration parameter. When enabled, this parameter causes data nodes to handle corrupted tuples in a fail-fast manner—in other words, whenever the data node detects a corrupted tuple, it forcibly shuts down if CrashOnCorruptedTuple [1833] is enabled. For backward compatibility, this parameter is disabled by default. (Bug #12598636)

- Added the ThreadConfig data node configuration parameter to enable control of multiple threads and CPUs when using ndbmtd, by assigning threads of one or more specified types to execute on one or more CPUs. This can provide more precise and flexible control over multiple threads than can be obtained using the LockExecuteThreadToCPU [1852] parameter. (Bug #11795581)

Bugs Fixed

- **Cluster Replication**: **Important Change**: A unique key constraint violation caused NDB slaves to stop rather than to continue when the slave_exec_mode [1644] was IDEMPOTENT. In such cases, NDB now behaves as other MySQL storage engines do when in IDEMPOTENT mode. (Bug #11756310)

- When a failure of multiple data nodes during a local checkpoint (LCP) that took a long time to complete included the node designated as master, any new data nodes attempting to start before all ongoing LCPs were completed later crashed. This was due to the fact that node takeover by the new master cannot be completed until there are no pending local checkpoints. Long-running LCPs such as those which triggered this issue can occur when fragment sizes are sufficiently large (see MySQL Cluster Nodes, Node Groups, Replicas, and Partitions, for more information). Now in such cases, data nodes (other than the new master) are kept from restarting until the takeover is complete. (Bug #13323589)

- When deleting from multiple tables using a unique key in the WHERE condition, the wrong rows were deleted. In addition, UPDATE triggers failed when rows were changed by deleting from or updating multiple tables. (Bug #12718336, Bug #61705, Bug #12728221)

- Shutting down a mysqld while under load caused the spurious error messages Opening ndb_binlog_index: killed and Unable to lock table ndb_binlog_index to be written in the cluster log. (Bug #11930428)

- **Cluster Replication**: The mysqlbinlog --database [350] option generated table mapping errors when used with NDB tables, unless the binary log was generated using --log-bin-use-v1-row-events=0 [1648]. (Bug #13067813)

- **Cluster Replication**: Replication of NDB tables having more columns on the slave than on the master did not always work correctly when any of the extra columns were NOT NULL, did not have a default value, or both. (Bug #11755904, Bug #47742)

- **Cluster API**: When more than 32KB of data must be sent in a single signal using the NDB API, the data is split across 2 or more signals each of which is smaller than 32kB, and these are then reassembled back into the original, full-length signal by the receiver. Such fragmented signals are used for some scan requests, as well as for SPJ `QueryOperation` requests. However, extra (spurious) signals could sometimes be sent when using fragmented signals, causing errors on the receiver; these implementation artifacts have now been eliminated. (Bug #13087016)

Changes in MySQL Cluster NDB 7.1.16 (5.1.56-ndb-7.1.16) (Not released)

MySQL Cluster NDB 7.1.16 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in previous MySQL Cluster NDB 7.1 releases.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.56 (see Changes in MySQL 5.1.56 (2011-03-01)).

Functionality Added or Changed

- **Cluster Replication**: **Important Change**: Due to the existing layout of binary log row events, it was not possible to extend them with extra information which could be safely ignored by old slaves. New versions of the `WRITE_ROW`, `UPDATE_ROW`, and `DELETE_ROW` events have been implemented; these are referred to as “Version 2” binary log events, and are intended for future enhancements such as improved conflict detection and resolution. The `TABLE_MAP` event is not affected.

  Version 2 binary log row events are not backward compatible, and cannot be read by older slaves. A new `mysqld` option `--log-bin-use-v1-row-events` [1648] can be used to force writing of Version 1 row events into the binary log. This can be used during upgrades to make a newer `mysqld` generate Version 1 binary log row events that can be read by older slaves.

- It is now possible to filter the output from `ndb_config` so that it displays only system, data node, or connection parameters and values, using one of the options `--system` [1974], `--nodes` [1974], or `--connections` [1974], respectively. In addition, it is now possible to specify from which data node the configuration data is obtained, using the `--config_from_node` [1972] option that is added in this release.

  For more information, see `ndb_config` — Extract MySQL Cluster Configuration Information. (Bug #11766870)

- **Cluster Replication**: Added two new conflict detection functions `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` useful in circular replication scenarios with two MySQL Clusters. Each of these functions requires designating one cluster as primary and one as secondary, and implements a “primary always wins” rule for determining whether to accept conflicting changes. When using `NDB$EPOCH()`, conflicting rows on the secondary are realigned with those on the primary; when using `NDB$EPOCH_TRANS()`, it is transactions containing rows in conflict (and any transactions which depend on them) on the secondary that are realigned.

  Using `NDB$EPOCH_TRANS()` as the conflict detection function has two additional requirements:

  1. The binary log must be written using Version 2 row events; that is, the `mysqld` processes on both the primary and the secondary must be started with `--log-bin-use-v1-row-events=0` [1648].

2. The secondary must include transaction IDs for all rows written into its binary log. This can be done by setting `--ndb-log-transaction-id=1` [1916]. (This server option is also added in this release.)

A number of new server status variables have been added to monitor conflict detection and resolution performed using these functions, including `Ndb_conflict_fn_epoch` [1947], `Ndb_conflict_fn_epoch_trans` [1947], and `Ndb_conflict_trans_row_conflict_count` [1948]. See MySQL Cluster Status Variables.

For more information, see MySQL Cluster Replication Conflict Resolution.

Bugs Fixed

- **Cluster API**: **Incompatible Change**: Restarting a machine hosting data nodes, SQL nodes, or both, caused such nodes when restarting to time out while trying to obtain node IDs.

  As part of the fix for this issue, the behavior and default values for the NDB API `Ndb_cluster_connection::connect()` method have been improved. Due to these changes, the version number for the included NDB client library (`libndbclient.so`) has been increased from 4.0.0 to 5.0.0. For NDB API applications, this means that as part of any upgrade, you must do both of the following:

  - Review and possibly modify any NDB API code that uses the `connect()` method, in order to take into account its changed default retry handling.
  - Recompile any NDB API applications using the new version of the client library.

  Also in connection with this issue, the default value for each of the two `mysqld` options `--ndb-wait-connected` [1919] and `--ndb-wait-setup` [1919] has been increased to 30 seconds (from 0 and 15, respectively). In addition, a hard-coded 30-second delay was removed, so that the value of `--ndb-wait-connected` [1919] is now handled correctly in all cases. (Bug #12543299)

- When replicating DML statements with `IGNORE` between clusters, the number of operations that failed due to nonexistent keys was expected to be no greater than the number of defined operations of any single type. Because the slave SQL thread defines operations of multiple types in batches together, code which relied on this assumption could cause `mysqld` to fail. (Bug #12859831)

- The maximum effective value for the `OverloadLimit` [1869] configuration parameter was limited by the value of `SendBufferMemory` [1870]. Now the value set for `OverloadLimit` [1869] is used correctly, up to this parameter's stated maximum (4G). (Bug #12712109)

- `AUTO_INCREMENT` values were not set correctly for `INSERT IGNORE` statements affecting `NDB` tables. This could lead such statements to fail with `Got error 4350 'Transaction already aborted' from NDBCLUSTER` when inserting multiple rows containing duplicate values. (Bug #11755237, Bug #46985)

- When failure handling of an API node takes longer than 300 seconds, extra debug information is included in the resulting output. In cases where the API node's node ID was greater than 48, these extra debug messages could lead to a crash, and confuing output otherwise. This was due to an attempt to provide information specific to data nodes for API nodes as well. (Bug #62208)

- In rare cases, a series of node restarts and crashes during restarts could lead to errors while reading the redo log. (Bug #62206)

- **Cluster Replication**: A transaction that updated many (thousands of) rows executed properly on the master but failed on the slave with the error `Lock wait timeout exceeded...`.

  This issue is known to affect MySQL Cluster NDB 7.1.13 and later. (Bug #12974714)

Changes in MySQL Cluster NDB 7.1.15a (5.1.56-ndb-7.1.15a) (2011-08-25)

MySQL Cluster NDB 7.1.15a is a new release of MySQL Cluster fixing a recently discovered critical issue in MySQL Cluster NDB 7.1.15. MySQL Cluster NDB 7.1.15a is in all other respects identical with MySQL Cluster NDB 7.1.15 (see Changes in MySQL Cluster NDB 7.1.15 (5.1.56-ndb-7.1.15) (2011-07-04)), which it replaces.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.56 (see Changes in MySQL 5.1.56 (2011-03-01)).

Bugs Fixed

- Setting `IndexMemory` [1819] or sometimes `DataMemory` [1817] to 2 GB or higher could lead to data node failures under some conditions. (Bug #12873640)

Changes in MySQL Cluster NDB 7.1.15 (5.1.56-ndb-7.1.15) (2011-07-04)

MySQL Cluster NDB 7.1.15 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in previous MySQL Cluster NDB 7.1 releases.

Important

A critical issue (Bug #12873640) was discovered in this release after it was made available; it has been replaced by MySQL Cluster NDB 7.1.15a. Users of previous MySQL Cluster NDB 7.1 releases should upgrade to MySQL Cluster NDB 7.1.15a or later. See Changes in MySQL Cluster NDB 7.1.15a (5.1.56-ndb-7.1.15a) (2011-08-25), for more information.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.56 (see Changes in MySQL 5.1.56 (2011-03-01)).

Functionality Added or Changed

- Added the `MaxDMLOperationsPerTransaction` [1822] data node configuration parameter, which can be used to limit the number of DML operations used by a transaction; if the transaction requires more than this many DML operations, the transaction is aborted. (Bug #12589613)

Bugs Fixed

- When global checkpoint indexes were written with no intervening end-of-file or megabyte border markers, this could sometimes lead to a situation in which the end of the redo log was mistakenly regarded as being between these GCIs, so that if the restart of a data node took place before the start of the next redo log was overwritten, the node encountered an `Error while reading the REDO log`. (Bug #12653993, Bug #61500)

  References: See also Bug #56961.

- Restarting a `mysqld` during a rolling upgrade with data nodes running a mix of old and new versions of the MySQL Cluster software caused the `mysqld` to run in read-only mode. (Bug #12651364, Bug #61498)
- Error reporting has been improved for cases in which API nodes are unable to connect due to apparent unavailability of node IDs. (Bug #12598398)
- Error messages for `Failed to convert connection` transporter registration problems were inspecific. (Bug #12589691)
- Under certain rare circumstances, a data node process could fail with Signal 11 during a restart. This was due to uninitialized variables in the `QMGR` kernel block. (Bug #12586190)
- Multiple management servers were unable to detect one another until all nodes had fully started. As part of the fix for this issue, two new status values `RESUME` and `CONNECTED` can be reported for management nodes in the output of the `ndb_mgm` client `SHOW` command (see Commands in the MySQL Cluster Management Client). Two corresponding status values `NDB_MGM_NODE_STATUS_RESUME` and `NDB_MGM_NODE_STATUS_CONNECTED` are also added to the list of possible values for an `ndb_mgm_node_status` data structure in the MGM API. (Bug #12352191, Bug #48301)
- Handling of the `MaxNoOfTables` [1829] and `MaxNoOfAttributes` [1828] configuration parameters was not consistent in all parts of the `NDB` kernel, and were only strictly enforced by the `DBDICT` and `SUMA` kernel blocks. This could lead to problems when tables could be created but not replicated. Now these parameters are treated by `SUMA` and `DBDICT` as suggested maximums rather than hard limits, as they are elsewhere in the `NDB` kernel. (Bug #61684)
- It was not possible to shut down a management node while one or more data nodes were stopped (for whatever reason). This issue was a regression introduced in MySQL Cluster NDB 7.0.24 and MySQL Cluster NDB 7.1.13. (Bug #61607)

  References: See also Bug #61147.
- **Cluster API**: Applications that included the header file `ndb_logevent.h` could not be built using the Microsoft Visual Studio C compiler or the Oracle (Sun) Studio C compiler due to empty struct definitions. (Bug #12678971)
- **Cluster API**: Within a transaction, after creating, executing, and closing a scan, calling `NdbTransaction::refresh()` after creating and executing but not closing a second scan caused the application to crash. (Bug #12646659)

Changes in MySQL Cluster NDB 7.1.14 (5.1.56-ndb-7.1.14) (2011-05-24)

MySQL Cluster NDB 7.1.14 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in previous MySQL Cluster NDB 7.1 releases.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.56 (see Changes in MySQL 5.1.56 (2011-03-01)).

Bugs Fixed

- The internal `Ndb_getinaddr()` function has been rewritten to use `getaddrinfo()` instead of `my_gethostbyname_r()` (which is removed in a later version of the MySQL Server). (Bug #12542120)

- `mysql_upgrade` failed when performing an online upgrade from MySQL Cluster NDB 7.1.8 or an earlier release to MySQL Cluster NDB 7.1.9 or later in which the SQL nodes were upgraded before the data nodes. This issue could occur during any online upgrade or downgrade where one or more `ndbinfo` tables had more, fewer, or differing columns between the two versions, and when the data nodes were not upgraded before the SQL nodes.

  For more information, see Upgrade and downgrade compatibility: MySQL Cluster NDB 7.x. (Bug #11885602, Bug #12581895, Bug #12581954)

- Two unused test files in `storage/ndb/test/sql` contained incorrect versions of the GNU Lesser General Public License. The files and the directory containing them have been removed. (Bug #11810156)

  References: See also Bug #11810224.

- Error 1302 gave the wrong error message (`Out of backup record`). This has been corrected to `A backup is already running`. (Bug #11793592)

- When using two management servers, issuing in an `ndb_mgm` client connected to one management server a `STOP` command for stopping the other management server caused Error 2002 (`Stop failed ... Send to process or receive failed.: Permanent error: Application error`), even though the `STOP` command actually succeeded, and the second `ndb_mgmd` was shut down. (Bug #61147)

- Renaming a table having `BLOB` or `TEXT` columns (or both) to another database caused the SQL node to crash, and the table to become inaccessible afterwards. (Bug #60484)

- Under heavy loads with many concurrent inserts, temporary failures in transactions could occur (and were misreported as being due to `NDB` Error 899 `Rowid already allocated`). As part of the fix for this issue, `NDB` Error 899 has been reclassified as an internal error, rather than as a temporary transaction error. (Bug #56051, Bug #11763354)

- In `ndbmtd`, a node connection event is detected by a `CMVMI` thread which sends a `CONNECT_REP` signal to the `QMGR` kernel block. In a few isolated circumstances, a signal might be transferred to `QMGR` directly by the `NDB` transporter before the `CONNECT_REP` signal actually arrived. This resulted in reports in the error log with status `Temporary error, restart node`, and the message `Internal program error`. (Bug #61025)

- **Disk Data**: Accounting for `MaxNoOfOpenFiles` was incorrect with regard to to data files in MySQL Cluster Disk Data tablespaces. This could lead to a crash when `MaxNoOfOpenFiles` was exceeded. (Bug #12581213)

- **Cluster Replication**: Operations that updated unique keys of `NDB` tables could cause duplicate key errors when trying to execute the binary log. (Previously, row events in the binary log were ordered according to the partitioning of the base table, which could differ in order within the epoch for that in which they were executed.

  To keep this from happening, unique keys are now updated in deferred mode, meaning that all table rows are updated before any unique indexes are checked. Thus, the order of the row updates is no longer important.

  You should be aware that deferring constraint checking in this way is currently supported only by `NDB`, and thus only for replication between NDB tables on both the master and the slave. You cannot replicate updates of unique keys successfully when replicating from `NDB` to a different storage engine such as `MyISAM` or `InnoDB`. (Bug #47952, Bug #11756082)

Changes in MySQL Cluster NDB 7.1.13 (5.1.56-ndb-7.1.13) (2011-04-26)

MySQL Cluster NDB 7.1.13 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in previous MySQL Cluster NDB 7.1 releases.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.56 (see Changes in MySQL 5.1.56 (2011-03-01)).

Functionality Added or Changed

- It is now possible to add data nodes online to a running MySQL Cluster without performing a rolling restart of the cluster or starting data node processes with the `--nowait-nodes` [1955] option. This can be done by setting `Nodegroup = 65536` [1815] in the `config.ini` file for any data nodes that should be started at a later time, when first starting the cluster. (It was possible to set `NodeGroup` [1815] to this value previously, but the management server failed to start.)

  As part of this fix, a new data node configuration parameter `StartNoNodeGroupTimeout` [1836] has been added. When the management server sees that there are data nodes with no node group (that is, nodes for which `Nodegroup = 65536` [1815]), it waits `StartNoNodeGroupTimeout` [1836] milliseconds before treating these nodes as though they were listed with the `--nowait-nodes` [1955] option, and proceeds to start.

  For more information, see Adding MySQL Cluster Data Nodes Online. (Bug #11766167, Bug #59213)

- A `config_generation` column has been added to the `nodes` table of the `ndbinfo` database. By checking this column, it is now possible to determine which version or versions of the MySQL Cluster configuration file are in effect on the data nodes. This information can be especially useful when performing a rolling restart of the cluster to update its configuration.

Bugs Fixed

- **Cluster API**: A unique index operation is executed in two steps: a lookup on an index table, and an operation on the base table. When the operation on the base table failed, while being executed in a batch with other operations that succeeded, this could lead to a hanging execute, eventually timing out with Error 4012 (`Request ndbd time-out, maybe due to high load or communication problems`). (Bug #12315582)

- A memory leak in `LGMAN`, that leaked 8 bytes of log buffer memory per 32k written, was introduced in MySQL Cluster NDB 7.0.9, effecting all MySQL Cluster NDB 7.1 releases as well as MySQL Cluster NDB 7.0.9 and later MySQL Cluster NDB 7.0 releases. (For example, when 128MB log buffer memory was used, it was exhausted after writing 512GB to the undo log.) This led to a GCP stop and data node failure. (Bug #60946)

  References: This bug was introduced by Bug #47966.

- When using `ndbmtd`, a MySQL Cluster configured with 32 data nodes failed to start correctly. (Bug #60943)

- When performing a TUP scan with locks in parallel, and with a highly concurrent load of inserts and deletions, the scan could sometimes fail to notice that a record had moved while waiting to acquire a lock on it, and so read the wrong record. During node recovery, this could lead to a crash of a node that was copying data to the node being started, and a possible forced shutdown of the cluster.

- **Cluster API**: Performing interpreted operations using a unique index did not work correctly, because the interpret bit was kept when sending the lookup to the index table.

Changes in MySQL Cluster NDB 7.1.12 (5.1.51-ndb-7.1.12) (2011-04-04)

MySQL Cluster NDB 7.1.12 is a new release of MySQL Cluster, incorporating new features in the NDBCLUSTER storage engine and fixing recently discovered bugs in previous MySQL Cluster NDB 7.1 releases.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.51 (see Changes in MySQL 5.1.51 (2010-09-10)).

Functionality Added or Changed

- Improved scaling of ordered index scans performance by removing a hard-coded limit (MAX_PARALLEL_INDEX_SCANS_PER_FRAG) and making the number of TUP or TUX scans per fragment configurable by adding the MaxParallelScansPerFragment [1825] data node configuration parameter. (Bug #11769048)

Bugs Fixed

- **Important Change**: Formerly, the --ndb-cluster-connection-pool server option set a status variable as well as a system variable. The status variable has been removed as redundant. (Bug #60119)
- A scan with a pushed condition (filter) using the CommittedRead lock mode could hang for a short interval when it was aborted when just as it had decided to send a batch. (Bug #11932525)
- When aborting a multi-read range scan exactly as it was changing ranges in the local query handler, LQH could fail to detect it, leaving the scan hanging. (Bug #11929643)
- Schema distribution did not take place for tables converted from another storage engine to NDB using ALTER TABLE; this meant that such tables were not always visible to all SQL nodes attached to the cluster. (Bug #11894966)
- A GCI value inserted by ndb_restore --restore_epoch [1996] into the ndb_apply_status table was actually 1 less than the correct value. (Bug #11885852)
- **Replication**: Error 1590 (ER_SLAVE_INCIDENT [3994]) caused the slave to stop even when it was started with --slave-skip-errors=1590 [1641]. (Bug #59889, Bug #11768580, Bug #11799671)
- **Disk Data**: Limits imposed by the size of SharedGlobalMemory [1856] were not always enforced consistently with regard to Disk Data undo buffers and log files. This could sometimes cause a CREATE LOGFILE GROUP or ALTER LOGFILE GROUP statement to fail for no apparent reason, or cause the log file group specified by InitialLogFileGroup [1859] not to be created when starting the cluster. (Bug #57317)
- **Cluster Replication**: Filtering the binary log using --binlog-ignore-db=mysql [1651] caused epochs not to be logged as expected in the ndb_apply_status table. (Bug #11765707, Bug #58698)
- **ClusterJ**: Binary columns can now be used as key columns.

  Error reporting when trying to use unsupported column types has been improved.

  Updates for DynamicObject persistent classes are now handled as expected. (Bug #11766757, Bug #59942)

- **ClusterJ**: ClusterJ incorrectly asked for the character set for a `LONGVARBINARY` column with `VARBINARY(256)` columns, leading to a VM crash caused by invalid memory access. (Bug #11766756, Bug #59941)

- The optimizer sometimes requested ordered access from a storage engine when ordered access was not required. (Bug #57601, Bug #11764737)

Changes in MySQL Cluster NDB 7.1.11 (5.1.51-ndb-7.1.11) (2011-02-25)

MySQL Cluster NDB 7.1.11 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in previous MySQL Cluster NDB 7.1 releases.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.51 (see Changes in MySQL 5.1.51 (2010-09-10)).

Functionality Added or Changed

- **Disk Data**: The `INFORMATION_SCHEMA.TABLES` table now provides disk usage as well as memory usage information for Disk Data tables. Also, `INFORMATION_SCHEMA.PARTITIONS`, formerly did not show any statistics for `NDB` tables. Now the `TABLE_ROWS`, `AVG_ROW_LENGTH`, `DATA_LENGTH`, `MAX_DATA_LENGTH`, and `DATA_FREE` columns contain correct information for the table's partitions.

- A new `--rewrite-database` [2003] option is added for `ndb_restore`, which makes it possible to restore to a database having a different name from that of the database in the backup.

  For more information, see `ndb_restore` — Restore a MySQL Cluster Backup. (Bug #54327)

- The NDB kernel now implements a number of statistical counters relating to actions performed by or affecting `Ndb` objects, such as starting, closing, or aborting transactions; primary key and unique key operations; table, range, and pruned scans; blocked threads waiting for various operations to complete; and data and events sent and received by `NDBCLUSTER`. These NDB API counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes. `mysqld` exposes these counters as system status variables; their values can be read in the output of `SHOW STATUS`, or by querying the `SESSION_STATUS` or `GLOBAL_STATUS` table in the `INFORMATION_SCHEMA` database. By comparing the values of these status variables prior to and following the execution of SQL statements that act on `NDB` tables, you can observe the corresponding actions taken on the NDB API level, which can be beneficial for monitoring and performance tuning of MySQL Cluster.

  For more information, see NDB API Statistics Counters and Variables, as well as MySQL Cluster Status Variables.

- Made it possible to enable multi-threaded building of ordered indexes during initial restarts, using the new `TwoPassInitialNodeRestartCopy` data node configuration parameter.

- Added the `--lossy-conversions` [1995] option for `ndb_restore`, which makes it possible to enable attribute demotion when restoring a MySQL Cluster from an `NDB` native backup.

  For additional information about type conversions currently supported by MySQL Cluster for attribute promotion and demotion, see Replication of Columns Having Different Data Types.

Bugs Fixed

- This issue affects all previous MySQL Cluster NDB 7.1 releases. (Bug #60045)
- `ndb_restore --rebuild-indexes` [2002] caused multi-threaded index building to occur on the master node only. (Bug #59920)
- Successive queries on the `counters` table from the same SQL node returned unchanging results. To fix this issue, and to prevent similar issues from occurring in the future, `ndbinfo` tables are now excluded from the query cache. (Bug #59831)
- When attempting to create a table on a MySQL Cluster with many standby data nodes (setting `Nodegroup=65536` [1815] in `config.ini` for the nodes that should wait, starting the nodes that should start immediately with the `--nowait-nodes` [1955] option, and using the `CREATE TABLE` statement's `MAX_ROWS` option), `mysqld` miscalculated the number of fragments to use. This caused the `CREATE TABLE` to fail.

  Note

  The `CREATE TABLE` failure caused by this issue in turn prevented any further attempts to create the table, even if the table structure was simplified or changed in such a way that the attempt should have succeeded. This “ghosting” issue is handled in Bug #59756.

  (Bug #59751)
- When a `CREATE TABLE` statement failed due to `NDB` error 1224 (`Too many fragments`), it was not possible to create the table afterward unless either it had no ordered indexes, or a `DROP TABLE` statement was issued first, even if the subsequent `CREATE TABLE` was valid and should otherwise have succeeded. (Bug #59756)

  References: See also Bug #59751.
- `NDB` sometimes treated a simple (not unique) ordered index as unique. (Bug #59519)
- The logic used in determining whether to collapse a range to a simple equality was faulty. In certain cases, this could cause `NDB` to treat a range as if it were a primary key lookup when determining the query plan to be used. Although this did not affect the actual result returned by the query, it could in such cases result in inefficient execution of queries due to the use of an inappropriate query plan. (Bug #59517)
- When a query used multiple references to or instances of the same physical tables, `NDB` failed to recognize these multiple instances as different tables; in such a case, `NDB` could incorrectly use condition pushdown on a condition referring to these other instances to be pushed to the data nodes, even though the condition should have been rejected as unpushable, leading to invalid results. (Bug #58791)
- **Cluster API**: When calling `NdbEventOperation::execute()` during a node restart, it was possible to get a spurious error 711 (`System busy with node restart, schema operations not allowed when a node is starting`). (Bug #59723)
- **Cluster API**: When an NDBAPI client application was waiting for more scan results after calling `NdbScanOperation::nextResult()`, the calling thread sometimes woke up even if no new batches for any fragment had arrived, which was unnecessary, and which could have a negative impact on the application's performance. (Bug #52298)
- An `OUTER JOIN` query using `WHERE col_name IS NULL` could return an incorrect result. (Bug #58490, Bug #11765513)

Changes in MySQL Cluster NDB 7.1.10 (5.1.51-ndb-7.1.10) (2011-01-26)

MySQL Cluster NDB 7.1.10 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 7.1.9a and previous MySQL Cluster releases.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.51 (see Changes in MySQL 5.1.51 (2010-09-10)).

Functionality Added or Changed

- **Important Change**: The following changes have been made with regard to the `TimeBetweenEpochsTimeout` [1840] data node configuration parameter:
  - The maximum possible value for this parameter has been increased from 32000 milliseconds to 256000 milliseconds.
  - Setting this parameter to zero now has the effect of disabling GCP stops caused by save timeouts, commit timeouts, or both.
  - The current value of this parameter and a warning are written to the cluster log whenever a GCP save takes longer than 1 minute or a GCP commit takes longer than 10 seconds.

  For more information, see Disk Data and `GCP Stop` errors. (Bug #58383)
- Added the `--skip-broken-objects` [2003] option for `ndb_restore`. This option causes `ndb_restore` to ignore tables corrupted due to missing blob parts tables, and to continue reading from the backup file and restoring the remaining tables. (Bug #54613)

  References: See also Bug #51652.
- Made it possible to exercise more direct control over handling of timeouts occurring when trying to flush redo logs to disk using two new data node configuration parameters `RedoOverCommitCounter` [1862] and `RedoOverCommitLimit` [1862], as well as the new API node configuration parameter `DefaultOperationRedoProblemAction` [1867], all added in this release. Now, when such timeouts occur more than a specified number of times for the flushing of a given redo log, any transactions that were to be written are instead aborted, and the operations contained in those transactions can be either re-tried or themselves aborted.

  For more information, see Redo log over-commit handling.
- **Cluster Replication**: Added the `--ndb-log-apply-status` [1915] server option, which causes a replication slave to apply updates to the master's `mysql.ndb_apply_status` table to its own `ndb_apply_status` table using its own server ID in place of the master's server ID. This option can be useful in circular or chain replication setups when you need to track updates to `ndb_apply_status` as they propagate from one MySQL Cluster to the next in the circle or chain.
- **Cluster API**: It is now possible to stop or restart a node even while other nodes are starting, using the MGM API `ndb_mgm_stop4()` or `ndb_mgm_restart4()` function, respectively, with the *`force`* parameter set to 1. (Bug #58451)

  References: See also Bug #58319.

Bugs Fixed

- **Cluster API**: In some circumstances, very large `BLOB` read and write operations in MySQL Cluster applications can cause excessive resource usage and even exhaustion of memory. To fix this issue and to provide increased stability when performing such operations, it is now possible to set limits on the volume of `BLOB` data to be read or written within a given transaction in such a way that when these limits are exceeded, the current transaction implicitly executes any accumulated operations. This avoids an excessive buildup of pending data which can result in resource exhaustion in the NDB

kernel. The limits on the amount of data to be read and on the amount of data to be written before this execution takes place can be configured separately. (In other words, it is now possible in MySQL Cluster to specify read batching and write batching that is specific to `BLOB` data.) These limits can be configured either on the NDB API level, or in the MySQL Server.

On the NDB API level, four new methods are added to the `NdbTransaction` object. `getMaxPendingBlobReadBytes()` and `setMaxPendingBlobReadBytes()` can be used to get and to set, respectively, the maximum amount of `BLOB` data to be read that accumulates before this implicit execution is triggered. `getMaxPendingBlobWriteBytes()` and `setMaxPendingBlobWriteBytes()` can be used to get and to set, respectively, the maximum volume of `BLOB` data to be written that accumulates before implicit execution occurs.

For the MySQL server, two new options are added. The `--ndb-blob-read-batch-bytes` [1913] option sets a limit on the amount of pending `BLOB` data to be read before triggering implicit execution, and the `--ndb-blob-write-batch-bytes` [1913] option controls the amount of pending `BLOB` data to be written. These limits can also be set using the `mysqld` configuration file, or read and set within the `mysql` client and other MySQL client applications using the corresponding server system variables. (Bug #59113)

- Two related problems could occur with read-committed scans made in parallel with transactions combining multiple (concurrent) operations:

  1. When committing a multiple-operation transaction that contained concurrent insert and update operations on the same record, the commit arrived first for the insert and then for the update. If a read-committed scan arrived between these operations, it could thus read incorrect data; in addition, if the scan read variable-size data, it could cause the data node to fail.

  2. When rolling back a multiple-operation transaction having concurrent delete and insert operations on the same record, the abort arrived first for the delete operation, and then for the insert. If a read-committed scan arrived between the delete and the insert, it could incorrectly assume that the record should not be returned (in other words, the scan treated the insert as though it had not yet been committed).

  (Bug #59496)

- On Windows platforms, issuing a `SHUTDOWN` command in the `ndb_mgm` client caused management processes that had been started with the `--nodaemon` [1965] option to exit abnormally. (Bug #59437)

- When executing a full table scan caused by a `WHERE` condition using *`unique_key`* `IS NULL` in combination with a join, `NDB` failed to close the scan. (Bug #58750)

  References: See also Bug #57481.

- A row insert or update followed by a delete operation on the same row within the same transaction could in some cases lead to a buffer overflow. (Bug #59242)

  References: See also Bug #56524. This bug was introduced by Bug #35208.

- Data nodes configured with very large amounts (multiple gigabytes) of `DiskPageBufferMemory` [1856] failed during startup with NDB error 2334 (`Job buffer congestion`). (Bug #58945)

  References: See also Bug #47984.

- The `FAIL_REP` signal, used inside the NDB kernel to declare that a node has failed, now includes the node ID of the node that detected the failure. This information can be useful in debugging. (Bug #58904)

- When handling failures of multiple data nodes, an error in the construction of internal signals could cause the cluster's remaining nodes to crash. This issue was most likely to affect clusters with large numbers of data nodes. (Bug #58240)
- Data nodes no longer allocated all memory prior to being ready to exchange heartbeat and other messages with management nodes, as in NDB 6.3 and earlier versions of MySQL Cluster. This caused problems when data nodes configured with large amounts of memory failed to show as connected or showed as being in the wrong start phase in the `ndb_mgm` client even after making their initial connections to and fetching their configuration data from the management server. With this fix, data nodes now allocate all memory as they did in earlier MySQL Cluster versions. (Bug #57568)
- Trying to drop an index while it was being used to perform scan updates caused data nodes to crash. (Bug #58277, Bug #57057)
- The number of rows affected by a statement that used a `WHERE` clause having an `IN` [942] condition with a value list containing a great many elements, and that deleted or updated enough rows such that `NDB` processed them in batches, was not computed or reported correctly. (Bug #58040)
- Issuing `EXPLAIN EXTENDED` for a query that would use condition pushdown could cause `mysqld` to crash. (Bug #58553, Bug #11765570)
- MySQL Cluster failed to compile correctly on FreeBSD 8.1 due to misplaced `#include` statements. (Bug #58034)
- In some circumstances, an SQL trigger on an `NDB` table could read stale data. (Bug #58538)
- A query having multiple predicates joined by `OR` in the `WHERE` clause and which used the `sort_union` access method (as shown using `EXPLAIN`) could return duplicate rows. (Bug #58280)
- During a node takeover, it was possible in some circumstances for one of the remaining nodes to send an extra transaction confirmation (`LQH_TRANSCONF`) signal to the `DBTC` kernel block, conceivably leading to a crash of the data node trying to take over as the new transaction coordinator. (Bug #58453)
- Some queries of the form `SELECT ... WHERE column IN (subquery)` against an `NDB` table could cause `mysqld` to hang in an endless loop. (Bug #58163)
- In some circumstances, it was possible for `mysqld` to begin a new multi-range read scan without having closed a previous one. This could lead to exhaustion of all scan operation objects, transaction objects, or lock objects (or some combination of these) in `NDB`, causing queries to fail with such errors as `Lock wait timeout exceeded` or `Connect failure - out of connection objects`. (Bug #57481)

  References: See also Bug #58750.
- Queries using `column IS [NOT] NULL` on a table with a unique index created with `USING HASH` on `column` always returned an empty result. (Bug #57032)
- The functions `strncasecmp` and `strcasecmp` were declared in `ndb_global.h` but never defined or used. The declarations have been removed. (Bug #58204)
- With `engine_condition_pushdown` [473] enabled, a query using `LIKE` on an `ENUM` column of an `NDB` table failed to return any results. This issue is resolved by disabling `engine_condition_pushdown` [473] when performing such queries. (Bug #53360)
- A query using `BETWEEN` as part of a pushed-down `WHERE` condition could cause mysqld to hang or crash. (Bug #57735)
- When a slash character (`/`) was used as part of the name of an index on an `NDB` table, attempting to execute a `TRUNCATE TABLE` statement on the table failed with the error `Index not found`, and the table was rendered unusable. (Bug #38914)

- **Disk Data**: **Partitioning**: When using multi-threaded data nodes, an `NDB` table created with a very large value for the `MAX_ROWS` option could—if this table was dropped and a new table with fewer partitions, but having the same table ID, was created—cause `ndbmtd` to crash when performing a system restart. This was because the server attempted to examine each partition whether or not it actually existed.

  This issue is the same as that reported in Bug #45154, except that the current issue is specific to `ndbmtd` instead of `ndbd`. (Bug #58638)

- **Disk Data**: In certain cases, a race condition could occur when `DROP LOGFILE GROUP` removed the logfile group while a read or write of one of the effected files was in progress, which in turn could lead to a crash of the data node. (Bug #59502)

- **Disk Data**: A race condition could sometimes be created when `DROP TABLESPACE` was run concurrently with a local checkpoint; this could in turn lead to a crash of the data node. (Bug #59501)

- **Disk Data**: Performing what should have been an online drop of a multi-column index was actually performed offline. (Bug #55618)

- **Disk Data**: When at least one data node was not running, queries against the `INFORMATION_SCHEMA.FILES` table took an excessive length of time to complete because the MySQL server waited for responses from any stopped nodes to time out. Now, in such cases, MySQL does not attempt to contact nodes which are not known to be running. (Bug #54199)

- **Cluster Replication**: When a `mysqld` performing replication of a MySQL Cluster that uses `ndbmtd` is forcibly disconnected (thus causing an `API_FAIL_REQ` signal to be sent), the `SUMA` kernel block iterates through all active subscriptions and disables them. If a given subscription has no more active users, then this subscription is also deactivated in the `DBTUP` kernel block.

  This process had no flow control, and when there were many subscriptions being deactivated (more than 512), this could cause an overflow in the short-time queue defined in the `DbtupProxy` class.

  The fix for this problem includes implementing proper flow control for this deactivation process and increasing the size of the short-time queue in `DbtupProxy`. (Bug #58693)

- **Cluster API**: It was not possible to obtain the status of nodes accurately after an attempt to stop a data node using `ndb_mgm_stop()` failed without returning an error. (Bug #58319)

- **Cluster API**: Attempting to read the same value (using `getValue()`) more than 9000 times within the same transaction caused the transaction to hang when executed. Now when more reads are performed in this way than can be accommodated in a single transaction, the call to `execute()` fails with a suitable error. (Bug #58110)

- **ClusterJ**: When building MySQL Cluster NDB 7.1 on Windows using `vcbuild` with parallelism set to 8, the `clusterj.jar` file was built before its dependencies, causing the build of this file to fail. (Bug #58563)

Changes in MySQL Cluster NDB 7.1.9a (5.1.51-ndb-7.1.9a) (2010-11-18)

MySQL Cluster NDB 7.1.9a is a new release of MySQL Cluster which fixes a critical upgrade issue discovered in MySQL Cluster NDB 7.1.9 shortly after it was released. It is otherwise identical to MySQL Cluster NDB 7.1.9.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.51 (see Changes in MySQL 5.1.51 (2010-09-10)).

Bugs Fixed

- **Important Note**: Issuing an `ALL DUMP` command during a rolling upgrade to MySQL Cluster NDB 7.1.9 caused the cluster to crash. (Bug #58256)
- **InnoDB**: **Packaging**: The `InnoDB` plugin was not included in MySQL Cluster RPM packages. (Bug #58283)

  References: See also Bug #54912.

Changes in MySQL Cluster NDB 7.1.9 (5.1.51-ndb-7.1.9) (2010-11-08)

MySQL Cluster NDB 7.1.9 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 7.1.8 and previous MySQL Cluster releases.

Important

A critical upgrade issue was discovered in MySQL Cluster NDB 7.1.9 shortly after release, causing it to be withdrawn and replaced with MySQL Cluster NDB 7.1.9a, which contains a fix for this issue. MySQL Cluster NDB 7.1.9a is otherwise identical to MySQL Cluster 7.1.9.

See Changes in MySQL Cluster NDB 7.1.9a (5.1.51-ndb-7.1.9a) (2010-11-18), for more information.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.51 (see Changes in MySQL 5.1.51 (2010-09-10)).

Functionality Added or Changed

- **Important Change**: **InnoDB**: Building the MySQL Server with the `InnoDB` plugin is now supported when building MySQL Cluster. For more information, see MySQL Cluster Installation. (Bug #54912)

  References: See also Bug #58283.

- **Important Change**: `ndbd` now bypasses use of Non-Uniform Memory Access support on Linux hosts by default. If your system supports NUMA, you can enable it and override `ndbd` use of interleaving by setting the `Numa` [1854] data node configuration parameter which is added in this release. See Defining Data Nodes: Realtime Performance Parameters, for more information. (Bug #57807)

- **Important Change**: The `Id` configuration parameter used with MySQL Cluster management, data, and API nodes (including SQL nodes) is now deprecated, and the `NodeId` parameter (long available as a synonym for `Id` when configuring these types of nodes) should be used instead. `Id` continues to be supported for reasons of backward compatibility, but now generates a warning when used with these types of nodes, and is subject to removal in a future release of MySQL Cluster.

  This change affects the name of the configuration parameter only, establishing a clear preference for `NodeId` over `Id` in the `[mgmd]`, `[ndbd]`, `[mysql]`, and `[api]` sections of the MySQL Cluster global configuration (`config.ini`) file. The behavior of unique identifiers for management, data, and SQL and API nodes in MySQL Cluster has not otherwise been altered.

  The `Id` parameter as used in the `[computer]` section of the MySQL Cluster global configuration file is not affected by this change.

- A new `diskpagebuffer` table, providing statistics on disk page buffer usage by Disk Data tables, is added to the `ndbinfo` information database. These statistics can be used to monitor performance of reads and writes on Disk Data tables, and to assist in the tuning of related parameters such as `DiskPageBufferMemory` [1856].

Bugs Fixed

- **Packaging**: MySQL Cluster RPM distributions did not include a `shared-compat` RPM for the MySQL Server, which meant that MySQL applications depending on `libmysqlclient.so.15` (MySQL 5.0 and earlier) no longer worked. (Bug #38596)

- On Windows, the angel process which monitors and (when necessary) restarts the data node process failed to spawn a new worker in some circumstances where the arguments vector contained extra items placed at its beginning. This could occur when the path to `ndbd.exe` or `ndbmtd.exe` contained one or more spaces. (Bug #57949)

- The disconnection of an API or management node due to missed heartbeats led to a race condition which could cause data nodes to crash. (Bug #57946)

- The method for calculating table schema versions used by schema transactions did not follow the established rules for recording schemas used in the `P0.SchemaLog` file. (Bug #57897)

  References: See also Bug #57896.

- The `LQHKEYREQ` request message used by the local query handler when checking the major schema version of a table, being only 16 bits wide, could cause this check to fail with an `Invalid schema version` error (`NDB` error code 1227). This issue occurred after creating and dropping (and re-creating) the same table 65537 times, then trying to insert rows into the table. (Bug #57896)

  References: See also Bug #57897.

- Transient errors during a local checkpoint were not retried, leading to a crash of the data node. Now when such errors occur, they are retried up to 10 times if necessary. (Bug #57650)

- When a data node angel process failed to fork off a new worker process (to replace one that had failed), the failure was not handled. This meant that the angel process either transformed itself into a worker process, or itself failed. In the first case, the data node continued to run, but there was no longer any angel to restart it in the event of failure, even with `StopOnError` [1832] set to 0. (Bug #53456)

- **Partitioning**: Trying to use the same column more than once in the partitioning key when partitioning a table by `KEY` caused `mysqld` to crash. Such duplication of key columns is now expressly disallowed, and fails with an appropriate error. (Bug #53354, Bug #57924)

- Data nodes compiled with `gcc` 4.5 or higher crashed during startup. (Bug #57761)

- Queries using `WHERE varchar_pk_column LIKE 'pattern%'` or `WHERE varchar_pk_column LIKE 'pattern_'` against an `NDB` table having a `VARCHAR` column as its primary key failed to return all matching rows. (Bug #56853)

- `ndb_restore` now retries failed transactions when replaying log entries, just as it does when restoring data. (Bug #57618)

- The `SUMA` kernel block has a 10-element ring buffer for storing out-of-order `SUB_GCP_COMPLETE_REP` signals received from the local query handlers when global checkpoints are completed. In some cases, exceeding the ring buffer capacity on all nodes of a node group at the same time caused the node group to fail with an assertion. (Bug #57563)

- During a GCP takeover, it was possible for one of the data nodes not to receive a `SUB_GCP_COMPLETE_REP` signal, with the result that it would report itself as `GCP_COMMITTING` while the other data nodes reported `GCP_PREPARING`. (Bug #57522)

- A GCP stop is detected using 2 parameters which determine the maximum time that a global checkpoint or epoch can go unchanged; one of these controls this timeout for GCPs and one controls the timeout for epochs. Suppose the cluster is configured such that `TimeBetweenEpochsTimeout` [1840] is 100 ms but `HeartbeatIntervalDbDb` [1836] is 1500 ms. A node failure can be signalled after 4 missed heartbeats—in this case, 6000 ms. However, this would exceed `TimeBetweenEpochsTimeout` [1840], causing false detection of a GCP. To prevent this from happening, the configured value for `TimeBetweenEpochsTimeout` [1840] is automatically adjusted, based on the values of `HeartbeatIntervalDbDb` [1836] and `ArbitrationTimeout` [1844].

  The current issue arose when the automatic adjustment routine did not correctly take into consideration the fact that, during cascading node-failures, several intervals of length `4 * (HeartbeatIntervalDBDB + ArbitrationTimeout)` may elapse before all node failures have internally been resolved. This could cause false GCP detection in the event of a cascading node failure. (Bug #57322)

- Specifying a `WHERE` clause of the form *`range1 OR range2`* when selecting from an `NDB` table having a primary key on multiple columns could result in Error 4259 `Invalid set of range scan bounds` if *`range2`* started exactly where *`range1`* ended and the primary key definition declared the columns in a different order relative to the order in the table's column list. (Such a query should simply return all rows in the table, since any expression *`value < constant OR value >= constant`* is always true.)

  Example. Suppose `t` is an `NDB` table defined by the following `CREATE TABLE` statement:

  ```
  CREATE TABLE t (a, b, PRIMARY KEY (b, a)) ENGINE NDB;
  ```

  This issue could then be triggered by a query such as this one:

  ```
  SELECT * FROM t WHERE b < 8 OR b >= 8;
  ```

  In addition, the order of the ranges in the `WHERE` clause was significant; the issue was not triggered, for example, by the query `SELECT * FROM t WHERE b <= 8 OR b > 8`. (Bug #57396)

- A number of cluster log warning messages relating to deprecated configuration parameters contained spelling, formatting, and other errors. (Bug #57381)

- The `MAX_ROWS` option for `CREATE TABLE` was ignored, which meant that it was not possible to enable multi-threaded building of indexes. (Bug #57360)

- Aborting a native `NDB` backup in the `ndb_mgm` client using the `ABORT BACKUP` command did not work correctly when using `ndbmtd`, in some cases leading to a crash of the cluster. (Bug #56285)

- Successive `CREATE NODEGROUP` and `DROP NODEGROUP` commands could cause `mysqld` processes to crash. (Bug #57164)

- **Disk Data**: When performing online DDL on Disk Data tables, scans and moving of the relevant tuples were done in more or less random order. This fix causes these scans to be done in the order of the tuples, which should improve performance of such operations due to the more sequential ordering of the scans. (Bug #57848)

  References: See also Bug #57827.

- **Disk Data**: Adding unique indexes to `NDB` Disk Data tables could take an extremely long time. This was particularly noticeable when using `ndb_restore --rebuild-indexes` [2002]. (Bug #57827)

- **Cluster Replication**: The `OPTION_ALLOW_BATCHING` bitmask had the same value as `OPTION_PROFILING`. This caused conflicts between using `--slave-allow-batching` [1930] and profiling. (Bug #57603)

- **Cluster Replication**: Replication of `SET` and `ENUM` columns represented using more than 1 byte (that is, `SET` columns with more than 8 members and `ENUM` columns with more than 256 constants) between platforms using different endianness failed when using the row-based format. This was because columns of these types are represented internally using integers, but the internal functions used by MySQL to handle them treated them as strings. (Bug #52131)

  References: See also Bug #53528.

- **Cluster API**: An application dropping a table at the same time that another application tried to set up a replication event on the same table could lead to a crash of the data node. The same issue could sometimes cause `NdbEventOperation::execute()` to hang. (Bug #57886)

- **Cluster API**: An NDB API client program under load could abort with an assertion error in `TransporterFacade::remove_from_cond_wait_queue`. (Bug #51775)

  References: See also Bug #32708.

Changes in MySQL Cluster NDB 7.1.8 (5.1.47-ndb-7.1.8) (2010-10-08)

MySQL Cluster NDB 7.1.8 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 7.1.7 and previous MySQL Cluster releases.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see Changes in MySQL 5.1.47 (2010-05-06)).

Functionality Added or Changed

- It is now possible using the `ndb_mgm` management client or the MGM API to force a data node shutdown or restart even if this would force the shutdown or restart of the entire cluster.

  In the management client, this is implemented through the addition of the `-f` (force) option to the `STOP` and `RESTART` commands. For more information, see Commands in the MySQL Cluster Management Client.

  The MGM API also adds two new methods for forcing such a node shutdown or restart; see `ndb_mgm_stop4()`, and `ndb_mgm_restart4()`, for more information about these methods. (Bug #54226)

- `mysqldump` as supplied with MySQL Cluster now has an `--add-drop-trigger` [294] option which adds a `DROP TRIGGER IF EXISTS` statement before each dumped trigger definition. (Bug #55691)

  References: See also Bug #34325, Bug #11747863.

- **Cluster API**: The MGM API function `ndb_mgm_get_version()`, which was previously internal, has now been moved to the public API. This function can be used to get `NDB` storage engine and other version information from the management server. (Bug #51310)

  References: See also Bug #51273.

Bugs Fixed

- At startup, an `ndbd` or `ndbmtd` process creates directories for its file system without checking to see whether they already exist. Portability code added in MySQL Cluster NDB 7.0.18 and MySQL Cluster

NDB 7.1.7 did not account for this fact, printing a spurious error message when a directory to be created already existed. This unneeded printout has been removed. (Bug #57087)

- The text file `cluster_change_hist.txt` containing old MySQL Cluster changelog information was no longer being maintained, and so has been removed from the tree. (Bug #56116)

- Memory pages used for `DataMemory` [1817], once assigned to ordered indexes, were not ever freed, even after any rows that belonged to the corresponding indexes had been deleted. (Bug #56829)

- A data node can be shut down having completed and synchronized a given GCI *x*, while having written a great many log records belonging to the next GCI *x* + 1, as part of normal operations. However, when starting, completing, and synchronizing GCI *x* + 1, then the log records from original start must not be read. To make sure that this does not happen, the REDO log reader finds the last GCI to restore, scans forward from that point, and erases any log records that were not (and should never be) used.

  The current issue occurred because this scan stopped immediately as soon as it encountered an empty page. This was problematic because the REDO log is divided into several files; thus, it could be that there were log records in the beginning of the next file, even if the end of the previous file was empty. These log records were never invalidated; following a start or restart, they could be reused, leading to a corrupt REDO log. (Bug #56961)

- An error in program flow in `ndbd.cpp` could result in data node shutdown routines being called multiple times. (Bug #56890)

- In certain cases, `DROP DATABASE` could sometimes leave behind a cached table object, which caused problems with subsequent DDL operations. (Bug #56840)

- Under certain rare conditions, attempting to start more than one `ndb_mgmd` process simultaneously using the `--reload` [1966] option caused a race condition such that none of the `ndb_mgmd` processes could start. (Bug #56844)

- When distributing `CREATE TABLE` and `DROP TABLE` operations among several SQL nodes attached to a MySQL Cluster. the `LOCK_OPEN` lock normally protecting `mysqld`'s internal table list is released so that other queries or DML statements are not blocked. However, to make sure that other DDL is not executed simultaneously, a global schema lock (implemented as a row-level lock by `NDB`) is used, such that all operations that can modify the state of the `mysqld` internal table list also need to acquire this global schema lock. The `SHOW TABLE STATUS` statement did not acquire this lock. (Bug #56841)

- When multiple SQL nodes were connected to the cluster and one of them stopped in the middle of a DDL operation, the `mysqld` process issuing the DDL timed out with the error `distributing tbl_name timed out. Ignoring`. (Bug #56763)

- MySQL Cluster stores, for each row in each `NDB` table, a Global Checkpoint Index (GCI) which identifies the last committed transaction that modified the row. As such, a GCI can be thought of as a coarse-grained row version.

  Due to changes in the format used by `NDB` to store local checkpoints (LCPs) in MySQL Cluster NDB 6.3.11, it could happen that, following cluster shutdown and subsequent recovery, the GCI values for some rows could be changed unnecessarily; this could possibly, over the course of many node or system restarts (or both), lead to an inconsistent database. (Bug #56770)

- An online `ALTER TABLE ... ADD COLUMN` operation that changed the table schema such that the number of 32-bit words used for the bitmask allocated to each DML operation increased during a transaction in DML which was performed prior to DDL which was followed by either another DML operation or—if using replication—a commit, led to data node failure.

  This was because the data node did not take into account that the bitmask for the before-image was smaller than the current bitmask, which caused the node to crash. (Bug #56524)

References: This bug is a regression of Bug #35208.

- On Windows, a data node refused to start in some cases unless the `ndbd.exe` executable was invoked using an absolute rather than a relative path. (Bug #56257)
- The failure of a data node during some scans could cause other data nodes to fail. (Bug #54945)
- Exhausting the number of available commit-ack markers (controlled by the `MaxNoOfConcurrentTransactions` [1821] parameter) led to a data node crash. (Bug #54944)
- When running a `SELECT` on an `NDB` table with `BLOB` or `TEXT` columns, memory was allocated for the columns but was not freed until the end of the `SELECT`. This could cause problems with excessive memory usage when dumping (using for example `mysqldump`) tables with such columns and having many rows, large column values, or both. (Bug #52313)

  References: See also Bug #56488, Bug #50310.
- **Cluster Replication**: When a `mysqld` process was shut down while it was still performing updates, it was possible for the entry containing binary log information for the final epoch preceding shutdown to be omitted from the `mysql.ndb_binlog_index` table. This could sometimes occur even during a normal shutdown of `mysqld`. (Bug #55909)
- **Cluster Replication**: When an SQL node starts, as part of setting up replication, it subscribes to data events from all data nodes using a `SUB_START_REQ` (subscription start request) signal. Atomicity of `SUB_START_REQ` is implemented such that, if any of the nodes returns an error, a `SUB_STOP_REQ` (subscription stop request) is sent to any nodes that replied with a `SUB_START_CONF` (subscription start confirmation). However, if all data nodes returned an error, `SUB_STOP_REQ` was not sent to any of them. This caused mysqld to hang when restarting (while waiting for a response), and subsequent data node restarts to hang as well. (Bug #56579)
- **Cluster Replication**: The graceful shutdown of a data node in the master cluster could sometimes cause rows to be skipped when writing transactions to the binary log. Testing following an initial fix for this issue revealed an additional case where the graceful shutdown of a data node was not handled properly. The current fix addresses this case. (Bug #55641)

  References: See also Bug #18538.
- **Cluster API**: The MGM API functions `ndb_mgm_stop()` and `ndb_mgm_restart()` set the error code and message without first checking whether the management server handle was `NULL`, which could lead to fatal errors in MGM API applications that depended on these functions. (Bug #57089)
- **Cluster API**: The MGM API function `ndb_mgm_get_version()` did not set the error message before returning with an error. With this fix, it is now possible to call `ndb_mgm_get_latest_error()` after a failed call to this function such that `ndb_mgm_get_latest_error()` returns an error number and error message, as expected of MGM API calls. (Bug #57088)

Changes in MySQL Cluster NDB 7.1.7 (5.1.47-ndb-7.1.7) (2010-09-03)

MySQL Cluster NDB 7.1.7 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 7.1.6 and previous MySQL Cluster releases.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see Changes in MySQL 5.1.47 (2010-05-06)).

Functionality Added or Changed

- **Important Change**: More finely grained control over restart-on-failure behavior is provided with two new data node configuration parameters `MaxStartFailRetries` [1863] and `StartFailRetryDelay` [1863]. `MaxStartFailRetries` [1863] limits the total number of retries made before giving up on starting the data node; `StartFailRetryDelay` [1863] sets the number of seconds between retry attempts.

  These parameters are used only if `StopOnError` [1832] is set to 0.

  For more information, see Defining MySQL Cluster Data Nodes. (Bug #54341)

Bugs Fixed

- **Important Change**: It is no longer possible to make a dump of the `ndbinfo` database using `mysqldump`. (Bug #54316)
- `ndb_restore` always reported 0 for the `GCPStop` (end point of the backup). Now it provides useful binary log position and epoch information. (Bug #56298)
- The `LockExecuteThreadToCPU [1852]` configuration parameter was not handled correctly for CPU ID values greater than 255. (Bug #56185)
- Trying to create a table having a `BLOB` or `TEXT` column with `DEFAULT ''` failed with the error `Illegal null attribute`. (An empty default is permitted and ignored by `MyISAM`; `NDB` should do the same.) (Bug #55121)
- Following a failure of the master data node, the new master sometimes experienced a race condition which caused the node to terminate with a **`GcpStop`** error. (Bug #56044)
- `ndb_mgmd --nodaemon` [1965] logged to the console in addition to the configured log destination. (Bug #54779)
- The warning `MaxNoOfExecutionThreads (#) > LockExecuteThreadToCPU count (#), this could cause contention` could be logged when running `ndbd`, even though the condition described can occur only when using `ndbmtd`. (Bug #54342)
- Startup messages previously written by `ndb_mgmd` to `stdout` are now written to the cluster log instead when `LogDestination` [1810] is set. (Bug #47595)
- The graceful shutdown of a data node could sometimes cause transactions to be aborted unnecessarily. (Bug #18538)

  References: See also Bug #55641.
- **Cluster Replication**: The graceful shutdown of a data node in the master cluster could sometimes cause rows to be skipped when writing transactions to the binary log, leading to an inconsistent slave cluster. (Bug #55641)

  References: See also Bug #18538.
- **Cluster Replication**: Specifying the `--expire_logs_days` [474] option when there were old binary logs to delete caused SQL nodes to crash on startup. (Bug #41751)

Changes in MySQL Cluster NDB 7.1.6 (5.1.47-ndb-7.1.6) (2010-08-16)

MySQL Cluster NDB 7.1.6 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 7.1.5 and previous MySQL Cluster releases.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see Changes in MySQL 5.1.47 (2010-05-06)).

Functionality Added or Changed

- Added the `DictTrace` data node configuration parameter, for use in debugging `NDB` code. For more information, see Defining MySQL Cluster Data Nodes. (Bug #55963)
- Added the `--server-id-bits` option for mysqld and mysqlbinlog.

  For `mysqld`, the `--server-id-bits` [1918] option indicates the number of least significant bits within the 32-bit server ID which actually identify the server. Indicating that the server ID uses less than 32 bits permits the remaining bits to be used for other purposes by NDB API applications using the Event API and `OperationOptions::AnyValue`.

  For `mysqlbinlog`, the `--server-id-bits` [353] option tells `mysqlbinlog` how to interpret the server IDs in the binary log when the binary log was written by a `mysqld` having its `server_id_bits` [1935] set to less than the maximum (32). (Bug #52305)

Bugs Fixed

- **Cluster API**: **Important Change**: The poll and select calls made by the MGM API were not interrupt-safe; that is, a signal caught by the process while waiting for an event on one or more sockets returned error -1 with `errno` set to `EINTR`. This caused problems with MGM API functions such as `ndb_logevent_get_next()` and `ndb_mgm_get_status2()`.

  To fix this problem, the internal `ndb_socket_poller::poll()` function has been made `EINTR`-safe.

  The old version of this function has been retained as `poll_unsafe()`, for use by those parts of NDB that do not need the `EINTR`-safe version of the function. (Bug #55906)
- Starting `ndb_mgmd` with `--config-cache=0` [1963] caused it to leak memory. (Bug #55205)
- When another data node failed, a given data node `DBTC` kernel block could time out while waiting for `DBDIH` to signal commits of pending transactions, leading to a crash. Now in such cases the timeout generates a prinout, and the data node continues to operate. (Bug #55715)
- An excessive number of timeout warnings (normally used only for debugging) were written to the data node logs. (Bug #53987)
- The TCP configuration parameters `HostName1` and `HostName2` were not displayed in the output of `ndb_config --configinfo` [1975]. (Bug #55839)
- It was possible for a `DROP DATABASE` statement to remove `NDB` hidden blob tables without removing the parent tables, with the result that the tables, although hidden to MySQL clients, were still visible in the output of `ndb_show_tables` but could not be dropped using `ndb_drop_table`. (Bug #54788)
- The `configure.js` option `WITHOUT_DYNAMIC_PLUGINS=TRUE` was ignored when building MySQL Cluster for Windows using `CMake`. Among the effects of this issue was that `CMake` attempted to build the `InnoDB` storage engine as a plugin (`.DLL` file) even though the `InnoDB Plugin` is not currently supported by MySQL Cluster. (Bug #54913)
- **Disk Data**: As an optimization when inserting a row to an empty page, the page is not read, but rather simply initialized. However, this optimzation was performed in all cases when an empty row

was inserted, even though it should have been done only if it was the first time that the page had been used by a table or fragment. This is because, if the page had been in use, and then all records had been released from it, the page still needed to be read to learn its log sequence number (LSN).

This caused problems only if the page had been flushed using an incorrect LSN and the data node failed before any local checkpoint was completed—which would remove any need to apply the undo log, hence the incorrect LSN was ignored.

The user-visible result of the incorrect LSN was that it caused the data node to fail during a restart. It was perhaps also possible (although not conclusively proven) that this issue could lead to incorrect data. (Bug #54986)

- **Cluster API**: Calling `NdbTransaction::refresh()` did not update the timer for `TransactionInactiveTimeout` [1841]. (Bug #54724)

Changes in MySQL Cluster NDB 7.1.5 (5.1.47-ndb-7.1.5) (2010-06-25)

MySQL Cluster NDB 7.1.5 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 7.1.4 and previous MySQL Cluster releases.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see Changes in MySQL 5.1.47 (2010-05-06)).

Functionality Added or Changed

- Restrictions on some types of mismatches in column definitions when restoring data using `ndb_restore` have been relaxed. These include the following types of mismatches:
  - Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
  - Different `STORAGE` settings (`MEMORY`, `DISK`)
  - Different default values
  - Different distribution key settings

  Now, when one of these types of mismatches in column definitions is encountered, `ndb_restore` no longer stops with an error; instead, it accepts the data and inserts it into the target table, while issuing a warning to the user.

  For more information, see `ndb_restore` — Restore a MySQL Cluster Backup. (Bug #54423)

  References: See also Bug #53810, Bug #54178, Bug #54242, Bug #54279.

- It is now possible to install management node and data node processes as Windows services. (See Installing MySQL Cluster Processes as Windows Services, for more information.) In addition, data node processes on Windows are now maintained by angel processes, just as they are on other platforms supported by MySQL Cluster.

Bugs Fixed

- The disconnection of all API nodes (including SQL nodes) during an `ALTER TABLE` caused a memory leak. (Bug #54685)

- If a node shutdown (either in isolation or as part of a system shutdown) occurred directly following a local checkpoint, it was possible that this local checkpoint would not be used when restoring the cluster. (Bug #54611)
- When adding multiple new node groups to a MySQL Cluster, it was necessary for each new node group to add only the nodes to be assigned to the new node group, create that node group using `CREATE NODEGROUP`, then repeat this process for each new node group to be added to the cluster. The fix for this issue makes it possible to add all of the new nodes at one time, and then issue several `CREATE NODEGROUP` commands in succession. (Bug #54497)
- The setting for `BuildIndexThreads` [1854] was ignored by `ndbmtd`, which made it impossible to use more than 4 cores for rebuilding indexes. (Bug #54521)
- A table having the maximum number of attributes permitted could not be backed up using the `ndb_mgm` client.

  Note

  The maximum number of attributes supported per table is not the same for all MySQL Cluster releases. See Limits Associated with Database Objects in MySQL Cluster, to determine the maximum that applies in the release which you are using.

  (Bug #54155)
- When performing an online alter table where 2 or more SQL nodes connected to the cluster were generating binary logs, an incorrect message could be sent from the data nodes, causing `mysqld` processes to crash. This problem was often difficult to detect, because restarting SQL node or data node processes could clear the error, and because the crash in `mysqld` did not occur until several minutes after the erroneous message was sent and received. (Bug #54168)
- The two MySQL Server options, `--ndb-wait-connected` [1919] and `--ndb-wait-setup` [1919], did not set the corresponding system variables. (Bug #48402)
- The presence of duplicate `[tcp]` sections in the `config.ini` file caused the management server to crash. Now in such cases, `ndb_mgmd` fails gracefully with an appropriate error message. (Bug #49400)
- **Cluster Replication**: An error in an `NDB` internal byte mask value could lead to corruption of replicated `BIT` column values. (Bug #54005)

  References: See also Bug #53622.
- **Cluster API**: When using the NDB API, it was possible to rename a table with the same name as that of an existing table.

  Note

  This issue did not affect table renames executed using SQL on MySQL servers acting as MySQL Cluster API nodes.

  (Bug #54651)
- **Cluster API**: An excessive number of client connections, such that more than 1024 file descriptors, sockets, or both were open, caused NDB API applications to crash. (Bug #34303)

Changes in MySQL Cluster NDB 7.1.4b (5.1.44-ndb-7.1.4b) (2010-06-18)

This release replaces MySQL Cluster NDB 7.1.4, fixing a critical issue in that version that was discovered shortly after its release (Bug #54242), as well as MySQL Cluster NDB 7.1.4a, which was not actually released due to Bug #54516 being found during testing. Users of MySQL Cluster NDB 7.1.3 or MySQL Cluster NDB 7.1.4 should upgrade to the 7.1.4b release as soon as possible.

Obtaining MySQL Cluster NDB 7.1.4b. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.44 (see Changes in MySQL 5.1.44 (2010-02-04)).

Functionality Added or Changed

- **Important Change**: Commercial binary releases of MySQL Cluster NDB 7.1 now include support for the `InnoDB` storage engine. (Bug #52945)

  References: The patch for the following bug was reverted: Bug #31989.

Bugs Fixed

- **Cluster API**: The value of an internal constant used in the implementation of the `NdbOperation` and `NdbScanOperation` classes caused MySQL Cluster NDB 7.0 NDB API applications compiled against MySQL Cluster NDB 7.0.14 or earlier to fail when run with MySQL Cluster 7.0.15, and MySQL Cluster NDB 7.1 NDB API applications compiled against MySQL Cluster NDB 7.1.3 or earlier to break when used with MySQL Cluster 7.1.4. (Bug #54516)

Changes in MySQL Cluster NDB 7.1.4a (5.1.44-ndb-7.1.4a) (Not released)

This was intended as a replacement release for MySQL Cluster NDB 7.1.4, fixing a critical issue in that version that was discovered shortly after its release (Bug #54242); however, MySQL Cluster NDB 7.1.4a was not actually released due to Bug #54516 being found during testing. Users of MySQL Cluster NDB 7.1.3 or MySQL Cluster NDB 7.1.4 should upgrade to the 7.1.4b release as soon as possible.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.44 (see Changes in MySQL 5.1.44 (2010-02-04)).

Bugs Fixed

- When using `mysqldump` to back up and restore schema information while using `ndb_restore` for restoring only the data, restoring to MySQL Cluster NDB 7.1.4 from an older version failed on tables having columns with default values. This was because versions of MySQL Cluster prior to MySQL Cluster NDB 7.1.4 did not have native support for default values.

  In addition, the MySQL Server supports `TIMESTAMP` columns having dynamic default values, such as `DEFAULT CURRENT_TIMESTAMP`; however, the current implementation of `NDB`-native default values permits only a constant default value.

  To fix this issue, the manner in which `NDB` treats `TIMESTAMP` columns is reverted to its pre-NDB-7.1.4 behavior (obtaining the default value from `mysqld` rather than `NDBCLUSTER`) except where a `TIMESTAMP` column uses a constant default, as in the case of a column declared as `TIMESTAMP DEFAULT 0` or `TIMESTAMP DEFAULT 20100607174832`. (Bug #54242)

Changes in MySQL Cluster NDB 7.1.4 (5.1.44-ndb-7.1.4) (2010-05-31)

MySQL Cluster NDB 7.1.4 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 7.1.3 and previous MySQL Cluster releases.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.44 (see Changes in MySQL 5.1.44 (2010-02-04)).

Functionality Added or Changed

- **Important Change**: The maximum number of attributes (columns plus indexes) per table has increased to 512.
- A `--wait-nodes` option has been added for `ndb_waiter`. When this option is used, the program waits only for the nodes having the listed IDs to reach the desired state. For more information, see `ndb_waiter` — Wait for MySQL Cluster to Reach a Given Status. (Bug #52323)
- As part of this change, new methods relating to default values have been added to the `Column` and `Table` classes in the NDB API. For more information, see `Column::getDefaultValue()`, `Column::setDefaultValue()`, and `Table::hasDefaultValues()`. (Bug #30529)
- Added the `--skip-unknown-objects` [2003] option for `ndb_restore`. This option causes `ndb_restore` to ignore any schema objects which it does not recognize. Currently, this is useful chiefly for restoring native backups made from a cluster running MySQL Cluster NDB 7.0 to a cluster running MySQL Cluster NDB 6.3.
- Added the MySQL Cluster management server option `--config-cache` [1963], which makes it possible to enable and disable configuration caching. This option is turned on by default; to disable configuration caching, start `ndb_mgmd` with `--config-cache=0` [1963], or with `--skip-config-cache`. See `ndb_mgmd` — The MySQL Cluster Management Server Daemon, for more information.

Bugs Fixed

- **Cluster API**: **Incompatible Change**: The default behavior of the NDB API Event API has changed as follows:

  Previously, when creating an `Event`, DDL operations (alter and drop operations on tables) were automatically reported on any event operation that used this event, but as a result of this change, this is no longer the case. Instead, you must now invoke the event's `setReport()` method, with the new `EventReport` value `ER_DDL`, to get this behavior.

  For existing NDB API applications where you wish to retain the old behavior, you must update the code as indicated previously, then recompile, following an upgrade. Otherwise, DDL operations are no longer reported after upgrading `libndbnclient`.

  For more information, see The `Event::EventReport` Type, and `Event::setReport()`. (Bug #53308)
- After creating `NDB` tables until creation of a table failed due to `NDB` error 905 `Out of attribute records (increase MaxNoOfAttributes)`, then increasing `MaxNoOfAttributes` [1828] and restarting all management node and data node processes, attempting to drop and re-create one of the tables failed with the error `Out of table records...`, even when sufficient table records were available. (Bug #53944)

References: See also Bug #52055. This bug is a regression of Bug #44294.

- Creating a Disk Data table, dropping it, then creating an in-memory table and performing a restart, could cause data node processes to fail with errors in the DBTUP kernel block if the new table's internal ID was the same as that of the old Disk Data table. This could occur because undo log handling during the restart did not check that the table having this ID was now in-memory only. (Bug #53935)

- An internal buffer allocator used by NDB has the form `alloc(wanted, minimum)` and attempts to allocate *wanted* pages, but is permitted to allocate a smaller number of pages, between *wanted* and *minimum*. However, this allocator could sometimes allocate fewer than *minimum* pages, causing problems with multi-threaded building of ordered indexes. (Bug #53580)

- A table created while ndb_table_no_logging [1930] was enabled was not always stored to disk, which could lead to a data node crash with `Error opening DIH schema files for table`. (Bug #53934)

- When compiled with support for epoll but this functionality is not available at runtime, MySQL Cluster tries to fall back to use the select() function in its place. However, an extra ndbout_c() call in the transporter registry code caused ndbd to fail instead. (Bug #53482)

- The value set for the ndb_mgmd option --ndb-nodeid [2017] was not verified prior to use as being within the permitted range (1 to 255, inclusive), leading to a crash of the management server. (Bug #53412)

- NDB truncated a column declared as DECIMAL(65,0) to a length of 64. Now such a column is accepted and handled correctly. In cases where the maximum length (65) is exceeded, NDB now raises an error instead of truncating. (Bug #53352)

- When creating an index, NDB failed to check whether the internal ID allocated to the index was within the permissible range, leading to an assertion. This issue could manifest itself as a data node failure with NDB error 707 (`No more table metadata records (increase MaxNoOfTables)`), when creating tables in rapid succession (for example, by a script, or when importing from mysqldump), even with a relatively high value for MaxNoOfTables [1829] and a relatively low number of tables. (Bug #52055)

- When the LogDestination [1810] parameter was set using with a relative path, the management server failed to store its value unless started with --initial [1965] or --reload [1966]. (Bug #52268)

- ndb_restore did not raise any errors if hashmap creation failed during execution. (Bug #51434)

- When an NDB log handler failed, the memory allocated to it was freed twice. (Bug #53200)

- Setting DataMemory [1817] higher than 4G on 32-bit platforms caused ndbd to crash, instead of failing gracefully with an error. (Bug #52536, Bug #50928)

- Specifying the node ID as part of the --ndb-connectstring [1914] option to mysqld was not handled correctly.

  The fix for this issue includes the following changes:

  - Multiple occurrences of any of the mysqld options --ndb-connectstring [1914], --ndb-mgmd-host [1915], and --ndb-nodeid [1916] are now handled in the same way as with other MySQL server options, in that the value set in the last occurrence of the option is the value that is used by mysqld.

    Now, if --ndb-nodeid [1916] is used, its value overrides that of any nodeid setting used in --ndb-connectstring [1914]. For example, starting mysqld with --ndb-connectstring=nodeid=1,10.100.1.100 --ndb-nodeid=3 now produces the same result as starting it with --ndb-connectstring=nodeid=3,10.100.1.100.

- The 1024-character limit on the length of the connectstring is removed, and `--ndb-connectstring` [1914] is now handled in this regard in the same way as other `mysqld` options.
- In the NDB API, a new constructor for `Ndb_cluster_connection` is added which takes as its arguments a connectstring and the node ID to force the API node to use.

(Bug #44299)

- NDB did not distinguish correctly between table names differing only by lettercase when `lower_case_table_names` [492] was set to 0. (Bug #33158)
- `ndb_mgm -e "ALL STATUS"` erroneously reported that data nodes remained in start phase 0 until they had actually started.
- **Replication**: A buffer overrun in the handling of `DATE` column values could cause `mysqlbinlog` to fail when reading logs containing certain combinations of DML statements on a table having a `DATE` column followed by dropping the table. (Bug #52202)
- **Cluster Replication**: Replication failed after a restart of the slave SQL node, due to an error in writing the `master.info` file. (Bug #52859)
- `ALTER TABLE` did not work correctly where the name of the table, the database, or both contained special characters, causing the MySQL server to crash. (Bug #52225)

  References: See also Bug #53409, Bug #14959.
- The performance of MySQL applications using non-persistent client connections was adversely affected due to many of these connections being kept waiting for an excessive length of time in cleanup phase while being closed. (Bug #48832)
- The MySQL client library mishandled `EINPROGRESS` errors for connections in nonblocking mode. This could lead to replication failures on hosts capable of resolving both IPv4 and IPv6 network addresses, when trying to resolve `localhost`. (Bug #37267)

  References: See also Bug #44344.

Changes in MySQL Cluster NDB 7.1.3 (5.1.44-ndb-7.1.3) (2010-04-12, General Availability)

MySQL Cluster NDB 7.1.3 is the first *General Availability* release in the MySQL Cluster NDB 7.1 release series, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 7.1.2-beta and previous MySQL Cluster releases.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.x, MySQL Cluster NDB 7.0, and MySQL Cluster NDB 7.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.44 (see Changes in MySQL 5.1.44 (2010-02-04)).

Functionality Added or Changed

- **Incompatible Change**: The schema for the `memoryusage` table of the `ndbinfo` information database has changed, as detailed in the following list:
  - The `max` column has been renamed to `total`.

- The `used` and `total` (formerly `max`) columns now display values in bytes rather than memory pages.
- Added the columns `used_pages` and `total_pages` to show the amount of a resource used and total amount available in pages.
- The size of the memory pages used for calculating data memory (`used_pages` and `total_pages` columns) is now 32K rather than 16K.

For more information, aee The `ndbinfo memoryusage` Table.

- **Important Change**: The experimental `pools` table has been removed from the `ndbinfo` database. Information useful to MySQL Cluster administration that was contained in this table should be available from other `ndbinfo` tables.
- **Important Note**: MySQL Cluster 7.1 is now supported for production use on Windows platforms.

Important

Some limitations specific to Windows remain; the most important of these are given in the following list:

- There is not yet any Windows installer for MySQL Cluster; you must extract, place, configure, and start the necessary MySQL Cluster executables manually.
- MySQL Cluster processes cannot yet be installed as Windows services. This means that each process executable must be run from a command prompt, and cannot be backgrounded. If you close the command prompt window in which you started the process, the process terminates.
- There is as yet no “angel” process for data nodes; if a data node process quits, it must be restarted manually.
- `ndb_error_reporter` is not yet available on Windows.
- The multi-threaded data node process (`ndbmtd`) is not yet included in the binary distribution. However, it should be built automatically if you build MySQL Cluster from source.

As with MySQL Cluster on other supported platforms, you cannot build MySQL Cluster for Windows from the MySQL Server 5.1 sources; you must use the source code from the MySQL Cluster NDB 7.1 tree.

- **Cluster Replication**: **Replication**: MySQL Cluster Replication now supports attribute promotion and demotion for row-based replication between columns of different but similar types on the master and the slave. For example, it is possible to promote an `INT` column on the master to a `BIGINT` column on the slave, and to demote a `TEXT` column to a `VARCHAR` column.

  The implementation of type demotion distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` [1646] global server system variable.

  For more information about attribute promotion and demotion for row-based replication in MySQL Cluster, see Attribute promotion and demotion (MySQL Cluster). (Bug #47163, Bug #46584)

Bugs Fixed

- **Cluster Replication**: **Important Change**: The `--ndb-log-empty-epochs` [1917] option was ignored. Setting the `ndb_log_empty_epochs` [1935] server system variable also had no effect.

  As part of the fix for this issue, rows for empty epochs are now recorded in the `ndb_binlog_index` table even when `--ndb-log-empty-epochs` [1917] is 0. (Bug #49559, Bug #11757505)

- If a node or cluster failure occurred while `mysqld` was scanning the `ndb.ndb_schema` table (which it does when attempting to connect to the cluster), insufficient error handling could lead to a crash by `mysqld` in certain cases. This could happen in a MySQL Cluster with a great many tables, when trying to restart data nodes while one or more `mysqld` processes were restarting. (Bug #52325)
- In MySQL Cluster NDB 7.0 and later, DDL operations are performed within schema transactions; the NDB kernel code for starting a schema transaction checks that all data nodes are at the same version before permitting a schema transaction to start. However, when a version mismatch was detected, the client was not actually informed of this problem, which caused the client to hang. (Bug #52228)
- After running a mixed series of node and system restarts, a system restart could hang or fail altogether. This was caused by setting the value of the newest completed global checkpoint too low for a data node performing a node restart, which led to the node reporting incorrect GCI intervals for its first local checkpoint. (Bug #52217)
- A `mysqld`, when attempting to access the `ndbinfo` database, crashed if could not contact the management server. (Bug #51067)
- When performing a complex mix of node restarts and system restarts, the node that was elected as master sometimes required optimized node recovery due to missing `REDO` information. When this happened, the node crashed with `Failure to recreate object ... during restart, error 721` (because the `DBDICT` restart code was run twice). Now when this occurs, node takeover is executed immediately, rather than being made to wait until the remaining data nodes have started. (Bug #52135)

  References: See also Bug #48436.
- The internal variable `ndb_new_handler`, which is no longer used, has been removed. (Bug #51858)
- `ha_ndbcluster.cc` was not compiled with the same `SAFEMALLOC` and `SAFE_MUTEX` flags as the MySQL Server. (Bug #51857)
- When debug compiling MySQL Cluster on Windows, the mysys library was not compiled with -DSAFEMALLOC and -DSAFE_MUTEX, due to the fact that my_socket.c was misnamed as my_socket.cc. (Bug #51856)
- Some values shown in the `memoryusage` table did not match corresponding values shown by the `ndb_mgm` client `ALL REPORT MEMORYUSAGE` command. (Bug #51735)
- Restoring a MySQL Cluster backup between platforms having different endianness failed when also restoring metadata and the backup contained a hashmap not already present in the database being restored to. This issue was discovered when trying to restore a backup made on Solaris/SPARC to a MySQL Cluster running on Solaris/x86, but could conceivably occur in other cases where the endianness of the platform on which the backup was taken differed from that of the platform being restored to. (Bug #51432)
- The `mysql` client `system` command did not work properly. This issue was only known to affect the version of the `mysql` client that was included with MySQL Cluster NDB 7.0 and MySQL Cluster NDB 7.1 releases. (Bug #48574)
- The redo log protects itself from being filled up by periodically checking how much space remains free. If insufficient redo log space is available, it sets the state `TAIL_PROBLEM` which results in transactions being aborted with error code 410 (`out of redo log`). However, this state was not set following a node restart, which meant that if a data node had insufficient redo log space following a node restart, it could crash a short time later with `Fatal error due to end of REDO log`. Now, this space is checked during node restarts. (Bug #51723)
- **Cluster API**: **Packaging**: The file `META-INF/services/org.apache.openjpa.lib.conf.ProductDerivation` was missing from the `clusterjpa` JAR file. This could cause setting `openjpa.BrokerFactory` to “`ndb`” to be rejected. (Bug #52106)

References: See also Bug #14192154.

- **Disk Data**: Inserts of blob column values into a MySQL Cluster Disk Data table that exhausted the tablespace resulted in misleading `no such tuple` error messages rather than the expected error `tablespace full`.

  This issue appeared similar to Bug #48113, but had a different underlying cause. (Bug #52201)

- **Disk Data**: DDL operations on Disk Data tables having a relatively small `UNDO_BUFFER_SIZE` could fail unexpectedly.

- **Cluster Replication**: When `mysqld` was started with `--binlog-do-db` [1649] or `--binlog-ignore-db` [1651], no `LOST_EVENTS` incident was written to the binary log. (Bug #47096)

- **Cluster API**: A number of issues were corrected in the NDB API coding examples found in the `storage/ndb/ndbapi-examples` directory in the MySQL Cluster source tree. These included possible endless recursion in `ndbapi_scan.cpp` as well as problems running some of the examples on systems using Windows or Mac OS X due to the lettercase used for some table names. (Bug #30552, Bug #30737)

Changes in MySQL Cluster NDB 7.1.2 (5.1.41-ndb-7.1.2) (2010-03-02)

MySQL Cluster NDB 7.1.2 is a new beta release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 7.1.1 and previous MySQL Cluster releases.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see Changes in MySQL 5.1.41 (2009-11-05)).

Functionality Added or Changed

- **Cluster API**: It is now possible to determine, using the `ndb_desc` utility or the NDB API, which data nodes contain replicas of which partitions. For `ndb_desc`, a new `--extra-node-info` [1982] option is added to cause this information to be included in its output. A new method `Table::getFragmentNodes()` is added to the NDB API for obtaining this information programmatically. (Bug #51184)

- Numeric codes used in management server status update messages in the cluster logs have been replaced with text descriptions. (Bug #49627)

  References: See also Bug #44248.

- A new configuration parameter `HeartbeatThreadPriority` makes it possible to select between a first-in, first-out or round-round scheduling policy for management node and API node heartbeat threads, as well as to set the priority of these threads. See Defining a MySQL Cluster Management Server, or Defining SQL and Other API Nodes in a MySQL Cluster, for more information. (Bug #49617)

- Start phases are now written to the data node logs. (Bug #49158)

- Formerly, the `REPORT` and `DUMP` commands returned output to all `ndb_mgm` clients connected to the same MySQL Cluster. Now, these commands return their output only to the `ndb_mgm` client that actually issued the command. (Bug #40865)

- **Disk Data**: The `ndb_desc` utility can now show the extent space and free extent space for subordinate `BLOB` and `TEXT` columns (stored in hidden `BLOB` tables by NDB). A `--blob-info` [1982] option has been added for this program that causes `ndb_desc` to generate a report for each subordinate `BLOB` table. For more information, see `ndb_desc` — Describe NDB Tables. (Bug #50599)

Bugs Fixed

- **Important Change**: The `DATA_MEMORY` column of the `memoryusage` table was renamed to `memory_type`. (Bug #50926)
- Information about several management client commands was missing from (that is, truncated in) the output of the `HELP` command. (Bug #46114)
- The output of the `ndb_mgm` client `REPORT BACKUPSTATUS` command could sometimes contain errors due to uninitialized data. (Bug #51316)
- The following issues were fixed in the `ndb_mgm` client `REPORT MEMORYUSAGE` command:
  - The client sometimes inserted extra `ndb_mgm>` prompts within the output.
  - For data nodes running `ndbmtd`, `IndexMemory` [1819] was reported before `DataMemory` [1817].
  - In addition, for data nodes running `ndbmtd`, there were multiple `IndexMemory` [1819] entries listed in the output.

  (Bug #50196)
- Issuing a command in the `ndb_mgm` client after it had lost its connection to the management server could cause the client to crash. (Bug #49219)
- A `GROUP BY` query against `NDB` tables sometimes did not use any indexes unless the query included a `FORCE INDEX` option. With this fix, indexes are used by such queries (where otherwise possible) even when `FORCE INDEX` is not specified. (Bug #50736)
- When deciding how to divide the REDO log, the `DBDIH` kernel block saved more than was needed to restore the previous local checkpoint, which could cause REDO log space to be exhausted prematurely (`NDB` error 410). (Bug #51547)
- DML operations can fail with `NDB` error 1220 (`REDO log files overloaded...`) if the opening and closing of REDO log files takes too much time. If this occurred as a GCI marker was being written in the REDO log while REDO log file 0 was being opened or closed, the error could persist until a GCP stop was encountered. This issue could be triggered when there was insufficient REDO log space (for example, with configuration parameter settings `NoOfFragmentLogFiles = 6` and `FragmentLogFileSize = 6M`) with a load including a very high number of updates. (Bug #51512)

  References: See also Bug #20904.
- A `SELECT` requiring a sort could fail with the error `Can't find record in 'table'` when run concurrently with a `DELETE` from the same table. (Bug #45687)
- An attempted online upgrade from a MySQL Cluster NDB 6.3 or 7.0 release to a MySQL Cluster NDB 7.1 release failed, as the first upgraded data node rejected the remaining data nodes as using incompatible versions. (Bug #51429)
- A side effect of the `ndb_restore --disable-indexes` [2002] and `--rebuild-indexes` [2002] options is to change the schema versions of indexes. When a `mysqld` later tried to drop a table that had been restored from backup using one or both of these options, the server failed to detect these changed indexes. This caused the table to be dropped, but the indexes to be left behind, leading to problems with subsequent backup and restore operations. (Bug #51374)

- `ndb_restore` crashed while trying to restore a corrupted backup, due to missing error handling. (Bug #51223)
- Replication of a MySQL Cluster using multi-threaded data nodes could fail with forced shutdown of some data nodes due to the fact that `ndbmtd` exhausted `LongMessageBuffer` [1825] much more quickly than `ndbd`. After this fix, passing of replication data between the `DBTUP` and `SUMA` NDB kernel blocks is done using `DataMemory` [1817] rather than `LongMessageBuffer` [1825].

  Until you can upgrade, you may be able to work around this issue by increasing the `LongMessageBuffer` [1825] setting; doubling the default should be sufficient in most cases. (Bug #46914)
- Setting `IndexMemory` [1819] greater than 2GB could cause data nodes to crash while starting. (Bug #51256)
- The `ndb_restore` message `Successfully created index `PRIMARY`...` was directed to `stderr` instead of `stdout`. (Bug #51037)
- An initial restart of a data node configured with a large amount of memory could fail with a `Pointer too large` error. (Bug #51027)

  References: This bug was introduced by Bug #47818.
- When using `NoOfReplicas` [1815] equal to 1 or 2, if data nodes from one node group were restarted 256 times and applications were running traffic such that it would encounter `NDB` error 1204 (`Temporary failure, distribution changed`), the live node in the node group would crash, causing the cluster to crash as well. The crash occurred only when the error was encountered on the 256th restart; having the error on any previous or subsequent restart did not cause any problems. (Bug #50930)
- `ndbmtd` started on a single-core machine could sometimes fail with a `Job Buffer Full` error when `MaxNoOfExecutionThreads` [1855] was set greater than `LockExecuteThreadToCPU` [1852]. Now a warning is logged when this occurs. (Bug #50582)
- When the `MemReportFrequency` [1849] configuration parameter was set in `config.ini`, the `ndb_mgm` client `REPORT MEMORYUSAGE` command printed its output multiple times. (Bug #37632)
- `ndb_mgm -e "... REPORT ..."` did not write any output to `stdout`.

  The fix for this issue also prevents the cluster log from being flooded with `INFO` messages when `DataMemory` [1817] usage reaches 100%, and insures that when the usage is decreased, an appropriate message is written to the cluster log. (Bug #31542, Bug #44183, Bug #49782)
- **Disk Data**: The error message returned after atttempting to execute `ALTER LOGFILE GROUP` on an nonexistent logfile group did not indicate the reason for the failure. (Bug #51111)
- **Cluster API**: When reading blob data with lock mode `LM_SimpleRead`, the lock was not upgraded as expected. (Bug #51034)
- **Cluster API**: An issue internal to `ndb_mgm` could cause problems when trying to start a large number of data nodes at the same time. (Bug #51273)

  References: See also Bug #51310.

Changes in MySQL Cluster NDB 7.1.1 (5.1.41-ndb-7.1.1) (2010-02-01, beta)

MySQL Cluster NDB 7.1.1 is a new beta release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 7.0 and previous MySQL Cluster releases.

Obtaining MySQL Cluster NDB 7.1. The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest

MySQL Cluster NDB 7.1 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.1 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.1. https://code.launchpad.net/~mysql/mysql-server/mysql-5.1-telco-6.3

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see Changes in MySQL 5.1.41 (2009-11-05)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- The `ndbinfo` database is added to provide MySQL Cluster metadata in real time. The tables making up this database contain information about memory, buffer, and other resource usage, as well as configuration parameters and settings, event counts, and other useful data. Access to `ndbinfo` is done by executing standard SQL queries on its tables using the `mysql` command-line client or other MySQL client application. No special setup procedures are required; `ndbinfo` is created automatically and visible in the output of `SHOW DATABASES` when the MySQL Server is connected to a MySQL Cluster.

  For more information, see The `ndbinfo` MySQL Cluster Information Database.

- **Cluster API**: ClusterJ 1.0 and ClusterJPA 1.0 are now available for programming Java applications with MySQL Cluster. ClusterJ is a Java connector providing an object-relational API for performing high-speed operations such as primary key lookups on a MySQL Cluster database, but does not require the use of the MySQL Server or JDBC (Connector/J). ClusterJ uses a new library NdbJTie which enables direct access from Java to the NDB API and thus to the `NDBCLUSTER` storage engine. ClusterJPA is a new implementation of OpenJPA, and can use either a JDBC connection to a MySQL Cluster SQL node (MySQL Server) or a direct connection to MySQL Cluster using NdbJTie, depending on availability and operational performance.

  ClusterJ, ClusterJPA, and NdbJTie require Java 1.5 or 1.6, and MySQL Cluster NDB 7.0 or later.

  All necessary libraries and other files for ClusterJ, ClusterJPA, and NdbJTie can be found in the MySQL Cluster NDB 7.1.1 or later distribution.

Bugs Fixed

- When a primary key lookup on an `NDB` table containing one or more `BLOB` columns was executed in a transaction, a shared lock on any blob tables used by the `NDB` table was held for the duration of the transaction. (This did not occur for indexed or non-indexed `WHERE` conditions.)

  Now in such cases, the lock is released after all `BLOB` data has been read. (Bug #49190)

Changes in MySQL Cluster NDB 7.1.0 (5.1.39-ndb-7.1.0) (Not released, alpha)

This version was for testing and internal use only, and not officially released.

Functionality Added or Changed

- **Important Change**: The default value of the `DiskIOThreadPool` [1857] data node configuration parameter has changed from 8 to 2.

- **Cluster Replication**: In circular replication, it was sometimes possible for an event to propagate such that it would be reapplied on all servers. This could occur when the originating server was removed from the replication circle and so could no longer act as the terminator of its own events, as normally happens in circular replication.

To prevent this from occurring, a new `IGNORE_SERVER_IDS` option is introduced for the `CHANGE MASTER TO` statement. This option takes a list of replication server IDs; events having a server ID which appears in this list are ignored and not applied. For more information, see `CHANGE MASTER TO` Syntax.

In conjunction with the introduction of `IGNORE_SERVER_IDS`, `SHOW SLAVE STATUS` has two new fields. `Replicate_Ignore_Server_Ids` displays information about ignored servers. `Master_Server_Id` displays the `server_id` [521] value from the master. (Bug #47037)

References: See also Bug #25998, Bug #27808.

Bugs Fixed

- **Cluster API**: **Incompatible Change**: Several NDB API methods were declared as `const`, but did not return an `lvalue`, which caused compiler warnings when using `gcc` 4.3 or newer to perform the build. The methods affected are `NdbEventOperation::tableNameChanged()`, `NdbEventOperation::tableFrmChanged()`, `NdbEventOperation::tableFragmentationChanged()`, `NdbEventOperation::tableRangeListChanged()`, and `NdbOperation::getType()`. (Bug #44840)

- **Important Change**: The `--with-ndb-port-base` option for `configure` has been removed. It is now handled as an unknown and invalid option if you attempt to use it when configuring a build of MySQL Cluster. (Bug #47941)

  References: See also Bug #38502.

- The value set by the `--ndb-cluster-connection-pool` [1912] option was not shown in the output of `SHOW STATUS LIKE 'NDB%'`. (Bug #44118)

- `mysqld` could sometimes crash during a commit while trying to handle NDB Error 4028 `Node failure caused abort of transaction`. (Bug #38577)

- When building a pluggable storage engine on Windows, the engine name could be based on the directory name where the engine was located, rather than the configured storage engine name. (Bug #47795)

- When building storage engines on Windows it was not possible to specify additional libraries within the `CMake` file required for the build. An `${engine}_LIBS` macro has been included in the files to support these additional storage-engine specific libraries. (Bug #47797)

- The `ARCHIVE` storage engine lost records during a bulk insert. (Bug #46961)

- On Mac OS X or Windows, sending a `SIGHUP` signal to the server or an asynchronous flush (triggered by `flush_time` [475]) caused the server to crash. (Bug #47525)

- When using the `ARCHIVE` storage engine, `SHOW TABLE STATUS` displayed incorrect information for `Max_data_length`, `Data_length` and `Avg_row_length`. (Bug #29203)

- Installation of MySQL on Windows would fail to set the correct location for the character set files, which could lead to `mysqld` and `mysql` failing to initialize properly. (Bug #17270)

Changes in MySQL Cluster NDB 7.0

This section contains change history information for MySQL Cluster releases based on version 7.0 of the `NDBCLUSTER` storage engine.

Important

Previously, version 7.0 of `NDBCLUSTER` was known as version 6.4, and early development versions of MySQL Cluster NDB 7.0 were known as “MySQL

> Cluster 6.4". The first four releases in this series were identified using NDB 6.4.x version numbers (NDB 6.4.0 through NDB 6.4.3).
>
> MySQL Cluster NDB 7.0.4 is the fifth release in this series. All future MySQL Cluster NDB 7.0 releases will use NDB 7.0.x version numbers.
>
> Users running MySQL Cluster NDB 6.4.3 should upgrade to MySQL Cluster NDB 7.0.4 (or a later MySQL Cluster NDB 7.0 release).

For an overview of new features added in MySQL Cluster NDB 7.0, see MySQL Cluster Development in MySQL Cluster NDB 7.0.

When upgrading to a MySQL Cluster NDB 7.0 release from earlier MySQL Cluster releases, you should be aware of the following issues:

- To perform an online upgrade to MySQL Cluster NDB 7.0 from a MySQL Cluster NDB 6.3 release, you must upgrade to MySQL Cluster NDB 7.0.6 or later. See Upgrade and downgrade compatibility: MySQL Cluster NDB 7.x, for more information.
- You cannot use a mix of MySQL Cluster NDB 7.0 and earlier binaries, except as part of an online upgrade (where this is supported). You should replace all existing MySQL Cluster executables with the MySQL Cluster NDB 7.0 versions.
- NDB API applications built against previous MySQL Cluster versions (NDB 6.3 and earlier) must be recompiled against against the MySQL Cluster NDB 7.0 sources.

Changes in MySQL Cluster NDB 7.0.36 (5.1.63-ndb-7.0.36) (Not yet released)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in previous MySQL Cluster NDB 7.0 releases.

Obtaining MySQL Cluster NDB 7.0. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.63 (see Changes in MySQL 5.1.63 (2012-05-07)).

> **Note**
>
> Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Version 5.1.63-ndb-7.0.36 has no changelog entries.

Changes in MySQL Cluster NDB 7.0.35 (5.1.63-ndb-7.0.35) (Not yet released)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in previous MySQL Cluster NDB 7.0 releases.

Obtaining MySQL Cluster NDB 7.0. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.63 (see Changes in MySQL 5.1.63 (2012-05-07)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Version 5.1.63-ndb-7.0.35 has no changelog entries.

Changes in MySQL Cluster NDB 7.0.34 (5.1.63-ndb-7.0.34) (Not yet released)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in previous MySQL Cluster NDB 7.0 releases.

Obtaining MySQL Cluster NDB 7.0. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.63 (see Changes in MySQL 5.1.63 (2012-05-07)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- If the Transaction Coordinator aborted a transaction in the “prepared” state, this could cause a resource leak. (Bug #14208924)
- When attempting to connect using a socket with a timeout, it was possible (if the timeout was exceeded) for the socket not to be set back to blocking. (Bug #14107173)
- In some circumstances, transactions could be lost during an online upgrade. (Bug #13834481)
- Attempting to add both a column and an index on that column in the same online `ALTER TABLE` statement caused `mysqld` to fail. Although this issue affected only the `mysqld` shipped with MySQL Cluster, the table named in the `ALTER TABLE` could use any storage engine for which online operations are supported. (Bug #12755722)
- **Cluster API**: When an NDB API application called `NdbScanOperation::nextResult()` again after the previous call had returned end-of-file (return code 1), a transaction object was leaked. Now when this happens, NDB returns error code 4210 (`Ndb sent more info than length specified`); previouslyu in such cases, -1 was returned. In addition, the extra transaction object associated with the scan is freed, by returning it to the transaction coordinator's idle list. (Bug #11748194)

Changes in MySQL Cluster NDB 7.0.33 (5.1.61-ndb-7.0.33) (Not released)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in previous MySQL Cluster NDB 7.0 releases.

Obtaining MySQL Cluster NDB 7.0. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.61 (see Changes in MySQL 5.1.61 (2012-01-10)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- `DUMP 2303` in the `ndb_mgm` client now includes the status of the single fragment scan record reserved for a local checkpoint. (Bug #13986128)
- A shortage of scan fragment records in `DBTC` resulted in a leak of concurrent scan table records and key operation records. (Bug #13966723)
- **Cluster Replication**: DDL statements could sometimes be missed during replication channel cutover, due to the fact that there may not be any epochs following the last applied epoch when the slave is up to date and no new epoch has been finalized on the master. Because epochs are not consecutively numbered, there may be a gap between the last applied epoch and the next epoch; thus it is not possible to determine the number assigned to the next epoch. This meant that, if the new master did not have all epochs, it was possible for those epochs containing only DDL statements to be skipped over.

  The fix for this problem includes modifications to mysqld binary logging code so that the next position in the binary log following the `COMMIT` event at the end of an epoch transaction, as well as the addition of two new columns `next_file` and `next_position` to the `mysql.ndb_binlog_index` table. In addition, a new replication channel cutover mechanism is defined that employs these new columns. To make use of the new cutover mechanism, it is necessary to modify the query used to obtain the start point; in addition, to simplify prevention of possible errors caused by duplication of DDL statements, a new shorthand value `ddl_exist_errors` is implemented for use with the `mysqld` option `--slave-skip-errors` [1641]. It is highly recommended that you use this option and value on the new replication slave when using the modified query.

  For more information, see Implementing Failover with MySQL Cluster Replication.

  Note that the existing replication channel cutover mechanism continues to function as before, including the same limitations described previously. (Bug #11762277, Bug #54854)

Changes in MySQL Cluster NDB 7.0.32 (5.1.61-ndb-7.0.32) (Not released)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in previous MySQL Cluster NDB 7.0 releases.

Obtaining MySQL Cluster NDB 7.0. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.61 (see Changes in MySQL 5.1.61 (2012-01-10)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- **Important Change**: The `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement can be used to create new table partitions after new empty nodes have been added to a MySQL Cluster. Usually, the number of partitions to create is determined automatically, such that, if no new partitions are required, then none are created. This behavior can be overridden by creating the original table using the `MAX_ROWS` option, which indicates that extra partitions should be created to store a large number of rows. However, in this case `ALTER ONLINE TABLE ... REORGANIZE PARTITION` simply uses the `MAX_ROWS` value specified in the original `CREATE TABLE` statement to determine the number of partitions required; since this value remains constant, so does the number of partitions, and so no new ones are created. This means that the table is not rebalanced, and the new data nodes remain empty.

  To solve this problem, support is added for `ALTER ONLINE TABLE ... MAX_ROWS=`*`newvalue`*, where *`newvalue`* is greater than the value used with `MAX_ROWS` in the original `CREATE TABLE` statement. This larger `MAX_ROWS` value implies that more partitions are required; these are allocated on the new data nodes, which restores the balanced distribution of the table data.

  For more information, see `ALTER TABLE` Syntax, and Adding MySQL Cluster Data Nodes Online. (Bug #13714648)

- When the `--skip-config-cache` [1963] and `--initial` [1965] options were used together, `ndb_mgmd` failed to start. (Bug #13857301)

- `ALTER ONLINE TABLE` failed when a `DEFAULT` option was used. (Bug #13830980)

- In some cases, restarting data nodes spent a very long time in Start Phase 101, when API nodes must connect to the starting node (using `NdbEventOperation`), when the API nodes trying to connect failed in a live-lock scenario. This connection process uses a handshake during which a small number of messages are exchanged, with a timeout used to detect failures during the handshake.

  Prior to this fix, this timeout was set such that, if one API node encountered the timeout, all other nodes connecting would do the same. The fix also decreases this timeout. This issue (and the effects of the fix) are most likely to be observed on relatively large configurations having 10 or more data nodes and 200 or more API nodes. (Bug #13825163)

- `ndbmtd` failed to restart when the size of a table definition exceeded 32K.

  (The size of a table definition is dependent upon a number of factors, but in general the 32K limit is encountered when a table has 250 to 300 columns.) (Bug #13824773)

- An initial start using `ndbmtd` could sometimes hang. This was due to a state which occurred when several threads tried to flush a socket buffer to a remote node. In such cases, to minimize flushing of socket buffers, only one thread actually performs the send, on behalf of all threads. However, it was possible in certain cases for there to be data in the socket buffer waiting to be sent with no thread ever being chosen to perform the send. (Bug #13809781)

- When trying to use `ndb_size.pl --hostname=`*`host`*`:`*`port`* to connect to a MySQL server running on a nonstandard port, the *`port`* argument was ignored. (Bug #13364905, Bug #62635)

- **Cluster Replication**: Error handling in conflict detection and resolution has been improved to include errors generated for reasons other than operation execution errors, and to distinguish better between permanent errors and transient errors. Transactions failing due to transient problems are now retried rather than leading to SQL node shutdown as occurred in some cases. (Bug #13428909)

Changes in MySQL Cluster NDB 7.0.31 (5.1.61-ndb-7.0.31) (2012-03-29)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in previous MySQL Cluster NDB 7.0 releases.

Obtaining MySQL Cluster NDB 7.0. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest

MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.61 (see Changes in MySQL 5.1.61 (2012-01-10)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- **Important Change**: A number of changes have been made in the configuration of transporter send buffers.

  1. The data node configuration parameter `ReservedSendBufferMemory` [1861] is now deprecated, and thus subject to removal in a future MySQL Cluster release. `ReservedSendBufferMemory` has been non-functional since it was introduced and remains so.

  2. `TotalSendBufferMemory` now works correctly with data nodes using `ndbmtd`.

  3. `SendBufferMemory` [1870] can now over-allocate into `SharedGlobalMemory` [1856] for `ndbmtd` data nodes (only).

  4. A new data node configuration parameter `ExtraSendBufferMemory` [1861] is introduced. Its purpose is to control how much additional memory can be allocated to the send buffer over and above that specified by `TotalSendBufferMemory` or `SendBufferMemory`. The default setting (0) allows up to 16MB to be allocated automatically.

  (Bug #13633845, Bug #11760629, Bug #53053)

- **Cluster Replication**: **Important Change**: The master limited the number of operations per transaction to 10000 (based on `TimeBetweenEpochs` [1840]). This could result in a larger number of data-modification operations in a single epoch than could be applied at one time, due to the limit imposed on the slave by its (own) setting for `MaxDMLOperationsPerTransaction` [1822].

  The fix for this issue is to allow a replication slave cluster to exceed the configured value of `MaxDMLOperationsPerTransaction` [1822] when necessary, so that it can apply all DML operations received from the master in the same transaction. (Bug #12825405)

- Setting `insert_id` [482] had no effect on the auto-increment counter for `NDB` tables. (Bug #13731134)

- A data node crashed when more than 16G fixed-size memory was allocated by `DBTUP` to one fragment (because the `DBACC` kernel block was not prepared to accept values greater than 32 bits from it, leading to an overflow). Now in such cases, the data node returns Error 889 `Table fragment fixed data reference has reached maximum possible value...`. When this happens, you can work around the problem by increasing the number of partitions used by the table (such as by using the `MAXROWS` option with `CREATE TABLE`). (Bug #13637411)

  References: See also Bug #11747870, Bug #34348.

- Several instances in the NDB code affecting the operation of multi-threaded data nodes, where `SendBufferMemory` was associated with a specific thread for an unnecessarily long time, have been identified and fixed, by minimizing the time that any of these buffers can be held exclusively by a given thread (send buffer memory being critical to operation of the entire node). (Bug #13618181)

- A very large value for `BackupWriteSize` [1851], as compared to `BackupMaxWriteSize` [1852], `BackupDataBufferSize` [1850], or `BackupLogBufferSize` [1850], could cause a local checkpoint or backup to hang. (Bug #13613344)

- Queries using `LIKE ... ESCAPE` on `NDB` tables failed when pushed down to the data nodes. Such queries are no longer pushed down, regardless of the value of `engine_condition_pushdown` [473]. (Bug #13604447, Bug #61064)

- To avoid TCP transporter overload, an overload flag is kept in the NDB kernel for each data node; this flag is used to abort key requests if needed, yielding error 1218 `Send Buffers overloaded in NDB kernel` in such cases. Scans can also put significant pressure on transporters, especially where scans with a high degree of parallelism are executed in a configuration with relatively small send buffers. However, in these cases, overload flags were not checked, which could lead to node failures due to send buffer exhaustion. Now, overload flags are checked by scans, and in cases where returning sufficient rows to match the batch size (`--ndb-batch-size` [1912] server option) would cause an overload, the number of rows is limited to what can be accommodated by the send buffer.

  See also Configuring MySQL Cluster Send Buffer Parameters. (Bug #13602508)

- A node failure and recovery while performing a scan on more than 32 partitions led to additional node failures during node takeover. (Bug #13528976)

- The `--skip-config-cache` [1963] option now causes `ndb_mgmd` to skip checking for the configuration directory, and thus to skip creating it in the event that it does not exist. (Bug #13428853)

- **Cluster Replication**: Conflict detection and resolution for statements updating a given table could be employed only on the same server where the table was created. When an `NDB` table is created by executing DDL on an SQL node, the binary log setup portion of the processing for the `CREATE TABLE` statement reads the table's conflict detection function from the ndb_replication table and sets up that function for the table. However, when the created table was discovered by other SQL nodes attached to the same MySQL Cluster due to schema distribution, the conflict detection function was not correctly set up. The same problem occurred when an `NDB` table was discovered as a result of selecting a database for the first time (such as when executing a `USE` statement), and when a table was discovered as a result of scanning all files at server startup.

  Both of these issues were due to a dependency of the conflict detection and resolution code on table objects, even in cases where checking for such objects might not be appropriate. With this fix, conflict detection and resolution for any `NDB` table works whether the table was created on the same SQL node, or on a different one. (Bug #13578660)

Changes in MySQL Cluster NDB 7.0.30 (5.1.56-ndb-7.0.30) (2012-02-08)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in previous MySQL Cluster NDB 7.0 releases.

Obtaining MySQL Cluster NDB 7.0. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.56 (see Changes in MySQL 5.1.56 (2011-03-01)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- At the beginning of a local checkpoint, each data node marks its local tables with a “to be checkpointed” flag. A failure of the master node during this process could cause either the LCP to hang, or one or more data nodes to be forcibly shut down. (Bug #13436481)

- A node failure while a `ANALYZE TABLE` statement was executing resulted in a hung connection (and the user was not informed of any error that would cause this to happen). (Bug #13416603)

  References: See also Bug #13407848.

- **Cluster Replication**: Under certain circumstances, the `Rows` count in the output of `SHOW TABLE STATUS` for a replicated slave `NDB` table could be misreported as many times larger than the result of `SELECT COUNT(*)` on the same table. (Bug #13440282)

Changes in MySQL Cluster NDB 7.0.29 (5.1.56-ndb-7.0.29) (2011-12-15)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in previous MySQL Cluster NDB 7.0 releases.

Obtaining MySQL Cluster NDB 7.0. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.56 (see Changes in MySQL 5.1.56 (2011-03-01)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- Added the `MinFreePct` [1820] data node configuration parameter, which specifies a percentage of data node resources to hold in reserve for restarts. The resources monitored are `DataMemory` [1817], `IndexMemory` [1819], and any per-table `MAX_ROWS` settings (see `CREATE TABLE` Syntax). The default value of `MinFreePct` [1820] is 5, which means that 5% from each these resources is now set aside for restarts. (Bug #13436216)

- Because the log event buffer used internally by data nodes was circular, periodic events such as statistics events caused it to be overwritten too quickly. Now the buffer is partitioned by log event category, and its default size has been increased from 4K to 8K. (Bug #13394771)

- The `BatchSize` [1866] and `BatchByteSize` [1866] configuration parameters, used to control the maximum sizes of result batches, are defined as integers. However, the values used to store these were incorrectly interpreted as numbers of bytes in the NDB kernel. This caused the `DBLQH` kernel block to fail to detect when the specified `BatchByteSize` [1866] was consumed. (Bug #13355055)

- Previously, forcing simultaneously the shutdown of multiple data nodes using `SHUTDOWN -F` in the `ndb_mgm` management client could cause the entire cluster to fail. Now in such cases, any such nodes are forced to abort immediately. (Bug #12928429)

- `SELECT` statements using `LIKE CONCAT(...)` [951] `OR LIKE CONCAT(...)` in the `WHERE` clause returned incorrect results when run against `NDB` tables. (Bug #11765142, Bug #58073)

- **Cluster Replication**: With many SQL nodes, all writing binary logs, connected to a MySQL Cluster, `RENAME TABLE` could cause data node processes (`ndbmtd`) to fail. (Bug #13447705)

- **Cluster Replication**: It was possible for `PURGE MASTER LOGS` and `SHOW BINARY LOGS` to deadlock when run concurrently. (Bug #13400021)

Changes in MySQL Cluster NDB 7.0.28 (5.1.56-ndb-7.0.28) (2011-11-23)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in previous MySQL Cluster NDB 7.0 releases.

Obtaining MySQL Cluster NDB 7.0. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.56 (see Changes in MySQL 5.1.56 (2011-03-01)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- Introduced the `CrashOnCorruptedTuple` [1833] data node configuration parameter. When enabled, this parameter causes data nodes to handle corrupted tuples in a fail-fast manner—in other words, whenever the data node detects a corrupted tuple, it forcibly shuts down if `CrashOnCorruptedTuple` [1833] is enabled. For backward compatibility, this parameter is disabled by default. (Bug #12598636)

Bugs Fixed

- When a failure of multiple data nodes during a local checkpoint (LCP) that took a long time to complete included the node designated as master, any new data nodes attempting to start before all ongoing LCPs were completed later crashed. This was due to the fact that node takeover by the new master cannot be completed until there are no pending local checkpoints. Long-running LCPs such as those which triggered this issue can occur when fragment sizes are sufficiently large (see MySQL Cluster Nodes, Node Groups, Replicas, and Partitions, for more information). Now in such cases, data nodes (other than the new master) are kept from restarting until the takeover is complete. (Bug #13323589)

- When deleting from multiple tables using a unique key in the `WHERE` condition, the wrong rows were deleted. In addition, `UPDATE` triggers failed when rows were changed by deleting from or updating multiple tables. (Bug #12718336, Bug #61705, Bug #12728221)

- A **`SubscriberNodeIdUndefined`** error was previously unhandled, resulting in a data node crash, but is now handled by NDB Error 1429, `Subscriber node undefined in SubStartReq`. (Bug #12598496)

- Shutting down a `mysqld` while under load caused the spurious error messages `Opening ndb_binlog_index: killed` and `Unable to lock table ndb_binlog_index` to be written in the cluster log. (Bug #11930428)

- **Cluster Replication**: The `mysqlbinlog --database` [350] option generated table mapping errors when used with `NDB` tables, unless the binary log was generated using `--log-bin-use-v1-row-events=0` [1648]. (Bug #13067813)

- **Cluster Replication**: Replication of `NDB` tables having more columns on the slave than on the master did not always work correctly when any of the extra columns were `NOT NULL`, did not have a default value, or both. (Bug #11755904, Bug #47742)

Changes in MySQL Cluster NDB 7.0.27 (5.1.56-ndb-7.0.27) (Not released)

This release incorporates new features in the NDBCLUSTER storage engine and fixes recently discovered bugs in previous MySQL Cluster NDB 7.0 releases.

Obtaining MySQL Cluster NDB 7.0. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.56 (see Changes in MySQL 5.1.56 (2011-03-01)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Cluster Replication**: **Important Change**: Due to the existing layout of binary log row events, it was not possible to extend them with extra information which could be safely ignored by old slaves. New versions of the WRITE_ROW, UPDATE_ROW, and DELETE_ROW events have been implemented; these are referred to as “Version 2” binary log events, and are intended for future enhancements such as improved conflict detection and resolution. The TABLE_MAP event is not affected.

  Version 2 binary log row events are not backward compatible, and cannot be read by older slaves. A new mysqld option --log-bin-use-v1-row-events [1648] can be used to force writing of Version 1 row events into the binary log. This can be used during upgrades to make a newer mysqld generate Version 1 binary log row events that can be read by older slaves.

- It is now possible to filter the output from ndb_config so that it displays only system, data node, or connection parameters and values, using one of the options --system [1974], --nodes [1974], or --connections [1974], respectively. In addition, it is now possible to specify from which data node the configuration data is obtained, using the --config_from_node [1972] option that is added in this release.

  For more information, see ndb_config — Extract MySQL Cluster Configuration Information. (Bug #11766870)

Bugs Fixed

- **Cluster API**: **Incompatible Change**: Restarting a machine hosting data nodes, SQL nodes, or both, caused such nodes when restarting to time out while trying to obtain node IDs.

  As part of the fix for this issue, the behavior and default values for the NDB API Ndb_cluster_connection::connect() method have been improved. Due to these changes, the version number for the included NDB client library (libndbclient.so) has been increased from 4.0.0 to 5.0.0. For NDB API applications, this means that as part of any upgrade, you must do both of the following:

  - Review and possibly modify any NDB API code that uses the connect() method, in order to take into account its changed default retry handling.
  - Recompile any NDB API applications using the new version of the client library.

  Also in connection with this issue, the default value for each of the two mysqld options --ndb-wait-connected [1919] and --ndb-wait-setup [1919] has been increased to 30 seconds

(from 0 and 15, respectively). In addition, a hard-coded 30-second delay was removed, so that the value of `--ndb-wait-connected` [1919] is now handled correctly in all cases. (Bug #12543299)

- Setting `IndexMemory` [1819] or sometimes `DataMemory` [1817] to 2 GB or higher could lead to data node failures under some conditions. (Bug #12873640)
- When replicating DML statements with `IGNORE` between clusters, the number of operations that failed due to nonexistent keys was expected to be no greater than the number of defined operations of any single type. Because the slave SQL thread defines operations of multiple types in batches together, code which relied on this assumption could cause `mysqld` to fail. (Bug #12859831)
- The maximum effective value for the `OverloadLimit` [1869] configuration parameter was limited by the value of `SendBufferMemory` [1870]. Now the value set for `OverloadLimit` [1869] is used correctly, up to this parameter's stated maximum (4G). (Bug #12712109)
- `AUTO_INCREMENT` values were not set correctly for `INSERT IGNORE` statements affecting `NDB` tables. This could lead such statements to fail with `Got error 4350 'Transaction already aborted' from NDBCLUSTER` when inserting multiple rows containing duplicate values. (Bug #11755237, Bug #46985)
- When failure handling of an API node takes longer than 300 seconds, extra debug information is included in the resulting output. In cases where the API node's node ID was greater than 48, these extra debug messages could lead to a crash, and confuing output otherwise. This was due to an attempt to provide information specific to data nodes for API nodes as well. (Bug #62208)
- In rare cases, a series of node restarts and crashes during restarts could lead to errors while reading the redo log. (Bug #62206)
- **Cluster Replication**: A transaction that updated many (thousands of) rows executed properly on the master but failed on the slave with the error `Lock wait timeout exceeded...`. (Bug #12974714)

Changes in MySQL Cluster NDB 7.0.26 (5.1.56-ndb-7.0.26) (2011-07-04)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in previous MySQL Cluster NDB 7.0 releases.

Obtaining MySQL Cluster NDB 7.0. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.56 (see Changes in MySQL 5.1.56 (2011-03-01)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- Added the `MaxDMLOperationsPerTransaction` [1822] data node configuration parameter, which can be used to limit the number of DML operations used by a transaction; if the transaction requires more than this many DML operations, the transaction is aborted. (Bug #12589613)

Bugs Fixed

- When global checkpoint indexes were written with no intervening end-of-file or megabyte border markers, this could sometimes lead to a situation in which the end of the redo log was mistakenly

regarded as being between these GCIs, so that if the restart of a data node took place before the start of the next redo log was overwritten, the node encountered an `Error while reading the REDO log`. (Bug #12653993, Bug #61500)

References: See also Bug #56961.

- Restarting a `mysqld` during a rolling upgrade with data nodes running a mix of old and new versions of the MySQL Cluster software caused the `mysqld` to run in read-only mode. (Bug #12651364, Bug #61498)
- Error reporting has been improved for cases in which API nodes are unable to connect due to apparent unavailability of node IDs. (Bug #12598398)
- Error messages for `Failed to convert connection` transporter registration problems were inspecific. (Bug #12589691)
- Under certain rare circumstances, a data node process could fail with Signal 11 during a restart. This was due to uninitialized variables in the `QMGR` kernel block. (Bug #12586190)
- Multiple management servers were unable to detect one another until all nodes had fully started. As part of the fix for this issue, two new status values `RESUME` and `CONNECTED` can be reported for management nodes in the output of the `ndb_mgm` client `SHOW` command (see Commands in the MySQL Cluster Management Client). Two corresponding status values `NDB_MGM_NODE_STATUS_RESUME` and `NDB_MGM_NODE_STATUS_CONNECTED` are also added to the list of possible values for an `ndb_mgm_node_status` data structure in the MGM API. (Bug #12352191, Bug #48301)
- Handling of the `MaxNoOfTables` [1829] and `MaxNoOfAttributes` [1828] configuration parameters was not consistent in all parts of the `NDB` kernel, and were only strictly enforced by the `DBDICT` and `SUMA` kernel blocks. This could lead to problems when tables could be created but not replicated. Now these parameters are treated by `SUMA` and `DBDICT` as suggested maximums rather than hard limits, as they are elsewhere in the `NDB` kernel. (Bug #61684)
- It was not possible to shut down a management node while one or more data nodes were stopped (for whatever reason). This issue was a regression introduced in MySQL Cluster NDB 7.0.24 and MySQL Cluster NDB 7.1.13. (Bug #61607)

  References: See also Bug #61147.
- **Cluster API**: Applications that included the header file `ndb_logevent.h` could not be built using the Microsoft Visual Studio C compiler or the Oracle (Sun) Studio C compiler due to empty struct definitions. (Bug #12678971)
- **Cluster API**: Within a transaction, after creating, executing, and closing a scan, calling `NdbTransaction::refresh()` after creating and executing but not closing a second scan caused the application to crash. (Bug #12646659)

Changes in MySQL Cluster NDB 7.0.25 (5.1.56-ndb-7.0.25) (2011-05-24)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in previous MySQL Cluster NDB 7.0 releases.

Obtaining MySQL Cluster NDB 7.0. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.56 (see Changes in MySQL 5.1.56 (2011-03-01)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- The internal `Ndb_getinaddr()` function has been rewritten to use `getaddrinfo()` instead of `my_gethostbyname_r()` (which is removed in a later version of the MySQL Server). (Bug #12542120)
- Two unused test files in `storage/ndb/test/sql` contained incorrect versions of the GNU Lesser General Public License. The files and the directory containing them have been removed. (Bug #11810156)

  References: See also Bug #11810224.
- Error 1302 gave the wrong error message (`Out of backup record`). This has been corrected to `A backup is already running`. (Bug #11793592)
- When using two management servers, issuing in an `ndb_mgm` client connected to one management server a `STOP` command for stopping the other management server caused Error 2002 (`Stop failed ... Send to process or receive failed.: Permanent error: Application error`), even though the `STOP` command actually succeeded, and the second `ndb_mgmd` was shut down. (Bug #61147)
- Renaming a table having `BLOB` or `TEXT` columns (or both) to another database caused the SQL node to crash, and the table to become inaccessible afterwards. (Bug #60484)
- Under heavy loads with many concurrent inserts, temporary failures in transactions could occur (and were misreported as being due to `NDB` Error 899 `Rowid already allocated`). As part of the fix for this issue, `NDB` Error 899 has been reclassified as an internal error, rather than as a temporary transaction error. (Bug #56051, Bug #11763354)
- In `ndbmtd`, a node connection event is detected by a `CMVMI` thread which sends a `CONNECT_REP` signal to the `QMGR` kernel block. In a few isolated circumstances, a signal might be transferred to `QMGR` directly by the `NDB` transporter before the `CONNECT_REP` signal actually arrived. This resulted in reports in the error log with status `Temporary error, restart node`, and the message `Internal program error`. (Bug #61025)
- **Disk Data**: Accounting for `MaxNoOfOpenFiles` was incorrect with regard to to data files in MySQL Cluster Disk Data tablespaces. This could lead to a crash when `MaxNoOfOpenFiles` was exceeded. (Bug #12581213)
- **Cluster Replication**: Operations that updated unique keys of `NDB` tables could cause duplicate key errors when trying to execute the binary log. (Previously, row events in the binary log were ordered according to the partitioning of the base table, which could differ in order within the epoch for that in which they were executed.

  To keep this from happening, unique keys are now updated in deferred mode, meaning that all table rows are updated before any unique indexes are checked. Thus, the order of the row updates is no longer important.

  You should be aware that deferring constraint checking in this way is currently supported only by `NDB`, and thus only for replication between NDB tables on both the master and the slave. You cannot replicate updates of unique keys successfully when replicating from `NDB` to a different storage engine such as `MyISAM` or `InnoDB`. (Bug #47952, Bug #11756082)

Changes in MySQL Cluster NDB 7.0.24 (5.1.56-ndb-7.0.24) (2011-04-26)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in previous MySQL Cluster NDB 7.0 releases.

Obtaining MySQL Cluster NDB 7.0. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.56 (see Changes in MySQL 5.1.56 (2011-03-01)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- It is now possible to add data nodes online to a running MySQL Cluster without performing a rolling restart of the cluster or starting data node processes with the `--nowait-nodes` [1955] option. This can be done by setting `Nodegroup = 65536` [1815] in the `config.ini` file for any data nodes that should be started at a later time, when first starting the cluster. (It was possible to set `NodeGroup` [1815] to this value previously, but the management server failed to start.)

  As part of this fix, a new data node configuration parameter `StartNoNodeGroupTimeout` [1836] has been added. When the management server sees that there are data nodes with no node group (that is, nodes for which `Nodegroup = 65536` [1815]), it waits `StartNoNodeGroupTimeout` [1836] milliseconds before treating these nodes as though they were listed with the `--nowait-nodes` [1955] option, and proceeds to start.

  For more information, see Adding MySQL Cluster Data Nodes Online. (Bug #11766167, Bug #59213)

- A `config_generation` column has been added to the `nodes` table of the `ndbinfo` database. By checking this column, it is now possible to determine which version or versions of the MySQL Cluster configuration file are in effect on the data nodes. This information can be especially useful when performing a rolling restart of the cluster to update its configuration.

Bugs Fixed

- **Cluster API**: A unique index operation is executed in two steps: a lookup on an index table, and an operation on the base table. When the operation on the base table failed, while being executed in a batch with other operations that succeeded, this could lead to a hanging execute, eventually timing out with Error 4012 (`Request ndbd time-out, maybe due to high load or communication problems`). (Bug #12315582)

- A memory leak in `LGMAN`, that leaked 8 bytes of log buffer memory per 32k written, was introduced in MySQL Cluster NDB 7.0.9, effecting all MySQL Cluster NDB 7.1 releases as well as MySQL Cluster NDB 7.0.9 and later MySQL Cluster NDB 7.0 releases. (For example, when 128MB log buffer memory was used, it was exhausted after writing 512GB to the undo log.) This led to a GCP stop and data node failure. (Bug #60946)

  References: This bug was introduced by Bug #47966.

- When using `ndbmtd`, a MySQL Cluster configured with 32 data nodes failed to start correctly. (Bug #60943)

- When performing a TUP scan with locks in parallel, and with a highly concurrent load of inserts and deletions, the scan could sometimes fail to notice that a record had moved while waiting to acquire a lock on it, and so read the wrong record. During node recovery, this could lead to a crash of a node that was copying data to the node being started, and a possible forced shutdown of the cluster.

- **Cluster API**: Performing interpreted operations using a unique index did not work correctly, because the interpret bit was kept when sending the lookup to the index table.

Changes in MySQL Cluster NDB 7.0.23 (5.1.51-ndb-7.0.23) (2011-04-04)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in previous MySQL Cluster NDB 7.0 releases.

Obtaining MySQL Cluster NDB 7.0. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.51 (see Changes in MySQL 5.1.51 (2010-09-10)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- Improved scaling of ordered index scans performance by removing a hard-coded limit (`MAX_PARALLEL_INDEX_SCANS_PER_FRAG`) and making the number of `TUP` or `TUX` scans per fragment configurable by adding the `MaxParallelScansPerFragment` [1825] data node configuration parameter. (Bug #11769048)

Bugs Fixed

- **Important Change**: Formerly, the `--ndb-cluster-connection-pool` server option set a status variable as well as a system variable. The status variable has been removed as redundant. (Bug #60119)
- A scan with a pushed condition (filter) using the `CommittedRead` lock mode could hang for a short interval when it was aborted when just as it had decided to send a batch. (Bug #11932525)
- When aborting a multi-read range scan exactly as it was changing ranges in the local query handler, LQH could fail to detect it, leaving the scan hanging. (Bug #11929643)
- Schema distribution did not take place for tables converted from another storage engine to `NDB` using `ALTER TABLE`; this meant that such tables were not always visible to all SQL nodes attached to the cluster. (Bug #11894966)
- A GCI value inserted by `ndb_restore --restore_epoch` [1996] into the `ndb_apply_status` table was actually 1 less than the correct value. (Bug #11885852)
- **Replication**: Error 1590 (`ER_SLAVE_INCIDENT` [3994]) caused the slave to stop even when it was started with `--slave-skip-errors=1590` [1641]. (Bug #59889, Bug #11768580, Bug #11799671)
- **Disk Data**: Limits imposed by the size of `SharedGlobalMemory` [1856] were not always enforced consistently with regard to Disk Data undo buffers and log files. This could sometimes cause a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement to fail for no apparent reason, or cause the log file group specified by `InitialLogFileGroup` [1859] not to be created when starting the cluster. (Bug #57317)
- **Cluster Replication**: Filtering the binary log using `--binlog-ignore-db=mysql` [1651] caused epochs not to be logged as expected in the `ndb_apply_status` table. (Bug #11765707, Bug #58698)

- The optimizer sometimes requested ordered access from a storage engine when ordered access was not required. (Bug #57601, Bug #11764737)

Changes in MySQL Cluster NDB 7.0.22 (5.1.51-ndb-7.0.22) (2011-02-25)

This release incorporates new features in the NDBCLUSTER storage engine and fixes recently discovered bugs in previous MySQL Cluster NDB 7.0 releases.

Obtaining MySQL Cluster NDB 7.0. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.51 (see Changes in MySQL 5.1.51 (2010-09-10)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Disk Data**: The INFORMATION_SCHEMA.TABLES table now provides disk usage as well as memory usage information for Disk Data tables. Also, INFORMATION_SCHEMA.PARTITIONS, formerly did not show any statistics for NDB tables. Now the TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH, MAX_DATA_LENGTH, and DATA_FREE columns contain correct information for the table's partitions.

- A new --rewrite-database [2003] option is added for ndb_restore, which makes it possible to restore to a database having a different name from that of the database in the backup.

  For more information, see ndb_restore — Restore a MySQL Cluster Backup. (Bug #54327)

- The NDB kernel now implements a number of statistical counters relating to actions performed by or affecting Ndb objects, such as starting, closing, or aborting transactions; primary key and unique key operations; table, range, and pruned scans; blocked threads waiting for various operations to complete; and data and events sent and received by NDBCLUSTER. These NDB API counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes. mysqld exposes these counters as system status variables; their values can be read in the output of SHOW STATUS, or by querying the SESSION_STATUS or GLOBAL_STATUS table in the INFORMATION_SCHEMA database. By comparing the values of these status variables prior to and following the execution of SQL statements that act on NDB tables, you can observe the corresponding actions taken on the NDB API level, which can be beneficial for monitoring and performance tuning of MySQL Cluster.

  For more information, see NDB API Statistics Counters and Variables, as well as MySQL Cluster Status Variables.

Bugs Fixed

- **Important Note**: Due to an error in merging the original fix, it did not appear MySQL Cluster NDB 7.0.21; this oversight has been corrected in the current release. (Bug #58256)

- This issue affects all previous MySQL Cluster NDB 7.0 releases. (Bug #60045)

- ndb_restore --rebuild-indexes [2002] caused multi-threaded index building to occur on the master node only. (Bug #59920)

- Successive queries on the counters table from the same SQL node returned unchanging results. To fix this issue, and to prevent similar issues from occurring in the future, ndbinfo tables are now excluded from the query cache. (Bug #59831)

- When attempting to create a table on a MySQL Cluster with many standby data nodes (setting `Nodegroup=65536` [1815] in `config.ini` for the nodes that should wait, starting the nodes that should start immediately with the `--nowait-nodes` [1955] option, and using the `CREATE TABLE` statement's `MAX_ROWS` option), `mysqld` miscalculated the number of fragments to use. This caused the `CREATE TABLE` to fail.

  Note

  The `CREATE TABLE` failure caused by this issue in turn prevented any further attempts to create the table, even if the table structure was simplified or changed in such a way that the attempt should have succeeded. This "ghosting" issue is handled in Bug #59756.

  (Bug #59751)

- When a `CREATE TABLE` statement failed due to `NDB` error 1224 (`Too many fragments`), it was not possible to create the table afterward unless either it had no ordered indexes, or a `DROP TABLE` statement was issued first, even if the subsequent `CREATE TABLE` was valid and should otherwise have succeeded. (Bug #59756)

  References: See also Bug #59751.

- `NDB` sometimes treated a simple (not unique) ordered index as unique. (Bug #59519)

- The logic used in determining whether to collapse a range to a simple equality was faulty. In certain cases, this could cause `NDB` to treat a range as if it were a primary key lookup when determining the query plan to be used. Although this did not affect the actual result returned by the query, it could in such cases result in inefficient execution of queries due to the use of an inappropriate query plan. (Bug #59517)

- When a query used multiple references to or instances of the same physical tables, `NDB` failed to recognize these multiple instances as different tables; in such a case, `NDB` could incorrectly use condition pushdown on a condition referring to these other instances to be pushed to the data nodes, even though the condition should have been rejected as unpushable, leading to invalid results. (Bug #58791)

- **Cluster API**: When calling `NdbEventOperation::execute()` during a node restart, it was possible to get a spurious error 711 (`System busy with node restart, schema operations not allowed when a node is starting`). (Bug #59723)

- **Cluster API**: When an NDBAPI client application was waiting for more scan results after calling `NdbScanOperation::nextResult()`, the calling thread sometimes woke up even if no new batches for any fragment had arrived, which was unnecessary, and which could have a negative impact on the application's performance. (Bug #52298)

- An `OUTER JOIN` query using `WHERE col_name IS NULL` could return an incorrect result. (Bug #58490, Bug #11765513)

- For a query that used a subquery that included `GROUP BY` inside a `< ANY()` construct, no rows were returned when there should have been. (Bug #56690, Bug #11763918)

- The "greedy" query plan optimizer failed to consider the size of intermediate query results when calculating the cost of a query. This could result in slowly executing queries when there are much faster execution plans available. (Bug #59326, Bug #11766256)

Changes in MySQL Cluster NDB 7.0.21 (5.1.51-ndb-7.0.21) (2011-01-26)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in previous MySQL Cluster NDB 7.0 releases.

Obtaining MySQL Cluster NDB 7.0. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest

MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.51 (see Changes in MySQL 5.1.51 (2010-09-10)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Important Change**: The following changes have been made with regard to the `TimeBetweenEpochsTimeout` [1840] data node configuration parameter:

  - The maximum possible value for this parameter has been increased from 32000 milliseconds to 256000 milliseconds.
  - Setting this parameter to zero now has the effect of disabling GCP stops caused by save timeouts, commit timeouts, or both.
  - The current value of this parameter and a warning are written to the cluster log whenever a GCP save takes longer than 1 minute or a GCP commit takes longer than 10 seconds.

  For more information, see Disk Data and `GCP Stop` errors. (Bug #58383)

- Added the `--skip-broken-objects` [2003] option for `ndb_restore`. This option causes `ndb_restore` to ignore tables corrupted due to missing blob parts tables, and to continue reading from the backup file and restoring the remaining tables. (Bug #54613)

  References: See also Bug #51652.

- **Cluster Replication**: Added the `--ndb-log-apply-status` [1915] server option, which causes a replication slave to apply updates to the master's `mysql.ndb_apply_status` table to its own `ndb_apply_status` table using its own server ID in place of the master's server ID. This option can be useful in circular or chain replication setups when you need to track updates to `ndb_apply_status` as they propagate from one MySQL Cluster to the next in the circle or chain.

- **Cluster API**: It is now possible to stop or restart a node even while other nodes are starting, using the MGM API `ndb_mgm_stop4()` or `ndb_mgm_restart4()` function, respectively, with the *`force`* parameter set to 1. (Bug #58451)

  References: See also Bug #58319.

Bugs Fixed

- **Cluster API**: In some circumstances, very large `BLOB` read and write operations in MySQL Cluster applications can cause excessive resource usage and even exhaustion of memory. To fix this issue and to provide increased stability when performing such operations, it is now possible to set limits on the volume of `BLOB` data to be read or written within a given transaction in such a way that when these limits are exceeded, the current transaction implicitly executes any accumulated operations. This avoids an excessive buildup of pending data which can result in resource exhaustion in the NDB kernel. The limits on the amount of data to be read and on the amount of data to be written before this execution takes place can be configured separately. (In other words, it is now possible in MySQL Cluster to specify read batching and write batching that is specific to `BLOB` data.) These limits can be configured either on the NDB API level, or in the MySQL Server.

  On the NDB API level, four new methods are added to the `NdbTransaction` object. `getMaxPendingBlobReadBytes()` and `setMaxPendingBlobReadBytes()` can be

used to get and to set, respectively, the maximum amount of `BLOB` data to be read that accumulates before this implicit execution is triggered. `getMaxPendingBlobWriteBytes()` and `setMaxPendingBlobWriteBytes()` can be used to get and to set, respectively, the maximum volume of `BLOB` data to be written that accumulates before implicit execution occurs.

For the MySQL server, two new options are added. The `--ndb-blob-read-batch-bytes` [1913] option sets a limit on the amount of pending `BLOB` data to be read before triggering implicit execution, and the `--ndb-blob-write-batch-bytes` [1913] option controls the amount of pending `BLOB` data to be written. These limits can also be set using the `mysqld` configuration file, or read and set within the `mysql` client and other MySQL client applications using the corresponding server system variables. (Bug #59113)

- Two related problems could occur with read-committed scans made in parallel with transactions combining multiple (concurrent) operations:

  1. When committing a multiple-operation transaction that contained concurrent insert and update operations on the same record, the commit arrived first for the insert and then for the update. If a read-committed scan arrived between these operations, it could thus read incorrect data; in addition, if the scan read variable-size data, it could cause the data node to fail.

  2. When rolling back a multiple-operation transaction having concurrent delete and insert operations on the same record, the abort arrived first for the delete operation, and then for the insert. If a read-committed scan arrived between the delete and the insert, it could incorrectly assume that the record should not be returned (in other words, the scan treated the insert as though it had not yet been committed).

  (Bug #59496)

- On Windows platforms, issuing a `SHUTDOWN` command in the `ndb_mgm` client caused management processes that had been started with the `--nodaemon` [1965] option to exit abnormally. (Bug #59437)

- When executing a full table scan caused by a `WHERE` condition using *`unique_key`* `IS NULL` in combination with a join, `NDB` failed to close the scan. (Bug #58750)

  References: See also Bug #57481.

- A row insert or update followed by a delete operation on the same row within the same transaction could in some cases lead to a buffer overflow. (Bug #59242)

  References: See also Bug #56524. This bug was introduced by Bug #35208.

- Data nodes configured with very large amounts (multiple gigabytes) of `DiskPageBufferMemory` [1856] failed during startup with NDB error 2334 (`Job buffer congestion`). (Bug #58945)

  References: See also Bug #47984.

- The `FAIL_REP` signal, used inside the NDB kernel to declare that a node has failed, now includes the node ID of the node that detected the failure. This information can be useful in debugging. (Bug #58904)

- When handling failures of multiple data nodes, an error in the construction of internal signals could cause the cluster's remaining nodes to crash. This issue was most likely to affect clusters with large numbers of data nodes. (Bug #58240)

- Data nodes no longer allocated all memory prior to being ready to exchange heartbeat and other messages with management nodes, as in NDB 6.3 and earlier versions of MySQL Cluster. This caused problems when data nodes configured with large amounts of memory failed to show as connected or showed as being in the wrong start phase in the `ndb_mgm` client even after making their initial connections to and fetching their configuration data from the management server. With

this fix, data nodes now allocate all memory as they did in earlier MySQL Cluster versions. (Bug #57568)

- Trying to drop an index while it was being used to perform scan updates caused data nodes to crash. (Bug #58277, Bug #57057)
- The number of rows affected by a statement that used a `WHERE` clause having an `IN` [942] condition with a value list containing a great many elements, and that deleted or updated enough rows such that `NDB` processed them in batches, was not computed or reported correctly. (Bug #58040)
- Issuing `EXPLAIN EXTENDED` for a query that would use condition pushdown could cause `mysqld` to crash. (Bug #58553, Bug #11765570)
- MySQL Cluster failed to compile correctly on FreeBSD 8.1 due to misplaced `#include` statements. (Bug #58034)
- In some circumstances, an SQL trigger on an `NDB` table could read stale data. (Bug #58538)
- A query having multiple predicates joined by `OR` in the `WHERE` clause and which used the `sort_union` access method (as shown using `EXPLAIN`) could return duplicate rows. (Bug #58280)
- During a node takeover, it was possible in some circumstances for one of the remaining nodes to send an extra transaction confirmation (`LQH_TRANSCONF`) signal to the `DBTC` kernel block, conceivably leading to a crash of the data node trying to take over as the new transaction coordinator. (Bug #58453)
- Some queries of the form `SELECT ... WHERE column IN (subquery)` against an `NDB` table could cause `mysqld` to hang in an endless loop. (Bug #58163)
- In some circumstances, it was possible for `mysqld` to begin a new multi-range read scan without having closed a previous one. This could lead to exhaustion of all scan operation objects, transaction objects, or lock objects (or some combination of these) in `NDB`, causing queries to fail with such errors as `Lock wait timeout exceeded` or `Connect failure - out of connection objects`. (Bug #57481)

  References: See also Bug #58750.
- Queries using `column IS` [`NOT`] `NULL` on a table with a unique index created with `USING HASH` on `column` always returned an empty result. (Bug #57032)
- The functions `strncasecmp` and `strcasecmp` were declared in `ndb_global.h` but never defined or used. The declarations have been removed. (Bug #58204)
- With `engine_condition_pushdown` [473] enabled, a query using `LIKE` on an `ENUM` column of an `NDB` table failed to return any results. This issue is resolved by disabling `engine_condition_pushdown` [473] when performing such queries. (Bug #53360)
- A query using `BETWEEN` as part of a pushed-down `WHERE` condition could cause mysqld to hang or crash. (Bug #57735)
- When a slash character (`/`) was used as part of the name of an index on an `NDB` table, attempting to execute a `TRUNCATE TABLE` statement on the table failed with the error `Index not found`, and the table was rendered unusable. (Bug #38914)
- **Disk Data**: **Partitioning**: When using multi-threaded data nodes, an `NDB` table created with a very large value for the `MAX_ROWS` option could—if this table was dropped and a new table with fewer partitions, but having the same table ID, was created—cause `ndbmtd` to crash when performing a system restart. This was because the server attempted to examine each partition whether or not it actually existed.

  This issue is the same as that reported in Bug #45154, except that the current issue is specific to `ndbmtd` instead of `ndbd`. (Bug #58638)

- **Disk Data**: In certain cases, a race condition could occur when `DROP LOGFILE GROUP` removed the logfile group while a read or write of one of the effected files was in progress, which in turn could lead to a crash of the data node. (Bug #59502)

- **Disk Data**: A race condition could sometimes be created when `DROP TABLESPACE` was run concurrently with a local checkpoint; this could in turn lead to a crash of the data node. (Bug #59501)

- **Disk Data**: Performing what should have been an online drop of a multi-column index was actually performed offline. (Bug #55618)

- **Disk Data**: When at least one data node was not running, queries against the `INFORMATION_SCHEMA.FILES` table took an excessive length of time to complete because the MySQL server waited for responses from any stopped nodes to time out. Now, in such cases, MySQL does not attempt to contact nodes which are not known to be running. (Bug #54199)

- **Cluster Replication**: When a `mysqld` performing replication of a MySQL Cluster that uses `ndbmtd` is forcibly disconnected (thus causing an `API_FAIL_REQ` signal to be sent), the `SUMA` kernel block iterates through all active subscriptions and disables them. If a given subscription has no more active users, then this subscription is also deactivated in the `DBTUP` kernel block.

  This process had no flow control, and when there were many subscriptions being deactivated (more than 512), this could cause an overflow in the short-time queue defined in the `DbtupProxy` class.

  The fix for this problem includes implementing proper flow control for this deactivation process and increasing the size of the short-time queue in `DbtupProxy`. (Bug #58693)

- **Cluster API**: It was not possible to obtain the status of nodes accurately after an attempt to stop a data node using `ndb_mgm_stop()` failed without returning an error. (Bug #58319)

- **Cluster API**: Attempting to read the same value (using `getValue()`) more than 9000 times within the same transaction caused the transaction to hang when executed. Now when more reads are performed in this way than can be accommodated in a single transaction, the call to `execute()` fails with a suitable error. (Bug #58110)

- A `NOT IN` predicate with a subquery containing a `HAVING` clause could retrieve too many rows, when the subquery itself returned `NULL`. (Bug #58818, Bug #11765815)

- Outer joins on a unique key could return incorrect results. (Bug #57034, Bug #11764219)

- `WHERE` conditions of the following forms were evaluated incorrectly and could return incorrect results:

  ```
  WHERE null-valued-const-expression NOT IN (subquery)
  WHERE null-valued-const-expression IN (subquery) IS UNKNOWN
  ```

  (Bug #58628, Bug #11765642)

- Condition pushdown optimization could push down conditions with incorrect column references. (Bug #58134, Bug #11765196)

- Outer joins with an empty table could produce incorrect results. (Bug #58422, Bug #11765451)

- `WHERE` conditions of the following form were evaluated incorrectly and could return incorrect results:

  ```
  WHERE column IN (subquery) IS UNKNOWN
  ```

  (Bug #58626)

Changes in MySQL Cluster NDB 7.0.20a (5.1.51-ndb-7.0.20a) (2010-11-18)

MySQL Cluster NDB 7.0.20a is a new release of MySQL Cluster which fixes a critical upgrade issue discovered in MySQL Cluster NDB 7.0.20 shortly after it was released. It is otherwise identical to MySQL Cluster NDB 7.0.20.

Obtaining MySQL Cluster NDB 7.0. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.51 (see Changes in MySQL 5.1.51 (2010-09-10)).

Bugs Fixed

- **Important Note**: Issuing an `ALL DUMP` command during a rolling upgrade to MySQL Cluster NDB 7.0.20 caused the cluster to crash. (Bug #58256)

Changes in MySQL Cluster NDB 7.0.20 (5.1.51-ndb-7.0.20) (2010-11-08)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.19.

Important

A critical upgrade issue was discovered in MySQL Cluster NDB 7.0.20 shortly after release, causing it to be withdrawn and replaced with MySQL Cluster NDB 7.0.20a, which contains a fix for this issue. MySQL Cluster NDB 7.0.20a is otherwise identical to MySQL Cluster 7.0.20.

See Changes in MySQL Cluster NDB 7.0.20a (5.1.51-ndb-7.0.20a) (2010-11-18), for more information.

Obtaining MySQL Cluster NDB 7.0. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.51 (see Changes in MySQL 5.1.51 (2010-09-10)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Important Change**: `ndbd` now bypasses use of Non-Uniform Memory Access support on Linux hosts by default. If your system supports NUMA, you can enable it and override `ndbd` use of interleaving by setting the `Numa` [1854] data node configuration parameter which is added in this release. See Defining Data Nodes: Realtime Performance Parameters, for more information. (Bug #57807)

- **Important Change**: The `Id` configuration parameter used with MySQL Cluster management, data, and API nodes (including SQL nodes) is now deprecated, and the `NodeId` parameter (long available as a synonym for `Id` when configuring these types of nodes) should be used instead. `Id` continues to be supported for reasons of backward compatibility, but now generates a warning when used with these types of nodes, and is subject to removal in a future release of MySQL Cluster.

  This change affects the name of the configuration parameter only, establishing a clear preference for `NodeId` over `Id` in the `[mgmd]`, `[ndbd]`, `[mysql]`, and `[api]` sections of the MySQL Cluster

global configuration (`config.ini`) file. The behavior of unique identifiers for management, data, and SQL and API nodes in MySQL Cluster has not otherwise been altered.

The `Id` parameter as used in the `[computer]` section of the MySQL Cluster global configuration file is not affected by this change.

Bugs Fixed

- **Packaging**: MySQL Cluster RPM distributions did not include a `shared-compat` RPM for the MySQL Server, which meant that MySQL applications depending on `libmysqlclient.so.15` (MySQL 5.0 and earlier) no longer worked. (Bug #38596)
- On Windows, the angel process which monitors and (when necessary) restarts the data node process failed to spawn a new worker in some circumstances where the arguments vector contained extra items placed at its beginning. This could occur when the path to `ndbd.exe` or `ndbmtd.exe` contained one or more spaces. (Bug #57949)
- The disconnection of an API or management node due to missed heartbeats led to a race condition which could cause data nodes to crash. (Bug #57946)
- The method for calculating table schema versions used by schema transactions did not follow the established rules for recording schemas used in the `P0.SchemaLog` file. (Bug #57897)

  References: See also Bug #57896.
- The `LQHKEYREQ` request message used by the local query handler when checking the major schema version of a table, being only 16 bits wide, could cause this check to fail with an `Invalid schema version` error (`NDB` error code 1227). This issue occurred after creating and dropping (and re-creating) the same table 65537 times, then trying to insert rows into the table. (Bug #57896)

  References: See also Bug #57897.
- Transient errors during a local checkpoint were not retried, leading to a crash of the data node. Now when such errors occur, they are retried up to 10 times if necessary. (Bug #57650)
- When a data node angel process failed to fork off a new worker process (to replace one that had failed), the failure was not handled. This meant that the angel process either transformed itself into a worker process, or itself failed. In the first case, the data node continued to run, but there was no longer any angel to restart it in the event of failure, even with `StopOnError` [1832] set to 0. (Bug #53456)
- **Partitioning**: Trying to use the same column more than once in the partitioning key when partitioning a table by `KEY` caused `mysqld` to crash. Such duplication of key columns is now expressly disallowed, and fails with an appropriate error. (Bug #53354, Bug #57924)
- Data nodes compiled with `gcc` 4.5 or higher crashed during startup. (Bug #57761)
- Queries using `WHERE varchar_pk_column LIKE 'pattern%'` or `WHERE varchar_pk_column LIKE 'pattern_'` against an `NDB` table having a `VARCHAR` column as its primary key failed to return all matching rows. (Bug #56853)
- `ndb_restore` now retries failed transactions when replaying log entries, just as it does when restoring data. (Bug #57618)
- The `SUMA` kernel block has a 10-element ring buffer for storing out-of-order `SUB_GCP_COMPLETE_REP` signals received from the local query handlers when global checkpoints are completed. In some cases, exceeding the ring buffer capacity on all nodes of a node group at the same time caused the node group to fail with an assertion. (Bug #57563)
- During a GCP takeover, it was possible for one of the data nodes not to receive a `SUB_GCP_COMPLETE_REP` signal, with the result that it would report itself as `GCP_COMMITTING` while the other data nodes reported `GCP_PREPARING`. (Bug #57522)

- A GCP stop is detected using 2 parameters which determine the maximum time that a global checkpoint or epoch can go unchanged; one of these controls this timeout for GCPs and one controls the timeout for epochs. Suppose the cluster is configured such that `TimeBetweenEpochsTimeout` [1840] is 100 ms but `HeartbeatIntervalDbDb` [1836] is 1500 ms. A node failure can be signalled after 4 missed heartbeats—in this case, 6000 ms. However, this would exceed `TimeBetweenEpochsTimeout` [1840], causing false detection of a GCP. To prevent this from happening, the configured value for `TimeBetweenEpochsTimeout` [1840] is automatically adjusted, based on the values of `HeartbeatIntervalDbDb` [1836] and `ArbitrationTimeout` [1844].

  The current issue arose when the automatic adjustment routine did not correctly take into consideration the fact that, during cascading node-failures, several intervals of length `4 * (HeartbeatIntervalDBDB + ArbitrationTimeout)` may elapse before all node failures have internally been resolved. This could cause false GCP detection in the event of a cascading node failure. (Bug #57322)

- Specifying a `WHERE` clause of the form *`range1 OR range2`* when selecting from an `NDB` table having a primary key on multiple columns could result in Error 4259 `Invalid set of range scan bounds` if *`range2`* started exactly where *`range1`* ended and the primary key definition declared the columns in a different order relative to the order in the table's column list. (Such a query should simply return all rows in the table, since any expression *`value < constant OR value >= constant`* is always true.)

  Example. Suppose `t` is an `NDB` table defined by the following `CREATE TABLE` statement:

  ```
  CREATE TABLE t (a, b, PRIMARY KEY (b, a)) ENGINE NDB;
  ```

  This issue could then be triggered by a query such as this one:

  ```
  SELECT * FROM t WHERE b < 8 OR b >= 8;
  ```

  In addition, the order of the ranges in the `WHERE` clause was significant; the issue was not triggered, for example, by the query `SELECT * FROM t WHERE b <= 8 OR b > 8`. (Bug #57396)

- A number of cluster log warning messages relating to deprecated configuration parameters contained spelling, formatting, and other errors. (Bug #57381)

- The `MAX_ROWS` option for `CREATE TABLE` was ignored, which meant that it was not possible to enable multi-threaded building of indexes. (Bug #57360)

- Aborting a native `NDB` backup in the `ndb_mgm` client using the `ABORT BACKUP` command did not work correctly when using `ndbmtd`, in some cases leading to a crash of the cluster. (Bug #56285)

- Successive `CREATE NODEGROUP` and `DROP NODEGROUP` commands could cause `mysqld` processes to crash. (Bug #57164)

- **Disk Data**: When performing online DDL on Disk Data tables, scans and moving of the relevant tuples were done in more or less random order. This fix causes these scans to be done in the order of the tuples, which should improve performance of such operations due to the more sequential ordering of the scans. (Bug #57848)

  References: See also Bug #57827.

- **Disk Data**: Adding unique indexes to `NDB` Disk Data tables could take an extremely long time. This was particularly noticeable when using `ndb_restore --rebuild-indexes` [2002]. (Bug #57827)

- **Cluster Replication**: The `OPTION_ALLOW_BATCHING` bitmask had the same value as `OPTION_PROFILING`. This caused conflicts between using `--slave-allow-batching` [1930] and profiling. (Bug #57603)

- **Cluster Replication**: Replication of `SET` and `ENUM` columns represented using more than 1 byte (that is, `SET` columns with more than 8 members and `ENUM` columns with more than 256 constants) between platforms using different endianness failed when using the row-based format. This was because columns of these types are represented internally using integers, but the internal functions used by MySQL to handle them treated them as strings. (Bug #52131)

  References: See also Bug #53528.

- **Cluster API**: An application dropping a table at the same time that another application tried to set up a replication event on the same table could lead to a crash of the data node. The same issue could sometimes cause `NdbEventOperation::execute()` to hang. (Bug #57886)

- **Cluster API**: An NDB API client program under load could abort with an assertion error in `TransporterFacade::remove_from_cond_wait_queue`. (Bug #51775)

  References: See also Bug #32708.

Changes in MySQL Cluster NDB 7.0.19 (5.1.47-ndb-7.0.19) (2010-10-08)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.18.

Obtaining MySQL Cluster NDB 7.0. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see Changes in MySQL 5.1.47 (2010-05-06)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- It is now possible using the `ndb_mgm` management client or the MGM API to force a data node shutdown or restart even if this would force the shutdown or restart of the entire cluster.

  In the management client, this is implemented through the addition of the `-f` (force) option to the `STOP` and `RESTART` commands. For more information, see Commands in the MySQL Cluster Management Client.

  The MGM API also adds two new methods for forcing such a node shutdown or restart; see `ndb_mgm_stop4()`, and `ndb_mgm_restart4()`, for more information about these methods. (Bug #54226)

- `mysqldump` as supplied with MySQL Cluster now has an `--add-drop-trigger` [294] option which adds a `DROP TRIGGER IF EXISTS` statement before each dumped trigger definition. (Bug #55691)

  References: See also Bug #34325, Bug #11747863.

- **Cluster API**: The MGM API function `ndb_mgm_get_version()`, which was previously internal, has now been moved to the public API. This function can be used to get `NDB` storage engine and other version information from the management server. (Bug #51310)

  References: See also Bug #51273.

Bugs Fixed

- At startup, an `ndbd` or `ndbmtd` process creates directories for its file system without checking to see whether they already exist. Portability code added in MySQL Cluster NDB 7.0.18 and MySQL Cluster NDB 7.1.7 did not account for this fact, printing a spurious error message when a directory to be created already existed. This unneeded printout has been removed. (Bug #57087)

- The text file `cluster_change_hist.txt` containing old MySQL Cluster changelog information was no longer being maintained, and so has been removed from the tree. (Bug #56116)

- Memory pages used for `DataMemory` [1817], once assigned to ordered indexes, were not ever freed, even after any rows that belonged to the corresponding indexes had been deleted. (Bug #56829)

- A data node can be shut down having completed and synchronized a given GCI *`x`*, while having written a great many log records belonging to the next GCI *`x`* + 1, as part of normal operations. However, when starting, completing, and synchronizing GCI *`x`* + 1, then the log records from original start must not be read. To make sure that this does not happen, the REDO log reader finds the last GCI to restore, scans forward from that point, and erases any log records that were not (and should never be) used.

  The current issue occurred because this scan stopped immediately as soon as it encountered an empty page. This was problematic because the REDO log is divided into several files; thus, it could be that there were log records in the beginning of the next file, even if the end of the previous file was empty. These log records were never invalidated; following a start or restart, they could be reused, leading to a corrupt REDO log. (Bug #56961)

- An error in program flow in `ndbd.cpp` could result in data node shutdown routines being called multiple times. (Bug #56890)

- In certain cases, `DROP DATABASE` could sometimes leave behind a cached table object, which caused problems with subsequent DDL operations. (Bug #56840)

- Under certain rare conditions, attempting to start more than one `ndb_mgmd` process simultaneously using the `--reload` [1966] option caused a race condition such that none of the `ndb_mgmd` processes could start. (Bug #56844)

- When distributing `CREATE TABLE` and `DROP TABLE` operations among several SQL nodes attached to a MySQL Cluster. the `LOCK_OPEN` lock normally protecting `mysqld`'s internal table list is released so that other queries or DML statements are not blocked. However, to make sure that other DDL is not executed simultaneously, a global schema lock (implemented as a row-level lock by `NDB`) is used, such that all operations that can modify the state of the `mysqld` internal table list also need to acquire this global schema lock. The `SHOW TABLE STATUS` statement did not acquire this lock. (Bug #56841)

- When multiple SQL nodes were connected to the cluster and one of them stopped in the middle of a DDL operation, the `mysqld` process issuing the DDL timed out with the error `distributing` *`tbl_name`* `timed out. Ignoring`. (Bug #56763)

- MySQL Cluster stores, for each row in each `NDB` table, a Global Checkpoint Index (GCI) which identifies the last committed transaction that modified the row. As such, a GCI can be thought of as a coarse-grained row version.

  Due to changes in the format used by `NDB` to store local checkpoints (LCPs) in MySQL Cluster NDB 6.3.11, it could happen that, following cluster shutdown and subsequent recovery, the GCI values for some rows could be changed unnecessarily; this could possibly, over the course of many node or system restarts (or both), lead to an inconsistent database. (Bug #56770)

- An online `ALTER TABLE ... ADD COLUMN` operation that changed the table schema such that the number of 32-bit words used for the bitmask allocated to each DML operation increased during a transaction in DML which was performed prior to DDL which was followed by either another DML operation or—if using replication—a commit, led to data node failure.

This was because the data node did not take into account that the bitmask for the before-image was smaller than the current bitmask, which caused the node to crash. (Bug #56524)

References: This bug is a regression of Bug #35208.

- On Windows, a data node refused to start in some cases unless the `ndbd.exe` executable was invoked using an absolute rather than a relative path. (Bug #56257)
- The failure of a data node during some scans could cause other data nodes to fail. (Bug #54945)
- Exhausting the number of available commit-ack markers (controlled by the `MaxNoOfConcurrentTransactions` [1821] parameter) led to a data node crash. (Bug #54944)
- When running a `SELECT` on an `NDB` table with `BLOB` or `TEXT` columns, memory was allocated for the columns but was not freed until the end of the `SELECT`. This could cause problems with excessive memory usage when dumping (using for example `mysqldump`) tables with such columns and having many rows, large column values, or both. (Bug #52313)

  References: See also Bug #56488, Bug #50310.

- **Cluster Replication**: When a `mysqld` process was shut down while it was still performing updates, it was possible for the entry containing binary log information for the final epoch preceding shutdown to be omitted from the `mysql.ndb_binlog_index` table. This could sometimes occur even during a normal shutdown of `mysqld`. (Bug #55909)
- **Cluster Replication**: When an SQL node starts, as part of setting up replication, it subscribes to data events from all data nodes using a `SUB_START_REQ` (subscription start request) signal. Atomicity of `SUB_START_REQ` is implemented such that, if any of the nodes returns an error, a `SUB_STOP_REQ` (subscription stop request) is sent to any nodes that replied with a `SUB_START_CONF` (subscription start confirmation). However, if all data nodes returned an error, `SUB_STOP_REQ` was not sent to any of them. This caused mysqld to hang when restarting (while waiting for a response), and subsequent data node restarts to hang as well. (Bug #56579)
- **Cluster Replication**: The graceful shutdown of a data node in the master cluster could sometimes cause rows to be skipped when writing transactions to the binary log. Testing following an initial fix for this issue revealed an additional case where the graceful shutdown of a data node was not handled properly. The current fix addresses this case. (Bug #55641)

  References: See also Bug #18538.

- **Cluster API**: The MGM API functions `ndb_mgm_stop()` and `ndb_mgm_restart()` set the error code and message without first checking whether the management server handle was `NULL`, which could lead to fatal errors in MGM API applications that depended on these functions. (Bug #57089)
- **Cluster API**: The MGM API function `ndb_mgm_get_version()` did not set the error message before returning with an error. With this fix, it is now possible to call `ndb_mgm_get_latest_error()` after a failed call to this function such that `ndb_mgm_get_latest_error()` returns an error number and error message, as expected of MGM API calls. (Bug #57088)

Changes in MySQL Cluster NDB 7.0.18 (5.1.47-ndb-7.0.18) (2010-09-03)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.17.

Obtaining MySQL Cluster NDB 7.0. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see Changes in MySQL 5.1.47 (2010-05-06)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Important Change**: More finely grained control over restart-on-failure behavior is provided with two new data node configuration parameters `MaxStartFailRetries` [1863] and `StartFailRetryDelay` [1863]. `MaxStartFailRetries` [1863] limits the total number of retries made before giving up on starting the data node; `StartFailRetryDelay` [1863] sets the number of seconds between retry attempts.

  These parameters are used only if `StopOnError` [1832] is set to 0.

  For more information, see Defining MySQL Cluster Data Nodes. (Bug #54341)

Bugs Fixed

- `ndb_restore` always reported 0 for the `GCPStop` (end point of the backup). Now it provides useful binary log position and epoch information. (Bug #56298)
- The `LockExecuteThreadToCPU [1852]` configuration parameter was not handled correctly for CPU ID values greater than 255. (Bug #56185)
- Trying to create a table having a `BLOB` or `TEXT` column with `DEFAULT ''` failed with the error `Illegal null attribute`. (An empty default is permitted and ignored by `MyISAM`; `NDB` should do the same.) (Bug #55121)
- Following a failure of the master data node, the new master sometimes experienced a race condition which caused the node to terminate with a **`GcpStop`** error. (Bug #56044)
- `ndb_mgmd --nodaemon` [1965] logged to the console in addition to the configured log destination. (Bug #54779)
- The warning `MaxNoOfExecutionThreads (#) > LockExecuteThreadToCPU count (#), this could cause contention` could be logged when running `ndbd`, even though the condition described can occur only when using `ndbmtd`. (Bug #54342)
- Startup messages previously written by `ndb_mgmd` to `stdout` are now written to the cluster log instead when `LogDestination` [1810] is set. (Bug #47595)
- The graceful shutdown of a data node could sometimes cause transactions to be aborted unnecessarily. (Bug #18538)

  References: See also Bug #55641.
- **Cluster Replication**: The graceful shutdown of a data node in the master cluster could sometimes cause rows to be skipped when writing transactions to the binary log, leading to an inconsistent slave cluster. (Bug #55641)

  References: See also Bug #18538.
- **Cluster Replication**: Specifying the `--expire_logs_days` [474] option when there were old binary logs to delete caused SQL nodes to crash on startup. (Bug #41751)

Changes in MySQL Cluster NDB 7.0.17 (5.1.47-ndb-7.0.17) (2010-08-16)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.16.

Obtaining MySQL Cluster NDB 7.0.17. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see Changes in MySQL 5.1.47 (2010-05-06)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- Added the `DictTrace` data node configuration parameter, for use in debugging `NDB` code. For more information, see Defining MySQL Cluster Data Nodes. (Bug #55963)
- Added the `--server-id-bits` option for mysqld and mysqlbinlog.

  For `mysqld`, the `--server-id-bits` [1918] option indicates the number of least significant bits within the 32-bit server ID which actually identify the server. Indicating that the server ID uses less than 32 bits permits the remaining bits to be used for other purposes by NDB API applications using the Event API and `OperationOptions::AnyValue`.

  For `mysqlbinlog`, the `--server-id-bits` [353] option tells `mysqlbinlog` how to interpret the server IDs in the binary log when the binary log was written by a `mysqld` having its `server_id_bits` [1935] set to less than the maximum (32). (Bug #52305)

Bugs Fixed

- **Cluster API**: **Important Change**: The poll and select calls made by the MGM API were not interrupt-safe; that is, a signal caught by the process while waiting for an event on one or more sockets returned error -1 with `errno` set to `EINTR`. This caused problems with MGM API functions such as `ndb_logevent_get_next()` and `ndb_mgm_get_status2()`.

  To fix this problem, the internal `ndb_socket_poller::poll()` function has been made `EINTR`-safe.

  The old version of this function has been retained as `poll_unsafe()`, for use by those parts of NDB that do not need the `EINTR`-safe version of the function. (Bug #55906)
- Starting `ndb_mgmd` with `--config-cache=0` [1963] caused it to leak memory. (Bug #55205)
- When another data node failed, a given data node `DBTC` kernel block could time out while waiting for `DBDIH` to signal commits of pending transactions, leading to a crash. Now in such cases the timeout generates a prinout, and the data node continues to operate. (Bug #55715)
- An excessive number of timeout warnings (normally used only for debugging) were written to the data node logs. (Bug #53987)
- The TCP configuration parameters `HostName1` and `HostName2` were not displayed in the output of `ndb_config --configinfo` [1975]. (Bug #55839)
- It was possible for a `DROP DATABASE` statement to remove `NDB` hidden blob tables without removing the parent tables, with the result that the tables, although hidden to MySQL clients, were still visible in the output of `ndb_show_tables` but could not be dropped using `ndb_drop_table`. (Bug #54788)
- The `configure.js` option `WITHOUT_DYNAMIC_PLUGINS=TRUE` was ignored when building MySQL Cluster for Windows using `CMake`. Among the effects of this issue was that `CMake` attempted

to build the `InnoDB` storage engine as a plugin (`.DLL` file) even though the `InnoDB Plugin` is not currently supported by MySQL Cluster. (Bug #54913)

- **Disk Data**: As an optimization when inserting a row to an empty page, the page is not read, but rather simply initialized. However, this optimzation was performed in all cases when an empty row was inserted, even though it should have been done only if it was the first time that the page had been used by a table or fragment. This is because, if the page had been in use, and then all records had been released from it, the page still needed to be read to learn its log sequence number (LSN).

  This caused problems only if the page had been flushed using an incorrect LSN and the data node failed before any local checkpoint was completed—which would remove any need to apply the undo log, hence the incorrect LSN was ignored.

  The user-visible result of the incorrect LSN was that it caused the data node to fail during a restart. It was perhaps also possible (although not conclusively proven) that this issue could lead to incorrect data. (Bug #54986)

- **Cluster API**: Calling `NdbTransaction::refresh()` did not update the timer for `TransactionInactiveTimeout` [1841]. (Bug #54724)

Changes in MySQL Cluster NDB 7.0.16 (5.1.47-ndb-7.0.16) (2010-06-25)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.15.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see Changes in MySQL 5.1.47 (2010-05-06)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- Restrictions on some types of mismatches in column definitions when restoring data using `ndb_restore` have been relaxed. These include the following types of mismatches:

  - Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
  - Different `STORAGE` settings (`MEMORY`, `DISK`)
  - Different default values
  - Different distribution key settings

  Now, when one of these types of mismatches in column definitions is encountered, `ndb_restore` no longer stops with an error; instead, it accepts the data and inserts it into the target table, while issuing a warning to the user.

  For more information, see `ndb_restore` — Restore a MySQL Cluster Backup. (Bug #54423)

  References: See also Bug #53810, Bug #54178, Bug #54242, Bug #54279.

- Introduced the `HeartbeatOrder` [1837] data node configuration parameter, which can be used to set the order in which heartbeats are transmitted between data nodes. This parameter can be useful in situations where multiple data nodes are running on the same host and a temporary disruption in connectivity between hosts would otherwise cause the loss of a node group, leading to failure of the cluster. (Bug #52182)

- It is now possible to install management node and data node processes as Windows services. (See Installing MySQL Cluster Processes as Windows Services, for more information.) In addition, data node processes on Windows are now maintained by angel processes, just as they are on other platforms supported by MySQL Cluster.

Bugs Fixed

- The disconnection of all API nodes (including SQL nodes) during an `ALTER TABLE` caused a memory leak. (Bug #54685)
- If a node shutdown (either in isolation or as part of a system shutdown) occurred directly following a local checkpoint, it was possible that this local checkpoint would not be used when restoring the cluster. (Bug #54611)
- When adding multiple new node groups to a MySQL Cluster, it was necessary for each new node group to add only the nodes to be assigned to the new node group, create that node group using `CREATE NODEGROUP`, then repeat this process for each new node group to be added to the cluster. The fix for this issue makes it possible to add all of the new nodes at one time, and then issue several `CREATE NODEGROUP` commands in succession. (Bug #54497)
- The setting for `BuildIndexThreads` [1854] was ignored by `ndbmtd`, which made it impossible to use more than 4 cores for rebuilding indexes. (Bug #54521)
- A table having the maximum number of attributes permitted could not be backed up using the `ndb_mgm` client.

  Note

  The maximum number of attributes supported per table is not the same for all MySQL Cluster releases. See Limits Associated with Database Objects in MySQL Cluster, to determine the maximum that applies in the release which you are using.

  (Bug #54155)
- When performing an online alter table where 2 or more SQL nodes connected to the cluster were generating binary logs, an incorrect message could be sent from the data nodes, causing `mysqld` processes to crash. This problem was often difficult to detect, because restarting SQL node or data node processes could clear the error, and because the crash in `mysqld` did not occur until several minutes after the erroneous message was sent and received. (Bug #54168)
- The two MySQL Server options, `--ndb-wait-connected` [1919] and `--ndb-wait-setup` [1919], did not set the corresponding system variables. (Bug #48402)
- During initial node restarts, initialization of the REDO log was always performed 1 node at a time, during start phase 4. Now this is done during start phase 2, so that the initialization can be performed in parallel, thus decreasing the time required for initial restarts involving multiple nodes. (Bug #50062)
- The presence of duplicate `[tcp]` sections in the `config.ini` file caused the management server to crash. Now in such cases, `ndb_mgmd` fails gracefully with an appropriate error message. (Bug #49400)
- **Cluster Replication**: An error in an `NDB` internal byte mask value could lead to corruption of replicated `BIT` column values. (Bug #54005)

  References: See also Bug #53622.
- **Cluster API**: When using the NDB API, it was possible to rename a table with the same name as that of an existing table.

Note

This issue did not affect table renames executed using SQL on MySQL servers acting as MySQL Cluster API nodes.

(Bug #54651)

- **Cluster API**: An excessive number of client connections, such that more than 1024 file descriptors, sockets, or both were open, caused NDB API applications to crash. (Bug #34303)

Changes in MySQL Cluster NDB 7.0.15b (5.1.44-ndb-7.0.15b) (2010-06-18)

This release replaces MySQL Cluster NDB 7.0.15, fixing a critical issue in that version that was discovered shortly after its release (Bug #54242), as well as MySQL Cluster NDB 7.0.15a, which was not actually released due to Bug #54516 being found during testing. Users of MySQL Cluster NDB 7.0.14 or MySQL Cluster NDB 7.0.15 should upgrade to the 7.0.15b release as soon as possible.

Obtaining MySQL Cluster NDB 7.0.15b. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.44 (see Changes in MySQL 5.1.44 (2010-02-04)).

Bugs Fixed

- **Cluster API**: The value of an internal constant used in the implementation of the `NdbOperation` and `NdbScanOperation` classes caused MySQL Cluster NDB 7.0 NDB API applications compiled against MySQL Cluster NDB 7.0.14 or earlier to fail when run with MySQL Cluster 7.0.15, and MySQL Cluster NDB 7.1 NDB API applications compiled against MySQL Cluster NDB 7.1.3 or earlier to break when used with MySQL Cluster 7.1.4. (Bug #54516)

Changes in MySQL Cluster NDB 7.0.15a (5.1.44-ndb-7.0.15a) (Not released)

This was intended as a replacement release for MySQL Cluster NDB 7.0.15, fixing a critical issue in that version that was discovered shortly after its release (Bug #54242); however, MySQL Cluster NDB 7.0.15a was not actually released due to Bug #54516 being found during testing. Users of MySQL Cluster NDB 7.0.14 or MySQL Cluster NDB 7.0.15 should upgrade to the 7.0.15b release as soon as possible.

The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.44 (see Changes in MySQL 5.1.44 (2010-02-04)).

Bugs Fixed

- When using `mysqldump` to back up and restore schema information while using `ndb_restore` for restoring only the data, restoring to MySQL Cluster NDB 7.1.4 from an older version failed on tables having columns with default values. This was because versions of MySQL Cluster prior to MySQL Cluster NDB 7.1.4 did not have native support for default values.

  In addition, the MySQL Server supports `TIMESTAMP` columns having dynamic default values, such as `DEFAULT CURRENT_TIMESTAMP`; however, the current implementation of `NDB`-native default values permits only a constant default value.

To fix this issue, the manner in which NDB treats TIMESTAMP columns is reverted to its pre-NDB-7.1.4 behavior (obtaining the default value from mysqld rather than NDBCLUSTER) except where a TIMESTAMP column uses a constant default, as in the case of a column declared as TIMESTAMP DEFAULT 0 or TIMESTAMP DEFAULT 20100607174832. (Bug #54242)

Changes in MySQL Cluster NDB 7.0.15 (5.1.44-ndb-7.0.15) (2010-05-31)

This release incorporates new features in the NDBCLUSTER storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.14.

Obtaining MySQL Cluster NDB 7.0.15. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.44 (see Changes in MySQL 5.1.44 (2010-02-04)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Important Change**: The maximum number of attributes (columns plus indexes) per table has increased to 512.
- A --wait-nodes option has been added for ndb_waiter. When this option is used, the program waits only for the nodes having the listed IDs to reach the desired state. For more information, see ndb_waiter — Wait for MySQL Cluster to Reach a Given Status. (Bug #52323)
- As part of this change, new methods relating to default values have been added to the Column and Table classes in the NDB API. For more information, see Column::getDefaultValue(), Column::setDefaultValue(), and Table::hasDefaultValues(). (Bug #30529)
- Added the --skip-unknown-objects [2003] option for ndb_restore. This option causes ndb_restore to ignore any schema objects which it does not recognize. Currently, this is useful chiefly for restoring native backups made from a cluster running MySQL Cluster NDB 7.0 to a cluster running MySQL Cluster NDB 6.3.
- Added the MySQL Cluster management server option --config-cache [1963], which makes it possible to enable and disable configuration caching. This option is turned on by default; to disable configuration caching, start ndb_mgmd with --config-cache=0 [1963], or with --skip-config-cache. See ndb_mgmd — The MySQL Cluster Management Server Daemon, for more information.

Bugs Fixed

- When attempting to create an NDB table on an SQL node that had not yet connected to a MySQL Cluster management server since the SQL node's last restart, the CREATE TABLE statement failed as expected, but with the unexpected Error 1495 For the partitioned engine it is necessary to define all partitions. (Bug #11747335, Bug #31853)
