- After creating NDB tables until creation of a table failed due to NDB error 905 Out of attribute records (increase MaxNoOfAttributes), then increasing MaxNoOfAttributes [1828] and restarting all management node and data node processes, attempting to drop and re-create one of the tables failed with the error Out of table records..., even when sufficient table records were available. (Bug #53944)

References: See also Bug #52055. This bug is a regression of Bug #44294.

- Creating a Disk Data table, dropping it, then creating an in-memory table and performing a restart, could cause data node processes to fail with errors in the DBTUP kernel block if the new table's internal ID was the same as that of the old Disk Data table. This could occur because undo log handling during the restart did not check that the table having this ID was now in-memory only. (Bug #53935)

- An internal buffer allocator used by NDB has the form `alloc(wanted, minimum)` and attempts to allocate *wanted* pages, but is permitted to allocate a smaller number of pages, between *wanted* and *minimum*. However, this allocator could sometimes allocate fewer than *minimum* pages, causing problems with multi-threaded building of ordered indexes. (Bug #53580)

- A table created while ndb_table_no_logging [1930] was enabled was not always stored to disk, which could lead to a data node crash with `Error opening DIH schema files for table`. (Bug #53934)

- When compiled with support for epoll but this functionality is not available at runtime, MySQL Cluster tries to fall back to use the `select()` function in its place. However, an extra `ndbout_c()` call in the transporter registry code caused ndbd to fail instead. (Bug #53482)

- The value set for the ndb_mgmd option --ndb-nodeid [2017] was not verified prior to use as being within the permitted range (1 to 255, inclusive), leading to a crash of the management server. (Bug #53412)

- NDB truncated a column declared as `DECIMAL(65,0)` to a length of 64. Now such a column is accepted and handled correctly. In cases where the maximum length (65) is exceeded, NDB now raises an error instead of truncating. (Bug #53352)

- When creating an index, NDB failed to check whether the internal ID allocated to the index was within the permissible range, leading to an assertion. This issue could manifest itself as a data node failure with NDB error 707 (`No more table metadata records (increase MaxNoOfTables)`), when creating tables in rapid succession (for example, by a script, or when importing from mysqldump), even with a relatively high value for MaxNoOfTables [1829] and a relatively low number of tables. (Bug #52055)

- When the LogDestination [1810] parameter was set using with a relative path, the management server failed to store its value unless started with --initial [1965] or --reload [1966]. (Bug #52268)

- ndb_restore did not raise any errors if hashmap creation failed during execution. (Bug #51434)

- When an NDB log handler failed, the memory allocated to it was freed twice. (Bug #53200)

- Setting DataMemory [1817] higher than 4G on 32-bit platforms caused ndbd to crash, instead of failing gracefully with an error. (Bug #52536, Bug #50928)

- Specifying the node ID as part of the --ndb-connectstring [1914] option to mysqld was not handled correctly.

  The fix for this issue includes the following changes:

  - Multiple occurrences of any of the mysqld options --ndb-connectstring [1914], --ndb-mgmd-host [1915], and --ndb-nodeid [1916] are now handled in the same way as with other MySQL server options, in that the value set in the last occurrence of the option is the value that is used by mysqld.

    Now, if --ndb-nodeid [1916] is used, its value overrides that of any nodeid setting used in --ndb-connectstring [1914]. For example, starting mysqld with --ndb-connectstring=nodeid=1,10.100.1.100 --ndb-nodeid=3 now produces the same result as starting it with --ndb-connectstring=nodeid=3,10.100.1.100.

- The 1024-character limit on the length of the connectstring is removed, and `--ndb-connectstring` [1914] is now handled in this regard in the same way as other `mysqld` options.
- In the NDB API, a new constructor for `Ndb_cluster_connection` is added which takes as its arguments a connectstring and the node ID to force the API node to use.

(Bug #44299)

- NDB did not distinguish correctly between table names differing only by lettercase when `lower_case_table_names` [492] was set to 0. (Bug #33158)
- `ndb_mgm -e "ALL STATUS"` erroneously reported that data nodes remained in start phase 0 until they had actually started.
- **Replication**: A buffer overrun in the handling of `DATE` column values could cause `mysqlbinlog` to fail when reading logs containing certain combinations of DML statements on a table having a `DATE` column followed by dropping the table. (Bug #52202)
- **Cluster Replication**: Replication failed after a restart of the slave SQL node, due to an error in writing the `master.info` file. (Bug #52859)
- `ALTER TABLE` did not work correctly where the name of the table, the database, or both contained special characters, causing the MySQL server to crash. (Bug #52225)

  References: See also Bug #53409, Bug #14959.
- The performance of MySQL applications using non-persistent client connections was adversely affected due to many of these connections being kept waiting for an excessive length of time in cleanup phase while being closed. (Bug #48832)
- The MySQL client library mishandled `EINPROGRESS` errors for connections in nonblocking mode. This could lead to replication failures on hosts capable of resolving both IPv4 and IPv6 network addresses, when trying to resolve `localhost`. (Bug #37267)

  References: See also Bug #44344.

Changes in MySQL Cluster NDB 7.0.14 (5.1.44-ndb-7.0.14) (2010-03-31)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.13.

Obtaining MySQL Cluster NDB 7.0.14. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.44 (see Changes in MySQL 5.1.44 (2010-02-04)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Cluster API**: It is now possible to determine, using the `ndb_desc` utility or the NDB API, which data nodes contain replicas of which partitions. For `ndb_desc`, a new `--extra-node-info` [1982] option is added to cause this information to be included in its output. A new

method `Table::getFragmentNodes()` is added to the NDB API for obtaining this information programmatically. (Bug #51184)

- Formerly, the `REPORT` and `DUMP` commands returned output to all `ndb_mgm` clients connected to the same MySQL Cluster. Now, these commands return their output only to the `ndb_mgm` client that actually issued the command. (Bug #40865)

- **Cluster Replication**: **Replication**: MySQL Cluster Replication now supports attribute promotion and demotion for row-based replication between columns of different but similar types on the master and the slave. For example, it is possible to promote an `INT` column on the master to a `BIGINT` column on the slave, and to demote a `TEXT` column to a `VARCHAR` column.

  The implementation of type demotion distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` [1646] global server system variable.

  For more information about attribute promotion and demotion for row-based replication in MySQL Cluster, see Attribute promotion and demotion (MySQL Cluster). (Bug #47163, Bug #46584)

Bugs Fixed

- **Cluster API**: **Incompatible Change**: The default behavior of the NDB API Event API has changed as follows:

  Previously, when creating an `Event`, DDL operations (alter and drop operations on tables) were automatically reported on any event operation that used this event, but as a result of this change, this is no longer the case. Instead, you must now invoke the event's `setReport()` method, with the new `EventReport` value `ER_DDL`, to get this behavior.

  For existing NDB API applications where you wish to retain the old behavior, you must update the code as indicated previously, then recompile, following an upgrade. Otherwise, DDL operations are no longer reported after upgrading `libndbnclient`.

  For more information, see The `Event::EventReport` Type, and `Event::setReport()`. (Bug #53308)

- **Cluster Replication**: **Important Change**: The `--ndb-log-empty-epochs` [1917] option was ignored. Setting the `ndb_log_empty_epochs` [1935] server system variable also had no effect.

  As part of the fix for this issue, rows for empty epochs are now recorded in the `ndb_binlog_index` table even when `--ndb-log-empty-epochs` [1917] is 0. (Bug #49559, Bug #11757505)

- If a node or cluster failure occurred while `mysqld` was scanning the `ndb.ndb_schema` table (which it does when attempting to connect to the cluster), insufficient error handling could lead to a crash by `mysqld` in certain cases. This could happen in a MySQL Cluster with a great many tables, when trying to restart data nodes while one or more `mysqld` processes were restarting. (Bug #52325)

- In MySQL Cluster NDB 7.0 and later, DDL operations are performed within schema transactions; the NDB kernel code for starting a schema transaction checks that all data nodes are at the same version before permitting a schema transaction to start. However, when a version mismatch was detected, the client was not actually informed of this problem, which caused the client to hang. (Bug #52228)

- After running a mixed series of node and system restarts, a system restart could hang or fail altogether. This was caused by setting the value of the newest completed global checkpoint too low for a data node performing a node restart, which led to the node reporting incorrect GCI intervals for its first local checkpoint. (Bug #52217)

- When performing a complex mix of node restarts and system restarts, the node that was elected as master sometimes required optimized node recovery due to missing `REDO` information. When this happened, the node crashed with `Failure to recreate object ... during restart, error 721` (because the `DBDICT` restart code was run twice). Now when this occurs, node

takeover is executed immediately, rather than being made to wait until the remaining data nodes have started. (Bug #52135)

References: See also Bug #48436.

- The internal variable `ndb_new_handler`, which is no longer used, has been removed. (Bug #51858)
- `ha_ndbcluster.cc` was not compiled with the same `SAFEMALLOC` and `SAFE_MUTEX` flags as the MySQL Server. (Bug #51857)
- When debug compiling MySQL Cluster on Windows, the mysys library was not compiled with -DSAFEMALLOC and -DSAFE_MUTEX, due to the fact that my_socket.c was misnamed as my_socket.cc. (Bug #51856)
- Restoring a MySQL Cluster backup between platforms having different endianness failed when also restoring metadata and the backup contained a hashmap not already present in the database being restored to. This issue was discovered when trying to restore a backup made on Solaris/SPARC to a MySQL Cluster running on Solaris/x86, but could conceivably occur in other cases where the endianness of the platform on which the backup was taken differed from that of the platform being restored to. (Bug #51432)
- The `mysql` client `system` command did not work properly. This issue was only known to affect the version of the `mysql` client that was included with MySQL Cluster NDB 7.0 and MySQL Cluster NDB 7.1 releases. (Bug #48574)
- The redo log protects itself from being filled up by periodically checking how much space remains free. If insufficient redo log space is available, it sets the state `TAIL_PROBLEM` which results in transactions being aborted with error code 410 (`out of redo log`). However, this state was not set following a node restart, which meant that if a data node had insufficient redo log space following a node restart, it could crash a short time later with `Fatal error due to end of REDO log`. Now, this space is checked during node restarts. (Bug #51723)
- Information about several management client commands was missing from (that is, truncated in) the output of the `HELP` command. (Bug #46114)
- The output of the `ndb_mgm` client `REPORT BACKUPSTATUS` command could sometimes contain errors due to uninitialized data. (Bug #51316)
- The following issues were fixed in the `ndb_mgm` client `REPORT MEMORYUSAGE` command:
  - The client sometimes inserted extra `ndb_mgm>` prompts within the output.
  - For data nodes running `ndbmtd`, `IndexMemory` [1819] was reported before `DataMemory` [1817].
  - In addition, for data nodes running `ndbmtd`, there were multiple `IndexMemory` [1819] entries listed in the output.

  (Bug #50196)
- Issuing a command in the `ndb_mgm` client after it had lost its connection to the management server could cause the client to crash. (Bug #49219)
- The internal `ErrorReporter::formatMessage()` method could in some cases cause a buffer overflow. (Bug #47120)
- A `GROUP BY` query against `NDB` tables sometimes did not use any indexes unless the query included a `FORCE INDEX` option. With this fix, indexes are used by such queries (where otherwise possible) even when `FORCE INDEX` is not specified. (Bug #50736)
- The `ndb_print_backup_file` utility failed to function, due to a previous internal change in the NDB code. (Bug #41512, Bug #48673)

- When the `MemReportFrequency` [1849] configuration parameter was set in `config.ini`, the `ndb_mgm` client `REPORT MEMORYUSAGE` command printed its output multiple times. (Bug #37632)
- `ndb_mgm -e "... REPORT ..."` did not write any output to `stdout`.

  The fix for this issue also prevents the cluster log from being flooded with `INFO` messages when `DataMemory` [1817] usage reaches 100%, and insures that when the usage is decreased, an appropriate message is written to the cluster log. (Bug #31542, Bug #44183, Bug #49782)
- **InnoDB**: **Replication**: Column length information generated by `InnoDB` did not match that generated by `MyISAM`, which caused invalid metadata to be written to the binary log when trying to replicate `BIT` columns. (Bug #49618)
- **Replication**: Metadata for `GEOMETRY` fields was not properly stored by the slave in its definitions of tables. (Bug #49836)

  References: See also Bug #48776.
- **Disk Data**: Inserts of blob column values into a MySQL Cluster Disk Data table that exhausted the tablespace resulted in misleading `no such tuple` error messages rather than the expected error `tablespace full`.

  This issue appeared similar to Bug #48113, but had a different underlying cause. (Bug #52201)
- **Disk Data**: The error message returned after atttempting to execute `ALTER LOGFILE GROUP` on an nonexistent logfile group did not indicate the reason for the failure. (Bug #51111)
- **Disk Data**: DDL operations on Disk Data tables having a relatively small `UNDO_BUFFER_SIZE` could fail unexpectedly.
- **Cluster Replication**: When `mysqld` was started with `--binlog-do-db` [1649] or `--binlog-ignore-db` [1651], no `LOST_EVENTS` incident was written to the binary log. (Bug #47096)
- **Cluster API**: When reading blob data with lock mode `LM_SimpleRead`, the lock was not upgraded as expected. (Bug #51034)
- **Cluster API**: A number of issues were corrected in the NDB API coding examples found in the `storage/ndb/ndbapi-examples` directory in the MySQL Cluster source tree. These included possible endless recursion in `ndbapi_scan.cpp` as well as problems running some of the examples on systems using Windows or Mac OS X due to the lettercase used for some table names. (Bug #30552, Bug #30737)
- On some Unix/Linux platforms, an error during build from source could be produced, referring to a missing `LT_INIT` program. This is due to versions of `libtool` 2.1 and earlier. (Bug #51009)
- 1) In rare cases, if a thread was interrupted during a `FLUSH PRIVILEGES` operation, a debug assertion occurred later due to improper diagnostics area setup. 2) A `KILL` operation could cause a console error message referring to a diagnostic area state without first ensuring that the state existed. (Bug #33982)

Changes in MySQL Cluster NDB 7.0.13 (5.1.41-ndb-7.0.13) (2010-03-04)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.12.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see Changes in MySQL 5.1.41 (2009-11-05)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- A new configuration parameter `HeartbeatThreadPriority` makes it possible to select between a first-in, first-out or round-round scheduling policy for management node and API node heartbeat threads, as well as to set the priority of these threads. See Defining a MySQL Cluster Management Server, or Defining SQL and Other API Nodes in a MySQL Cluster, for more information. (Bug #49617)
- Start phases are now written to the data node logs. (Bug #49158)
- **Disk Data**: The `ndb_desc` utility can now show the extent space and free extent space for subordinate `BLOB` and `TEXT` columns (stored in hidden `BLOB` tables by NDB). A `--blob-info` [1982] option has been added for this program that causes `ndb_desc` to generate a report for each subordinate `BLOB` table. For more information, see `ndb_desc` — Describe NDB Tables. (Bug #50599)

Bugs Fixed

- When performing a system restart of a MySQL Cluster where multi-threaded data nodes were in use, there was a slight risk that the restart would hang due to incorrect serialization of signals passed between LQH instances and proxies; some signals were sent using a proxy, and others directly, which meant that the order in which they were sent and received could not be guaranteed. If signals arrived in the wrong order, this could cause one or more data nodes to hang. Now all signals that need to be sent and received in the same order are sent using the same path. (Bug #51645)
- When one or more data nodes read their LCPs and applied undo logs significantly faster than others, this could lead to a race condition causing system restarts of data nodes to hang. This could most often occur when using both `ndbd` and `ndbmtd` processes for the data nodes. (Bug #51644)
- When deciding how to divide the REDO log, the `DBDIH` kernel block saved more than was needed to restore the previous local checkpoint, which could cause REDO log space to be exhausted prematurely (`NDB` error 410). (Bug #51547)
- DML operations can fail with `NDB` error 1220 (`REDO log files overloaded...`) if the opening and closing of REDO log files takes too much time. If this occurred as a GCI marker was being written in the REDO log while REDO log file 0 was being opened or closed, the error could persist until a GCP stop was encountered. This issue could be triggered when there was insufficient REDO log space (for example, with configuration parameter settings `NoOfFragmentLogFiles = 6` and `FragmentLogFileSize = 6M`) with a load including a very high number of updates. (Bug #51512)

  References: See also Bug #20904.
- A `SELECT` requiring a sort could fail with the error `Can't find record in 'table'` when run concurrently with a `DELETE` from the same table. (Bug #45687)
- A side effect of the `ndb_restore --disable-indexes` [2002] and `--rebuild-indexes` [2002] options is to change the schema versions of indexes. When a `mysqld` later tried to drop a table that had been restored from backup using one or both of these options, the server failed to detect these changed indexes. This caused the table to be dropped, but the indexes to be left behind, leading to problems with subsequent backup and restore operations. (Bug #51374)
- `ndb_restore` crashed while trying to restore a corrupted backup, due to missing error handling. (Bug #51223)
- Replication of a MySQL Cluster using multi-threaded data nodes could fail with forced shutdown of some data nodes due to the fact that `ndbmtd` exhausted `LongMessageBuffer` [1825] much more quickly than `ndbd`. After this fix, passing of replication data between the `DBTUP` and `SUMA` NDB kernel blocks is done using `DataMemory` [1817] rather than `LongMessageBuffer` [1825].

  Until you can upgrade, you may be able to work around this issue by increasing the `LongMessageBuffer` [1825] setting; doubling the default should be sufficient in most cases. (Bug #46914)

- The `ndb_restore` message `Successfully created index `PRIMARY`...` was directed to `stderr` instead of `stdout`. (Bug #51037)
- When using `NoOfReplicas` [1815] equal to 1 or 2, if data nodes from one node group were restarted 256 times and applications were running traffic such that it would encounter `NDB` error 1204 (`Temporary failure, distribution changed`), the live node in the node group would crash, causing the cluster to crash as well. The crash occurred only when the error was encountered on the 256th restart; having the error on any previous or subsequent restart did not cause any problems. (Bug #50930)
- **Cluster API**: An issue internal to `ndb_mgm` could cause problems when trying to start a large number of data nodes at the same time. (Bug #51273)

  References: See also Bug #51310.

Changes in MySQL Cluster NDB 7.0.12b (5.1.41-ndb-7.0.12b) (2010-02-18)

This is a replacement release for MySQL Cluster NDB 7.0.12a, fixing a critical issue in that version that was discovered shortly after its release (Bug #51256). MySQL Cluster NDB 7.0.12b is identical in all other respects to MySQL Cluster NDB 7.0.12 and MySQL Cluster NDB 7.0.12a. Users of MySQL Cluster NDB 7.0.12 or MySQL Cluster NDB 7.0.12a (only) should upgrade to the 7.0.12b release as soon as possible.

This is a testing release only, for the purpose of testing the fix for Bug #49190 (now also incorporating the fix for Bug #51027 and Bug #51256). This release is otherwise identical to MySQL Cluster NDB 7.0.11b; users of MySQL Cluster NDB 7.0.11 or MySQL Cluster NDB 7.0.11a who are not interested in testing this change should upgrade to MySQL Cluster NDB 7.0.11b (if they have not done so already), then wait until MySQL Cluster NDB 7.0.13 becomes available.

Obtaining MySQL Cluster NDB 7.0.12a. This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 7.0.12a from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.41-ndb-7.0.12a/. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see Changes in MySQL 5.1.41 (2009-11-05)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- An initial restart of a data node configured with a large amount of memory could fail with a `Pointer too large` error. (Bug #51027)

  References: This bug was introduced by Bug #47818.

Changes in MySQL Cluster NDB 7.0.12a (5.1.41-ndb-7.0.12a) (2010-02-15)

Note

MySQL Cluster NDB 7.0.12a was withdrawn shortly after release, due to Bug #51256. Users of the original 7.0.12 release should upgrade to MySQL Cluster NDB 7.0.12b, which fixes this issue (and others). Users of MySQL Cluster NDB 7.0.11 or MySQL Cluster NDB 7.0.11a should upgrade to MySQL Cluster NDB 7.0.11b, if they have not done so already.

This is a replacement release for MySQL Cluster NDB 7.0.12, fixing a critical issue in that version that was discovered shortly after its release (Bug #51027). MySQL Cluster NDB 7.0.12a is identical in

all other respects to MySQL Cluster NDB 7.0.12. Users of MySQL Cluster NDB 7.0.12 (only) should upgrade to the 7.0.12a release as soon as possible.

This is a testing release only, for the purpose of testing the fix for Bug #49190 (now also incorporating the fix for Bug #51027). This release is otherwise identical to MySQL Cluster NDB 7.0.11b; users of MySQL Cluster NDB 7.0.11 or MySQL Cluster NDB 7.0.11a who are not interested in testing this change should upgrade to MySQL Cluster NDB 7.0.11b (if they have not done so already), then wait until MySQL Cluster NDB 7.0.13 becomes available.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see Changes in MySQL 5.1.41 (2009-11-05)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- An initial restart of a data node configured with a large amount of memory could fail with a `Pointer too large` error. (Bug #51027)

  References: This bug was introduced by Bug #47818.

Changes in MySQL Cluster NDB 7.0.12 (5.1.41-ndb-7.0.12) (2010-02-03)

Note

MySQL Cluster NDB 7.0.12 was withdrawn shortly after release, due to Bug #51027. Users of the original 7.0.12 release should upgrade to MySQL Cluster NDB 7.0.12b, which fixes this issue (and others). Users of MySQL Cluster NDB 7.0.11 or MySQL Cluster NDB 7.0.11a should upgrade to MySQL Cluster NDB 7.0.11b, if they have not done so already.

This is a testing release only, for the purpose of testing the fix for Bug #49190. This release is otherwise identical to MySQL Cluster NDB 7.0.11b; users of MySQL Cluster NDB 7.0.11 or MySQL Cluster NDB 7.0.11a who are not interested in testing this change should upgrade to MySQL Cluster NDB 7.0.11b (if they have not done so already), then wait until MySQL Cluster NDB 7.0.13 becomes available.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see Changes in MySQL 5.1.41 (2009-11-05)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- Numeric codes used in management server status update messages in the cluster logs have been replaced with text descriptions. (Bug #49627)

  References: See also Bug #44248.

Bugs Fixed

- `ndbmtd` started on a single-core machine could sometimes fail with a `Job Buffer Full` error when `MaxNoOfExecutionThreads` [1855] was set greater than `LockExecuteThreadToCPU` [1852]. Now a warning is logged when this occurs. (Bug #50582)

- When a primary key lookup on an `NDB` table containing one or more `BLOB` columns was executed in a transaction, a shared lock on any blob tables used by the `NDB` table was held for the duration of the transaction. (This did not occur for indexed or non-indexed `WHERE` conditions.)

  Now in such cases, the lock is released after all `BLOB` data has been read. (Bug #49190)

Changes in MySQL Cluster NDB 7.0.11b (5.1.41-ndb-7.0.11b) (2010-02-18)

This is a replacement release for MySQL Cluster NDB 7.0.11a, fixing a critical issue in that version that was discovered shortly after its release (Bug #51256). MySQL Cluster NDB 7.0.11b is identical in all other respects to MySQL Cluster NDB 7.0.11a. Users of MySQL Cluster NDB 7.0.11 or MySQL Cluster NDB 7.0.11a should upgrade to the 7.0.11b release as soon as possible. Users of previous MySQL Cluster NDB 7.0 releases should bypass the 7.0.11 and 7.0.11a releases, and upgrade to 7.0.11b instead.

Obtaining MySQL Cluster NDB 7.0.11b. This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 7.0.11b from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.41-ndb-7.0.11b/. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see Changes in MySQL 5.1.41 (2009-11-05)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- Setting `IndexMemory` [1819] greater than 2GB could cause data nodes to crash while starting. (Bug #51256)

Changes in MySQL Cluster NDB 7.0.11a (5.1.41-ndb-7.0.11a) (2010-02-15)

This is a replacement release for MySQL Cluster NDB 7.0.11, fixing a critical issue in that version that was discovered shortly after its release (Bug #51027). MySQL Cluster NDB 7.0.11a is identical in all other respects to MySQL Cluster NDB 7.0.11. Users of MySQL Cluster NDB 7.0.11 should upgrade to the 7.0.11a release as soon as possible. Users of previous MySQL Cluster NDB 7.0 releases should bypass the 7.0.11 release and upgrade to 7.0.11a instead.

Obtaining MySQL Cluster NDB 7.0.11a. This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 7.0.11a from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.41-ndb-7.0.11a/. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see Changes in MySQL 5.1.41 (2009-11-05)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- An initial restart of a data node configured with a large amount of memory could fail with a `Pointer too large` error. (Bug #51027)

  References: This bug was introduced by Bug #47818.

Changes in MySQL Cluster NDB 7.0.11 (5.1.41-ndb-7.0.11) (2010-02-02)

Note

MySQL Cluster NDB 7.0.11 was withdrawn shortly after release, due to Bug #51027. Users should upgrade to MySQL Cluster NDB 7.0.11a, which fixes this issue.

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.10.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.39 (see Changes in MySQL 5.1.41 (2009-11-05)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Important Change**: The maximum permitted value of the `ndb_autoincrement_prefetch_sz` [1921] system variable has been increased from 256 to 65536. (Bug #50621)

- Added multi-threaded ordered index building capability during system restarts or node restarts, controlled by the `BuildIndexThreads` [1854] data node configuration parameter (also introduced in this release).

- **Cluster Replication**: In circular replication, it was sometimes possible for an event to propagate such that it would be reapplied on all servers. This could occur when the originating server was removed from the replication circle and so could no longer act as the terminator of its own events, as normally happens in circular replication.

  To prevent this from occurring, a new `IGNORE_SERVER_IDS` option is introduced for the `CHANGE MASTER TO` statement. This option takes a list of replication server IDs; events having a server ID which appears in this list are ignored and not applied. For more information, see `CHANGE MASTER TO` Syntax.

  In conjunction with the introduction of `IGNORE_SERVER_IDS`, `SHOW SLAVE STATUS` has two new fields. `Replicate_Ignore_Server_Ids` displays information about ignored servers. `Master_Server_Id` displays the `server_id` [521] value from the master. (Bug #47037)

  References: See also Bug #25998, Bug #27808.

- **Cluster Replication**: Due to the fact that no timestamp is available for delete operations, a delete using `NDB$MAX()` is actually processed as `NDB$OLD`. However, because this is not optimal for some use cases, `NDB$MAX_DELETE_WIN()` is added as a conflict resolution function; if the “timestamp” column value for a given row adding or updating an existing row coming from the master is higher than that on the slave, it is applied (as with `NDB$MAX()`); however, delete operations are treated as always having the higher value.

  See `NDB$MAX_DELETE_WIN(column_name)`, for more information. (Bug #50650)

Bugs Fixed

- `ndbmtd` was not built on Windows (`CMake` did not provide a build target for it). (Bug #49325)

- When attempting to join a running cluster whose management server had been started with the `--nowait-nodes` [1967] option and having SQL nodes with dynamically allocated node IDs, a second

management server failed with spurious `INTERNAL ERROR: Found dynamic ports with value in config...` error messages. (Bug #49807)

- Under some circumstances, the `DBTC` kernel block could send an excessive number of commit and completion messages which could lead to a the job buffer filling up and node failure. This was especially likely to occur when using `ndbmtd` with a single data node. (Bug #45989)

- If a query on an `NDB` table compared a constant string value to a column, and the length of the string was greater than that of the column, condition pushdown did not work correctly. (The string was truncated to fit the column length before being pushed down.) Now in such cases, the condition is no longer pushed down. (Bug #49459)

- When performing a `DELETE` that included a left join from an `NDB` table, only the first matching row was deleted. (Bug #47054)

- Initial start of partitioned nodes did not work correctly. This issue was observed in MySQL Cluster NDB 7.0 only. (Bug #50661)

- The `CREATE NODEGROUP` client command in `ndb_mgm` could sometimes cause the forced shutdown of a data node. (Bug #50594)

- During Start Phases 1 and 2, the `STATUS` command sometimes (falsely) returned `Not Connected` for data nodes running `ndbmtd`. (Bug #47818)

- When setting the `LockPagesInMainMemory` [1832] configuration parameter failed, only the error `Failed to memlock pages...` was returned. Now in such cases the operating system's error code is also returned. (Bug #49724)

- Local query handler information was not reported or written to the cluster log correctly. This issue is thought to have been introduced in MySQL Cluster NDB 7.0.10. (Bug #50467)

- Online upgrades from MySQL Cluster NDB 7.0.9b to MySQL Cluster NDB 7.0.10 did not work correctly. Current MySQL Cluster NDB 7.0 users should upgrade directly to MySQL Cluster NDB 7.0.11 or later.

  This issue is not known to have affected MySQL Cluster NDB 6.3, and it should be possible to upgrade from MySQL Cluster NDB 6.3 to MySQL Cluster NDB 7.0.10 without problems. See Upgrade and Downgrade Compatibility: MySQL Cluster NDB 6.x, for more information. (Bug #50433)

- Dropping unique indexes in parallel while they were in use could cause node and cluster failures. (Bug #50118)

- Performing intensive inserts and deletes in parallel with a high scan load could a data node crashes due to a failure in the `DBACC` kernel block. This was because checking for when to perform bucket splits or merges considered the first 4 scans only. (Bug #48700)

- `mysqld` could sometimes crash during a commit while trying to handle NDB Error 4028 `Node failure caused abort of transaction`. (Bug #38577)

- When setting `LockPagesInMainMemory` [1832], the stated memory was not allocated when the node was started, but rather only when the memory was used by the data node process for other reasons. (Bug #37430)

- Trying to insert more rows than would fit into an `NDB` table caused data nodes to crash. Now in such situations, the insert fails gracefully with error 633 `Table fragment hash index has reached maximum possible size`. (Bug #34348)

- The `ARCHIVE` storage engine lost records during a bulk insert. (Bug #46961)

- On Mac OS X or Windows, sending a `SIGHUP` signal to the server or an asynchronous flush (triggered by `flush_time` [475]) caused the server to crash. (Bug #47525)

- When using the `ARCHIVE` storage engine, `SHOW TABLE STATUS` displayed incorrect information for `Max_data_length`, `Data_length` and `Avg_row_length`. (Bug #29203)

Changes in MySQL Cluster NDB 7.0.10 (5.1.39-ndb-7.0.10) (2009-12-15)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.9a.

Obtaining MySQL Cluster NDB 7.0.10. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.39 (see Changes in MySQL 5.1.39 (2009-09-04)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- The output from `ndb_config --configinfo` [1975] `--xml` [1976] now indicates, for each configuration parameter, the following restart type information:

  - Whether a system restart or a node restart is required when resetting that parameter;
  - Whether cluster nodes need to be restarted using the `--initial` option when resetting the parameter.

  (Bug #47366)

- This enhanced functionality is supported for upgrades from MySQL Cluster NDB 6.3 when the `NDB` engine version is 6.3.29 or later. (Bug #48528, Bug #49163)

- Added the `ndb_mgmd --nowait-nodes` [1967] option, which permits a cluster that is configured to use multiple management servers to be started using fewer than the number configured. This is most likely to be useful when a cluster is configured with two management servers and you wish to start the cluster using only one of them.

  See `ndb_mgmd` — The MySQL Cluster Management Server Daemon, for more information. (Bug #48669)

Bugs Fixed

- Node takeover during a system restart occurs when the REDO log for one or more data nodes is out of date, so that a node restart is invoked for that node or those nodes. If this happens while a `mysqld` process is attached to the cluster as an SQL node, the `mysqld` takes a global schema lock (a row lock), while trying to set up cluster-internal replication.

  However, this setup process could fail, causing the global schema lock to be held for an excessive length of time, which made the node restart hang as well. As a result, the mysqld failed to set up cluster-internal replication, which led to tables being read only, and caused one node to hang during the restart.

Note

This issue could actually occur in MySQL Cluster NDB 7.0 only, but the fix was also applied MySQL Cluster NDB 6.3, to keep the two codebases in alignment.

(Bug #49560)

- Starting a `mysqld` process with `--ndb-nodeid` [1916] (either as a command-line option or by assigning it a value in `my.cnf`) caused the `mysqld` to get only the corresponding connection from the `[mysqld]` section in the `config.ini` file having the matching ID, even when connection pooling was enabled (that is, when the `mysqld` process was started with `--ndb-cluster-connection-pool` [1912] set greater than 1). (Bug #48405)

  References: See also Bug #27644, Bug #38590, Bug #41592.

- Attempting to create more than 11435 tables failed with Error 306 (`Out of fragment records in DIH`). (Bug #49156)

- If the master data node receiving a request from a newly started API or data node for a node ID died before the request has been handled, the management server waited (and kept a mutex) until all handling of this node failure was complete before responding to any other connections, instead of responding to other connections as soon as it was informed of the node failure (that is, it waited until it had received a NF_COMPLETEREP signal rather than a NODE_FAILREP signal). On visible effect of this misbehavior was that it caused management client commands such as SHOW and ALL STATUS to respond with unnecessary slowness in such circumstances. (Bug #49207)

- Sending `SIGHUP` to a `mysqld` running with the `--ndbcluster` [1915] and `--log-bin` [1647] options caused the process to crash instead of refreshing its log files. (Bug #49515)

- When evaluating the options `--include-databases` [1999], `--include-tables` [2000], `--exclude-databases` [2001], and `--exclude-tables` [2001], the `ndb_restore` program overwrote the result of the database-level options with the result of the table-level options rather than merging these results together, sometimes leading to unexpected and unpredictable results.

  As part of the fix for this problem, the semantics of these options have been clarified; because of this, the rules governing their evaluation have changed slightly. These changes be summed up as follows:

  - All `--include-*` and `--exclude-*` options are now evaluated from right to left in the order in which they are passed to `ndb_restore`.
  - All `--include-*` and `--exclude-*` options are now cumulative.
  - In the event of a conflict, the first (rightmost) option takes precedence.

  For more detailed information and examples, see `ndb_restore` — Restore a MySQL Cluster Backup. (Bug #48907)

- When performing tasks that generated large amounts of I/O (such as when using `ndb_restore`), an internal memory buffer could overflow, causing data nodes to fail with signal 6.

  Subsequent analysis showed that this buffer was not actually required, so this fix removes it. (Bug #48861)

- Exhaustion of send buffer memory or long signal memory caused data nodes to crash. Now an appropriate error message is provided instead when this situation occurs. (Bug #48852)

- In some situations, when it was not possible for an SQL node to start a schema transaction (necessary, for instance, as part of an online `ALTER TABLE`), `NDBCLUSTER` did not correctly indicate the error to the MySQL server, which led `mysqld` to crash. (Bug #48841)

- When employing NDB native backup to back up and restore an empty NDB table that used a non-sequential AUTO_INCREMENT value, the AUTO_INCREMENT value was not restored correctly. (Bug #48005)

- NDB stores blob column data in a separate, hidden table that is not accessible from MySQL. If this table was missing for some reason (such as accidental deletion of the file corresponding to the hidden table) when making a MySQL Cluster native backup, ndb_restore crashed when attempting to restore the backup. Now in such cases, ndb_restore fails with the error message `Table table_name has blob column (column_name) with missing parts table in backup` instead. (Bug #47289)

- Under certain conditions, accounting of the number of free scan records in the local query handler could be incorrect, so that during node recovery or a local checkpoint operations, the LQH could find itself lacking a scan record that is expected to find, causing the node to crash. (Bug #48697)

  References: See also Bug #48564.

- The creation of an ordered index on a table undergoing DDL operations could cause a data node crash under certain timing-dependent conditions. (Bug #48604)

- When running many parallel scans, a local checkpoint (which performs a scan internally) could find itself not getting a scan record, which led to a data node crash. Now an extra scan record is reserved for this purpose, and a problem with obtaining the scan record returns an appropriate error (error code 489, `Too many active scans`). (Bug #48564)

- During an LCP master takeover, when the newly elected master did not receive a COPY_GCI LCP protocol message but other nodes participating in the local checkpoint had received one, the new master could use an uninitialized variable, which caused it to crash. (Bug #48584)

- When using very large transactions containing many inserts, ndbmtd could fail with `Signal 11` without an easily detectable reason, due to an internal variable being unitialized in the event that the LongMessageBuffer [1825] was overloaded. Now, the variable is initialized in such cases, avoiding the crash, and an appropriate error message is generated. (Bug #48441)

  References: See also Bug #46914.

- `ndb_config --xml --configinfo` now indicates that parameters belonging in the [SCI], [SCI DEFAULT], [SHM], and [SHM DEFAULT] sections of the config.ini file are deprecated or experimental, as appropriate. (Bug #47365)

- During a node restart, logging was enabled on a per-fragment basis as the copying of each fragment was completed but local checkpoints were not enabled until all fragments were copied, making it possible to run out of redo log file space (NDB error code 410) before the restart was complete. Now logging is enabled only after all fragments has been copied, just prior to enabling local checkpoints. (Bug #48474)

- The configuration check that each management server runs to verify that all connected ndb_mgmd processes have the same configuration could fail when a configuration change took place while this check was in progress. Now in such cases, the configuration check is rescheduled for a later time, after the change is complete. (Bug #48143)

- A data node crashing while restarting, followed by a system restart could lead to incorrect handling of redo log metadata, causing the system restart to fail with `Error while reading REDO log`. (Bug #48436)

- Creating an NDB table with an excessive number of large BIT columns caused the cluster to fail. Now, an attempt to create such a table is rejected with error 791 (`Too many total bits in bitfields`). (Bug #42046)

  References: See also Bug #42047.

- In MySQL Cluster NDB 7.0, `ndb_config` and `ndb_error_reporter` were printing warnings about management and data nodes running on the same host to `stdout` instead of `stderr`, as was the case in earlier MySQL Cluster release series. (Bug #44689, Bug #49160)

  References: See also Bug #25941.

- `DROP DATABASE` failed when there were stale temporary `NDB` tables in the database. This situation could occur if `mysqld` crashed during execution of a `DROP TABLE` statement after the table definition had been removed from `NDBCLUSTER` but before the corresponding `.ndb` file had been removed from the crashed SQL node's data directory. Now, when `mysqld` executes `DROP DATABASE`, it checks for these files and removes them if there are no corresponding table definitions for them found in `NDBCLUSTER`. (Bug #44529)

- When a long-running transaction lasting long enough to cause Error 410 (`REDO log files overloaded`) was later committed or rolled back, it could happen that `NDBCLUSTER` was not able to release the space used for the REDO log, so that the error condition persisted indefinitely.

  The most likely cause of such transactions is a bug in the application using MySQL Cluster. This fix should handle most cases where this might occur. (Bug #36500)

- Deprecation and usage information obtained from `ndb_config --configinfo [1975]` regarding the `PortNumber` [1810] and `ServerPort` [1814] configuration parameters was improved. (Bug #24584)

- **Disk Data**: Repeatedly creating and then dropping Disk Data tables could eventually lead to data node failures. (Bug #45794, Bug #48910)

- **Disk Data**: When running a write-intensive workload with a very large disk page buffer cache, CPU usage approached 100% during a local checkpoint of a cluster containing Disk Data tables. (Bug #49532)

- **Disk Data**: `NDBCLUSTER` failed to provide a valid error message it failed to commit schema transactions during an initial start if the cluster was configured using the `InitialLogFileGroup` [1859] parameter. (Bug #48517)

- **Disk Data**: In certain limited cases, it was possible when the cluster contained Disk Data tables for `ndbmtd` to crash during a system restart. (Bug #48498)

  References: See also Bug #47832.

- **Disk Data**: When a crash occurs due to a problem in Disk Data code, the currently active page list is printed to `stdout` (that is, in one or more `ndb_`*`nodeid`*`_out.log` files). One of these lists could contain an endless loop; this caused a printout that was effectively never-ending. Now in such cases, a maximum of 512 entries is printed from each list. (Bug #42431)

- **Disk Data**: When the `FileSystemPathUndoFiles` [1858] configuration parameter was set to an non-existent path, the data nodes shut down with the generic error code 2341 (`Internal program error`). Now in such cases, the error reported is error 2815 (`File not found`).

- **Cluster Replication**: When `expire_logs_days` [474] was set, the thread performing the purge of the log files could deadlock, causing all binary log operations to stop. (Bug #49536)

- **Cluster API**: When a DML operation failed due to a uniqueness violation on an `NDB` table having more than one unique index, it was difficult to determine which constraint caused the failure; it was necessary to obtain an `NdbError` object, then decode its `details` property, which in could lead to memory management issues in application code.

  To help solve this problem, a new API method `Ndb::getNdbErrorDetail()` is added, providing a well-formatted string containing more precise information about the index that caused the unque constraint violation. The following additional changes are also made in the NDB API:

  - Use of `NdbError.details` is now deprecated in favor of the new method.

- The `NdbDictionary::listObjects()` method has been modified to provide more information.

  For more information, see `Ndb::getNdbErrorDetail()`, The `NdbError` Structure, and `Dictionary::listObjects()`. (Bug #48851)

- **Cluster API**: When using blobs, calling `getBlobHandle()` requires the full key to have been set using `equal()`, because `getBlobHandle()` must access the key for adding blob table operations. However, if `getBlobHandle()` was called without first setting all parts of the primary key, the application using it crashed. Now, an appropriate error code is returned instead. (Bug #28116, Bug #48973)

- The `mysql_real_connect()` C API function only attempted to connect to the first IP address returned for a hostname. This could be a problem if a hostname mapped to multiple IP address and the server was not bound to the first one returned. Now `mysql_real_connect()` attempts to connect to all IPv4 or IPv6 addresses that a domain name maps to. (Bug #45017)

  References: See also Bug #47757.

Changes in MySQL Cluster NDB 7.0.9b (5.1.39-ndb-7.0.9b) (2009-11-10)

This release includes a fix for Bug #48651, which was discovered in MySQL Cluster NDB 7.0.9a shortly after release. The MySQL Cluster NDB 7.0.9b release is identical in all other respects to MySQL Cluster NDB 7.0.9a. Users who have already installed MySQL Cluster NDB 7.0.9a should upgrade to MySQL Cluster NDB 7.0.9b as soon as possible; users seeking to upgrade from any other previous MySQL Cluster 7.0 release should upgrade to MySQL Cluster NDB 7.0.9b instead.

Obtaining MySQL Cluster NDB 7.0.9b. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.39 (see Changes in MySQL 5.1.39 (2009-09-04)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- Using a large number of small fragment log files could cause `NDBCLUSTER` to crash while trying to read them during a restart. This issue was first observed with 1024 fragment log files of 16 MB each. (Bug #48651)

Changes in MySQL Cluster NDB 7.0.9a (5.1.39-ndb-7.0.9a) (2009-11-05)

Important

MySQL Cluster NDB 7.0.9a was pulled shortly after release due to Bug #48651. Users seeking to upgrade from a previous MySQL Cluster NDB 7.0 release should instead use MySQL Cluster NDB 7.0.9b, which contains a fix for this bug, in addition to all bugfixes and improvements made in MySQL Cluster NDB 7.0.9a.

This release includes a fix for Bug #48531, which was discovered in MySQL Cluster NDB 7.0.9 shortly after release. The MySQL Cluster NDB 7.0.9a release is identical in all other respects to MySQL

Cluster NDB 7.0.9. Users who have already installed MySQL Cluster NDB 7.0.9 should upgrade to MySQL Cluster NDB 7.0.9a as soon as possible; users seeking to upgrade from any other previous MySQL Cluster 7.0 release should upgrade to MySQL Cluster NDB 7.0.9a instead.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.39 (see Changes in MySQL 5.1.39 (2009-09-04)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- When the combined length of all names of tables using the `NDB` storage engine was greater than or equal to 1024 bytes, issuing the `START BACKUP` command in the `ndb_mgm` client caused the cluster to crash. (Bug #48531)

Changes in MySQL Cluster NDB 7.0.9 (5.1.39-ndb-7.0.9) (2009-10-31)

Important

MySQL Cluster NDB 7.0.9 and 7.0.9a were pulled shortly after being released due to Bug #48531 and Bug #48651. Users seeking to upgrade from a previous MySQL Cluster NDB 7.0 release should instead use MySQL Cluster NDB 7.0.9b, which contains fixes for these critical bugs, in addition to all bugfixes and improvements made in MySQL Cluster NDB 7.0.9.

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.8a.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.39 (see Changes in MySQL 5.1.39 (2009-09-04)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Performance**: Significant improvements in redo log handling and other file system operations can yield a considerable reduction in the time required for restarts. While actual restart times observed in a production setting will naturally vary according to database size, hardware, and other conditions, our own preliminary testing shows that these optimizations can yield startup times that are faster than those typical of previous MySQL Cluster releases by a factor of 50 or more.

Bugs Fixed

- **Important Change**: The `--with-ndb-port-base` option for `configure` did not function correctly, and has been deprecated. Attempting to use this option produces the warning `Ignoring deprecated option --with-ndb-port-base`.

  Beginning with MySQL Cluster NDB 7.1.0, the deprecation warning itself is removed, and the `--with-ndb-port-base` option is simply handled as an unknown and invalid option if you try to use it. (Bug #47941)

  References: See also Bug #38502.

- For `UPDATE IGNORE` statements, batching of updates is now disabled. This is because such statements failed when batching of updates was employed if any updates violated a unique constraint, to the fact a unique constraint violation could not be handled without aborting the transaction. (Bug #48036)

- When an `UPDATE` statement was issued against an `NDB` table where an index was used to identify rows but no data was actually changed, the `NDB` storage returned zero found rows.

  For example, consider the table created and populated using these statements:

  ```
  CREATE TABLE t1
  (
      c1 INT NOT NULL,
      c2 INT NOT NULL,
      PRIMARY KEY(c1),
      KEY(c2)
  )
  ENGINE = NDB;

  INSERT INTO t1 VALUES(1, 1);
  ```

  The following `UPDATE` statements, even though they did not change any rows, each still matched a row, but this was reported incorrectly in both cases, as shown here:

  ```
  mysql> UPDATE t1 SET c2 = 1 WHERE c1 = 1;
  Query OK, 0 rows affected (0.00 sec)
  Rows matched: 0  Changed: 0  Warnings: 0

  mysql> UPDATE t1 SET c1 = 1 WHERE c2 = 1;
  Query OK, 0 rows affected (0.00 sec)
  Rows matched: 0  Changed: 0  Warnings: 0
  ```

  Now in such cases, the number of rows matched is correct. (In the case of each of the example `UPDATE` statements just shown, this is displayed as Rows matched: 1, as it should be.)

  This issue could affect `UPDATE` statements involving any indexed columns in `NDB` tables, regardless of the type of index (including `KEY`, `UNIQUE KEY`, and `PRIMARY KEY`) or the number of columns covered by the index. (Bug #47955)

- After upgrading a MySQL Cluster containing tables having unique indexes from an NDB 6.3 release to an NDB 7.0 release, attempts to create new unique indexes failed with `inconsistent trigger` errors (error code `293`).

  For more information (including a workaround for previous MySQL Cluster NDB 7.0 releases), see Upgrade and downgrade compatibility: MySQL Cluster NDB 7.x. (Bug #48416)

- When a data node failed to start due to inability to recreate or drop objects during schema restoration (for example: insufficient memory was available to the data node process on account of issues not directly related to MySQL Cluster on the host machine), the reason for the failure was not provided. Now is such cases, a more informative error message is logged. (Bug #48232)

- A table that was created following an upgrade from a MySQL Cluster NDB 6.3 release to MySQL Cluster NDB 7.0 (starting with version 6.4.0) or later was dropped by a system restart. This was due to a change in the format of `NDB` schema files and the fact that the upgrade of the format of existing `NDB` 6.3 schema files to the `NDB` 7.0 format failed to change the version number contained in the file; this meant that a system restart re-ran the upgrade routine, which interpreted the newly created table as an uncommitted table (which by definition ought not to be saved). Now the version number of upgraded `NDB` 6.3 schema files is set correctly during the upgrade process. (Bug #48227)

- In certain cases, performing very large inserts on `NDB` tables when using `ndbmtd` caused the memory allocations for ordered or unique indexes (or both) to be exceeded. This could cause aborted transactions and possibly lead to data node failures. (Bug #48037)

  References: See also Bug #48113.

- Performing a system restart of the cluster after having performed a table reorganization which added partitions caused the cluster to become inconsistent, possibly leading to a forced shutdown, in either of the following cases:

  1. When a local checkpoint was in progress but had not yet completed, new partitions were not restored; that is, data that was supposed to be moved could be lost instead, leading to an inconsistent cluster. This was due to an issue whereby the `DBDIH` kernel block did not save the new table definition and instead used the old one (the version having fewer partitions).

  2. When the most recent LCP had completed, ordered indexes and unlogged tables were still not saved (since these did not participate in the LCP). In this case, the cluster crashed during a subsequent system restart, due to the inconsistency between the main table and the ordered index.

  Now, `DBDIH` is forced in such cases to use the version of the table definition held by the `DBDICT` kernel block, which was (already) correct and up to date. (Bug #46585)

- `SHOW CREATE TABLE` did not display the `AUTO_INCREMENT` value for `NDB` tables having `AUTO_INCREMENT` columns. (Bug #47865)

- In some cases, `ndbmtd` could allocate more space for the undo buffer than was actually available, leading to a failure in the `LGMAN` kernel block and subsequent failure of the data node. (Bug #47966)

- Starting a data node with a very large amount of `DataMemory` [1817] (approximately 90G or more) could lead to crash of the node due to job buffer congestion. (Bug #47984)

- On Solaris, shutting down a management node failed when issuing the command to do so from a client connected to a different management node. (Bug #47948)

- After changing the value of `DiskSyncSize` [1842] to 4294967039 (the maximum) in the `config.ini` file and reloading the cluster configuration, the new value was displayed in the update information written into the cluster log as a signed number instead of unsigned. (Bug #47944)

  References: See also Bug #47932.

- On Solaris 10 for SPARC, `ndb_mgmd` failed to parse the `config.ini` file when the `DiskSyncSize` [1842] configuration parameter, whose permitted range of values is 32768 to 4294967039, was set equal to 4294967040 (which is also the value of the internal constant `MAX_INT_RNIL`), nor could `DiskSyncSize` [1842] be set successfully any higher than the minimum value. (Bug #47932)

  References: See also Bug #47944.

- Setting `FragmentLogFileSize` [1826] to a value greater than 256 MB led to errors when trying to read the redo log file. (Bug #47908)

- `ndb_mgmd` failed to close client connections that had timed out. After running for some time, a race condition could develop in the management server, due to `ndb_mgmd` having exhausted all of its file descriptors in this fashion. (Bug #45497)

  References: See also Bug #47712.

- An optimization in MySQL Cluster NDB 7.0 causes the `DBDICT` kernel block to copy several tables at a time when synchronizing the data dictionary to a newly started node; previously, this was done one table at a time. However, when `NDB` tables were sufficiently large and numerous, the internal buffer for storing them could fill up, causing a data node crash.

  In testing, it was found that having 100 `NDB` tables with 128 columns each was enough to trigger this issue. (Bug #47859)

- When starting a node and synchronizing tables, memory pages were allocated even for empty fragments. In certain situations, this could lead to insufficient memory. (Bug #47782)

- Under some circumstances, when a scan encountered an error early in processing by the DBTC kernel block (see The DBTC Block), a node could crash as a result. Such errors could be caused by applications sending incorrect data, or, more rarely, by a DROP TABLE operation executed in parallel with a scan. (Bug #47831)

- In some cases, the MySQL Server tried to use an error status whose value had never been set. The problem in the code that caused this, in hostname.cc, manifested when using debug builds of mysqld in MySQL Cluster replication.

  This fix brings MySQL Cluster's error handling in hostname.cc in line with what is implemented in MySQL 5.4. (Bug #47548)

- During an upgrade, newer nodes (NDB kernel block DBTUP) could in some cases try to use the long signal format for communication with older nodes (DBUTIL kernel block) that did not understand the newer format, causing older data nodes to fail after restarting. (Bug #47740)

- configure failed to honor the --with-zlib-dir option when trying to build MySQL Cluster from source. (Bug #47223)

- A very small race-condition between NODE_FAILREP and LQH_TRANSREQ signals when handling node failure could lead to operations (locks) not being taken over when they should have been, and subsequently becoming stale. This could lead to node restart failures, and applications getting into endless lock-conflicts with operations that were not released until the node was restarted. (Bug #47715)

  References: See also Bug #41297.

- ndbd was not built correctly when compiled using gcc 4.4.0. (The ndbd binary was built, but could not be started.) (Bug #46113)

- When starting a cluster with a great many tables, it was possible for MySQL client connections as well as the slave SQL thread to issue DML statements against MySQL Cluster tables before mysqld had finished connecting to the cluster and making all tables writeable. This resulted in Table ... is read only errors for clients and the Slave SQL thread.

  This issue is fixed by introducing the --ndb-wait-setup [1919] option for the MySQL server. This provides a configurable maximum amount of time that mysqld waits for all NDB tables to become writeable, before enabling MySQL clients or the slave SQL thread to connect. (Bug #40679)

  References: See also Bug #46955.

- When building MySQL Cluster, it was possible to configure the build using --with-ndb-port without supplying a port number. Now in such cases, configure fails with an error. (Bug #38502)

  References: See also Bug #47941.

- If a node failed while sending a fragmented long signal, the receiving node did not free long signal assembly resources that it had allocated for the fragments of the long signal that had already been received. (Bug #44607)

- Numeric configuration parameters set in my.cnf were interpreted as signed rather than unsigned values. The effect of this was that values of 2G or more were truncated with the warning [MgmSrvr] Warning: option '*opt_name*': signed value *opt_value* adjusted to 2147483647. Now such parameter values are treated as unsigned, so that this truncation does not take place.

  This issue did not effect parameters set in config.ini. (Bug #44448)

- When a copying operation exhausted the available space on a data node while copying large BLOB columns, this could lead to failure of the data node and a Table is full error on the SQL node which was executing the operation. Examples of such operations could include an ALTER TABLE that changed an INT column to a BLOB column, or a bulk insert of BLOB data that failed due to running out of space or to a duplicate key error. (Bug #34583, Bug #48040)

References: See also Bug #41674, Bug #45768.

- When the MySQL server SQL mode included `STRICT_TRANS_TABLES` [576], storage engine warnings and error codes specific to `NDB` were returned when errors occurred, instead of the MySQL server errors and error codes expected by some programming APIs (such as Connector/J) and applications. (Bug #35990)

- **Replication**: When `mysqlbinlog --verbose` [354] was used to read a binary log that had been written using row-based format, the output for events that updated some but not all columns of tables was not correct. (Bug #47323)

- **Disk Data**: A local checkpoint of an empty fragment could cause a crash during a system restart which was based on that LCP. (Bug #47832)

  References: See also Bug #41915.

- **Disk Data**: Multi-threaded data nodes could in some cases attempt to access the same memory structure in parallel, in a non-safe manner. This could result in data node failure when running `ndbmtd` while using Disk Data tables. (Bug #44195)

  References: See also Bug #46507.

- **Cluster Replication**: When using multiple active replication channels, it was sometimes possible that a node group would fail on the slave cluster, causing the slave cluster to shut down. (Bug #47935)

- **Cluster Replication**: When recording a binary log using the `--ndb-log-update-as-write` [2143] and `--ndb-log-updated-only` [2143] options (both enabled by default) and later attempting to apply that binary log with `mysqlbinlog`, any operations that were played back from the log but which updated only some (but not all) columns caused any columns that were not updated to be reset to their default values. (Bug #47674)

  References: See also Bug #47323, Bug #46662.

- **Cluster Replication**: `mysqlbinlog` failed to apply correctly a binary log that had been recorded using `--ndb-log-update-as-write=1` [2143]. (Bug #46662)

  References: See also Bug #47323, Bug #47674.

- **Cluster API**: If an NDB API program reads the same column more than once, it is possible exceed the maximum permissible message size, in which case the operation should be aborted due to NDB error 880 `Tried to read too much - too many getValue calls`, however due to a change introduced in MySQL Cluster NDB 6.3.18, the check for this was not done correctly, which instead caused a data node crash. (Bug #48266)

- **Cluster API**: The NDB API methods `Dictionary::listEvents()`, `Dictionary::listIndexes()`, `Dictionary::listObjects()`, and `NdbOperation::getErrorLine()` formerly had both `const` and non-`const` variants. The non-`const` versions of these methods have been removed. In addition, the `NdbOperation::getBlobHandle()` method has been re-implemented to provide consistent internal semantics. (Bug #47798)

- **Cluster API**: A duplicate read of a column caused NDB API applications to crash. (Bug #45282)

- **Cluster API**: The error handling shown in the example file `ndbapi_scan.cpp` included with the MySQL Cluster distribution was incorrect. (Bug #39573)

- Installation of MySQL on Windows would fail to set the correct location for the character set files, which could lead to `mysqld` and `mysql` failing to initialize properly. (Bug #17270)

Changes in MySQL Cluster NDB 7.0.8a (5.1.37-ndb-7.0.8a) (2009-10-07)

This release includes a fix for Bug #47844, which was discovered in MySQL Cluster NDB 7.0.8 shortly after release. The MySQL Cluster NDB 7.0.8a release is identical in all other respects to MySQL Cluster NDB 7.0.8. Users who have already installed MySQL Cluster NDB 7.0.8 should upgrade to MySQL Cluster NDB 7.0.8a as soon as possible; users seeking to upgrade from MySQL Cluster NDB 7.0.7 or another previous MySQL Cluster 7.0 release should upgrade to MySQL Cluster NDB 7.0.8a instead.

Obtaining MySQL Cluster NDB 7.0.8a. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.37 (see Changes in MySQL 5.1.37 (2009-07-13)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- The disconnection of an API or SQL node having a node ID greater than 49 caused a forced shutdown of the cluster. (Bug #47844)
- The error message text for `NDB` error code 410 (`REDO log files overloaded...`) was truncated. (Bug #23662)

Changes in MySQL Cluster NDB 7.0.8 (5.1.37-ndb-7.0.8) (2009-09-30)

Important

MySQL Cluster NDB 7.0.8 was pulled shortly after release due to Bug #47844. Users seeking to upgrade from a previous MySQL Cluster NDB 7.0 release should instead use MySQL Cluster NDB 7.0.8a, which contains a fix for this bug, in addition to all bugfixes and improvements made in MySQL Cluster NDB 7.0.8.

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.7.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.37 (see Changes in MySQL 5.1.37 (2009-07-13)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- A new option `--log-name` [1965] is added for `ndb_mgmd`. This option can be used to provide a name for the current node and then to identify it in messages written to the cluster log. For more information, see `ndb_mgmd` — The MySQL Cluster Management Server Daemon. (Bug #47643)
- `--config-dir` is now accepted by `ndb_mgmd` as an alias for the `--configdir` [1963] option. (Bug #42013)

- **Disk Data**: Two new columns have been added to the output of `ndb_desc` to make it possible to determine how much of the disk space allocated to a given table or fragment remains free. (This information is not available from the `INFORMATION_SCHEMA.FILES` table, since the `FILES` table applies only to Disk Data files.) For more information, see `ndb_desc` — Describe NDB Tables. (Bug #47131)

Bugs Fixed

- **Important Change**: Previously, the MySQL Cluster management node and data node programs, when run on Windows platforms, required the `--nodaemon` option to produce console output. Now, these programs run in the foreground when invoked from the command line on Windows, which is the same behavior that `mysqld.exe` displays on Windows. (Bug #45588)

- **Cluster Replication**: **Important Change**: In a MySQL Cluster acting as a replication slave and having multiple SQL nodes, only the SQL node receiving events directly from the master recorded DDL statements in its binary logs unless this SQL node also had binary logging enabled; otherwise, other SQL nodes in the slave cluster failed to log DDL statements, regardless of their individual `--log-bin` [1647] settings.

  The fix for this issue aligns binary logging of DDL statements with that of DML statements. In particular, you should take note of the following:

  - DDL and DML statements on the master cluster are logged with the server ID of the server that actually writes the log.
  - DDL and DML statements on the master cluster are logged by any attached `mysqld` that has binary logging enabled.
  - Replicated DDL and DML statements on the slave are logged by any attached mysqld that has both `--log-bin` [1647] and `--log-slave-updates` [1628] enabled.
  - Replicated DDL and DML statements are logged with the server ID of the original (master) MySQL server by any attached `mysqld` that has both `--log-bin` [1647] and `--log-slave-updates` [1628] enabled.

  Affect on upgrades. When upgrading from a previous MySQL CLuster release, you should perform either one of the following:

  a. Upgrade servers that are performing binary logging before those that are not; do not perform any DDL on “old” SQL nodes until all SQL nodes have been upgraded.

  b. Make sure that `--log-slave-updates` [1628] is enabled on all SQL nodes performing binary logging prior to the upgrade, so that all DDL is captured.

  Note

  Logging of DML statements was not affected by this issue.

  (Bug #45756)

- When reloading the management server configuration, only the last changed parameter was logged. (Bug #47036)

- Now, when started with `--initial` [1965] `--reload` [1966], `ndb_mgmd` tries to connect to and to copy the configuration of an existing `ndb_mgmd` process with a confirmed configuration. This works only if another management server is found, and the configuration files used by both management nodes are exactly the same.

  If no other management server is found, the local configuration file is read and used. With this change, it is now necessary when performing a rolling restart of a MySQL Cluster having multiple management nodes, to stop all `ndb_mgmd` processes, and when restarting them, to start the first of

these with the `--reload` [1966] or `--initial` [1965] option (or both options), and then to start any remaining management nodes without using either of these two options. For more information, see Performing a Rolling Restart of a MySQL Cluster. (Bug #45495, Bug #46488, Bug #11753966, Bug #11754823)

References: See also Bug #42015, Bug #11751233.

- The NDB kernel's parser (in `ndb/src/common/util/Parser.cpp`) did not interpret the backslash ("`\`") character correctly. (Bug #47426)

- The following issues with error logs generated by `ndbmtd` were addressed:

  1. The version string was sometimes truncated, or even not shown, depending on the number of threads in use (the more threads, the worse the problem). Now the version string is shown in full, as well as the file names for all tracefiles (where available).

  2. In the event of a crash, the thread number of the thread that crashed was not printed. Now this information is supplied, if available.

  (Bug #47629)

- `mysqld` allocated an excessively large buffer for handling `BLOB` values due to overestimating their size. (For each row, enough space was allocated to accommodate *every* `BLOB` or `TEXT` column value in the result set.) This could adversely affect performance when using tables containing `BLOB` or `TEXT` columns; in a few extreme cases, this issue could also cause the host system to run out of memory unexpectedly. (Bug #47574)

  References: See also Bug #47572, Bug #47573.

- `NDBCLUSTER` uses a dynamically allocated buffer to store `BLOB` or `TEXT` column data that is read from rows in MySQL Cluster tables.

  When an instance of the `NDBCLUSTER` table handler was recycled (this can happen due to table definition cache pressure or to operations such as `FLUSH TABLES` or `ALTER TABLE`), if the last row read contained blobs of zero length, the buffer was not freed, even though the reference to it was lost. This resulted in a memory leak.

  For example, consider the table defined and populated as shown here:

  ```
  CREATE TABLE t (a INT PRIMARY KEY, b LONGTEXT) ENGINE=NDB;

  INSERT INTO t VALUES (1, REPEAT('F', 20000));
  INSERT INTO t VALUES (2, '');
  ```

  Now execute repeatedly a `SELECT` on this table, such that the zero-length `LONGTEXT` row is last, followed by a `FLUSH TABLES` statement (which forces the handler object to be re-used), as shown here:

  ```

  SELECT a, length(b) FROM bl ORDER BY a;
  FLUSH TABLES;
  ```

  Prior to the fix, this resulted in a memory leak proportional to the size of the stored `LONGTEXT` value each time these two statements were executed. (Bug #47573)

  References: See also Bug #47572, Bug #47574.

- Large transactions involving joins between tables containing `BLOB` columns used excessive memory. (Bug #47572)

  References: See also Bug #47573, Bug #47574.

- After an NDB table had an ALTER ONLINE TABLE operation performed on it in a MySQL Cluster running a MySQL Cluster NDB 6.3.x release, it could not be upgraded online to a MySQL Cluster NDB 7.0.x release. This issue was detected using MySQL Cluster NDB 6.3.20, but is likely to effect any MySQL Cluster NDB 6.3.x release supporting online DDL operations. (Bug #47542)
- When using multi-threaded data nodes (ndbmtd) with NoOfReplicas [1815] set to a value greater than 2, attempting to restart any of the data nodes caused a forced shutdown of the entire cluster. (Bug #47530)
- A variable was left uninitialized while a data node copied data from its peers as part of its startup routine; if the starting node died during this phase, this could lead a crash of the cluster when the node was later restarted. (Bug #47505)
- Handling of LQH_TRANS_REQ signals was done incorrectly in DBLQH when the transaction coordinator failed during a LQH_TRANS_REQ session. This led to incorrect handling of multiple node failures, particularly when using ndbmtd. (Bug #47476)
- When using ndbmtd, a parallel DROP TABLE operation could cause data nodes to have different views of which tables should be included in local checkpoints; this discrepancy could lead to a node failure during an LCP. (Bug #46873)
- During an online alter table operation, the new table definition was made available for users during the prepare-phase when it should only be exposed during and after a commit. This issue could affect NDB API applications, mysqld processes, or data node processes. (Bug #47375)
- Aborting an online add column operation (for example, due to resource problems on a single data node, but not others) could lead to a forced node shutdown. (Bug #47364)
- On Windows, ndbd --initial [1954] could hang in an endless loop while attempting to remove directories. (Bug #45402)
- When a data node restarts, it first runs the redo log until reaching the latest restorable global checkpoint; after this it scans the remainder of the redo log file, searching for entries that should be invalidated so they are not used in any subsequent restarts. (It is possible, for example, if restoring GCI number 25, that there might be entries belonging to GCI 26 in the redo log.) However, under certain rare conditions, during the invalidation process, the redo log files themselves were not always closed while scanning ahead in the redo log. In rare cases, this could lead to MaxNoOfOpenFiles [1827] being exceeded, causing a the data node to crash. (Bug #47171)
- Clients attempting to connect to the cluster during shutdown could sometimes cause the management server to crash. (Bug #47325)
- Using triggers on NDB tables caused ndb_autoincrement_prefetch_sz [1921] to be treated as having the NDB kernel's internal default value (32) and the value for this variable as set on the cluster's SQL nodes to be ignored. (Bug #46712)
- The size of the table descriptor pool used in the DBTUP kernel block was incorrect. This could lead to a data node crash when an LQH sent a CREATE_TAB_REF signal. (Bug #47215)

  References: See also Bug #44908.
- For very large values of MaxNoOfTables [1829] + MaxNoOfAttributes [1828], the calculation for StringMemory [1819] could overflow when creating large numbers of tables, leading to NDB error 773 (Out of string memory, please modify StringMemory config parameter), even when StringMemory [1819] was set to 100 (100 percent). (Bug #47170)
- The default value for the StringMemory [1819] configuration parameter, unlike other MySQL Cluster configuration parameters, was not set in ndb/src/mgmsrv/ConfigInfo.cpp. (Bug #47166)
- Signals from a failed API node could be received after an API_FAILREQ signal (see Operations and Signals) has been received from that node, which could result in invalid states for processing

subsequent signals. Now, all pending signals from a failing API node are processed before any API_FAILREQ signal is received. (Bug #47039)

References: See also Bug #44607.

- When started with the --initial [1965] and --reload [1966] options, if ndb_mgmd could not find a configuration file or connect to another management server, it appeared to hang. Now, when trying to fetch its configuration from another management node, ndb_mgmd checks and signals (Trying to get configuration from other mgmd(s)) each 30 seconds that it has not yet done so. (Bug #42015)

  References: See also Bug #45495.

- When performing auto-discovery of tables on individual SQL nodes, NDBCLUSTER attempted to overwrite existing MyISAM .frm files and corrupted them.

  Workaround. In the mysql client, create a new table (t2) with same definition as the corrupted table (t1). Use your system shell or file manager to rename the old .MYD file to the new file name (for example, mv t1.MYD t2.MYD). In the mysql client, repair the new table, drop the old one, and rename the new table using the old file name (for example, RENAME TABLE t2 TO t1).

  (Bug #42614)

- When a data node received a TAKE_OVERTCCONF signal from the master before that node had received a NODE_FAILREP, a race condition could in theory result. (Bug #37688)

  References: See also Bug #25364, Bug #28717.

- Running an ALTER TABLE statement while an NDB backup was in progress caused mysqld to crash. (Bug #44695)

- Running ndb_restore with the --print or --print_log option could cause it to crash. (Bug #40428, Bug #33040)

- An insert on an NDB table was not always flushed properly before performing a scan. One way in which this issue could manifest was that LAST_INSERT_ID() [1036] sometimes failed to return correct values when using a trigger on an NDB table. (Bug #38034)

- For multi-threaded data nodes, insufficient fragment records were allocated in the DBDIH NDB kernel block, which could lead to error 306 when creating many tables; the number of fragment records allocated did not take into account the number of LQH instances. (Bug #44908)

- Some joins on large NDB tables having TEXT or BLOB columns could cause mysqld processes to leak memory. The joins did not need to reference the TEXT or BLOB columns directly for this issue to occur. (Bug #36701)

- On Mac OS X 10.5, commands entered in the management client failed and sometimes caused the client to hang, although management client commands invoked using the --execute [1970] (or -e) option from the system shell worked normally.

  For example, the following command failed with an error and hung until killed manually, as shown here:

  ```
  ndb_mgm> SHOW
  Warning, event thread startup failed, degraded printouts as result, errno=36
  ^C
  ```

  However, the same management client command, invoked from the system shell as shown here, worked correctly:

  ```
  shell> ndb_mgm -e "SHOW"
  ```

  (Bug #35751)

References: See also Bug #34438.

- **Replication**: In some cases, a `STOP SLAVE` statement could cause the replication slave to crash. This issue was specific to MySQL on Windows or Macintosh platforms. (Bug #45238, Bug #45242, Bug #45243, Bug #46013, Bug #46014, Bug #46030)

  References: See also Bug #40796.

- **Disk Data**: Calculation of free space for Disk Data table fragments was sometimes done incorrectly. This could lead to unnecessary allocation of new extents even when sufficient space was available in existing ones for inserted data. In some cases, this might also lead to crashes when restarting data nodes.

  Note

  This miscalculation was not reflected in the contents of the `INFORMATION_SCHEMA.FILES` table, as it applied to extents allocated to a fragment, and not to a file.

  (Bug #47072)

- **Cluster API**: In some circumstances, if an API node encountered a data node failure between the creation of a transaction and the start of a scan using that transaction, then any subsequent calls to `startTransaction()` and `closeTransaction()` could cause the same transaction to be started and closed repeatedly. (Bug #47329)

- **Cluster API**: Performing multiple operations using the same primary key within the same `NdbTransaction::execute()` call could lead to a data node crash.

  Note

  This fix does not make change the fact that performing multiple operations using the same primary key within the same `execute()` is not supported; because there is no way to determine the order of such operations, the result of such combined operations remains undefined.

  (Bug #44065)

  References: See also Bug #44015.

- **API**: The fix for Bug #24507 could lead in some cases to client application failures due to a race condition. Now the server waits for the “dummy” thread to return before exiting, thus making sure that only one thread can initialize the POSIX threads library. (Bug #42850)

Changes in MySQL Cluster NDB 7.0.7 (5.1.35-ndb-7.0.7) (2009-08-26)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.6.

Obtaining MySQL Cluster NDB 7.0.7. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.35 (see Changes in MySQL 5.1.35 (2009-05-13)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Important Change**: The default value of the `DiskIOThreadPool` [1857] data node configuration parameter has changed from 8 to 2.
- On Solaris platforms, the MySQL Cluster management server and NDB API applications now use `CLOCK_REALTIME` as the default clock. (Bug #46183)
- A new option `--exclude-missing-columns` has been added for the `ndb_restore` program. In the event that any tables in the database or databases being restored to have fewer columns than the same-named tables in the backup, the extra columns in the backup's version of the tables are ignored. For more information, see `ndb_restore` — Restore a MySQL Cluster Backup. (Bug #43139)
- Formerly, node IDs were represented in the cluster log using a complex hexadecimal/binary encoding scheme. Now, node IDs are reported in the cluster log using numbers in standard decimal notation. (Bug #44248)
-

  Note

  This issue, originally resolved in MySQL 5.1.16, re-occurred due to a later (unrelated) change. The fix has been re-applied.

  (Bug #25984)
- Previously, it was possible to disable arbitration only by setting `ArbitrationRank` to 0 on all management and API nodes. A new data node configuration parameter `Arbitration` [1844] simplifies this task; to disable arbitration, you can now use `Arbitration = Disabled` in the `[ndbd default]` section of the `config.ini` file.

  It is now also possible to configure arbitration in such a way that the cluster waits until the time determined by `ArbitrationTimeout` [1844] passes for an external manager to perform arbitration instead of handling it internally. This can be done by setting `Arbitration = WaitExternal` in the `[ndbd default]` section of the `config.ini` file.

  The default value for the Arbitration parameter is `Default`, which permits arbitration to proceed normally, as determined by the `ArbitrationRank` settings for the management and API nodes.

  For more information, see Defining MySQL Cluster Data Nodes.

Bugs Fixed

- **Important Change**: The IPv6 loopback address `::1` was interpreted as a hostname rather than a numeric IP address.

  In addition, the IPv6-enabled server on Windows interpreted the hostname `localhost` as `::1` only, which failed to match the default `'root'@'127.0.0.1'` account in the `mysql.user` privilege table.

  Note

  As a result of this fix, a `'root'@'::1'` account is added to the `mysql.user` table as one of the default accounts created during MySQL installation.

  (Bug #43006)

  References: See also Bug #38247, Bug #11753779, Bug #45584, Bug #45606.

- **Packaging**: The `pkg` installer for MySQL Cluster on Solaris did not perform a complete installation due to an invalid directory reference in the postinstall script. (Bug #41998)
- The output from `ndb_config --configinfo` [1975] `--xml` [1975] contained quote characters (`"`) within quoted XML attributes, causing it to be not well-formed. (Bug #46891)
- When using multi-threaded data node processes (`ndbmtd`), it was possible for LQH threads to continue running even after all `NDB` tables had been dropped. This meant that dropping the last remaining `NDB` table during a local checkpoint could cause multi-threaded data nodes to fail. (Bug #46890)
- During a global checkpoint, LQH threads could run unevenly, causing a circular buffer overflow by the Subscription Manager, which led to data node failure. (Bug #46782)

  References: See also Bug #46123, Bug #46723, Bug #45612.
- Killing MySQL Cluster nodes immediately following a local checkpoint could lead to a crash of the cluster when later attempting to perform a system restart.

  The exact sequence of events causing this issue was as follows:

  1. Local checkpoint occurs.
  2. Immediately following the LCP, kill the master data node.
  3. Kill the remaining data nodes within a few seconds of killing the master.
  4. Attempt to restart the cluster.

  (Bug #46412)
- Restarting the cluster following a local checkpoint and an online `ALTER TABLE` on a non-empty table caused data nodes to crash. (Bug #46651)
- A combination of index creation and drop operations (or creating and dropping tables having indexes) with node and system restarts could lead to a crash. (Bug #46552)
- Creating an index when the cluster had run out of table records could cause data nodes to crash. (Bug #46295)
- When combining an index scan and a delete with a primary key delete, the index scan and delete failed to initialize a flag properly. This could in rare circumstances cause a data node to crash. (Bug #46069)
- Following an upgrade from MySQL Cluster NDB 6.3.x to MySQL Cluster NDB 7.0.6, DDL and backup operations failed. (Bug #46494, Bug #46563)
- Full table scans failed to execute when the cluster contained more than 21 table fragments.

  Note

  The number of table fragments in the cluster can be calculated as the number of data nodes, times 8 (that is, times the value of the internal constant `MAX_FRAG_PER_NODE`), divided by the number of replicas. Thus, when `NoOfReplicas = 1` at least 3 data nodes were required to trigger this issue, and when `NoOfReplicas = 2` at least 4 data nodes were required to do so.

  (Bug #46490)
- `OPTIMIZE TABLE` on an `NDB` table could in some cases cause SQL and data nodes to crash. This issue was observed with both `ndbd` and `ndbmtd`. (Bug #45971)

- Ending a line in the `config.ini` file with an extra semicolon character (`;`) caused reading the file to fail with a parsing error. (Bug #46242)
- On Windows, the internal `basestring_vsprintf()` function did not return a POSIX-compliant value as expected, causing the management server to crash when trying to start a MySQL Cluster with more than 4 data nodes. (Bug #45733)
- The `AutoReconnect` [1867] configuration parameter for API nodes (including SQL nodes) has been added. This is intended to prevent API nodes from re-using allocated node IDs during cluster restarts. For more information, see Defining SQL and Other API Nodes in a MySQL Cluster.

  This fix also introduces two new methods of the NDB API `Ndb_cluster_connection` class: `set_auto_reconnect()` and `get_auto_reconnect()`. (Bug #45921)
- DML statements run during an upgrade from MySQL Cluster NDB 6.3 to NDB 7.0 were not handled correctly. (Bug #45917)
- The signals used by `ndb_restore` to send progress information about backups to the cluster log accessed the cluster transporter without using any locks. Because of this, it was theoretically possible that these signals could be interefered with by heartbeat signals if both were sent at the same time, causing the `ndb_restore` messages to be corrupted. (Bug #45646)
- Due to changes in the way that `NDBCLUSTER` handles schema changes (implementation of schema transactions) in MySQL Cluster NDB 7.0, it was not possible to create MySQL Cluster tables having more than 16 indexes using a single `CREATE TABLE` statement.

  This issue occurs only in MySQL Cluster NDB 7.0 releases prior to 7.0.7 (including releases numbered NDB 6.4.x).

  If you are not yet able to upgrade from an earlier MySQL Cluster NDB 7.0 release, you can work around this problem by creating the table without any indexes, then adding the indexes using a separate `CREATE INDEX` statement for each index. (Bug #45525)
- `storage/ndb/src/common/util/CMakeLists.txt` did not build the `BaseString-t` test program for Windows as the equivalent `storage/ndb/src/common/util/Makefile.am` does when building MySQL Cluster on Unix platforms. (Bug #45099)
- The warning message `Possible bug in Dbdih::execBLOCK_COMMIT_ORD ...` could sometimes appear in the cluster log. This warning is obsolete, and has been removed. (Bug #44563)
- `ALTER TABLE REORGANIZE PARTITION` could fail with Error 741 (`Unsupported alter table`) if the appropriate hash-map was not present. This could occur when adding nodes online; for example, when going from 2 data nodes to 3 data nodes with `NoOfReplicas=1`, or from 4 data nodes to 6 data nodes with `NoOfReplicas=2`. (Bug #44301)
- In some cases, `OPTIMIZE TABLE` on an `NDB` table did not free any `DataMemory` [1817]. (Bug #43683)
- Problems could arise when using `VARCHAR` columns whose size was greater than 341 characters and which used the `utf8_unicode_ci` collation. In some cases, this combination of conditions could cause certain queries and `OPTIMIZE TABLE` statements to crash `mysqld`. (Bug #45053)
- Previously, a `GCP STOP` event was written to the cluster log as an `INFO` event. Now it is logged as a `WARNING` event instead. (Bug #43853)
- Debugging code causing `ndbd` to use file compression on NTFS file systems failed with an error. (The code was removed.) This issue affected debug builds of MySQL Cluster on Windows platforms only. (Bug #44418)
- If the cluster crashed during the execution of a `CREATE LOGFILE GROUP` statement, the cluster could not be restarted afterward. (Bug #36702)

  References: See also Bug #34102.

- **Disk Data**: **Partitioning**: An `NDB` table created with a very large value for the `MAX_ROWS` option could—if this table was dropped and a new table with fewer partitions, but having the same table ID, was created—cause `ndbd` to crash when performing a system restart. This was because the server attempted to examine each partition whether or not it actually existed. (Bug #45154)

  References: See also Bug #58638.

- **Disk Data**: If the value set in the `config.ini` file for `FileSystemPathDD` [1857], `FileSystemPathDataFiles` [1858], or `FileSystemPathUndoFiles` [1858] was identical to the value set for `FileSystemPath` [1816], that parameter was ignored when starting the data node with `--initial` [1954] option. As a result, the Disk Data files in the corresponding directory were not removed when performing an initial start of the affected data node or data nodes. (Bug #46243)

- For an IPv6-enabled MySQL server, privileges specified using standard IPv4 addresses for hosts were not matched (only IPv4-mapped addresses were handled correctly).

  As part of the fix for this bug, a new build option `--disable-ipv6` has been introduced. Compiling MySQL with this option causes all IPv6-specific code in the server to be ignored.

  Important

  If the server has been compiled using `--disable-ipv6`, it is not able to resolve hostnames correctly when run in an IPv6 environment.

  (Bug #11754062, Bug #45606)

  References: See also Bug #38247, Bug #43006, Bug #45584.

- The hostname cache failed to work correctly. (Bug #45584)

  References: See also Bug #38247, Bug #43006, Bug #11753779, Bug #45606.

- An IPv6-enabled MySQL server did not resolve the IP addresses of incoming connections correctly, with the result that a connection that attempted to match any privilege table entries using fully qualified domain names for hostnames or hostnames using wildcards were dropped. (Bug #38247)

  References: See also Bug #43006, Bug #11753779, Bug #45584, Bug #45606.

Changes in MySQL Cluster NDB 7.0.6 (5.1.34-ndb-7.0.6) (2009-05-26)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.5.

Obtaining MySQL Cluster NDB 7.0.5. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.34 (see Changes in MySQL 5.1.34 (2009-04-02)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- The `ndb_config` utility program can now provide an offline dump of all MySQL Cluster configuration parameters including information such as default and permitted values, brief description, and

applicable section of the `config.ini` file. A dump in text format is produced when running `ndb_config` with the new `--configinfo` option, and in XML format when the options `--configinfo --xml` are used together. For more information and examples, see `ndb_config` — Extract MySQL Cluster Configuration Information.

Bugs Fixed

- **Important Change**: **Partitioning**: User-defined partitioning of an `NDBCLUSTER` table without any primary key sometimes failed, and could cause `mysqld` to crash.

  Now, if you wish to create an `NDBCLUSTER` table with user-defined partitioning, the table must have an explicit primary key, and all columns listed in the partitioning expression must be part of the primary key. The hidden primary key used by the `NDBCLUSTER` storage engine is not sufficient for this purpose. However, if the list of columns is empty (that is, the table is defined using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

  This change does not effect the partitioning of tables using any storage engine other than `NDBCLUSTER`. (Bug #40709)

- **Important Change**: Previously, the configuration parameter `NoOfReplicas` [1815] had no default value. Now the default for `NoOfReplicas` [1815] is 2, which is the recommended value in most settings. (Bug #44746)

- **Important Note**: It was not possible to perform an online upgrade from any MySQL Cluster NDB 6.x release to MySQL Cluster NDB 7.0.5 or any to earlier MySQL Cluster NDB 7.0 release.

  With this fix, it is possible in MySQL Cluster NDB 7.0.6 and later to perform online upgrades from MySQL Cluster NDB 6.3.8 and later MySQL Cluster NDB 6.3 releases, or from MySQL Cluster NDB 7.0.5 or later MySQL Cluster NDB 7.0 releases. Online upgrades to MySQL Cluster NDB 7.0 releases previous to MySQL Cluster NDB 7.0.6 from earlier MySQL Cluster releases remain unsupported; online upgrades from MySQL Cluster NDB 7.0 releases previous to MySQL Cluster NDB 7.0.5 (including NDB 6.4.x beta releases) to later MySQL Cluster NDB 7.0 releases also remain unsupported. (Bug #44294)

- `ndb_config --xml [1975]` did not output any entries for the `HostName` parameter. In addition, the default listed for `MaxNoOfFiles` was outside the permitted range of values. (Bug #44749)

  References: See also Bug #44685, Bug #44746.

- The output of `ndb_config --xml [1975]` did not provide information about all sections of the configuration file. (Bug #44685)

  References: See also Bug #44746, Bug #44749.

- An internal NDB API buffer was not properly initialized. (Bug #44977)

- When a data node had written its GCI marker to the first page of a megabyte, and that node was later killed during restart after having processed that page (marker) but before completing a LCP, the data node could fail with file system errors. (Bug #44952)

  References: See also Bug #42564, Bug #44291.

- Repeated starting and stopping of data nodes could cause ndb_mgmd to fail. This issue was observed on Solaris/SPARC. (Bug #43974)

- When `ndb_config` could not find the file referenced by the `--config-file` option, it tried to read `my.cnf` instead, then failed with a misleading error message. (Bug #44846)

- When a data node was down so long that its most recent local checkpoint depended on a global checkpoint that was no longer restorable, it was possible for it to be unable to use optimized node recovery when being restarted later. (Bug #44844)

References: See also Bug #26913.

- When restarting a data nodes, management and API nodes reconnecting to it failed to re-use existing ports that had already been dynamically allocated for communications with that data node. (Bug #44866)
- When using large numbers of configuration parameters, the management server took an excessive amount of time (several minutes or more) to load these from the configuration cache when starting. This problem occurred when there were more than 32 configuration parameters specified, and became progressively worse with each additional multiple of 32 configuration parameters. (Bug #44488)
- Online upgrades to MySQL Cluster NDB 7.0 from a MySQL Cluster NDB 6.3 release could fail due to changes in the handling of key lengths and unique indexes during node recovery. (Bug #44827)
- Building the MySQL Cluster NDB 7.0 tree failed when using the `icc` compiler. (Bug #44310)
- SSL connections to SQL nodes failed on big-endian platforms. (Bug #44295)
- An NDB internal timing function did not work correctly on Windows and could cause `mysqld` to fail on some AMD processors, or when running inside a virtual machine. (Bug #44276)
- A number of incorrectly formatted output strings in the source code caused compiler warnings. (Bug #43878)
- Use of `__builtin_expect()` had the side effect that compiler warnings about misuse of `=` (assignment) instead of `==` in comparisons were lost when building in debug mode. This is no longer employed when configuring the build with the `--with-debug` option. (Bug #44570)

  References: See also Bug #44567.
- Inspection of the code revealed that several assignment operators (`=`) were used in place of comparison operators (`==`) in `DbdihMain.cpp`. (Bug #44567)

  References: See also Bug #44570.
- It was possible for NDB API applications to insert corrupt data into the database, which could subquently lead to data node crashes. Now, stricter checking is enforced on input data for inserts and updates. (Bug #44132)
- `NDBCLUSTER` did not build correctly on Solaris 9 platforms. (Bug #39080)

  References: See also Bug #39036, Bug #39038.
- Signals providing node state information (`NODE_STATE_REP` and `CHANGE_NODE_STATE_REQ`) were not propagated to all blocks of `ndbmtd`. This could cause the following problems:
  - Inconsistent redo logs when performing a graceful shutdown;
  - Data nodes crashing when later restarting the cluster, data nodes needing to perform node recovery during the system restart, or both.

  (Bug #44291)

  References: See also Bug #42564.
- When trying to use a data node with an older version of the management server, the data node crashed on startup. (Bug #43699)
- In some cases, data node restarts during a system restart could fail due to insufficient redo log space. (Bug #43156)

- `ndb_restore` failed when trying to restore data on a big-endian machine from a backup file created on a little-endian machine. (Bug #44069)
- The output of `ndbd --help` did not provide clear information about the program's `--initial` and `--initial-start` options. (Bug #28905)
- It was theoretically possible for the value of a nonexistent column to be read as `NULL`, rather than causing an error. (Bug #27843)
- **Disk Data**: During a checkpoint, restore points are created for both the on-disk and in-memory parts of a Disk Data table. Under certain rare conditions, the in-memory restore point could include or exclude a row that should have been in the snapshot. This would later lead to a crash during or following recovery.

  This issue was somewhat more likely to be encountered when using `ndbmtd`. (Bug #41915)

  References: See also Bug #47832.
- **Disk Data**: This fix supercedes and improves on an earlier fix made for this bug in MySQL 5.1.18. (Bug #24521)
- **Cluster Replication**: A failure when setting up replication events could lead to subsequent data node failures. (Bug #44915)

Changes in MySQL Cluster NDB 7.0.5 (5.1.32-ndb-7.0.5) (2009-04-20, General Availability)

This *General Availability* (GA) release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.4.

Obtaining MySQL Cluster NDB 7.0.5. The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 6.4 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.32 (see Changes in MySQL 5.1.32 (2009-02-14)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- Two new server status variables `Ndb_scan_count` [1949] and `Ndb_pruned_scan_count` [1949] have been introduced. `Ndb_scan_count` [1949] gives the number of scans executed since the cluster was last started. `Ndb_pruned_scan_count` [1949] gives the number of scans for which `NDBCLUSTER` was able to use partition pruning. Together, these variables can be used to help determine in the MySQL server whether table scans are pruned by `NDBCLUSTER`. (Bug #44153)

Bugs Fixed

- **Important Note**: Due to problem discovered after the code freeze for this release, it is not possible to perform an online upgrade from any MySQL Cluster NDB 6.x release to MySQL Cluster NDB 7.0.5 or any earlier MySQL Cluster NDB 7.0 release.

  This issue is fixed in MySQL Cluster NDB 7.0.6 and later for upgrades from MySQL Cluster NDB 6.3.8 and later MySQL Cluster NDB 6.3 releases, or from MySQL Cluster NDB 7.0.5. (Bug #44294)

- **Cluster Replication**: If data node failed during an event creation operation, there was a slight risk that a surviving data node could send an invalid table reference back to NDB, causing the operation to fail with a false Error 723 (`No such table`). This could take place when a data node failed as a `mysqld` process was setting up MySQL Cluster Replication. (Bug #43754)

- **Cluster API**: The following issues occurred when performing an online (rolling) upgrade of a cluster to a version of MySQL Cluster that supports configuration caching from a version that does not:

  1. When using multiple management servers, after upgrading and restarting one `ndb_mgmd`, any remaining management servers using the previous version of `ndb_mgmd` could not synchronize their configuration data.

  2. The MGM API `ndb_mgm_get_configuration_nodeid()` function failed to obtain configuration data.

  (Bug #43641)

- If the number of fragments per table rises above a certain threshold, the `DBDIH` kernel block's on-disk table-definition grows large enough to occupy 2 pages. However, in MySQL Cluster NDB 7.0 (including MySQL Cluster NDB 6.4 releases), only 1 page was actually written, causing table definitions stored on disk to be incomplete.

  This issue was not observed in MySQL Cluster release series prior to MySQL Cluster NDB 7.0. (Bug #44135)

- `TransactionDeadlockDetectionTimeout` [1841] values less than 100 were treated as 100. This could cause scans to time out unexpectedly. (Bug #44099)

- The file `ndberror.c` contained a C++-style comment, which caused builds to fail with some C compilers. (Bug #44036)

- The setting for `ndb_use_transactions` [1932] was ignored. This issue was only known to occur in MySQL Cluster NDB 6.4.3 and MySQL Cluster NDB 7.0.4. (Bug #43236)

- `ndb_restore` crashed when trying to restore a backup made to a MySQL Cluster running on a platform having different endianness from that on which the original backup was taken. (Bug #39540)

- PID files for the data and management node daemons were not removed following a normal shutdown. (Bug #37225)

- `ndb_restore --print_data` [1997] did not handle `DECIMAL` columns correctly. (Bug #37171)

- A race condition could occur when a data node failed to restart just before being included in the next global checkpoint. This could cause other data nodes to fail. (Bug #43888)

- When a data node process had been killed after allocating a node ID, but before making contact with any other data node processes, it was not possible to restart it due to a node ID allocation failure.

  This issue could effect either `ndbd` or `ndbmtd` processes. (Bug #43224)

  References: This bug was introduced by Bug #42973.

- Invoking the management client `START BACKUP` command from the system shell (for example, as `ndb_mgm -e "START BACKUP"`) did not work correctly, unless the backup ID was included when the command was invoked.

  Now, the backup ID is no longer required in such cases, and the backup ID that is automatically generated is printed to stdout, similar to how this is done when invoking `START BACKUP` within the management client. (Bug #31754)

- When aborting an operation involving both an insert and a delete, the insert and delete were aborted separately. This was because the transaction coordinator did not know that the operations affected

on same row, and, in the case of a committed-read (tuple or index) scan, the abort of the insert was performed first, then the row was examined after the insert was aborted but before the delete was aborted. In some cases, this would leave the row in a inconsistent state. This could occur when a local checkpoint was performed during a backup. This issue did not affect primary ley operations or scans that used locks (these are serialized).

After this fix, for ordered indexes, all operations that follow the operation to be aborted are now also aborted.

- **Disk Data**: When using multi-threaded data nodes, `DROP TABLE` statements on Disk Data tables could hang. (Bug #43825)
- **Disk Data**: This fix completes one that was made for this issue in MySQL Cluster NDB-7.0.4, which did not rectify the problem in all cases. (Bug #43632)
- **Cluster Replication**: When creating or altering a table an `NdbEventOperation` is created by the `mysqld` process to monitor the table for subsequent logging in the binlog. If this happened during a node restart there was a chance that the reference count on this event operation object could be incorrect, which could lead to an assert in debug MySQL Cluster builds. (Bug #43752)
- **Cluster API**: `BIT` columns created using the native NDB API format that were not created as nullable could still sometimes be overwritten, or cause other columns to be overwritten.

  This issue did not effect tables having `BIT` columns created using the mysqld format (always used by MySQL Cluster SQL nodes). (Bug #43802)
- **Cluster API**: If the largest offset of a `RecordSpecification` used for an `NdbRecord` object was for the `NULL` bits (and thus not a column), this offset was not taken into account when calculating the size used for the `RecordSpecification`. This meant that the space for the `NULL` bits could be overwritten by key or other information. (Bug #43891)

Changes in MySQL Cluster NDB 7.0.4 (5.1.32-ndb-7.0.4) (2008-03-18)

This is a new Beta development release, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 6.4.3. All feature additions and bugfixes that were made in MySQL Cluster releases having NDB 6.4.x release numbers are included in MySQL Cluster 7.0.4.

Important

MySQL Cluster NDB 7.0.4 is the successor to MySQL Cluster NDB 6.4.3. Users running MySQL Cluster NDB 6.4.3 should upgrade to MySQL Cluster NDB 7.0.4 or a later 7.0.x release.

Obtaining MySQL Cluster NDB 7.0.4. MySQL Cluster NDB 7.0.4 is a source-only release. You can obtain the source code from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.32-ndb-7.0.4/.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 6.4 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.32 (see Changes in MySQL 5.1.32 (2009-02-14)).

Note

This Beta release, as any other pre-production release, should not be installed on *production* level systems or systems with critical data. Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Important Change**: The default values for a number of MySQL Cluster configuration parameters relating to memory usage and buffering have changed. These parameters include `RedoBuffer` [1846], `LongMessageBuffer` [1825], `BackupMemory` [1851], `BackupDataBufferSize` [1850], `BackupLogBufferSize` [1850], `BackupWriteSize` [1851], `BackupMaxWriteSize` [1852], `SendBufferMemory` [1870] (when applied to TCP transporters), and `ReceiveBufferMemory` [1871].

  For more information, see MySQL Cluster Configuration.

- When restoring from backup, `ndb_restore` now reports the last global checkpoint reached when the backup was taken. (Bug #37384)

Bugs Fixed

- **Cluster API**: Partition pruning did not work correctly for queries involving multiple range scans.

  As part of the fix for this issue, several improvements have been made in the NDB API, including the addition of a new `NdbScanOperation::getPruned()` method, a new variant of `NdbIndexScanOperation::setBound()`, and a new `PartitionSpec` data structure. (Bug #37934)

- The management server failed to start correctly in daemon mode. (Bug #43559)

- Some queries using combinations of logical and comparison operators on an indexed column in the `WHERE` clause could fail with the error `Got error 4541 'IndexBound has no bound information' from NDBCLUSTER`. (Bug #42857)

- Following a `DROP NODEGROUP` command, the output of `SHOW` in the `ndb_mgm` cliently was not updated to reflect the fact that the data nodes affected by this command were no longer part of a node group. (Bug #43413)

- It was not possible to add new data nodes to the cluster online using multi-threaded data node processes (`ndbmtd`). (Bug #43108)

- `TimeBetweenLocalCheckpoints` [1839] was measured from the end of one local checkpoint to the beginning of the next, rather than from the beginning of one LCP to the beginning of the next. This meant that the time spent performing the LCP was not taken into account when determining the `TimeBetweenLocalCheckpoints` [1839] interval, so that LCPs were not started often enough, possibly causing data nodes to run out of redo log space prematurely. (Bug #43567)

- Using indexes containing variable-sized columns could lead to internal errors when the indexes were being built. (Bug #43226)

- When using `ndbmtd`, multiple data node failures caused the remaining data nodes to fail as well. (Bug #43109)

- **Disk Data**: When using multi-threaded data nodes, dropping a Disk Data table followed by a data node restart led to a crash. (Bug #43632)

- **Disk Data**: When using `ndbmtd`, repeated high-volume inserts (on the order of 10000 rows inserted at a time) on a Disk Data table would eventually lead to a data node crash. (Bug #41398)

- **Disk Data**: When a log file group had an undo log file whose size was too small, restarting data nodes failed with `Read underflow` errors.

  As a result of this fix, the minimum permitted `INTIAL_SIZE` for an undo log file is now `1M` (1 megabyte). (Bug #29574)

- **Cluster API**: Ordered index scans using `NdbRecord` formerly expressed a `BoundEQ` range as separate lower and upper bounds, resulting in 2 copies of the column values being sent to the NDB kernel.

Now, when a range is specified by `NdbScanOperation::setBound()`, the passed pointers, key lengths, and inclusive bits are compared, and only one copy of the equal key columns is sent to the kernel. This makes such operations more efficient, as half the amount of `KeyInfo` is now sent for a `BoundEQ` range as before. (Bug #38793)

- **Cluster API**: When performing insert or write operations, `NdbRecord` permits key columns to be specified in both the key record and in the attribute record. Only one key column value for each key column should be sent to the NDB kernel, but this was not guaranteed. This is now ensured as follows: For insert and write operations, key column values are taken from the key record; for scan takeover update operations, key column values are taken from the attribute record. (Bug #42238)

- **Cluster API**: The default `NdbRecord` structures created by `NdbDictionary` could have overlapping null bits and data fields. (Bug #43590)

Changes in MySQL Cluster NDB 6.4.3 (5.1.32-ndb-6.4.3) (2009-02-23)

This is a new Beta development release, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 6.4.2.

Important

The successor version to MySQL Cluster NDB 6.4.3 is MySQL Cluster NDB 7.0.4. See Changes in MySQL Cluster NDB 7.0.4 (5.1.32-ndb-7.0.4) (2008-03-18).

Obtaining MySQL Cluster NDB 6.4.3. MySQL Cluster NDB 6.4.3 is a source-only release. You can obtain the source code from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.32-ndb-6.4.3/.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 6.4 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.32 (see Changes in MySQL 5.1.32 (2009-02-14)).

Note

This Beta release, as any other pre-production release, should not be installed on *production* level systems or systems with critical data. Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Important Change**: **Replication**: `RESET MASTER` and `RESET SLAVE` now reset the values shown for `Last_IO_Error`, `Last_IO_Errno`, `Last_SQL_Error`, and `Last_SQL_Errno` in the output of `SHOW SLAVE STATUS`. (Bug #34654)

  References: See also Bug #44270.

- A new data node configuration parameter `MaxLCPStartDelay` [1828] has been introduced to facilitate parallel node recovery by causing a local checkpoint to be delayed while recovering nodes are synchronizing data dictionaries and other meta-information. For more information about this parameter, see Defining MySQL Cluster Data Nodes. (Bug #43053)

- New options are introduced for `ndb_restore` for determining which tables or databases should be restored:

  - `--include-tables` and `--include-databases` can be used to restore specific tables or databases.

  - `--exclude-tables` and `--exclude-databases` can be used to exclude the specified tables or databases from being restored.

For more information about these options, see ndb_restore — Restore a MySQL Cluster Backup. (Bug #40429)

- **Disk Data**: It is now possible to specify default locations for Disk Data data files and undo log files, either together or separately, using the data node configuration parameters FileSystemPathDD [1857], FileSystemPathDataFiles [1858], and FileSystemPathUndoFiles [1858]. For information about these configuration parameters, see *Disk Data file system parameters*.

  It is also now possible to specify a log file group, tablespace, or both, that is created when the cluster is started, using the InitialLogFileGroup [1859] and InitialTablespace [1859] data node configuration parameters. For information about these configuration parameters, see *Disk Data object creation parameters*.

Bugs Fixed

- **Performance**: Updates of the SYSTAB_0 system table to obtain a unique identifier did not use transaction hints for tables having no primary key. In such cases the NDB kernel used a cache size of 1. This meant that each insert into a table not having a primary key required an update of the corresponding SYSTAB_0 entry, creating a potential performance bottleneck.

  With this fix, inserts on NDB tables without primary keys can be under some conditions be performed up to 100% faster than previously. (Bug #39268)

- **Important Note**: It is not possible in this release to install the InnoDB plugin if InnoDB support has been compiled into mysqld. (Bug #42610)

  References: This bug was introduced by Bug #29263.

- **Packaging**: Packages for MySQL Cluster were missing the libndbclient.so and libndbclient.a files. (Bug #42278)

- **Partitioning**: Executing ALTER TABLE ... REORGANIZE PARTITION on an NDBCLUSTER table having only one partition caused mysqld to crash. (Bug #41945)

  References: See also Bug #40389.

- If the cluster configuration cache file was larger than 32K, the management server would not start. (Bug #42543)

- In some cases, NDB did not check correctly whether tables had changed before trying to use the query cache. This could result in a crash of the debug MySQL server. (Bug #40464)

- When using ndbmtd, NDB kernel threads could hang while trying to start the data nodes with LockPagesInMainMemory [1832] set to 1. (Bug #43021)

- Backup IDs greater than 2^{31} were not handled correctly, causing negative values to be used in backup directory names and printouts. (Bug #43042)

- Given a MySQL Cluster containing no data (that is, whose data nodes had all been started using --initial, and into which no data had yet been imported) and having an empty backup directory, executing START BACKUP with a user-specified backup ID caused the data nodes to crash. (Bug #41031)

- When using multiple management servers and starting several API nodes (possibly including one or more SQL nodes) whose connectstrings listed the management servers in different order, it was possible for 2 API nodes to be assigned the same node ID. When this happened it was possible for an API node not to get fully connected, consequently producing a number of errors whose cause was not easily recognizable. (Bug #42973)

- Triggers on NDBCLUSTER tables caused such tables to become locked. (Bug #42751)

References: See also Bug #16229, Bug #18135.

- `ndb_error_reporter` worked correctly only with GNU `tar`. (With other versions of `tar`, it produced empty archives.) (Bug #42753)

- When using multi-threaded data nodes, their `DataMemory` [1817] and `IndexMemory` [1819] usage as reported was multiplied by the number of local query handlers (worker threads), making it appear that much more memory was being used than was actually the case. (Bug #42215)

  References: See also Bug #42765.

- When using multi-threaded data nodes, `IndexMemory` [1819], `MaxNoOfLocalOperations` [1822], and `MaxNoOfLocalScans` [1824] were effectively multiplied by the number of local query handlers in use by each `ndbmtd` instance. (Bug #42765)

  References: See also Bug #42215.

- When performing more than 32 index or tuple scans on a single fragment, the scans could be left hanging. This caused unnecessary timeouts, and in addition could possibly lead to a hang of an LCP. (Bug #42559)

  References: This bug is a regression of Bug #42084.

- A data node failure that occurred between calls to `NdbIndexScanOperation::readTuples(SF_OrderBy)` and `NdbTransaction::execute()` was not correctly handled; a subsequent call to `nextResult()` caused a null pointer to be deferenced, leading to a segfault in `mysqld`. (Bug #42545)

- Issuing `SHOW GLOBAL STATUS LIKE 'NDB%'` before `mysqld` had connected to the cluster caused a segmentation fault. (Bug #42458)

- Data node failures that occurred before all data nodes had connected to the cluster were not handled correctly, leading to additional data node failures. (Bug #42422)

- When using `ndbmtd` for all data nodes, repeated failures of one data node during DML operations caused other data nodes to fail. (Bug #42450)

- **Disk Data**: Repeated insert and delete operations on disk-based tables could lead to failures in the NDB Tablespace Manager (`TSMAN` kernel block). (Bug #40344)

- **Disk Data**: Creating a Disk Data tablespace with a very large extent size caused the data nodes to fail. The issue was observed when using extent sizes of 100 MB and larger. (Bug #39096)

- **Disk Data**: It was not possible to add an in-memory column online to a table that used a table-level or column-level `STORAGE DISK` option. The same issue prevented `ALTER ONLINE TABLE ... REORGANIZE PARTITION` from working on Disk Data tables. (Bug #42549)

- **Disk Data**: Using a path or file name longer than 128 characters for Disk Data undo log files and tablespace data files caused a number of issues, including failures of `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, and `ALTER TABLESPACE` statements, as well as crashes of management nodes and data nodes.

  With this fix, the maximum length for path and file names used for Disk Data undo log files and tablespace data files is now the same as the maximum for the operating system. (Bug #31769, Bug #31770, Bug #31772)

- **Disk Data**: Trying to execute a `CREATE LOGFILE GROUP` statement using a value greater than `150M` for `UNDO_BUFFER_SIZE` caused data nodes to crash.

  As a result of this fix, the upper limit for `UNDO_BUFFER_SIZE` is now `600M`; attempting to set a higher value now fails gracefully with an error. (Bug #34102)

References: See also Bug #36702.

- **Disk Data**: When attempting to create a tablespace that already existed, the error message returned was `Table or index with given name already exists`. (Bug #32662)

- **Disk Data**: Attempting to perform a system restart of the cluster where there existed a logfile group without and undo log files caused the data nodes to crash.

  Note

  While issuing a `CREATE LOGFILE GROUP` statement without an `ADD UNDOFILE` option fails with an error in the MySQL server, this situation could arise if an SQL node failed during the execution of a valid `CREATE LOGFILE GROUP` statement; it is also possible to create a logfile group without any undo log files using the NDB API.

  (Bug #17614)

- **Cluster Replication**: Primary key updates on `MyISAM` and `InnoDB` tables failed to replicate to `NDBCLUSTER` tables. (Bug #42921)

- **Cluster Replication**: Being disconnected from the cluster while setting up the binary log caused `mysqld` to hang or crash. (Bug #43045)

- **Cluster API**: Some error messages from `ndb_mgmd` contained newline (`\n`) characters. This could break the MGM API protocol, which uses the newline as a line separator. (Bug #43104)

- **Cluster API**: When using an ordered index scan without putting all key columns in the read mask, this invalid use of the NDB API went undetected, which resulted in the use of uninitialized memory. (Bug #42591)

Changes in MySQL Cluster NDB 6.4.2 (5.1.31-ndb-6.4.2) (2009-01-28)

This is a new Beta development release, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 6.4.1.

Obtaining MySQL Cluster NDB 6.4.2. MySQL Cluster NDB 6.4.2 is a source-only release. You can obtain the source code from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.31-ndb-6.4.2/.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 6.4 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.31 (see Changes in MySQL 5.1.31 (2009-01-19)).

Note

This Beta release, as any other pre-production release, should not be installed on *production* level systems or systems with critical data. Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- Connections using IPv6 were not handled correctly by `mysqld`. (Bug #42413)

  References: See also Bug #42412, Bug #38247.

- When a cluster backup failed with Error 1304 (Node *`node_id1`*: Backup request from *`node_id2`* failed to start), no clear reason for the failure was provided.

  As part of this fix, MySQL Cluster now retries backups in the event of sequence errors. (Bug #42354)

References: See also Bug #22698.

- When using `ndbmtd`, setting `MaxNoOfExecutionThreads` to a value higher than the actual number of cores available and with insufficient `SharedGlobalMemory` [1856] caused the data nodes to crash.

  The fix for this issue changes the behavior of `ndbmtd` such that its internal job buffers no longer rely on `SharedGlobalMemory` [1856]. (Bug #42254)

- Issuing `SHOW ENGINE NDBCLUSTER STATUS` on an SQL node before the management server had connected to the cluster caused `mysqld` to crash. (Bug #42264)

Changes in MySQL Cluster NDB 6.4.1 (5.1.31-ndb-6.4.1) (2009-01-21)

This is a new Beta development release, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 6.4.0.

Obtaining MySQL Cluster NDB 6.4.1. MySQL Cluster NDB 6.4.1 is a source-only release. You can obtain the source code from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.31-ndb-6.4.1/.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 6.4 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.31 (see Changes in MySQL 5.1.31 (2009-01-19)).

Note

This Beta release, as any other pre-production release, should not be installed on *production* level systems or systems with critical data. Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Important Change**: Formerly, when the management server failed to create a transporter for a data node connection, `net_write_timeout` [506] seconds elapsed before the data node was actually permitted to disconnect. Now in such cases the disconnection occurs immediately. (Bug #41965)

  References: See also Bug #41713.

- Formerly, when using MySQL Cluster Replication, records for “empty” epochs—that is, epochs in which no changes to `NDBCLUSTER` data or tables took place—were inserted into the `ndb_apply_status` and `ndb_binlog_index` tables on the slave even when `--log-slave-updates` [1628] was disabled. Beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.13 this was changed so that these “empty” epochs were no longer logged. However, it is now possible to re-enable the older behavior (and cause “empty” epochs to be logged) by using the `--ndb-log-empty-epochs` option. For more information, see Replication Slave Options and Variables.

  References: See also Bug #37472.

- **Cluster Replication**: IPv6 networking is now supported between MySQL Cluster SQL nodes. This means that it is now possible to replicate between instances of MySQL Cluster using IPv6 addresses.

Important

Currently, other MySQL Cluster processes (`ndbd`, `ndbmtd`, `ndb_mgmd`, and `ndb_mgm`) do not support IPv6 connections. This means that all MySQL Cluster data nodes, management servers, and management clients must

connect to and be accessible from one another using IPv4. In addition, SQL nodes must use IPv4 to communicate with the cluster. There is also not yet any support in the NDB and MGM APIs for IPv6, which means that applications written using the MySQL Cluster APIs must make connections using IPv4. For more information, see Known Issues in MySQL Cluster Replication.

Bugs Fixed

- Trying to execute an `ALTER ONLINE TABLE ... ADD COLUMN` statement while inserting rows into the table caused `mysqld` to crash. (Bug #41905)
- When a data node connects to the management server, the node sends its node ID and transporter type; the management server then verifies that there is a transporter set up for that node and that it is in the correct state, and then sends back an acknowledgment to the connecting node. If the transporter was not in the correct state, no reply was sent back to the connecting node, which would then hang until a read timeout occurred (60 seconds). Now, if the transporter is not in the correct state, the management server acknowledges this promptly, and the node immediately disconnects. (Bug #41713)

  References: See also Bug #41965.
- When using `ndbmtd`, one thread could flood another thread, which would cause the system to stop with a `job buffer full` condition (currently implemented as an abort). This could be caused by committing or aborting a large transaction (50000 rows or more) on a single data node running `ndbmtd`. To prevent this from happening, the number of signals that can be accepted by the system threads is calculated before executing them, and only executing them if sufficient space is found. (Bug #42052)
- A maximum of 11 `TUP` scans were permitted in parallel. (Bug #42084)
- The management server could hang after attempting to halt it with the `STOP` command in the management client. (Bug #42056)

  References: See also Bug #40922.
- Issuing `EXIT` in the management client sometimes caused the client to hang. (Bug #40922)
- MySQL Cluster would not compile when using `libwrap`. This issue was known to occur only in MySQL Cluster NDB 6.4.0. (Bug #41918)
- In the event that a MySQL Cluster backup failed due to file permissions issues, conflicting reports were issued in the management client. (Bug #34526)
- If all data nodes were shut down, MySQL clients were unable to access `NDBCLUSTER` tables and data even after the data nodes were restarted, unless the MySQL clients themselves were restarted. (Bug #33626)

Changes in MySQL Cluster NDB 6.4.0 (5.1.30-ndb-6.4.0) (2008-12-22, Beta)

This is a new Beta development release, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in previous MySQL Cluster releases.

Obtaining MySQL Cluster NDB 6.4.0. MySQL Cluster NDB 6.4.0 is a source-only release. You can obtain the source code from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.30-ndb-6.4.0/.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, and 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.30 (see Changes in MySQL 5.1.30 (2008-11-14, General Availability)).

Note

This Beta release, as any other pre-production release, should not be installed on *production* level systems or systems with critical data. Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Important Change**: MySQL Cluster now caches its configuration data. This means that, by default, the management server only reads the global configuration file (usually named `config.ini`) the first time that it is started, and does not automatically re-read the this file when restarted. This behavior can be controlled using new management server options (`--config-dir`, `--initial`, and `--reload`) that have been added for this purpose. For more information, see MySQL Cluster Configuration Files, and `ndb_mgmd` — The MySQL Cluster Management Server Daemon.

- It is now possible while in Single User Mode to restart all data nodes using `ALL RESTART` in the management client. Restarting of individual nodes while in Single User Mode remains not permitted. (Bug #31056)

- It is now possible when performing a cluster backup to determine whether the backup matches the state of the data when the backup began or when it ended, using the new `START BACKUP` options `SNAPSHOTSTART` and `SNAPSHOTEND` in the management client. See Using The MySQL Cluster Management Client to Create a Backup, for more information.

- A multi-threaded version of the MySQL Cluster data node daemon is now available. The multi-threaded `ndbmtd` binary is similar to `ndbd` and functions in much the same way, but is intended for use on machines with multiple CPU cores.

  For more information, see `ndbmtd` — The MySQL Cluster Data Node Daemon (Multi-Threaded).

- It is now possible to add data nodes to a MySQL Cluster online—that is, to a running MySQL Cluster without shutting it down.

  For information about the procedure for adding data nodes online, see Adding MySQL Cluster Data Nodes Online.

- **Cluster API**: Two new `Ndb_cluster_connection` methods have been added to help in diagnosing problems with NDB API client connections. The `get_latest_error()` method tells whether or not the latest connection attempt succeeded; if the attempt failed, `get_latest_error_msg()` provides an error message giving the reason.

Bugs Fixed

- API nodes disconnected too agressively from cluster when data nodes were being restarted. This could sometimes lead to the API node being unable to access the cluster at all during a rolling restart. (Bug #41462)

- When long signal buffer exhaustion in the `ndbd` process resulted in a signal being dropped, the usual handling mechanism did not take fragmented signals into account. This could result in a crash of the data node because the fragmented signal handling mechanism was not able to work with the missing fragments. (Bug #39235)

- Status messages shown in the management client when restarting a management node were inappropriate and misleading. Now, when restarting a management node, the messages displayed are as follows, where *`node_id`* is the management node's node ID:

```
ndb_mgm> node_id RESTART
Shutting down MGM node node_id for restart
Node node_id is being restarted

ndb_mgm>
```

(Bug #29275)

- The failure of a master node during a DDL operation caused the cluster to be unavailable for further DDL operations until it was restarted; failures of nonmaster nodes during DLL operations caused the cluster to become completely inaccessible. (Bug #36718)
- A data node failure when `NoOfReplicas` [1815] was greater than 2 caused all cluster SQL nodes to crash. (Bug #18621)
- **Partitioning**: A query on a user-partitioned table caused MySQL to crash, where the query had the following characteristics:
  - The query's `WHERE` clause referenced an indexed column that was also in the partitioning key.
  - The query's `WHERE` clause included a value found in the partition.
  - The query's `WHERE` clause used the `<` or `<>` operators to compare with the indexed column's value with a constant.
  - The query used an `ORDER BY` clause, and the same indexed column was used in the `ORDER BY` clause.
  - The `ORDER BY` clause used an explicit or implicit `ASC` sort priority.

  Two examples of such a query are given here, where `a` represents an indexed column used in the table's partitioning key:

  1. `SELECT * FROM table WHERE a < constant ORDER BY a;`
  2. `SELECT * FROM table WHERE a <> constant ORDER BY a;`

  (Bug #40954)

  References: This bug was introduced by Bug #30573, Bug #33257, Bug #33555.

Changes in MySQL Cluster NDB 6.3

This section contains change history information for MySQL Cluster releases based on version 6.3 of the `NDBCLUSTER` storage engine.

For an overview of new features added in MySQL Cluster NDB 6.3, see MySQL Cluster Development in MySQL Cluster NDB 6.3.

Changes in MySQL Cluster NDB 6.3.50 (5.1.61-ndb-6.3.50) (Not yet released)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

Obtaining MySQL Cluster NDB 6.3. The latest MySQL Cluster NDB 6.3 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 6.3 release can be obtained from the same location. You can also access the MySQL Cluster NDB 6.3 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-5.1-telco-6.3.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.61 (see Changes in MySQL 5.1.61 (2012-01-10)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Version 5.1.61-ndb-6.3.50 has no changelog entries.

Changes in MySQL Cluster NDB 6.3.49 (5.1.61-ndb-6.3.49) (Not yet released)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

Obtaining MySQL Cluster NDB 6.3. The latest MySQL Cluster NDB 6.3 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 6.3 release can be obtained from the same location. You can also access the MySQL Cluster NDB 6.3 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-5.1-telco-6.3.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.61 (see Changes in MySQL 5.1.61 (2012-01-10)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Version 5.1.61-ndb-6.3.49 has no changelog entries.

Changes in MySQL Cluster NDB 6.3.48 (5.1.61-ndb-6.3.48) (2012-04-10)

This is an update release, incorporating improvements originally made in MySQL Server into the previous MySQL Cluster NDB 6.3 release.

Obtaining MySQL Cluster NDB 6.3. The latest MySQL Cluster NDB 6.3 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 6.3 release can be obtained from the same location. You can also access the MySQL Cluster NDB 6.3 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-5.1-telco-6.3.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.61 (see Changes in MySQL 5.1.61 (2012-01-10)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Changes in MySQL Cluster NDB 6.3.47 (5.1.56-ndb-6.3.47) (2011-11-23)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

Obtaining MySQL Cluster NDB 6.3. The latest MySQL Cluster NDB 6.3 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 6.3 release can be obtained from the same location. You can also access the MySQL Cluster NDB 6.3 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-5.1-telco-6.3.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.56 (see Changes in MySQL 5.1.56 (2011-03-01)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- When a failure of multiple data nodes during a local checkpoint (LCP) that took a long time to complete included the node designated as master, any new data nodes attempting to start before all ongoing LCPs were completed later crashed. This was due to the fact that node takeover by the new master cannot be completed until there are no pending local checkpoints. Long-running LCPs such as those which triggered this issue can occur when fragment sizes are sufficiently large (see MySQL Cluster Nodes, Node Groups, Replicas, and Partitions, for more information). Now in such cases, data nodes (other than the new master) are kept from restarting until the takeover is complete. (Bug #13323589)

- When deleting from multiple tables using a unique key in the `WHERE` condition, the wrong rows were deleted. In addition, `UPDATE` triggers failed when rows were changed by deleting from or updating multiple tables. (Bug #12718336, Bug #61705, Bug #12728221)

Changes in MySQL Cluster NDB 6.3.46 (5.1.56-ndb-6.3.46) (Not released)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

Obtaining MySQL Cluster NDB 6.3. The latest MySQL Cluster NDB 6.3 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 6.3 release can be obtained from the same location. You can also access the MySQL Cluster NDB 6.3 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-5.1-telco-6.3.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.56 (see Changes in MySQL 5.1.56 (2011-03-01)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- When replicating DML statements with `IGNORE` between clusters, the number of operations that failed due to nonexistent keys was expected to be no greater than the number of defined operations of any single type. Because the slave SQL thread defines operations of multiple types in batches together, code which relied on this assumption could cause `mysqld` to fail. (Bug #12859831)

- When failure handling of an API node takes longer than 300 seconds, extra debug information is included in the resulting output. In cases where the API node's node ID was greater than 48, these extra debug messages could lead to a crash, and confuing output otherwise. This was due to an attempt to provide information specific to data nodes for API nodes as well. (Bug #62208)

- In rare cases, a series of node restarts and crashes during restarts could lead to errors while reading the redo log. (Bug #62206)

Changes in MySQL Cluster NDB 6.3.45 (5.1.56-ndb-6.3.45) (2011-07-04)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

Obtaining MySQL Cluster NDB 6.3. The latest MySQL Cluster NDB 6.3 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest

MySQL Cluster NDB 6.3 release can be obtained from the same location. You can also access the MySQL Cluster NDB 6.3 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-5.1-telco-6.3.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.56 (see Changes in MySQL 5.1.56 (2011-03-01)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- When global checkpoint indexes were written with no intervening end-of-file or megabyte border markers, this could sometimes lead to a situation in which the end of the redo log was mistakenly regarded as being between these GCIs, so that if the restart of a data node took place before the start of the next redo log was overwritten, the node encountered an `Error while reading the REDO log`. (Bug #12653993, Bug #61500)

  References: See also Bug #56961.

- Error reporting has been improved for cases in which API nodes are unable to connect due to apparent unavailability of node IDs. (Bug #12598398)

- Error messages for `Failed to convert connection` transporter registration problems were inspecific. (Bug #12589691)

- Under certain rare circumstances, a data node process could fail with Signal 11 during a restart. This was due to uninitialized variables in the `QMGR` kernel block. (Bug #12586190)

- Handling of the `MaxNoOfTables` [1829] and `MaxNoOfAttributes` [1828] configuration parameters was not consistent in all parts of the `NDB` kernel, and were only strictly enforced by the `DBDICT` and `SUMA` kernel blocks. This could lead to problems when tables could be created but not replicated. Now these parameters are treated by `SUMA` and `DBDICT` as suggested maximums rather than hard limits, as they are elsewhere in the `NDB` kernel. (Bug #61684)

- **Cluster API**: Within a transaction, after creating, executing, and closing a scan, calling `NdbTransaction::refresh()` after creating and executing but not closing a second scan caused the application to crash. (Bug #12646659)

Changes in MySQL Cluster NDB 6.3.44 (5.1.56-ndb-6.3.44) (2011-05-19)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

Obtaining MySQL Cluster NDB 6.3. The latest MySQL Cluster NDB 6.3 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 6.3 release can be obtained from the same location. You can also access the MySQL Cluster NDB 6.3 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-5.1-telco-6.3.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.56 (see Changes in MySQL 5.1.56 (2011-03-01)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- Two unused test files in `storage/ndb/test/sql` contained incorrect versions of the GNU Lesser General Public License. The files and the directory containing them have been removed. (Bug #11810156)

  References: See also Bug #11810224.

Changes in MySQL Cluster NDB 6.3.43 (5.1.56-ndb-6.3.43) (2011-04-26)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

Obtaining MySQL Cluster NDB 6.3. The latest MySQL Cluster NDB 6.3 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 6.3 release can be obtained from the same location. You can also access the MySQL Cluster NDB 6.3 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-5.1-telco-6.3.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.56 (see Changes in MySQL 5.1.56 (2011-03-01)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- **Cluster API**: Performing interpreted operations using a unique index did not work correctly, because the interpret bit was kept when sending the lookup to the index table.

Changes in MySQL Cluster NDB 6.3.42 (5.1.51-ndb-6.3.42) (2011-04-04)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

Obtaining MySQL Cluster NDB 6.3. The latest MySQL Cluster NDB 6.3 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 6.3 release can be obtained from the same location. You can also access the MySQL Cluster NDB 6.3 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-5.1-telco-6.3.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.51 (see Changes in MySQL 5.1.51 (2010-09-10)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- A scan with a pushed condition (filter) using the `CommittedRead` lock mode could hang for a short interval when it was aborted when just as it had decided to send a batch. (Bug #11932525)

- When aborting a multi-read range scan exactly as it was changing ranges in the local query handler, LQH could fail to detect it, leaving the scan hanging. (Bug #11929643)

- **Replication**: Error 1590 (`ER_SLAVE_INCIDENT` [3994]) caused the slave to stop even when it was started with `--slave-skip-errors=1590` [1641]. (Bug #59889, Bug #11768580, Bug #11799671)

- **Disk Data**: Limits imposed by the size of `SharedGlobalMemory` [1856] were not always enforced consistently with regard to Disk Data undo buffers and log files. This could sometimes cause a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement to fail for no apparent reason, or cause the log file group specified by `InitialLogFileGroup` [1859] not to be created when starting the cluster. (Bug #57317)

- **Cluster Replication**: Filtering the binary log using `--binlog-ignore-db=mysql` [1651] caused epochs not to be logged as expected in the `ndb_apply_status` table. (Bug #11765707, Bug #58698)

Changes in MySQL Cluster NDB 6.3.41 (5.1.51-ndb-6.3.41) (2011-02-25)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

Obtaining MySQL Cluster NDB 6.3. The latest MySQL Cluster NDB 6.3 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 6.3 release can be obtained from the same location. You can also access the MySQL Cluster NDB 6.3 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-5.1-telco-6.3.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.51 (see Changes in MySQL 5.1.51 (2010-09-10)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- A new `--rewrite-database` [2003] option is added for `ndb_restore`, which makes it possible to restore to a database having a different name from that of the database in the backup.

  For more information, see `ndb_restore` — Restore a MySQL Cluster Backup. (Bug #54327)

Changes in MySQL Cluster NDB 6.3.40 (5.1.51-ndb-6.3.40) (2011-01-26)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

Obtaining MySQL Cluster NDB 6.3. The latest MySQL Cluster NDB 6.3 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 6.3 release can be obtained from the same location. You can also access the MySQL Cluster NDB 6.3 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-5.1-telco-6.3.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.51 (see Changes in MySQL 5.1.51 (2010-09-10)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- Added the `--skip-broken-objects` [2003] option for `ndb_restore`. This option causes `ndb_restore` to ignore tables corrupted due to missing blob parts tables, and to continue reading from the backup file and restoring the remaining tables. (Bug #54613)

  References: See also Bug #51652.

Bugs Fixed

- Two related problems could occur with read-committed scans made in parallel with transactions combining multiple (concurrent) operations:

  1. When committing a multiple-operation transaction that contained concurrent insert and update operations on the same record, the commit arrived first for the insert and then for the update. If a read-committed scan arrived between these operations, it could thus read incorrect data; in addition, if the scan read variable-size data, it could cause the data node to fail.

  2. When rolling back a multiple-operation transaction having concurrent delete and insert operations on the same record, the abort arrived first for the delete operation, and then for the insert. If a read-committed scan arrived between the delete and the insert, it could incorrectly assume that the record should not be returned (in other words, the scan treated the insert as though it had not yet been committed).

  (Bug #59496)

- A row insert or update followed by a delete operation on the same row within the same transaction could in some cases lead to a buffer overflow. (Bug #59242)

  References: See also Bug #56524. This bug was introduced by Bug #35208.

- The `FAIL_REP` signal, used inside the NDB kernel to declare that a node has failed, now includes the node ID of the node that detected the failure. This information can be useful in debugging. (Bug #58904)

- When handling failures of multiple data nodes, an error in the construction of internal signals could cause the cluster's remaining nodes to crash. This issue was most likely to affect clusters with large numbers of data nodes. (Bug #58240)

- Trying to drop an index while it was being used to perform scan updates caused data nodes to crash. (Bug #58277, Bug #57057)

- The number of rows affected by a statement that used a `WHERE` clause having an `IN` [942] condition with a value list containing a great many elements, and that deleted or updated enough rows such that `NDB` processed them in batches, was not computed or reported correctly. (Bug #58040)

- Issuing `EXPLAIN EXTENDED` for a query that would use condition pushdown could cause `mysqld` to crash. (Bug #58553, Bug #11765570)

- In some circumstances, an SQL trigger on an `NDB` table could read stale data. (Bug #58538)

- A query having multiple predicates joined by `OR` in the `WHERE` clause and which used the `sort_union` access method (as shown using `EXPLAIN`) could return duplicate rows. (Bug #58280)

- During a node takeover, it was possible in some circumstances for one of the remaining nodes to send an extra transaction confirmation (`LQH_TRANSCONF`) signal to the `DBTC` kernel block, conceivably leading to a crash of the data node trying to take over as the new transaction coordinator. (Bug #58453)

- Some queries of the form `SELECT ... WHERE column IN (subquery)` against an `NDB` table could cause `mysqld` to hang in an endless loop. (Bug #58163)

- In some circumstances, it was possible for `mysqld` to begin a new multi-range read scan without having closed a previous one. This could lead to exhaustion of all scan operation objects, transaction objects, or lock objects (or some combination of these) in `NDB`, causing queries to fail with such errors as `Lock wait timeout exceeded` or `Connect failure - out of connection objects`. (Bug #57481)

  References: See also Bug #58750.

- Queries using *`column`* `IS` [`NOT`] `NULL` on a table with a unique index created with `USING HASH` on *`column`* always returned an empty result. (Bug #57032)

- With `engine_condition_pushdown` [473] enabled, a query using `LIKE` on an `ENUM` column of an `NDB` table failed to return any results. This issue is resolved by disabling `engine_condition_pushdown` [473] when performing such queries. (Bug #53360)

- A query using `BETWEEN` as part of a pushed-down `WHERE` condition could cause mysqld to hang or crash. (Bug #57735)

- When a slash character (`/`) was used as part of the name of an index on an `NDB` table, attempting to execute a `TRUNCATE TABLE` statement on the table failed with the error `Index not found`, and the table was rendered unusable. (Bug #38914)

- **Disk Data**: In certain cases, a race condition could occur when `DROP LOGFILE GROUP` removed the logfile group while a read or write of one of the effected files was in progress, which in turn could lead to a crash of the data node. (Bug #59502)

- **Disk Data**: A race condition could sometimes be created when `DROP TABLESPACE` was run concurrently with a local checkpoint; this could in turn lead to a crash of the data node. (Bug #59501)

- **Disk Data**: Performing what should have been an online drop of a multi-column index was actually performed offline. (Bug #55618)

- **Disk Data**: When at least one data node was not running, queries against the `INFORMATION_SCHEMA.FILES` table took an excessive length of time to complete because the MySQL server waited for responses from any stopped nodes to time out. Now, in such cases, MySQL does not attempt to contact nodes which are not known to be running. (Bug #54199)

- **Cluster API**: Attempting to read the same value (using `getValue()`) more than 9000 times within the same transaction caused the transaction to hang when executed. Now when more reads are performed in this way than can be accommodated in a single transaction, the call to `execute()` fails with a suitable error. (Bug #58110)

Changes in MySQL Cluster NDB 6.3.39 (5.1.51-ndb-6.3.39) (2010-11-08)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

Obtaining MySQL Cluster NDB 6.3. The latest MySQL Cluster NDB 6.3 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 6.3 release can be obtained from the same location. You can also access the MySQL Cluster NDB 6.3 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-5.1-telco-6.3.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.51 (see Changes in MySQL 5.1.51 (2010-09-10)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Important Change**: The `Id` configuration parameter used with MySQL Cluster management, data, and API nodes (including SQL nodes) is now deprecated, and the `NodeId` parameter (long available as a synonym for `Id` when configuring these types of nodes) should be used instead. `Id` continues to be supported for reasons of backward compatibility, but now generates a warning when used with these types of nodes, and is subject to removal in a future release of MySQL Cluster.

  This change affects the name of the configuration parameter only, establishing a clear preference for `NodeId` over `Id` in the `[mgmd]`, `[ndbd]`, `[mysql]`, and `[api]` sections of the MySQL Cluster global configuration (`config.ini`) file. The behavior of unique identifiers for management, data, and SQL and API nodes in MySQL Cluster has not otherwise been altered.

  The `Id` parameter as used in the `[computer]` section of the MySQL Cluster global configuration file is not affected by this change.

Bugs Fixed

- **Packaging**: MySQL Cluster RPM distributions did not include a `shared-compat` RPM for the MySQL Server, which meant that MySQL applications depending on `libmysqlclient.so.15` (MySQL 5.0 and earlier) no longer worked. (Bug #38596)

- The `LQHKEYREQ` request message used by the local query handler when checking the major schema version of a table, being only 16 bits wide, could cause this check to fail with an `Invalid schema version` error (`NDB` error code 1227). This issue occurred after creating and dropping (and re-creating) the same table 65537 times, then trying to insert rows into the table. (Bug #57896)

  References: See also Bug #57897.

- When a data node angel process failed to fork off a new worker process (to replace one that had failed), the failure was not handled. This meant that the angel process either transformed itself into a worker process, or itself failed. In the first case, the data node continued to run, but there was no longer any angel to restart it in the event of failure, even with `StopOnError` [1832] set to 0. (Bug #53456)

- An internal buffer overrun could cause a data node to fail. (Bug #57767)

- Data nodes compiled with `gcc` 4.5 or higher crashed during startup. (Bug #57761)

- Queries using `WHERE varchar_pk_column LIKE 'pattern%'` or `WHERE varchar_pk_column LIKE 'pattern_'` against an `NDB` table having a `VARCHAR` column as its primary key failed to return all matching rows. (Bug #56853)

- `ndb_restore` now retries failed transactions when replaying log entries, just as it does when restoring data. (Bug #57618)

- During a GCP takeover, it was possible for one of the data nodes not to receive a `SUB_GCP_COMPLETE_REP` signal, with the result that it would report itself as `GCP_COMMITTING` while the other data nodes reported `GCP_PREPARING`. (Bug #57522)

- A GCP stop is detected using 2 parameters which determine the maximum time that a global checkpoint or epoch can go unchanged; one of these controls this timeout for GCPs and one controls the timeout for epochs. Suppose the cluster is configured such that `TimeBetweenEpochsTimeout` [1840] is 100 ms but `HeartbeatIntervalDbDb` [1836] is 1500 ms. A node failure can be signalled after 4 missed heartbeats—in this case, 6000 ms. However, this would exceed `TimeBetweenEpochsTimeout` [1840], causing false detection of a GCP. To prevent this from happening, the configured value for `TimeBetweenEpochsTimeout` [1840] is automatically adjusted, based on the values of `HeartbeatIntervalDbDb` [1836] and `ArbitrationTimeout` [1844].

  The current issue arose when the automatic adjustment routine did not correctly take into consideration the fact that, during cascading node-failures, several intervals of length `4 *`

`(HeartbeatIntervalDBDB + ArbitrationTimeout)` may elapse before all node failures have internally been resolved. This could cause false GCP detection in the event of a cascading node failure. (Bug #57322)

- Specifying a `WHERE` clause of the form *`range1 OR range2`* when selecting from an `NDB` table having a primary key on multiple columns could result in Error 4259 `Invalid set of range scan bounds` if *`range2`* started exactly where *`range1`* ended and the primary key definition declared the columns in a different order relative to the order in the table's column list. (Such a query should simply return all rows in the table, since any expression *`value < constant OR value >= constant`* is always true.)

  Example. Suppose `t` is an `NDB` table defined by the following `CREATE TABLE` statement:

  ```
  CREATE TABLE t (a, b, PRIMARY KEY (b, a)) ENGINE NDB;
  ```

  This issue could then be triggered by a query such as this one:

  ```
  SELECT * FROM t WHERE b < 8 OR b >= 8;
  ```

  In addition, the order of the ranges in the `WHERE` clause was significant; the issue was not triggered, for example, by the query `SELECT * FROM t WHERE b <= 8 OR b > 8`. (Bug #57396)

- **Disk Data**: Adding unique indexes to `NDB` Disk Data tables could take an extremely long time. This was particularly noticeable when using `ndb_restore --rebuild-indexes [2002]`. (Bug #57827)

- **Cluster Replication**: The `OPTION_ALLOW_BATCHING` bitmask had the same value as `OPTION_PROFILING`. This caused conflicts between using `--slave-allow-batching` [1930] and profiling. (Bug #57603)

- **Cluster Replication**: Replication of `SET` and `ENUM` columns represented using more than 1 byte (that is, `SET` columns with more than 8 members and `ENUM` columns with more than 256 constants) between platforms using different endianness failed when using the row-based format. This was because columns of these types are represented internally using integers, but the internal functions used by MySQL to handle them treated them as strings. (Bug #52131)

  References: See also Bug #53528.

- **Cluster API**: An application dropping a table at the same time that another application tried to set up a replication event on the same table could lead to a crash of the data node. The same issue could sometimes cause `NdbEventOperation::execute()` to hang. (Bug #57886)

- **Cluster API**: An NDB API client program under load could abort with an assertion error in `TransporterFacade::remove_from_cond_wait_queue`. (Bug #51775)

  References: See also Bug #32708.

Changes in MySQL Cluster NDB 6.3.38 (5.1.47-ndb-6.3.38) (2010-10-08)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

Obtaining MySQL Cluster NDB 6.3. The latest MySQL Cluster NDB 6.3 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 6.3 release can be obtained from the same location. You can also access the MySQL Cluster NDB 6.3 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-5.1-telco-6.3.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see Changes in MySQL 5.1.47 (2010-05-06)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- `mysqldump` as supplied with MySQL Cluster now has an `--add-drop-trigger` [294] option which adds a `DROP TRIGGER IF EXISTS` statement before each dumped trigger definition. (Bug #55691)

  References: See also Bug #34325, Bug #11747863.

- **Cluster API**: The MGM API function `ndb_mgm_get_version()`, which was previously internal, has now been moved to the public API. This function can be used to get `NDB` storage engine and other version information from the management server. (Bug #51310)

  References: See also Bug #51273.

Bugs Fixed

- The text file `cluster_change_hist.txt` containing old MySQL Cluster changelog information was no longer being maintained, and so has been removed from the tree. (Bug #56116)

- Memory pages used for `DataMemory` [1817], once assigned to ordered indexes, were not ever freed, even after any rows that belonged to the corresponding indexes had been deleted. (Bug #56829)

- A data node can be shut down having completed and synchronized a given GCI *`x`*, while having written a great many log records belonging to the next GCI *`x`* + 1, as part of normal operations. However, when starting, completing, and synchronizing GCI *`x`* + 1, then the log records from original start must not be read. To make sure that this does not happen, the REDO log reader finds the last GCI to restore, scans forward from that point, and erases any log records that were not (and should never be) used.

  The current issue occurred because this scan stopped immediately as soon as it encountered an empty page. This was problematic because the REDO log is divided into several files; thus, it could be that there were log records in the beginning of the next file, even if the end of the previous file was empty. These log records were never invalidated; following a start or restart, they could be reused, leading to a corrupt REDO log. (Bug #56961)

- An error in program flow in `ndbd.cpp` could result in data node shutdown routines being called multiple times. (Bug #56890)

- In certain cases, `DROP DATABASE` could sometimes leave behind a cached table object, which caused problems with subsequent DDL operations. (Bug #56840)

- When distributing `CREATE TABLE` and `DROP TABLE` operations among several SQL nodes attached to a MySQL Cluster. the `LOCK_OPEN` lock normally protecting `mysqld`'s internal table list is released so that other queries or DML statements are not blocked. However, to make sure that other DDL is not executed simultaneously, a global schema lock (implemented as a row-level lock by `NDB`) is used, such that all operations that can modify the state of the `mysqld` internal table list also need to acquire this global schema lock. The `SHOW TABLE STATUS` statement did not acquire this lock. (Bug #56841)

- When multiple SQL nodes were connected to the cluster and one of them stopped in the middle of a DDL operation, the `mysqld` process issuing the DDL timed out with the error `distributing` *`tbl_name`* `timed out. Ignoring`. (Bug #56763)

- MySQL Cluster stores, for each row in each `NDB` table, a Global Checkpoint Index (GCI) which identifies the last committed transaction that modified the row. As such, a GCI can be thought of as a coarse-grained row version.

Due to changes in the format used by NDB to store local checkpoints (LCPs) in MySQL Cluster NDB 6.3.11, it could happen that, following cluster shutdown and subsequent recovery, the GCI values for some rows could be changed unnecessarily; this could possibly, over the course of many node or system restarts (or both), lead to an inconsistent database. (Bug #56770)

- An online ALTER TABLE ... ADD COLUMN operation that changed the table schema such that the number of 32-bit words used for the bitmask allocated to each DML operation increased during a transaction in DML which was performed prior to DDL which was followed by either another DML operation or—if using replication—a commit, led to data node failure.

  This was because the data node did not take into account that the bitmask for the before-image was smaller than the current bitmask, which caused the node to crash. (Bug #56524)

  References: This bug is a regression of Bug #35208.

- The failure of a data node during some scans could cause other data nodes to fail. (Bug #54945)

- Exhausting the number of available commit-ack markers (controlled by the MaxNoOfConcurrentTransactions [1821] parameter) led to a data node crash. (Bug #54944)

- When running a SELECT on an NDB table with BLOB or TEXT columns, memory was allocated for the columns but was not freed until the end of the SELECT. This could cause problems with excessive memory usage when dumping (using for example mysqldump) tables with such columns and having many rows, large column values, or both. (Bug #52313)

  References: See also Bug #56488, Bug #50310.

- **Cluster Replication**: When a mysqld process was shut down while it was still performing updates, it was possible for the entry containing binary log information for the final epoch preceding shutdown to be omitted from the mysql.ndb_binlog_index table. This could sometimes occur even during a normal shutdown of mysqld. (Bug #55909)

- **Cluster Replication**: When an SQL node starts, as part of setting up replication, it subscribes to data events from all data nodes using a SUB_START_REQ (subscription start request) signal. Atomicity of SUB_START_REQ is implemented such that, if any of the nodes returns an error, a SUB_STOP_REQ (subscription stop request) is sent to any nodes that replied with a SUB_START_CONF (subscription start confirmation). However, if all data nodes returned an error, SUB_STOP_REQ was not sent to any of them. This caused mysqld to hang when restarting (while waiting for a response), and subsequent data node restarts to hang as well. (Bug #56579)

- **Cluster Replication**: The graceful shutdown of a data node in the master cluster could sometimes cause rows to be skipped when writing transactions to the binary log. Testing following an initial fix for this issue revealed an additional case where the graceful shutdown of a data node was not handled properly. The current fix addresses this case. (Bug #55641)

  References: See also Bug #18538.

Changes in MySQL Cluster NDB 6.3.37 (5.1.47-ndb-6.3.37) (2010-09-03)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

Obtaining MySQL Cluster NDB 6.3. The latest MySQL Cluster NDB 6.3 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 6.3 release can be obtained from the same location. You can also access the MySQL Cluster NDB 6.3 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-5.1-telco-6.3.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see Changes in MySQL 5.1.47 (2010-05-06)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Important Change**: More finely grained control over restart-on-failure behavior is provided with two new data node configuration parameters `MaxStartFailRetries` [1863] and `StartFailRetryDelay` [1863]. `MaxStartFailRetries` [1863] limits the total number of retries made before giving up on starting the data node; `StartFailRetryDelay` [1863] sets the number of seconds between retry attempts.

  These parameters are used only if `StopOnError` [1832] is set to 0.

  For more information, see Defining MySQL Cluster Data Nodes. (Bug #54341)

Bugs Fixed

- Following a failure of the master data node, the new master sometimes experienced a race condition which caused the node to terminate with a **`GcpStop`** error. (Bug #56044)
- The warning `MaxNoOfExecutionThreads (#) > LockExecuteThreadToCPU count (#), this could cause contention` could be logged when running `ndbd`, even though the condition described can occur only when using `ndbmtd`. (Bug #54342)
- The graceful shutdown of a data node could sometimes cause transactions to be aborted unnecessarily. (Bug #18538)

  References: See also Bug #55641.
- **Cluster Replication**: The graceful shutdown of a data node in the master cluster could sometimes cause rows to be skipped when writing transactions to the binary log, leading to an inconsistent slave cluster. (Bug #55641)

  References: See also Bug #18538.
- **Cluster Replication**: Specifying the `--expire_logs_days` [474] option when there were old binary logs to delete caused SQL nodes to crash on startup. (Bug #41751)

Changes in MySQL Cluster NDB 6.3.36 (5.1.47-ndb-6.3.36) (2010-08-16)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

Obtaining MySQL Cluster NDB 6.3. The latest MySQL Cluster NDB 6.3 binaries for supported platforms can be obtained from http://dev.mysql.com/downloads/cluster/. Source code for the latest MySQL Cluster NDB 6.3 release can be obtained from the same location. You can also access the MySQL Cluster NDB 6.3 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-5.1-telco-6.3.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see Changes in MySQL 5.1.47 (2010-05-06)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- Added the `DictTrace` data node configuration parameter, for use in debugging `NDB` code. For more information, see Defining MySQL Cluster Data Nodes. (Bug #55963)

Bugs Fixed

- **Cluster API**: **Important Change**: The poll and select calls made by the MGM API were not interrupt-safe; that is, a signal caught by the process while waiting for an event on one or more sockets returned error -1 with `errno` set to `EINTR`. This caused problems with MGM API functions such as `ndb_logevent_get_next()` and `ndb_mgm_get_status2()`.

  To fix this problem, the internal `ndb_socket_poller::poll()` function has been made `EINTR`-safe.

  The old version of this function has been retained as `poll_unsafe()`, for use by those parts of NDB that do not need the `EINTR`-safe version of the function. (Bug #55906)

- When another data node failed, a given data node `DBTC` kernel block could time out while waiting for `DBDIH` to signal commits of pending transactions, leading to a crash. Now in such cases the timeout generates a prinout, and the data node continues to operate. (Bug #55715)

- An excessive number of timeout warnings (normally used only for debugging) were written to the data node logs. (Bug #53987)

- It was possible for a `DROP DATABASE` statement to remove `NDB` hidden blob tables without removing the parent tables, with the result that the tables, although hidden to MySQL clients, were still visible in the output of `ndb_show_tables` but could not be dropped using `ndb_drop_table`. (Bug #54788)

- The `configure.js` option `WITHOUT_DYNAMIC_PLUGINS=TRUE` was ignored when building MySQL Cluster for Windows using `CMake`. Among the effects of this issue was that `CMake` attempted to build the `InnoDB` storage engine as a plugin (`.DLL` file) even though the `InnoDB Plugin` is not currently supported by MySQL Cluster. (Bug #54913)

- **Disk Data**: As an optimization when inserting a row to an empty page, the page is not read, but rather simply initialized. However, this optimzation was performed in all cases when an empty row was inserted, even though it should have been done only if it was the first time that the page had been used by a table or fragment. This is because, if the page had been in use, and then all records had been released from it, the page still needed to be read to learn its log sequence number (LSN).

  This caused problems only if the page had been flushed using an incorrect LSN and the data node failed before any local checkpoint was completed—which would remove any need to apply the undo log, hence the incorrect LSN was ignored.

  The user-visible result of the incorrect LSN was that it caused the data node to fail during a restart. It was perhaps also possible (although not conclusively proven) that this issue could lead to incorrect data. (Bug #54986)

- **Cluster Replication**: When inserting rows into the `mysql.ndb_binlog_index` table, duplicate key errors occurred when the size of the epoch number (a 64-bit integer) exceeded 2^{53}. This happened because the `NDB` storage engine handler called the wrong overloaded variant of a MySQL Server internal API (the `Field::store()` method), which resulted in the epoch being mapped to a 64-bit double precision floating point number and a corresponding loss of accuracy for numbers greater than 2^{53}. (Bug #35217)

- **Cluster API**: Calling `NdbTransaction::refresh()` did not update the timer for `TransactionInactiveTimeout` [1841]. (Bug #54724)

Changes in MySQL Cluster NDB 6.3.35 (5.1.47-ndb-6.3.35) (2010-06-25)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see Changes in MySQL 5.1.47 (2010-05-06)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- Restrictions on some types of mismatches in column definitions when restoring data using `ndb_restore` have been relaxed. These include the following types of mismatches:

  - Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
  - Different `STORAGE` settings (`MEMORY`, `DISK`)
  - Different default values
  - Different distribution key settings

  Now, when one of these types of mismatches in column definitions is encountered, `ndb_restore` no longer stops with an error; instead, it accepts the data and inserts it into the target table, while issuing a warning to the user.

  For more information, see `ndb_restore` — Restore a MySQL Cluster Backup. (Bug #54423)

  References: See also Bug #53810, Bug #54178, Bug #54242, Bug #54279.

- Introduced the `HeartbeatOrder` [1837] data node configuration parameter, which can be used to set the order in which heartbeats are transmitted between data nodes. This parameter can be useful in situations where multiple data nodes are running on the same host and a temporary disruption in connectivity between hosts would otherwise cause the loss of a node group, leading to failure of the cluster. (Bug #52182)

Bugs Fixed

- The disconnection of all API nodes (including SQL nodes) during an `ALTER TABLE` caused a memory leak. (Bug #54685)
- If a node shutdown (either in isolation or as part of a system shutdown) occurred directly following a local checkpoint, it was possible that this local checkpoint would not be used when restoring the cluster. (Bug #54611)
- A table having the maximum number of attributes permitted could not be backed up using the `ndb_mgm` client.

  Note

  The maximum number of attributes supported per table is not the same for all MySQL Cluster releases. See Limits Associated with Database Objects in MySQL Cluster, to determine the maximum that applies in the release which you are using.

  (Bug #54155)

- When performing an online alter table where 2 or more SQL nodes connected to the cluster were generating binary logs, an incorrect message could be sent from the data nodes, causing `mysqld` processes to crash. This problem was often difficult to detect, because restarting SQL node or data node processes could clear the error, and because the crash in `mysqld` did not occur until several minutes after the erroneous message was sent and received. (Bug #54168)

- During initial node restarts, initialization of the REDO log was always performed 1 node at a time, during start phase 4. Now this is done during start phase 2, so that the initialization can be performed in parallel, thus decreasing the time required for initial restarts involving multiple nodes. (Bug #50062)

- **Cluster Replication**: An error in an `NDB` internal byte mask value could lead to corruption of replicated `BIT` column values. (Bug #54005)

  References: See also Bug #53622.

- **Cluster API**: When using the NDB API, it was possible to rename a table with the same name as that of an existing table.

  Note

  This issue did not affect table renames executed using SQL on MySQL servers acting as MySQL Cluster API nodes.

  (Bug #54651)

- **Cluster API**: An excessive number of client connections, such that more than 1024 file descriptors, sockets, or both were open, caused NDB API applications to crash. (Bug #34303)

Changes in MySQL Cluster NDB 6.3.34 (5.1.44-ndb-6.3.34) (2010-05-31)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 6.3.34 from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.44-ndb-6.3.34/.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.44 (see Changes in MySQL 5.1.44 (2010-02-04)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- A `--wait-nodes` option has been added for `ndb_waiter`. When this option is used, the program waits only for the nodes having the listed IDs to reach the desired state. For more information, see `ndb_waiter` — Wait for MySQL Cluster to Reach a Given Status. (Bug #52323)

- Added the `--skip-unknown-objects` [2003] option for `ndb_restore`. This option causes `ndb_restore` to ignore any schema objects which it does not recognize. Currently, this is useful chiefly for restoring native backups made from a cluster running MySQL Cluster NDB 7.0 to a cluster running MySQL Cluster NDB 6.3.

Bugs Fixed

- **Cluster API**: **Incompatible Change**: The default behavior of the NDB API Event API has changed as follows:

  Previously, when creating an `Event`, DDL operations (alter and drop operations on tables) were automatically reported on any event operation that used this event, but as a result of this change, this is no longer the case. Instead, you must now invoke the event's `setReport()` method, with the new `EventReport` value `ER_DDL`, to get this behavior.

For existing NDB API applications where you wish to retain the old behavior, you must update the code as indicated previously, then recompile, following an upgrade. Otherwise, DDL operations are no longer reported after upgrading `libndbnclient`.

For more information, see The `Event::EventReport` Type, and `Event::setReport()`. (Bug #53308)

- When attempting to create an `NDB` table on an SQL node that had not yet connected to a MySQL Cluster management server since the SQL node's last restart, the `CREATE TABLE` statement failed as expected, but with the unexpected Error 1495 `For the partitioned engine it is necessary to define all partitions`. (Bug #11747335, Bug #31853)

- Creating a Disk Data table, dropping it, then creating an in-memory table and performing a restart, could cause data node processes to fail with errors in the `DBTUP` kernel block if the new table's internal ID was the same as that of the old Disk Data table. This could occur because undo log handling during the restart did not check that the table having this ID was now in-memory only. (Bug #53935)

- An internal buffer allocator used by `NDB` has the form `alloc(wanted, minimum)` and attempts to allocate *`wanted`* pages, but is permitted to allocate a smaller number of pages, between *`wanted`* and *`minimum`*. However, this allocator could sometimes allocate fewer than *`minimum`* pages, causing problems with multi-threaded building of ordered indexes. (Bug #53580)

- A table created while `ndb_table_no_logging` [1930] was enabled was not always stored to disk, which could lead to a data node crash with `Error opening DIH schema files for table`. (Bug #53934)

- When compiled with support for `epoll` but this functionality is not available at runtime, MySQL Cluster tries to fall back to use the `select()` function in its place. However, an extra `ndbout_c()` call in the transporter registry code caused `ndbd` to fail instead. (Bug #53482)

- `NDB` truncated a column declared as `DECIMAL(65,0)` to a length of 64. Now such a column is accepted and handled correctly. In cases where the maximum length (65) is exceeded, `NDB` now raises an error instead of truncating. (Bug #53352)

- Setting `DataMemory` [1817] higher than 4G on 32-bit platforms caused `ndbd` to crash, instead of failing gracefully with an error. (Bug #52536, Bug #50928)

- When a watchdog shutdown occurred due to an error, the process was not terminated quickly enough, sometimes resulting in a hang. (To correct this, the internal `_exit()` function is now called in such situations, rather than `exit()`.) (Bug #53246)

- NDB did not distinguish correctly between table names differing only by lettercase when `lower_case_table_names` [492] was set to 0. (Bug #33158)

- `ndb_mgm -e "ALL STATUS"` erroneously reported that data nodes remained in start phase 0 until they had actually started.

- **Replication**: A buffer overrun in the handling of `DATE` column values could cause `mysqlbinlog` to fail when reading logs containing certain combinations of DML statements on a table having a `DATE` column followed by dropping the table. (Bug #52202)

- **Cluster Replication**: Replication failed after a restart of the slave SQL node, due to an error in writing the `master.info` file. (Bug #52859)

- `ALTER TABLE` did not work correctly where the name of the table, the database, or both contained special characters, causing the MySQL server to crash. (Bug #52225)

  References: See also Bug #53409, Bug #14959.

Changes in MySQL Cluster NDB 6.3.33 (5.1.44-ndb-6.3.33) (2010-03-31)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

You can obtain the GPL source code and GPL binaries for supported platforms for MySQL Cluster NDB 6.3.33 from http://dev.mysql.com/downloads/cluster/.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.44 (see Changes in MySQL 5.1.44 (2010-02-04)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Cluster API**: It is now possible to determine, using the `ndb_desc` utility or the NDB API, which data nodes contain replicas of which partitions. For `ndb_desc`, a new `--extra-node-info` [1982] option is added to cause this information to be included in its output. A new method `Table::getFragmentNodes()` is added to the NDB API for obtaining this information programmatically. (Bug #51184)

- Formerly, the `REPORT` and `DUMP` commands returned output to all `ndb_mgm` clients connected to the same MySQL Cluster. Now, these commands return their output only to the `ndb_mgm` client that actually issued the command. (Bug #40865)

- **Cluster Replication**: **Replication**: MySQL Cluster Replication now supports attribute promotion and demotion for row-based replication between columns of different but similar types on the master and the slave. For example, it is possible to promote an `INT` column on the master to a `BIGINT` column on the slave, and to demote a `TEXT` column to a `VARCHAR` column.

  The implementation of type demotion distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` [1646] global server system variable.

  For more information about attribute promotion and demotion for row-based replication in MySQL Cluster, see Attribute promotion and demotion (MySQL Cluster). (Bug #47163, Bug #46584)

Bugs Fixed

- **Cluster Replication**: **Important Change**: The `--ndb-log-empty-epochs` [1917] option was ignored. Setting the `ndb_log_empty_epochs` [1935] server system variable also had no effect.

  As part of the fix for this issue, rows for empty epochs are now recorded in the `ndb_binlog_index` table even when `--ndb-log-empty-epochs` [1917] is 0. (Bug #49559, Bug #11757505)

- If a node or cluster failure occurred while `mysqld` was scanning the `ndb.ndb_schema` table (which it does when attempting to connect to the cluster), insufficient error handling could lead to a crash by `mysqld` in certain cases. This could happen in a MySQL Cluster with a great many tables, when trying to restart data nodes while one or more `mysqld` processes were restarting. (Bug #52325)

- After running a mixed series of node and system restarts, a system restart could hang or fail altogether. This was caused by setting the value of the newest completed global checkpoint too low for a data node performing a node restart, which led to the node reporting incorrect GCI intervals for its first local checkpoint. (Bug #52217)

- When performing a complex mix of node restarts and system restarts, the node that was elected as master sometimes required optimized node recovery due to missing `REDO` information. When this

happened, the node crashed with `Failure to recreate object ... during restart, error 721` (because the `DBDICT` restart code was run twice). Now when this occurs, node takeover is executed immediately, rather than being made to wait until the remaining data nodes have started. (Bug #52135)

References: See also Bug #48436.

- The redo log protects itself from being filled up by periodically checking how much space remains free. If insufficient redo log space is available, it sets the state `TAIL_PROBLEM` which results in transactions being aborted with error code 410 (`out of redo log`). However, this state was not set following a node restart, which meant that if a data node had insufficient redo log space following a node restart, it could crash a short time later with `Fatal error due to end of REDO log`. Now, this space is checked during node restarts. (Bug #51723)

- The output of the `ndb_mgm` client `REPORT BACKUPSTATUS` command could sometimes contain errors due to uninitialized data. (Bug #51316)

- The `ndb_mgm` client sometimes inserted extra prompts within the output of the `REPORT MEMORYUSAGE` command. (Bug #50196)

- Issuing a command in the `ndb_mgm` client after it had lost its connection to the management server could cause the client to crash. (Bug #49219)

- A `GROUP BY` query against `NDB` tables sometimes did not use any indexes unless the query included a `FORCE INDEX` option. With this fix, indexes are used by such queries (where otherwise possible) even when `FORCE INDEX` is not specified. (Bug #50736)

- The `ndb_print_backup_file` utility failed to function, due to a previous internal change in the NDB code. (Bug #41512, Bug #48673)

- When the `MemReportFrequency` [1849] configuration parameter was set in `config.ini`, the `ndb_mgm` client `REPORT MEMORYUSAGE` command printed its output multiple times. (Bug #37632)

- `ndb_mgm -e "... REPORT ..."` did not write any output to `stdout`.

  The fix for this issue also prevents the cluster log from being flooded with `INFO` messages when `DataMemory` [1817] usage reaches 100%, and insures that when the usage is decreased, an appropriate message is written to the cluster log. (Bug #31542, Bug #44183, Bug #49782)

- **InnoDB**: **Replication**: Column length information generated by `InnoDB` did not match that generated by `MyISAM`, which caused invalid metadata to be written to the binary log when trying to replicate `BIT` columns. (Bug #49618)

- **Replication**: Metadata for `GEOMETRY` fields was not properly stored by the slave in its definitions of tables. (Bug #49836)

  References: See also Bug #48776.

- **Disk Data**: Inserts of blob column values into a MySQL Cluster Disk Data table that exhausted the tablespace resulted in misleading `no such tuple` error messages rather than the expected error `tablespace full`.

  This issue appeared similar to Bug #48113, but had a different underlying cause. (Bug #52201)

- **Disk Data**: The error message returned after atttempting to execute `ALTER LOGFILE GROUP` on an nonexistent logfile group did not indicate the reason for the failure. (Bug #51111)

- **Cluster Replication**: When `mysqld` was started with `--binlog-do-db` [1649] or `--binlog-ignore-db` [1651], no `LOST_EVENTS` incident was written to the binary log. (Bug #47096)

- **Cluster API**: When reading blob data with lock mode `LM_SimpleRead`, the lock was not upgraded as expected. (Bug #51034)

- **Cluster API**: A number of issues were corrected in the NDB API coding examples found in the `storage/ndb/ndbapi-examples` directory in the MySQL Cluster source tree. These included possible endless recursion in `ndbapi_scan.cpp` as well as problems running some of the examples on systems using Windows or Mac OS X due to the lettercase used for some table names. (Bug #30552, Bug #30737)

- 1) In rare cases, if a thread was interrupted during a `FLUSH PRIVILEGES` operation, a debug assertion occurred later due to improper diagnostics area setup. 2) A `KILL` operation could cause a console error message referring to a diagnostic area state without first ensuring that the state existed. (Bug #33982)

Changes in MySQL Cluster NDB 6.3.32 (5.1.41-ndb-6.3.32) (2010-03-04)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see Changes in MySQL 5.1.41 (2009-11-05)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- A new configuration parameter `HeartbeatThreadPriority` makes it possible to select between a first-in, first-out or round-round scheduling policy for management node and API node heartbeat threads, as well as to set the priority of these threads. See Defining a MySQL Cluster Management Server, or Defining SQL and Other API Nodes in a MySQL Cluster, for more information. (Bug #49617)

- **Disk Data**: The `ndb_desc` utility can now show the extent space and free extent space for subordinate `BLOB` and `TEXT` columns (stored in hidden `BLOB` tables by NDB). A `--blob-info` [1982] option has been added for this program that causes `ndb_desc` to generate a report for each subordinate `BLOB` table. For more information, see `ndb_desc` — Describe NDB Tables. (Bug #50599)

Bugs Fixed

- When one or more data nodes read their LCPs and applied undo logs significantly faster than others, this could lead to a race condition causing system restarts of data nodes to hang. This could most often occur when using both `ndbd` and `ndbmtd` processes for the data nodes. (Bug #51644)

- When deciding how to divide the REDO log, the `DBDIH` kernel block saved more than was needed to restore the previous local checkpoint, which could cause REDO log space to be exhausted prematurely (`NDB` error 410). (Bug #51547)

- DML operations can fail with `NDB` error 1220 (`REDO log files overloaded...`) if the opening and closing of REDO log files takes too much time. If this occurred as a GCI marker was being written in the REDO log while REDO log file 0 was being opened or closed, the error could persist until a GCP stop was encountered. This issue could be triggered when there was insufficient REDO log space (for example, with configuration parameter settings `NoOfFragmentLogFiles = 6` and `FragmentLogFileSize = 6M`) with a load including a very high number of updates. (Bug #51512)

  References: See also Bug #20904.

- A `SELECT` requiring a sort could fail with the error `Can't find record in 'table'` when run concurrently with a `DELETE` from the same table. (Bug #45687)

- During an online upgrade from MySQL Cluster NDB 6.2 to MySQL Cluster NDB 6.3, a sufficiently large amount of traffic with more than 1 DML operation per transaction could lead.an NDB 6.3 data node to crash an NDB 6.2 data node with an internal error in the `DBLQH` kernel block. (Bug #51389)

- A side effect of the `ndb_restore --disable-indexes` [2002] and `--rebuild-indexes` [2002] options is to change the schema versions of indexes. When a `mysqld` later tried to drop a table that had been restored from backup using one or both of these options, the server failed to detect these changed indexes. This caused the table to be dropped, but the indexes to be left behind, leading to problems with subsequent backup and restore operations. (Bug #51374)

- `ndb_restore` crashed while trying to restore a corrupted backup, due to missing error handling. (Bug #51223)

- The `ndb_restore` message `Successfully created index `PRIMARY`...` was directed to `stderr` instead of `stdout`. (Bug #51037)

- When using `NoOfReplicas` [1815] equal to 1 or 2, if data nodes from one node group were restarted 256 times and applications were running traffic such that it would encounter `NDB` error 1204 (`Temporary failure, distribution changed`), the live node in the node group would crash, causing the cluster to crash as well. The crash occurred only when the error was encountered on the 256th restart; having the error on any previous or subsequent restart did not cause any problems. (Bug #50930)

- **Cluster API**: An issue internal to `ndb_mgm` could cause problems when trying to start a large number of data nodes at the same time. (Bug #51273)

  References: See also Bug #51310.

Changes in MySQL Cluster NDB 6.3.31b (5.1.41-ndb-6.3.31b) (2010-02-18)

This is a replacement release for MySQL Cluster NDB 6.3.31a, fixing a critical issue in that version that was discovered shortly after its release (Bug #51256). MySQL Cluster NDB 6.3.31b is identical in all other respects to MySQL Cluster NDB 6.3.31a. Users of MySQL Cluster NDB 6.3.31 or MySQL Cluster NDB 6.3.31a should upgrade to the 6.3.31b release as soon as possible. Users of previous MySQL Cluster NDB 6.3 releases should bypass the 6.3.31 and 6.3.31a releases, and upgrade to 6.3.31b instead.

Obtaining MySQL Cluster NDB 6.3.31b. This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 6.3.31b from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.41-ndb-6.3.31b/. You can also access the MySQL Cluster NDB 6.3 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-5.1-telco-6.3.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see Changes in MySQL 5.1.41 (2009-11-05)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- Setting `IndexMemory` [1819] greater than 2GB could cause data nodes to crash while starting. (Bug #51256)

Changes in MySQL Cluster NDB 6.3.31a (5.1.41-ndb-6.3.31a) (2010-02-15)

Note

MySQL Cluster NDB 6.3.31a was withdrawn shortly after release, due to Bug #51256. Users should upgrade to MySQL Cluster NDB 6.3.31b, which fixes this issue.

This is a replacement release for MySQL Cluster NDB 6.3.31, fixing a critical issue in that version that was discovered shortly after its release (Bug #51027). MySQL Cluster NDB 6.3.31a is identical in all other respects to MySQL Cluster NDB 6.3.31. Users of MySQL Cluster NDB 6.3.31 should upgrade to the 6.3.31a release as soon as possible. Users of previous MySQL Cluster NDB 6.3 releases should bypass the 6.3.31 release and upgrade to 6.3.31a instead.

Obtaining MySQL Cluster NDB 6.3.31a. This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 6.3.31a from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.41-ndb-6.3.31a/. You can also access the MySQL Cluster NDB 6.3 development source tree at https://code.launchpad.net/~mysql/mysql-server/mysql-5.1-telco-6.3.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see Changes in MySQL 5.1.41 (2009-11-05)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- An initial restart of a data node configured with a large amount of memory could fail with a `Pointer too large` error. (Bug #51027)

  References: This bug was introduced by Bug #47818.

Changes in MySQL Cluster NDB 6.3.31 (5.1.41-ndb-6.3.31) (2010-02-02)

Note

MySQL Cluster NDB 6.3.31 was withdrawn shortly after release, due to Bug #51027. Users should upgrade to MySQL Cluster NDB 6.3.31a, which fixes this issue.

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see Changes in MySQL 5.1.41 (2009-11-05)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Important Change**: The maximum permitted value of the `ndb_autoincrement_prefetch_sz` [1921] system variable has been increased from 256 to 65536. (Bug #50621)

- **Cluster Replication**: In circular replication, it was sometimes possible for an event to propagate such that it would be reapplied on all servers. This could occur when the originating server was removed from the replication circle and so could no longer act as the terminator of its own events, as normally happens in circular replication.

  To prevent this from occurring, a new `IGNORE_SERVER_IDS` option is introduced for the `CHANGE MASTER TO` statement. This option takes a list of replication server IDs; events having a server ID which appears in this list are ignored and not applied. For more information, see `CHANGE MASTER TO` Syntax.

  In conjunction with the introduction of `IGNORE_SERVER_IDS`, `SHOW SLAVE STATUS` has two new fields. `Replicate_Ignore_Server_Ids` displays information about ignored servers. `Master_Server_Id` displays the `server_id` [521] value from the master. (Bug #47037)

  References: See also Bug #25998, Bug #27808.

- **Cluster Replication**: Due to the fact that no timestamp is available for delete operations, a delete using `NDB$MAX()` is actually processed as `NDB$OLD`. However, because this is not optimal for some use cases, `NDB$MAX_DELETE_WIN()` is added as a conflict resolution function; if the “timestamp” column value for a given row adding or updating an existing row coming from the master is higher than that on the slave, it is applied (as with `NDB$MAX()`); however, delete operations are treated as always having the higher value.

  See `NDB$MAX_DELETE_WIN(column_name)`, for more information. (Bug #50650)

Bugs Fixed

- If a query on an `NDB` table compared a constant string value to a column, and the length of the string was greater than that of the column, condition pushdown did not work correctly. (The string was truncated to fit the column length before being pushed down.) Now in such cases, the condition is no longer pushed down. (Bug #49459)

- When performing a `DELETE` that included a left join from an `NDB` table, only the first matching row was deleted. (Bug #47054)

- During Start Phases 1 and 2, the `STATUS` command sometimes (falsely) returned `Not Connected` for data nodes running `ndbmtd`. (Bug #47818)

- When setting the `LockPagesInMainMemory` [1832] configuration parameter failed, only the error `Failed to memlock pages...` was returned. Now in such cases the operating system's error code is also returned. (Bug #49724)

- Dropping unique indexes in parallel while they were in use could cause node and cluster failures. (Bug #50118)

- Setting `BuildIndexThreads` [1854] greater than 1 with more than 31 ordered indexes caused node and system restarts to fail. (Bug #50266)

- Performing intensive inserts and deletes in parallel with a high scan load could a data node crashes due to a failure in the `DBACC` kernel block. This was because checking for when to perform bucket splits or merges considered the first 4 scans only. (Bug #48700)

- `mysqld` could sometimes crash during a commit while trying to handle NDB Error 4028 `Node failure caused abort of transaction`. (Bug #38577)

- When setting `LockPagesInMainMemory` [1832], the stated memory was not allocated when the node was started, but rather only when the memory was used by the data node process for other reasons. (Bug #37430)

- Trying to insert more rows than would fit into an `NDB` table caused data nodes to crash. Now in such situations, the insert fails gracefully with error 633 `Table fragment hash index has reached maximum possible size`. (Bug #34348)

- **Disk Data**: When a crash occurs due to a problem in Disk Data code, the currently active page list is printed to `stdout` (that is, in one or more `ndb_nodeid_out.log` files). One of these lists could contain an endless loop; this caused a printout that was effectively never-ending. Now in such cases, a maximum of 512 entries is printed from each list. (Bug #42431)

- The `ARCHIVE` storage engine lost records during a bulk insert. (Bug #46961)

- On Mac OS X or Windows, sending a `SIGHUP` signal to the server or an asynchronous flush (triggered by `flush_time` [475]) caused the server to crash. (Bug #47525)

- When using the `ARCHIVE` storage engine, `SHOW TABLE STATUS` displayed incorrect information for `Max_data_length`, `Data_length` and `Avg_row_length`. (Bug #29203)

Changes in MySQL Cluster NDB 6.3.30 (5.1.39-ndb-6.3.30) (2009-12-15)

This special-purpose evaluation release incorporates all bugfixes and feature changes from previous MySQL Cluster NDB 6.3 releases plus one new feature for evaluation. Most users of MySQL Cluster NDB 6.3 do not require this release; instead, you should use MySQL Cluster NDB 6.3.29 until MySQL Cluster NDB 6.3.31 is released.

This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 6.3.30 from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.39-ndb-6.3.30/.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.39 (see Changes in MySQL 5.1.39 (2009-09-04)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- Added multi-threaded ordered index building capability during system restarts or node restarts, controlled by the `BuildIndexThreads` [1854] data node configuration parameter (also introduced in this release).

Changes in MySQL Cluster NDB 6.3.29 (5.1.39-ndb-6.3.29) (2009-12-15)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 6.3.29 from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.39-ndb-6.3.29/.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.39 (see Changes in MySQL 5.1.39 (2009-09-04)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- The output from `ndb_config --configinfo` [1975] `--xml` [1976] now indicates, for each configuration parameter, the following restart type information:

- Whether a system restart or a node restart is required when resetting that parameter;
- Whether cluster nodes need to be restarted using the `--initial` option when resetting the parameter.

(Bug #47366)

- This enhanced functionality is supported for upgrades to MySQL Cluster NDB 7.0 when the `NDB` engine version is 7.0.10 or later. (Bug #48528, Bug #49163)

Bugs Fixed

- Node takeover during a system restart occurs when the REDO log for one or more data nodes is out of date, so that a node restart is invoked for that node or those nodes. If this happens while a `mysqld` process is attached to the cluster as an SQL node, the `mysqld` takes a global schema lock (a row lock), while trying to set up cluster-internal replication.

  However, this setup process could fail, causing the global schema lock to be held for an excessive length of time, which made the node restart hang as well. As a result, the mysqld failed to set up cluster-internal replication, which led to tables being read only, and caused one node to hang during the restart.

  Note

  This issue could actually occur in MySQL Cluster NDB 7.0 only, but the fix was also applied MySQL Cluster NDB 6.3, to keep the two codebases in alignment.

  (Bug #49560)

- If the master data node receiving a request from a newly started API or data node for a node ID died before the request has been handled, the management server waited (and kept a mutex) until all handling of this node failure was complete before responding to any other connections, instead of responding to other connections as soon as it was informed of the node failure (that is, it waited until it had received a NF_COMPLETEREP signal rather than a NODE_FAILREP signal). On visible effect of this misbehavior was that it caused management client commands such as SHOW and ALL STATUS to respond with unnecessary slowness in such circumstances. (Bug #49207)

- Sending `SIGHUP` to a `mysqld` running with the `--ndbcluster` [1915] and `--log-bin` [1647] options caused the process to crash instead of refreshing its log files. (Bug #49515)

- When evaluating the options `--include-databases` [1999], `--include-tables` [2000], `--exclude-databases` [2001], and `--exclude-tables` [2001], the `ndb_restore` program overwrote the result of the database-level options with the result of the table-level options rather than merging these results together, sometimes leading to unexpected and unpredictable results.

  As part of the fix for this problem, the semantics of these options have been clarified; because of this, the rules governing their evaluation have changed slightly. These changes be summed up as follows:

  - All `--include-*` and `--exclude-*` options are now evaluated from right to left in the order in which they are passed to `ndb_restore`.
  - All `--include-*` and `--exclude-*` options are now cumulative.
  - In the event of a conflict, the first (rightmost) option takes precedence.

  For more detailed information and examples, see `ndb_restore` — Restore a MySQL Cluster Backup. (Bug #48907)

- When performing tasks that generated large amounts of I/O (such as when using `ndb_restore`), an internal memory buffer could overflow, causing data nodes to fail with signal 6.

Subsequent analysis showed that this buffer was not actually required, so this fix removes it. (Bug #48861)

- Exhaustion of send buffer memory or long signal memory caused data nodes to crash. Now an appropriate error message is provided instead when this situation occurs. (Bug #48852)
- When employing NDB native backup to back up and restore an empty NDB table that used a non-sequential AUTO_INCREMENT value, the AUTO_INCREMENT value was not restored correctly. (Bug #48005)
- NDB stores blob column data in a separate, hidden table that is not accessible from MySQL. If this table was missing for some reason (such as accidental deletion of the file corresponding to the hidden table) when making a MySQL Cluster native backup, ndb_restore crashed when attempting to restore the backup. Now in such cases, ndb_restore fails with the error message `Table table_name has blob column (column_name) with missing parts table in backup` instead. (Bug #47289)
- Under certain conditions, accounting of the number of free scan records in the local query handler could be incorrect, so that during node recovery or a local checkpoint operations, the LQH could find itself lacking a scan record that is expected to find, causing the node to crash. (Bug #48697)

  References: See also Bug #48564.
- The creation of an ordered index on a table undergoing DDL operations could cause a data node crash under certain timing-dependent conditions. (Bug #48604)
- When running many parallel scans, a local checkpoint (which performs a scan internally) could find itself not getting a scan record, which led to a data node crash. Now an extra scan record is reserved for this purpose, and a problem with obtaining the scan record returns an appropriate error (error code 489, `Too many active scans`). (Bug #48564)
- During an LCP master takeover, when the newly elected master did not receive a COPY_GCI LCP protocol message but other nodes participating in the local checkpoint had received one, the new master could use an uninitialized variable, which caused it to crash. (Bug #48584)
- `ndb_config --xml --configinfo` now indicates that parameters belonging in the [SCI], [SCI DEFAULT], [SHM], and [SHM DEFAULT] sections of the config.ini file are deprecated or experimental, as appropriate. (Bug #47365)
- During a node restart, logging was enabled on a per-fragment basis as the copying of each fragment was completed but local checkpoints were not enabled until all fragments were copied, making it possible to run out of redo log file space (NDB error code 410) before the restart was complete. Now logging is enabled only after all fragments has been copied, just prior to enabling local checkpoints. (Bug #48474)
- Creating an NDB table with an excessive number of large BIT columns caused the cluster to fail. Now, an attempt to create such a table is rejected with error 791 (`Too many total bits in bitfields`). (Bug #42046)

  References: See also Bug #42047.
- DROP DATABASE failed when there were stale temporary NDB tables in the database. This situation could occur if mysqld crashed during execution of a DROP TABLE statement after the table definition had been removed from NDBCLUSTER but before the corresponding .ndb file had been removed from the crashed SQL node's data directory. Now, when mysqld executes DROP DATABASE, it checks for these files and removes them if there are no corresponding table definitions for them found in NDBCLUSTER. (Bug #44529)
- When a long-running transaction lasting long enough to cause Error 410 (`REDO log files overloaded`) was later committed or rolled back, it could happen that NDBCLUSTER was not able to release the space used for the REDO log, so that the error condition persisted indefinitely.

The most likely cause of such transactions is a bug in the application using MySQL Cluster. This fix should handle most cases where this might occur. (Bug #36500)

- Deprecation and usage information obtained from `ndb_config --configinfo` [1975] regarding the `PortNumber` [1810] and `ServerPort` [1814] configuration parameters was improved. (Bug #24584)
- **Disk Data**: Repeatedly creating and then dropping Disk Data tables could eventually lead to data node failures. (Bug #45794, Bug #48910)
- **Disk Data**: When running a write-intensive workload with a very large disk page buffer cache, CPU usage approached 100% during a local checkpoint of a cluster containing Disk Data tables. (Bug #49532)
- **Disk Data**: When the `FileSystemPathUndoFiles` [1858] configuration parameter was set to an non-existent path, the data nodes shut down with the generic error code 2341 (`Internal program error`). Now in such cases, the error reported is error 2815 (`File not found`).
- **Cluster Replication**: When `expire_logs_days` [474] was set, the thread performing the purge of the log files could deadlock, causing all binary log operations to stop. (Bug #49536)
- **Cluster API**: When a DML operation failed due to a uniqueness violation on an `NDB` table having more than one unique index, it was difficult to determine which constraint caused the failure; it was necessary to obtain an `NdbError` object, then decode its `details` property, which in could lead to memory management issues in application code.

  To help solve this problem, a new API method `Ndb::getNdbErrorDetail()` is added, providing a well-formatted string containing more precise information about the index that caused the unque constraint violation. The following additional changes are also made in the NDB API:

  - Use of `NdbError.details` is now deprecated in favor of the new method.
  - The `NdbDictionary::listObjects()` method has been modified to provide more information.

  For more information, see `Ndb::getNdbErrorDetail()`, The `NdbError` Structure, and `Dictionary::listObjects()`. (Bug #48851)
- **Cluster API**: When using blobs, calling `getBlobHandle()` requires the full key to have been set using `equal()`, because `getBlobHandle()` must access the key for adding blob table operations. However, if `getBlobHandle()` was called without first setting all parts of the primary key, the application using it crashed. Now, an appropriate error code is returned instead. (Bug #28116, Bug #48973)

Changes in MySQL Cluster NDB 6.3.28b (5.1.39-ndb-6.3.28b) (2009-11-10)

This release includes a fix for Bug #48651, which was discovered in MySQL Cluster NDB 6.3.28a shortly after release. The MySQL Cluster NDB 6.3.28b release is identical in all other respects to MySQL Cluster NDB 6.3.28a. Users who have already installed MySQL Cluster NDB 6.3.28a should upgrade to MySQL Cluster NDB 6.3.28b as soon as possible; users seeking to upgrade from any other previous MySQL Cluster 6.3 release should upgrade to MySQL Cluster NDB 6.3.28b instead.

This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 6.3.28b from http://dev.mysql.com/downloads/cluster/.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.39 (see Changes in MySQL 5.1.39 (2009-09-04)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- When the combined length of all names of tables using the `NDB` storage engine was greater than or equal to 1024 bytes, issuing the `START BACKUP` command in the `ndb_mgm` client caused the cluster to crash. (Bug #48531)

Changes in MySQL Cluster NDB 6.3.28a (5.1.39-ndb-6.3.28a) (2009-11-05)

Important

MySQL Cluster NDB 6.3.28a was pulled shortly after release due to Bug #48651. Users seeking to upgrade from a previous MySQL Cluster NDB 6.3 release should instead use MySQL Cluster NDB 6.3.28b, which contains a fix for this bug, in addition to all bugfixes and improvements made in MySQL Cluster NDB 6.3.28a.

This release includes a fix for Bug #48531, which was discovered in MySQL Cluster NDB 6.3.28 shortly after release. The MySQL Cluster NDB 6.3.28a release is identical in all other respects to MySQL Cluster NDB 6.3.28. Users who have already installed MySQL Cluster NDB 6.3.28 should upgrade to MySQL Cluster NDB 6.3.28a as soon as possible; users seeking to upgrade from any other previous MySQL Cluster 6.3 release should upgrade to MySQL Cluster NDB 6.3.28a instead.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.39 (see Changes in MySQL 5.1.39 (2009-09-04)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- When the combined length of all names of tables using the `NDB` storage engine was greater than or equal to 1024 bytes, issuing the `START BACKUP` command in the `ndb_mgm` client caused the cluster to crash. (Bug #48531)

Changes in MySQL Cluster NDB 6.3.28 (5.1.39-ndb-6.3.28) (2009-10-31)

Important

MySQL Cluster NDB 6.3.28 and 6.3.28a were pulled shortly after being released due to Bug #48531 and Bug #48651. Users seeking to upgrade from a previous MySQL Cluster NDB 6.3 release should instead use MySQL Cluster NDB 6.3.28b, which contains fixes for these critical bugs, in addition to all bugfixes and improvements made in MySQL Cluster NDB 6.3.28.

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.39 (see Changes in MySQL 5.1.39 (2009-09-04)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Performance**: Significant improvements in redo log handling and other file system operations can yield a considerable reduction in the time required for restarts. While actual restart times observed in a production setting will naturally vary according to database size, hardware, and other conditions, our own preliminary testing shows that these optimizations can yield startup times that are faster than those typical of previous MySQL Cluster releases by a factor of 50 or more.

Bugs Fixed

- **Important Change**: The `--with-ndb-port-base` option for `configure` did not function correctly, and has been deprecated. Attempting to use this option produces the warning `Ignoring deprecated option --with-ndb-port-base`.

  Beginning with MySQL Cluster NDB 7.1.0, the deprecation warning itself is removed, and the `--with-ndb-port-base` option is simply handled as an unknown and invalid option if you try to use it. (Bug #47941)

  References: See also Bug #38502.

- For `UPDATE IGNORE` statements, batching of updates is now disabled. This is because such statements failed when batching of updates was employed if any updates violated a unique constraint, to the fact a unique constraint violation could not be handled without aborting the transaction. (Bug #48036)

- When an `UPDATE` statement was issued against an `NDB` table where an index was used to identify rows but no data was actually changed, the `NDB` storage returned zero found rows.

  For example, consider the table created and populated using these statements:

  ```
  CREATE TABLE t1
  (
      c1 INT NOT NULL,
      c2 INT NOT NULL,
      PRIMARY KEY(c1),
      KEY(c2)
  )
  ENGINE = NDB;

  INSERT INTO t1 VALUES(1, 1);
  ```

  The following `UPDATE` statements, even though they did not change any rows, each still matched a row, but this was reported incorrectly in both cases, as shown here:

  ```
  mysql> UPDATE t1 SET c2 = 1 WHERE c1 = 1;
  Query OK, 0 rows affected (0.00 sec)
  Rows matched: 0  Changed: 0  Warnings: 0

  mysql> UPDATE t1 SET c1 = 1 WHERE c2 = 1;
  Query OK, 0 rows affected (0.00 sec)
  Rows matched: 0  Changed: 0  Warnings: 0
  ```

  Now in such cases, the number of rows matched is correct. (In the case of each of the example `UPDATE` statements just shown, this is displayed as Rows matched: 1, as it should be.)

  This issue could affect `UPDATE` statements involving any indexed columns in `NDB` tables, regardless of the type of index (including `KEY`, `UNIQUE KEY`, and `PRIMARY KEY`) or the number of columns covered by the index. (Bug #47955)

- In certain cases, performing very large inserts on `NDB` tables when using `ndbmtd` caused the memory allocations for ordered or unique indexes (or both) to be exceeded. This could cause aborted transactions and possibly lead to data node failures. (Bug #48037)

  References: See also Bug #48113.

- `SHOW CREATE TABLE` did not display the `AUTO_INCREMENT` value for `NDB` tables having `AUTO_INCREMENT` columns. (Bug #47865)

- Starting a data node with a very large amount of `DataMemory` [1817] (approximately 90G or more) could lead to crash of the node due to job buffer congestion. (Bug #47984)

- On Solaris, shutting down a management node failed when issuing the command to do so from a client connected to a different management node. (Bug #47948)

- Setting `FragmentLogFileSize` [1826] to a value greater than 256 MB led to errors when trying to read the redo log file. (Bug #47908)

- When starting a node and synchronizing tables, memory pages were allocated even for empty fragments. In certain situations, this could lead to insufficient memory. (Bug #47782)

- Under some circumstances, when a scan encountered an error early in processing by the `DBTC` kernel block (see The `DBTC` Block), a node could crash as a result. Such errors could be caused by applications sending incorrect data, or, more rarely, by a `DROP TABLE` operation executed in parallel with a scan. (Bug #47831)

- `configure` failed to honor the `--with-zlib-dir` option when trying to build MySQL Cluster from source. (Bug #47223)

- A very small race-condition between `NODE_FAILREP` and `LQH_TRANSREQ` signals when handling node failure could lead to operations (locks) not being taken over when they should have been, and subsequently becoming stale. This could lead to node restart failures, and applications getting into endless lock-conflicts with operations that were not released until the node was restarted. (Bug #47715)

  References: See also Bug #41297.

- `ndbd` was not built correctly when compiled using `gcc` 4.4.0. (The `ndbd` binary was built, but could not be started.) (Bug #46113)

- When starting a cluster with a great many tables, it was possible for MySQL client connections as well as the slave SQL thread to issue DML statements against MySQL Cluster tables before `mysqld` had finished connecting to the cluster and making all tables writeable. This resulted in `Table ... is read only` errors for clients and the Slave SQL thread.

  This issue is fixed by introducing the `--ndb-wait-setup` [1919] option for the MySQL server. This provides a configurable maximum amount of time that `mysqld` waits for all `NDB` tables to become writeable, before enabling MySQL clients or the slave SQL thread to connect. (Bug #40679)

  References: See also Bug #46955.

- When building MySQL Cluster, it was possible to configure the build using `--with-ndb-port` without supplying a port number. Now in such cases, `configure` fails with an error. (Bug #38502)

  References: See also Bug #47941.

- If a node failed while sending a fragmented long signal, the receiving node did not free long signal assembly resources that it had allocated for the fragments of the long signal that had already been received. (Bug #44607)

- When a copying operation exhausted the available space on a data node while copying large `BLOB` columns, this could lead to failure of the data node and a `Table is full` error on the SQL node which was executing the operation. Examples of such operations could include an `ALTER TABLE` that changed an `INT` column to a `BLOB` column, or a bulk insert of `BLOB` data that failed due to running out of space or to a duplicate key error. (Bug #34583, Bug #48040)

  References: See also Bug #41674, Bug #45768.

- When the MySQL server SQL mode included `STRICT_TRANS_TABLES` [576], storage engine warnings and error codes specific to `NDB` were returned when errors occurred, instead of the MySQL server errors and error codes expected by some programming APIs (such as Connector/J) and applications. (Bug #35990)

- **Replication**: When `mysqlbinlog --verbose` [354] was used to read a binary log that had been written using row-based format, the output for events that updated some but not all columns of tables was not correct. (Bug #47323)

- **Disk Data**: A local checkpoint of an empty fragment could cause a crash during a system restart which was based on that LCP. (Bug #47832)

  References: See also Bug #41915.

- **Cluster Replication**: When using multiple active replication channels, it was sometimes possible that a node group would fail on the slave cluster, causing the slave cluster to shut down. (Bug #47935)

- **Cluster Replication**: When recording a binary log using the `--ndb-log-update-as-write` [2143] and `--ndb-log-updated-only` [2143] options (both enabled by default) and later attempting to apply that binary log with `mysqlbinlog`, any operations that were played back from the log but which updated only some (but not all) columns caused any columns that were not updated to be reset to their default values. (Bug #47674)

  References: See also Bug #47323, Bug #46662.

- **Cluster Replication**: `mysqlbinlog` failed to apply correctly a binary log that had been recorded using `--ndb-log-update-as-write=1` [2143]. (Bug #46662)

  References: See also Bug #47323, Bug #47674.

- **Cluster API**: If an NDB API program reads the same column more than once, it is possible exceed the maximum permissible message size, in which case the operation should be aborted due to NDB error 880 `Tried to read too much - too many getValue calls`, however due to a change introduced in MySQL Cluster NDB 6.3.18, the check for this was not done correctly, which instead caused a data node crash. (Bug #48266)

- **Cluster API**: The NDB API methods `Dictionary::listEvents()`, `Dictionary::listIndexes()`, `Dictionary::listObjects()`, and `NdbOperation::getErrorLine()` formerly had both `const` and non-`const` variants. The non-`const` versions of these methods have been removed. In addition, the `NdbOperation::getBlobHandle()` method has been re-implemented to provide consistent internal semantics. (Bug #47798)

- **Cluster API**: A duplicate read of a column caused NDB API applications to crash. (Bug #45282)

- **Cluster API**: The error handling shown in the example file `ndbapi_scan.cpp` included with the MySQL Cluster distribution was incorrect. (Bug #39573)

- Installation of MySQL on Windows would fail to set the correct location for the character set files, which could lead to `mysqld` and `mysql` failing to initialize properly. (Bug #17270)

Changes in MySQL Cluster NDB 6.3.27a (5.1.37-ndb-6.3.27a) (2009-10-07)

This release includes a fix for Bug #47844, which was discovered in MySQL Cluster NDB 6.3.27 shortly after release. The MySQL Cluster NDB 6.3.27a release is identical in all other respects to MySQL Cluster NDB 6.3.27. Users who have already installed MySQL Cluster NDB 6.3.27 should upgrade to MySQL Cluster NDB 6.3.27a as soon as possible; users seeking to upgrade from MySQL Cluster NDB 6.3.26 or another previous MySQL Cluster 6.3 release should upgrade to MySQL Cluster NDB 6.3.27a instead.

This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 6.3.27a from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.37-ndb-6.3.27a/.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.37 (see Changes in MySQL 5.1.37 (2009-07-13)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- The disconnection of an API or SQL node having a node ID greater than 49 caused a forced shutdown of the cluster. (Bug #47844)
- The error message text for `NDB` error code 410 (`REDO log files overloaded...`) was truncated. (Bug #23662)

Changes in MySQL Cluster NDB 6.3.27 (5.1.37-ndb-6.3.27) (2009-09-30)

Important

MySQL Cluster NDB 6.3.27 was pulled shortly after release due to Bug #47844. Users seeking to upgrade from a previous MySQL Cluster NDB 6.3 release should instead use MySQL Cluster NDB 6.3.27a, which contains a fix for this bug, in addition to all bugfixes and improvements made in MySQL Cluster NDB 6.3.27.

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.37 (see Changes in MySQL 5.1.37 (2009-07-13)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Disk Data**: Two new columns have been added to the output of `ndb_desc` to make it possible to determine how much of the disk space allocated to a given table or fragment remains free. (This information is not available from the `INFORMATION_SCHEMA.FILES` table, since the `FILES` table applies only to Disk Data files.) For more information, see `ndb_desc` — Describe NDB Tables. (Bug #47131)

Bugs Fixed

- **Cluster Replication**: **Important Change**: In a MySQL Cluster acting as a replication slave and having multiple SQL nodes, only the SQL node receiving events directly from the master recorded DDL statements in its binary logs unless this SQL node also had binary logging enabled; otherwise, other SQL nodes in the slave cluster failed to log DDL statements, regardless of their individual `--log-bin` [1647] settings.

  The fix for this issue aligns binary logging of DDL statements with that of DML statements. In particular, you should take note of the following:

  - DDL and DML statements on the master cluster are logged with the server ID of the server that actually writes the log.

- DDL and DML statements on the master cluster are logged by any attached `mysqld` that has binary logging enabled.
- Replicated DDL and DML statements on the slave are logged by any attached mysqld that has both `--log-bin` [1647] and `--log-slave-updates` [1628] enabled.
- Replicated DDL and DML statements are logged with the server ID of the original (master) MySQL server by any attached `mysqld` that has both `--log-bin` [1647] and `--log-slave-updates` [1628] enabled.

Affect on upgrades. When upgrading from a previous MySQL CLuster release, you should perform either one of the following:

a. Upgrade servers that are performing binary logging before those that are not; do not perform any DDL on “old” SQL nodes until all SQL nodes have been upgraded.

b. Make sure that `--log-slave-updates` [1628] is enabled on all SQL nodes performing binary logging prior to the upgrade, so that all DDL is captured.

Note

Logging of DML statements was not affected by this issue.

(Bug #45756)

- `mysqld` allocated an excessively large buffer for handling `BLOB` values due to overestimating their size. (For each row, enough space was allocated to accommodate *every* `BLOB` or `TEXT` column value in the result set.) This could adversely affect performance when using tables containing `BLOB` or `TEXT` columns; in a few extreme cases, this issue could also cause the host system to run out of memory unexpectedly. (Bug #47574)

  References: See also Bug #47572, Bug #47573.

- `NDBCLUSTER` uses a dynamically allocated buffer to store `BLOB` or `TEXT` column data that is read from rows in MySQL Cluster tables.

  When an instance of the `NDBCLUSTER` table handler was recycled (this can happen due to table definition cache pressure or to operations such as `FLUSH TABLES` or `ALTER TABLE`), if the last row read contained blobs of zero length, the buffer was not freed, even though the reference to it was lost. This resulted in a memory leak.

  For example, consider the table defined and populated as shown here:

```
CREATE TABLE t (a INT PRIMARY KEY, b LONGTEXT) ENGINE=NDB;

INSERT INTO t VALUES (1, REPEAT('F', 20000));
INSERT INTO t VALUES (2, '');
```

  Now execute repeatedly a `SELECT` on this table, such that the zero-length `LONGTEXT` row is last, followed by a `FLUSH TABLES` statement (which forces the handler object to be re-used), as shown here:

```

SELECT a, length(b) FROM bl ORDER BY a;
FLUSH TABLES;
```

  Prior to the fix, this resulted in a memory leak proportional to the size of the stored `LONGTEXT` value each time these two statements were executed. (Bug #47573)

  References: See also Bug #47572, Bug #47574.

- Large transactions involving joins between tables containing `BLOB` columns used excessive memory. (Bug #47572)

  References: See also Bug #47573, Bug #47574.

- A variable was left uninitialized while a data node copied data from its peers as part of its startup routine; if the starting node died during this phase, this could lead a crash of the cluster when the node was later restarted. (Bug #47505)

- When a data node restarts, it first runs the redo log until reaching the latest restorable global checkpoint; after this it scans the remainder of the redo log file, searching for entries that should be invalidated so they are not used in any subsequent restarts. (It is possible, for example, if restoring GCI number 25, that there might be entries belonging to GCI 26 in the redo log.) However, under certain rare conditions, during the invalidation process, the redo log files themselves were not always closed while scanning ahead in the redo log. In rare cases, this could lead to `MaxNoOfOpenFiles` [1827] being exceeded, causing a the data node to crash. (Bug #47171)

- Using triggers on `NDB` tables caused `ndb_autoincrement_prefetch_sz` [1921] to be treated as having the NDB kernel's internal default value (32) and the value for this variable as set on the cluster's SQL nodes to be ignored. (Bug #46712)

- For very large values of `MaxNoOfTables` [1829] + `MaxNoOfAttributes` [1828], the calculation for `StringMemory` [1819] could overflow when creating large numbers of tables, leading to `NDB` error 773 (`Out of string memory, please modify StringMemory config parameter`), even when `StringMemory` [1819] was set to `100` (100 percent). (Bug #47170)

- The default value for the `StringMemory` [1819] configuration parameter, unlike other MySQL Cluster configuration parameters, was not set in `ndb/src/mgmsrv/ConfigInfo.cpp`. (Bug #47166)

- Signals from a failed API node could be received after an `API_FAILREQ` signal (see Operations and Signals) has been received from that node, which could result in invalid states for processing subsequent signals. Now, all pending signals from a failing API node are processed before any `API_FAILREQ` signal is received. (Bug #47039)

  References: See also Bug #44607.

- When performing auto-discovery of tables on individual SQL nodes, `NDBCLUSTER` attempted to overwrite existing `MyISAM .frm` files and corrupted them.

  Workaround. In the `mysql` client, create a new table (`t2`) with same definition as the corrupted table (`t1`). Use your system shell or file manager to rename the old `.MYD` file to the new file name (for example, `mv t1.MYD t2.MYD`). In the `mysql` client, repair the new table, drop the old one, and rename the new table using the old file name (for example, `RENAME TABLE t2 TO t1`).

  (Bug #42614)

- When a data node received a `TAKE_OVERTCCONF` signal from the master before that node had received a `NODE_FAILREP`, a race condition could in theory result. (Bug #37688)

  References: See also Bug #25364, Bug #28717.

- Running an `ALTER TABLE` statement while an `NDB` backup was in progress caused `mysqld` to crash. (Bug #44695)

- Running `ndb_restore` with the `--print` or `--print_log` option could cause it to crash. (Bug #40428, Bug #33040)

- An insert on an `NDB` table was not always flushed properly before performing a scan. One way in which this issue could manifest was that `LAST_INSERT_ID()` [1036] sometimes failed to return correct values when using a trigger on an `NDB` table. (Bug #38034)

- Some joins on large `NDB` tables having `TEXT` or `BLOB` columns could cause `mysqld` processes to leak memory. The joins did not need to reference the `TEXT` or `BLOB` columns directly for this issue to occur. (Bug #36701)

- On Mac OS X 10.5, commands entered in the management client failed and sometimes caused the client to hang, although management client commands invoked using the `--execute` [1970] (or `-e`) option from the system shell worked normally.

  For example, the following command failed with an error and hung until killed manually, as shown here:

  ```
  ndb_mgm> SHOW
  Warning, event thread startup failed, degraded printouts as result, errno=36
  ^C
  ```

  However, the same management client command, invoked from the system shell as shown here, worked correctly:

  ```
  shell> ndb_mgm -e "SHOW"
  ```

  (Bug #35751)

  References: See also Bug #34438.

- **Replication**: In some cases, a `STOP SLAVE` statement could cause the replication slave to crash. This issue was specific to MySQL on Windows or Macintosh platforms. (Bug #45238, Bug #45242, Bug #45243, Bug #46013, Bug #46014, Bug #46030)

  References: See also Bug #40796.

- **Disk Data**: Calculation of free space for Disk Data table fragments was sometimes done incorrectly. This could lead to unnecessary allocation of new extents even when sufficient space was available in existing ones for inserted data. In some cases, this might also lead to crashes when restarting data nodes.

  Note

  This miscalculation was not reflected in the contents of the `INFORMATION_SCHEMA.FILES` table, as it applied to extents allocated to a fragment, and not to a file.

  (Bug #47072)

- **Cluster API**: In some circumstances, if an API node encountered a data node failure between the creation of a transaction and the start of a scan using that transaction, then any subsequent calls to `startTransaction()` and `closeTransaction()` could cause the same transaction to be started and closed repeatedly. (Bug #47329)

- **Cluster API**: Performing multiple operations using the same primary key within the same `NdbTransaction::execute()` call could lead to a data node crash.

  Note

  This fix does not make change the fact that performing multiple operations using the same primary key within the same `execute()` is not supported; because there is no way to determine the order of such operations, the result of such combined operations remains undefined.

  (Bug #44065)

  References: See also Bug #44015.

- **API**: The fix for Bug #24507 could lead in some cases to client application failures due to a race condition. Now the server waits for the “dummy” thread to return before exiting, thus making sure that only one thread can initialize the POSIX threads library. (Bug #42850)

Changes in MySQL Cluster NDB 6.3.26 (5.1.35-ndb-6.3.26) (2009-08-26)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.35 (see Changes in MySQL 5.1.35 (2009-05-13)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- On Solaris platforms, the MySQL Cluster management server and NDB API applications now use `CLOCK_REALTIME` as the default clock. (Bug #46183)
- A new option `--exclude-missing-columns` has been added for the `ndb_restore` program. In the event that any tables in the database or databases being restored to have fewer columns than the same-named tables in the backup, the extra columns in the backup's version of the tables are ignored. For more information, see `ndb_restore` — Restore a MySQL Cluster Backup. (Bug #43139)
-

  Note

  This issue, originally resolved in MySQL 5.1.16, re-occurred due to a later (unrelated) change. The fix has been re-applied.

  (Bug #25984)

Bugs Fixed

- Killing MySQL Cluster nodes immediately following a local checkpoint could lead to a crash of the cluster when later attempting to perform a system restart.

  The exact sequence of events causing this issue was as follows:

  1. Local checkpoint occurs.
  2. Immediately following the LCP, kill the master data node.
  3. Kill the remaining data nodes within a few seconds of killing the master.
  4. Attempt to restart the cluster.

  (Bug #46412)

- Restarting the cluster following a local checkpoint and an online `ALTER TABLE` on a non-empty table caused data nodes to crash. (Bug #46651)
- When combining an index scan and a delete with a primary key delete, the index scan and delete failed to initialize a flag properly. This could in rare circumstances cause a data node to crash. (Bug #46069)
- Full table scans failed to execute when the cluster contained more than 21 table fragments.

Note

The number of table fragments in the cluster can be calculated as the number of data nodes, times 8 (that is, times the value of the internal constant `MAX_FRAG_PER_NODE`), divided by the number of replicas. Thus, when `NoOfReplicas = 1` at least 3 data nodes were required to trigger this issue, and when `NoOfReplicas = 2` at least 4 data nodes were required to do so.

(Bug #46490)

- `OPTIMIZE TABLE` on an `NDB` table could in some cases cause SQL and data nodes to crash. This issue was observed with both `ndbd` and `ndbmtd`. (Bug #45971)
- Ending a line in the `config.ini` file with an extra semicolon character (`;`) caused reading the file to fail with a parsing error. (Bug #46242)
- The `AutoReconnect` [1867] configuration parameter for API nodes (including SQL nodes) has been added. This is intended to prevent API nodes from re-using allocated node IDs during cluster restarts. For more information, see Defining SQL and Other API Nodes in a MySQL Cluster.

  This fix also introduces two new methods of the NDB API `Ndb_cluster_connection` class: `set_auto_reconnect()` and `get_auto_reconnect()`. (Bug #45921)
- The signals used by `ndb_restore` to send progress information about backups to the cluster log accessed the cluster transporter without using any locks. Because of this, it was theoretically possible that these signals could be interefered with by heartbeat signals if both were sent at the same time, causing the `ndb_restore` messages to be corrupted. (Bug #45646)
- The warning message `Possible bug in Dbdih::execBLOCK_COMMIT_ORD ...` could sometimes appear in the cluster log. This warning is obsolete, and has been removed. (Bug #44563)
- In some cases, `OPTIMIZE TABLE` on an `NDB` table did not free any `DataMemory` [1817]. (Bug #43683)
- Problems could arise when using `VARCHAR` columns whose size was greater than 341 characters and which used the `utf8_unicode_ci` collation. In some cases, this combination of conditions could cause certain queries and `OPTIMIZE TABLE` statements to crash `mysqld`. (Bug #45053)
- An internal NDB API buffer was not properly initialized. (Bug #44977)
- When a data node had written its GCI marker to the first page of a megabyte, and that node was later killed during restart after having processed that page (marker) but before completing a LCP, the data node could fail with file system errors. (Bug #44952)

  References: See also Bug #42564, Bug #44291.
- If the cluster crashed during the execution of a `CREATE LOGFILE GROUP` statement, the cluster could not be restarted afterward. (Bug #36702)

  References: See also Bug #34102.
- **Disk Data**: **Partitioning**: An `NDB` table created with a very large value for the `MAX_ROWS` option could—if this table was dropped and a new table with fewer partitions, but having the same table ID, was created—cause `ndbd` to crash when performing a system restart. This was because the server attempted to examine each partition whether or not it actually existed. (Bug #45154)

  References: See also Bug #58638.
- **Disk Data**: If the value set in the `config.ini` file for `FileSystemPathDD` [1857], `FileSystemPathDataFiles` [1858], or `FileSystemPathUndoFiles` [1858] was identical to the value set for `FileSystemPath` [1816], that parameter was ignored when starting the data node

with `--initial` [1954] option. As a result, the Disk Data files in the corresponding directory were not removed when performing an initial start of the affected data node or data nodes. (Bug #46243)

- **Disk Data**: During a checkpoint, restore points are created for both the on-disk and in-memory parts of a Disk Data table. Under certain rare conditions, the in-memory restore point could include or exclude a row that should have been in the snapshot. This would later lead to a crash during or following recovery. (Bug #41915)

  References: See also Bug #47832.

Changes in MySQL Cluster NDB 6.3.25 (5.1.34-ndb-6.3.25) (2009-05-25)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.34 (see Changes in MySQL 5.1.34 (2009-04-02)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- Two new server status variables `Ndb_scan_count` [1949] and `Ndb_pruned_scan_count` [1949] have been introduced. `Ndb_scan_count` [1949] gives the number of scans executed since the cluster was last started. `Ndb_pruned_scan_count` [1949] gives the number of scans for which `NDBCLUSTER` was able to use partition pruning. Together, these variables can be used to help determine in the MySQL server whether table scans are pruned by `NDBCLUSTER`. (Bug #44153)

- The `ndb_config` utility program can now provide an offline dump of all MySQL Cluster configuration parameters including information such as default and permitted values, brief description, and applicable section of the `config.ini` file. A dump in text format is produced when running `ndb_config` with the new `--configinfo` option, and in XML format when the options `--configinfo --xml` are used together. For more information and examples, see `ndb_config` — Extract MySQL Cluster Configuration Information.

Bugs Fixed

- **Important Change**: **Partitioning**: User-defined partitioning of an `NDBCLUSTER` table without any primary key sometimes failed, and could cause `mysqld` to crash.

  Now, if you wish to create an `NDBCLUSTER` table with user-defined partitioning, the table must have an explicit primary key, and all columns listed in the partitioning expression must be part of the primary key. The hidden primary key used by the `NDBCLUSTER` storage engine is not sufficient for this purpose. However, if the list of columns is empty (that is, the table is defined using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

  This change does not effect the partitioning of tables using any storage engine other than `NDBCLUSTER`. (Bug #40709)

- **Important Change**: Previously, the configuration parameter `NoOfReplicas` [1815] had no default value. Now the default for `NoOfReplicas` [1815] is 2, which is the recommended value in most settings. (Bug #44746)

- **Packaging**: The `pkg` installer for MySQL Cluster on Solaris did not perform a complete installation due to an invalid directory reference in the postinstall script. (Bug #41998)

- `ndb_config --xml` [1975] did not output any entries for the `HostName` parameter. In addition, the default listed for `MaxNoOfFiles` was outside the permitted range of values. (Bug #44749)

References: See also Bug #44685, Bug #44746.

- The output of `ndb_config --xml [1975]` did not provide information about all sections of the configuration file. (Bug #44685)

  References: See also Bug #44746, Bug #44749.

- When `ndb_config` could not find the file referenced by the `--config-file` option, it tried to read `my.cnf` instead, then failed with a misleading error message. (Bug #44846)

- When a data node was down so long that its most recent local checkpoint depended on a global checkpoint that was no longer restorable, it was possible for it to be unable to use optimized node recovery when being restarted later. (Bug #44844)

  References: See also Bug #26913.

- Inspection of the code revealed that several assignment operators (`=`) were used in place of comparison operators (`==`) in `DbdihMain.cpp`. (Bug #44567)

  References: See also Bug #44570.

- It was possible for NDB API applications to insert corrupt data into the database, which could subquently lead to data node crashes. Now, stricter checking is enforced on input data for inserts and updates. (Bug #44132)

- `NDBCLUSTER` did not build correctly on Solaris 9 platforms. (Bug #39080)

  References: See also Bug #39036, Bug #39038.

- When trying to use a data node with an older version of the management server, the data node crashed on startup. (Bug #43699)

- In some cases, data node restarts during a system restart could fail due to insufficient redo log space. (Bug #43156)

- `ndb_restore` failed when trying to restore data on a big-endian machine from a backup file created on a little-endian machine. (Bug #44069)

- The file `ndberror.c` contained a C++-style comment, which caused builds to fail with some C compilers. (Bug #44036)

- `ndb_restore --print_data [1997]` did not handle `DECIMAL` columns correctly. (Bug #37171)

- The output of `ndbd --help` did not provide clear information about the program's `--initial` and `--initial-start` options. (Bug #28905)

- It was theoretically possible for the value of a nonexistent column to be read as `NULL`, rather than causing an error. (Bug #27843)

- **Disk Data**: This fix supercedes and improves on an earlier fix made for this bug in MySQL 5.1.18. (Bug #24521)

- **Cluster Replication**: A failure when setting up replication events could lead to subsequent data node failures. (Bug #44915)

Changes in MySQL Cluster NDB 6.3.24 (5.1.32-ndb-6.3.24) (2009-04-09)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 6.3.24 from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.32-ndb-6.3.24/.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.32 (see Changes in MySQL 5.1.32 (2009-02-14)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- **Cluster Replication**: If data node failed during an event creation operation, there was a slight risk that a surviving data node could send an invalid table reference back to NDB, causing the operation to fail with a false Error 723 (`No such table`). This could take place when a data node failed as a `mysqld` process was setting up MySQL Cluster Replication. (Bug #43754)

- **Cluster API**: Partition pruning did not work correctly for queries involving multiple range scans.

  As part of the fix for this issue, several improvements have been made in the NDB API, including the addition of a new `NdbScanOperation::getPruned()` method, a new variant of `NdbIndexScanOperation::setBound()`, and a new `PartitionSpec` data structure. (Bug #37934)

- `TransactionDeadlockDetectionTimeout` [1841] values less than 100 were treated as 100. This could cause scans to time out unexpectedly. (Bug #44099)

- `ndb_restore` crashed when trying to restore a backup made to a MySQL Cluster running on a platform having different endianness from that on which the original backup was taken. (Bug #39540)

- A race condition could occur when a data node failed to restart just before being included in the next global checkpoint. This could cause other data nodes to fail. (Bug #43888)

- When a data node process had been killed after allocating a node ID, but before making contact with any other data node processes, it was not possible to restart it due to a node ID allocation failure.

  This issue could effect either `ndbd` or `ndbmtd` processes. (Bug #43224)

  References: This bug was introduced by Bug #42973.

- Some queries using combinations of logical and comparison operators on an indexed column in the `WHERE` clause could fail with the error `Got error 4541 'IndexBound has no bound information' from NDBCLUSTER`. (Bug #42857)

- `TimeBetweenLocalCheckpoints` [1839] was measured from the end of one local checkpoint to the beginning of the next, rather than from the beginning of one LCP to the beginning of the next. This meant that the time spent performing the LCP was not taken into account when determining the `TimeBetweenLocalCheckpoints` [1839] interval, so that LCPs were not started often enough, possibly causing data nodes to run out of redo log space prematurely. (Bug #43567)

- Using indexes containing variable-sized columns could lead to internal errors when the indexes were being built. (Bug #43226)

- When aborting an operation involving both an insert and a delete, the insert and delete were aborted separately. This was because the transaction coordinator did not know that the operations affected on same row, and, in the case of a committed-read (tuple or index) scan, the abort of the insert was performed first, then the row was examined after the insert was aborted but before the delete was aborted. In some cases, this would leave the row in a inconsistent state. This could occur when a local checkpoint was performed during a backup. This issue did not affect primary ley operations or scans that used locks (these are serialized).

  After this fix, for ordered indexes, all operations that follow the operation to be aborted are now also aborted.

- **Disk Data**: When a log file group had an undo log file whose size was too small, restarting data nodes failed with `Read underflow` errors.

  As a result of this fix, the minimum permitted `INTIAL_SIZE` for an undo log file is now `1M` (1 megabyte). (Bug #29574)

- **Cluster Replication**: When creating or altering a table an `NdbEventOperation` is created by the `mysqld` process to monitor the table for subsequent logging in the binlog. If this happened during a node restart there was a chance that the reference count on this event operation object could be incorrect, which could lead to an assert in debug MySQL Cluster builds. (Bug #43752)

- **Cluster API**: `BIT` columns created using the native NDB API format that were not created as nullable could still sometimes be overwritten, or cause other columns to be overwritten.

  This issue did not effect tables having `BIT` columns created using the mysqld format (always used by MySQL Cluster SQL nodes). (Bug #43802)

- **Cluster API**: If the largest offset of a `RecordSpecification` used for an `NdbRecord` object was for the `NULL` bits (and thus not a column), this offset was not taken into account when calculating the size used for the `RecordSpecification`. This meant that the space for the `NULL` bits could be overwritten by key or other information. (Bug #43891)

- **Cluster API**: Ordered index scans using `NdbRecord` formerly expressed a `BoundEQ` range as separate lower and upper bounds, resulting in 2 copies of the column values being sent to the NDB kernel.

  Now, when a range is specified by `NdbScanOperation::setBound()`, the passed pointers, key lengths, and inclusive bits are compared, and only one copy of the equal key columns is sent to the kernel. This makes such operations more efficient, as half the amount of `KeyInfo` is now sent for a `BoundEQ` range as before. (Bug #38793)

- **Cluster API**: When performing insert or write operations, `NdbRecord` permits key columns to be specified in both the key record and in the attribute record. Only one key column value for each key column should be sent to the NDB kernel, but this was not guaranteed. This is now ensured as follows: For insert and write operations, key column values are taken from the key record; for scan takeover update operations, key column values are taken from the attribute record. (Bug #42238)

- **Cluster API**: The default `NdbRecord` structures created by `NdbDictionary` could have overlapping null bits and data fields. (Bug #43590)

Changes in MySQL Cluster NDB 6.3.23 (5.1.32-ndb-6.3.23) (2009-02-24)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 6.3.23 from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.32-ndb-6.3.23/.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.32 (see Changes in MySQL 5.1.32 (2009-02-14)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Important Change**: **Replication**: `RESET MASTER` and `RESET SLAVE` now reset the values shown for `Last_IO_Error`, `Last_IO_Errno`, `Last_SQL_Error`, and `Last_SQL_Errno` in the output of `SHOW SLAVE STATUS`. (Bug #34654)

References: See also Bug #44270.

- A new data node configuration parameter `MaxLCPStartDelay` [1828] has been introduced to facilitate parallel node recovery by causing a local checkpoint to be delayed while recovering nodes are synchronizing data dictionaries and other meta-information. For more information about this parameter, see Defining MySQL Cluster Data Nodes. (Bug #43053)

Bugs Fixed

- **Performance**: Updates of the `SYSTAB_0` system table to obtain a unique identifier did not use transaction hints for tables having no primary key. In such cases the NDB kernel used a cache size of 1. This meant that each insert into a table not having a primary key required an update of the corresponding `SYSTAB_0` entry, creating a potential performance bottleneck.

  With this fix, inserts on `NDB` tables without primary keys can be under some conditions be performed up to 100% faster than previously. (Bug #39268)

- **Packaging**: Packages for MySQL Cluster were missing the `libndbclient.so` and `libndbclient.a` files. (Bug #42278)

- **Partitioning**: Executing `ALTER TABLE ... REORGANIZE PARTITION` on an `NDBCLUSTER` table having only one partition caused `mysqld` to crash. (Bug #41945)

  References: See also Bug #40389.

- In some cases, `NDB` did not check correctly whether tables had changed before trying to use the query cache. This could result in a crash of the debug MySQL server. (Bug #40464)

- When using `ndbmtd`, NDB kernel threads could hang while trying to start the data nodes with `LockPagesInMainMemory` [1832] set to 1. (Bug #43021)

- Backup IDs greater than 2^{31} were not handled correctly, causing negative values to be used in backup directory names and printouts. (Bug #43042)

- Given a MySQL Cluster containing no data (that is, whose data nodes had all been started using `--initial`, and into which no data had yet been imported) and having an empty backup directory, executing `START BACKUP` with a user-specified backup ID caused the data nodes to crash. (Bug #41031)

- When using multiple management servers and starting several API nodes (possibly including one or more SQL nodes) whose connectstrings listed the management servers in different order, it was possible for 2 API nodes to be assigned the same node ID. When this happened it was possible for an API node not to get fully connected, consequently producing a number of errors whose cause was not easily recognizable. (Bug #42973)

- Triggers on `NDBCLUSTER` tables caused such tables to become locked. (Bug #42751)

  References: See also Bug #16229, Bug #18135.

- `ndb_error_reporter` worked correctly only with GNU `tar`. (With other versions of `tar`, it produced empty archives.) (Bug #42753)

- **Disk Data**: Creating a Disk Data tablespace with a very large extent size caused the data nodes to fail. The issue was observed when using extent sizes of 100 MB and larger. (Bug #39096)

- **Disk Data**: It was not possible to add an in-memory column online to a table that used a table-level or column-level `STORAGE DISK` option. The same issue prevented `ALTER ONLINE TABLE ... REORGANIZE PARTITION` from working on Disk Data tables. (Bug #42549)

- **Disk Data**: Using a path or file name longer than 128 characters for Disk Data undo log files and tablespace data files caused a number of issues, including failures of `CREATE LOGFILE GROUP`,

`ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, and `ALTER TABLESPACE` statements, as well as crashes of management nodes and data nodes.

With this fix, the maximum length for path and file names used for Disk Data undo log files and tablespace data files is now the same as the maximum for the operating system. (Bug #31769, Bug #31770, Bug #31772)

- **Disk Data**: Trying to execute a `CREATE LOGFILE GROUP` statement using a value greater than `150M` for `UNDO_BUFFER_SIZE` caused data nodes to crash.

  As a result of this fix, the upper limit for `UNDO_BUFFER_SIZE` is now `600M`; attempting to set a higher value now fails gracefully with an error. (Bug #34102)

  References: See also Bug #36702.

- **Disk Data**: When attempting to create a tablespace that already existed, the error message returned was `Table or index with given name already exists`. (Bug #32662)

- **Disk Data**: Attempting to perform a system restart of the cluster where there existed a logfile group without and undo log files caused the data nodes to crash.

  Note

  While issuing a `CREATE LOGFILE GROUP` statement without an `ADD UNDOFILE` option fails with an error in the MySQL server, this situation could arise if an SQL node failed during the execution of a valid `CREATE LOGFILE GROUP` statement; it is also possible to create a logfile group without any undo log files using the NDB API.

  (Bug #17614)

- **Cluster Replication**: Primary key updates on `MyISAM` and `InnoDB` tables failed to replicate to `NDBCLUSTER` tables. (Bug #42921)

- **Cluster Replication**: Being disconnected from the cluster while setting up the binary log caused `mysqld` to hang or crash. (Bug #43045)

- **Cluster API**: Some error messages from `ndb_mgmd` contained newline (`\n`) characters. This could break the MGM API protocol, which uses the newline as a line separator. (Bug #43104)

- **Cluster API**: When using an ordered index scan without putting all key columns in the read mask, this invalid use of the NDB API went undetected, which resulted in the use of uninitialized memory. (Bug #42591)

Changes in MySQL Cluster NDB 6.3.22 (5.1.31-ndb-6.3.22) (2009-02-09)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 6.3.22 from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.31-ndb-6.3.22/.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.31 (see Changes in MySQL 5.1.31 (2009-01-19)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- New options are introduced for `ndb_restore` for determining which tables or databases should be restored:

  - `--include-tables` and `--include-databases` can be used to restore specific tables or databases.

  - `--exclude-tables` and `--exclude-databases` can be used to exclude the specified tables or databases from being restored.

  For more information about these options, see `ndb_restore` — Restore a MySQL Cluster Backup. (Bug #40429)

Bugs Fixed

- When performing more than 32 index or tuple scans on a single fragment, the scans could be left hanging. This caused unnecessary timeouts, and in addition could possibly lead to a hang of an LCP. (Bug #42559)

  References: This bug is a regression of Bug #42084.

- A data node failure that occurred between calls to `NdbIndexScanOperation::readTuples(SF_OrderBy)` and `NdbTransaction::execute()` was not correctly handled; a subsequent call to `nextResult()` caused a null pointer to be deferenced, leading to a segfault in `mysqld`. (Bug #42545)

- Issuing `SHOW GLOBAL STATUS LIKE 'NDB%'` before `mysqld` had connected to the cluster caused a segmentation fault. (Bug #42458)

- Data node failures that occurred before all data nodes had connected to the cluster were not handled correctly, leading to additional data node failures. (Bug #42422)

- When a cluster backup failed with Error 1304 (Node *`node_id1`*: Backup request from *`node_id2`* failed to start), no clear reason for the failure was provided.

  As part of this fix, MySQL Cluster now retries backups in the event of sequence errors. (Bug #42354)

  References: See also Bug #22698.

- Issuing `SHOW ENGINE NDBCLUSTER STATUS` on an SQL node before the management server had connected to the cluster caused `mysqld` to crash. (Bug #42264)

Changes in MySQL Cluster NDB 6.3.21 (5.1.31-ndb-6.3.21) (2009-01-19)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

Note

MySQL Cluster NDB 6.3.21 was withdrawn due to issues discovered after its release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.31 (see Changes in MySQL 5.1.31 (2009-01-19)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Important Change**: Formerly, when the management server failed to create a transporter for a data node connection, `net_write_timeout` [506] seconds elapsed before the data node was actually permitted to disconnect. Now in such cases the disconnection occurs immediately. (Bug #41965)

  References: See also Bug #41713.

- It is now possible while in Single User Mode to restart all data nodes using `ALL RESTART` in the management client. Restarting of individual nodes while in Single User Mode remains not permitted. (Bug #31056)

- Formerly, when using MySQL Cluster Replication, records for “empty” epochs—that is, epochs in which no changes to `NDBCLUSTER` data or tables took place—were inserted into the `ndb_apply_status` and `ndb_binlog_index` tables on the slave even when `--log-slave-updates` [1628] was disabled. Beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.13 this was changed so that these “empty” epochs were no longer logged. However, it is now possible to re-enable the older behavior (and cause “empty” epochs to be logged) by using the `--ndb-log-empty-epochs` option. For more information, see Replication Slave Options and Variables.

  References: See also Bug #37472.

Bugs Fixed

- Trying to execute an `ALTER ONLINE TABLE ... ADD COLUMN` statement while inserting rows into the table caused `mysqld` to crash. (Bug #41905)

- API nodes disconnected too agressively from cluster when data nodes were being restarted. This could sometimes lead to the API node being unable to access the cluster at all during a rolling restart. (Bug #41462)

- A maximum of 11 `TUP` scans were permitted in parallel. (Bug #42084)

- Issuing `EXIT` in the management client sometimes caused the client to hang. (Bug #40922)

- If the master node failed during a global checkpoint, it was possible in some circumstances for the new master to use an incorrect value for the global checkpoint index. This could occur only when the cluster used more than one node group. (Bug #41469)

- It was not possible to perform online upgrades from a MySQL Cluster NDB 6.2 release to MySQL Cluster NDB 6.3.8 or a later MySQL Cluster NDB 6.3 release. (Bug #41435)

- An abort path in the `DBLQH` kernel block failed to release a commit acknowledgment marker. This meant that, during node failure handling, the local query handler could be added multiple times to the marker record which could lead to additional node failures due an array overflow. (Bug #41296)

- During node failure handling (of a data node other than the master), there was a chance that the master was waiting for a `GCP_NODEFINISHED` signal from the failed node after having received it from all other data nodes. If this occurred while the failed node had a transaction that was still being committed in the current epoch, the master node could crash in the `DBTC` kernel block when discovering that a transaction actually belonged to an epoch which was already completed. (Bug #41295)

- Cluster log files were opened twice by internal log-handling code, resulting in a resource leak. (Bug #41362)

- In the event that a MySQL Cluster backup failed due to file permissions issues, conflicting reports were issued in the management client. (Bug #34526)

- If all data nodes were shut down, MySQL clients were unable to access `NDBCLUSTER` tables and data even after the data nodes were restarted, unless the MySQL clients themselves were restarted. (Bug #33626)

- **Disk Data**: Starting a cluster under load such that Disk Data tables used most of the undo buffer could cause data node failures.

  The fix for this bug also corrected an issue in the `LGMAN` kernel block where the amount of free space left in the undo buffer was miscalculated, causing buffer overruns. This could cause records in the buffer to be overwritten, leading to problems when restarting data nodes. (Bug #28077)

- **Cluster Replication**: Sometimes, when using the `--ndb_log_orig` option, the `orig_epoch` and `orig_server_id` columns of the `ndb_binlog_index` table on the slave contained the ID and epoch of the local server instead. (Bug #41601)

- **Cluster API**: `mgmapi.h` contained constructs which only worked in C++, but not in C. (Bug #27004)

Changes in MySQL Cluster NDB 6.3.20 (5.1.30-ndb-6.3.20) (2008-12-17)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

Obtaining MySQL Cluster NDB 6.3. You can download MySQL Cluster NDB 6.3.20 source code and binaries for supported platforms from http://dev.mysql.com/downloads/cluster/.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.30 (see Changes in MySQL 5.1.30 (2008-11-14, General Availability)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Cluster API**: Two new `Ndb_cluster_connection` methods have been added to help in diagnosing problems with NDB API client connections. The `get_latest_error()` method tells whether or not the latest connection attempt succeeded; if the attempt failed, `get_latest_error_msg()` provides an error message giving the reason.

Bugs Fixed

- Statements of the form `UPDATE ... ORDER BY ... LIMIT` run against `NDBCLUSTER` tables failed to update all matching rows, or failed with the error `Can't find record in 'table_name'`. (Bug #40081)

- Issuing `SHOW TABLES` repeatedly could cause `NDBCLUSTER` tables to be dropped. (Bug #40854)

- Start phase reporting was inconsistent between the management client and the cluster log. (Bug #39667)

- If a transaction was aborted during the handling of a data node failure, this could lead to the later handling of an API node failure not being completed. (Bug #41214)

- Status messages shown in the management client when restarting a management node were inappropriate and misleading. Now, when restarting a management node, the messages displayed are as follows, where *`node_id`* is the management node's node ID:

```
ndb_mgm> node_id RESTART
Shutting down MGM node node_id for restart
Node node_id is being restarted

ndb_mgm>
```

  (Bug #29275)

- **Partitioning**: A query on a user-partitioned table caused MySQL to crash, where the query had the following characteristics:

  - The query's `WHERE` clause referenced an indexed column that was also in the partitioning key.
  - The query's `WHERE` clause included a value found in the partition.
  - The query's `WHERE` clause used the `<` or `<>` operators to compare with the indexed column's value with a constant.
  - The query used an `ORDER BY` clause, and the same indexed column was used in the `ORDER BY` clause.
  - The `ORDER BY` clause used an explicit or implicit `ASC` sort priority.

  Two examples of such a query are given here, where `a` represents an indexed column used in the table's partitioning key:

  1. `SELECT * FROM table WHERE a < constant ORDER BY a;`
  2. `SELECT * FROM table WHERE a <> constant ORDER BY a;`

  This bug was introduced in MySQL Cluster NDB 6.3.19. (Bug #40954)

  References: This bug was introduced by Bug #30573, Bug #33257, Bug #33555.

- **Replication**: Issuing the statement `CHANGE MASTER TO ... MASTER_HEARTBEAT_PERIOD = period` using a value for *`period`* outside the permitted range caused the slave to crash. (Bug #39077)

- **Disk Data**: This improves on a previous fix for this issue that was made in MySQL Cluster 6.3.8. (Bug #37116)

  References: See also Bug #29186.

- **Cluster API**: When creating a scan using an `NdbScanFilter` object, it was possible to specify conditions against a `BIT` column, but the correct rows were not returned when the scan was executed.

  As part of this fix, 4 new comparison operators have been implemented for use with scans on `BIT` columns:

  - `COL_AND_MASK_EQ_MASK`
  - `COL_AND_MASK_NE_MASK`
  - `COL_AND_MASK_EQ_ZERO`
  - `COL_AND_MASK_NE_ZERO`

  For more information about these operators, see The `NdbScanFilter::BinaryCondition` Type.

  Equivalent methods are now also defined for `NdbInterpretedCode`; for more information, see `NdbInterpretedCode` Bitwise Comparison Operations. (Bug #40535)

Changes in MySQL Cluster NDB 6.3.19 (5.1.29-ndb-6.3.19) (2008-11-21)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.29 (see Changes in MySQL 5.1.29 (2008-10-11)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Cluster API**: **Important Change**: MGM API applications exited without raising any errors if the connection to the management server was lost. The fix for this issue includes two changes:

  1. The MGM API now provides its own `SIGPIPE` handler to catch the “broken pipe” error that occurs when writing to a closed or reset socket. This means that MGM API now behaves the same as NDB API in this regard.

  2. A new function `ndb_mgm_set_ignore_sigpipe()` has been added to the MGM API. This function makes it possible to bypass the `SIGPIPE` handler provided by the MGM API.

  (Bug #40498)

- **Cluster Replication**: **Important Note**: This release of MySQL Cluster derives in part from MySQL 5.1.29, where the default value for the `--binlog-format` [419] option changed to `STATEMENT`. That change does *not* affect this or future MySQL Cluster NDB 6.x releases, where the default value for this option remains `MIXED`, since MySQL Cluster Replication does not work with the statement-based format. (Bug #40586)

- When performing an initial start of a data node, fragment log files were always created sparsely—that is, not all bytes were written. Now it is possible to override this behavior using the new `InitFragmentLogFiles` [1827] configuration parameter. (Bug #40847)

Bugs Fixed

- **Cluster API**: Failed operations on `BLOB` and `TEXT` columns were not always reported correctly to the originating SQL node. Such errors were sometimes reported as being due to timeouts, when the actual problem was a transporter overload due to insufficient buffer space. (Bug #39867, Bug #39879)

- Memory leaks could occur in handling of strings used for storing cluster metadata and providing output to users. (Bug #38662)

- Undo logs and data files were created in 32K increments. Now these files are created in 512K increments, resulting in shorter creation times. (Bug #40815)

- A segfault in `Logger::Log` caused `ndbd` to hang indefinitely. This fix improves on an earlier one for this issue, first made in MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.17. (Bug #39180)

  References: See also Bug #38609.

- Redo log creation was very slow on some platforms, causing MySQL Cluster to start more slowly than necessary with some combinations of hardware and operating system. This was due to all write operations being synchronized to disk while creating a redo log file. Now this synchronization occurs only after the redo log has been created. (Bug #40734)

- Transaction failures took longer to handle than was necessary.

  When a data node acting as transaction coordinator (TC) failed, the surviving data nodes did not inform the API node initiating the transaction of this until the failure had been processed by all protocols. However, the API node needed only to know about failure handling by the transaction protocol—that is, it needed to be informed only about the TC takeover process. Now, API nodes

(including MySQL servers acting as cluster SQL nodes) are informed as soon as the TC takeover is complete, so that it can carry on operating more quickly. (Bug #40697)

- Events logged after setting `ALL CLUSTERLOG STATISTICS=15` in the management client did not always include the node ID of the reporting node. (Bug #39839)
- It was theoretically possible for stale data to be read from `NDBCLUSTER` tables when the transaction isolation level was set to `ReadCommitted`. (Bug #40543)
- The `LockExecuteThreadToCPU` [1852] and `LockMaintThreadsToCPU` [1853] parameters did not work on Solaris. (Bug #40521)
- Restoring a MySQL Cluster from a dump made using `mysqldump` failed due to a spurious error: `Can't execute the given command because you have active locked tables or an active transaction`. (Bug #40346)
- `SET SESSION ndb_optimized_node_selection = 1` failed with an invalid warning message. (Bug #40457)
- A restarting data node could fail with an error in the `DBDIH` kernel block when a local or global checkpoint was started or triggered just as the node made a request for data from another data node. (Bug #40370)
- `O_DIRECT` was incorrectly disabled when making MySQL Cluster backups. (Bug #40205)
- The MySQL Query Cache did not function correctly with `NDBCLUSTER` tables containing `TEXT` columns. (Bug #39295)
- Heavy DDL usage caused the `mysqld` processes to hang due to a timeout error (`NDB` error code 266). (Bug #39885)
- Executing `EXPLAIN SELECT` on an `NDBCLUSTER` table could cause `mysqld` to crash. (Bug #39872)
- A duplicate key or other error raised when inserting into an `NDBCLUSTER` table caused the current transaction to abort, after which any SQL statement other than a `ROLLBACK` failed. With this fix, the `NDBCLUSTER` storage engine now performs an implicit rollback when a transaction is aborted in this way; it is no longer necessary to issue an explicit `ROLLBACK` statement, and the next statement that is issued automatically begins a new transaction.

  Note

  It remains necessary in such cases to retry the complete transaction, regardless of which statement caused it to be aborted.

  (Bug #32656)

  References: See also Bug #47654.
- Error messages for `NDBCLUSTER` error codes 1224 and 1227 were missing. (Bug #28496)
- **Partitioning**: Dropping or creating an index on a partitioned table managed by the `InnoDB` Plugin locked the table. (Bug #37453)
- **Disk Data**: Issuing concurrent `CREATE TABLESPACE`, `ALTER TABLESPACE`, `CREATE LOGFILE GROUP`, or `ALTER LOGFILE GROUP` statements on separate SQL nodes caused a resource leak that led to data node crashes when these statements were used again later. (Bug #40921)
- **Disk Data**: Disk-based variable-length columns were not always handled like their memory-based equivalents, which could potentially lead to a crash of cluster data nodes. (Bug #39645)
- **Disk Data**: `O_SYNC` was incorrectly disabled on platforms that do not support `O_DIRECT`. This issue was noted on Solaris but could have affected other platforms not having `O_DIRECT` capability. (Bug #34638)

- **Cluster API**: The MGM API function `ndb_mgm_listen_event()` ignored bind addresses.

  As part of this fix, it is now possible to specify bind addresses in connectstrings. See The MySQL Cluster Connectstring, for more information. (Bug #38473)

- **Cluster API**: It was not always possible to access parent objects directly from `NdbBlob`, `NdbOperation`, and `NdbScanOperation` objects. To alleviate this problem, a new `getNdbOperation()` method has been added to `NdbBlob` and new getNdbTransaction() methods have been added to `NdbOperation` and `NdbScanOperation`. In addition, a const variant of `NdbOperation::getErrorLine()` is now also available. (Bug #40242)

- **Cluster API**: `NdbScanOperation::getBlobHandle()` failed when used with incorrect column names or numbers. (Bug #40241)

- **Cluster API**: The MGM API reset error codes on management server handles before checking them. This meant that calling an MGM API function with a null handle caused applications to crash. (Bug #40455)

- **Cluster API**: The NDB API example programs included in MySQL Cluster source distributions failed to compile. (Bug #37491)

  References: See also Bug #40238.

Changes in MySQL Cluster NDB 6.3.18 (5.1.28-ndb-6.3.18) (2008-10-03)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

Obtaining MySQL Cluster NDB 6.3. You can download the latest MySQL Cluster NDB 6.3 source code and binaries for supported platforms from http://dev.mysql.com/downloads/cluster/.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.28 (see Changes in MySQL 5.1.28 (2008-08-28)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- It is no longer a requirement for database autodiscovery that an SQL node already be connected to the cluster at the time that a database is created on another SQL node. It is no longer necessary to issue `CREATE DATABASE` (or `CREATE SCHEMA`) statements on an SQL node joining the cluster after a database is created for the new SQL node to see the database and any `NDBCLUSTER` tables that it contains. (Bug #39612)

Bugs Fixed

- When a transaction included a multi-row insert to an `NDBCLUSTER` table that caused a constraint violation, the transaction failed to roll back. (Bug #395638)

- After a forced shutdown and initial restart of the cluster, it was possible for SQL nodes to retain `.frm` files corresponding to `NDBCLUSTER` tables that had been dropped, and thus to be unaware that these tables no longer existed. In such cases, attempting to re-create the tables using `CREATE TABLE IF NOT EXISTS` could fail with a spurious `Table ... doesn't exist` error. (Bug #37921)

- When restarting a data node, an excessively long shutdown message could cause the node process to crash. (Bug #38580)

- Starting the MySQL Server with the `--ndbcluster` [1915] option plus an invalid command-line option (for example, using `mysqld --ndbcluster --foobar`) caused it to hang while shutting down the binlog thread. (Bug #39635)
- Dropping and then re-creating a database on one SQL node caused other SQL nodes to hang. (Bug #39613)
- Unique identifiers in tables having no primary key were not cached. This fix has been observed to increase the efficiency of `INSERT` operations on such tables by as much as 50%. (Bug #39267)
- A statement of the form `DELETE FROM table WHERE primary_key=value` or `UPDATE table WHERE primary_key=value` where there was no row whose primary key column had the stated `value` appeared to succeed, with the server reporting that 1 row had been changed.

  This issue was only known to affect MySQL Cluster NDB 6.3.11 and later NDB 6.3 versions. (Bug #37153)
- Setting a low value of `MaxNoOfLocalScans` [1824] (< 100) and performing a large number of (certain) scans could cause the Transaction Coordinator to run out of scan fragment records, and then crash. Now when this resource is exhausted, the cluster returns Error 291 (`Out of scanfrag records in TC (increase MaxNoOfLocalScans)`) instead. (Bug #39549)
- Creating a unique index on an `NDBCLUSTER` table caused a memory leak in the `NDB` subscription manager (`SUMA`) which could lead to mysqld hanging, due to the fact that the resource shortage was not reported back to the `NDB` kernel correctly. (Bug #39518)

  References: See also Bug #39450.
- Embedded `libmysqld` with `NDB` did not drop table events. (Bug #39450)
- **Cluster Replication**: In some cases, dropping a database on the master could cause table logging to fail on the slave, or, when using a debug build, could cause the slave `mysqld` to fail completely. (Bug #39404)
- **Cluster API**: Passing a value greater than 65535 to `NdbInterpretedCode::add_val()` and `NdbInterpretedCode::sub_val()` caused these methods to have no effect. (Bug #39536)

Changes in MySQL Cluster NDB 6.3.17 (5.1.27-ndb-6.3.17) (2008-08-28)

This is a new release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. Previously, MySQL Cluster NDB 6.3 releases were source-only releases which required compiling and installing using the instructions found in Installing MySQL from Source, and in MySQL Cluster Installation. Beginning with MySQL Cluster NDB 6.3.17, binaries built from NDB 6.3 sources are also available. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from http://dev.mysql.com/downloads/cluster/.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.27 (see Changes in MySQL 5.1.27 (Not released)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- **Packaging**: Support for the `InnoDB` storage engine was missing from the GPL source releases. An updated GPL source tarball `mysql-5.1.27-ndb-6.3.17-innodb.tar.gz` which includes code for building `InnoDB` can be found on the MySQL FTP site.

- `MgmtSrvr::allocNodeId()` left a mutex locked following an `Ambiguity for node if %d` error. (Bug #39158)
- An invalid path specification caused `mysql-test-run.pl` to fail. (Bug #39026)
- During transactional coordinator takeover (directly after node failure), the LQH finding an operation in the `LOG_COMMIT` state sent an `LQH_TRANS_CONF` signal twice, causing the TC to fail. (Bug #38930)
- An invalid memory access caused the management server to crash on Solaris Sparc platforms. (Bug #38628)
- A segfault in `Logger::Log` caused `ndbd` to hang indefinitely. (Bug #38609)
- `ndb_mgmd` failed to start on older Linux distributions (2.4 kernels) that did not support e-polling. (Bug #38592)
- `ndb_mgmd` sometimes performed unnecessary network I/O with the client. This in combination with other factors led to long-running threads that were attempting to write to clients that no longer existed. (Bug #38563)
- `ndb_restore` failed with a floating point exception due to a division by zero error when trying to restore certain data files. (Bug #38520)
- A failed connection to the management server could cause a resource leak in `ndb_mgmd`. (Bug #38424)
- Failure to parse configuration parameters could cause a memory leak in the NDB log parser. (Bug #38380)
- Renaming an `NDBCLUSTER` table on one SQL node, caused a trigger on this table to be deleted on another SQL node. (Bug #36658)
- Attempting to add a `UNIQUE INDEX` twice to an `NDBCLUSTER` table, then deleting rows from the table could cause the MySQL Server to crash. (Bug #35599)
- `ndb_restore` failed when a single table was specified. (Bug #33801)
- `GCP_COMMIT` did not wait for transaction takeover during node failure. This could cause `GCP_SAVE_REQ` to be executed too early. This could also cause (very rarely) replication to skip rows. (Bug #30780)
- **Cluster Replication**: During a parallel node restart, the starting nodes could (sometimes) incorrectly synchronize subscriptions among themselves. Instead, this synchronization now takes place only among nodes that have actually (completely) started. (Bug #38767)
- **Cluster API**: Certain Multi-Range Read scans involving `IS NULL` and `IS NOT NULL` comparisons failed with an error in the `NDB` local query handler. (Bug #38204)
- **Cluster API**: Creating an `NdbScanFilter` object using an `NdbScanOperation` object that had not yet had its `readTuples()` method called resulted in a crash when later attempting to use the `NdbScanFilter`. (Bug #37986)
- **Cluster API**: Executing an `NdbRecord` interpreted delete created with an `ANYVALUE` option caused the transaction to abort. (Bug #37672)
- **Cluster API**: Support for Multi-Range Read index scans using the old API (using, for example, `NdbIndexScanOperation::setBound()` or `NdbIndexScanOperation::end_of_bound()`) were dropped in MySQL Cluster NDB 6.2. This functionality is restored in MySQL Cluster NDB 6.3 beginning with 6.3.17, but remains unavailable in MySQL Cluster NDB 6.2. Both MySQL Cluster NDB 6.2 and 6.3 support Multi-Range Read scans through the `NdbRecord` API. (Bug #38791)
- **Cluster API**: The `NdbScanOperation::readTuples()` method could be called multiple times without error. (Bug #38717)

- **Cluster API**: Problems with the public headers prevented `NDB` applications from being built with warnings turned on. (Bug #38177)

Changes in MySQL Cluster NDB 6.3.16 (5.1.24-ndb-6.3.16) (2008-06-27)

This is a new source release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in Installing MySQL from Source, and in MySQL Cluster Installation. You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.24 (see Changes in MySQL 5.1.24 (2008-04-08)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- Event buffer lag reports are now written to the cluster log. (Bug #37427)
- Added the `--no-binlog` option for `ndb_restore`. When used, this option prevents information being written to SQL node binary logs from the restoration of a cluster backup. (Bug #30452)

Bugs Fixed

- **Cluster API**: Changing the system time on data nodes could cause MGM API applications to hang and the data nodes to crash. (Bug #35607)
- Failure of a data node could sometimes cause mysqld to crash. (Bug #37628)
- `DELETE ... WHERE unique_index_column=value` deleted the wrong row from the table. (Bug #37516)
- If subscription was terminated while a node was down, the epoch was not properly acknowledged by that node. (Bug #37442)
- `libmysqld` failed to wait for the cluster binlog thread to terminate before exiting. (Bug #37429)
- In rare circumstances, a connection followed by a disconnection could give rise to a “stale” connection where the connection still existed but was not seen by the transporter. (Bug #37338)
- Queries against `NDBCLUSTER` tables were cached only if `autocommit` [461] was in use. (Bug #36692)
- **Cluster Replication**: Data was written to the binlog with `--log-slave-updates` [1628] disabled. (Bug #37472)
- **Cluster API**: When some operations succeeded and some failed following a call to `NdbTransaction::execute(Commit, AO_IgnoreOnError)`, a race condition could cause spurious occurrences of NDB API Error 4011 (`Internal error`). (Bug #37158)
- **Cluster API**: A buffer overrun in `NdbBlob::setValue()` caused erroneous results on Mac OS X. (Bug #31284)
- **Cluster API**: Creating a table on an SQL node, then starting an NDB API application that listened for events from this table, then dropping the table from an SQL node, prevented data node restarts. (Bug #32949, Bug #37279)

Changes in MySQL Cluster NDB 6.3.15 (5.1.24-ndb-6.3.15) (2008-05-30)

This is a new source release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in Installing MySQL from Source, and in MySQL Cluster Installation. You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.24 (see Changes in MySQL 5.1.24 (2008-04-08)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- Under some circumstances, a failed `CREATE TABLE` could mean that subsequent `CREATE TABLE` statements caused node failures. (Bug #37092)
- A fail attempt to create an `NDB` table could in some cases lead to resource leaks or cluster failures. (Bug #37072)
- Attempting to create a native backup of `NDB` tables having a large number of `NULL` columns and data could lead to node failures. (Bug #37039)
- In certain rare situations, `ndb_size.pl` could fail with the error `Can't use string ("value") as a HASH ref while "strict refs" in use`. (Bug #43022)
- Where column values to be compared in a query were of the `VARCHAR` or `VARBINARY` types, `NDBCLUSTER` passed a value padded to the full size of the column, which caused unnecessary data to be sent to the data nodes. This also had the effect of wasting CPU and network bandwidth, and causing condition pushdown to be disabled where it could (and should) otherwise have been applied. (Bug #35393)
- Checking of API node connections was not efficiently handled. (Bug #36843)
- Attempting to delete a nonexistent row from a table containing a `TEXT` or `BLOB` column within a transaction caused the transaction to fail. (Bug #36756)

  References: See also Bug #36851.
- If the combined total of tables and indexes in the cluster was greater than 4096, issuing `START BACKUP` caused data nodes to fail. (Bug #36044)
- When dropping a table failed for any reason (such as when in single user mode) then the corresponding `.ndb` file was still removed.
- **Replication**: When flushing tables, there was a slight chance that the flush occurred between the processing of one table map event and the next. Since the tables were opened one by one, subsequent locking of tables would cause the slave to crash. This problem was observed when replicating `NDBCLUSTER` or `InnoDB` tables, when executing multi-table updates, and when a trigger or a stored routine performed an (additional) insert on a table so that two tables were effectively being inserted into in the same statement. (Bug #36197)
- **Cluster API**: Ordered index scans were not pruned correctly where a partitioning key was specified with an EQ-bound. (Bug #36950)

- **Cluster API**: When an insert operation involving `BLOB` data was attempted on a row which already existed, no duplicate key error was correctly reported and the transaction is incorrectly aborted. In some cases, the existing row could also become corrupted. (Bug #36851)

  References: See also Bug #26756.

- **Cluster API**: `NdbApi.hpp` depended on `ndb_global.h`, which was not actually installed, causing the compilation of programs that used `NdbApi.hpp` to fail. (Bug #35853)

Changes in MySQL Cluster NDB 6.3.14 (5.1.24-ndb-6.3.14) (2008-05-11)

This is a new source release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in Installing MySQL from Source, and in MySQL Cluster Installation. You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.24 (see Changes in MySQL 5.1.24 (2008-04-08)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- A race condition caused by a failure in epoll handling could cause data nodes to fail. (Bug #36537)
- Under certain rare circumstances, the failure of the new master node while attempting a node takeover would cause takeover errors to repeat without being resolved. (Bug #36199, Bug #36246, Bug #36247, Bug #36276)
- When more than one SQL node connected to the cluster at the same time, creation of the `mysql.ndb_schema` table failed on one of them with an explicit `Table exists` error, which was not necessary. (Bug #35943)
- `mysqld` failed to start after running `mysql_upgrade`. (Bug #35708)
- `SET GLOBAL ndb_extra_logging` caused `mysqld` to crash. (Bug #36547)
- Notification of a cascading master node failures could sometimes not be transmitted correctly (that is, transmission of the `NF_COMPLETEREP` signal could fail), leading to transactions hanging and timing out (`NDB` error 4012), scans hanging, and failure of the management server process. (Bug #32645)
- `NDB` error 1427 (`Api node died, when SUB_START_REQ reached node`) was incorrectly classified as a schema error rather than a temporary error.
- If an API node disconnected and then reconnected during Start Phase 8, then the connection could be “blocked”—that is, the `QMGR` kernel block failed to detect that the API node was in fact connected to the cluster, causing issues with the `NDB` Subscription Manager (`SUMA`).
- **Cluster Replication**: Performing `SELECT ... FROM mysql.ndb_apply_status` before the `mysqld` process had connected to the cluster failed, and caused this table never to be created. (Bug #36123)
- **Cluster API**: Accessing the debug version of `libndbclient` using `dlopen()` resulted in a segmentation fault. (Bug #35927)

- **Cluster API**: Attempting to pass a nonexistent column name to the `equal()` and `setValue()` methods of `NdbOperation` caused NDB API applications to crash. Now the column name is checked, and an error is returned in the event that the column is not found. (Bug #33747)

- **Cluster API**: Relocation errors were encountered when trying to compile NDB API applications on a number of platforms, including 64-bit Linux. As a result, `libmysys`, `libmystrings`, and `libdbug` have been changed from normal libraries to “noinst” `libtool` helper libraries. They are no longer installed as separate libraries; instead, all necessary symbols from these are added directly to `libndbclient`. This means that NDB API programs now need to be linked using only `-lndbclient`. (Bug #29791, Bug #11746931)

Changes in MySQL Cluster NDB 6.3.13 (5.1.24-ndb-6.3.13) (2008-04-10)

This is a new source release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in Installing MySQL from Source, and in MySQL Cluster Installation. You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.24 (see Changes in MySQL 5.1.24 (2008-04-08)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- The `ndbd` and `ndb_mgmd` man pages have been reclassified from volume 1 to volume 8. (Bug #34642)

Bugs Fixed

- **Important Change**: `mysqld_safe` now traps Signal 13 (`SIGPIPE`) so that this signal no longer kills the MySQL server process. (Bug #33984)

- Node or system restarts could fail due an unitialized variable in the `DTUP` kernel block. This issue was found in MySQL Cluster NDB 6.3.11. (Bug #35797)

- It was not possible to determine the value used for the `--ndb-cluster-connection-pool` option in the `mysql` client. Now this value is reported as a system status variable. (Bug #35573)

- If an error occurred while executing a statement involving a `BLOB` or `TEXT` column of an `NDB` table, a memory leak could result. (Bug #35593)

- The `ndb_waiter` utility wrongly calculated timeouts. (Bug #35435)

- A `SELECT` on a table with a nonindexed, large `VARCHAR` column which resulted in condition pushdown on this column could cause `mysqld` to crash. (Bug #35413)

- `ndb_restore` incorrectly handled some data types when applying log files from backups. (Bug #35343)

- In some circumstances, a stopped data node was handled incorrectly, leading to redo log space being exhausted following an initial restart of the node, or an initial or partial restart of the cluster (the wrong CGI might be used in such cases). This could happen, for example, when a node was stopped following the creation of a new table, but before a new LCP could be executed. (Bug #35241)

- `SELECT ... LIKE ...` queries yielded incorrect results when used on `NDB` tables. As part of this fix, condition pushdown of such queries has been disabled; re-enabling it is expected to be done as part of a later, permanent fix for this issue. (Bug #35185)
- `ndb_mgmd` reported errors to `STDOUT` rather than to `STDERR`. (Bug #35169)
- Nested Multi-Range Read scans failed when the second Multi-Range Read released the first read's unprocessed operations, sometimes leading to an SQL node crash. (Bug #35137)
- In some situations, a problem with synchronizing checkpoints between nodes could cause a system restart or a node restart to fail with `Error 630 during restore of TX`. (Bug #34756)

  References: This bug is a regression of Bug #34033.
- When a secondary index on a `DECIMAL` column was used to retrieve data from an `NDB` table, no results were returned even if the target table had a matched value in the column that was defined with the secondary index. (Bug #34515)
- An `UPDATE` on an `NDB` table that set a new value for a unique key column could cause subsequent queries to fail. (Bug #34208)
- If a data node in one node group was placed in the “not started” state (using *`node_id`* `RESTART -n`), it was not possible to stop a data node in a different node group. (Bug #34201)
- Numerous `NDBCLUSTER` test failures occurred in builds compiled using `icc` on IA64 platforms. (Bug #31239)
- A node failure during an initial node restart followed by another node start could cause the master data node to fail, because it incorrectly gave the node permission to start even if the invalidated node's LCP was still running. (Bug #34702)
- `REPLACE` statements did not work correctly with `NDBCLUSTER` tables when all columns were not explicitly listed. (Bug #22045)
- If a `START BACKUP` command was issued while `ndb_restore` was running, the backup being restored could be overwritten. (Bug #26498)
- `CREATE TABLE` and `ALTER TABLE` statements using `ENGINE=NDB` or `ENGINE=NDBCLUSTER` caused `mysqld` to fail on Solaris 10 for x86 platforms. (Bug #19911)
- **Replication**: A `CHANGE MASTER TO` statement with no `MASTER_HEARTBEAT_PERIOD` option failed to reset the heartbeat period to its default value. (Bug #34686)
- **Cluster Replication**: In some cases, when updating only one or some columns in a table, the complete row was written to the binary log instead of only the updated column or columns, even when `ndb_log_updated_only` was set to 1. (Bug #35208)
- **Cluster Replication**: Using `--ndb-wait-connected` [1919] caused the server to wait for a partial connection, plus an additional 3 seconds for a complete connection to the cluster. This could lead to issues with setting up the binary log. (Bug #34757)
- **Cluster API**: Closing a scan before it was executed caused the application to segfault. (Bug #36375)
- **Cluster API**: Scans having no bounds set were handled incorrectly. (Bug #35876)
- **Cluster API**: Using NDB API applications from older MySQL Cluster versions with `libndbclient` from newer ones caused the cluster to fail. (Bug #36124)
- **Cluster API**: Some ordered index scans could return tuples out of order. (Bug #35908)
- **Cluster API**: `NdbScanFilter::getNdbOperation()`, which was inadvertently removed in MySQL Cluster NDB 6.3.11, has been restored. (Bug #35854)

- Executing a `FLUSH PRIVILEGES` statement after creating a temporary table in the `mysql` database with the same name as one of the MySQL system tables caused the server to crash.

  Note

  While it is possible to shadow a system table in this way, the temporary table exists only for the current user and connection, and does not effect any user privileges.

  (Bug #33275)

- Enabling the `read_only` [517] system variable while `autocommit` [461] mode was enabled caused `SELECT` statements for transactional storage engines to fail. (Bug #35732)

Changes in MySQL Cluster NDB 6.3.12 (5.1.23-ndb-6.3.12) (2008-04-05)

MySQL Cluster NDB 6.3.12 was pulled due to issues discovered shortly after its release, and is no longer available. Users of MySQL Cluster NDB 6.3.10 and earlier MySQL Cluster NDB 6.3 releases should upgrade to MySQL Cluster NDB 6.3.13 or later.

For information about bugfixes and feature enhancements that were originally scheduled to appear for the first time in this release, see Changes in MySQL Cluster NDB 6.3.13 (5.1.24-ndb-6.3.13) (2008-04-10).

Changes in MySQL Cluster NDB 6.3.11 (5.1.23-ndb-6.3.11) (2008-03-28)

This release was pulled due to issues discovered shortly after its release, and is no longer available. Users of MySQL Cluster NDB 6.3.10 and earlier MySQL Cluster NDB 6.3 releases should upgrade to MySQL Cluster NDB 6.3.13 or later.

For information about bugfixes and feature enhancements that were originally scheduled to appear for the first time in this release, see Changes in MySQL Cluster NDB 6.3.13 (5.1.24-ndb-6.3.13) (2008-04-10).

Changes in MySQL Cluster NDB 6.3.10 (5.1.23-ndb-6.3.10) (2008-02-17)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in Installing MySQL from Source, and in MySQL Cluster Installation. You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see Changes in MySQL 5.1.23 (2008-01-29)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- Due to the reduction of the number of local checkpoints from 3 to 2 in MySQL Cluster NDB 6.3.8, a data node using ndbd from MySQL Cluster NDB 6.3.8 or later started using a file system from an earlier version could incorrectly invalidate local checkpoints too early during the startup process, causing the node to fail. (Bug #34596)

Changes in MySQL Cluster NDB 6.3.9 (5.1.23-ndb-6.3.9) (2008-02-12)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in Installing MySQL from Source, and in MySQL Cluster Installation. You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see Changes in MySQL 5.1.23 (2008-01-29)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- Beginning with this version, MySQL Cluster NDB 6.3.*x* releases once again include the `InnoDB` storage engine. To enable `InnoDB`, you must configure the build using `--with-innodb`.

Bugs Fixed

- When configured with `NDB` support, MySQL failed to compile using `gcc` 4.3 on 64bit FreeBSD systems. (Bug #34169)
- When configured with `NDB` support, MySQL failed to compile on 64bit FreeBSD systems. (Bug #34046)
- Cluster failures could sometimes occur when performing more than three parallel takeovers during node restarts or system restarts. This affected MySQL Cluster NDB 6.3.*x* releases only. (Bug #34445)
- Upgrades of a cluster using while a `DataMemory` [1817] setting in excess of 16 GB caused data nodes to fail. (Bug #34378)
- Performing many SQL statements on `NDB` tables while in `autocommit` [461] mode caused a memory leak in `mysqld`. (Bug #34275)
- In certain rare circumstances, a race condition could occur between an aborted insert and a delete leading a data node crash. (Bug #34260)
- Multi-table updates using ordered indexes during handling of node failures could cause other data nodes to fail. (Bug #34216)
- The failure of a DDL statement could sometimes lead to node failures when attempting to execute subsequent DDL statements. (Bug #34160)
- Extremely long `SELECT` statements (where the text of the statement was in excess of 50000 characters) against `NDB` tables returned empty results. (Bug #34107)
- Statements executing multiple inserts performed poorly on `NDB` tables having `AUTO_INCREMENT` columns. (Bug #33534)
- The `ndb_waiter` utility polled `ndb_mgmd` excessively when obtaining the status of cluster data nodes. (Bug #32025)

  References: See also Bug #32023.
- Transaction atomicity was sometimes not preserved between reads and inserts under high loads. (Bug #31477)

- Having tables with a great many columns could cause Cluster backups to fail. (Bug #30172)
- **Cluster Replication**: **Disk Data**: Statements violating unique keys on Disk Data tables (such as attempting to insert `NULL` into a `NOT NULL` column) could cause data nodes to fail. When the statement was executed from the binlog, this could also result in failure of the slave cluster. (Bug #34118)
- **Disk Data**: Updating in-memory columns of one or more rows of Disk Data table, followed by deletion of these rows and re-insertion of them, caused data node failures. (Bug #33619)
- **Cluster Replication**: Setting `--replicate-ignore-db=mysql` [1635] caused the `mysql.ndb_apply_status` table not to be replicated, breaking Cluster Replication. (Bug #28170)

Changes in MySQL Cluster NDB 6.3.8 (5.1.23-ndb-6.3.8) (2008-01-29, General Availability)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in Installing MySQL from Source, and in MySQL Cluster Installation. You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see Changes in MySQL 5.1.23 (2008-01-29)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Cluster API**: **Important Change**: Because `NDB_LE_MemoryUsage.page_size_kb` shows memory page sizes in bytes rather than kilobytes, it has been renamed to `page_size_bytes`. The name `page_size_kb` is now deprecated and thus subject to removal in a future release, although it currently remains supported for reasons of backward compatibility. See The `Ndb_logevent_type` Type, for more information about `NDB_LE_MemoryUsage`. (Bug #30271)
- `OPTIMIZE TABLE` can now be interrupted. This can be done, for example, by killing the SQL thread performing the `OPTIMIZE` operation.
- Persistence of `NDB` tables can now be controlled using the session variables `ndb_table_temporary` [1931] and `ndb_table_no_logging` [1930]. `ndb_table_no_logging` [1930] causes `NDB` tables not to be checkpointed to disk. `ndb_table_temporary` [1931] has the same effect; in addition, when `ndb_table_temporary` [1931] is used, no `NDB` table schema files are created.
- Node recovery can now be done in parallel, rather than sequentially, which can result in much faster recovery times.
- The `mysqld` option `--ndb-batch-size` has been added. This enables control of the size of batches used for running transactions.
- Now only 2 local checkpoints are stored, rather than 3 as in previous MySQL Cluster versions. This lowers disk space requirements and reduces the size and number of redo log files needed.
- `ndb_restore` now supports basic *attribute promotion*; that is, data from a column of a given type can be restored to a column using a “larger” type. For example, Cluster backup data taken from a `SMALLINT` column can be restored to a `MEDIUMINT`, `INT`, or `BIGINT` column.

For more information, see `ndb_restore` — Restore a MySQL Cluster Backup.

Bugs Fixed

- **Disk Data**: **Important Change**: It is no longer possible on 32-bit systems to issue statements appearing to create Disk Data log files or data files greater than 4 GB in size. (Trying to create log files or data files larger than 4 GB on 32-bit systems led to unrecoverable data node failures; such statements now fail with `NDB` error 1515.) (Bug #29186)
- **Replication**: The code implementing heartbeats did not check for possible errors in some circumstances; this kept the dump thread hanging while waiting for heartbeats loop even though the slave was no longer connected. (Bug #33332)
- Some tuple scans caused the wrong memory page to be accessed, leading to invalid results. This issue could affect both in-memory and Disk Data tables. (Bug #33739)
- Issuing an `INSERT ... ON DUPLICATE KEY UPDATE` concurrently with or following a `TRUNCATE TABLE` statement on an `NDB` table failed with `NDB` error 4350 `Transaction already aborted`. (Bug #29851)
- The server failed to reject properly the creation of an `NDB` table having an unindexed `AUTO_INCREMENT` column. (Bug #30417)
- A failure to initialize an internal variable led to sporadic crashes during cluster testing. (Bug #33715)
- A race condition could occur (very rarely) when the release of a GCI was followed by a data node failure. (Bug #33793)
- `DROP TABLE` did not free all data memory. This bug was observed in MySQL Cluster NDB 6.3.7 only. (Bug #33802)
- A periodic failure to flush the send buffer by the `NDB` TCP transporter could cause a unnecessary delay of 10 ms between operations. (Bug #34005)
- High numbers of insert operations, delete operations, or both could cause `NDB` error 899 (`Rowid already allocated`) to occur unnecessarily. (Bug #34033)
- Under some circumstances, a recovering data node did not use its own data, instead copying data from another node even when this was not required. This in effect bypassed the optimized node recovery protocol and caused recovery times to be unnecessarily long. (Bug #26913)
- It was possible in `config.ini` to define cluster nodes having node IDs greater than the maximum permitted value. (Bug #28298)
- The Cluster backup process could not detect when there was no more disk space and instead continued to run until killed manually. Now the backup fails with an appropriate error when disk space is exhausted. (Bug #28647)
- **Cluster Replication**: Consecutive DDL statements involving tables (`CREATE TABLE`, `ALTER TABLE`, and `DROP TABLE`) could be executed so quickly that previous DDL statements upon which they depended were not yet written in the binary log.

  For example, if `DROP TABLE foo` was issued immediately following `CREATE TABLE foo`, the `DROP` statement could fail because the `CREATE` had not yet been recorded. (Bug #34006)
- **Cluster Replication**: `ndb_restore -e` restored excessively large values to the `ndb_apply_status` table's `epoch` column when restoring to a MySQL Cluster version supporting Micro-GCPs from an older version that did not support these.

  A workaround when restoring to MySQL Cluster releases supporting micro-GCPs previous to MySQL Cluster NDB 6.3.8 is to perform a 32-bit shift on the `epoch` column values to reduce them to their proper size. (Bug #33406)

- **Cluster API**: When reading a `BIT(64)` value using `NdbOperation:getValue()`, 12 bytes were written to the buffer rather than the expected 8 bytes. (Bug #33750)

- **Cluster API**: Transactions containing inserts or reads would hang during `NdbTransaction::execute()` calls made from NDB API applications built against a MySQL Cluster version that did not support micro-GCPs accessing a later version that supported micro-GCPs. This issue was observed while upgrading from MySQL Cluster NDB 6.1.23 to MySQL Cluster NDB 6.2.10 when the API application built against the earlier version attempted to access a data node already running the later version, even after disabling micro-GCPs by setting `TimeBetweenEpochs` [1840] equal to 0. (Bug #33895)

Changes in MySQL Cluster NDB 6.3.7 (5.1.23-ndb-6.3.7) (2007-12-19)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in Installing MySQL from Source, and in MySQL Cluster Installation. You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see Changes in MySQL 5.1.23 (2008-01-29)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- It is now possible to cause statements occurring within the same transaction to be run as a batch by setting the session variable `transaction_allow_batching` [1932] to `1` or `ON`.

Note

To use this feature, `autocommit` [461] must be disabled.

- `OPTIMIZE TABLE` is now supported for `NDBCLUSTER` tables, subject to the following limitations:

  - Only in-memory tables are supported. `OPTIMIZE` still has no effect on Disk Data tables.

  - Only variable-length columns are supported. However, you can force columns defined using fixed-length data types to be dynamic using the `ROW_FORMAT` or `COLUMN_FORMAT` option with a `CREATE TABLE` or `ALTER TABLE` statement.

  Memory reclaimed from an `NDB` table using `OPTIMIZE` is generally available to the cluster, and not confined to the table from which it was recovered, unlike the case with memory freed using `DELETE`.

  The performance of `OPTIMIZE` on `NDB` tables can be regulated by adjusting the value of the `ndb_optimization_delay` system variable.

- Compressed local checkpoints and backups are now supported, resulting in a space savings of 50% or more over uncompressed LCPs and backups. Compression of these can be enabled in the `config.ini` file using the two new data node configuration parameters `CompressedLCP` [1834] and `CompressedBackup` [1834], respectively.

Bugs Fixed

- **Partitioning**: When partition pruning on an `NDB` table resulted in an ordered index scan spanning only one partition, any descending flag for the scan was wrongly discarded, causing `ORDER BY`

`DESC` to be treated as `ORDER BY ASC`, `MAX()` to be handled incorrectly, and similar problems. (Bug #33061)

- When all data and SQL nodes in the cluster were shut down abnormally (that is, other than by using `STOP` in the cluster management client), `ndb_mgm` used excessive amounts of CPU. (Bug #33237)
- When using micro-GCPs, if a node failed while preparing for a global checkpoint, the master node would use the wrong GCI. (Bug #32922)
- Under some conditions, performing an `ALTER TABLE` on an `NDBCLUSTER` table failed with a `Table is full` error, even when only 25% of `DataMemory` [1817] was in use and the result should have been a table using less memory (for example, changing a `VARCHAR(100)` column to `VARCHAR(80)`). (Bug #32670)
- **Cluster Replication**: **Replication**: Where a table being replicated had a `TEXT` or `BLOB` column, an `UPDATE` on the master that did not refer explicitly to this column in the `WHERE` clause stopped the SQL thread on the slave with `Error in Write_rows event: row application failed. Got error 4288 'Blob handle for column not available' from NDBCLUSTER`. (Bug #30674)
- **Cluster Replication**: Creating the `mysql.ndb_replication` table with the wrong number of columns for the primary key caused `mysqld` to crash. Now a `CREATE TABLE [mysql.]ndb_replication` statement that is invalid for this reason fails with the error `Bad schema for mysql.ndb_replication table. Message: Wrong number of primary keys, expected` *`number`*. (Bug #33159)

Changes in MySQL Cluster NDB 6.3.6 (5.1.22-ndb-6.3.6) (2007-11-08)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in Installing MySQL from Source, and in MySQL Cluster Installation. You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see Changes in MySQL 5.1.22 (2007-09-24, Release Candidate)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Important Note**: MySQL Cluster NDB 6.2 and 6.3 source archives are now available in separate commercial and GPL versions. Due to licensing concerns, previous MySQL Cluster NDB 6.2 and 6.3 source archives were removed from the FTP site.
- The output of the `ndb_mgm` client `SHOW` and `STATUS` commands now indicates when the cluster is in single user mode. (Bug #27999)
- Introduced the `Ndb_execute_count` [1948] status variable, which measures the number of round trips made by queries to the `NDB` kernel.
- Batched operations are now better supported for `DELETE` and `UPDATE`. (`UPDATE WHERE...` and multiple `DELETE`.)
- Unnecessary reads when performing a primary key or unique key update have been reduced, and in some cases, eliminated. (It is almost never necessary to read a record prior to an update, the lone exception to this being when a primary key is updated, since this requires a delete followed by an

insert, which must be prepared by reading the record.) Depending on the number of primary key and unique key lookups that are performed per transaction, this can yield a considerable improvement in performance.

Bugs Fixed

- The NDB management client command *node_id* REPORT MEMORY provided no output when *node_id* was the node ID of a management or API node. Now, when this occurs, the management client responds with Node *node_id*: is not a data node. (Bug #29485)
- ndb_restore displayed incorrect backup file version information. This meant (for example) that, when attempting to restore a backup made from a MySQL 5.1.22 cluster to a MySQL Cluster NDB 6.3.3 cluster, the restore process failed with the error Restore program older than backup version. Not supported. Use new restore program. (Bug #31723)
- Following an upgrade, ndb_mgmd would fail with an *ArbitrationError*. (Bug #31690)
- The NDB storage engine code was not safe for strict-alias optimization in gcc 4.2.1. (Bug #31761)
- An error with an if statement in sql/ha_ndbcluster.cc could potentially lead to an infinite loop in case of failure when working with AUTO_INCREMENT columns in NDB tables. (Bug #31810)
- An insert or update with combined range and equality constraints failed when run against an NDB table with the error Got unknown error from NDB. An example of such a statement would be UPDATE t1 SET b = 5 WHERE a IN (7,8) OR a >= 10;. (Bug #31874)
- Performing DELETE operations after a data node had been shut down could lead to inconsistent data following a restart of the node. (Bug #26450)
- UPDATE IGNORE could sometimes fail on NDB tables due to the use of unitialized data when checking for duplicate keys to be ignored. (Bug #25817)
- **Cluster Replication**: **Replication**: A node failure during replication could lead to buckets out of order; now active subscribers are checked for, rather than empty buckets. (Bug #31701)
- **Cluster Replication**: When the master mysqld crashed or was restarted, no LOST_EVENTS entry was made in the binlog. (Bug #31484)

  References: See also Bug #21494.
- **Cluster Replication**: Updates performed unnecessary writes to the primary keys of the rows being updated. (Bug #31841)
- **Cluster Replication**: Slave batching did not work correctly with UPDATE statements. (Bug #31787)

Changes in MySQL Cluster NDB 6.3.5 (5.1.22-ndb-6.3.5) (2007-10-17)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in Installing MySQL from Source, and in MySQL Cluster Installation. You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see Changes in MySQL 5.1.22 (2007-09-24, Release Candidate)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- A query against a table with `TEXT` or `BLOB` columns that would return more than a certain amount of data failed with `Got error 4350 'Transaction already aborted' from NDBCLUSTER`. (Bug #31482)

  References: This bug was introduced by Bug #29102.

- **Cluster Replication**: In some cases, not all tables were properly initialized before the binary log thread was started. (Bug #31618)

Changes in MySQL Cluster NDB 6.3.4 (5.1.22-ndb-6.3.4) (2007-10-15)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in Installing MySQL from Source, and in MySQL Cluster Installation. You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see Changes in MySQL 5.1.22 (2007-09-24, Release Candidate)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Incompatible Change**: The `--ndb_optimized_node_selection` startup option for `mysqld` now permits a wider range of values and corresponding behaviors for SQL nodes when selecting a transaction coordinator.

  You should be aware that the default value and behavior as well as the value type used for this option have changed, and that you may need to update the setting used for this option in your `my.cnf` file prior to upgrading `mysqld`. See Server System Variables, for more information.

- **Replication**: On MySQL replication slaves having multiple network interfaces, it is now possible to set which interface to use for connecting to the master using the `MASTER_BIND='interface'` option in a `CHANGE MASTER TO` statement. (Bug #25939, Bug #11746389)

- **Cluster Replication**: A new configuration parameter `TimeBetweenEpochsTimeout` [1840] enables a timeout to be set for time between epochs. (Bug #31276)

- **Cluster Replication**: A replication heartbeat mechanism has been added to facilitate monitoring. This provides an alternative to checking log files, making it possible to detect in real time when a slave has failed.

  Configuration of heartbeats is done using a new `MASTER_HEARTBEAT_PERIOD = interval` clause for the `CHANGE MASTER TO` statement (see `CHANGE MASTER TO` Syntax); monitoring can be done by checking the values of the status variables `Slave_heartbeat_period` [1949] and `Slave_received_heartbeats` [1949] (see Server Status Variables).

  The addition of replication heartbeats addresses a number of issues:

  - Relay logs were rotated every `slave_net_timeout` [1645] seconds even if no statements were being replicated.

- `SHOW SLAVE STATUS` displayed an incorrect value for `Seconds_Behind_Master` following a `FLUSH LOGS` statement.
- Replication master-slave connections used `slave_net_timeout` [1645] for connection timeouts.

(Bug #20435, Bug #29309, Bug #30932)

- **Cluster Replication**: Support for a new conflict resolution function `NDB$OLD()` has been added for handling simultaneous updates in multi-master and circular replication setups. A new status variable `Ndb_conflict_fn_old` [1947] tracks the number of times that updates are prevented from being applied due to this type of conflict resolution. See MySQL Cluster Replication Conflict Resolution, for more information.
- A `--bind-address` [261] option has been added to a number of MySQL client programs: `mysql`, `mysqldump`, `mysqladmin`, `mysqlbinlog`, `mysqlcheck`, `mysqlimport`, and `mysqlshow`. This is for use on a computer having multiple network interfaces, and enables you to choose which interface is used to connect to the MySQL server.

  A corresponding change was made to the `mysql_options()` C API function, which now has a `MYSQL_OPT_BIND` option for specifying the interface. The argument is a host name or IP address (specified as a string).
- Additional checks were implemented to catch unsupported online `ALTER TABLE` operations. Currently it is not possible to reorder columns or to change the storage engine used for a table using online `ALTER TABLE`.

  Some redundant checks made during online creation of indexes were removed.

Bugs Fixed

- It was possible in some cases for a node group to be “lost” due to missed local checkpoints following a system restart. (Bug #31525)
- A node failure during a local checkpoint could lead to a subsequent failure of the cluster during a system restart. (Bug #31257)
- An interpreted program of sufficient size and complexity could cause all cluster data nodes to shut down due to buffer overruns. (Bug #29390)
- `ndb_mgm --help` did not display any information about the `-a` option. (Bug #29509)
- `NDB` tables having names containing nonalphanumeric characters (such as “`$`”) were not discovered correctly. (Bug #31470)
- A cluster restart could sometimes fail due to an issue with table IDs. (Bug #30975)
- Transaction timeouts were not handled well in some circumstances, leading to excessive number of transactions being aborted unnecessarily. (Bug #30379)
- In some cases, the cluster managment server logged entries multiple times following a restart of `ndb_mgmd`. (Bug #29565)
- The cluster log was formatted inconsistently and contained extraneous newline characters. (Bug #25064)
- A transaction was not aborted following the failure of statement. (Bug #31320)
- The `mysqld_safe` script contained a syntax error. (Bug #30624)
- Online `ALTER` operations involving a column whose data type has an implicit default value left behind temporary `.frm` files, causing subsequent `DROP DATABASE` statements to fail. (Bug #31097)
- Errors could sometimes occur during an online `ADD COLUMN` under load. (Bug #31082)

- Transactions were committed prematurely when `LOCK TABLE` and `SET autocommit = 0` were used together. (Bug #30996)

Changes in MySQL Cluster NDB 6.3.3 (5.1.22-ndb-6.3.3) (2007-09-20)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in Installing MySQL from Source, and in MySQL Cluster Installation. You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see Changes in MySQL 5.1.22 (2007-09-24, Release Candidate)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- Mapping of `NDB` error codes to MySQL storage engine error codes has been improved. (Bug #28423)
- **Cluster Replication**: **Replication**: A server status variable `ndb_conflict_fn_max` now provides a count of the number of times that conflict resolution for MySQL Cluster Replication has been applied.

  See MySQL Cluster Replication Conflict Resolution, for more information.

Bugs Fixed

- **Partitioning**: `EXPLAIN PARTITIONS` reported partition usage by queries on `NDB` tables according to the standard MySQL hash function than the hash function used in the `NDB` storage engine. (Bug #29550)
- Attempting to restore a backup made on a cluster host using one endian to a machine using the other endian could cause the cluster to fail. (Bug #29674)
- Restoring a backup made on a cluster host using one endian to a machine using the other endian failed for `BLOB` and `DATETIME` columns. (Bug #27543, Bug #30024)
- The description of the `--print` option provided in the output from `ndb_restore --help` was incorrect. (Bug #27683)
- Errors could sometimes occur during an online `ADD COLUMN` under load. (Bug #31082)

Changes in MySQL Cluster NDB 6.3.2 (5.1.22-ndb-6.3.2) (2007-09-07)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in Installing MySQL from Source, and in MySQL Cluster Installation. You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see Changes in MySQL 5.1.22 (2007-09-24, Release Candidate)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- A new cluster management server startup option `--bind-address` [1962] makes it possible to restrict management client connections to `ndb_mgmd` to a single host and port. For more information, see `ndb_mgmd` — The MySQL Cluster Management Server Daemon.

- It is now possible to control whether fixed-width or variable-width storage is used for a given column of an `NDB` table by means of the `COLUMN_FORMAT` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

  It is also possible to control whether a given column of an `NDB` table is stored in memory or on disk, using the `STORAGE` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

  For permitted values and other information about `COLUMN_FORMAT` and `STORAGE`, see `CREATE TABLE` Syntax.

- Online `ADD COLUMN`, `ADD INDEX`, and `DROP INDEX` operations can now be performed explicitly for `NDB` tables—that is, without copying or locking of the affected tables—using `ALTER ONLINE TABLE`. Indexes can also be created and dropped online using `CREATE INDEX` and `DROP INDEX`, respectively, using the `ONLINE` keyword.

  You can force operations that would otherwise be performed online to be done offline using the `OFFLINE` keyword.

  Renaming of tables and columns for `NDB` and `MyISAM` tables is performed in place without table copying.

  For more information, see `ALTER TABLE` Online Operations, `CREATE INDEX` Syntax, and `DROP INDEX` Syntax.

- **Cluster Replication**: The protocol for handling global checkpoints has been changed. It is now possible to control how often the GCI number is updated, and how often global checkpoints are written to disk, using the `TimeBetweenEpochs` [1840] configuration parameter. This improves the reliability and performance of MySQL Cluster Replication.

  GCPs handled using the new protocol are sometimes referred to as “micro-GCPs”.

- **Cluster Replication**: Multi-way replication failover and recovery for `NDB` is facilitated with the introduction of the `--ndb-log-orig` option. When `mysqld` is started with this option, the originating server ID and epoch of each binlog event is recorded in the `mysql.ndb_binlog_index` table, which now contains two additional columns `orig_server_id` and `orig_epoch` for storing this information. In such cases, a single epoch on a slave may be represented by multiple rows in the slave's `ndb_binlog_index` table, one for each epoch as it originated from a master.

Bugs Fixed

- When an `NDB` event was left behind but the corresponding table was later recreated and received a new table ID, the event could not be dropped. (Bug #30877)

- When creating an `NDB` table with a column that has `COLUMN_FORMAT = DYNAMIC`, but the table itself uses `ROW_FORMAT=FIXED`, the table is considered dynamic, but any columns for which the row format is unspecified default to `FIXED`. Now in such cases the server issues the warning `Row format FIXED incompatible with dynamic attribute column_name`. (Bug #30276)

- An insufficiently descriptive and potentially misleading Error 4006 (`Connect failure - out of connection objects...`) was produced when either of the following two conditions occurred:

1. There were no more transaction records in the transaction coordinator

2. An NDB object in the NDB API was initialized with insufficient parallelism

Separate error messages are now generated for each of these two cases. (Bug #11313)

- For micro-GCPs, the assignment of “fake” CGI events no longer cause buckets to be sent out of order. Now, when assigning a GCI to a non-GCI event (that is, creating a pseudo-GCI or “fake” CGI), the GCI that is to arrive is always initiated, even if no known GCI exists, which could occur in the event of a node failure. (Bug #30884)

Changes in MySQL Cluster NDB 6.3.1 (5.1.19-ndb-6.3.1) (2007-07-04)

This is a new Beta development release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in Installing MySQL from Source, and in MySQL Cluster Installation. You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.19 (see Changes in MySQL 5.1.19 (2007-05-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- Batching of transactions was not handled correctly in some cases. (Bug #29525)

Changes in MySQL Cluster NDB 6.3.0 (5.1.19-ndb-6.3.0) (2007-07-02, Beta)

This is the first development release for MySQL Cluster NDB 6.3, based on version 6.3 of the NDBCLUSTER storage engine.

Obtaining MySQL Cluster NDB 6.3. This is a source-only release, which you must compile and install using the instructions found in Installing MySQL from Source, and in MySQL Cluster Installation. You can download the GPL source tarball from the MySQL FTP site at ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/.

This Beta release incorporates all bugfixes and feature changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.19 (see Changes in MySQL 5.1.19 (2007-05-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- A new configuration parameter ODirect [1833] causes NDB to attempt using O_DIRECT writes for LCP, backups, and redo logs, often lowering CPU usage.

- Reporting functionality has been significantly enhanced in this release:

  - A new configuration parameter BackupReportFrequency [1851] now makes it possible to cause the management client to provide status reports at regular intervals as well as for such reports to be written to the cluster log (depending on cluster event logging levels).

- A new `REPORT` command has been added in the cluster management client. `REPORT BackupStatus` enables you to obtain a backup status report at any time during a backup. `REPORT MemoryUsage` reports the current data memory and index memory used by each data node. For more about the `REPORT` command, see Commands in the MySQL Cluster Management Client.

- `ndb_restore` now provides running reports of its progress when restoring a backup. In addition, a complete report status report on the backup is written to the cluster log.

- **Cluster Replication**: This release implements conflict resolution, which makes it possible to determine on a per-table basis whether or not an update to a given row on the master should be applied on the slave. For more information, see MySQL Cluster Replication Conflict Resolution.

Changes in MySQL Cluster NDB 6.2

This section contains change history information for MySQL Cluster releases based on version 6.2 of the `NDBCLUSTER` storage engine.

For an overview of new features added in MySQL Cluster NDB 6.2, see MySQL Cluster Development in MySQL Cluster NDB 6.2.

Changes in MySQL Cluster NDB 6.2.19 (5.1.51-ndb-6.2.19) (Not yet released)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.51 (see Changes in MySQL 5.1.51 (2010-09-10)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Important Change**: The `Id` configuration parameter used with MySQL Cluster management, data, and API nodes (including SQL nodes) is now deprecated, and the `NodeId` parameter (long available as a synonym for `Id` when configuring these types of nodes) should be used instead. `Id` continues to be supported for reasons of backward compatibility, but now generates a warning when used with these types of nodes, and is subject to removal in a future release of MySQL Cluster.

  This change affects the name of the configuration parameter only, establishing a clear preference for `NodeId` over `Id` in the `[mgmd]`, `[ndbd]`, `[mysql]`, and `[api]` sections of the MySQL Cluster global configuration (`config.ini`) file. The behavior of unique identifiers for management, data, and SQL and API nodes in MySQL Cluster has not otherwise been altered.

  The `Id` parameter as used in the `[computer]` section of the MySQL Cluster global configuration file is not affected by this change.

Changes in MySQL Cluster NDB 6.2.18 (5.1.34-ndb-6.2.18) (2009-06-01)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.34 (see Changes in MySQL 5.1.34 (2009-04-02)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- **Important Change**: **Partitioning**: User-defined partitioning of an `NDBCLUSTER` table without any primary key sometimes failed, and could cause `mysqld` to crash.

  Now, if you wish to create an `NDBCLUSTER` table with user-defined partitioning, the table must have an explicit primary key, and all columns listed in the partitioning expression must be part of the primary key. The hidden primary key used by the `NDBCLUSTER` storage engine is not sufficient for this purpose. However, if the list of columns is empty (that is, the table is defined using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

  This change does not effect the partitioning of tables using any storage engine other than `NDBCLUSTER`. (Bug #40709)

- An internal NDB API buffer was not properly initialized. (Bug #44977)

- When a data node had written its GCI marker to the first page of a megabyte, and that node was later killed during restart after having processed that page (marker) but before completing a LCP, the data node could fail with file system errors. (Bug #44952)

  References: See also Bug #42564, Bug #44291.

- Inspection of the code revealed that several assignment operators (`=`) were used in place of comparison operators (`==`) in `DbdihMain.cpp`. (Bug #44567)

  References: See also Bug #44570.

- It was possible for NDB API applications to insert corrupt data into the database, which could subquently lead to data node crashes. Now, stricter checking is enforced on input data for inserts and updates. (Bug #44132)

- When trying to use a data node with an older version of the management server, the data node crashed on startup. (Bug #43699)

- In some cases, data node restarts during a system restart could fail due to insufficient redo log space. (Bug #43156)

- `TransactionDeadlockDetectionTimeout` [1841] values less than 100 were treated as 100. This could cause scans to time out unexpectedly. (Bug #44099)

- The file `ndberror.c` contained a C++-style comment, which caused builds to fail with some C compilers. (Bug #44036)

- `ndb_restore --print_data` [1997] did not handle `DECIMAL` columns correctly. (Bug #37171)

- A race condition could occur when a data node failed to restart just before being included in the next global checkpoint. This could cause other data nodes to fail. (Bug #43888)

- Some queries using combinations of logical and comparison operators on an indexed column in the `WHERE` clause could fail with the error `Got error 4541 'IndexBound has no bound information' from NDBCLUSTER`. (Bug #42857)

- Using indexes containing variable-sized columns could lead to internal errors when the indexes were being built. (Bug #43226)

- The output of `ndbd --help` did not provide clear information about the program's `--initial` and `--initial-start` options. (Bug #28905)

- It was theoretically possible for the value of a nonexistent column to be read as `NULL`, rather than causing an error. (Bug #27843)

- When aborting an operation involving both an insert and a delete, the insert and delete were aborted separately. This was because the transaction coordinator did not know that the operations affected on same row, and, in the case of a committed-read (tuple or index) scan, the abort of the insert was performed first, then the row was examined after the insert was aborted but before the delete was aborted. In some cases, this would leave the row in a inconsistent state. This could occur when a local checkpoint was performed during a backup. This issue did not affect primary ley operations or scans that used locks (these are serialized).

  After this fix, for ordered indexes, all operations that follow the operation to be aborted are now also aborted.

- **Disk Data**: **Partitioning**: An `NDB` table created with a very large value for the `MAX_ROWS` option could—if this table was dropped and a new table with fewer partitions, but having the same table ID, was created—cause `ndbd` to crash when performing a system restart. This was because the server attempted to examine each partition whether or not it actually existed. (Bug #45154)

  References: See also Bug #58638.

- **Disk Data**: During a checkpoint, restore points are created for both the on-disk and in-memory parts of a Disk Data table. Under certain rare conditions, the in-memory restore point could include or exclude a row that should have been in the snapshot. This would later lead to a crash during or following recovery. (Bug #41915)

  References: See also Bug #47832.

- **Disk Data**: When a log file group had an undo log file whose size was too small, restarting data nodes failed with `Read underflow` errors.

  As a result of this fix, the minimum permitted `INTIAL_SIZE` for an undo log file is now `1M` (1 megabyte). (Bug #29574)

- **Disk Data**: This fix supercedes and improves on an earlier fix made for this bug in MySQL 5.1.18. (Bug #24521)

- **Cluster Replication**: A failure when setting up replication events could lead to subsequent data node failures. (Bug #44915)

- **Cluster API**: If the largest offset of a `RecordSpecification` used for an `NdbRecord` object was for the `NULL` bits (and thus not a column), this offset was not taken into account when calculating the size used for the `RecordSpecification`. This meant that the space for the `NULL` bits could be overwritten by key or other information. (Bug #43891)

- **Cluster API**: Ordered index scans using `NdbRecord` formerly expressed a `BoundEQ` range as separate lower and upper bounds, resulting in 2 copies of the column values being sent to the NDB kernel.

  Now, when a range is specified by `NdbScanOperation::setBound()`, the passed pointers, key lengths, and inclusive bits are compared, and only one copy of the equal key columns is sent to the kernel. This makes such operations more efficient, as half the amount of `KeyInfo` is now sent for a `BoundEQ` range as before. (Bug #38793)

- **Cluster API**: When performing insert or write operations, `NdbRecord` permits key columns to be specified in both the key record and in the attribute record. Only one key column value for each key column should be sent to the NDB kernel, but this was not guaranteed. This is now ensured as follows: For insert and write operations, key column values are taken from the key record; for scan takeover update operations, key column values are taken from the attribute record. (Bug #42238)

- **Cluster API**: The default `NdbRecord` structures created by `NdbDictionary` could have overlapping null bits and data fields. (Bug #43590)

Changes in MySQL Cluster NDB 6.2.17 (5.1.32-ndb-6.2.17) (2008-10-19)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.32 (see Changes in MySQL 5.1.32 (2009-02-14)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Important Change**: Formerly, when the management server failed to create a transporter for a data node connection, `net_write_timeout` [506] seconds elapsed before the data node was actually permitted to disconnect. Now in such cases the disconnection occurs immediately. (Bug #41965)

  References: See also Bug #41713.

- **Important Change**: **Replication**: `RESET MASTER` and `RESET SLAVE` now reset the values shown for `Last_IO_Error`, `Last_IO_Errno`, `Last_SQL_Error`, and `Last_SQL_Errno` in the output of `SHOW SLAVE STATUS`. (Bug #34654)

  References: See also Bug #44270.

- **Cluster Replication**: **Important Note**: This release of MySQL Cluster derives in part from MySQL 5.1.29, where the default value for the `--binlog-format` [419] option changed to `STATEMENT`. That change does *not* affect this or future MySQL Cluster NDB 6.x releases, where the default value for this option remains `MIXED`, since MySQL Cluster Replication does not work with the statement-based format. (Bug #40586)

- **Disk Data**: It is now possible to specify default locations for Disk Data data files and undo log files, either together or separately, using the data node configuration parameters `FileSystemPathDD` [1857], `FileSystemPathDataFiles` [1858], and `FileSystemPathUndoFiles` [1858]. For information about these configuration parameters, see *Disk Data file system parameters*.

  It is also now possible to specify a log file group, tablespace, or both, that is created when the cluster is started, using the `InitialLogFileGroup` [1859] and `InitialTablespace` [1859] data node configuration parameters. For information about these configuration parameters, see *Disk Data object creation parameters*.

Bugs Fixed

- **Performance**: Updates of the `SYSTAB_0` system table to obtain a unique identifier did not use transaction hints for tables having no primary key. In such cases the NDB kernel used a cache size of 1. This meant that each insert into a table not having a primary key required an update of the corresponding `SYSTAB_0` entry, creating a potential performance bottleneck.

  With this fix, inserts on `NDB` tables without primary keys can be under some conditions be performed up to 100% faster than previously. (Bug #39268)

- **Packaging**: Packages for MySQL Cluster were missing the `libndbclient.so` and `libndbclient.a` files. (Bug #42278)

- **Partitioning**: Executing `ALTER TABLE ... REORGANIZE PARTITION` on an `NDBCLUSTER` table having only one partition caused `mysqld` to crash. (Bug #41945)

  References: See also Bug #40389.

- **Cluster API**: Failed operations on `BLOB` and `TEXT` columns were not always reported correctly to the originating SQL node. Such errors were sometimes reported as being due to timeouts, when the actual problem was a transporter overload due to insufficient buffer space. (Bug #39867, Bug #39879)

- In some cases, `NDB` did not check correctly whether tables had changed before trying to use the query cache. This could result in a crash of the debug MySQL server. (Bug #40464)

- Trying to execute an `ALTER ONLINE TABLE ... ADD COLUMN` statement while inserting rows into the table caused `mysqld` to crash. (Bug #41905)

- When using `ndbmtd`, NDB kernel threads could hang while trying to start the data nodes with `LockPagesInMainMemory` [1832] set to 1. (Bug #43021)

- Backup IDs greater than 2^{31} were not handled correctly, causing negative values to be used in backup directory names and printouts. (Bug #43042)

- Given a MySQL Cluster containing no data (that is, whose data nodes had all been started using `--initial`, and into which no data had yet been imported) and having an empty backup directory, executing `START BACKUP` with a user-specified backup ID caused the data nodes to crash. (Bug #41031)

- When using multiple management servers and starting several API nodes (possibly including one or more SQL nodes) whose connectstrings listed the management servers in different order, it was possible for 2 API nodes to be assigned the same node ID. When this happened it was possible for an API node not to get fully connected, consequently producing a number of errors whose cause was not easily recognizable. (Bug #42973)

- Triggers on `NDBCLUSTER` tables caused such tables to become locked. (Bug #42751)

  References: See also Bug #16229, Bug #18135.

- `ndb_error_reporter` worked correctly only with GNU `tar`. (With other versions of `tar`, it produced empty archives.) (Bug #42753)

- API nodes disconnected too agressively from cluster when data nodes were being restarted. This could sometimes lead to the API node being unable to access the cluster at all during a rolling restart. (Bug #41462)

- When performing more than 32 index or tuple scans on a single fragment, the scans could be left hanging. This caused unnecessary timeouts, and in addition could possibly lead to a hang of an LCP. (Bug #42559)

  References: This bug is a regression of Bug #42084.

- A data node failure that occurred between calls to `NdbIndexScanOperation::readTuples(SF_OrderBy)` and `NdbTransaction::execute()` was not correctly handled; a subsequent call to `nextResult()` caused a null pointer to be deferenced, leading to a segfault in `mysqld`. (Bug #42545)

- Issuing `SHOW GLOBAL STATUS LIKE 'NDB%'` before `mysqld` had connected to the cluster caused a segmentation fault. (Bug #42458)

- Data node failures that occurred before all data nodes had connected to the cluster were not handled correctly, leading to additional data node failures. (Bug #42422)

- When a cluster backup failed with Error 1304 (Node *`node_id1`*: Backup request from *`node_id2`* failed to start), no clear reason for the failure was provided.

  As part of this fix, MySQL Cluster now retries backups in the event of sequence errors. (Bug #42354)

  References: See also Bug #22698.

- Issuing `SHOW ENGINE NDBCLUSTER STATUS` on an SQL node before the management server had connected to the cluster caused `mysqld` to crash. (Bug #42264)
- A maximum of 11 `TUP` scans were permitted in parallel. (Bug #42084)
- Issuing `EXIT` in the management client sometimes caused the client to hang. (Bug #40922)
- If the master node failed during a global checkpoint, it was possible in some circumstances for the new master to use an incorrect value for the global checkpoint index. This could occur only when the cluster used more than one node group. (Bug #41469)
- Start phase reporting was inconsistent between the management client and the cluster log. (Bug #39667)
- An abort path in the `DBLQH` kernel block failed to release a commit acknowledgment marker. This meant that, during node failure handling, the local query handler could be added multiple times to the marker record which could lead to additional node failures due an array overflow. (Bug #41296)
- During node failure handling (of a data node other than the master), there was a chance that the master was waiting for a `GCP_NODEFINISHED` signal from the failed node after having received it from all other data nodes. If this occurred while the failed node had a transaction that was still being committed in the current epoch, the master node could crash in the `DBTC` kernel block when discovering that a transaction actually belonged to an epoch which was already completed. (Bug #41295)
- If a transaction was aborted during the handling of a data node failure, this could lead to the later handling of an API node failure not being completed. (Bug #41214)
- Memory leaks could occur in handling of strings used for storing cluster metadata and providing output to users. (Bug #38662)
- A segfault in `Logger::Log` caused `ndbd` to hang indefinitely. This fix improves on an earlier one for this issue, first made in MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.17. (Bug #39180)

  References: See also Bug #38609.
- Redo log creation was very slow on some platforms, causing MySQL Cluster to start more slowly than necessary with some combinations of hardware and operating system. This was due to all write operations being synchronized to disk while creating a redo log file. Now this synchronization occurs only after the redo log has been created. (Bug #40734)
- Transaction failures took longer to handle than was necessary.

  When a data node acting as transaction coordinator (TC) failed, the surviving data nodes did not inform the API node initiating the transaction of this until the failure had been processed by all protocols. However, the API node needed only to know about failure handling by the transaction protocol—that is, it needed to be informed only about the TC takeover process. Now, API nodes (including MySQL servers acting as cluster SQL nodes) are informed as soon as the TC takeover is complete, so that it can carry on operating more quickly. (Bug #40697)
- Events logged after setting `ALL CLUSTERLOG STATISTICS=15` in the management client did not always include the node ID of the reporting node. (Bug #39839)
- It was theoretically possible for stale data to be read from `NDBCLUSTER` tables when the transaction isolation level was set to `ReadCommitted`. (Bug #40543)
- Restoring a MySQL Cluster from a dump made using `mysqldump` failed due to a spurious error: `Can't execute the given command because you have active locked tables or an active transaction`. (Bug #40346)
- `O_DIRECT` was incorrectly disabled when making MySQL Cluster backups. (Bug #40205)

- The MySQL Query Cache did not function correctly with `NDBCLUSTER` tables containing `TEXT` columns. (Bug #39295)
- In the event that a MySQL Cluster backup failed due to file permissions issues, conflicting reports were issued in the management client. (Bug #34526)
- A duplicate key or other error raised when inserting into an `NDBCLUSTER` table caused the current transaction to abort, after which any SQL statement other than a `ROLLBACK` failed. With this fix, the `NDBCLUSTER` storage engine now performs an implicit rollback when a transaction is aborted in this way; it is no longer necessary to issue an explicit `ROLLBACK` statement, and the next statement that is issued automatically begins a new transaction.

  Note

  It remains necessary in such cases to retry the complete transaction, regardless of which statement caused it to be aborted.

  (Bug #32656)

  References: See also Bug #47654.
- Error messages for `NDBCLUSTER` error codes 1224 and 1227 were missing. (Bug #28496)
- **Partitioning**: A query on a user-partitioned table caused MySQL to crash, where the query had the following characteristics:
  - The query's `WHERE` clause referenced an indexed column that was also in the partitioning key.
  - The query's `WHERE` clause included a value found in the partition.
  - The query's `WHERE` clause used the `<` or `<>` operators to compare with the indexed column's value with a constant.
  - The query used an `ORDER BY` clause, and the same indexed column was used in the `ORDER BY` clause.
  - The `ORDER BY` clause used an explicit or implicit `ASC` sort priority.

  Two examples of such a query are given here, where `a` represents an indexed column used in the table's partitioning key:

  1. `SELECT * FROM table WHERE a < constant ORDER BY a;`
  2. `SELECT * FROM table WHERE a <> constant ORDER BY a;`

  (Bug #40954)

  References: This bug was introduced by Bug #30573, Bug #33257, Bug #33555.
- **Partitioning**: Dropping or creating an index on a partitioned table managed by the `InnoDB` Plugin locked the table. (Bug #37453)
- **Disk Data**: Creating a Disk Data tablespace with a very large extent size caused the data nodes to fail. The issue was observed when using extent sizes of 100 MB and larger. (Bug #39096)
- **Disk Data**: It was not possible to add an in-memory column online to a table that used a table-level or column-level `STORAGE DISK` option. The same issue prevented `ALTER ONLINE TABLE ... REORGANIZE PARTITION` from working on Disk Data tables. (Bug #42549)
- **Disk Data**: Creation of a tablespace data file whose size was greater than 4 GB failed silently on 32-bit platforms. (Bug #37116)

  References: See also Bug #29186.

- **Disk Data**: Issuing concurrent `CREATE TABLESPACE`, `ALTER TABLESPACE`, `CREATE LOGFILE GROUP`, or `ALTER LOGFILE GROUP` statements on separate SQL nodes caused a resource leak that led to data node crashes when these statements were used again later. (Bug #40921)

- **Disk Data**: Disk-based variable-length columns were not always handled like their memory-based equivalents, which could potentially lead to a crash of cluster data nodes. (Bug #39645)

- **Disk Data**: Using a path or file name longer than 128 characters for Disk Data undo log files and tablespace data files caused a number of issues, including failures of `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, and `ALTER TABLESPACE` statements, as well as crashes of management nodes and data nodes.

  With this fix, the maximum length for path and file names used for Disk Data undo log files and tablespace data files is now the same as the maximum for the operating system. (Bug #31769, Bug #31770, Bug #31772)

- **Disk Data**: Trying to execute a `CREATE LOGFILE GROUP` statement using a value greater than `150M` for `UNDO_BUFFER_SIZE` caused data nodes to crash.

  As a result of this fix, the upper limit for `UNDO_BUFFER_SIZE` is now `600M`; attempting to set a higher value now fails gracefully with an error. (Bug #34102)

  References: See also Bug #36702.

- **Disk Data**: When attempting to create a tablespace that already existed, the error message returned was `Table or index with given name already exists`. (Bug #32662)

- **Disk Data**: `O_SYNC` was incorrectly disabled on platforms that do not support `O_DIRECT`. This issue was noted on Solaris but could have affected other platforms not having `O_DIRECT` capability. (Bug #34638)

- **Disk Data**: Starting a cluster under load such that Disk Data tables used most of the undo buffer could cause data node failures.

  The fix for this bug also corrected an issue in the `LGMAN` kernel block where the amount of free space left in the undo buffer was miscalculated, causing buffer overruns. This could cause records in the buffer to be overwritten, leading to problems when restarting data nodes. (Bug #28077)

- **Disk Data**: Attempting to perform a system restart of the cluster where there existed a logfile group without and undo log files caused the data nodes to crash.

  Note

  While issuing a `CREATE LOGFILE GROUP` statement without an `ADD UNDOFILE` option fails with an error in the MySQL server, this situation could arise if an SQL node failed during the execution of a valid `CREATE LOGFILE GROUP` statement; it is also possible to create a logfile group without any undo log files using the NDB API.

  (Bug #17614)

- **Cluster Replication**: Sometimes, when using the `--ndb_log_orig` option, the `orig_epoch` and `orig_server_id` columns of the `ndb_binlog_index` table on the slave contained the ID and epoch of the local server instead. (Bug #41601)

- **Cluster API**: Some error messages from `ndb_mgmd` contained newline (`\n`) characters. This could break the MGM API protocol, which uses the newline as a line separator. (Bug #43104)

- **Cluster API**: When using an ordered index scan without putting all key columns in the read mask, this invalid use of the NDB API went undetected, which resulted in the use of uninitialized memory. (Bug #42591)

- **Cluster API**: It was not always possible to access parent objects directly from `NdbBlob`, `NdbOperation`, and `NdbScanOperation` objects. To alleviate this problem, a new `getNdbOperation()` method has been added to `NdbBlob` and new getNdbTransaction() methods have been added to `NdbOperation` and `NdbScanOperation`. In addition, a const variant of `NdbOperation::getErrorLine()` is now also available. (Bug #40242)

- **Cluster API**: `NdbScanOperation::getBlobHandle()` failed when used with incorrect column names or numbers. (Bug #40241)

- **Cluster API**: The MGM API reset error codes on management server handles before checking them. This meant that calling an MGM API function with a null handle caused applications to crash. (Bug #40455)

- **Cluster API**: The NDB API example programs included in MySQL Cluster source distributions failed to compile. (Bug #37491)

  References: See also Bug #40238.

- **Cluster API**: `mgmapi.h` contained constructs which only worked in C++, but not in C. (Bug #27004)

Changes in MySQL Cluster NDB 6.2.16 (5.1.28-ndb-6.2.16) (2008-10-08)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.28-ndb-6.2.16.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.28 (see Changes in MySQL 5.1.28 (2008-08-28)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- It is no longer a requirement for database autodiscovery that an SQL node already be connected to the cluster at the time that a database is created on another SQL node. It is no longer necessary to issue `CREATE DATABASE` (or `CREATE SCHEMA`) statements on an SQL node joining the cluster after a database is created for the new SQL node to see the database and any `NDBCLUSTER` tables that it contains. (Bug #39612)

Bugs Fixed

- After a forced shutdown and initial restart of the cluster, it was possible for SQL nodes to retain `.frm` files corresponding to `NDBCLUSTER` tables that had been dropped, and thus to be unaware that these tables no longer existed. In such cases, attempting to re-create the tables using `CREATE TABLE IF NOT EXISTS` could fail with a spurious `Table ... doesn't exist` error. (Bug #37921)

- When restarting a data node, an excessively long shutdown message could cause the node process to crash. (Bug #38580)

- Starting the MySQL Server with the `--ndbcluster` [1915] option plus an invalid command-line option (for example, using `mysqld --ndbcluster --foobar`) caused it to hang while shutting down the binlog thread. (Bug #39635)

- Heavy DDL usage caused the `mysqld` processes to hang due to a timeout error (`NDB` error code 266). (Bug #39885)

- Executing `EXPLAIN SELECT` on an `NDBCLUSTER` table could cause `mysqld` to crash. (Bug #39872)
- Dropping and then re-creating a database on one SQL node caused other SQL nodes to hang. (Bug #39613)
- Unique identifiers in tables having no primary key were not cached. This fix has been observed to increase the efficiency of `INSERT` operations on such tables by as much as 50%. (Bug #39267)
- Setting a low value of `MaxNoOfLocalScans` [1824] (< 100) and performing a large number of (certain) scans could cause the Transaction Coordinator to run out of scan fragment records, and then crash. Now when this resource is exhausted, the cluster returns Error 291 (`Out of scanfrag records in TC (increase MaxNoOfLocalScans)`) instead. (Bug #39549)
- Creating a unique index on an `NDBCLUSTER` table caused a memory leak in the `NDB` subscription manager (`SUMA`) which could lead to mysqld hanging, due to the fact that the resource shortage was not reported back to the `NDB` kernel correctly. (Bug #39518)

  References: See also Bug #39450.
- `MgmtSrvr::allocNodeId()` left a mutex locked following an `Ambiguity for node if %d` error. (Bug #39158)
- An invalid path specification caused `mysql-test-run.pl` to fail. (Bug #39026)
- During transactional coordinator takeover (directly after node failure), the LQH finding an operation in the `LOG_COMMIT` state sent an `LQH_TRANS_CONF` signal twice, causing the TC to fail. (Bug #38930)
- An invalid memory access caused the management server to crash on Solaris Sparc platforms. (Bug #38628)
- A segfault in `Logger::Log` caused `ndbd` to hang indefinitely. (Bug #38609)
- `ndb_mgmd` failed to start on older Linux distributions (2.4 kernels) that did not support e-polling. (Bug #38592)
- `ndb_mgmd` sometimes performed unnecessary network I/O with the client. This in combination with other factors led to long-running threads that were attempting to write to clients that no longer existed. (Bug #38563)
- `ndb_restore` failed with a floating point exception due to a division by zero error when trying to restore certain data files. (Bug #38520)
- A failed connection to the management server could cause a resource leak in `ndb_mgmd`. (Bug #38424)
- Failure to parse configuration parameters could cause a memory leak in the NDB log parser. (Bug #38380)
- Renaming an `NDBCLUSTER` table on one SQL node, caused a trigger on this table to be deleted on another SQL node. (Bug #36658)
- Attempting to add a `UNIQUE INDEX` twice to an `NDBCLUSTER` table, then deleting rows from the table could cause the MySQL Server to crash. (Bug #35599)
- `ndb_restore` failed when a single table was specified. (Bug #33801)
- `GCP_COMMIT` did not wait for transaction takeover during node failure. This could cause `GCP_SAVE_REQ` to be executed too early. This could also cause (very rarely) replication to skip rows. (Bug #30780)
- **Cluster Replication**: In some cases, dropping a database on the master could cause table logging to fail on the slave, or, when using a debug build, could cause the slave `mysqld` to fail completely. (Bug #39404)

- **Cluster Replication**: During a parallel node restart, the starting nodes could (sometimes) incorrectly synchronize subscriptions among themselves. Instead, this synchronization now takes place only among nodes that have actually (completely) started. (Bug #38767)
- **Cluster Replication**: Data was written to the binlog with `--log-slave-updates` [1628] disabled. (Bug #37472)
- **Cluster API**: Certain Multi-Range Read scans involving `IS NULL` and `IS NOT NULL` comparisons failed with an error in the `NDB` local query handler. (Bug #38204)
- **Cluster API**: Creating an `NdbScanFilter` object using an `NdbScanOperation` object that had not yet had its `readTuples()` method called resulted in a crash when later attempting to use the `NdbScanFilter`. (Bug #37986)
- **Cluster API**: Executing an `NdbRecord` interpreted delete created with an `ANYVALUE` option caused the transaction to abort. (Bug #37672)
- **Cluster API**: Passing a value greater than 65535 to `NdbInterpretedCode::add_val()` and `NdbInterpretedCode::sub_val()` caused these methods to have no effect. (Bug #39536)
- **Cluster API**: The `NdbScanOperation::readTuples()` method could be called multiple times without error. (Bug #38717)
- **Cluster API**: Problems with the public headers prevented `NDB` applications from being built with warnings turned on. (Bug #38177)
- **Cluster API**: Accessing the debug version of `libndbclient` using `dlopen()` resulted in a segmentation fault. (Bug #35927)

Changes in MySQL Cluster NDB 6.2.15 (5.1.23-ndb-6.2.15) (2008-05-22)

This is re-release of MySQL Cluster NDB 6.2.14 providing binaries for supported platforms. For more information, see Changes in MySQL Cluster NDB 6.2.14 (5.1.23-ndb-6.2.14) (2008-03-05).

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from http://dev.mysql.com/downloads/cluster/.

Changes in MySQL Cluster NDB 6.2.14 (5.1.23-ndb-6.2.14) (2008-03-05)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from http://dev.mysql.com/downloads/cluster/.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see Changes in MySQL 5.1.23 (2008-01-29)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- Added the `MaxBufferedEpochs` [1840] data node configuration parameter, which controls the maximum number of unprocessed epochs by which a subscribing node can lag. Subscribers which exceed this number are disconnected and forced to reconnect.

  See Defining MySQL Cluster Data Nodes, for more information.

- **Replication**: Introduced the `slave_exec_mode` [1644] system variable to control whether idempotent or strict mode is used for replication conflict resolution. Idempotent mode suppresses

duplicate-key, no-key-found, and some other errors, and is needed for circular replication, multi-master replication, and some other complex replication setups when using MySQL Cluster, where idempotent mode is the default. However, strict mode is the default for storage engines other than `NDB`. (Bug #31609)

- **Cluster Replication**: `RESET MASTER` now uses `TRUNCATE TABLE` rather than `DELETE` to clear the `mysql.ndb_binlog_index` table. This improves the performance of the statement and is less likely to leave the table in a fragmented state. (Bug #34356)

- Formerly, when the MySQL server crashed, the generated stack dump was numeric and required external tools to properly resolve the names of functions. This is not very helpful to users having a limited knowledge of debugging techniques. In addition, the generated stack trace contained only the names of functions and was formatted differently for each platform due to different stack layouts.

  Now it is possible to take advantage of newer versions of the GNU C Library provide a set of functions to obtain and manipulate stack traces from within the program. On systems that use the ELF binary format, the stack trace contains important information such as the shared object where the call was generated, an offset into the function, and the actual return address. Having the function name also makes possible the name demangling of C++ functions.

  The library generates meaningful stack traces on the following platforms: i386, x86_64, PowerPC, IA64, Alpha, and S390. On other platforms, a numeric stack trace is still produced, and the use of the `resolve_stack_dump` utility is still required. (Bug #31891)

- `mysqltest` now has `mkdir` and `rmdir` commands for creating and removing directories. (Bug #31004)

- Added the `Uptime_since_flush_status` [571] status variable, which indicates the number of seconds since the most recent `FLUSH STATUS` statement. (Community contribution by Jeremy Cole) (Bug #24822)

Bugs Fixed

- **Performance**: `InnoDB` exhibited thread thrashing with more than 50 concurrent connections under an update-intensive workload. (Bug #22868)

- **Incompatible Change**: The `UPDATE` statement permitted `NULL` to be assigned to `NOT NULL` columns (the implicit default value for the column data type was assigned). This was changed so that on error occurs.

  This change was reverted, because the original report was determined not to be a bug: Assigning `NULL` to a `NOT NULL` column in an `UPDATE` statement should produce an error only in strict SQL mode and set the column to the implicit default with a warning otherwise, which was the original behavior. See Data Type Default Values, and Bug #39265. (Bug #33699)

- **Incompatible Change**: Previously, the parser accepted the ODBC `{ OJ ... LEFT OUTER JOIN ...}` syntax for writing left outer joins. The parser now permits `{ OJ ... }` to be used to write other types of joins, such as `INNER JOIN` or `RIGHT OUTER JOIN`. This helps with compatibility with some third-party applications, but is not official ODBC syntax.

  A consequence of this change is that the parser no longer permits nested `{ OJ ... }` constructs (which are not legal ODBC syntax, anyway). Queries that use such constructs should be rewritten. For example, this query is now produces an error:

```
SELECT * FROM
   {OJ
      {OJ a LEFT OUTER JOIN b ON a.a1=b.a1}
      LEFT OUTER JOIN c ON b.b1 = c.b1};
```

  That can be replaced by any of the following rewrites:

```
SELECT * FROM
```

```
    {OJ a LEFT OUTER JOIN b
          LEFT OUTER JOIN c ON b.b1 = c.b1 ON a.a1=b.a1};

SELECT * FROM
   {OJ a LEFT OUTER JOIN b ON a.a1=b.a1
         LEFT OUTER JOIN c ON b.b1 = c.b1};

SELECT * FROM
     a LEFT OUTER JOIN b ON a.a1=b.a1 LEFT OUTER JOIN c ON b.b1 = c.b1;
```

The first two are legal according to ODBC, and you nest the joins inside a single `{ OJ ...}` clause. The third is standard SQL syntax, without ODBC decoration. It can be used with parentheses to emphasize the evaluation order:

```
SELECT * FROM
     ((a LEFT OUTER JOIN b ON a.a1=b.a1)
         LEFT OUTER JOIN c ON b.b1 = c.b1);
```

(Bug #28317)

- **Important Change**: **Replication**: When the master crashed during an update on a transactional table while in `autocommit` [461] mode, the slave failed. This fix causes every transaction (including `autocommit` [461] transactions) to be recorded in the binary log as starting with a `BEGIN` and ending with a `COMMIT` or `ROLLBACK`.

  Note

  The current fix does *not* cause nontransactional changes to be wrapped in `BEGIN` ... `COMMIT` or `BEGIN` ... `ROLLBACK` when written to the binary log. For this purpose, any statements affecting tables using a nontransactional storage engine such as `MyISAM` are regarded as nontransactional, even when `autocommit` [461] is enabled.

  (Bug #26395)

  References: See also Bug #29288, Bug #49522.

- **Replication**: **Important Note**: Network timeouts between the master and the slave could result in corruption of the relay log. This fix rectifies a long-standing replication issue when using unreliable networks, including replication over wide area networks such as the Internet. If you experience reliability issues and see many `You have an error in your SQL syntax` errors on replication slaves, we strongly recommend that you upgrade to a MySQL version which includes this fix. (Bug #26489)

- **Replication**: When the Windows version of `mysqlbinlog` read 4.1 binlogs containing `LOAD DATA INFILE` statements, it output backslashes as path separators, causing problems for client programs expecting forward slashes. In such cases, it now converts `\\` to `/` in directory paths. (Bug #34355)

- **Replication**: `mysqlbinlog` failed to release all of its memory after terminating abnormally. (Bug #33247)

- **Replication**: `mysqlbinlog` from a 5.1 or later MySQL distribution could not read binary logs generated by a 4.1 server when the logs contained `LOAD DATA INFILE` statements. (Bug #34141)

  References: This bug was introduced by Bug #32407.

- **Replication**: `SHOW SLAVE STATUS` failed when slave I/O was about to terminate. (Bug #34305)

- **Replication**: The error message generated due to lack of a default value for an extra column was not sufficiently informative. (Bug #32971)

- **Replication**: A `CREATE USER`, `DROP USER`, or `RENAME USER` statement that fails on the master, or that is a duplicate of any of these statements, is no longer written to the binlog; previously, either of these occurrences could cause the slave to fail. (Bug #33862)

References: See also Bug #29749.

- **Replication**: Setting `server_id` [521] did not update its value for the current session. (Bug #28908)
- **Replication**: SQL statements containing comments using `--` syntax were not replayable by `mysqlbinlog`, even though such statements replicated correctly. (Bug #32205)
- **Replication**: Issuing a `DROP VIEW` statement caused replication to fail if the view did not actually exist. (Bug #30998)
- **Replication**: When a user variable was used inside an `INSERT` statement, the corresponding binlog event was not written to the binlog correctly. (Bug #32580)
- **Replication**: Replicating write, update, or delete events from a master running MySQL 5.1.15 or earlier to a slave running 5.1.16 or later caused the slave to crash. (Bug #31581)
- **Replication**: When using row-based replication from a master running MySQL 5.1.21 or earlier to a slave running 5.1.22 or later, updates of integer columns failed on the slave with `Error in Unknown event: row application failed`. (Bug #31583)

  References: This bug was introduced by Bug #21842.
- **Replication**: When using row-based replication, deletes from a table with a foreign key constraint failed on the slave. (Bug #32468)
- **Replication**: When using row-based replication, the slave stopped when attempting to delete nonexistent rows from a slave table without a primary key. In addition, no error was reported when this occurred. (Bug #31552)
- **Replication**: Replication crashed with the `NDB` storage engine when `mysqld` was started with `--character-set-server=ucs2` [422]. (Bug #29562)
- **Replication**: Replication of `LOAD DATA INFILE` could fail when `read_buffer_size` [516] was larger than `max_allowed_packet` [493]. (Bug #30435)
- **Replication**: Some older servers wrote events to the binary log using different numbering from what is currently used, even though the file format number in the file is the same. Slaves running MySQL 5.1.18 and later could not read these binary logs properly. Binary logs from these older versions now are recognized and event numbers are mapped to the current numbering so that they can be interpreted properly. (Bug #27779, Bug #32434)

  References: This bug was introduced by Bug #22583.
- **Cluster Replication**: Using `--ndb-wait-connected` [1919] caused the server to wait for a partial connection, plus an additional 3 seconds for a complete connection to the cluster. This could lead to issues with setting up the binary log. (Bug #34757)
- **Cluster API**: Closing a scan before it was executed caused the application to segfault. (Bug #36375)
- **Cluster API**: Scans having no bounds set were handled incorrectly. (Bug #35876)
- **Cluster API**: Using NDB API applications from older MySQL Cluster versions with `libndbclient` from newer ones caused the cluster to fail. (Bug #36124)
- `SET GLOBAL myisam_max_sort_file_size=DEFAULT` set `myisam_max_sort_file_size` [501] to an incorrect value. (Bug #33382)

  References: See also Bug #31177.
- Granting the `UPDATE` [628] privilege on one column of a view caused the server to crash. (Bug #33201)

- The server crashed when executing a query that had a subquery containing an equality X=Y where Y referred to a named select list expression from the parent select. The server crashed when trying to use the X=Y equality for `ref` [697]-based access. (Bug #33794)
- Resetting the query cache by issuing a `SET GLOBAL query_cache_size=0` statement caused the server to crash if it concurrently was saving a new result set to the query cache. (Bug #30887)
- `mysqld` displayed the `--enable-pstack` [426] option in its help message even if MySQL was configured without `--with-pstack`. (Bug #29836)
- The server could crash when `REPEAT` or another control instruction was used in conjunction with labels and a `LEAVE` instruction. (Bug #33618)
- `ROUND(X,D)` [977] or `TRUNCATE(X,D)` [978] for nonconstant values of *D* could crash the server if these functions were used in an `ORDER BY` that was resolved using `filesort`. (Bug #30889)
- For `DECIMAL` columns used with the `ROUND(X,D)` [977] or `TRUNCATE(X,D)` [978] function with a nonconstant value of *D*, adding an `ORDER BY` for the function result produced misordered output. (Bug #33143)

  References: See also Bug #33402, Bug #30617.
- `ORDER BY ... DESC` sorts could produce misordered results. (Bug #33697)
- The `Com_create_function` status variable was not incremented properly. (Bug #30252)
- The `Table_locks_waited` [570] waited variable was not incremented in the cases that a lock had to be waited for but the waiting thread was killed or the request was aborted. (Bug #30331)
- Tables in the `mysql` database that stored the current `sql_mode` [526] value as part of stored program definitions were not updated with newer mode values (`NO_ENGINE_SUBSTITUTION` [574], `PAD_CHAR_TO_FULL_LENGTH` [575]). This causes various problems defining stored programs if those modes were included in the current `sql_mode` [526] value. (Bug #32633)
- The `SHOW ENGINE INNODB STATUS` and `SHOW ENGINE INNODB MUTEX` statements incorrectly required the `SUPER` [628] privilege rather than the `PROCESS` [627] privilege. (Bug #32710)
- Use of stored functions in the `WHERE` clause for `SHOW OPEN TABLES` caused a server crash. (Bug #34166)
- Large unsigned integers were improperly handled for prepared statements, resulting in truncation or conversion to negative numbers. (Bug #33798)
- Views were treated as insertable even if some base table columns with no default value were omitted from the view definition. (This is contrary to the condition for insertability that a view must contain all columns in the base table that do not have a default value.) (Bug #29477)
- The parser rules for the `SHOW PROFILE` statement were revised to work with older versions of `bison`. (Bug #27433)
- `CREATE ... SELECT` did not always set `DEFAULT` column values in the new table. (Bug #21380)
- `mysqlcheck -A -r` did not correctly identify all tables that needed repairing. (Bug #25347)
- `resolveip` failed to produce correct results for host names that begin with a digit. (Bug #27427)
- Warnings for deprecated syntax constructs used in stored routines make sense to report only when the routine is being created, but they were also being reported when the routine was parsed for loading into the execution cache. Now they are reported only at routine creation time. (Bug #21801)
- If a `SELECT` calls a stored function in a transaction, and a statement within the function fails, that statement should roll back. Furthermore, if `ROLLBACK` is executed after that, the entire transaction should be rolled back. Before this fix, the failed statement did not roll back when it failed (even

though it might ultimately get rolled back by a `ROLLBACK` later that rolls back the entire transaction). (Bug #12713)

References: See also Bug #34655.

Changes in MySQL Cluster NDB 6.2.13 (5.1.23-ndb-6.2.13) (2008-02-22)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from http://dev.mysql.com/downloads/cluster/.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see Changes in MySQL 5.1.23 (2008-01-29)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- A node failure during an initial node restart followed by another node start could cause the master data node to fail, because it incorrectly gave the node permission to start even if the invalidated node's LCP was still running. (Bug #34702)

Changes in MySQL Cluster NDB 6.2.12 (5.1.23-ndb-6.2.12) (2008-02-12)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from http://dev.mysql.com/downloads/cluster/.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see Changes in MySQL 5.1.23 (2008-01-29)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- Beginning with this version, MySQL Cluster NDB 6.3.*x* releases once again include the `InnoDB` storage engine. To enable `InnoDB`, you must configure the build using `--with-innodb`.

Bugs Fixed

- When configured with `NDB` support, MySQL failed to compile using `gcc` 4.3 on 64bit FreeBSD systems. (Bug #34169)
- Upgrades of a cluster using while a `DataMemory` [1817] setting in excess of 16 GB caused data nodes to fail. (Bug #34378)
- Performing many SQL statements on `NDB` tables while in `autocommit` [461] mode caused a memory leak in `mysqld`. (Bug #34275)
- In certain rare circumstances, a race condition could occur between an aborted insert and a delete leading a data node crash. (Bug #34260)

- Multi-table updates using ordered indexes during handling of node failures could cause other data nodes to fail. (Bug #34216)
- The failure of a DDL statement could sometimes lead to node failures when attempting to execute subsequent DDL statements. (Bug #34160)
- Extremely long `SELECT` statements (where the text of the statement was in excess of 50000 characters) against `NDB` tables returned empty results. (Bug #34107)
- Statements executing multiple inserts performed poorly on `NDB` tables having `AUTO_INCREMENT` columns. (Bug #33534)
- The `ndb_waiter` utility polled `ndb_mgmd` excessively when obtaining the status of cluster data nodes. (Bug #32025)

  References: See also Bug #32023.
- Transaction atomicity was sometimes not preserved between reads and inserts under high loads. (Bug #31477)
- Having tables with a great many columns could cause Cluster backups to fail. (Bug #30172)
- **Cluster Replication**: **Disk Data**: Statements violating unique keys on Disk Data tables (such as attempting to insert `NULL` into a `NOT NULL` column) could cause data nodes to fail. When the statement was executed from the binlog, this could also result in failure of the slave cluster. (Bug #34118)
- **Disk Data**: Updating in-memory columns of one or more rows of Disk Data table, followed by deletion of these rows and re-insertion of them, caused data node failures. (Bug #33619)
- **Cluster Replication**: Setting `--replicate-ignore-db=mysql` [1635] caused the `mysql.ndb_apply_status` table not to be replicated, breaking Cluster Replication. (Bug #28170)

Changes in MySQL Cluster NDB 6.2.11 (5.1.23-ndb-6.2.11) (2008-01-28)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from http://dev.mysql.com/downloads/cluster/.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see Changes in MySQL 5.1.23 (2008-01-29)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Cluster API**: **Important Change**: Because `NDB_LE_MemoryUsage.page_size_kb` shows memory page sizes in bytes rather than kilobytes, it has been renamed to `page_size_bytes`. The name `page_size_kb` is now deprecated and thus subject to removal in a future release, although it currently remains supported for reasons of backward compatibility. See The `Ndb_logevent_type` Type, for more information about `NDB_LE_MemoryUsage`. (Bug #30271)

Bugs Fixed

- Some tuple scans caused the wrong memory page to be accessed, leading to invalid results. This issue could affect both in-memory and Disk Data tables. (Bug #33739)

- Issuing an `INSERT ... ON DUPLICATE KEY UPDATE` concurrently with or following a `TRUNCATE TABLE` statement on an `NDB` table failed with `NDB` error 4350 `Transaction already aborted`. (Bug #29851)
- The server failed to reject properly the creation of an `NDB` table having an unindexed `AUTO_INCREMENT` column. (Bug #30417)
- A race condition could occur (very rarely) when the release of a GCI was followed by a data node failure. (Bug #33793)
- A periodic failure to flush the send buffer by the `NDB` TCP transporter could cause a unnecessary delay of 10 ms between operations. (Bug #34005)
- High numbers of insert operations, delete operations, or both could cause `NDB` error 899 (`Rowid already allocated`) to occur unnecessarily. (Bug #34033)
- It was possible in `config.ini` to define cluster nodes having node IDs greater than the maximum permitted value. (Bug #28298)
- The Cluster backup process could not detect when there was no more disk space and instead continued to run until killed manually. Now the backup fails with an appropriate error when disk space is exhausted. (Bug #28647)
- **Cluster Replication**: `ndb_restore -e` restored excessively large values to the `ndb_apply_status` table's `epoch` column when restoring to a MySQL Cluster version supporting Micro-GCPs from an older version that did not support these.

  A workaround when restoring to MySQL Cluster releases supporting micro-GCPs previous to MySQL Cluster NDB 6.3.8 is to perform a 32-bit shift on the `epoch` column values to reduce them to their proper size. (Bug #33406)
- **Cluster API**: When reading a `BIT(64)` value using `NdbOperation:getValue()`, 12 bytes were written to the buffer rather than the expected 8 bytes. (Bug #33750)
- **Cluster API**: Transactions containing inserts or reads would hang during `NdbTransaction::execute()` calls made from NDB API applications built against a MySQL Cluster version that did not support micro-GCPs accessing a later version that supported micro-GCPs. This issue was observed while upgrading from MySQL Cluster NDB 6.1.23 to MySQL Cluster NDB 6.2.10 when the API application built against the earlier version attempted to access a data node already running the later version, even after disabling micro-GCPs by setting `TimeBetweenEpochs` [1840] equal to 0. (Bug #33895)

Changes in MySQL Cluster NDB 6.2.10 (5.1.23-ndb-6.2.10) (2007-12-19)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from http://dev.mysql.com/downloads/cluster/.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see Changes in MySQL 5.1.23 (2008-01-29)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- **Partitioning**: When partition pruning on an `NDB` table resulted in an ordered index scan spanning only one partition, any descending flag for the scan was wrongly discarded, causing `ORDER BY`

`DESC` to be treated as `ORDER BY ASC`, `MAX()` to be handled incorrectly, and similar problems. (Bug #33061)

- When all data and SQL nodes in the cluster were shut down abnormally (that is, other than by using `STOP` in the cluster management client), `ndb_mgm` used excessive amounts of CPU. (Bug #33237)
- When using micro-GCPs, if a node failed while preparing for a global checkpoint, the master node would use the wrong GCI. (Bug #32922)
- Under some conditions, performing an `ALTER TABLE` on an `NDBCLUSTER` table failed with a `Table is full` error, even when only 25% of `DataMemory` [1817] was in use and the result should have been a table using less memory (for example, changing a `VARCHAR(100)` column to `VARCHAR(80)`). (Bug #32670)

Changes in MySQL Cluster NDB 6.2.9 (5.1.22-ndb-6.2.9) (2007-11-22)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from http://dev.mysql.com/downloads/cluster/.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see Changes in MySQL 5.1.22 (2007-09-24, Release Candidate)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- Added the `ndb_mgm` client command `DUMP 8011`, which dumps all subscribers to the cluster log. See `DUMP 8011`, for more information.

Bugs Fixed

- The failure of a master node could lead to subsequent failures in local checkpointing. (Bug #32160)
- High numbers of API nodes on a slow or congested network could cause connection negotiation to time out prematurely, leading to the following issues:
  - Excessive retries
  - Excessive CPU usage
  - Partially connected API nodes

  (Bug #32359)
- A local checkpoint could sometimes be started before the previous LCP was restorable from a global checkpoint. (Bug #32519)
- Adding a new `TINYTEXT` column to an `NDB` table which used `COLUMN_FORMAT = DYNAMIC`, and when binary logging was enabled, caused all cluster `mysqld` processes to crash. (Bug #30213)
- After adding a new column of one of the `TEXT` or `BLOB` types to an `NDB` table which used `COLUMN_FORMAT = DYNAMIC`, it was no longer possible to access or drop the table using SQL. (Bug #30205)
- A restart of the cluster failed when more than 1 REDO phase was in use. (Bug #22696)

- **Cluster Replication**: **Replication**: Where a table being replicated had a `TEXT` or `BLOB` column, an `UPDATE` on the master that did not refer explicitly to this column in the `WHERE` clause stopped the SQL thread on the slave with `Error in Write_rows event: row application failed. Got error 4288 'Blob handle for column not available' from NDBCLUSTER`. (Bug #30674)
- **Cluster Replication**: Under certain conditions, the slave stopped processing relay logs. This resulted in the logs never being cleared and the slave eventually running out of disk space. (Bug #31958)

Changes in MySQL Cluster NDB 6.2.8 (5.1.22-ndb-6.2.8) (2007-11-08)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from http://dev.mysql.com/downloads/cluster/.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see Changes in MySQL 5.1.22 (2007-09-24, Release Candidate)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Important Note**: MySQL Cluster NDB 6.2 and 6.3 source archives are now available in separate commercial and GPL versions. Due to licensing concerns, previous MySQL Cluster NDB 6.2 and 6.3 source archives were removed from the FTP site.
- The output of the `ndb_mgm` client `SHOW` and `STATUS` commands now indicates when the cluster is in single user mode. (Bug #27999)

Bugs Fixed

- The `NDB` management client command *`node_id`* `REPORT MEMORY` provided no output when *`node_id`* was the node ID of a management or API node. Now, when this occurs, the management client responds with `Node` *`node_id`*`: is not a data node`. (Bug #29485)
- In a cluster running in diskless mode and with arbitration disabled, the failure of a data node during an insert operation caused other data node to fail. (Bug #31980)
- Following an upgrade, `ndb_mgmd` would fail with an *`ArbitrationError`*. (Bug #31690)
- The `NDB` storage engine code was not safe for strict-alias optimization in `gcc` 4.2.1. (Bug #31761)
- An error with an `if` statement in `sql/ha_ndbcluster.cc` could potentially lead to an infinite loop in case of failure when working with `AUTO_INCREMENT` columns in `NDB` tables. (Bug #31810)
- An insert or update with combined range and equality constraints failed when run against an `NDB` table with the error `Got unknown error from NDB`. An example of such a statement would be `UPDATE t1 SET b = 5 WHERE a IN (7,8) OR a >= 10;`. (Bug #31874)
- Performing `DELETE` operations after a data node had been shut down could lead to inconsistent data following a restart of the node. (Bug #26450)
- `UPDATE IGNORE` could sometimes fail on `NDB` tables due to the use of unitialized data when checking for duplicate keys to be ignored. (Bug #25817)
- **Cluster Replication**: **Replication**: A node failure during replication could lead to buckets out of order; now active subscribers are checked for, rather than empty buckets. (Bug #31701)

- **Cluster Replication**: When the master `mysqld` crashed or was restarted, no `LOST_EVENTS` entry was made in the binlog. (Bug #31484)

  References: See also Bug #21494.

Changes in MySQL Cluster NDB 6.2.7 (5.1.22-ndb-6.2.7) (2007-10-10)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from http://dev.mysql.com/downloads/cluster/.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see Changes in MySQL 5.1.22 (2007-09-24, Release Candidate)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Cluster Replication**: A new configuration parameter `TimeBetweenEpochsTimeout` [1840] enables a timeout to be set for time between epochs. (Bug #31276)
- Additional checks were implemented to catch unsupported online `ALTER TABLE` operations. Currently it is not possible to reorder columns or to change the storage engine used for a table using online `ALTER TABLE`.

  Some redundant checks made during online creation of indexes were removed.

Bugs Fixed

- It was possible in some cases for a node group to be “lost” due to missed local checkpoints following a system restart. (Bug #31525)
- A node failure during a local checkpoint could lead to a subsequent failure of the cluster during a system restart. (Bug #31257)
- `ndb_mgm --help` did not display any information about the `-a` option. (Bug #29509)
- `NDB` tables having names containing nonalphanumeric characters (such as “`$`”) were not discovered correctly. (Bug #31470)
- A cluster restart could sometimes fail due to an issue with table IDs. (Bug #30975)
- Transaction timeouts were not handled well in some circumstances, leading to excessive number of transactions being aborted unnecessarily. (Bug #30379)
- In some cases, the cluster managment server logged entries multiple times following a restart of `ndb_mgmd`. (Bug #29565)
- The cluster log was formatted inconsistently and contained extraneous newline characters. (Bug #25064)
- The `mysqld_safe` script contained a syntax error. (Bug #30624)
- Online `ALTER` operations involving a column whose data type has an implicit default value left behind temporary `.frm` files, causing subsequent `DROP DATABASE` statements to fail. (Bug #31097)
- Transactions were committed prematurely when `LOCK TABLE` and `SET autocommit = 0` were used together. (Bug #30996)

Changes in MySQL Cluster NDB 6.2.6 (5.1.22-ndb-6.2.6) (2007-09-20)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from http://dev.mysql.com/downloads/cluster/.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see Changes in MySQL 5.1.22 (2007-09-24, Release Candidate)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- Mapping of `NDB` error codes to MySQL storage engine error codes has been improved. (Bug #28423)

Bugs Fixed

- **Partitioning**: `EXPLAIN PARTITIONS` reported partition usage by queries on `NDB` tables according to the standard MySQL hash function than the hash function used in the `NDB` storage engine. (Bug #29550)
- When an `NDB` event was left behind but the corresponding table was later recreated and received a new table ID, the event could not be dropped. (Bug #30877)
- Attempting to restore a backup made on a cluster host using one endian to a machine using the other endian could cause the cluster to fail. (Bug #29674)
- Restoring a backup made on a cluster host using one endian to a machine using the other endian failed for `BLOB` and `DATETIME` columns. (Bug #27543, Bug #30024)
- The description of the `--print` option provided in the output from `ndb_restore --help` was incorrect. (Bug #27683)
- An insufficiently descriptive and potentially misleading Error 4006 (`Connect failure - out of connection objects...`) was produced when either of the following two conditions occurred:

  1. There were no more transaction records in the transaction coordinator
  2. An `NDB` object in the NDB API was initialized with insufficient parallelism

  Separate error messages are now generated for each of these two cases. (Bug #11313)
- For micro-GCPs, the assignment of “fake” CGI events no longer cause buckets to be sent out of order. Now, when assigning a GCI to a non-GCI event (that is, creating a pseudo-GCI or “fake” CGI), the GCI that is to arrive is always initiated, even if no known GCI exists, which could occur in the event of a node failure. (Bug #30884)

Changes in MySQL Cluster NDB 6.2.5 (5.1.22-ndb-6.2.5) (2007-09-06, General Availability)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from http://dev.mysql.com/downloads/cluster/.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see Changes in MySQL 5.1.22 (2007-09-24, Release Candidate)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- The following improvements have been made in the `ndb_size.pl` utility:
  - The script can now be used with multiple databases; lists of databases and tables can also be excluded from analysis.
  - Schema name information has been added to index table calculations.
  - The database name is now an optional parameter, the exclusion of which causes all databases to be examined.
  - If selecting from `INFORMATION_SCHEMA` fails, the script now attempts to fall back to `SHOW TABLES`.
  - A `--real_table_name` option has been added; this designates a table to handle unique index size calculations.
  - The report title has been amended to cover cases where more than one database is being analyzed.

  Support for a `--socket` option was also added.

  For more information, see `ndb_size.pl` — NDBCLUSTER Size Requirement Estimator. (Bug #28683, Bug #28253)
- A new cluster management server startup option `--bind-address` [1962] makes it possible to restrict management client connections to `ndb_mgmd` to a single host and port. For more information, see `ndb_mgmd` — The MySQL Cluster Management Server Daemon.
- It is now possible to control whether fixed-width or variable-width storage is used for a given column of an `NDB` table by means of the `COLUMN_FORMAT` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

  It is also possible to control whether a given column of an `NDB` table is stored in memory or on disk, using the `STORAGE` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

  For permitted values and other information about `COLUMN_FORMAT` and `STORAGE`, see `CREATE TABLE` Syntax.
- Online `ADD COLUMN`, `ADD INDEX`, and `DROP INDEX` operations can now be performed explicitly for `NDB` tables—that is, without copying or locking of the affected tables—using `ALTER ONLINE TABLE`. Indexes can also be created and dropped online using `CREATE INDEX` and `DROP INDEX`, respectively, using the `ONLINE` keyword.

  You can force operations that would otherwise be performed online to be done offline using the `OFFLINE` keyword.

  Renaming of tables and columns for `NDB` and `MyISAM` tables is performed in place without table copying.

  For more information, see `ALTER TABLE` Online Operations, `CREATE INDEX` Syntax, and `DROP INDEX` Syntax.
- **Cluster Replication**: The protocol for handling global checkpoints has been changed. It is now possible to control how often the GCI number is updated, and how often global checkpoints are

written to disk, using the TimeBetweenEpochs [1840] configuration parameter. This improves the reliability and performance of MySQL Cluster Replication.

GCPs handled using the new protocol are sometimes referred to as “micro-GCPs”.

Bugs Fixed

- Reads on BLOB columns were not locked when they needed to be to guarantee consistency. (Bug #29102)

  References: See also Bug #31482.

- Using the --ndb-cluster-connection-pool option for mysqld caused DDL statements to be executed twice. (Bug #30598)

- A query using joins between several large tables and requiring unique index lookups failed to complete, eventually returning Unknown Error after a very long period of time. This occurred due to inadequate handling of instances where the Transaction Coordinator ran out of TransactionBufferMemory [1823], when the cluster should have returned NDB error code 4012 (Request ndbd time-out). (Bug #28804)

- When handling BLOB columns, the addition of read locks to the lock queue was not handled correctly. (Bug #30764)

- Discovery of NDB tables did not work correctly with INFORMATION_SCHEMA. (Bug #30667)

- A file system close operation could fail during a node or system restart. (Bug #30646)

- ndb_size.pl failed on tables with FLOAT columns whose definitions included commas (for example, FLOAT(6,2)). (Bug #29228)

- When creating an NDB table with a column that has COLUMN_FORMAT = DYNAMIC, but the table itself uses ROW_FORMAT=FIXED, the table is considered dynamic, but any columns for which the row format is unspecified default to FIXED. Now in such cases the server issues the warning Row format FIXED incompatible with dynamic attribute *column_name*. (Bug #30276)

- An attempt to perform a SELECT ... FROM INFORMATION_SCHEMA.TABLES whose result included information about NDB tables for which the user had no privileges crashed the MySQL Server on which the query was performed. (Bug #26793)

- **Cluster Replication**: An issue with the mysql.ndb_apply_status table could cause NDB schema autodiscovery to fail in certain rare circumstances. (Bug #20872)

- **Cluster Replication**: Cluster replication did not handle large VARCHAR columns correctly. (Bug #29904)

- **Cluster API**: A call to CHECK_TIMEDOUT_RET() in mgmapi.cpp should have been a call to DBUG_CHECK_TIMEDOUT_RET(). (Bug #30681)

Changes in MySQL Cluster NDB 6.2.4 (5.1.19-ndb-6.2.4) (2007-07-04)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from http://dev.mysql.com/downloads/cluster/.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.19 (see Changes in MySQL 5.1.19 (2007-05-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- Replica redo logs were inconsistently handled during a system restart. (Bug #29354)
- When restarting a data node, queries could hang during that node's start phase 5, and continue only after the node had entered phase 6. (Bug #29364)
- **Disk Data**: Disk data meta-information that existed in `ndbd` might not be visible to `mysqld`. (Bug #28720)
- **Disk Data**: Performing Disk Data schema operations during a node restart could cause forced shutdowns of other data nodes. (Bug #29501)
- **Disk Data**: The number of free extents was incorrectly reported for some tablespaces. (Bug #28642)
- Batching of transactions was not handled correctly in some cases. (Bug #29525)

Changes in MySQL Cluster NDB 6.2.3 (5.1.19-ndb-6.2.3) (2007-07-02)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from http://dev.mysql.com/downloads/cluster/.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.18 (see Changes in MySQL 5.1.18 (2007-05-08)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- Replica redo logs were inconsistently handled during a system restart. (Bug #29354)
- When restarting a data node, queries could hang during that node's start phase 5, and continue only after the node had entered phase 6. (Bug #29364)
- **Disk Data**: Disk data meta-information that existed in `ndbd` might not be visible to `mysqld`. (Bug #28720)
- **Disk Data**: Performing Disk Data schema operations during a node restart could cause forced shutdowns of other data nodes. (Bug #29501)
- **Disk Data**: The number of free extents was incorrectly reported for some tablespaces. (Bug #28642)
- Batching of transactions was not handled correctly in some cases. (Bug #29525)

Changes in MySQL Cluster NDB 6.2.2 (5.1.18-ndb-6.2.2) (2007-05-07)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from http://dev.mysql.com/downloads/cluster/.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.18 (see Changes in MySQL 5.1.18 (2007-05-08)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- Added the `mysqld` option `--ndb-cluster-connection-pool` that enables a single MySQL server to use multiple connections to the cluster. This enables scaling out using multiple MySQL clients per SQL node instead of or in addition to using multiple SQL nodes with the cluster.

  For more information about this option, see MySQL Server Options and Variables for MySQL Cluster.

- New cluster management client `DUMP` commands were added to aid in tracking transactions, scan operations, and locks. See `DUMP 2350`, `DUMP 2352`, and `DUMP 2550`, for more information.

Changes in MySQL Cluster NDB 6.2.1 (5.1.18-ndb-6.2.1) (2007-04-30)

This is a Beta development release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from http://dev.mysql.com/downloads/cluster/.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.2 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.18 (see Changes in MySQL 5.1.18 (2007-05-08)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- Multiple operations involving deletes followed by reads were not handled correctly.

  Note

  This issue could also affect MySQL Cluster Replication.

  (Bug #28276)

- **Cluster API**: Using `NdbBlob::writeData()` to write data in the middle of an existing blob value (that is, updating the value) could overwrite some data past the end of the data to be changed. (Bug #27018)

- Incorrect handling of fragmentation in a node takeover during a restart could cause stale data to be copied to the starting node, leading eventually to failure of the node. (Bug #27434)

- An incorrect assertion was made when sending a `TCKEYFAILREF` or `TCKEYCONF` message to a failed data node. (Bug #26814)

Changes in MySQL Cluster NDB 6.2.0 (5.1.16-ndb-6.2.0) (2007-03-03, Beta)

This is the first MySQL Cluster NDB 6.2 development release, based on version 6.2 of the `NDBCLUSTER` storage engine.

Obtaining MySQL Cluster NDB 6.2. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from http://dev.mysql.com/downloads/cluster/.

This Beta release incorporates bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.16 (see Changes in MySQL 5.1.16 (2007-02-26)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- An `--ndb-wait-connected` [1919] option has been added for `mysqld`. When used, it causes `mysqld` wait a specified amount of time to be connected to the cluster before accepting client connections.
- **Cluster API**: It is now possible to iterate over all existing `NDB` objects using three new methods of the `Ndb_cluster_connection` class:
  - `lock_ndb_objects()`
  - `get_next_ndb_object()`
  - `unlock_ndb_objects()`
- **Cluster API**: The `Ndb::startTransaction()` method now provides an alternative interface for starting a transaction.
- Memory allocation has been improved on 32-bit architectures that enables using close to 3GB for `DataMemory` [1817] and `IndexMemory` [1819] combined.
- A new `TcpBind_INADDR_ANY` configuration parameter enables data nodes node to bind `INADDR_ANY` instead of a host name or IP address in the `config.ini` file.
- It is now possible to disable arbitration by setting `ArbitrationRank` equal to `0` on all nodes.

Changes in MySQL Cluster NDB 6.1

This section contains change history information for MySQL Cluster releases based on version 6.1 of the `NDBCLUSTER` storage engine.

For an overview of features that were added added in MySQL Cluster NDB 6.1, see MySQL Cluster Development in MySQL Cluster NDB 6.1.

Note

MySQL Cluster NDB 6.1 is no longer being developed or maintained, and the information presented in the next few sections should be considered to be of historical interest only. If you are using MySQL Cluster NDB 6.1, you should upgrade as soon as possible to the most recent version of MySQL Cluster NDB 6.2 or later MySQL Cluster release series.

Changes in MySQL Cluster NDB 6.1.23 (5.1.15-ndb-6.1.23) (2007-11-20)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Changes in MySQL 5.1.15 (2007-01-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- The `NDB` storage engine code was not safe for strict-alias optimization in `gcc` 4.2.1. (Bug #31761)
- **Cluster Replication**: Under certain conditions, the slave stopped processing relay logs. This resulted in the logs never being cleared and the slave eventually running out of disk space. (Bug #31958)

Changes in MySQL Cluster NDB 6.1.22 (5.1.15-ndb-6.1.22) (2007-10-19)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as "MySQL Cluster Carrier Grade Edition 6.1.x") is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Changes in MySQL 5.1.15 (2007-01-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- It was possible in some cases for a node group to be "lost" due to missed local checkpoints following a system restart. (Bug #31525)
- **Cluster Replication**: **Replication**: A node failure during replication could lead to buckets out of order; now active subscribers are checked for, rather than empty buckets. (Bug #31701)

Changes in MySQL Cluster NDB 6.1.21 (5.1.15-ndb-6.1.21) (2007-10-01)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as "MySQL Cluster Carrier Grade Edition 6.1.x") is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Changes in MySQL 5.1.15 (2007-01-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- A node failure during a local checkpoint could lead to a subsequent failure of the cluster during a system restart. (Bug #31257)
- A cluster restart could sometimes fail due to an issue with table IDs. (Bug #30975)

Changes in MySQL Cluster NDB 6.1.20 (5.1.15-ndb-6.1.20) (2007-09-14)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as "MySQL Cluster Carrier Grade Edition 6.1.x") is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Changes in MySQL 5.1.15 (2007-01-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- **Cluster Replication**: **Replication**: Incorrect handling of `INSERT` plus `DELETE` operations with regard to local checkpoints caused data node failures in multi-master replication setups. (Bug #30914)

Changes in MySQL Cluster NDB 6.1.19 (5.1.15-ndb-6.1.19) (2007-08-01)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as "MySQL Cluster Carrier Grade Edition 6.1.x") is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Changes in MySQL 5.1.15 (2007-01-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- Whenever a TCP send buffer is over 80% full, temporary error 1218 (`Send Buffers overloaded in NDB kernel`) is now returned. See SendBufferMemory [1870] for more information.
- An `INFO` event is now sent if the time between global checkpoints is excessive, or if `DUMP 7901` is issued in the management client.

Changes in MySQL Cluster NDB 6.1.18 (5.1.15-ndb-6.1.18) (Not released)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as "MySQL Cluster Carrier Grade Edition 6.1.x") is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Changes in MySQL 5.1.15 (2007-01-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- When restarting a data node, queries could hang during that node's start phase 5, and continue only after the node had entered phase 6. (Bug #29364)
- **Replication**: Storage engine error conditions in row-based replication were not correctly reported to the user. (Bug #29570)
- **Disk Data**: Disk data meta-information that existed in `ndbd` might not be visible to `mysqld`. (Bug #28720)
- **Disk Data**: The number of free extents was incorrectly reported for some tablespaces. (Bug #28642)

Changes in MySQL Cluster NDB 6.1.17 (5.1.15-ndb-6.1.17) (2007-07-03)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as "MySQL Cluster Carrier Grade Edition 6.1.x") is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Changes in MySQL 5.1.15 (2007-01-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Cluster Replication**: **Replication**: Batching of updates on cluster replication slaves, enabled using the `--slave-allow-batching` [1930] option for `mysqld`.

Bugs Fixed

- Replica redo logs were inconsistently handled during a system restart. (Bug #29354)

Changes in MySQL Cluster NDB 6.1.16 (5.1.15-ndb-6.1.16) (2007-06-29)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as "MySQL Cluster Carrier Grade Edition 6.1.x") is no longer being developed or maintained; if you are

using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Changes in MySQL 5.1.15 (2007-01-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- The wrong data pages were sometimes invalidated following a global checkpoint. (Bug #29067)
- An invalid comparison made during `REDO` validation that could lead to an `Error while reading REDO log` condition. (Bug #29118)
- If at least 2 files were involved in `REDO` invalidation, then file 0 of page 0 was not updated and so pointed to an invalid part of the redo log. (Bug #29057)
- When a node failed to respond to a `COPY_GCI` signal as part of a global checkpoint, the master node was killed instead of the node that actually failed. (Bug #29331)
- **Disk Data**: When dropping a page, the stack's bottom entry could sometime be left “cold” rather than “hot”, violating the rules for stack pruning. (Bug #29176)

Changes in MySQL Cluster NDB 6.1.15 (5.1.15-ndb-6.1.15) (2007-06-20)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Changes in MySQL 5.1.15 (2007-01-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- Memory corruption could occur due to a problem in the `DBTUP` kernel block. (Bug #29229)

Changes in MySQL Cluster NDB 6.1.14 (5.1.15-ndb-6.1.14) (2007-06-19)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Changes in MySQL 5.1.15 (2007-01-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- In the event that two data nodes in the same node group and participating in a GCP crashed before they had written their respective `P0.sysfile` files, `QMGR` could refuse to start, issuing an invalid `Insufficient nodes for restart` error instead. (Bug #29167)

Changes in MySQL Cluster NDB 6.1.13 (5.1.15-ndb-6.1.13) (2007-06-15)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as "MySQL Cluster Carrier Grade Edition 6.1.x") is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Changes in MySQL 5.1.15 (2007-01-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- Read ahead was implemented for backups of Disk Data tables, resulting in a 10 to 15% increase in backup speed of Disk Data tables. (Bug #29099)

Bugs Fixed

- **Cluster API**: `NdbApi.hpp` depended on `ndb_global.h`, which was not actually installed, causing the compilation of programs that used `NdbApi.hpp` to fail. (Bug #35853)

Changes in MySQL Cluster NDB 6.1.12 (5.1.15-ndb-6.1.12) (2007-06-13)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as "MySQL Cluster Carrier Grade Edition 6.1.x") is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Changes in MySQL 5.1.15 (2007-01-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- New cluster management client `DUMP` commands were added to aid in tracking transactions, scan operations, and locks. See `DUMP 2350`, `DUMP 2352`, and `DUMP 2550`.
- Backup dump output was extended to provide more information.

Bugs Fixed

- It is now possible to set the maximum size of the allocation unit for table memory using the `MaxAllocate` [1825] configuration parameter. (Bug #29044)

Changes in MySQL Cluster NDB 6.1.11 (5.1.15-ndb-6.1.11) (2007-06-06)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as "MySQL Cluster Carrier Grade Edition 6.1.x") is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Changes in MySQL 5.1.15 (2007-01-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Important Change**: The `TimeBetweenWatchdogCheckInitial` [1835] configuration parameter was added to enable setting of a separate watchdog timeout for memory allocation during startup of the data nodes. (Bug #28899)
- A new configuration parameter `ODirect` [1833] causes `NDB` to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering CPU usage.
- It is now possible to set the size of redo log files (fragment log files) using the `FragmentLogFileSize` [1826] configuration parameter.

Bugs Fixed

- Having large amounts of memory locked caused swapping to disk. (Bug #28751)
- LCP files were not removed following an initial system restart. (Bug #28726)
- **Disk Data**: Repeated `INSERT` and `DELETE` operations on a Disk Data table having one or more large `VARCHAR` columns could cause data nodes to fail. (Bug #20612)

Changes in MySQL Cluster NDB 6.1.10 (5.1.15-ndb-6.1.10) (2007-05-30)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as "MySQL Cluster Carrier Grade Edition 6.1.x") is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Changes in MySQL 5.1.15 (2007-01-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- Some unneeded printouts in the `ndbd` out file were removed.
- A new `times` printout was added in the `ndbd` watchdog thread.
- The names of some log and other files were changed to avoid issues with the `tar` command's 99-character file name limit.

Bugs Fixed

- Setting `InitialNoOfOpenFiles` [1827] equal to `MaxNoOfOpenFiles` [1827] caused an error. This was due to the fact that the actual value of `MaxNoOfOpenFiles` [1827] as used by the cluster was offset by 1 from the value set in `config.ini`. (Bug #28749)
- A corrupt schema file could cause a `File already open` error. (Bug #28770)
- A regression in the heartbeat monitoring code could lead to node failure under high load. This issue affected MySQL 5.1.19 and MySQL Cluster NDB 6.1.10 only. (Bug #28783)
- A race condition could result when nonmaster nodes (in addition to the master node) tried to update active status due to a local checkpoint (that is, between `NODE_FAILREP` and `COPY_GCIREQ` events). Now only the master updates the active status. (Bug #28717)
- A fast global checkpoint under high load with high usage of the redo buffer caused data nodes to fail. (Bug #28653)
- **Disk Data**: When loading data into a cluster following a version upgrade, the data nodes could forcibly shut down due to page and buffer management failures (that is, `ndbrequire` failures in `PGMAN`). (Bug #28525)

Changes in MySQL Cluster NDB 6.1.9 (5.1.15-ndb-6.1.9) (2007-05-24)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Changes in MySQL 5.1.15 (2007-01-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- When an API node sent more than 1024 signals in a single batch, `NDB` would process only the first 1024 of these, and then hang. (Bug #28443)

- **Disk Data**: The cluster backup process scanned in `ACC` index order, which had bad effects for disk data. (Bug #28593)

Changes in MySQL Cluster NDB 6.1.8 (5.1.15-ndb-6.1.8) (2007-05-05)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as "MySQL Cluster Carrier Grade Edition 6.1.x") is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Changes in MySQL 5.1.15 (2007-01-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- Local checkpoint files relating to dropped `NDB` tables were not removed. (Bug #28348)
- Repeated insertion of data generated by `mysqldump` into `NDB` tables could eventually lead to failure of the cluster. (Bug #27437)
- **Disk Data**: Extremely large inserts into Disk Data tables could lead to data node failure in some circumstances. (Bug #27942)
- **Cluster API**: In a multi-operation transaction, a delete operation followed by the insertion of an implicit `NULL` failed to overwrite an existing value. (Bug #20535)
- Setting `MaxNoOfTables` [1829] very low and relative to `DataMemory` [1817] caused `Out of memory in Ndb Kernel` errors when inserting relatively small amounts of data into NDB tables. (Bug #24173)

Changes in MySQL Cluster NDB 6.1.7 (5.1.15-ndb-6.1.7) (2007-05-05)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as "MySQL Cluster Carrier Grade Edition 6.1.x") is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Changes in MySQL 5.1.15 (2007-01-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Cluster Replication**: **Incompatible Change**: The schema for the `ndb_apply_status` table in the `mysql` system database has changed. When upgrading to this release from a previous MySQL

Cluster NDB 6.x or mainline MySQL 5.1 release, you must drop the `mysql.ndb_apply_status` table, then restart the server for the table to be re-created with the new schema.

See MySQL Cluster Replication Schema and Tables, for additional information.

Bugs Fixed

- An `INSERT` followed by a delete `DELETE` on the same `NDB` table caused a memory leak. (Bug #27756)

  References: This bug was introduced by Bug #20612.

- The cluster waited 30 seconds instead of 30 milliseconds before reading table statistics. (Bug #28093)

- Under some circumstances, a node restart could fail to update the Global Checkpoint Index (GCI). (Bug #28023)

- Under certain rare circumstances, `ndbd` could get caught in an infinite loop when one transaction took a read lock and then a second transaction attempted to obtain a write lock on the same tuple in the lock queue. (Bug #28073)

- Under certain rare circumstances performing a `DROP TABLE` or `TRUNCATE TABLE` on an `NDB` table could cause a node failure or forced cluster shutdown. (Bug #27581)

- Memory usage of a `mysqld` process grew even while idle. (Bug #27560)

- Performing a delete followed by an insert during a local checkpoint could cause a `Rowid already allocated` error. (Bug #27205)

- **Cluster Replication**: **Disk Data**: An issue with replication of Disk Data tables could in some cases lead to node failure. (Bug #28161)

- **Disk Data**: When restarting a data node following the creation of a large number of Disk Data objects (approximately 200 such objects), the cluster could not assign a node ID to the restarting node. (Bug #25741)

- **Disk Data**: Changing a column specification or issuing a `TRUNCATE TABLE` statement on a Disk Data table caused the table to become an in-memory table.

  This fix supersedes an incomplete fix that was made for this issue in MySQL 5.1.15. (Bug #24667, Bug #25296)

- **Disk Data**: Changes to a Disk Data table made as part of a transaction could not be seen by the client performing the changes until the transaction had been committed. (Bug #27757)

- **Cluster Replication**: Some queries that updated multiple tables were not backed up correctly. (Bug #27748)

- **Cluster Replication**: Under very high loads, checkpoints could be read or written with checkpoint indexes out of order. (Bug #27651)

- **Cluster Replication**: It was possible for API nodes to begin interacting with the cluster subscription manager before they were fully connected to the cluster. (Bug #27728)

- **Cluster API**: An issue with the way in which the `Dictionary::listEvents()` method freed resources could sometimes lead to memory corruption. (Bug #27663)

- `mysqldump` could not dump log tables. (Bug #26121)

- The `--with-readline` option for `configure` did not work for commercial source packages, but no error message was printed to that effect. Now a message is printed. (Bug #25530)

Changes in MySQL Cluster NDB 6.1.6 (5.1.15-ndb-6.1.6) (Not released)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as "MySQL Cluster Carrier Grade Edition 6.1.x") is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Changes in MySQL 5.1.15 (2007-01-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Cluster Replication**: **Incompatible Change**: The schema for the `ndb_apply_status` table in the `mysql` system database has changed. When upgrading to this release from a previous MySQL Cluster NDB 6.x or mainline MySQL 5.1 release, you must drop the `mysql.ndb_apply_status` table, then restart the server for the table to be re-created with the new schema.

  See MySQL Cluster Replication Schema and Tables, for additional information.

Bugs Fixed

- A data node failing while another data node was restarting could leave the cluster in an inconsistent state. In certain rare cases, this could lead to a race condition and the eventual forced shutdown of the cluster. (Bug #27466)
- `mysqld` processes would sometimes crash under high load.

  Note

  This fix improves on and replaces a fix for this bug that was made in MySQL Cluster NDB 6.1.5.

  (Bug #26825)
- When a data node was taking over as the master node, a race condition could sometimes occur as the node was assuming responsibility for handling of global checkpoints. (Bug #27283)
- It was not possible to set `LockPagesInMainMemory` [1832] equal to `0`. (Bug #27291)
- A race condition could sometimes occur if the node acting as master failed while node IDs were still being allocated during startup. (Bug #27286)
- `mysqld` could crash shortly after a data node failure following certain DML operations. (Bug #27169)
- The same failed request from an API node could be handled by the cluster multiple times, resulting in reduced performance. (Bug #27087)
- The failure of a data node while restarting could cause other data nodes to hang or crash. (Bug #27003)
- **Disk Data**: `DROP INDEX` on a Disk Data table did not always move data from memory into the tablespace. (Bug #25877)
- **Cluster Replication**: Trying to replicate a large number of frequent updates with a relatively small relay log (`max-relay-log-size` set to 1M or less) could cause the slave to crash. (Bug #27529)

- **Cluster API**: An issue with the way in which the `Dictionary::listEvents()` method freed resources could sometimes lead to memory corruption. (Bug #27663)
- **Cluster API**: A delete operation using a scan followed by an insert using a scan could cause a data node to fail. (Bug #27203)

Changes in MySQL Cluster NDB 6.1.5 (5.1.15-ndb-6.1.5) (2007-03-15)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as "MySQL Cluster Carrier Grade Edition 6.1.x") is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Changes in MySQL 5.1.15 (2007-01-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- **Cluster Replication**: **Incompatible Change**: The schema for the `ndb_apply_status` table in the `mysql` system database has changed. When upgrading to this release from a previous MySQL Cluster NDB 6.x or mainline MySQL 5.1 release, you must drop the `mysql.ndb_apply_status` table, then restart the server for the table to be re-created with the new schema.

  See MySQL Cluster Replication Schema and Tables, for additional information.

Bugs Fixed

- An infinite loop in an internal logging function could cause trace logs to fill up with `Unknown Signal type` error messages and thus grow to unreasonable sizes. (Bug #26720)
- `mysqld` processes would sometimes crash under high load.

  Note

  This fix was reverted in MySQL Cluster NDB 6.1.6.

  (Bug #26825)
- Creating a table on one SQL node while in single user mode caused other SQL nodes to crash. (Bug #26997)
- **Disk Data**: When creating a log file group, setting `INITIAL_SIZE` to less than `UNDO_BUFFER_SIZE` caused data nodes to crash. (Bug #25743)

Changes in MySQL Cluster NDB 6.1.4 (5.1.15-ndb-6.1.4) (2007-03-09)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as "MySQL Cluster Carrier Grade Edition 6.1.x") is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Changes in MySQL 5.1.15 (2007-01-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- An `--ndb-wait-connected` [1919] option has been added for `mysqld`. When used, it causes `mysqld` wait a specified amount of time to be connected to the cluster before accepting client connections.
- **Cluster API**: It is now possible to iterate over all existing `NDB` objects using three new methods of the `Ndb_cluster_connection` class:
  - `lock_ndb_objects()`
  - `get_next_ndb_object()`
  - `unlock_ndb_objects()`
- **Cluster API**: It is now possible to specify the transaction coordinator when starting a transaction. See `Ndb::startTransaction()`, for more information.
- Data node memory allocation has been improved. On 32-bit platforms, it should now be possible to use close to 3GB RAM for `IndexMemory` [1819] and `DataMemory` [1817] combined.

Bugs Fixed

- An inadvertent use of unaligned data caused `ndb_restore` to fail on some 64-bit platforms, including Sparc and Itanium-2. (Bug #26739)
- Using only the `--print_data` [1997] option (and no other options) with `ndb_restore` caused `ndb_restore` to fail. (Bug #26741)

  References: This bug was introduced by Bug #14612.
- Assigning a node ID greater than 63 to an SQL node caused an out of bounds error in `mysqld`. It should now be possible to assign to SQL nodes node IDs up to 255. (Bug #26663)

Changes in MySQL Cluster NDB 6.1.3 (5.1.15-ndb-6.1.3) (2007-02-25)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Changes in MySQL 5.1.15 (2007-01-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- The `ndb_show_tables` utility now displays information about table events. See `ndb_show_tables` — Display List of NDB Tables, for more information.
- The `ndbd_redo_log_reader` utility is now part of the default build. For more information, see `ndbd_redo_log_reader` — Check and Print Content of Cluster Redo Log.
- **Cluster API**: A new `listEvents()` method has been added to the `Dictionary` class.
- It is now possible to disable arbitration by setting `ArbitrationRank = 0` on all management and SQL nodes.

Bugs Fixed

- An invalid pointer was returned following a `FSCLOSECONF` signal when accessing the REDO logs during a node restart or system restart. (Bug #26515)
- No appropriate error message was provided when there was insufficient REDO log file space for the cluster to start. (Bug #25801)
- The message `Error 0 in readAutoIncrementValue(): no Error` was written to the error log whenever `SHOW TABLE STATUS` was performed on a Cluster table that did not have an `AUTO_INCREMENT` column.

  Note

  This improves on and supersedes an earlier fix that was made for this issue in MySQL 5.1.12.

  (Bug #21033)
- The **`InvalidUndoBufferSize`** error used the same error code (`763`) as the **`IncompatibleVersions`** error. **`InvalidUndoBufferSize`** now uses its own error code (`779`). (Bug #26490)
- Under some circumstances, following the restart of a management node, all data nodes would connect to it normally, but some of them subsequently failed to log any events to the management node. (Bug #26293)
- The `LockPagesInMainMemory` [1832] parameter was not read until after distributed communication had already started between cluster nodes. When the value of this parameter was `1`, this could sometimes result in data node failure due to missed heartbeats. (Bug #26454)
- Takeover for local checkpointing due to multiple failures of master nodes was sometimes incorrectly handled. (Bug #26457)
- The failure of a data node when restarting it with `--initial` could lead to failures of subsequent data node restarts. (Bug #26481)
- A memory allocation failure in `SUMA` (the cluster Subscription Manager) could cause the cluster to crash. (Bug #25239)
- **Disk Data**: Use of a tablespace whose `INITIAL_SIZE` was greater than 1 GB could cause the cluster to crash. (Bug #26487)
- **Disk Data**: A memory overflow could occur with tables having a large amount of data stored on disk, or with queries using a very high degree of parallelism on Disk Data tables. (Bug #26514)

Changes in MySQL Cluster NDB 6.1.2 (5.1.15-ndb-6.1.2) (2007-02-07)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as "MySQL Cluster Carrier Grade Edition 6.1.x") is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Changes in MySQL 5.1.15 (2007-01-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Bugs Fixed

- Using node IDs greater than 48 could sometimes lead to incorrect memory access and a subsequent forced shutdown of the cluster. (Bug #26267)

Changes in MySQL Cluster NDB 6.1.1 (5.1.15-ndb-6.1.1) (2007-02-01)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as "MySQL Cluster Carrier Grade Edition 6.1.x") is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.1 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Changes in MySQL 5.1.15 (2007-01-25)).

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- A single cluster can now support up to 255 API nodes, including MySQL servers acting as SQL nodes. See Issues Exclusive to MySQL Cluster, for more information.

Bugs Fixed

- A memory leak could cause problems during a node or cluster shutdown or failure. (Bug #25997)
- **Cluster API**: **Disk Data**: A delete and a read performed in the same operation could cause one or more data nodes to crash. This could occur when the operation affected more than 5 columns concurrently, or when one or more of the columns was of the `VARCHAR` type and was stored on disk. (Bug #25794)
- An element could sometimes be inserted twice into the hash table, causing a data node to crash. (Bug #25286)

Changes in MySQL Cluster NDB 6.1.0 (5.1.14-ndb-6.1.0) (2006-12-20)

This is the first MySQL Cluster NDB 6.1 release, incorporating new features and bugfixes made for the `NDBCLUSTER` storage engine made since branching from MySQL 5.1.14 standard (see Changes in MySQL 5.1.14 (2006-12-05)).

MySQL Cluster NDB 6.1 no longer in development. MySQL Cluster NDB 6.1 (formerly known as "MySQL Cluster Carrier Grade Edition 6.1.x") is no longer being developed or maintained; if you are

using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

Note

Please refer to our bug database at http://bugs.mysql.com/ for more details about the individual bugs fixed in this version.

Functionality Added or Changed

- A new configuration parameter `MemReportFrequency` [1849] enables additional control of data node memory usage. Previously, only warnings at predetermined percentages of memory allocation were given; setting this parameter enables that behavior to be overridden.

Bugs Fixed

- When a data node was shut down using the management client `STOP` command, a connection event (`NDB_LE_Connected`) was logged instead of a disconnection event (`NDB_LE_Disconnected`). (Bug #22773)
- `SELECT` statements with a `BLOB` or `TEXT` column in the selected column list and a `WHERE` condition including a primary key lookup on a `VARCHAR` primary key produced empty result sets. (Bug #19956)
- **Disk Data**: `MEDIUMTEXT` columns of Disk Data tables were stored in memory rather than on disk, even if the columns were not indexed. (Bug #25001)
- **Disk Data**: When restoring from backup a cluster containing any Disk Data tables with hidden primary keys, a node failure resulted which could lead to a crash of the cluster. (Bug #24166)
- **Disk Data**: Repeated `CREATE`, `DROP`, or `TRUNCATE TABLE` in various combinations with system restarts between these operations could lead to the eventual failure of a system restart. (Bug #21948)
- **Disk Data**: Performing a node restart with a newly dropped Disk Data table could lead to failure of the node during the restart. (Bug #24917)
- **Disk Data**: Extents that should have been available for re-use following a `DROP TABLE` operation were not actually made available again until after the cluster had performed a local checkpoint. (Bug #17605)
- **Cluster API**: A unique index lookup on a nonexistent tuple could lead to a data node timeout (error 4012). (Bug #25059)
- **Cluster API**: Invoking the `NdbTransaction::execute()` method using execution type `Commit` and abort option `AO_IgnoreError` could lead to a crash of the transaction coordinator (`DBTC`). (Bug #25090)
- **Cluster API**: When using the `NdbTransaction::execute()` method, a very long timeout (greater than 5 minutes) could result if the last data node being polled was disconnected from the cluster. (Bug #24949)
- **Cluster API**: Due to an error in the computation of table fragment arrays, some transactions were not executed from the correct starting point. (Bug #24914)
- Under certain rare circumstances, local checkpoints were not performed properly, leading to an inability to restart one or more data nodes. (Bug #24664)

Release Series Changelogs: MySQL Cluster NDB 6.X and 7.X

This section contains unified changelog information for each MySQL Cluster release series (NDB 6.1, NDB 6.2, NDB 6.3, and NDB 7.0).

For changelogs covering individual MySQL Cluster NDB 6.X and MySQL Cluster NDB 7.X releases, see Changes in MySQL Cluster NDB 6.1 - 7.1.

For general information about features added in MySQL Cluster NDB 6.X and 7.X, see MySQL Cluster Development History.

An overview of features added in MySQL 5.1 not specific to MySQL Cluster can be found here: What Is New in MySQL 5.1. For a complete list of all bugfixes and features changes made in MySQL 5.1 that are not specific to MySQL Cluster, see Changes in Release 5.1.x (Production).

Changes in the MySQL Cluster NDB 7.1 Series

This section contains unified change history highlights for all MySQL Cluster releases based on version 7.1 of the `NDBCLUSTER` storage engine through MySQL Cluster NDB 7.1.25. Included are all changelog entries in the categories *MySQL Cluster*, *Disk Data*, and *Cluster API*.

For an overview of features that were added in MySQL Cluster NDB 7.1, see MySQL Cluster Development in MySQL Cluster NDB 7.1.

- Changes in MySQL Cluster NDB 7.1.23 (5.1.63-ndb-7.1.23) [2382]
- Changes in MySQL Cluster NDB 7.1.22 (5.1.61-ndb-7.1.22) [2382]
- Changes in MySQL Cluster NDB 7.1.21 (5.1.61-ndb-7.1.21) [2382]
- Changes in MySQL Cluster NDB 7.1.20 (5.1.61-ndb-7.1.20) [2383]
- Changes in MySQL Cluster NDB 7.1.19 (5.1.56-ndb-7.1.19) [2384]
- Changes in MySQL Cluster NDB 7.1.18 (5.1.56-ndb-7.1.18) [2385]
- Changes in MySQL Cluster NDB 7.1.17 (5.1.56-ndb-7.1.17) [2385]
- Changes in MySQL Cluster NDB 7.1.16 (5.1.56-ndb-7.1.16) [2386]
- Changes in MySQL Cluster NDB 7.1.15a (5.1.56-ndb-7.1.15a) [2387]
- Changes in MySQL Cluster NDB 7.1.15 (5.1.56-ndb-7.1.15) [2387]
- Changes in MySQL Cluster NDB 7.1.14 (5.1.56-ndb-7.1.14) [2388]
- Changes in MySQL Cluster NDB 7.1.13 (5.1.56-ndb-7.1.13) [2389]
- Changes in MySQL Cluster NDB 7.1.12 (5.1.51-ndb-7.1.12) [2390]
- Changes in MySQL Cluster NDB 7.1.11 (5.1.51-ndb-7.1.11) [2390]
- Changes in MySQL Cluster NDB 7.1.10 (5.1.51-ndb-7.1.10) [2392]
- Changes in MySQL Cluster NDB 7.1.9a (5.1.51-ndb-7.1.9a) [2396]
- Changes in MySQL Cluster NDB 7.1.9 (5.1.51-ndb-7.1.9) [2396]
- Changes in MySQL Cluster NDB 7.1.8 (5.1.47-ndb-7.1.8) [2398]
- Changes in MySQL Cluster NDB 7.1.7 (5.1.47-ndb-7.1.7) [2400]
- Changes in MySQL Cluster NDB 7.1.6 (5.1.47-ndb-7.1.6) [2401]
- Changes in MySQL Cluster NDB 7.1.5 (5.1.47-ndb-7.1.5) [2402]
- Changes in MySQL Cluster NDB 7.1.4b (5.1.44-ndb-7.1.4b) [2403]

- Changes in MySQL Cluster NDB 7.1.4a (5.1.44-ndb-7.1.4a) [2404]
- Changes in MySQL Cluster NDB 7.1.4 (5.1.44-ndb-7.1.4) [2404]
- Changes in MySQL Cluster NDB 7.1.3 (5.1.44-ndb-7.1.3) [2406]
- Changes in MySQL Cluster NDB 7.1.2 (5.1.41-ndb-7.1.2) [2409]
- Changes in MySQL Cluster NDB 7.1.1 (5.1.41-ndb-7.1.1) [2411]
- Changes in MySQL Cluster NDB 7.1.0 (5.1.39-ndb-7.1.0) [2412]

Changes in MySQL Cluster NDB 7.1.23 (5.1.63-ndb-7.1.23)

Bugs Fixed

- If the Transaction Coordinator aborted a transaction in the “prepared” state, this could cause a resource leak. (Bug #14208924)
- When attempting to connect using a socket with a timeout, it was possible (if the timeout was exceeded) for the socket not to be set back to blocking. (Bug #14107173)
- In some circumstances, transactions could be lost during an online upgrade. (Bug #13834481)
- When an `NDB` table was created during a data node restart, the operation was rolled back in the `NDB` engine, but not on the SQL node where it was executed. This was due to the table `.FRM` files not being cleaned up following the operation that was rolled back by `NDB`. Now in such cases these files are removed. (Bug #13824846)
- Attempting to add both a column and an index on that column in the same online `ALTER TABLE` statement caused `mysqld` to fail. Although this issue affected only the `mysqld` shipped with MySQL Cluster, the table named in the `ALTER TABLE` could use any storage engine for which online operations are supported. (Bug #12755722)
- **Cluster API**: When an NDB API application called `NdbScanOperation::nextResult()` again after the previous call had returned end-of-file (return code 1), a transaction object was leaked. Now when this happens, NDB returns error code 4210 (`Ndb sent more info than length specified`); previouslyu in such cases, -1 was returned. In addition, the extra transaction object associated with the scan is freed, by returning it to the transaction coordinator's idle list. (Bug #11748194)

Changes in MySQL Cluster NDB 7.1.22 (5.1.61-ndb-7.1.22)

Bugs Fixed

- `DUMP 2303` in the `ndb_mgm` client now includes the status of the single fragment scan record reserved for a local checkpoint. (Bug #13986128)
- A shortage of scan fragment records in `DBTC` resulted in a leak of concurrent scan table records and key operation records. (Bug #13966723)

Changes in MySQL Cluster NDB 7.1.21 (5.1.61-ndb-7.1.21)

Bugs Fixed

- **Important Change**: The `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement can be used to create new table partitions after new empty nodes have been added to a MySQL Cluster. Usually, the number of partitions to create is determined automatically, such that, if no new partitions are required, then none are created. This behavior can be overridden by creating the original table using the `MAX_ROWS` option, which indicates that extra partitions should be created to store a large number of rows. However, in this case `ALTER ONLINE TABLE ... REORGANIZE PARTITION` simply uses the `MAX_ROWS` value specified in the original `CREATE TABLE` statement to

determine the number of partitions required; since this value remains constant, so does the number of partitions, and so no new ones are created. This means that the table is not rebalanced, and the new data nodes remain empty.

To solve this problem, support is added for `ALTER ONLINE TABLE ... MAX_ROWS=newvalue`, where *`newvalue`* is greater than the value used with `MAX_ROWS` in the original `CREATE TABLE` statement. This larger `MAX_ROWS` value implies that more partitions are required; these are allocated on the new data nodes, which restores the balanced distribution of the table data.

For more information, see `ALTER TABLE` Syntax, and Adding MySQL Cluster Data Nodes Online. (Bug #13714648)

- When the `--skip-config-cache` [1963] and `--initial` [1965] options were used together, `ndb_mgmd` failed to start. (Bug #13857301)
- `ALTER ONLINE TABLE` failed when a `DEFAULT` option was used. (Bug #13830980)
- In some cases, restarting data nodes spent a very long time in Start Phase 101, when API nodes must connect to the starting node (using `NdbEventOperation`), when the API nodes trying to connect failed in a live-lock scenario. This connection process uses a handshake during which a small number of messages are exchanged, with a timeout used to detect failures during the handshake.

  Prior to this fix, this timeout was set such that, if one API node encountered the timeout, all other nodes connecting would do the same. The fix also decreases this timeout. This issue (and the effects of the fix) are most likely to be observed on relatively large configurations having 10 or more data nodes and 200 or more API nodes. (Bug #13825163)
- `ndbmtd` failed to restart when the size of a table definition exceeded 32K.

  (The size of a table definition is dependent upon a number of factors, but in general the 32K limit is encountered when a table has 250 to 300 columns.) (Bug #13824773)
- An initial start using `ndbmtd` could sometimes hang. This was due to a state which occurred when several threads tried to flush a socket buffer to a remote node. In such cases, to minimize flushing of socket buffers, only one thread actually performs the send, on behalf of all threads. However, it was possible in certain cases for there to be data in the socket buffer waiting to be sent with no thread ever being chosen to perform the send. (Bug #13809781)
- When trying to use `ndb_size.pl --hostname=`*`host:port`* to connect to a MySQL server running on a nonstandard port, the *`port`* argument was ignored. (Bug #13364905, Bug #62635)

Changes in MySQL Cluster NDB 7.1.20 (5.1.61-ndb-7.1.20)

Bugs Fixed

- **Important Change**: A number of changes have been made in the configuration of transporter send buffers.

  1. The data node configuration parameter `ReservedSendBufferMemory` [1861] is now deprecated, and thus subject to removal in a future MySQL Cluster release. `ReservedSendBufferMemory` has been non-functional since it was introduced and remains so.
  2. `TotalSendBufferMemory` now works correctly with data nodes using `ndbmtd`.
  3. `SendBufferMemory` [1870] can now over-allocate into `SharedGlobalMemory` [1856] for `ndbmtd` data nodes (only).
  4. A new data node configuration parameter `ExtraSendBufferMemory` [1861] is introduced. Its purpose is to control how much additional memory can be allocated to the send buffer over and

above that specified by `TotalSendBufferMemory` or `SendBufferMemory`. The default setting (0) allows up to 16MB to be allocated automatically.

(Bug #13633845, Bug #11760629, Bug #53053)

- Setting `insert_id` [482] had no effect on the auto-increment counter for `NDB` tables. (Bug #13731134)

- A data node crashed when more than 16G fixed-size memory was allocated by `DBTUP` to one fragment (because the `DBACC` kernel block was not prepared to accept values greater than 32 bits from it, leading to an overflow). Now in such cases, the data node returns Error 889 `Table fragment fixed data reference has reached maximum possible value...`. When this happens, you can work around the problem by increasing the number of partitions used by the table (such as by using the `MAXROWS` option with `CREATE TABLE`). (Bug #13637411)

  References: See also Bug #11747870, Bug #34348.

- Several instances in the NDB code affecting the operation of multi-threaded data nodes, where `SendBufferMemory` was associated with a specific thread for an unnecessarily long time, have been identified and fixed, by minimizing the time that any of these buffers can be held exclusively by a given thread (send buffer memory being critical to operation of the entire node). (Bug #13618181)

- A very large value for `BackupWriteSize` [1851], as compared to `BackupMaxWriteSize` [1852], `BackupDataBufferSize` [1850], or `BackupLogBufferSize` [1850], could cause a local checkpoint or backup to hang. (Bug #13613344)

- Queries using `LIKE ... ESCAPE` on `NDB` tables failed when pushed down to the data nodes. Such queries are no longer pushed down, regardless of the value of `engine_condition_pushdown` [473]. (Bug #13604447, Bug #61064)

- To avoid TCP transporter overload, an overload flag is kept in the NDB kernel for each data node; this flag is used to abort key requests if needed, yielding error 1218 `Send Buffers overloaded in NDB kernel` in such cases. Scans can also put significant pressure on transporters, especially where scans with a high degree of parallelism are executed in a configuration with relatively small send buffers. However, in these cases, overload flags were not checked, which could lead to node failures due to send buffer exhaustion. Now, overload flags are checked by scans, and in cases where returning sufficient rows to match the batch size (`--ndb-batch-size` [1912] server option) would cause an overload, the number of rows is limited to what can be accommodated by the send buffer.

  See also Configuring MySQL Cluster Send Buffer Parameters. (Bug #13602508)

- A `SELECT` from an `NDB` table using `LIKE` with a multi-byte column (such as `utf8`) did not return the correct result when `engine_condition_pushdown` [473] was enabled. (Bug #13579318, Bug #64039)

  References: See also Bug #13608135.

- A node failure and recovery while performing a scan on more than 32 partitions led to additional node failures during node takeover. (Bug #13528976)

- The `--skip-config-cache` [1963] option now causes `ndb_mgmd` to skip checking for the configuration directory, and thus to skip creating it in the event that it does not exist. (Bug #13428853)

Changes in MySQL Cluster NDB 7.1.19 (5.1.56-ndb-7.1.19)

Bugs Fixed

- Accessing a table having a `BLOB` column but no primary key following a restart of the SQL node failed with Error 1 (`Unknown error code`). (Bug #13563280)

- At the beginning of a local checkpoint, each data node marks its local tables with a “to be checkpointed” flag. A failure of the master node during this process could cause either the LCP to hang, or one or more data nodes to be forcibly shut down. (Bug #13436481)

- A node failure while a `ANALYZE TABLE` statement was executing resulted in a hung connection (and the user was not informed of any error that would cause this to happen). (Bug #13416603)

  References: See also Bug #13407848.

Changes in MySQL Cluster NDB 7.1.18 (5.1.56-ndb-7.1.18)

Bugs Fixed

- Added the `MinFreePct` [1820] data node configuration parameter, which specifies a percentage of data node resources to hold in reserve for restarts. The resources monitored are `DataMemory` [1817], `IndexMemory` [1819], and any per-table `MAX_ROWS` settings (see `CREATE TABLE` Syntax). The default value of `MinFreePct` [1820] is 5, which means that 5% from each these resources is now set aside for restarts. (Bug #13436216)

- Because the log event buffer used internally by data nodes was circular, periodic events such as statistics events caused it to be overwritten too quickly. Now the buffer is partitioned by log event category, and its default size has been increased from 4K to 8K. (Bug #13394771)

- The `BatchSize` [1866] and `BatchByteSize` [1866] configuration parameters, used to control the maximum sizes of result batches, are defined as integers. However, the values used to store these were incorrectly interpreted as numbers of bytes in the NDB kernel. This caused the `DBLQH` kernel block to fail to detect when the specified `BatchByteSize` [1866] was consumed.

  In addition, the `DBSPJ` kernel block could miscalculate statistics for adaptive parallelism. (Bug #13355055)

- Previously, forcing simultaneously the shutdown of multiple data nodes using `SHUTDOWN -F` in the `ndb_mgm` management client could cause the entire cluster to fail. Now in such cases, any such nodes are forced to abort immediately. (Bug #12928429)

- A **`SubscriberNodeIdUndefined`** error was previously unhandled, resulting in a data node crash, but is now handled by NDB Error 1429, `Subscriber node undefined in SubStartReq`. (Bug #12598496)

- `SELECT` statements using `LIKE CONCAT(...)` [951] `OR LIKE CONCAT(...)` in the `WHERE` clause returned incorrect results when run against `NDB` tables. (Bug #11765142, Bug #58073)

Changes in MySQL Cluster NDB 7.1.17 (5.1.56-ndb-7.1.17)

Functionality Added or Changed

- Introduced the `CrashOnCorruptedTuple` [1833] data node configuration parameter. When enabled, this parameter causes data nodes to handle corrupted tuples in a fail-fast manner —in other words, whenever the data node detects a corrupted tuple, it forcibly shuts down if `CrashOnCorruptedTuple` [1833] is enabled. For backward compatibility, this parameter is disabled by default. (Bug #12598636)

- Added the `ThreadConfig` data node configuration parameter to enable control of multiple threads and CPUs when using `ndbmtd`, by assigning threads of one or more specified types to execute on one or more CPUs. This can provide more precise and flexible control over multiple threads than can be obtained using the `LockExecuteThreadToCPU` [1852] parameter. (Bug #11795581)

Bugs Fixed

- When a failure of multiple data nodes during a local checkpoint (LCP) that took a long time to complete included the node designated as master, any new data nodes attempting to start before all ongoing LCPs were completed later crashed. This was due to the fact that node takeover by the new

master cannot be completed until there are no pending local checkpoints. Long-running LCPs such as those which triggered this issue can occur when fragment sizes are sufficiently large (see MySQL Cluster Nodes, Node Groups, Replicas, and Partitions, for more information). Now in such cases, data nodes (other than the new master) are kept from restarting until the takeover is complete. (Bug #13323589)

- When deleting from multiple tables using a unique key in the `WHERE` condition, the wrong rows were deleted. In addition, `UPDATE` triggers failed when rows were changed by deleting from or updating multiple tables. (Bug #12718336, Bug #61705, Bug #12728221)

- Shutting down a `mysqld` while under load caused the spurious error messages `Opening ndb_binlog_index: killed` and `Unable to lock table ndb_binlog_index` to be written in the cluster log. (Bug #11930428)

- **Cluster API**: When more than 32KB of data must be sent in a single signal using the NDB API, the data is split across 2 or more signals each of which is smaller than 32kB, and these are then reassembled back into the original, full-length signal by the receiver. Such fragmented signals are used for some scan requests, as well as for SPJ `QueryOperation` requests. However, extra (spurious) signals could sometimes be sent when using fragmented signals, causing errors on the receiver; these implementation artifacts have now been eliminated. (Bug #13087016)

Changes in MySQL Cluster NDB 7.1.16 (5.1.56-ndb-7.1.16)

Functionality Added or Changed

- It is now possible to filter the output from `ndb_config` so that it displays only system, data node, or connection parameters and values, using one of the options `--system` [1974], `--nodes` [1974], or `--connections` [1974], respectively. In addition, it is now possible to specify from which data node the configuration data is obtained, using the `--config_from_node` [1972] option that is added in this release.

  For more information, see `ndb_config` — Extract MySQL Cluster Configuration Information. (Bug #11766870)

Bugs Fixed

- **Cluster API**: **Incompatible Change**: Restarting a machine hosting data nodes, SQL nodes, or both, caused such nodes when restarting to time out while trying to obtain node IDs.

  As part of the fix for this issue, the behavior and default values for the NDB API `Ndb_cluster_connection::connect()` method have been improved. Due to these changes, the version number for the included NDB client library (`libndbclient.so`) has been increased from 4.0.0 to 5.0.0. For NDB API applications, this means that as part of any upgrade, you must do both of the following:

  - Review and possibly modify any NDB API code that uses the `connect()` method, in order to take into account its changed default retry handling.

  - Recompile any NDB API applications using the new version of the client library.

  Also in connection with this issue, the default value for each of the two `mysqld` options `--ndb-wait-connected` [1919] and `--ndb-wait-setup` [1919] has been increased to 30 seconds (from 0 and 15, respectively). In addition, a hard-coded 30-second delay was removed, so that the value of `--ndb-wait-connected` [1919] is now handled correctly in all cases. (Bug #12543299)

- **Cluster API**: **Incompatible Change**: Restarting a machine hosting data nodes, SQL nodes, or both, caused such nodes when restarting to time out while trying to obtain node IDs.

  As part of the fix for this issue, the behavior and default values for the NDB API `Ndb_cluster_connection::connect()` method have been improved. Due to these changes, the version number for the included NDB client library (`libndbclient.so`) has been increased

from 4.0.0 to 5.0.0. For NDB API applications, this means that as part of any upgrade, you must do both of the following:

- Review and possibly modify any NDB API code that uses the `connect()` method, in order to take into account its changed default retry handling.
- Recompile any NDB API applications using the new version of the client library.

Also in connection with this issue, the default value for each of the two `mysqld` options `--ndb-wait-connected` [1919] and `--ndb-wait-setup` [1919] has been increased to 30 seconds (from 0 and 15, respectively). In addition, a hard-coded 30-second delay was removed, so that the value of `--ndb-wait-connected` [1919] is now handled correctly in all cases. (Bug #12543299)

- When replicating DML statements with `IGNORE` between clusters, the number of operations that failed due to nonexistent keys was expected to be no greater than the number of defined operations of any single type. Because the slave SQL thread defines operations of multiple types in batches together, code which relied on this assumption could cause `mysqld` to fail. (Bug #12859831)
- The maximum effective value for the `OverloadLimit` [1869] configuration parameter was limited by the value of `SendBufferMemory` [1870]. Now the value set for `OverloadLimit` [1869] is used correctly, up to this parameter's stated maximum (4G). (Bug #12712109)
- `AUTO_INCREMENT` values were not set correctly for `INSERT IGNORE` statements affecting `NDB` tables. This could lead such statements to fail with `Got error 4350 'Transaction already aborted' from NDBCLUSTER` when inserting multiple rows containing duplicate values. (Bug #11755237, Bug #46985)
- When failure handling of an API node takes longer than 300 seconds, extra debug information is included in the resulting output. In cases where the API node's node ID was greater than 48, these extra debug messages could lead to a crash, and confuing output otherwise. This was due to an attempt to provide information specific to data nodes for API nodes as well. (Bug #62208)
- In rare cases, a series of node restarts and crashes during restarts could lead to errors while reading the redo log. (Bug #62206)

Changes in MySQL Cluster NDB 7.1.15a (5.1.56-ndb-7.1.15a)

Bugs Fixed

- Setting `IndexMemory` [1819] or sometimes `DataMemory` [1817] to 2 GB or higher could lead to data node failures under some conditions. (Bug #12873640)

Changes in MySQL Cluster NDB 7.1.15 (5.1.56-ndb-7.1.15)

Functionality Added or Changed

- Added the `MaxDMLOperationsPerTransaction` [1822] data node configuration parameter, which can be used to limit the number of DML operations used by a transaction; if the transaction requires more than this many DML operations, the transaction is aborted. (Bug #12589613)

Bugs Fixed

- When global checkpoint indexes were written with no intervening end-of-file or megabyte border markers, this could sometimes lead to a situation in which the end of the redo log was mistakenly regarded as being between these GCIs, so that if the restart of a data node took place before the start of the next redo log was overwritten, the node encountered an `Error while reading the REDO log`. (Bug #12653993, Bug #61500)

  References: See also Bug #56961.

- Restarting a `mysqld` during a rolling upgrade with data nodes running a mix of old and new versions of the MySQL Cluster software caused the `mysqld` to run in read-only mode. (Bug #12651364, Bug #61498)

- Error reporting has been improved for cases in which API nodes are unable to connect due to apparent unavailability of node IDs. (Bug #12598398)
- Error messages for `Failed to convert connection` transporter registration problems were inspecific. (Bug #12589691)
- Under certain rare circumstances, a data node process could fail with Signal 11 during a restart. This was due to uninitialized variables in the `QMGR` kernel block. (Bug #12586190)
- Multiple management servers were unable to detect one another until all nodes had fully started. As part of the fix for this issue, two new status values `RESUME` and `CONNECTED` can be reported for management nodes in the output of the `ndb_mgm` client `SHOW` command (see Commands in the MySQL Cluster Management Client). Two corresponding status values `NDB_MGM_NODE_STATUS_RESUME` and `NDB_MGM_NODE_STATUS_CONNECTED` are also added to the list of possible values for an `ndb_mgm_node_status` data structure in the MGM API. (Bug #12352191, Bug #48301)
- Handling of the `MaxNoOfTables` [1829] and `MaxNoOfAttributes` [1828] configuration parameters was not consistent in all parts of the `NDB` kernel, and were only strictly enforced by the `DBDICT` and `SUMA` kernel blocks. This could lead to problems when tables could be created but not replicated. Now these parameters are treated by `SUMA` and `DBDICT` as suggested maximums rather than hard limits, as they are elsewhere in the `NDB` kernel. (Bug #61684)
- It was not possible to shut down a management node while one or more data nodes were stopped (for whatever reason). This issue was a regression introduced in MySQL Cluster NDB 7.0.24 and MySQL Cluster NDB 7.1.13. (Bug #61607)

  References: See also Bug #61147.
- **Cluster API**: Applications that included the header file `ndb_logevent.h` could not be built using the Microsoft Visual Studio C compiler or the Oracle (Sun) Studio C compiler due to empty struct definitions. (Bug #12678971)
- **Cluster API**: Within a transaction, after creating, executing, and closing a scan, calling `NdbTransaction::refresh()` after creating and executing but not closing a second scan caused the application to crash. (Bug #12646659)

Changes in MySQL Cluster NDB 7.1.14 (5.1.56-ndb-7.1.14)

Bugs Fixed

- The internal `Ndb_getinaddr()` function has been rewritten to use `getaddrinfo()` instead of `my_gethostbyname_r()` (which is removed in a later version of the MySQL Server). (Bug #12542120)
- `mysql_upgrade` failed when performing an online upgrade from MySQL Cluster NDB 7.1.8 or an earlier release to MySQL Cluster NDB 7.1.9 or later in which the SQL nodes were upgraded before the data nodes. This issue could occur during any online upgrade or downgrade where one or more `ndbinfo` tables had more, fewer, or differing columns between the two versions, and when the data nodes were not upgraded before the SQL nodes.

  For more information, see Upgrade and downgrade compatibility: MySQL Cluster NDB 7.x. (Bug #11885602, Bug #12581895, Bug #12581954)
- Two unused test files in `storage/ndb/test/sql` contained incorrect versions of the GNU Lesser General Public License. The files and the directory containing them have been removed. (Bug #11810156)

  References: See also Bug #11810224.
- Error 1302 gave the wrong error message (`Out of backup record`). This has been corrected to `A backup is already running`. (Bug #11793592)

- When using two management servers, issuing in an `ndb_mgm` client connected to one management server a `STOP` command for stopping the other management server caused Error 2002 (`Stop failed ... Send to process or receive failed.: Permanent error: Application error`), even though the `STOP` command actually succeeded, and the second `ndb_mgmd` was shut down. (Bug #61147)

- Renaming a table having `BLOB` or `TEXT` columns (or both) to another database caused the SQL node to crash, and the table to become inaccessible afterwards. (Bug #60484)

- Under heavy loads with many concurrent inserts, temporary failures in transactions could occur (and were misreported as being due to `NDB` Error 899 `Rowid already allocated`). As part of the fix for this issue, `NDB` Error 899 has been reclassified as an internal error, rather than as a temporary transaction error. (Bug #56051, Bug #11763354)

- In `ndbmtd`, a node connection event is detected by a `CMVMI` thread which sends a `CONNECT_REP` signal to the `QMGR` kernel block. In a few isolated circumstances, a signal might be transferred to `QMGR` directly by the `NDB` transporter before the `CONNECT_REP` signal actually arrived. This resulted in reports in the error log with status `Temporary error, restart node`, and the message `Internal program error`. (Bug #61025)

- **Disk Data**: Accounting for `MaxNoOfOpenFiles` was incorrect with regard to to data files in MySQL Cluster Disk Data tablespaces. This could lead to a crash when `MaxNoOfOpenFiles` was exceeded. (Bug #12581213)

Changes in MySQL Cluster NDB 7.1.13 (5.1.56-ndb-7.1.13)

Functionality Added or Changed

- It is now possible to add data nodes online to a running MySQL Cluster without performing a rolling restart of the cluster or starting data node processes with the `--nowait-nodes` [1955] option. This can be done by setting `Nodegroup = 65536` [1815] in the `config.ini` file for any data nodes that should be started at a later time, when first starting the cluster. (It was possible to set `NodeGroup` [1815] to this value previously, but the management server failed to start.)

  As part of this fix, a new data node configuration parameter `StartNoNodeGroupTimeout` [1836] has been added. When the management server sees that there are data nodes with no node group (that is, nodes for which `Nodegroup = 65536` [1815]), it waits `StartNoNodeGroupTimeout` [1836] milliseconds before treating these nodes as though they were listed with the `--nowait-nodes` [1955] option, and proceeds to start.

  For more information, see Adding MySQL Cluster Data Nodes Online. (Bug #11766167, Bug #59213)

- A `config_generation` column has been added to the `nodes` table of the `ndbinfo` database. By checking this column, it is now possible to determine which version or versions of the MySQL Cluster configuration file are in effect on the data nodes. This information can be especially useful when performing a rolling restart of the cluster to update its configuration.

Bugs Fixed

- **Cluster API**: A unique index operation is executed in two steps: a lookup on an index table, and an operation on the base table. When the operation on the base table failed, while being executed in a batch with other operations that succeeded, this could lead to a hanging execute, eventually timing out with Error 4012 (`Request ndbd time-out, maybe due to high load or communication problems`). (Bug #12315582)

- **Cluster API**: A unique index operation is executed in two steps: a lookup on an index table, and an operation on the base table. When the operation on the base table failed, while being executed in a batch with other operations that succeeded, this could lead to a hanging execute, eventually timing out with Error 4012 (`Request ndbd time-out, maybe due to high load or communication problems`). (Bug #12315582)

- A memory leak in LGMAN, that leaked 8 bytes of log buffer memory per 32k written, was introduced in MySQL Cluster NDB 7.0.9, effecting all MySQL Cluster NDB 7.1 releases as well as MySQL Cluster NDB 7.0.9 and later MySQL Cluster NDB 7.0 releases. (For example, when 128MB log buffer memory was used, it was exhausted after writing 512GB to the undo log.) This led to a GCP stop and data node failure. (Bug #60946)

  References: This bug was introduced by Bug #47966.

- When using ndbmtd, a MySQL Cluster configured with 32 data nodes failed to start correctly. (Bug #60943)

- When performing a TUP scan with locks in parallel, and with a highly concurrent load of inserts and deletions, the scan could sometimes fail to notice that a record had moved while waiting to acquire a lock on it, and so read the wrong record. During node recovery, this could lead to a crash of a node that was copying data to the node being started, and a possible forced shutdown of the cluster.

- **Cluster API**: Performing interpreted operations using a unique index did not work correctly, because the interpret bit was kept when sending the lookup to the index table.

Changes in MySQL Cluster NDB 7.1.12 (5.1.51-ndb-7.1.12)

Functionality Added or Changed

- Improved scaling of ordered index scans performance by removing a hard-coded limit (MAX_PARALLEL_INDEX_SCANS_PER_FRAG) and making the number of TUP or TUX scans per fragment configurable by adding the MaxParallelScansPerFragment [1825] data node configuration parameter. (Bug #11769048)

Bugs Fixed

- **Important Change**: Formerly, the --ndb-cluster-connection-pool server option set a status variable as well as a system variable. The status variable has been removed as redundant. (Bug #60119)

- A scan with a pushed condition (filter) using the CommittedRead lock mode could hang for a short interval when it was aborted when just as it had decided to send a batch. (Bug #11932525)

- When aborting a multi-read range scan exactly as it was changing ranges in the local query handler, LQH could fail to detect it, leaving the scan hanging. (Bug #11929643)

- Schema distribution did not take place for tables converted from another storage engine to NDB using ALTER TABLE; this meant that such tables were not always visible to all SQL nodes attached to the cluster. (Bug #11894966)

- A GCI value inserted by ndb_restore --restore_epoch [1996] into the ndb_apply_status table was actually 1 less than the correct value. (Bug #11885852)

- **Disk Data**: Limits imposed by the size of SharedGlobalMemory [1856] were not always enforced consistently with regard to Disk Data undo buffers and log files. This could sometimes cause a CREATE LOGFILE GROUP or ALTER LOGFILE GROUP statement to fail for no apparent reason, or cause the log file group specified by InitialLogFileGroup [1859] not to be created when starting the cluster. (Bug #57317)

Changes in MySQL Cluster NDB 7.1.11 (5.1.51-ndb-7.1.11)

Functionality Added or Changed

- **Disk Data**: The INFORMATION_SCHEMA.TABLES table now provides disk usage as well as memory usage information for Disk Data tables. Also, INFORMATION_SCHEMA.PARTITIONS, formerly did not show any statistics for NDB tables. Now the TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH, MAX_DATA_LENGTH, and DATA_FREE columns contain correct information for the table's partitions.

- **Disk Data**: The `INFORMATION_SCHEMA.TABLES` table now provides disk usage as well as memory usage information for Disk Data tables. Also, `INFORMATION_SCHEMA.PARTITIONS`, formerly did not show any statistics for `NDB` tables. Now the `TABLE_ROWS`, `AVG_ROW_LENGTH`, `DATA_LENGTH`, `MAX_DATA_LENGTH`, and `DATA_FREE` columns contain correct information for the table's partitions.

- A new `--rewrite-database` [2003] option is added for `ndb_restore`, which makes it possible to restore to a database having a different name from that of the database in the backup.

  For more information, see `ndb_restore` — Restore a MySQL Cluster Backup. (Bug #54327)

- The NDB kernel now implements a number of statistical counters relating to actions performed by or affecting `Ndb` objects, such as starting, closing, or aborting transactions; primary key and unique key operations; table, range, and pruned scans; blocked threads waiting for various operations to complete; and data and events sent and received by `NDBCLUSTER`. These NDB API counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes. `mysqld` exposes these counters as system status variables; their values can be read in the output of `SHOW STATUS`, or by querying the `SESSION_STATUS` or `GLOBAL_STATUS` table in the `INFORMATION_SCHEMA` database. By comparing the values of these status variables prior to and following the execution of SQL statements that act on `NDB` tables, you can observe the corresponding actions taken on the NDB API level, which can be beneficial for monitoring and performance tuning of MySQL Cluster.

  For more information, see NDB API Statistics Counters and Variables, as well as MySQL Cluster Status Variables.

- Made it possible to enable multi-threaded building of ordered indexes during initial restarts, using the new `TwoPassInitialNodeRestartCopy` data node configuration parameter.

- Added the `--lossy-conversions` [1995] option for `ndb_restore`, which makes it possible to enable attribute demotion when restoring a MySQL Cluster from an `NDB` native backup.

  For additional information about type conversions currently supported by MySQL Cluster for attribute promotion and demotion, see Replication of Columns Having Different Data Types.

Bugs Fixed

- This issue affects all previous MySQL Cluster NDB 7.1 releases. (Bug #60045)

- `ndb_restore --rebuild-indexes [2002]` caused multi-threaded index building to occur on the master node only. (Bug #59920)

- Successive queries on the `counters` table from the same SQL node returned unchanging results. To fix this issue, and to prevent similar issues from occurring in the future, `ndbinfo` tables are now excluded from the query cache. (Bug #59831)

- When attempting to create a table on a MySQL Cluster with many standby data nodes (setting `Nodegroup=65536` [1815] in `config.ini` for the nodes that should wait, starting the nodes that should start immediately with the `--nowait-nodes` [1955] option, and using the `CREATE TABLE` statement's `MAX_ROWS` option), `mysqld` miscalculated the number of fragments to use. This caused the `CREATE TABLE` to fail.

  Note

  The `CREATE TABLE` failure caused by this issue in turn prevented any further attempts to create the table, even if the table structure was simplified or changed in such a way that the attempt should have succeeded. This “ghosting” issue is handled in Bug #59756.

  (Bug #59751)

- When a `CREATE TABLE` statement failed due to `NDB` error 1224 (`Too many fragments`), it was not possible to create the table afterward unless either it had no ordered indexes, or a `DROP TABLE`

statement was issued first, even if the subsequent `CREATE TABLE` was valid and should otherwise have succeeded. (Bug #59756)

References: See also Bug #59751.

- `NDB` sometimes treated a simple (not unique) ordered index as unique. (Bug #59519)
- The logic used in determining whether to collapse a range to a simple equality was faulty. In certain cases, this could cause `NDB` to treat a range as if it were a primary key lookup when determining the query plan to be used. Although this did not affect the actual result returned by the query, it could in such cases result in inefficient execution of queries due to the use of an inappropriate query plan. (Bug #59517)
- When a query used multiple references to or instances of the same physical tables, `NDB` failed to recognize these multiple instances as different tables; in such a case, `NDB` could incorrectly use condition pushdown on a condition referring to these other instances to be pushed to the data nodes, even though the condition should have been rejected as unpushable, leading to invalid results. (Bug #58791)
- **Cluster API**: When calling `NdbEventOperation::execute()` during a node restart, it was possible to get a spurious error 711 (`System busy with node restart, schema operations not allowed when a node is starting`). (Bug #59723)
- **Cluster API**: When an NDBAPI client application was waiting for more scan results after calling `NdbScanOperation::nextResult()`, the calling thread sometimes woke up even if no new batches for any fragment had arrived, which was unnecessary, and which could have a negative impact on the application's performance. (Bug #52298)

Changes in MySQL Cluster NDB 7.1.10 (5.1.51-ndb-7.1.10)

Functionality Added or Changed

- **Important Change**: The following changes have been made with regard to the `TimeBetweenEpochsTimeout` [1840] data node configuration parameter:
  - The maximum possible value for this parameter has been increased from 32000 milliseconds to 256000 milliseconds.
  - Setting this parameter to zero now has the effect of disabling GCP stops caused by save timeouts, commit timeouts, or both.
  - The current value of this parameter and a warning are written to the cluster log whenever a GCP save takes longer than 1 minute or a GCP commit takes longer than 10 seconds.

  For more information, see Disk Data and `GCP Stop` errors. (Bug #58383)
- Added the `--skip-broken-objects` [2003] option for `ndb_restore`. This option causes `ndb_restore` to ignore tables corrupted due to missing blob parts tables, and to continue reading from the backup file and restoring the remaining tables. (Bug #54613)

  References: See also Bug #51652.
- Made it possible to exercise more direct control over handling of timeouts occurring when trying to flush redo logs to disk using two new data node configuration parameters `RedoOverCommitCounter` [1862] and `RedoOverCommitLimit` [1862], as well as the new API node configuration parameter `DefaultOperationRedoProblemAction` [1867], all added in this release. Now, when such timeouts occur more than a specified number of times for the flushing of a given redo log, any transactions that were to be written are instead aborted, and the operations contained in those transactions can be either re-tried or themselves aborted.

  For more information, see Redo log over-commit handling.

- **Cluster API**: It is now possible to stop or restart a node even while other nodes are starting, using the MGM API `ndb_mgm_stop4()` or `ndb_mgm_restart4()` function, respectively, with the *`force`* parameter set to 1. (Bug #58451)

  References: See also Bug #58319.

Bugs Fixed

- **Cluster API**: In some circumstances, very large `BLOB` read and write operations in MySQL Cluster applications can cause excessive resource usage and even exhaustion of memory. To fix this issue and to provide increased stability when performing such operations, it is now possible to set limits on the volume of `BLOB` data to be read or written within a given transaction in such a way that when these limits are exceeded, the current transaction implicitly executes any accumulated operations. This avoids an excessive buildup of pending data which can result in resource exhaustion in the NDB kernel. The limits on the amount of data to be read and on the amount of data to be written before this execution takes place can be configured separately. (In other words, it is now possible in MySQL Cluster to specify read batching and write batching that is specific to `BLOB` data.) These limits can be configured either on the NDB API level, or in the MySQL Server.

  On the NDB API level, four new methods are added to the `NdbTransaction` object. `getMaxPendingBlobReadBytes()` and `setMaxPendingBlobReadBytes()` can be used to get and to set, respectively, the maximum amount of `BLOB` data to be read that accumulates before this implicit execution is triggered. `getMaxPendingBlobWriteBytes()` and `setMaxPendingBlobWriteBytes()` can be used to get and to set, respectively, the maximum volume of `BLOB` data to be written that accumulates before implicit execution occurs.

  For the MySQL server, two new options are added. The `--ndb-blob-read-batch-bytes` [1913] option sets a limit on the amount of pending `BLOB` data to be read before triggering implicit execution, and the `--ndb-blob-write-batch-bytes` [1913] option controls the amount of pending `BLOB` data to be written. These limits can also be set using the `mysqld` configuration file, or read and set within the `mysql` client and other MySQL client applications using the corresponding server system variables. (Bug #59113)

- **Cluster API**: In some circumstances, very large `BLOB` read and write operations in MySQL Cluster applications can cause excessive resource usage and even exhaustion of memory. To fix this issue and to provide increased stability when performing such operations, it is now possible to set limits on the volume of `BLOB` data to be read or written within a given transaction in such a way that when these limits are exceeded, the current transaction implicitly executes any accumulated operations. This avoids an excessive buildup of pending data which can result in resource exhaustion in the NDB kernel. The limits on the amount of data to be read and on the amount of data to be written before this execution takes place can be configured separately. (In other words, it is now possible in MySQL Cluster to specify read batching and write batching that is specific to `BLOB` data.) These limits can be configured either on the NDB API level, or in the MySQL Server.

  On the NDB API level, four new methods are added to the `NdbTransaction` object. `getMaxPendingBlobReadBytes()` and `setMaxPendingBlobReadBytes()` can be used to get and to set, respectively, the maximum amount of `BLOB` data to be read that accumulates before this implicit execution is triggered. `getMaxPendingBlobWriteBytes()` and `setMaxPendingBlobWriteBytes()` can be used to get and to set, respectively, the maximum volume of `BLOB` data to be written that accumulates before implicit execution occurs.

  For the MySQL server, two new options are added. The `--ndb-blob-read-batch-bytes` [1913] option sets a limit on the amount of pending `BLOB` data to be read before triggering implicit execution, and the `--ndb-blob-write-batch-bytes` [1913] option controls the amount of pending `BLOB` data to be written. These limits can also be set using the `mysqld` configuration file, or read and set within the `mysql` client and other MySQL client applications using the corresponding server system variables. (Bug #59113)

- Two related problems could occur with read-committed scans made in parallel with transactions combining multiple (concurrent) operations:

1. When committing a multiple-operation transaction that contained concurrent insert and update operations on the same record, the commit arrived first for the insert and then for the update. If a read-committed scan arrived between these operations, it could thus read incorrect data; in addition, if the scan read variable-size data, it could cause the data node to fail.

2. When rolling back a multiple-operation transaction having concurrent delete and insert operations on the same record, the abort arrived first for the delete operation, and then for the insert. If a read-committed scan arrived between the delete and the insert, it could incorrectly assume that the record should not be returned (in other words, the scan treated the insert as though it had not yet been committed).

(Bug #59496)

- On Windows platforms, issuing a `SHUTDOWN` command in the `ndb_mgm` client caused management processes that had been started with the `--nodaemon` [1965] option to exit abnormally. (Bug #59437)

- When executing a full table scan caused by a `WHERE` condition using *`unique_key`* `IS NULL` in combination with a join, `NDB` failed to close the scan. (Bug #58750)

  References: See also Bug #57481.

- A row insert or update followed by a delete operation on the same row within the same transaction could in some cases lead to a buffer overflow. (Bug #59242)

  References: See also Bug #56524. This bug was introduced by Bug #35208.

- Data nodes configured with very large amounts (multiple gigabytes) of `DiskPageBufferMemory` [1856] failed during startup with NDB error 2334 (`Job buffer congestion`). (Bug #58945)

  References: See also Bug #47984.

- The `FAIL_REP` signal, used inside the NDB kernel to declare that a node has failed, now includes the node ID of the node that detected the failure. This information can be useful in debugging. (Bug #58904)

- When handling failures of multiple data nodes, an error in the construction of internal signals could cause the cluster's remaining nodes to crash. This issue was most likely to affect clusters with large numbers of data nodes. (Bug #58240)

- Data nodes no longer allocated all memory prior to being ready to exchange heartbeat and other messages with management nodes, as in NDB 6.3 and earlier versions of MySQL Cluster. This caused problems when data nodes configured with large amounts of memory failed to show as connected or showed as being in the wrong start phase in the `ndb_mgm` client even after making their initial connections to and fetching their configuration data from the management server. With this fix, data nodes now allocate all memory as they did in earlier MySQL Cluster versions. (Bug #57568)

- Trying to drop an index while it was being used to perform scan updates caused data nodes to crash. (Bug #58277, Bug #57057)

- The number of rows affected by a statement that used a `WHERE` clause having an `IN` [942] condition with a value list containing a great many elements, and that deleted or updated enough rows such that `NDB` processed them in batches, was not computed or reported correctly. (Bug #58040)

- MySQL Cluster failed to compile correctly on FreeBSD 8.1 due to misplaced `#include` statements. (Bug #58034)

- In some circumstances, an SQL trigger on an `NDB` table could read stale data. (Bug #58538)

- A query having multiple predicates joined by `OR` in the `WHERE` clause and which used the `sort_union` access method (as shown using `EXPLAIN`) could return duplicate rows. (Bug #58280)
- During a node takeover, it was possible in some circumstances for one of the remaining nodes to send an extra transaction confirmation (`LQH_TRANSCONF`) signal to the `DBTC` kernel block, conceivably leading to a crash of the data node trying to take over as the new transaction coordinator. (Bug #58453)
- Some queries of the form `SELECT ... WHERE column IN (subquery)` against an `NDB` table could cause `mysqld` to hang in an endless loop. (Bug #58163)
- In some circumstances, it was possible for `mysqld` to begin a new multi-range read scan without having closed a previous one. This could lead to exhaustion of all scan operation objects, transaction objects, or lock objects (or some combination of these) in `NDB`, causing queries to fail with such errors as `Lock wait timeout exceeded` or `Connect failure - out of connection objects`. (Bug #57481)

  References: See also Bug #58750.
- Queries using `column IS [NOT] NULL` on a table with a unique index created with `USING HASH` on `column` always returned an empty result. (Bug #57032)
- The functions `strncasecmp` and `strcasecmp` were declared in `ndb_global.h` but never defined or used. The declarations have been removed. (Bug #58204)
- With `engine_condition_pushdown` [473] enabled, a query using `LIKE` on an `ENUM` column of an `NDB` table failed to return any results. This issue is resolved by disabling `engine_condition_pushdown` [473] when performing such queries. (Bug #53360)
- A query using `BETWEEN` as part of a pushed-down `WHERE` condition could cause mysqld to hang or crash. (Bug #57735)
- When a slash character (`/`) was used as part of the name of an index on an `NDB` table, attempting to execute a `TRUNCATE TABLE` statement on the table failed with the error `Index not found`, and the table was rendered unusable. (Bug #38914)
- **Disk Data**: **Partitioning**: When using multi-threaded data nodes, an `NDB` table created with a very large value for the `MAX_ROWS` option could—if this table was dropped and a new table with fewer partitions, but having the same table ID, was created—cause `ndbmtd` to crash when performing a system restart. This was because the server attempted to examine each partition whether or not it actually existed.

  This issue is the same as that reported in Bug #45154, except that the current issue is specific to `ndbmtd` instead of `ndbd`. (Bug #58638)
- **Disk Data**: In certain cases, a race condition could occur when `DROP LOGFILE GROUP` removed the logfile group while a read or write of one of the effected files was in progress, which in turn could lead to a crash of the data node. (Bug #59502)
- **Disk Data**: A race condition could sometimes be created when `DROP TABLESPACE` was run concurrently with a local checkpoint; this could in turn lead to a crash of the data node. (Bug #59501)
- **Disk Data**: Performing what should have been an online drop of a multi-column index was actually performed offline. (Bug #55618)
- **Disk Data**: When at least one data node was not running, queries against the `INFORMATION_SCHEMA.FILES` table took an excessive length of time to complete because the MySQL server waited for responses from any stopped nodes to time out. Now, in such cases, MySQL does not attempt to contact nodes which are not known to be running. (Bug #54199)
- **Cluster API**: It was not possible to obtain the status of nodes accurately after an attempt to stop a data node using `ndb_mgm_stop()` failed without returning an error. (Bug #58319)

- **Cluster API**: Attempting to read the same value (using `getValue()`) more than 9000 times within the same transaction caused the transaction to hang when executed. Now when more reads are performed in this way than can be accommodated in a single transaction, the call to `execute()` fails with a suitable error. (Bug #58110)

Changes in MySQL Cluster NDB 7.1.9a (5.1.51-ndb-7.1.9a)

Bugs Fixed

- **Important Note**: Issuing an `ALL DUMP` command during a rolling upgrade to MySQL Cluster NDB 7.1.9 caused the cluster to crash. (Bug #58256)

- **InnoDB**: **Packaging**: The `InnoDB` plugin was not included in MySQL Cluster RPM packages. (Bug #58283)

  References: See also Bug #54912.

Changes in MySQL Cluster NDB 7.1.9 (5.1.51-ndb-7.1.9)

Functionality Added or Changed

- **Important Change**: **InnoDB**: Building the MySQL Server with the `InnoDB` plugin is now supported when building MySQL Cluster. For more information, see MySQL Cluster Installation. (Bug #54912)

  References: See also Bug #58283.

- **Important Change**: `ndbd` now bypasses use of Non-Uniform Memory Access support on Linux hosts by default. If your system supports NUMA, you can enable it and override `ndbd` use of interleaving by setting the `Numa` [1854] data node configuration parameter which is added in this release. See Defining Data Nodes: Realtime Performance Parameters, for more information. (Bug #57807)

- **Important Change**: The `Id` configuration parameter used with MySQL Cluster management, data, and API nodes (including SQL nodes) is now deprecated, and the `NodeId` parameter (long available as a synonym for `Id` when configuring these types of nodes) should be used instead. `Id` continues to be supported for reasons of backward compatibility, but now generates a warning when used with these types of nodes, and is subject to removal in a future release of MySQL Cluster.

  This change affects the name of the configuration parameter only, establishing a clear preference for `NodeId` over `Id` in the `[mgmd]`, `[ndbd]`, `[mysql]`, and `[api]` sections of the MySQL Cluster global configuration (`config.ini`) file. The behavior of unique identifiers for management, data, and SQL and API nodes in MySQL Cluster has not otherwise been altered.

  The `Id` parameter as used in the `[computer]` section of the MySQL Cluster global configuration file is not affected by this change.

- A new `diskpagebuffer` table, providing statistics on disk page buffer usage by Disk Data tables, is added to the `ndbinfo` information database. These statistics can be used to monitor performance of reads and writes on Disk Data tables, and to assist in the tuning of related parameters such as `DiskPageBufferMemory` [1856].

Bugs Fixed

- **Packaging**: MySQL Cluster RPM distributions did not include a `shared-compat` RPM for the MySQL Server, which meant that MySQL applications depending on `libmysqlclient.so.15` (MySQL 5.0 and earlier) no longer worked. (Bug #38596)

- On Windows, the angel process which monitors and (when necessary) restarts the data node process failed to spawn a new worker in some circumstances where the arguments vector contained extra items placed at its beginning. This could occur when the path to `ndbd.exe` or `ndbmtd.exe` contained one or more spaces. (Bug #57949)

- The disconnection of an API or management node due to missed heartbeats led to a race condition which could cause data nodes to crash. (Bug #57946)
- The method for calculating table schema versions used by schema transactions did not follow the established rules for recording schemas used in the `P0.SchemaLog` file. (Bug #57897)

  References: See also Bug #57896.
- The `LQHKEYREQ` request message used by the local query handler when checking the major schema version of a table, being only 16 bits wide, could cause this check to fail with an `Invalid schema version` error (`NDB` error code 1227). This issue occurred after creating and dropping (and re-creating) the same table 65537 times, then trying to insert rows into the table. (Bug #57896)

  References: See also Bug #57897.
- Transient errors during a local checkpoint were not retried, leading to a crash of the data node. Now when such errors occur, they are retried up to 10 times if necessary. (Bug #57650)
- When a data node angel process failed to fork off a new worker process (to replace one that had failed), the failure was not handled. This meant that the angel process either transformed itself into a worker process, or itself failed. In the first case, the data node continued to run, but there was no longer any angel to restart it in the event of failure, even with `StopOnError` [1832] set to 0. (Bug #53456)
- Data nodes compiled with `gcc` 4.5 or higher crashed during startup. (Bug #57761)
- Queries using `WHERE varchar_pk_column LIKE 'pattern%'` or `WHERE varchar_pk_column LIKE 'pattern_'` against an `NDB` table having a `VARCHAR` column as its primary key failed to return all matching rows. (Bug #56853)
- `ndb_restore` now retries failed transactions when replaying log entries, just as it does when restoring data. (Bug #57618)
- The `SUMA` kernel block has a 10-element ring buffer for storing out-of-order `SUB_GCP_COMPLETE_REP` signals received from the local query handlers when global checkpoints are completed. In some cases, exceeding the ring buffer capacity on all nodes of a node group at the same time caused the node group to fail with an assertion. (Bug #57563)
- During a GCP takeover, it was possible for one of the data nodes not to receive a `SUB_GCP_COMPLETE_REP` signal, with the result that it would report itself as `GCP_COMMITTING` while the other data nodes reported `GCP_PREPARING`. (Bug #57522)
- A GCP stop is detected using 2 parameters which determine the maximum time that a global checkpoint or epoch can go unchanged; one of these controls this timeout for GCPs and one controls the timeout for epochs. Suppose the cluster is configured such that `TimeBetweenEpochsTimeout` [1840] is 100 ms but `HeartbeatIntervalDbDb` [1836] is 1500 ms. A node failure can be signalled after 4 missed heartbeats—in this case, 6000 ms. However, this would exceed `TimeBetweenEpochsTimeout` [1840], causing false detection of a GCP. To prevent this from happening, the configured value for `TimeBetweenEpochsTimeout` [1840] is automatically adjusted, based on the values of `HeartbeatIntervalDbDb` [1836] and `ArbitrationTimeout` [1844].

  The current issue arose when the automatic adjustment routine did not correctly take into consideration the fact that, during cascading node-failures, several intervals of length `4 * (HeartbeatIntervalDBDB + ArbitrationTimeout)` may elapse before all node failures have internally been resolved. This could cause false GCP detection in the event of a cascading node failure. (Bug #57322)
- Specifying a `WHERE` clause of the form *`range1`* `OR` *`range2`* when selecting from an `NDB` table having a primary key on multiple columns could result in Error 4259 `Invalid set of range scan bounds` if *`range2`* started exactly where *`range1`* ended and the primary key definition declared the columns in a different order relative to the order in the table's column list. (Such a query

should simply return all rows in the table, since any expression *`value < constant OR value >= constant`* is always true.)

Example. Suppose `t` is an `NDB` table defined by the following `CREATE TABLE` statement:

```
CREATE TABLE t (a, b, PRIMARY KEY (b, a)) ENGINE NDB;
```

This issue could then be triggered by a query such as this one:

```
SELECT * FROM t WHERE b < 8 OR b >= 8;
```

In addition, the order of the ranges in the `WHERE` clause was significant; the issue was not triggered, for example, by the query `SELECT * FROM t WHERE b <= 8 OR b > 8`. (Bug #57396)

- A number of cluster log warning messages relating to deprecated configuration parameters contained spelling, formatting, and other errors. (Bug #57381)
- The `MAX_ROWS` option for `CREATE TABLE` was ignored, which meant that it was not possible to enable multi-threaded building of indexes. (Bug #57360)
- Aborting a native `NDB` backup in the `ndb_mgm` client using the `ABORT BACKUP` command did not work correctly when using `ndbmtd`, in some cases leading to a crash of the cluster. (Bug #56285)
- Successive `CREATE NODEGROUP` and `DROP NODEGROUP` commands could cause `mysqld` processes to crash. (Bug #57164)
- **Disk Data**: When performing online DDL on Disk Data tables, scans and moving of the relevant tuples were done in more or less random order. This fix causes these scans to be done in the order of the tuples, which should improve performance of such operations due to the more sequential ordering of the scans. (Bug #57848)

  References: See also Bug #57827.
- **Disk Data**: Adding unique indexes to `NDB` Disk Data tables could take an extremely long time. This was particularly noticeable when using `ndb_restore --rebuild-indexes [2002]`. (Bug #57827)
- **Cluster API**: An application dropping a table at the same time that another application tried to set up a replication event on the same table could lead to a crash of the data node. The same issue could sometimes cause `NdbEventOperation::execute()` to hang. (Bug #57886)
- **Cluster API**: An NDB API client program under load could abort with an assertion error in `TransporterFacade::remove_from_cond_wait_queue`. (Bug #51775)

  References: See also Bug #32708.

Changes in MySQL Cluster NDB 7.1.8 (5.1.47-ndb-7.1.8)

Functionality Added or Changed

- It is now possible using the `ndb_mgm` management client or the MGM API to force a data node shutdown or restart even if this would force the shutdown or restart of the entire cluster.

  In the management client, this is implemented through the addition of the `-f` (force) option to the `STOP` and `RESTART` commands. For more information, see Commands in the MySQL Cluster Management Client.

  The MGM API also adds two new methods for forcing such a node shutdown or restart; see `ndb_mgm_stop4()`, and `ndb_mgm_restart4()`, for more information about these methods. (Bug #54226)
- `mysqldump` as supplied with MySQL Cluster now has an `--add-drop-trigger` [294] option which adds a `DROP TRIGGER IF EXISTS` statement before each dumped trigger definition. (Bug #55691)

References: See also Bug #34325, Bug #11747863.

- **Cluster API**: The MGM API function `ndb_mgm_get_version()`, which was previously internal, has now been moved to the public API. This function can be used to get `NDB` storage engine and other version information from the management server. (Bug #51310)

  References: See also Bug #51273.

Bugs Fixed

- At startup, an `ndbd` or `ndbmtd` process creates directories for its file system without checking to see whether they already exist. Portability code added in MySQL Cluster NDB 7.0.18 and MySQL Cluster NDB 7.1.7 did not account for this fact, printing a spurious error message when a directory to be created already existed. This unneeded printout has been removed. (Bug #57087)

- The text file `cluster_change_hist.txt` containing old MySQL Cluster changelog information was no longer being maintained, and so has been removed from the tree. (Bug #56116)

- Memory pages used for `DataMemory` [1817], once assigned to ordered indexes, were not ever freed, even after any rows that belonged to the corresponding indexes had been deleted. (Bug #56829)

- A data node can be shut down having completed and synchronized a given GCI *x*, while having written a great many log records belonging to the next GCI *x* + 1, as part of normal operations. However, when starting, completing, and synchronizing GCI *x* + 1, then the log records from original start must not be read. To make sure that this does not happen, the REDO log reader finds the last GCI to restore, scans forward from that point, and erases any log records that were not (and should never be) used.

  The current issue occurred because this scan stopped immediately as soon as it encountered an empty page. This was problematic because the REDO log is divided into several files; thus, it could be that there were log records in the beginning of the next file, even if the end of the previous file was empty. These log records were never invalidated; following a start or restart, they could be reused, leading to a corrupt REDO log. (Bug #56961)

- An error in program flow in `ndbd.cpp` could result in data node shutdown routines being called multiple times. (Bug #56890)

- In certain cases, `DROP DATABASE` could sometimes leave behind a cached table object, which caused problems with subsequent DDL operations. (Bug #56840)

- Under certain rare conditions, attempting to start more than one `ndb_mgmd` process simultaneously using the `--reload` [1966] option caused a race condition such that none of the `ndb_mgmd` processes could start. (Bug #56844)

- When distributing `CREATE TABLE` and `DROP TABLE` operations among several SQL nodes attached to a MySQL Cluster. the `LOCK_OPEN` lock normally protecting `mysqld`'s internal table list is released so that other queries or DML statements are not blocked. However, to make sure that other DDL is not executed simultaneously, a global schema lock (implemented as a row-level lock by `NDB`) is used, such that all operations that can modify the state of the `mysqld` internal table list also need to acquire this global schema lock. The `SHOW TABLE STATUS` statement did not acquire this lock. (Bug #56841)

- When multiple SQL nodes were connected to the cluster and one of them stopped in the middle of a DDL operation, the `mysqld` process issuing the DDL timed out with the error `distributing tbl_name timed out. Ignoring`. (Bug #56763)

- MySQL Cluster stores, for each row in each `NDB` table, a Global Checkpoint Index (GCI) which identifies the last committed transaction that modified the row. As such, a GCI can be thought of as a coarse-grained row version.

Due to changes in the format used by NDB to store local checkpoints (LCPs) in MySQL Cluster NDB 6.3.11, it could happen that, following cluster shutdown and subsequent recovery, the GCI values for some rows could be changed unnecessarily; this could possibly, over the course of many node or system restarts (or both), lead to an inconsistent database. (Bug #56770)

- An online ALTER TABLE ... ADD COLUMN operation that changed the table schema such that the number of 32-bit words used for the bitmask allocated to each DML operation increased during a transaction in DML which was performed prior to DDL which was followed by either another DML operation or—if using replication—a commit, led to data node failure.

  This was because the data node did not take into account that the bitmask for the before-image was smaller than the current bitmask, which caused the node to crash. (Bug #56524)

  References: This bug is a regression of Bug #35208.

- On Windows, a data node refused to start in some cases unless the ndbd.exe executable was invoked using an absolute rather than a relative path. (Bug #56257)

- The failure of a data node during some scans could cause other data nodes to fail. (Bug #54945)

- Exhausting the number of available commit-ack markers (controlled by the MaxNoOfConcurrentTransactions [1821] parameter) led to a data node crash. (Bug #54944)

- When running a SELECT on an NDB table with BLOB or TEXT columns, memory was allocated for the columns but was not freed until the end of the SELECT. This could cause problems with excessive memory usage when dumping (using for example mysqldump) tables with such columns and having many rows, large column values, or both. (Bug #52313)

  References: See also Bug #56488, Bug #50310.

- **Cluster API**: The MGM API functions ndb_mgm_stop() and ndb_mgm_restart() set the error code and message without first checking whether the management server handle was NULL, which could lead to fatal errors in MGM API applications that depended on these functions. (Bug #57089)

- **Cluster API**: The MGM API function ndb_mgm_get_version() did not set the error message before returning with an error. With this fix, it is now possible to call ndb_mgm_get_latest_error() after a failed call to this function such that ndb_mgm_get_latest_error() returns an error number and error message, as expected of MGM API calls. (Bug #57088)

Changes in MySQL Cluster NDB 7.1.7 (5.1.47-ndb-7.1.7)

Functionality Added or Changed

- **Important Change**: More finely grained control over restart-on-failure behavior is provided with two new data node configuration parameters MaxStartFailRetries [1863] and StartFailRetryDelay [1863]. MaxStartFailRetries [1863] limits the total number of retries made before giving up on starting the data node; StartFailRetryDelay [1863] sets the number of seconds between retry attempts.

  These parameters are used only if StopOnError [1832] is set to 0.

  For more information, see Defining MySQL Cluster Data Nodes. (Bug #54341)

Bugs Fixed

- **Important Change**: It is no longer possible to make a dump of the ndbinfo database using mysqldump. (Bug #54316)

- ndb_restore always reported 0 for the GCPStop (end point of the backup). Now it provides useful binary log position and epoch information. (Bug #56298)

- The `LockExecuteThreadToCPU [1852]` configuration parameter was not handled correctly for CPU ID values greater than 255. (Bug #56185)

- Trying to create a table having a `BLOB` or `TEXT` column with `DEFAULT ''` failed with the error `Illegal null attribute`. (An empty default is permitted and ignored by `MyISAM`; `NDB` should do the same.) (Bug #55121)

- Following a failure of the master data node, the new master sometimes experienced a race condition which caused the node to terminate with a **`GcpStop`** error. (Bug #56044)

- `ndb_mgmd --nodaemon [1965]` logged to the console in addition to the configured log destination. (Bug #54779)

- The warning `MaxNoOfExecutionThreads (#) > LockExecuteThreadToCPU count (#), this could cause contention` could be logged when running `ndbd`, even though the condition described can occur only when using `ndbmtd`. (Bug #54342)

- Startup messages previously written by `ndb_mgmd` to `stdout` are now written to the cluster log instead when `LogDestination [1810]` is set. (Bug #47595)

- The graceful shutdown of a data node could sometimes cause transactions to be aborted unnecessarily. (Bug #18538)

  References: See also Bug #55641.

Changes in MySQL Cluster NDB 7.1.6 (5.1.47-ndb-7.1.6)

Functionality Added or Changed

- Added the `DictTrace` data node configuration parameter, for use in debugging `NDB` code. For more information, see Defining MySQL Cluster Data Nodes. (Bug #55963)

- Added the `--server-id-bits` option for mysqld and mysqlbinlog.

  For `mysqld`, the `--server-id-bits [1918]` option indicates the number of least significant bits within the 32-bit server ID which actually identify the server. Indicating that the server ID uses less than 32 bits permits the remaining bits to be used for other purposes by NDB API applications using the Event API and `OperationOptions::AnyValue`.

  For `mysqlbinlog`, the `--server-id-bits [353]` option tells `mysqlbinlog` how to interpret the server IDs in the binary log when the binary log was written by a `mysqld` having its `server_id_bits [1935]` set to less than the maximum (32). (Bug #52305)

Bugs Fixed

- **Cluster API**: **Important Change**: The poll and select calls made by the MGM API were not interrupt-safe; that is, a signal caught by the process while waiting for an event on one or more sockets returned error -1 with `errno` set to `EINTR`. This caused problems with MGM API functions such as `ndb_logevent_get_next()` and `ndb_mgm_get_status2()`.

  To fix this problem, the internal `ndb_socket_poller::poll()` function has been made `EINTR`-safe.

  The old version of this function has been retained as `poll_unsafe()`, for use by those parts of NDB that do not need the `EINTR`-safe version of the function. (Bug #55906)

- Starting `ndb_mgmd` with `--config-cache=0 [1963]` caused it to leak memory. (Bug #55205)

- When another data node failed, a given data node `DBTC` kernel block could time out while waiting for `DBDIH` to signal commits of pending transactions, leading to a crash. Now in such cases the timeout generates a prinout, and the data node continues to operate. (Bug #55715)

- An excessive number of timeout warnings (normally used only for debugging) were written to the data node logs. (Bug #53987)
- The TCP configuration parameters `HostName1` and `HostName2` were not displayed in the output of `ndb_config --configinfo` [1975]. (Bug #55839)
- It was possible for a `DROP DATABASE` statement to remove `NDB` hidden blob tables without removing the parent tables, with the result that the tables, although hidden to MySQL clients, were still visible in the output of `ndb_show_tables` but could not be dropped using `ndb_drop_table`. (Bug #54788)
- The `configure.js` option `WITHOUT_DYNAMIC_PLUGINS=TRUE` was ignored when building MySQL Cluster for Windows using `CMake`. Among the effects of this issue was that `CMake` attempted to build the `InnoDB` storage engine as a plugin (`.DLL` file) even though the `InnoDB Plugin` is not currently supported by MySQL Cluster. (Bug #54913)
- **Disk Data**: As an optimization when inserting a row to an empty page, the page is not read, but rather simply initialized. However, this optimzation was performed in all cases when an empty row was inserted, even though it should have been done only if it was the first time that the page had been used by a table or fragment. This is because, if the page had been in use, and then all records had been released from it, the page still needed to be read to learn its log sequence number (LSN).

  This caused problems only if the page had been flushed using an incorrect LSN and the data node failed before any local checkpoint was completed—which would remove any need to apply the undo log, hence the incorrect LSN was ignored.

  The user-visible result of the incorrect LSN was that it caused the data node to fail during a restart. It was perhaps also possible (although not conclusively proven) that this issue could lead to incorrect data. (Bug #54986)
- **Cluster API**: Calling `NdbTransaction::refresh()` did not update the timer for `TransactionInactiveTimeout` [1841]. (Bug #54724)

Changes in MySQL Cluster NDB 7.1.5 (5.1.47-ndb-7.1.5)

Functionality Added or Changed

- Restrictions on some types of mismatches in column definitions when restoring data using `ndb_restore` have been relaxed. These include the following types of mismatches:
  - Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
  - Different `STORAGE` settings (`MEMORY`, `DISK`)
  - Different default values
  - Different distribution key settings

  Now, when one of these types of mismatches in column definitions is encountered, `ndb_restore` no longer stops with an error; instead, it accepts the data and inserts it into the target table, while issuing a warning to the user.

  For more information, see `ndb_restore` — Restore a MySQL Cluster Backup. (Bug #54423)

  References: See also Bug #53810, Bug #54178, Bug #54242, Bug #54279.
- It is now possible to install management node and data node processes as Windows services. (See Installing MySQL Cluster Processes as Windows Services, for more information.) In addition, data node processes on Windows are now maintained by angel processes, just as they are on other platforms supported by MySQL Cluster.

Bugs Fixed

- The disconnection of all API nodes (including SQL nodes) during an `ALTER TABLE` caused a memory leak. (Bug #54685)
- If a node shutdown (either in isolation or as part of a system shutdown) occurred directly following a local checkpoint, it was possible that this local checkpoint would not be used when restoring the cluster. (Bug #54611)
- When adding multiple new node groups to a MySQL Cluster, it was necessary for each new node group to add only the nodes to be assigned to the new node group, create that node group using `CREATE NODEGROUP`, then repeat this process for each new node group to be added to the cluster. The fix for this issue makes it possible to add all of the new nodes at one time, and then issue several `CREATE NODEGROUP` commands in succession. (Bug #54497)
- The setting for `BuildIndexThreads` [1854] was ignored by `ndbmtd`, which made it impossible to use more than 4 cores for rebuilding indexes. (Bug #54521)
- A table having the maximum number of attributes permitted could not be backed up using the `ndb_mgm` client.

  Note

  The maximum number of attributes supported per table is not the same for all MySQL Cluster releases. See Limits Associated with Database Objects in MySQL Cluster, to determine the maximum that applies in the release which you are using.

  (Bug #54155)
- When performing an online alter table where 2 or more SQL nodes connected to the cluster were generating binary logs, an incorrect message could be sent from the data nodes, causing `mysqld` processes to crash. This problem was often difficult to detect, because restarting SQL node or data node processes could clear the error, and because the crash in `mysqld` did not occur until several minutes after the erroneous message was sent and received. (Bug #54168)
- The two MySQL Server options, `--ndb-wait-connected` [1919] and `--ndb-wait-setup` [1919], did not set the corresponding system variables. (Bug #48402)
- The presence of duplicate `[tcp]` sections in the `config.ini` file caused the management server to crash. Now in such cases, `ndb_mgmd` fails gracefully with an appropriate error message. (Bug #49400)
- **Cluster API**: When using the NDB API, it was possible to rename a table with the same name as that of an existing table.

  Note

  This issue did not affect table renames executed using SQL on MySQL servers acting as MySQL Cluster API nodes.

  (Bug #54651)
- **Cluster API**: An excessive number of client connections, such that more than 1024 file descriptors, sockets, or both were open, caused NDB API applications to crash. (Bug #34303)

Changes in MySQL Cluster NDB 7.1.4b (5.1.44-ndb-7.1.4b)

Functionality Added or Changed

- **Important Change**: Commercial binary releases of MySQL Cluster NDB 7.1 now include support for the `InnoDB` storage engine. (Bug #52945)

  References: The patch for the following bug was reverted: Bug #31989.

Bugs Fixed

- **Cluster API**: The value of an internal constant used in the implementation of the `NdbOperation` and `NdbScanOperation` classes caused MySQL Cluster NDB 7.0 NDB API applications compiled against MySQL Cluster NDB 7.0.14 or earlier to fail when run with MySQL Cluster 7.0.15, and MySQL Cluster NDB 7.1 NDB API applications compiled against MySQL Cluster NDB 7.1.3 or earlier to break when used with MySQL Cluster 7.1.4. (Bug #54516)

Changes in MySQL Cluster NDB 7.1.4a (5.1.44-ndb-7.1.4a)

Bugs Fixed

- When using `mysqldump` to back up and restore schema information while using `ndb_restore` for restoring only the data, restoring to MySQL Cluster NDB 7.1.4 from an older version failed on tables having columns with default values. This was because versions of MySQL Cluster prior to MySQL Cluster NDB 7.1.4 did not have native support for default values.

  In addition, the MySQL Server supports `TIMESTAMP` columns having dynamic default values, such as `DEFAULT CURRENT_TIMESTAMP`; however, the current implementation of `NDB`-native default values permits only a constant default value.

  To fix this issue, the manner in which `NDB` treats `TIMESTAMP` columns is reverted to its pre-NDB-7.1.4 behavior (obtaining the default value from `mysqld` rather than `NDBCLUSTER`) except where a `TIMESTAMP` column uses a constant default, as in the case of a column declared as `TIMESTAMP DEFAULT 0` or `TIMESTAMP DEFAULT 20100607174832`. (Bug #54242)

Changes in MySQL Cluster NDB 7.1.4 (5.1.44-ndb-7.1.4)

Functionality Added or Changed

- **Important Change**: The maximum number of attributes (columns plus indexes) per table has increased to 512.

- A `--wait-nodes` option has been added for `ndb_waiter`. When this option is used, the program waits only for the nodes having the listed IDs to reach the desired state. For more information, see `ndb_waiter` — Wait for MySQL Cluster to Reach a Given Status. (Bug #52323)

- As part of this change, new methods relating to default values have been added to the `Column` and `Table` classes in the NDB API. For more information, see `Column::getDefaultValue()`, `Column::setDefaultValue()`, and `Table::hasDefaultValues()`. (Bug #30529)

- Added the `--skip-unknown-objects` [2003] option for `ndb_restore`. This option causes `ndb_restore` to ignore any schema objects which it does not recognize. Currently, this is useful chiefly for restoring native backups made from a cluster running MySQL Cluster NDB 7.0 to a cluster running MySQL Cluster NDB 6.3.

- Added the MySQL Cluster management server option `--config-cache` [1963], which makes it possible to enable and disable configuration caching. This option is turned on by default; to disable configuration caching, start `ndb_mgmd` with `--config-cache=0` [1963], or with `--skip-config-cache`. See `ndb_mgmd` — The MySQL Cluster Management Server Daemon, for more information.

Bugs Fixed

- **Cluster API**: **Incompatible Change**: The default behavior of the NDB API Event API has changed as follows:

  Previously, when creating an `Event`, DDL operations (alter and drop operations on tables) were automatically reported on any event operation that used this event, but as a result of this change, this is no longer the case. Instead, you must now invoke the event's `setReport()` method, with the new `EventReport` value `ER_DDL`, to get this behavior.

For existing NDB API applications where you wish to retain the old behavior, you must update the code as indicated previously, then recompile, following an upgrade. Otherwise, DDL operations are no longer reported after upgrading `libndbnclient`.

For more information, see The `Event::EventReport` Type, and `Event::setReport()`. (Bug #53308)

- **Cluster API**: **Incompatible Change**: The default behavior of the NDB API Event API has changed as follows:

  Previously, when creating an `Event`, DDL operations (alter and drop operations on tables) were automatically reported on any event operation that used this event, but as a result of this change, this is no longer the case. Instead, you must now invoke the event's `setReport()` method, with the new `EventReport` value `ER_DDL`, to get this behavior.

  For existing NDB API applications where you wish to retain the old behavior, you must update the code as indicated previously, then recompile, following an upgrade. Otherwise, DDL operations are no longer reported after upgrading `libndbnclient`.

  For more information, see The `Event::EventReport` Type, and `Event::setReport()`. (Bug #53308)

- After creating `NDB` tables until creation of a table failed due to `NDB` error 905 `Out of attribute records (increase MaxNoOfAttributes)`, then increasing `MaxNoOfAttributes` [1828] and restarting all management node and data node processes, attempting to drop and re-create one of the tables failed with the error `Out of table records...`, even when sufficient table records were available. (Bug #53944)

  References: See also Bug #52055. This bug is a regression of Bug #44294.

- Creating a Disk Data table, dropping it, then creating an in-memory table and performing a restart, could cause data node processes to fail with errors in the `DBTUP` kernel block if the new table's internal ID was the same as that of the old Disk Data table. This could occur because undo log handling during the restart did not check that the table having this ID was now in-memory only. (Bug #53935)

- An internal buffer allocator used by `NDB` has the form `alloc(wanted, minimum)` and attempts to allocate *`wanted`* pages, but is permitted to allocate a smaller number of pages, between *`wanted`* and *`minimum`*. However, this allocator could sometimes allocate fewer than *`minimum`* pages, causing problems with multi-threaded building of ordered indexes. (Bug #53580)

- A table created while `ndb_table_no_logging` [1930] was enabled was not always stored to disk, which could lead to a data node crash with `Error opening DIH schema files for table`. (Bug #53934)

- When compiled with support for `epoll` but this functionality is not available at runtime, MySQL Cluster tries to fall back to use the `select()` function in its place. However, an extra `ndbout_c()` call in the transporter registry code caused `ndbd` to fail instead. (Bug #53482)

- The value set for the `ndb_mgmd` option `--ndb-nodeid` [2017] was not verified prior to use as being within the permitted range (1 to 255, inclusive), leading to a crash of the management server. (Bug #53412)

- `NDB` truncated a column declared as `DECIMAL(65,0)` to a length of 64. Now such a column is accepted and handled correctly. In cases where the maximum length (65) is exceeded, `NDB` now raises an error instead of truncating. (Bug #53352)

- When creating an index, `NDB` failed to check whether the internal ID allocated to the index was within the permissible range, leading to an assertion. This issue could manifest itself as a data node failure with `NDB` error 707 (`No more table metadata records (increase MaxNoOfTables)`),

when creating tables in rapid succession (for example, by a script, or when importing from `mysqldump`), even with a relatively high value for `MaxNoOfTables` [1829] and a relatively low number of tables. (Bug #52055)

- When the `LogDestination` [1810] parameter was set using with a relative path, the management server failed to store its value unless started with `--initial` [1965] or `--reload` [1966]. (Bug #52268)
- `ndb_restore` did not raise any errors if hashmap creation failed during execution. (Bug #51434)
- When an `NDB` log handler failed, the memory allocated to it was freed twice. (Bug #53200)
- Setting `DataMemory` [1817] higher than 4G on 32-bit platforms caused `ndbd` to crash, instead of failing gracefully with an error. (Bug #52536, Bug #50928)
- Specifying the node ID as part of the `--ndb-connectstring` [1914] option to `mysqld` was not handled correctly.

  The fix for this issue includes the following changes:

  - Multiple occurrences of any of the `mysqld` options `--ndb-connectstring` [1914], `--ndb-mgmd-host` [1915], and `--ndb-nodeid` [1916] are now handled in the same way as with other MySQL server options, in that the value set in the last occurrence of the option is the value that is used by `mysqld`.

    Now, if `--ndb-nodeid` [1916] is used, its value overrides that of any `nodeid` setting used in `--ndb-connectstring` [1914]. For example, starting `mysqld` with `--ndb-connectstring=nodeid=1,10.100.1.100 --ndb-nodeid=3` now produces the same result as starting it with `--ndb-connectstring=nodeid=3,10.100.1.100`.
  - The 1024-character limit on the length of the connectstring is removed, and `--ndb-connectstring` [1914] is now handled in this regard in the same way as other `mysqld` options.
  - In the NDB API, a new constructor for `Ndb_cluster_connection` is added which takes as its arguments a connectstring and the node ID to force the API node to use.

  (Bug #44299)
- NDB did not distinguish correctly between table names differing only by lettercase when `lower_case_table_names` [492] was set to 0. (Bug #33158)
- `ndb_mgm -e "ALL STATUS"` erroneously reported that data nodes remained in start phase 0 until they had actually started.

Changes in MySQL Cluster NDB 7.1.3 (5.1.44-ndb-7.1.3)

Functionality Added or Changed

- **Incompatible Change**: The schema for the `memoryusage` table of the `ndbinfo` information database has changed, as detailed in the following list:
  - The `max` column has been renamed to `total`.
  - The `used` and `total` (formerly `max`) columns now display values in bytes rather than memory pages.
  - Added the columns `used_pages` and `total_pages` to show the amount of a resource used and total amount available in pages.
  - The size of the memory pages used for calculating data memory (`used_pages` and `total_pages` columns) is now 32K rather than 16K.

  For more information, aee The `ndbinfo memoryusage` Table.

- **Incompatible Change**: The schema for the `memoryusage` table of the `ndbinfo` information database has changed, as detailed in the following list:

  - The `max` column has been renamed to `total`.
  - The `used` and `total` (formerly `max`) columns now display values in bytes rather than memory pages.
  - Added the columns `used_pages` and `total_pages` to show the amount of a resource used and total amount available in pages.
  - The size of the memory pages used for calculating data memory (`used_pages` and `total_pages` columns) is now 32K rather than 16K.

  For more information, aee The `ndbinfo memoryusage` Table.

- **Important Change**: The experimental `pools` table has been removed from the `ndbinfo` database. Information useful to MySQL Cluster administration that was contained in this table should be available from other `ndbinfo` tables.

- **Important Note**: MySQL Cluster 7.1 is now supported for production use on Windows platforms.

  Important

  Some limitations specific to Windows remain; the most important of these are given in the following list:

  - There is not yet any Windows installer for MySQL Cluster; you must extract, place, configure, and start the necessary MySQL Cluster executables manually.
  - MySQL Cluster processes cannot yet be installed as Windows services. This means that each process executable must be run from a command prompt, and cannot be backgrounded. If you close the command prompt window in which you started the process, the process terminates.
  - There is as yet no “angel” process for data nodes; if a data node process quits, it must be restarted manually.
  - `ndb_error_reporter` is not yet available on Windows.
  - The multi-threaded data node process (`ndbmtd`) is not yet included in the binary distribution. However, it should be built automatically if you build MySQL Cluster from source.

  As with MySQL Cluster on other supported platforms, you cannot build MySQL Cluster for Windows from the MySQL Server 5.1 sources; you must use the source code from the MySQL Cluster NDB 7.1 tree.

Bugs Fixed

- If a node or cluster failure occurred while `mysqld` was scanning the `ndb.ndb_schema` table (which it does when attempting to connect to the cluster), insufficient error handling could lead to a crash by `mysqld` in certain cases. This could happen in a MySQL Cluster with a great many tables, when trying to restart data nodes while one or more `mysqld` processes were restarting. (Bug #52325)

- In MySQL Cluster NDB 7.0 and later, DDL operations are performed within schema transactions; the NDB kernel code for starting a schema transaction checks that all data nodes are at the same version before permitting a schema transaction to start. However, when a version mismatch was detected, the client was not actually informed of this problem, which caused the client to hang. (Bug #52228)

- After running a mixed series of node and system restarts, a system restart could hang or fail altogether. This was caused by setting the value of the newest completed global checkpoint too low

for a data node performing a node restart, which led to the node reporting incorrect GCI intervals for its first local checkpoint. (Bug #52217)

- A `mysqld`, when attempting to access the `ndbinfo` database, crashed if could not contact the management server. (Bug #51067)
- When performing a complex mix of node restarts and system restarts, the node that was elected as master sometimes required optimized node recovery due to missing `REDO` information. When this happened, the node crashed with `Failure to recreate object ... during restart, error 721` (because the `DBDICT` restart code was run twice). Now when this occurs, node takeover is executed immediately, rather than being made to wait until the remaining data nodes have started. (Bug #52135)

  References: See also Bug #48436.
- The internal variable `ndb_new_handler`, which is no longer used, has been removed. (Bug #51858)
- `ha_ndbcluster.cc` was not compiled with the same `SAFEMALLOC` and `SAFE_MUTEX` flags as the MySQL Server. (Bug #51857)
- When debug compiling MySQL Cluster on Windows, the mysys library was not compiled with -DSAFEMALLOC and -DSAFE_MUTEX, due to the fact that my_socket.c was misnamed as my_socket.cc. (Bug #51856)
- Some values shown in the `memoryusage` table did not match corresponding values shown by the `ndb_mgm` client `ALL REPORT MEMORYUSAGE` command. (Bug #51735)
- Restoring a MySQL Cluster backup between platforms having different endianness failed when also restoring metadata and the backup contained a hashmap not already present in the database being restored to. This issue was discovered when trying to restore a backup made on Solaris/SPARC to a MySQL Cluster running on Solaris/x86, but could conceivably occur in other cases where the endianness of the platform on which the backup was taken differed from that of the platform being restored to. (Bug #51432)
- The `mysql` client `system` command did not work properly. This issue was only known to affect the version of the `mysql` client that was included with MySQL Cluster NDB 7.0 and MySQL Cluster NDB 7.1 releases. (Bug #48574)
- The redo log protects itself from being filled up by periodically checking how much space remains free. If insufficient redo log space is available, it sets the state `TAIL_PROBLEM` which results in transactions being aborted with error code 410 (`out of redo log`). However, this state was not set following a node restart, which meant that if a data node had insufficient redo log space following a node restart, it could crash a short time later with `Fatal error due to end of REDO log`. Now, this space is checked during node restarts. (Bug #51723)
- **Cluster API**: **Packaging**: The file `META-INF/services/org.apache.openjpa.lib.conf.ProductDerivation` was missing from the `clusterjpa` JAR file. This could cause setting `openjpa.BrokerFactory` to “`ndb`” to be rejected. (Bug #52106)

  References: See also Bug #14192154.
- **Disk Data**: Inserts of blob column values into a MySQL Cluster Disk Data table that exhausted the tablespace resulted in misleading `no such tuple` error messages rather than the expected error `tablespace full`.

  This issue appeared similar to Bug #48113, but had a different underlying cause. (Bug #52201)
- **Disk Data**: DDL operations on Disk Data tables having a relatively small `UNDO_BUFFER_SIZE` could fail unexpectedly.

- **Cluster API**: A number of issues were corrected in the NDB API coding examples found in the `storage/ndb/ndbapi-examples` directory in the MySQL Cluster source tree. These included possible endless recursion in `ndbapi_scan.cpp` as well as problems running some of the examples on systems using Windows or Mac OS X due to the lettercase used for some table names. (Bug #30552, Bug #30737)

Changes in MySQL Cluster NDB 7.1.2 (5.1.41-ndb-7.1.2)

Functionality Added or Changed

- **Cluster API**: It is now possible to determine, using the `ndb_desc` utility or the NDB API, which data nodes contain replicas of which partitions. For `ndb_desc`, a new `--extra-node-info` [1982] option is added to cause this information to be included in its output. A new method `Table::getFragmentNodes()` is added to the NDB API for obtaining this information programmatically. (Bug #51184)

- **Cluster API**: It is now possible to determine, using the `ndb_desc` utility or the NDB API, which data nodes contain replicas of which partitions. For `ndb_desc`, a new `--extra-node-info` [1982] option is added to cause this information to be included in its output. A new method `Table::getFragmentNodes()` is added to the NDB API for obtaining this information programmatically. (Bug #51184)

- Numeric codes used in management server status update messages in the cluster logs have been replaced with text descriptions. (Bug #49627)

  References: See also Bug #44248.

- A new configuration parameter `HeartbeatThreadPriority` makes it possible to select between a first-in, first-out or round-round scheduling policy for management node and API node heartbeat threads, as well as to set the priority of these threads. See Defining a MySQL Cluster Management Server, or Defining SQL and Other API Nodes in a MySQL Cluster, for more information. (Bug #49617)

- Start phases are now written to the data node logs. (Bug #49158)

- Formerly, the `REPORT` and `DUMP` commands returned output to all `ndb_mgm` clients connected to the same MySQL Cluster. Now, these commands return their output only to the `ndb_mgm` client that actually issued the command. (Bug #40865)

- **Disk Data**: The `ndb_desc` utility can now show the extent space and free extent space for subordinate `BLOB` and `TEXT` columns (stored in hidden `BLOB` tables by NDB). A `--blob-info` [1982] option has been added for this program that causes `ndb_desc` to generate a report for each subordinate `BLOB` table. For more information, see `ndb_desc` — Describe NDB Tables. (Bug #50599)

Bugs Fixed

- **Important Change**: The `DATA_MEMORY` column of the `memoryusage` table was renamed to `memory_type`. (Bug #50926)

- Information about several management client commands was missing from (that is, truncated in) the output of the `HELP` command. (Bug #46114)

- The output of the `ndb_mgm` client `REPORT BACKUPSTATUS` command could sometimes contain errors due to uninitialized data. (Bug #51316)

- The following issues were fixed in the `ndb_mgm` client `REPORT MEMORYUSAGE` command:

  - The client sometimes inserted extra `ndb_mgm>` prompts within the output.

  - For data nodes running `ndbmtd`, `IndexMemory` [1819] was reported before `DataMemory` [1817].

- In addition, for data nodes running `ndbmtd`, there were multiple `IndexMemory` [1819] entries listed in the output.

(Bug #50196)

- Issuing a command in the `ndb_mgm` client after it had lost its connection to the management server could cause the client to crash. (Bug #49219)

- A `GROUP BY` query against `NDB` tables sometimes did not use any indexes unless the query included a `FORCE INDEX` option. With this fix, indexes are used by such queries (where otherwise possible) even when `FORCE INDEX` is not specified. (Bug #50736)

- When deciding how to divide the REDO log, the `DBDIH` kernel block saved more than was needed to restore the previous local checkpoint, which could cause REDO log space to be exhausted prematurely (`NDB` error 410). (Bug #51547)

- DML operations can fail with `NDB` error 1220 (`REDO log files overloaded...`) if the opening and closing of REDO log files takes too much time. If this occurred as a GCI marker was being written in the REDO log while REDO log file 0 was being opened or closed, the error could persist until a GCP stop was encountered. This issue could be triggered when there was insufficient REDO log space (for example, with configuration parameter settings `NoOfFragmentLogFiles = 6` and `FragmentLogFileSize = 6M`) with a load including a very high number of updates. (Bug #51512)

  References: See also Bug #20904.

- A `SELECT` requiring a sort could fail with the error `Can't find record in 'table'` when run concurrently with a `DELETE` from the same table. (Bug #45687)

- An attempted online upgrade from a MySQL Cluster NDB 6.3 or 7.0 release to a MySQL Cluster NDB 7.1 release failed, as the first upgraded data node rejected the remaining data nodes as using incompatible versions. (Bug #51429)

- A side effect of the `ndb_restore --disable-indexes` [2002] and `--rebuild-indexes` [2002] options is to change the schema versions of indexes. When a `mysqld` later tried to drop a table that had been restored from backup using one or both of these options, the server failed to detect these changed indexes. This caused the table to be dropped, but the indexes to be left behind, leading to problems with subsequent backup and restore operations. (Bug #51374)

- `ndb_restore` crashed while trying to restore a corrupted backup, due to missing error handling. (Bug #51223)

- Replication of a MySQL Cluster using multi-threaded data nodes could fail with forced shutdown of some data nodes due to the fact that `ndbmtd` exhausted `LongMessageBuffer` [1825] much more quickly than `ndbd`. After this fix, passing of replication data between the `DBTUP` and `SUMA` NDB kernel blocks is done using `DataMemory` [1817] rather than `LongMessageBuffer` [1825].

  Until you can upgrade, you may be able to work around this issue by increasing the `LongMessageBuffer` [1825] setting; doubling the default should be sufficient in most cases. (Bug #46914)

- Setting `IndexMemory` [1819] greater than 2GB could cause data nodes to crash while starting. (Bug #51256)

- The `ndb_restore` message `Successfully created index `PRIMARY`...` was directed to `stderr` instead of `stdout`. (Bug #51037)

- An initial restart of a data node configured with a large amount of memory could fail with a `Pointer too large` error. (Bug #51027)

  References: This bug was introduced by Bug #47818.

- When using `NoOfReplicas` [1815] equal to 1 or 2, if data nodes from one node group were restarted 256 times and applications were running traffic such that it would encounter `NDB` error 1204 (`Temporary failure, distribution changed`), the live node in the node group would crash, causing the cluster to crash as well. The crash occurred only when the error was encountered on the 256th restart; having the error on any previous or subsequent restart did not cause any problems. (Bug #50930)

- `ndbmtd` started on a single-core machine could sometimes fail with a `Job Buffer Full` error when `MaxNoOfExecutionThreads` [1855] was set greater than `LockExecuteThreadToCPU` [1852]. Now a warning is logged when this occurs. (Bug #50582)

- When the `MemReportFrequency` [1849] configuration parameter was set in `config.ini`, the `ndb_mgm` client `REPORT MEMORYUSAGE` command printed its output multiple times. (Bug #37632)

- `ndb_mgm -e "... REPORT ..."` did not write any output to `stdout`.

  The fix for this issue also prevents the cluster log from being flooded with `INFO` messages when `DataMemory` [1817] usage reaches 100%, and insures that when the usage is decreased, an appropriate message is written to the cluster log. (Bug #31542, Bug #44183, Bug #49782)

- **Disk Data**: The error message returned after atttempting to execute `ALTER LOGFILE GROUP` on an nonexistent logfile group did not indicate the reason for the failure. (Bug #51111)

- **Cluster API**: When reading blob data with lock mode `LM_SimpleRead`, the lock was not upgraded as expected. (Bug #51034)

- **Cluster API**: An issue internal to `ndb_mgm` could cause problems when trying to start a large number of data nodes at the same time. (Bug #51273)

  References: See also Bug #51310.

Changes in MySQL Cluster NDB 7.1.1 (5.1.41-ndb-7.1.1)

Functionality Added or Changed

- The `ndbinfo` database is added to provide MySQL Cluster metadata in real time. The tables making up this database contain information about memory, buffer, and other resource usage, as well as configuration parameters and settings, event counts, and other useful data. Access to `ndbinfo` is done by executing standard SQL queries on its tables using the `mysql` command-line client or other MySQL client application. No special setup procedures are required; `ndbinfo` is created automatically and visible in the output of `SHOW DATABASES` when the MySQL Server is connected to a MySQL Cluster.

  For more information, see The `ndbinfo` MySQL Cluster Information Database.

- **Cluster API**: ClusterJ 1.0 and ClusterJPA 1.0 are now available for programming Java applications with MySQL Cluster. ClusterJ is a Java connector providing an object-relational API for performing high-speed operations such as primary key lookups on a MySQL Cluster database, but does not require the use of the MySQL Server or JDBC (Connector/J). ClusterJ uses a new library NdbJTie which enables direct access from Java to the NDB API and thus to the `NDBCLUSTER` storage engine. ClusterJPA is a new implementation of OpenJPA, and can use either a JDBC connection to a MySQL Cluster SQL node (MySQL Server) or a direct connection to MySQL Cluster using NdbJTie, depending on availability and operational performance.

  ClusterJ, ClusterJPA, and NdbJTie require Java 1.5 or 1.6, and MySQL Cluster NDB 7.0 or later.

  All necessary libraries and other files for ClusterJ, ClusterJPA, and NdbJTie can be found in the MySQL Cluster NDB 7.1.1 or later distribution.

Bugs Fixed

- When a primary key lookup on an `NDB` table containing one or more `BLOB` columns was executed in a transaction, a shared lock on any blob tables used by the `NDB` table was held for the duration of the transaction. (This did not occur for indexed or non-indexed `WHERE` conditions.)

  Now in such cases, the lock is released after all `BLOB` data has been read. (Bug #49190)

Changes in MySQL Cluster NDB 7.1.0 (5.1.39-ndb-7.1.0)

This version was for testing and internal use only, and not officially released.

Functionality Added or Changed

- **Important Change**: The default value of the `DiskIOThreadPool` [1857] data node configuration parameter has changed from 8 to 2.

Bugs Fixed

- **Cluster API**: **Incompatible Change**: Several NDB API methods were declared as `const`, but did not return an `lvalue`, which caused compiler warnings when using `gcc` 4.3 or newer to perform the build. The methods affected are `NdbEventOperation::tableNameChanged()`, `NdbEventOperation::tableFrmChanged()`, `NdbEventOperation::tableFragmentationChanged()`, `NdbEventOperation::tableRangeListChanged()`, and `NdbOperation::getType()`. (Bug #44840)

- **Cluster API**: **Incompatible Change**: Several NDB API methods were declared as `const`, but did not return an `lvalue`, which caused compiler warnings when using `gcc` 4.3 or newer to perform the build. The methods affected are `NdbEventOperation::tableNameChanged()`, `NdbEventOperation::tableFrmChanged()`, `NdbEventOperation::tableFragmentationChanged()`, `NdbEventOperation::tableRangeListChanged()`, and `NdbOperation::getType()`. (Bug #44840)

- **Important Change**: The `--with-ndb-port-base` option for `configure` has been removed. It is now handled as an unknown and invalid option if you attempt to use it when configuring a build of MySQL Cluster. (Bug #47941)

  References: See also Bug #38502.

- The value set by the `--ndb-cluster-connection-pool` [1912] option was not shown in the output of `SHOW STATUS LIKE 'NDB%'`. (Bug #44118)

- `mysqld` could sometimes crash during a commit while trying to handle NDB Error 4028 `Node failure caused abort of transaction`. (Bug #38577)

Changes in the MySQL Cluster NDB 7.0 Series

This section contains unified change history highlights for all MySQL Cluster releases based on version 7.0 of the `NDBCLUSTER` storage engine through MySQL Cluster NDB 7.0.36. Included are all changelog entries in the categories *MySQL Cluster*, *Disk Data*, and *Cluster API*.

Early MySQL Cluster NDB 7.0 releases tagged “NDB 6.4.x” are also included in this listing.

For an overview of features that were added in MySQL Cluster NDB 7.0, see MySQL Cluster Development in MySQL Cluster NDB 7.0.

- Changes in MySQL Cluster NDB 7.0.34 (5.1.63-ndb-7.0.34) [2414]
- Changes in MySQL Cluster NDB 7.0.33 (5.1.61-ndb-7.0.33) [2414]
- Changes in MySQL Cluster NDB 7.0.32 (5.1.61-ndb-7.0.32) [2414]
- Changes in MySQL Cluster NDB 7.0.31 (5.1.61-ndb-7.0.31) [2415]

- Changes in MySQL Cluster NDB 7.0.30 (5.1.56-ndb-7.0.30) [2416]
- Changes in MySQL Cluster NDB 7.0.29 (5.1.56-ndb-7.0.29) [2416]
- Changes in MySQL Cluster NDB 7.0.28 (5.1.56-ndb-7.0.28) [2417]
- Changes in MySQL Cluster NDB 7.0.27 (5.1.56-ndb-7.0.27) [2417]
- Changes in MySQL Cluster NDB 7.0.26 (5.1.56-ndb-7.0.26) [2419]
- Changes in MySQL Cluster NDB 7.0.25 (5.1.56-ndb-7.0.25) [2420]
- Changes in MySQL Cluster NDB 7.0.24 (5.1.56-ndb-7.0.24) [2420]
- Changes in MySQL Cluster NDB 7.0.23 (5.1.51-ndb-7.0.23) [2421]
- Changes in MySQL Cluster NDB 7.0.22 (5.1.51-ndb-7.0.22) [2422]
- Changes in MySQL Cluster NDB 7.0.21 (5.1.51-ndb-7.0.21) [2423]
- Changes in MySQL Cluster NDB 7.0.20a (5.1.51-ndb-7.0.20a) [2427]
- Changes in MySQL Cluster NDB 7.0.20 (5.1.51-ndb-7.0.20) [2427]
- Changes in MySQL Cluster NDB 7.0.19 (5.1.47-ndb-7.0.19) [2429]
- Changes in MySQL Cluster NDB 7.0.18 (5.1.47-ndb-7.0.18) [2431]
- Changes in MySQL Cluster NDB 7.0.17 (5.1.47-ndb-7.0.17) [2432]
- Changes in MySQL Cluster NDB 7.0.16 (5.1.47-ndb-7.0.16) [2433]
- Changes in MySQL Cluster NDB 7.0.15b (5.1.44-ndb-7.0.15b) [2434]
- Changes in MySQL Cluster NDB 7.0.15a (5.1.44-ndb-7.0.15a) [2434]
- Changes in MySQL Cluster NDB 7.0.15 (5.1.44-ndb-7.0.15) [2435]
- Changes in MySQL Cluster NDB 7.0.14 (5.1.44-ndb-7.0.14) [2437]
- Changes in MySQL Cluster NDB 7.0.13 (5.1.41-ndb-7.0.13) [2439]
- Changes in MySQL Cluster NDB 7.0.12b (5.1.41-ndb-7.0.12b) [2441]
- Changes in MySQL Cluster NDB 7.0.12a (5.1.41-ndb-7.0.12a) [2441]
- Changes in MySQL Cluster NDB 7.0.12 (5.1.41-ndb-7.0.12) [2441]
- Changes in MySQL Cluster NDB 7.0.11b (5.1.41-ndb-7.0.11b) [2441]
- Changes in MySQL Cluster NDB 7.0.11a (5.1.41-ndb-7.0.11a) [2441]
- Changes in MySQL Cluster NDB 7.0.11 (5.1.41-ndb-7.0.11) [2441]
- Changes in MySQL Cluster NDB 7.0.10 (5.1.39-ndb-7.0.10) [2443]
- Changes in MySQL Cluster NDB 7.0.9b (5.1.39-ndb-7.0.9b) [2446]
- Changes in MySQL Cluster NDB 7.0.9a (5.1.39-ndb-7.0.9a) [2446]
- Changes in MySQL Cluster NDB 7.0.9 (5.1.39-ndb-7.0.9) [2447]
- Changes in MySQL Cluster NDB 7.0.8a (5.1.37-ndb-7.0.8a) [2451]
- Changes in MySQL Cluster NDB 7.0.8 (5.1.37-ndb-7.0.8) [2451]

- Changes in MySQL Cluster NDB 7.0.7 (5.1.35-ndb-7.0.7) [2455]
- Changes in MySQL Cluster NDB 7.0.6 (5.1.34-ndb-7.0.6) [2458]
- Changes in MySQL Cluster NDB 7.0.5 (5.1.32-ndb-7.0.5) [2460]
- Changes in MySQL Cluster NDB 7.0.4 (5.1.32-ndb-7.0.4) [2462]
- Changes in MySQL Cluster NDB 6.4.3 (5.1.32-ndb-6.4.3) [2463]
- Changes in MySQL Cluster NDB 6.4.2 (5.1.31-ndb-6.4.2) [2466]
- Changes in MySQL Cluster NDB 6.4.1 (5.1.31-ndb-6.4.1) [2467]
- Changes in MySQL Cluster NDB 6.4.0 (5.1.30-ndb-6.4.0) [2468]

Changes in MySQL Cluster NDB 7.0.34 (5.1.63-ndb-7.0.34)

Bugs Fixed

- If the Transaction Coordinator aborted a transaction in the “prepared” state, this could cause a resource leak. (Bug #14208924)
- When attempting to connect using a socket with a timeout, it was possible (if the timeout was exceeded) for the socket not to be set back to blocking. (Bug #14107173)
- In some circumstances, transactions could be lost during an online upgrade. (Bug #13834481)
- Attempting to add both a column and an index on that column in the same online `ALTER TABLE` statement caused `mysqld` to fail. Although this issue affected only the `mysqld` shipped with MySQL Cluster, the table named in the `ALTER TABLE` could use any storage engine for which online operations are supported. (Bug #12755722)
- **Cluster API**: When an NDB API application called `NdbScanOperation::nextResult()` again after the previous call had returned end-of-file (return code 1), a transaction object was leaked. Now when this happens, NDB returns error code 4210 (`Ndb sent more info than length specified`); previouslyu in such cases, -1 was returned. In addition, the extra transaction object associated with the scan is freed, by returning it to the transaction coordinator's idle list. (Bug #11748194)

Changes in MySQL Cluster NDB 7.0.33 (5.1.61-ndb-7.0.33)

Bugs Fixed

- `DUMP 2303` in the `ndb_mgm` client now includes the status of the single fragment scan record reserved for a local checkpoint. (Bug #13986128)
- A shortage of scan fragment records in `DBTC` resulted in a leak of concurrent scan table records and key operation records. (Bug #13966723)

Changes in MySQL Cluster NDB 7.0.32 (5.1.61-ndb-7.0.32)

Bugs Fixed

- **Important Change**: The `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement can be used to create new table partitions after new empty nodes have been added to a MySQL Cluster. Usually, the number of partitions to create is determined automatically, such that, if no new partitions are required, then none are created. This behavior can be overridden by creating the original table using the `MAX_ROWS` option, which indicates that extra partitions should be created to store a large number of rows. However, in this case `ALTER ONLINE TABLE ... REORGANIZE PARTITION` simply uses the `MAX_ROWS` value specified in the original `CREATE TABLE` statement to determine the number of partitions required; since this value remains constant, so does the number

of partitions, and so no new ones are created. This means that the table is not rebalanced, and the new data nodes remain empty.

To solve this problem, support is added for `ALTER ONLINE TABLE ... MAX_ROWS=newvalue`, where *`newvalue`* is greater than the value used with `MAX_ROWS` in the original `CREATE TABLE` statement. This larger `MAX_ROWS` value implies that more partitions are required; these are allocated on the new data nodes, which restores the balanced distribution of the table data.

For more information, see `ALTER TABLE` Syntax, and Adding MySQL Cluster Data Nodes Online. (Bug #13714648)

- When the `--skip-config-cache` [1963] and `--initial` [1965] options were used together, `ndb_mgmd` failed to start. (Bug #13857301)
- `ALTER ONLINE TABLE` failed when a `DEFAULT` option was used. (Bug #13830980)
- In some cases, restarting data nodes spent a very long time in Start Phase 101, when API nodes must connect to the starting node (using `NdbEventOperation`), when the API nodes trying to connect failed in a live-lock scenario. This connection process uses a handshake during which a small number of messages are exchanged, with a timeout used to detect failures during the handshake.

  Prior to this fix, this timeout was set such that, if one API node encountered the timeout, all other nodes connecting would do the same. The fix also decreases this timeout. This issue (and the effects of the fix) are most likely to be observed on relatively large configurations having 10 or more data nodes and 200 or more API nodes. (Bug #13825163)
- `ndbmtd` failed to restart when the size of a table definition exceeded 32K.

  (The size of a table definition is dependent upon a number of factors, but in general the 32K limit is encountered when a table has 250 to 300 columns.) (Bug #13824773)
- An initial start using `ndbmtd` could sometimes hang. This was due to a state which occurred when several threads tried to flush a socket buffer to a remote node. In such cases, to minimize flushing of socket buffers, only one thread actually performs the send, on behalf of all threads. However, it was possible in certain cases for there to be data in the socket buffer waiting to be sent with no thread ever being chosen to perform the send. (Bug #13809781)
- When trying to use `ndb_size.pl --hostname=`*`host:port`* to connect to a MySQL server running on a nonstandard port, the *`port`* argument was ignored. (Bug #13364905, Bug #62635)

Changes in MySQL Cluster NDB 7.0.31 (5.1.61-ndb-7.0.31)

Bugs Fixed

- **Important Change**: A number of changes have been made in the configuration of transporter send buffers.

  1. The data node configuration parameter `ReservedSendBufferMemory` [1861] is now deprecated, and thus subject to removal in a future MySQL Cluster release. `ReservedSendBufferMemory` has been non-functional since it was introduced and remains so.
  2. `TotalSendBufferMemory` now works correctly with data nodes using `ndbmtd`.
  3. `SendBufferMemory` [1870] can now over-allocate into `SharedGlobalMemory` [1856] for `ndbmtd` data nodes (only).
  4. A new data node configuration parameter `ExtraSendBufferMemory` [1861] is introduced. Its purpose is to control how much additional memory can be allocated to the send buffer over and above that specified by `TotalSendBufferMemory` or `SendBufferMemory`. The default setting (0) allows up to 16MB to be allocated automatically.

(Bug #13633845, Bug #11760629, Bug #53053)

- Setting `insert_id` [482] had no effect on the auto-increment counter for `NDB` tables. (Bug #13731134)
- A data node crashed when more than 16G fixed-size memory was allocated by `DBTUP` to one fragment (because the `DBACC` kernel block was not prepared to accept values greater than 32 bits from it, leading to an overflow). Now in such cases, the data node returns Error 889 `Table fragment fixed data reference has reached maximum possible value...`. When this happens, you can work around the problem by increasing the number of partitions used by the table (such as by using the `MAXROWS` option with `CREATE TABLE`). (Bug #13637411)

  References: See also Bug #11747870, Bug #34348.
- Several instances in the NDB code affecting the operation of multi-threaded data nodes, where `SendBufferMemory` was associated with a specific thread for an unnecessarily long time, have been identified and fixed, by minimizing the time that any of these buffers can be held exclusively by a given thread (send buffer memory being critical to operation of the entire node). (Bug #13618181)
- A very large value for `BackupWriteSize` [1851], as compared to `BackupMaxWriteSize` [1852], `BackupDataBufferSize` [1850], or `BackupLogBufferSize` [1850], could cause a local checkpoint or backup to hang. (Bug #13613344)
- Queries using `LIKE ... ESCAPE` on `NDB` tables failed when pushed down to the data nodes. Such queries are no longer pushed down, regardless of the value of `engine_condition_pushdown` [473]. (Bug #13604447, Bug #61064)
- To avoid TCP transporter overload, an overload flag is kept in the NDB kernel for each data node; this flag is used to abort key requests if needed, yielding error 1218 `Send Buffers overloaded in NDB kernel` in such cases. Scans can also put significant pressure on transporters, especially where scans with a high degree of parallelism are executed in a configuration with relatively small send buffers. However, in these cases, overload flags were not checked, which could lead to node failures due to send buffer exhaustion. Now, overload flags are checked by scans, and in cases where returning sufficient rows to match the batch size (`--ndb-batch-size` [1912] server option) would cause an overload, the number of rows is limited to what can be accommodated by the send buffer.

  See also Configuring MySQL Cluster Send Buffer Parameters. (Bug #13602508)
- A node failure and recovery while performing a scan on more than 32 partitions led to additional node failures during node takeover. (Bug #13528976)
- The `--skip-config-cache` [1963] option now causes `ndb_mgmd` to skip checking for the configuration directory, and thus to skip creating it in the event that it does not exist. (Bug #13428853)

Changes in MySQL Cluster NDB 7.0.30 (5.1.56-ndb-7.0.30)

Bugs Fixed

- At the beginning of a local checkpoint, each data node marks its local tables with a “to be checkpointed” flag. A failure of the master node during this process could cause either the LCP to hang, or one or more data nodes to be forcibly shut down. (Bug #13436481)
- A node failure while a `ANALYZE TABLE` statement was executing resulted in a hung connection (and the user was not informed of any error that would cause this to happen). (Bug #13416603)

  References: See also Bug #13407848.

Changes in MySQL Cluster NDB 7.0.29 (5.1.56-ndb-7.0.29)

Bugs Fixed

- Added the `MinFreePct` [1820] data node configuration parameter, which specifies a percentage of data node resources to hold in reserve for restarts. The resources monitored are `DataMemory` [1817], `IndexMemory` [1819], and any per-table `MAX_ROWS` settings (see `CREATE TABLE` Syntax). The default value of `MinFreePct` [1820] is 5, which means that 5% from each these resources is now set aside for restarts. (Bug #13436216)

- Because the log event buffer used internally by data nodes was circular, periodic events such as statistics events caused it to be overwritten too quickly. Now the buffer is partitioned by log event category, and its default size has been increased from 4K to 8K. (Bug #13394771)

- The `BatchSize` [1866] and `BatchByteSize` [1866] configuration parameters, used to control the maximum sizes of result batches, are defined as integers. However, the values used to store these were incorrectly interpreted as numbers of bytes in the NDB kernel. This caused the `DBLQH` kernel block to fail to detect when the specified `BatchByteSize` [1866] was consumed. (Bug #13355055)

- Previously, forcing simultaneously the shutdown of multiple data nodes using `SHUTDOWN -F` in the `ndb_mgm` management client could cause the entire cluster to fail. Now in such cases, any such nodes are forced to abort immediately. (Bug #12928429)

- `SELECT` statements using `LIKE CONCAT(...)` [951] `OR LIKE CONCAT(...)` in the `WHERE` clause returned incorrect results when run against `NDB` tables. (Bug #11765142, Bug #58073)

Changes in MySQL Cluster NDB 7.0.28 (5.1.56-ndb-7.0.28)

Functionality Added or Changed

- Introduced the `CrashOnCorruptedTuple` [1833] data node configuration parameter. When enabled, this parameter causes data nodes to handle corrupted tuples in a fail-fast manner —in other words, whenever the data node detects a corrupted tuple, it forcibly shuts down if `CrashOnCorruptedTuple` [1833] is enabled. For backward compatibility, this parameter is disabled by default. (Bug #12598636)

Bugs Fixed

- When a failure of multiple data nodes during a local checkpoint (LCP) that took a long time to complete included the node designated as master, any new data nodes attempting to start before all ongoing LCPs were completed later crashed. This was due to the fact that node takeover by the new master cannot be completed until there are no pending local checkpoints. Long-running LCPs such as those which triggered this issue can occur when fragment sizes are sufficiently large (see MySQL Cluster Nodes, Node Groups, Replicas, and Partitions, for more information). Now in such cases, data nodes (other than the new master) are kept from restarting until the takeover is complete. (Bug #13323589)

- When deleting from multiple tables using a unique key in the `WHERE` condition, the wrong rows were deleted. In addition, `UPDATE` triggers failed when rows were changed by deleting from or updating multiple tables. (Bug #12718336, Bug #61705, Bug #12728221)

- A **`SubscriberNodeIdUndefined`** error was previously unhandled, resulting in a data node crash, but is now handled by NDB Error 1429, `Subscriber node undefined in SubStartReq`. (Bug #12598496)

- Shutting down a `mysqld` while under load caused the spurious error messages `Opening ndb_binlog_index: killed` and `Unable to lock table ndb_binlog_index` to be written in the cluster log. (Bug #11930428)

Changes in MySQL Cluster NDB 7.0.27 (5.1.56-ndb-7.0.27)

Functionality Added or Changed

- It is now possible to filter the output from `ndb_config` so that it displays only system, data node, or connection parameters and values, using one of the options `--system` [1974], `--nodes` [1974], or

`--connections` [1974], respectively. In addition, it is now possible to specify from which data node the configuration data is obtained, using the `--config_from_node` [1972] option that is added in this release.

For more information, see `ndb_config` — Extract MySQL Cluster Configuration Information. (Bug #11766870)

Bugs Fixed

- **Cluster API**: **Incompatible Change**: Restarting a machine hosting data nodes, SQL nodes, or both, caused such nodes when restarting to time out while trying to obtain node IDs.

  As part of the fix for this issue, the behavior and default values for the NDB API `Ndb_cluster_connection::connect()` method have been improved. Due to these changes, the version number for the included NDB client library (`libndbclient.so`) has been increased from 4.0.0 to 5.0.0. For NDB API applications, this means that as part of any upgrade, you must do both of the following:

  - Review and possibly modify any NDB API code that uses the `connect()` method, in order to take into account its changed default retry handling.
  - Recompile any NDB API applications using the new version of the client library.

  Also in connection with this issue, the default value for each of the two `mysqld` options `--ndb-wait-connected` [1919] and `--ndb-wait-setup` [1919] has been increased to 30 seconds (from 0 and 15, respectively). In addition, a hard-coded 30-second delay was removed, so that the value of `--ndb-wait-connected` [1919] is now handled correctly in all cases. (Bug #12543299)

- **Cluster API**: **Incompatible Change**: Restarting a machine hosting data nodes, SQL nodes, or both, caused such nodes when restarting to time out while trying to obtain node IDs.

  As part of the fix for this issue, the behavior and default values for the NDB API `Ndb_cluster_connection::connect()` method have been improved. Due to these changes, the version number for the included NDB client library (`libndbclient.so`) has been increased from 4.0.0 to 5.0.0. For NDB API applications, this means that as part of any upgrade, you must do both of the following:

  - Review and possibly modify any NDB API code that uses the `connect()` method, in order to take into account its changed default retry handling.
  - Recompile any NDB API applications using the new version of the client library.

  Also in connection with this issue, the default value for each of the two `mysqld` options `--ndb-wait-connected` [1919] and `--ndb-wait-setup` [1919] has been increased to 30 seconds (from 0 and 15, respectively). In addition, a hard-coded 30-second delay was removed, so that the value of `--ndb-wait-connected` [1919] is now handled correctly in all cases. (Bug #12543299)

- Setting `IndexMemory` [1819] or sometimes `DataMemory` [1817] to 2 GB or higher could lead to data node failures under some conditions. (Bug #12873640)

- When replicating DML statements with `IGNORE` between clusters, the number of operations that failed due to nonexistent keys was expected to be no greater than the number of defined operations of any single type. Because the slave SQL thread defines operations of multiple types in batches together, code which relied on this assumption could cause `mysqld` to fail. (Bug #12859831)

- The maximum effective value for the `OverloadLimit` [1869] configuration parameter was limited by the value of `SendBufferMemory` [1870]. Now the value set for `OverloadLimit` [1869] is used correctly, up to this parameter's stated maximum (4G). (Bug #12712109)

- `AUTO_INCREMENT` values were not set correctly for `INSERT IGNORE` statements affecting `NDB` tables. This could lead such statements to fail with `Got error 4350 'Transaction already`

`aborted' from NDBCLUSTER` when inserting multiple rows containing duplicate values. (Bug #11755237, Bug #46985)

- When failure handling of an API node takes longer than 300 seconds, extra debug information is included in the resulting output. In cases where the API node's node ID was greater than 48, these extra debug messages could lead to a crash, and confuing output otherwise. This was due to an attempt to provide information specific to data nodes for API nodes as well. (Bug #62208)

- In rare cases, a series of node restarts and crashes during restarts could lead to errors while reading the redo log. (Bug #62206)

Changes in MySQL Cluster NDB 7.0.26 (5.1.56-ndb-7.0.26)

Functionality Added or Changed

- Added the `MaxDMLOperationsPerTransaction` [1822] data node configuration parameter, which can be used to limit the number of DML operations used by a transaction; if the transaction requires more than this many DML operations, the transaction is aborted. (Bug #12589613)

Bugs Fixed

- When global checkpoint indexes were written with no intervening end-of-file or megabyte border markers, this could sometimes lead to a situation in which the end of the redo log was mistakenly regarded as being between these GCIs, so that if the restart of a data node took place before the start of the next redo log was overwritten, the node encountered an `Error while reading the REDO log`. (Bug #12653993, Bug #61500)

  References: See also Bug #56961.

- Restarting a `mysqld` during a rolling upgrade with data nodes running a mix of old and new versions of the MySQL Cluster software caused the `mysqld` to run in read-only mode. (Bug #12651364, Bug #61498)

- Error reporting has been improved for cases in which API nodes are unable to connect due to apparent unavailability of node IDs. (Bug #12598398)

- Error messages for `Failed to convert connection` transporter registration problems were inspecific. (Bug #12589691)

- Under certain rare circumstances, a data node process could fail with Signal 11 during a restart. This was due to uninitialized variables in the `QMGR` kernel block. (Bug #12586190)

- Multiple management servers were unable to detect one another until all nodes had fully started. As part of the fix for this issue, two new status values `RESUME` and `CONNECTED` can be reported for management nodes in the output of the `ndb_mgm` client `SHOW` command (see Commands in the MySQL Cluster Management Client). Two corresponding status values `NDB_MGM_NODE_STATUS_RESUME` and `NDB_MGM_NODE_STATUS_CONNECTED` are also added to the list of possible values for an `ndb_mgm_node_status` data structure in the MGM API. (Bug #12352191, Bug #48301)

- Handling of the `MaxNoOfTables` [1829] and `MaxNoOfAttributes` [1828] configuration parameters was not consistent in all parts of the `NDB` kernel, and were only strictly enforced by the `DBDICT` and `SUMA` kernel blocks. This could lead to problems when tables could be created but not replicated. Now these parameters are treated by `SUMA` and `DBDICT` as suggested maximums rather than hard limits, as they are elsewhere in the `NDB` kernel. (Bug #61684)

- It was not possible to shut down a management node while one or more data nodes were stopped (for whatever reason). This issue was a regression introduced in MySQL Cluster NDB 7.0.24 and MySQL Cluster NDB 7.1.13. (Bug #61607)

  References: See also Bug #61147.

- **Cluster API**: Applications that included the header file `ndb_logevent.h` could not be built using the Microsoft Visual Studio C compiler or the Oracle (Sun) Studio C compiler due to empty struct definitions. (Bug #12678971)

- **Cluster API**: Within a transaction, after creating, executing, and closing a scan, calling `NdbTransaction::refresh()` after creating and executing but not closing a second scan caused the application to crash. (Bug #12646659)

Changes in MySQL Cluster NDB 7.0.25 (5.1.56-ndb-7.0.25)

Bugs Fixed

- The internal `Ndb_getinaddr()` function has been rewritten to use `getaddrinfo()` instead of `my_gethostbyname_r()` (which is removed in a later version of the MySQL Server). (Bug #12542120)

- Two unused test files in `storage/ndb/test/sql` contained incorrect versions of the GNU Lesser General Public License. The files and the directory containing them have been removed. (Bug #11810156)

  References: See also Bug #11810224.

- Error 1302 gave the wrong error message (`Out of backup record`). This has been corrected to `A backup is already running`. (Bug #11793592)

- When using two management servers, issuing in an `ndb_mgm` client connected to one management server a `STOP` command for stopping the other management server caused Error 2002 (`Stop failed ... Send to process or receive failed.: Permanent error: Application error`), even though the `STOP` command actually succeeded, and the second `ndb_mgmd` was shut down. (Bug #61147)

- Renaming a table having `BLOB` or `TEXT` columns (or both) to another database caused the SQL node to crash, and the table to become inaccessible afterwards. (Bug #60484)

- Under heavy loads with many concurrent inserts, temporary failures in transactions could occur (and were misreported as being due to `NDB` Error 899 `Rowid already allocated`). As part of the fix for this issue, `NDB` Error 899 has been reclassified as an internal error, rather than as a temporary transaction error. (Bug #56051, Bug #11763354)

- In `ndbmtd`, a node connection event is detected by a `CMVMI` thread which sends a `CONNECT_REP` signal to the `QMGR` kernel block. In a few isolated circumstances, a signal might be transferred to `QMGR` directly by the `NDB` transporter before the `CONNECT_REP` signal actually arrived. This resulted in reports in the error log with status `Temporary error, restart node`, and the message `Internal program error`. (Bug #61025)

- **Disk Data**: Accounting for `MaxNoOfOpenFiles` was incorrect with regard to to data files in MySQL Cluster Disk Data tablespaces. This could lead to a crash when `MaxNoOfOpenFiles` was exceeded. (Bug #12581213)

Changes in MySQL Cluster NDB 7.0.24 (5.1.56-ndb-7.0.24)

Functionality Added or Changed

- It is now possible to add data nodes online to a running MySQL Cluster without performing a rolling restart of the cluster or starting data node processes with the `--nowait-nodes` [1955] option. This can be done by setting `Nodegroup = 65536` [1815] in the `config.ini` file for any data nodes that should be started at a later time, when first starting the cluster. (It was possible to set `NodeGroup` [1815] to this value previously, but the management server failed to start.)

  As part of this fix, a new data node configuration parameter `StartNoNodeGroupTimeout` [1836] has been added. When the management server sees that there are data nodes with

no node group (that is, nodes for which `Nodegroup = 65536` [1815]), it waits `StartNoNodeGroupTimeout` [1836] milliseconds before treating these nodes as though they were listed with the `--nowait-nodes` [1955] option, and proceeds to start.

For more information, see Adding MySQL Cluster Data Nodes Online. (Bug #11766167, Bug #59213)

- A `config_generation` column has been added to the `nodes` table of the `ndbinfo` database. By checking this column, it is now possible to determine which version or versions of the MySQL Cluster configuration file are in effect on the data nodes. This information can be especially useful when performing a rolling restart of the cluster to update its configuration.

Bugs Fixed

- **Cluster API**: A unique index operation is executed in two steps: a lookup on an index table, and an operation on the base table. When the operation on the base table failed, while being executed in a batch with other operations that succeeded, this could lead to a hanging execute, eventually timing out with Error 4012 (`Request ndbd time-out, maybe due to high load or communication problems`). (Bug #12315582)

- **Cluster API**: A unique index operation is executed in two steps: a lookup on an index table, and an operation on the base table. When the operation on the base table failed, while being executed in a batch with other operations that succeeded, this could lead to a hanging execute, eventually timing out with Error 4012 (`Request ndbd time-out, maybe due to high load or communication problems`). (Bug #12315582)

- A memory leak in `LGMAN`, that leaked 8 bytes of log buffer memory per 32k written, was introduced in MySQL Cluster NDB 7.0.9, effecting all MySQL Cluster NDB 7.1 releases as well as MySQL Cluster NDB 7.0.9 and later MySQL Cluster NDB 7.0 releases. (For example, when 128MB log buffer memory was used, it was exhausted after writing 512GB to the undo log.) This led to a GCP stop and data node failure. (Bug #60946)

  References: This bug was introduced by Bug #47966.

- When using `ndbmtd`, a MySQL Cluster configured with 32 data nodes failed to start correctly. (Bug #60943)

- When performing a TUP scan with locks in parallel, and with a highly concurrent load of inserts and deletions, the scan could sometimes fail to notice that a record had moved while waiting to acquire a lock on it, and so read the wrong record. During node recovery, this could lead to a crash of a node that was copying data to the node being started, and a possible forced shutdown of the cluster.

- **Cluster API**: Performing interpreted operations using a unique index did not work correctly, because the interpret bit was kept when sending the lookup to the index table.

Changes in MySQL Cluster NDB 7.0.23 (5.1.51-ndb-7.0.23)

Functionality Added or Changed

- Improved scaling of ordered index scans performance by removing a hard-coded limit (`MAX_PARALLEL_INDEX_SCANS_PER_FRAG`) and making the number of `TUP` or `TUX` scans per fragment configurable by adding the `MaxParallelScansPerFragment` [1825] data node configuration parameter. (Bug #11769048)

Bugs Fixed

- **Important Change**: Formerly, the `--ndb-cluster-connection-pool` server option set a status variable as well as a system variable. The status variable has been removed as redundant. (Bug #60119)

- A scan with a pushed condition (filter) using the `CommittedRead` lock mode could hang for a short interval when it was aborted when just as it had decided to send a batch. (Bug #11932525)

- When aborting a multi-read range scan exactly as it was changing ranges in the local query handler, LQH could fail to detect it, leaving the scan hanging. (Bug #11929643)
- Schema distribution did not take place for tables converted from another storage engine to `NDB` using `ALTER TABLE`; this meant that such tables were not always visible to all SQL nodes attached to the cluster. (Bug #11894966)
- A GCI value inserted by `ndb_restore --restore_epoch` [1996] into the `ndb_apply_status` table was actually 1 less than the correct value. (Bug #11885852)
- **Disk Data**: Limits imposed by the size of `SharedGlobalMemory` [1856] were not always enforced consistently with regard to Disk Data undo buffers and log files. This could sometimes cause a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement to fail for no apparent reason, or cause the log file group specified by `InitialLogFileGroup` [1859] not to be created when starting the cluster. (Bug #57317)

Changes in MySQL Cluster NDB 7.0.22 (5.1.51-ndb-7.0.22)

Functionality Added or Changed

- **Disk Data**: The `INFORMATION_SCHEMA.TABLES` table now provides disk usage as well as memory usage information for Disk Data tables. Also, `INFORMATION_SCHEMA.PARTITIONS`, formerly did not show any statistics for `NDB` tables. Now the `TABLE_ROWS`, `AVG_ROW_LENGTH`, `DATA_LENGTH`, `MAX_DATA_LENGTH`, and `DATA_FREE` columns contain correct information for the table's partitions.
- **Disk Data**: The `INFORMATION_SCHEMA.TABLES` table now provides disk usage as well as memory usage information for Disk Data tables. Also, `INFORMATION_SCHEMA.PARTITIONS`, formerly did not show any statistics for `NDB` tables. Now the `TABLE_ROWS`, `AVG_ROW_LENGTH`, `DATA_LENGTH`, `MAX_DATA_LENGTH`, and `DATA_FREE` columns contain correct information for the table's partitions.
- A new `--rewrite-database` [2003] option is added for `ndb_restore`, which makes it possible to restore to a database having a different name from that of the database in the backup.

  For more information, see `ndb_restore` — Restore a MySQL Cluster Backup. (Bug #54327)
- The NDB kernel now implements a number of statistical counters relating to actions performed by or affecting `Ndb` objects, such as starting, closing, or aborting transactions; primary key and unique key operations; table, range, and pruned scans; blocked threads waiting for various operations to complete; and data and events sent and received by `NDBCLUSTER`. These NDB API counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes. `mysqld` exposes these counters as system status variables; their values can be read in the output of `SHOW STATUS`, or by querying the `SESSION_STATUS` or `GLOBAL_STATUS` table in the `INFORMATION_SCHEMA` database. By comparing the values of these status variables prior to and following the execution of SQL statements that act on `NDB` tables, you can observe the corresponding actions taken on the NDB API level, which can be beneficial for monitoring and performance tuning of MySQL Cluster.

  For more information, see NDB API Statistics Counters and Variables, as well as MySQL Cluster Status Variables.

Bugs Fixed

- **Important Note**: Due to an error in merging the original fix, it did not appear MySQL Cluster NDB 7.0.21; this oversight has been corrected in the current release. (Bug #58256)
- This issue affects all previous MySQL Cluster NDB 7.0 releases. (Bug #60045)
- `ndb_restore --rebuild-indexes [2002]` caused multi-threaded index building to occur on the master node only. (Bug #59920)
- Successive queries on the `counters` table from the same SQL node returned unchanging results. To fix this issue, and to prevent similar issues from occurring in the future, `ndbinfo` tables are now excluded from the query cache. (Bug #59831)

- When attempting to create a table on a MySQL Cluster with many standby data nodes (setting `Nodegroup=65536` [1815] in `config.ini` for the nodes that should wait, starting the nodes that should start immediately with the `--nowait-nodes` [1955] option, and using the `CREATE TABLE` statement's `MAX_ROWS` option), `mysqld` miscalculated the number of fragments to use. This caused the `CREATE TABLE` to fail.

  Note

  The `CREATE TABLE` failure caused by this issue in turn prevented any further attempts to create the table, even if the table structure was simplified or changed in such a way that the attempt should have succeeded. This “ghosting” issue is handled in Bug #59756.

  (Bug #59751)

- When a `CREATE TABLE` statement failed due to `NDB` error 1224 (`Too many fragments`), it was not possible to create the table afterward unless either it had no ordered indexes, or a `DROP TABLE` statement was issued first, even if the subsequent `CREATE TABLE` was valid and should otherwise have succeeded. (Bug #59756)

  References: See also Bug #59751.

- `NDB` sometimes treated a simple (not unique) ordered index as unique. (Bug #59519)

- The logic used in determining whether to collapse a range to a simple equality was faulty. In certain cases, this could cause `NDB` to treat a range as if it were a primary key lookup when determining the query plan to be used. Although this did not affect the actual result returned by the query, it could in such cases result in inefficient execution of queries due to the use of an inappropriate query plan. (Bug #59517)

- When a query used multiple references to or instances of the same physical tables, `NDB` failed to recognize these multiple instances as different tables; in such a case, `NDB` could incorrectly use condition pushdown on a condition referring to these other instances to be pushed to the data nodes, even though the condition should have been rejected as unpushable, leading to invalid results. (Bug #58791)

- **Cluster API**: When calling `NdbEventOperation::execute()` during a node restart, it was possible to get a spurious error 711 (`System busy with node restart, schema operations not allowed when a node is starting`). (Bug #59723)

- **Cluster API**: When an NDBAPI client application was waiting for more scan results after calling `NdbScanOperation::nextResult()`, the calling thread sometimes woke up even if no new batches for any fragment had arrived, which was unnecessary, and which could have a negative impact on the application's performance. (Bug #52298)

Changes in MySQL Cluster NDB 7.0.21 (5.1.51-ndb-7.0.21)

Functionality Added or Changed

- **Important Change**: The following changes have been made with regard to the `TimeBetweenEpochsTimeout` [1840] data node configuration parameter:

  - The maximum possible value for this parameter has been increased from 32000 milliseconds to 256000 milliseconds.

  - Setting this parameter to zero now has the effect of disabling GCP stops caused by save timeouts, commit timeouts, or both.

  - The current value of this parameter and a warning are written to the cluster log whenever a GCP save takes longer than 1 minute or a GCP commit takes longer than 10 seconds.

  For more information, see Disk Data and `GCP Stop` errors. (Bug #58383)

- Added the `--skip-broken-objects` [2003] option for `ndb_restore`. This option causes `ndb_restore` to ignore tables corrupted due to missing blob parts tables, and to continue reading from the backup file and restoring the remaining tables. (Bug #54613)

  References: See also Bug #51652.

- **Cluster API**: It is now possible to stop or restart a node even while other nodes are starting, using the MGM API `ndb_mgm_stop4()` or `ndb_mgm_restart4()` function, respectively, with the *`force`* parameter set to 1. (Bug #58451)

  References: See also Bug #58319.

Bugs Fixed

- **Cluster API**: In some circumstances, very large `BLOB` read and write operations in MySQL Cluster applications can cause excessive resource usage and even exhaustion of memory. To fix this issue and to provide increased stability when performing such operations, it is now possible to set limits on the volume of `BLOB` data to be read or written within a given transaction in such a way that when these limits are exceeded, the current transaction implicitly executes any accumulated operations. This avoids an excessive buildup of pending data which can result in resource exhaustion in the NDB kernel. The limits on the amount of data to be read and on the amount of data to be written before this execution takes place can be configured separately. (In other words, it is now possible in MySQL Cluster to specify read batching and write batching that is specific to `BLOB` data.) These limits can be configured either on the NDB API level, or in the MySQL Server.

  On the NDB API level, four new methods are added to the `NdbTransaction` object. `getMaxPendingBlobReadBytes()` and `setMaxPendingBlobReadBytes()` can be used to get and to set, respectively, the maximum amount of `BLOB` data to be read that accumulates before this implicit execution is triggered. `getMaxPendingBlobWriteBytes()` and `setMaxPendingBlobWriteBytes()` can be used to get and to set, respectively, the maximum volume of `BLOB` data to be written that accumulates before implicit execution occurs.

  For the MySQL server, two new options are added. The `--ndb-blob-read-batch-bytes` [1913] option sets a limit on the amount of pending `BLOB` data to be read before triggering implicit execution, and the `--ndb-blob-write-batch-bytes` [1913] option controls the amount of pending `BLOB` data to be written. These limits can also be set using the `mysqld` configuration file, or read and set within the `mysql` client and other MySQL client applications using the corresponding server system variables. (Bug #59113)

- **Cluster API**: In some circumstances, very large `BLOB` read and write operations in MySQL Cluster applications can cause excessive resource usage and even exhaustion of memory. To fix this issue and to provide increased stability when performing such operations, it is now possible to set limits on the volume of `BLOB` data to be read or written within a given transaction in such a way that when these limits are exceeded, the current transaction implicitly executes any accumulated operations. This avoids an excessive buildup of pending data which can result in resource exhaustion in the NDB kernel. The limits on the amount of data to be read and on the amount of data to be written before this execution takes place can be configured separately. (In other words, it is now possible in MySQL Cluster to specify read batching and write batching that is specific to `BLOB` data.) These limits can be configured either on the NDB API level, or in the MySQL Server.

  On the NDB API level, four new methods are added to the `NdbTransaction` object. `getMaxPendingBlobReadBytes()` and `setMaxPendingBlobReadBytes()` can be used to get and to set, respectively, the maximum amount of `BLOB` data to be read that accumulates before this implicit execution is triggered. `getMaxPendingBlobWriteBytes()` and `setMaxPendingBlobWriteBytes()` can be used to get and to set, respectively, the maximum volume of `BLOB` data to be written that accumulates before implicit execution occurs.

  For the MySQL server, two new options are added. The `--ndb-blob-read-batch-bytes` [1913] option sets a limit on the amount of pending `BLOB` data to be read before triggering implicit execution, and the `--ndb-blob-write-batch-bytes` [1913] option controls the amount of

pending `BLOB` data to be written. These limits can also be set using the `mysqld` configuration file, or read and set within the `mysql` client and other MySQL client applications using the corresponding server system variables. (Bug #59113)

- Two related problems could occur with read-committed scans made in parallel with transactions combining multiple (concurrent) operations:

  1. When committing a multiple-operation transaction that contained concurrent insert and update operations on the same record, the commit arrived first for the insert and then for the update. If a read-committed scan arrived between these operations, it could thus read incorrect data; in addition, if the scan read variable-size data, it could cause the data node to fail.

  2. When rolling back a multiple-operation transaction having concurrent delete and insert operations on the same record, the abort arrived first for the delete operation, and then for the insert. If a read-committed scan arrived between the delete and the insert, it could incorrectly assume that the record should not be returned (in other words, the scan treated the insert as though it had not yet been committed).

  (Bug #59496)

- On Windows platforms, issuing a `SHUTDOWN` command in the `ndb_mgm` client caused management processes that had been started with the `--nodaemon` [1965] option to exit abnormally. (Bug #59437)

- When executing a full table scan caused by a `WHERE` condition using *`unique_key`* `IS NULL` in combination with a join, `NDB` failed to close the scan. (Bug #58750)

  References: See also Bug #57481.

- A row insert or update followed by a delete operation on the same row within the same transaction could in some cases lead to a buffer overflow. (Bug #59242)

  References: See also Bug #56524. This bug was introduced by Bug #35208.

- Data nodes configured with very large amounts (multiple gigabytes) of `DiskPageBufferMemory` [1856] failed during startup with NDB error 2334 (`Job buffer congestion`). (Bug #58945)

  References: See also Bug #47984.

- The `FAIL_REP` signal, used inside the NDB kernel to declare that a node has failed, now includes the node ID of the node that detected the failure. This information can be useful in debugging. (Bug #58904)

- When handling failures of multiple data nodes, an error in the construction of internal signals could cause the cluster's remaining nodes to crash. This issue was most likely to affect clusters with large numbers of data nodes. (Bug #58240)

- Data nodes no longer allocated all memory prior to being ready to exchange heartbeat and other messages with management nodes, as in NDB 6.3 and earlier versions of MySQL Cluster. This caused problems when data nodes configured with large amounts of memory failed to show as connected or showed as being in the wrong start phase in the `ndb_mgm` client even after making their initial connections to and fetching their configuration data from the management server. With this fix, data nodes now allocate all memory as they did in earlier MySQL Cluster versions. (Bug #57568)

- Trying to drop an index while it was being used to perform scan updates caused data nodes to crash. (Bug #58277, Bug #57057)

- The number of rows affected by a statement that used a `WHERE` clause having an `IN` [942] condition with a value list containing a great many elements, and that deleted or updated enough rows such that `NDB` processed them in batches, was not computed or reported correctly. (Bug #58040)

- MySQL Cluster failed to compile correctly on FreeBSD 8.1 due to misplaced `#include` statements. (Bug #58034)
- In some circumstances, an SQL trigger on an `NDB` table could read stale data. (Bug #58538)
- A query having multiple predicates joined by `OR` in the `WHERE` clause and which used the `sort_union` access method (as shown using `EXPLAIN`) could return duplicate rows. (Bug #58280)
- During a node takeover, it was possible in some circumstances for one of the remaining nodes to send an extra transaction confirmation (`LQH_TRANSCONF`) signal to the `DBTC` kernel block, conceivably leading to a crash of the data node trying to take over as the new transaction coordinator. (Bug #58453)
- Some queries of the form `SELECT ... WHERE column IN (subquery)` against an `NDB` table could cause `mysqld` to hang in an endless loop. (Bug #58163)
- In some circumstances, it was possible for `mysqld` to begin a new multi-range read scan without having closed a previous one. This could lead to exhaustion of all scan operation objects, transaction objects, or lock objects (or some combination of these) in `NDB`, causing queries to fail with such errors as `Lock wait timeout exceeded` or `Connect failure - out of connection objects`. (Bug #57481)

  References: See also Bug #58750.
- Queries using `column IS [NOT] NULL` on a table with a unique index created with `USING HASH` on `column` always returned an empty result. (Bug #57032)
- The functions `strncasecmp` and `strcasecmp` were declared in `ndb_global.h` but never defined or used. The declarations have been removed. (Bug #58204)
- With `engine_condition_pushdown` [473] enabled, a query using `LIKE` on an `ENUM` column of an `NDB` table failed to return any results. This issue is resolved by disabling `engine_condition_pushdown` [473] when performing such queries. (Bug #53360)
- A query using `BETWEEN` as part of a pushed-down `WHERE` condition could cause mysqld to hang or crash. (Bug #57735)
- When a slash character (`/`) was used as part of the name of an index on an `NDB` table, attempting to execute a `TRUNCATE TABLE` statement on the table failed with the error `Index not found`, and the table was rendered unusable. (Bug #38914)
- **Disk Data**: **Partitioning**: When using multi-threaded data nodes, an `NDB` table created with a very large value for the `MAX_ROWS` option could—if this table was dropped and a new table with fewer partitions, but having the same table ID, was created—cause `ndbmtd` to crash when performing a system restart. This was because the server attempted to examine each partition whether or not it actually existed.

  This issue is the same as that reported in Bug #45154, except that the current issue is specific to `ndbmtd` instead of `ndbd`. (Bug #58638)
- **Disk Data**: In certain cases, a race condition could occur when `DROP LOGFILE GROUP` removed the logfile group while a read or write of one of the effected files was in progress, which in turn could lead to a crash of the data node. (Bug #59502)
- **Disk Data**: A race condition could sometimes be created when `DROP TABLESPACE` was run concurrently with a local checkpoint; this could in turn lead to a crash of the data node. (Bug #59501)
- **Disk Data**: Performing what should have been an online drop of a multi-column index was actually performed offline. (Bug #55618)
- **Disk Data**: When at least one data node was not running, queries against the `INFORMATION_SCHEMA.FILES` table took an excessive length of time to complete because the

MySQL server waited for responses from any stopped nodes to time out. Now, in such cases, MySQL does not attempt to contact nodes which are not known to be running. (Bug #54199)

- **Cluster API**: It was not possible to obtain the status of nodes accurately after an attempt to stop a data node using `ndb_mgm_stop()` failed without returning an error. (Bug #58319)
- **Cluster API**: Attempting to read the same value (using `getValue()`) more than 9000 times within the same transaction caused the transaction to hang when executed. Now when more reads are performed in this way than can be accommodated in a single transaction, the call to `execute()` fails with a suitable error. (Bug #58110)

Changes in MySQL Cluster NDB 7.0.20a (5.1.51-ndb-7.0.20a)

Bugs Fixed

- **Important Note**: Issuing an `ALL DUMP` command during a rolling upgrade to MySQL Cluster NDB 7.0.20 caused the cluster to crash. (Bug #58256)

Changes in MySQL Cluster NDB 7.0.20 (5.1.51-ndb-7.0.20)

Functionality Added or Changed

- **Important Change**: `ndbd` now bypasses use of Non-Uniform Memory Access support on Linux hosts by default. If your system supports NUMA, you can enable it and override `ndbd` use of interleaving by setting the `Numa` [1854] data node configuration parameter which is added in this release. See Defining Data Nodes: Realtime Performance Parameters, for more information. (Bug #57807)
- **Important Change**: The `Id` configuration parameter used with MySQL Cluster management, data, and API nodes (including SQL nodes) is now deprecated, and the `NodeId` parameter (long available as a synonym for `Id` when configuring these types of nodes) should be used instead. `Id` continues to be supported for reasons of backward compatibility, but now generates a warning when used with these types of nodes, and is subject to removal in a future release of MySQL Cluster.

  This change affects the name of the configuration parameter only, establishing a clear preference for `NodeId` over `Id` in the `[mgmd]`, `[ndbd]`, `[mysql]`, and `[api]` sections of the MySQL Cluster global configuration (`config.ini`) file. The behavior of unique identifiers for management, data, and SQL and API nodes in MySQL Cluster has not otherwise been altered.

  The `Id` parameter as used in the `[computer]` section of the MySQL Cluster global configuration file is not affected by this change.

Bugs Fixed

- **Packaging**: MySQL Cluster RPM distributions did not include a `shared-compat` RPM for the MySQL Server, which meant that MySQL applications depending on `libmysqlclient.so.15` (MySQL 5.0 and earlier) no longer worked. (Bug #38596)
- On Windows, the angel process which monitors and (when necessary) restarts the data node process failed to spawn a new worker in some circumstances where the arguments vector contained extra items placed at its beginning. This could occur when the path to `ndbd.exe` or `ndbmtd.exe` contained one or more spaces. (Bug #57949)
- The disconnection of an API or management node due to missed heartbeats led to a race condition which could cause data nodes to crash. (Bug #57946)
- The method for calculating table schema versions used by schema transactions did not follow the established rules for recording schemas used in the `P0.SchemaLog` file. (Bug #57897)

  References: See also Bug #57896.
- The `LQHKEYREQ` request message used by the local query handler when checking the major schema version of a table, being only 16 bits wide, could cause this check to fail with an `Invalid schema`

version error (NDB error code 1227). This issue occurred after creating and dropping (and re-creating) the same table 65537 times, then trying to insert rows into the table. (Bug #57896)

References: See also Bug #57897.

- Transient errors during a local checkpoint were not retried, leading to a crash of the data node. Now when such errors occur, they are retried up to 10 times if necessary. (Bug #57650)
- When a data node angel process failed to fork off a new worker process (to replace one that had failed), the failure was not handled. This meant that the angel process either transformed itself into a worker process, or itself failed. In the first case, the data node continued to run, but there was no longer any angel to restart it in the event of failure, even with StopOnError [1832] set to 0. (Bug #53456)
- Data nodes compiled with gcc 4.5 or higher crashed during startup. (Bug #57761)
- Queries using WHERE *varchar_pk_column* LIKE '*pattern*%' or WHERE *varchar_pk_column* LIKE '*pattern*_' against an NDB table having a VARCHAR column as its primary key failed to return all matching rows. (Bug #56853)
- ndb_restore now retries failed transactions when replaying log entries, just as it does when restoring data. (Bug #57618)
- The SUMA kernel block has a 10-element ring buffer for storing out-of-order SUB_GCP_COMPLETE_REP signals received from the local query handlers when global checkpoints are completed. In some cases, exceeding the ring buffer capacity on all nodes of a node group at the same time caused the node group to fail with an assertion. (Bug #57563)
- During a GCP takeover, it was possible for one of the data nodes not to receive a SUB_GCP_COMPLETE_REP signal, with the result that it would report itself as GCP_COMMITTING while the other data nodes reported GCP_PREPARING. (Bug #57522)
- A GCP stop is detected using 2 parameters which determine the maximum time that a global checkpoint or epoch can go unchanged; one of these controls this timeout for GCPs and one controls the timeout for epochs. Suppose the cluster is configured such that TimeBetweenEpochsTimeout [1840] is 100 ms but HeartbeatIntervalDbDb [1836] is 1500 ms. A node failure can be signalled after 4 missed heartbeats—in this case, 6000 ms. However, this would exceed TimeBetweenEpochsTimeout [1840], causing false detection of a GCP. To prevent this from happening, the configured value for TimeBetweenEpochsTimeout [1840] is automatically adjusted, based on the values of HeartbeatIntervalDbDb [1836] and ArbitrationTimeout [1844].

  The current issue arose when the automatic adjustment routine did not correctly take into consideration the fact that, during cascading node-failures, several intervals of length 4 * (HeartbeatIntervalDBDB + ArbitrationTimeout) may elapse before all node failures have internally been resolved. This could cause false GCP detection in the event of a cascading node failure. (Bug #57322)
- Specifying a WHERE clause of the form *range1* OR *range2* when selecting from an NDB table having a primary key on multiple columns could result in Error 4259 Invalid set of range scan bounds if *range2* started exactly where *range1* ended and the primary key definition declared the columns in a different order relative to the order in the table's column list. (Such a query should simply return all rows in the table, since any expression *value* < *constant* OR *value* >= *constant* is always true.)

  Example. Suppose t is an NDB table defined by the following CREATE TABLE statement:

```
CREATE TABLE t (a, b, PRIMARY KEY (b, a)) ENGINE NDB;
```

  This issue could then be triggered by a query such as this one:

```
SELECT * FROM t WHERE b < 8 OR b >= 8;
```

In addition, the order of the ranges in the `WHERE` clause was significant; the issue was not triggered, for example, by the query `SELECT * FROM t WHERE b <= 8 OR b > 8`. (Bug #57396)

- A number of cluster log warning messages relating to deprecated configuration parameters contained spelling, formatting, and other errors. (Bug #57381)
- The `MAX_ROWS` option for `CREATE TABLE` was ignored, which meant that it was not possible to enable multi-threaded building of indexes. (Bug #57360)
- Aborting a native `NDB` backup in the `ndb_mgm` client using the `ABORT BACKUP` command did not work correctly when using `ndbmtd`, in some cases leading to a crash of the cluster. (Bug #56285)
- Successive `CREATE NODEGROUP` and `DROP NODEGROUP` commands could cause `mysqld` processes to crash. (Bug #57164)
- **Disk Data**: When performing online DDL on Disk Data tables, scans and moving of the relevant tuples were done in more or less random order. This fix causes these scans to be done in the order of the tuples, which should improve performance of such operations due to the more sequential ordering of the scans. (Bug #57848)

  References: See also Bug #57827.
- **Disk Data**: Adding unique indexes to `NDB` Disk Data tables could take an extremely long time. This was particularly noticeable when using `ndb_restore --rebuild-indexes [2002]`. (Bug #57827)
- **Cluster API**: An application dropping a table at the same time that another application tried to set up a replication event on the same table could lead to a crash of the data node. The same issue could sometimes cause `NdbEventOperation::execute()` to hang. (Bug #57886)
- **Cluster API**: An NDB API client program under load could abort with an assertion error in `TransporterFacade::remove_from_cond_wait_queue`. (Bug #51775)

  References: See also Bug #32708.

Changes in MySQL Cluster NDB 7.0.19 (5.1.47-ndb-7.0.19)

Functionality Added or Changed

- It is now possible using the `ndb_mgm` management client or the MGM API to force a data node shutdown or restart even if this would force the shutdown or restart of the entire cluster.

  In the management client, this is implemented through the addition of the `-f` (force) option to the `STOP` and `RESTART` commands. For more information, see Commands in the MySQL Cluster Management Client.

  The MGM API also adds two new methods for forcing such a node shutdown or restart; see `ndb_mgm_stop4()`, and `ndb_mgm_restart4()`, for more information about these methods. (Bug #54226)
- `mysqldump` as supplied with MySQL Cluster now has an `--add-drop-trigger` [294] option which adds a `DROP TRIGGER IF EXISTS` statement before each dumped trigger definition. (Bug #55691)

  References: See also Bug #34325, Bug #11747863.
- **Cluster API**: The MGM API function `ndb_mgm_get_version()`, which was previously internal, has now been moved to the public API. This function can be used to get `NDB` storage engine and other version information from the management server. (Bug #51310)

  References: See also Bug #51273.

Bugs Fixed

- At startup, an `ndbd` or `ndbmtd` process creates directories for its file system without checking to see whether they already exist. Portability code added in MySQL Cluster NDB 7.0.18 and MySQL Cluster NDB 7.1.7 did not account for this fact, printing a spurious error message when a directory to be created already existed. This unneeded printout has been removed. (Bug #57087)

- The text file `cluster_change_hist.txt` containing old MySQL Cluster changelog information was no longer being maintained, and so has been removed from the tree. (Bug #56116)

- Memory pages used for `DataMemory` [1817], once assigned to ordered indexes, were not ever freed, even after any rows that belonged to the corresponding indexes had been deleted. (Bug #56829)

- A data node can be shut down having completed and synchronized a given GCI *`x`*, while having written a great many log records belonging to the next GCI *`x`* + 1, as part of normal operations. However, when starting, completing, and synchronizing GCI *`x`* + 1, then the log records from original start must not be read. To make sure that this does not happen, the REDO log reader finds the last GCI to restore, scans forward from that point, and erases any log records that were not (and should never be) used.

  The current issue occurred because this scan stopped immediately as soon as it encountered an empty page. This was problematic because the REDO log is divided into several files; thus, it could be that there were log records in the beginning of the next file, even if the end of the previous file was empty. These log records were never invalidated; following a start or restart, they could be reused, leading to a corrupt REDO log. (Bug #56961)

- An error in program flow in `ndbd.cpp` could result in data node shutdown routines being called multiple times. (Bug #56890)

- In certain cases, `DROP DATABASE` could sometimes leave behind a cached table object, which caused problems with subsequent DDL operations. (Bug #56840)

- Under certain rare conditions, attempting to start more than one `ndb_mgmd` process simultaneously using the `--reload` [1966] option caused a race condition such that none of the `ndb_mgmd` processes could start. (Bug #56844)

- When distributing `CREATE TABLE` and `DROP TABLE` operations among several SQL nodes attached to a MySQL Cluster. the `LOCK_OPEN` lock normally protecting `mysqld`'s internal table list is released so that other queries or DML statements are not blocked. However, to make sure that other DDL is not executed simultaneously, a global schema lock (implemented as a row-level lock by `NDB`) is used, such that all operations that can modify the state of the `mysqld` internal table list also need to acquire this global schema lock. The `SHOW TABLE STATUS` statement did not acquire this lock. (Bug #56841)

- When multiple SQL nodes were connected to the cluster and one of them stopped in the middle of a DDL operation, the `mysqld` process issuing the DDL timed out with the error `distributing` *`tbl_name`* `timed out. Ignoring`. (Bug #56763)

- MySQL Cluster stores, for each row in each `NDB` table, a Global Checkpoint Index (GCI) which identifies the last committed transaction that modified the row. As such, a GCI can be thought of as a coarse-grained row version.

  Due to changes in the format used by `NDB` to store local checkpoints (LCPs) in MySQL Cluster NDB 6.3.11, it could happen that, following cluster shutdown and subsequent recovery, the GCI values for some rows could be changed unnecessarily; this could possibly, over the course of many node or system restarts (or both), lead to an inconsistent database. (Bug #56770)

- An online `ALTER TABLE ... ADD COLUMN` operation that changed the table schema such that the number of 32-bit words used for the bitmask allocated to each DML operation increased during a transaction in DML which was performed prior to DDL which was followed by either another DML operation or—if using replication—a commit, led to data node failure.

This was because the data node did not take into account that the bitmask for the before-image was smaller than the current bitmask, which caused the node to crash. (Bug #56524)

References: This bug is a regression of Bug #35208.

- On Windows, a data node refused to start in some cases unless the `ndbd.exe` executable was invoked using an absolute rather than a relative path. (Bug #56257)
- The failure of a data node during some scans could cause other data nodes to fail. (Bug #54945)
- Exhausting the number of available commit-ack markers (controlled by the `MaxNoOfConcurrentTransactions` [1821] parameter) led to a data node crash. (Bug #54944)
- When running a `SELECT` on an `NDB` table with `BLOB` or `TEXT` columns, memory was allocated for the columns but was not freed until the end of the `SELECT`. This could cause problems with excessive memory usage when dumping (using for example `mysqldump`) tables with such columns and having many rows, large column values, or both. (Bug #52313)

  References: See also Bug #56488, Bug #50310.
- **Cluster API**: The MGM API functions `ndb_mgm_stop()` and `ndb_mgm_restart()` set the error code and message without first checking whether the management server handle was `NULL`, which could lead to fatal errors in MGM API applications that depended on these functions. (Bug #57089)
- **Cluster API**: The MGM API function `ndb_mgm_get_version()` did not set the error message before returning with an error. With this fix, it is now possible to call `ndb_mgm_get_latest_error()` after a failed call to this function such that `ndb_mgm_get_latest_error()` returns an error number and error message, as expected of MGM API calls. (Bug #57088)

Changes in MySQL Cluster NDB 7.0.18 (5.1.47-ndb-7.0.18)

Functionality Added or Changed

- **Important Change**: More finely grained control over restart-on-failure behavior is provided with two new data node configuration parameters `MaxStartFailRetries` [1863] and `StartFailRetryDelay` [1863]. `MaxStartFailRetries` [1863] limits the total number of retries made before giving up on starting the data node; `StartFailRetryDelay` [1863] sets the number of seconds between retry attempts.

  These parameters are used only if `StopOnError` [1832] is set to 0.

  For more information, see Defining MySQL Cluster Data Nodes. (Bug #54341)

Bugs Fixed

- `ndb_restore` always reported 0 for the `GCPStop` (end point of the backup). Now it provides useful binary log position and epoch information. (Bug #56298)
- The `LockExecuteThreadToCPU [1852]` configuration parameter was not handled correctly for CPU ID values greater than 255. (Bug #56185)
- Trying to create a table having a `BLOB` or `TEXT` column with `DEFAULT ''` failed with the error `Illegal null attribute`. (An empty default is permitted and ignored by `MyISAM`; `NDB` should do the same.) (Bug #55121)
- Following a failure of the master data node, the new master sometimes experienced a race condition which caused the node to terminate with a **`GcpStop`** error. (Bug #56044)
- `ndb_mgmd --nodaemon` [1965] logged to the console in addition to the configured log destination. (Bug #54779)

- The warning `MaxNoOfExecutionThreads (#) > LockExecuteThreadToCPU count (#), this could cause contention` could be logged when running `ndbd`, even though the condition described can occur only when using `ndbmtd`. (Bug #54342)

- Startup messages previously written by `ndb_mgmd` to `stdout` are now written to the cluster log instead when `LogDestination` [1810] is set. (Bug #47595)

- The graceful shutdown of a data node could sometimes cause transactions to be aborted unnecessarily. (Bug #18538)

  References: See also Bug #55641.

Changes in MySQL Cluster NDB 7.0.17 (5.1.47-ndb-7.0.17)

Functionality Added or Changed

- Added the `DictTrace` data node configuration parameter, for use in debugging `NDB` code. For more information, see Defining MySQL Cluster Data Nodes. (Bug #55963)

- Added the `--server-id-bits` option for mysqld and mysqlbinlog.

  For `mysqld`, the `--server-id-bits` [1918] option indicates the number of least significant bits within the 32-bit server ID which actually identify the server. Indicating that the server ID uses less than 32 bits permits the remaining bits to be used for other purposes by NDB API applications using the Event API and `OperationOptions::AnyValue`.

  For `mysqlbinlog`, the `--server-id-bits` [353] option tells `mysqlbinlog` how to interpret the server IDs in the binary log when the binary log was written by a `mysqld` having its `server_id_bits` [1935] set to less than the maximum (32). (Bug #52305)

Bugs Fixed

- **Cluster API**: **Important Change**: The poll and select calls made by the MGM API were not interrupt-safe; that is, a signal caught by the process while waiting for an event on one or more sockets returned error -1 with `errno` set to `EINTR`. This caused problems with MGM API functions such as `ndb_logevent_get_next()` and `ndb_mgm_get_status2()`.

  To fix this problem, the internal `ndb_socket_poller::poll()` function has been made `EINTR`-safe.

  The old version of this function has been retained as `poll_unsafe()`, for use by those parts of NDB that do not need the `EINTR`-safe version of the function. (Bug #55906)

- Starting `ndb_mgmd` with `--config-cache=0` [1963] caused it to leak memory. (Bug #55205)

- When another data node failed, a given data node `DBTC` kernel block could time out while waiting for `DBDIH` to signal commits of pending transactions, leading to a crash. Now in such cases the timeout generates a prinout, and the data node continues to operate. (Bug #55715)

- An excessive number of timeout warnings (normally used only for debugging) were written to the data node logs. (Bug #53987)

- The TCP configuration parameters `HostName1` and `HostName2` were not displayed in the output of `ndb_config --configinfo` [1975]. (Bug #55839)

- It was possible for a `DROP DATABASE` statement to remove `NDB` hidden blob tables without removing the parent tables, with the result that the tables, although hidden to MySQL clients, were still visible in the output of `ndb_show_tables` but could not be dropped using `ndb_drop_table`. (Bug #54788)

- The `configure.js` option `WITHOUT_DYNAMIC_PLUGINS=TRUE` was ignored when building MySQL Cluster for Windows using `CMake`. Among the effects of this issue was that `CMake` attempted

to build the `InnoDB` storage engine as a plugin (`.DLL` file) even though the `InnoDB Plugin` is not currently supported by MySQL Cluster. (Bug #54913)

- **Disk Data**: As an optimization when inserting a row to an empty page, the page is not read, but rather simply initialized. However, this optimzation was performed in all cases when an empty row was inserted, even though it should have been done only if it was the first time that the page had been used by a table or fragment. This is because, if the page had been in use, and then all records had been released from it, the page still needed to be read to learn its log sequence number (LSN).

  This caused problems only if the page had been flushed using an incorrect LSN and the data node failed before any local checkpoint was completed—which would remove any need to apply the undo log, hence the incorrect LSN was ignored.

  The user-visible result of the incorrect LSN was that it caused the data node to fail during a restart. It was perhaps also possible (although not conclusively proven) that this issue could lead to incorrect data. (Bug #54986)

- **Cluster API**: Calling `NdbTransaction::refresh()` did not update the timer for `TransactionInactiveTimeout` [1841]. (Bug #54724)

Changes in MySQL Cluster NDB 7.0.16 (5.1.47-ndb-7.0.16)

Functionality Added or Changed

- Restrictions on some types of mismatches in column definitions when restoring data using `ndb_restore` have been relaxed. These include the following types of mismatches:

  - Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
  - Different `STORAGE` settings (`MEMORY`, `DISK`)
  - Different default values
  - Different distribution key settings

  Now, when one of these types of mismatches in column definitions is encountered, `ndb_restore` no longer stops with an error; instead, it accepts the data and inserts it into the target table, while issuing a warning to the user.

  For more information, see `ndb_restore` — Restore a MySQL Cluster Backup. (Bug #54423)

  References: See also Bug #53810, Bug #54178, Bug #54242, Bug #54279.

- Introduced the `HeartbeatOrder` [1837] data node configuration parameter, which can be used to set the order in which heartbeats are transmitted between data nodes. This parameter can be useful in situations where multiple data nodes are running on the same host and a temporary disruption in connectivity between hosts would otherwise cause the loss of a node group, leading to failure of the cluster. (Bug #52182)

- It is now possible to install management node and data node processes as Windows services. (See Installing MySQL Cluster Processes as Windows Services, for more information.) In addition, data node processes on Windows are now maintained by angel processes, just as they are on other platforms supported by MySQL Cluster.

Bugs Fixed

- The disconnection of all API nodes (including SQL nodes) during an `ALTER TABLE` caused a memory leak. (Bug #54685)

- If a node shutdown (either in isolation or as part of a system shutdown) occurred directly following a local checkpoint, it was possible that this local checkpoint would not be used when restoring the cluster. (Bug #54611)

- When adding multiple new node groups to a MySQL Cluster, it was necessary for each new node group to add only the nodes to be assigned to the new node group, create that node group using `CREATE NODEGROUP`, then repeat this process for each new node group to be added to the cluster. The fix for this issue makes it possible to add all of the new nodes at one time, and then issue several `CREATE NODEGROUP` commands in succession. (Bug #54497)
- The setting for `BuildIndexThreads` [1854] was ignored by `ndbmtd`, which made it impossible to use more than 4 cores for rebuilding indexes. (Bug #54521)
- A table having the maximum number of attributes permitted could not be backed up using the `ndb_mgm` client.

  Note

  The maximum number of attributes supported per table is not the same for all MySQL Cluster releases. See Limits Associated with Database Objects in MySQL Cluster, to determine the maximum that applies in the release which you are using.

  (Bug #54155)
- When performing an online alter table where 2 or more SQL nodes connected to the cluster were generating binary logs, an incorrect message could be sent from the data nodes, causing `mysqld` processes to crash. This problem was often difficult to detect, because restarting SQL node or data node processes could clear the error, and because the crash in `mysqld` did not occur until several minutes after the erroneous message was sent and received. (Bug #54168)
- The two MySQL Server options, `--ndb-wait-connected` [1919] and `--ndb-wait-setup` [1919], did not set the corresponding system variables. (Bug #48402)
- During initial node restarts, initialization of the REDO log was always performed 1 node at a time, during start phase 4. Now this is done during start phase 2, so that the initialization can be performed in parallel, thus decreasing the time required for initial restarts involving multiple nodes. (Bug #50062)
- The presence of duplicate `[tcp]` sections in the `config.ini` file caused the management server to crash. Now in such cases, `ndb_mgmd` fails gracefully with an appropriate error message. (Bug #49400)
- **Cluster API**: When using the NDB API, it was possible to rename a table with the same name as that of an existing table.

  Note

  This issue did not affect table renames executed using SQL on MySQL servers acting as MySQL Cluster API nodes.

  (Bug #54651)
- **Cluster API**: An excessive number of client connections, such that more than 1024 file descriptors, sockets, or both were open, caused NDB API applications to crash. (Bug #34303)

Changes in MySQL Cluster NDB 7.0.15b (5.1.44-ndb-7.0.15b)

Bugs Fixed

- **Cluster API**: The value of an internal constant used in the implementation of the `NdbOperation` and `NdbScanOperation` classes caused MySQL Cluster NDB 7.0 NDB API applications compiled against MySQL Cluster NDB 7.0.14 or earlier to fail when run with MySQL Cluster 7.0.15, and MySQL Cluster NDB 7.1 NDB API applications compiled against MySQL Cluster NDB 7.1.3 or earlier to break when used with MySQL Cluster 7.1.4. (Bug #54516)

Changes in MySQL Cluster NDB 7.0.15a (5.1.44-ndb-7.0.15a)

Bugs Fixed

- When using `mysqldump` to back up and restore schema information while using `ndb_restore` for restoring only the data, restoring to MySQL Cluster NDB 7.1.4 from an older version failed on tables having columns with default values. This was because versions of MySQL Cluster prior to MySQL Cluster NDB 7.1.4 did not have native support for default values.

  In addition, the MySQL Server supports `TIMESTAMP` columns having dynamic default values, such as `DEFAULT CURRENT_TIMESTAMP`; however, the current implementation of `NDB`-native default values permits only a constant default value.

  To fix this issue, the manner in which `NDB` treats `TIMESTAMP` columns is reverted to its pre-NDB-7.1.4 behavior (obtaining the default value from `mysqld` rather than `NDBCLUSTER`) except where a `TIMESTAMP` column uses a constant default, as in the case of a column declared as `TIMESTAMP DEFAULT 0` or `TIMESTAMP DEFAULT 20100607174832`. (Bug #54242)

Changes in MySQL Cluster NDB 7.0.15 (5.1.44-ndb-7.0.15)

Functionality Added or Changed

- **Important Change**: The maximum number of attributes (columns plus indexes) per table has increased to 512.

- A `--wait-nodes` option has been added for `ndb_waiter`. When this option is used, the program waits only for the nodes having the listed IDs to reach the desired state. For more information, see `ndb_waiter` — Wait for MySQL Cluster to Reach a Given Status. (Bug #52323)

- As part of this change, new methods relating to default values have been added to the `Column` and `Table` classes in the NDB API. For more information, see `Column::getDefaultValue()`, `Column::setDefaultValue()`, and `Table::hasDefaultValues()`. (Bug #30529)

- Added the `--skip-unknown-objects` [2003] option for `ndb_restore`. This option causes `ndb_restore` to ignore any schema objects which it does not recognize. Currently, this is useful chiefly for restoring native backups made from a cluster running MySQL Cluster NDB 7.0 to a cluster running MySQL Cluster NDB 6.3.

- Added the MySQL Cluster management server option `--config-cache` [1963], which makes it possible to enable and disable configuration caching. This option is turned on by default; to disable configuration caching, start `ndb_mgmd` with `--config-cache=0` [1963], or with `--skip-config-cache`. See `ndb_mgmd` — The MySQL Cluster Management Server Daemon, for more information.

Bugs Fixed

- When attempting to create an `NDB` table on an SQL node that had not yet connected to a MySQL Cluster management server since the SQL node's last restart, the `CREATE TABLE` statement failed as expected, but with the unexpected Error 1495 `For the partitioned engine it is necessary to define all partitions`. (Bug #11747335, Bug #31853)

- After creating `NDB` tables until creation of a table failed due to `NDB` error 905 `Out of attribute records (increase MaxNoOfAttributes)`, then increasing `MaxNoOfAttributes` [1828] and restarting all management node and data node processes, attempting to drop and re-create one of the tables failed with the error `Out of table records...`, even when sufficient table records were available. (Bug #53944)

  References: See also Bug #52055. This bug is a regression of Bug #44294.

- Creating a Disk Data table, dropping it, then creating an in-memory table and performing a restart, could cause data node processes to fail with errors in the `DBTUP` kernel block if the new table's internal ID was the same as that of the old Disk Data table. This could occur because undo log handling during the restart did not check that the table having this ID was now in-memory only. (Bug #53935)

- An internal buffer allocator used by NDB has the form `alloc(wanted, minimum)` and attempts to allocate *wanted* pages, but is permitted to allocate a smaller number of pages, between *wanted* and *minimum*. However, this allocator could sometimes allocate fewer than *minimum* pages, causing problems with multi-threaded building of ordered indexes. (Bug #53580)

- A table created while ndb_table_no_logging [1930] was enabled was not always stored to disk, which could lead to a data node crash with `Error opening DIH schema files for table`. (Bug #53934)

- When compiled with support for epoll but this functionality is not available at runtime, MySQL Cluster tries to fall back to use the select() function in its place. However, an extra ndbout_c() call in the transporter registry code caused ndbd to fail instead. (Bug #53482)

- The value set for the ndb_mgmd option --ndb-nodeid [2017] was not verified prior to use as being within the permitted range (1 to 255, inclusive), leading to a crash of the management server. (Bug #53412)

- NDB truncated a column declared as DECIMAL(65,0) to a length of 64. Now such a column is accepted and handled correctly. In cases where the maximum length (65) is exceeded, NDB now raises an error instead of truncating. (Bug #53352)

- When creating an index, NDB failed to check whether the internal ID allocated to the index was within the permissible range, leading to an assertion. This issue could manifest itself as a data node failure with NDB error 707 (`No more table metadata records (increase MaxNoOfTables)`), when creating tables in rapid succession (for example, by a script, or when importing from mysqldump), even with a relatively high value for MaxNoOfTables [1829] and a relatively low number of tables. (Bug #52055)

- When the LogDestination [1810] parameter was set using with a relative path, the management server failed to store its value unless started with --initial [1965] or --reload [1966]. (Bug #52268)

- ndb_restore did not raise any errors if hashmap creation failed during execution. (Bug #51434)

- When an NDB log handler failed, the memory allocated to it was freed twice. (Bug #53200)

- Setting DataMemory [1817] higher than 4G on 32-bit platforms caused ndbd to crash, instead of failing gracefully with an error. (Bug #52536, Bug #50928)

- Specifying the node ID as part of the --ndb-connectstring [1914] option to mysqld was not handled correctly.

  The fix for this issue includes the following changes:

  - Multiple occurrences of any of the mysqld options --ndb-connectstring [1914], --ndb-mgmd-host [1915], and --ndb-nodeid [1916] are now handled in the same way as with other MySQL server options, in that the value set in the last occurrence of the option is the value that is used by mysqld.

    Now, if --ndb-nodeid [1916] is used, its value overrides that of any nodeid setting used in --ndb-connectstring [1914]. For example, starting mysqld with --ndb-connectstring=nodeid=1,10.100.1.100 --ndb-nodeid=3 now produces the same result as starting it with --ndb-connectstring=nodeid=3,10.100.1.100.

  - The 1024-character limit on the length of the connectstring is removed, and --ndb-connectstring [1914] is now handled in this regard in the same way as other mysqld options.

  - In the NDB API, a new constructor for Ndb_cluster_connection is added which takes as its arguments a connectstring and the node ID to force the API node to use.

  (Bug #44299)

- NDB did not distinguish correctly between table names differing only by lettercase when `lower_case_table_names` [492] was set to 0. (Bug #33158)
- `ndb_mgm -e "ALL STATUS"` erroneously reported that data nodes remained in start phase 0 until they had actually started.

Changes in MySQL Cluster NDB 7.0.14 (5.1.44-ndb-7.0.14)

Functionality Added or Changed

- **Cluster API**: It is now possible to determine, using the `ndb_desc` utility or the NDB API, which data nodes contain replicas of which partitions. For `ndb_desc`, a new `--extra-node-info` [1982] option is added to cause this information to be included in its output. A new method `Table::getFragmentNodes()` is added to the NDB API for obtaining this information programmatically. (Bug #51184)
- **Cluster API**: It is now possible to determine, using the `ndb_desc` utility or the NDB API, which data nodes contain replicas of which partitions. For `ndb_desc`, a new `--extra-node-info` [1982] option is added to cause this information to be included in its output. A new method `Table::getFragmentNodes()` is added to the NDB API for obtaining this information programmatically. (Bug #51184)
- Formerly, the `REPORT` and `DUMP` commands returned output to all `ndb_mgm` clients connected to the same MySQL Cluster. Now, these commands return their output only to the `ndb_mgm` client that actually issued the command. (Bug #40865)

Bugs Fixed

- **Cluster API**: **Incompatible Change**: The default behavior of the NDB API Event API has changed as follows:

  Previously, when creating an `Event`, DDL operations (alter and drop operations on tables) were automatically reported on any event operation that used this event, but as a result of this change, this is no longer the case. Instead, you must now invoke the event's `setReport()` method, with the new `EventReport` value `ER_DDL`, to get this behavior.

  For existing NDB API applications where you wish to retain the old behavior, you must update the code as indicated previously, then recompile, following an upgrade. Otherwise, DDL operations are no longer reported after upgrading `libndbnclient`.

  For more information, see The `Event::EventReport` Type, and `Event::setReport()`. (Bug #53308)
- **Cluster API**: **Incompatible Change**: The default behavior of the NDB API Event API has changed as follows:

  Previously, when creating an `Event`, DDL operations (alter and drop operations on tables) were automatically reported on any event operation that used this event, but as a result of this change, this is no longer the case. Instead, you must now invoke the event's `setReport()` method, with the new `EventReport` value `ER_DDL`, to get this behavior.

  For existing NDB API applications where you wish to retain the old behavior, you must update the code as indicated previously, then recompile, following an upgrade. Otherwise, DDL operations are no longer reported after upgrading `libndbnclient`.

  For more information, see The `Event::EventReport` Type, and `Event::setReport()`. (Bug #53308)
- If a node or cluster failure occurred while `mysqld` was scanning the `ndb.ndb_schema` table (which it does when attempting to connect to the cluster), insufficient error handling could lead to a crash by `mysqld` in certain cases. This could happen in a MySQL Cluster with a great many tables, when trying to restart data nodes while one or more `mysqld` processes were restarting. (Bug #52325)

- In MySQL Cluster NDB 7.0 and later, DDL operations are performed within schema transactions; the NDB kernel code for starting a schema transaction checks that all data nodes are at the same version before permitting a schema transaction to start. However, when a version mismatch was detected, the client was not actually informed of this problem, which caused the client to hang. (Bug #52228)

- After running a mixed series of node and system restarts, a system restart could hang or fail altogether. This was caused by setting the value of the newest completed global checkpoint too low for a data node performing a node restart, which led to the node reporting incorrect GCI intervals for its first local checkpoint. (Bug #52217)

- When performing a complex mix of node restarts and system restarts, the node that was elected as master sometimes required optimized node recovery due to missing `REDO` information. When this happened, the node crashed with `Failure to recreate object ... during restart, error 721` (because the `DBDICT` restart code was run twice). Now when this occurs, node takeover is executed immediately, rather than being made to wait until the remaining data nodes have started. (Bug #52135)

  References: See also Bug #48436.

- The internal variable `ndb_new_handler`, which is no longer used, has been removed. (Bug #51858)

- `ha_ndbcluster.cc` was not compiled with the same `SAFEMALLOC` and `SAFE_MUTEX` flags as the MySQL Server. (Bug #51857)

- When debug compiling MySQL Cluster on Windows, the mysys library was not compiled with -DSAFEMALLOC and -DSAFE_MUTEX, due to the fact that my_socket.c was misnamed as my_socket.cc. (Bug #51856)

- Restoring a MySQL Cluster backup between platforms having different endianness failed when also restoring metadata and the backup contained a hashmap not already present in the database being restored to. This issue was discovered when trying to restore a backup made on Solaris/SPARC to a MySQL Cluster running on Solaris/x86, but could conceivably occur in other cases where the endianness of the platform on which the backup was taken differed from that of the platform being restored to. (Bug #51432)

- The `mysql` client `system` command did not work properly. This issue was only known to affect the version of the `mysql` client that was included with MySQL Cluster NDB 7.0 and MySQL Cluster NDB 7.1 releases. (Bug #48574)

- The redo log protects itself from being filled up by periodically checking how much space remains free. If insufficient redo log space is available, it sets the state `TAIL_PROBLEM` which results in transactions being aborted with error code 410 (`out of redo log`). However, this state was not set following a node restart, which meant that if a data node had insufficient redo log space following a node restart, it could crash a short time later with `Fatal error due to end of REDO log`. Now, this space is checked during node restarts. (Bug #51723)

- Information about several management client commands was missing from (that is, truncated in) the output of the `HELP` command. (Bug #46114)

- The output of the `ndb_mgm` client `REPORT BACKUPSTATUS` command could sometimes contain errors due to uninitialized data. (Bug #51316)

- The following issues were fixed in the `ndb_mgm` client `REPORT MEMORYUSAGE` command:

  - The client sometimes inserted extra `ndb_mgm>` prompts within the output.

  - For data nodes running `ndbmtd`, `IndexMemory` [1819] was reported before `DataMemory` [1817].

  - In addition, for data nodes running `ndbmtd`, there were multiple `IndexMemory` [1819] entries listed in the output.

  (Bug #50196)

- Issuing a command in the `ndb_mgm` client after it had lost its connection to the management server could cause the client to crash. (Bug #49219)
- The internal `ErrorReporter::formatMessage()` method could in some cases cause a buffer overflow. (Bug #47120)
- A `GROUP BY` query against `NDB` tables sometimes did not use any indexes unless the query included a `FORCE INDEX` option. With this fix, indexes are used by such queries (where otherwise possible) even when `FORCE INDEX` is not specified. (Bug #50736)
- The `ndb_print_backup_file` utility failed to function, due to a previous internal change in the NDB code. (Bug #41512, Bug #48673)
- When the `MemReportFrequency` [1849] configuration parameter was set in `config.ini`, the `ndb_mgm` client `REPORT MEMORYUSAGE` command printed its output multiple times. (Bug #37632)
- `ndb_mgm -e "... REPORT ..."` did not write any output to `stdout`.

  The fix for this issue also prevents the cluster log from being flooded with `INFO` messages when `DataMemory` [1817] usage reaches 100%, and insures that when the usage is decreased, an appropriate message is written to the cluster log. (Bug #31542, Bug #44183, Bug #49782)
- **Disk Data**: Inserts of blob column values into a MySQL Cluster Disk Data table that exhausted the tablespace resulted in misleading `no such tuple` error messages rather than the expected error `tablespace full`.

  This issue appeared similar to Bug #48113, but had a different underlying cause. (Bug #52201)
- **Disk Data**: The error message returned after atttempting to execute `ALTER LOGFILE GROUP` on an nonexistent logfile group did not indicate the reason for the failure. (Bug #51111)
- **Disk Data**: DDL operations on Disk Data tables having a relatively small `UNDO_BUFFER_SIZE` could fail unexpectedly.
- **Cluster API**: When reading blob data with lock mode `LM_SimpleRead`, the lock was not upgraded as expected. (Bug #51034)
- **Cluster API**: A number of issues were corrected in the NDB API coding examples found in the `storage/ndb/ndbapi-examples` directory in the MySQL Cluster source tree. These included possible endless recursion in `ndbapi_scan.cpp` as well as problems running some of the examples on systems using Windows or Mac OS X due to the lettercase used for some table names. (Bug #30552, Bug #30737)

Changes in MySQL Cluster NDB 7.0.13 (5.1.41-ndb-7.0.13)

Functionality Added or Changed

- A new configuration parameter `HeartbeatThreadPriority` makes it possible to select between a first-in, first-out or round-round scheduling policy for management node and API node heartbeat threads, as well as to set the priority of these threads. See Defining a MySQL Cluster Management Server, or Defining SQL and Other API Nodes in a MySQL Cluster, for more information. (Bug #49617)
- Start phases are now written to the data node logs. (Bug #49158)
- **Disk Data**: The `ndb_desc` utility can now show the extent space and free extent space for subordinate `BLOB` and `TEXT` columns (stored in hidden `BLOB` tables by NDB). A `--blob-info` [1982] option has been added for this program that causes `ndb_desc` to generate a report for

each subordinate `BLOB` table. For more information, see `ndb_desc` — Describe NDB Tables. (Bug #50599)

Bugs Fixed

- When performing a system restart of a MySQL Cluster where multi-threaded data nodes were in use, there was a slight risk that the restart would hang due to incorrect serialization of signals passed between LQH instances and proxies; some signals were sent using a proxy, and others directly, which meant that the order in which they were sent and received could not be guaranteed. If signals arrived in the wrong order, this could cause one or more data nodes to hang. Now all signals that need to be sent and received in the same order are sent using the same path. (Bug #51645)

- When one or more data nodes read their LCPs and applied undo logs significantly faster than others, this could lead to a race condition causing system restarts of data nodes to hang. This could most often occur when using both `ndbd` and `ndbmtd` processes for the data nodes. (Bug #51644)

- When deciding how to divide the REDO log, the `DBDIH` kernel block saved more than was needed to restore the previous local checkpoint, which could cause REDO log space to be exhausted prematurely (`NDB` error 410). (Bug #51547)

- DML operations can fail with `NDB` error 1220 (`REDO log files overloaded...`) if the opening and closing of REDO log files takes too much time. If this occurred as a GCI marker was being written in the REDO log while REDO log file 0 was being opened or closed, the error could persist until a GCP stop was encountered. This issue could be triggered when there was insufficient REDO log space (for example, with configuration parameter settings `NoOfFragmentLogFiles = 6` and `FragmentLogFileSize = 6M`) with a load including a very high number of updates. (Bug #51512)

  References: See also Bug #20904.

- A `SELECT` requiring a sort could fail with the error `Can't find record in 'table'` when run concurrently with a `DELETE` from the same table. (Bug #45687)

- A side effect of the `ndb_restore --disable-indexes` [2002] and `--rebuild-indexes` [2002] options is to change the schema versions of indexes. When a `mysqld` later tried to drop a table that had been restored from backup using one or both of these options, the server failed to detect these changed indexes. This caused the table to be dropped, but the indexes to be left behind, leading to problems with subsequent backup and restore operations. (Bug #51374)

- `ndb_restore` crashed while trying to restore a corrupted backup, due to missing error handling. (Bug #51223)

- Replication of a MySQL Cluster using multi-threaded data nodes could fail with forced shutdown of some data nodes due to the fact that `ndbmtd` exhausted `LongMessageBuffer` [1825] much more quickly than `ndbd`. After this fix, passing of replication data between the `DBTUP` and `SUMA` NDB kernel blocks is done using `DataMemory` [1817] rather than `LongMessageBuffer` [1825].

  Until you can upgrade, you may be able to work around this issue by increasing the `LongMessageBuffer` [1825] setting; doubling the default should be sufficient in most cases. (Bug #46914)

- The `ndb_restore` message `Successfully created index `PRIMARY`...` was directed to `stderr` instead of `stdout`. (Bug #51037)

- When using `NoOfReplicas` [1815] equal to 1 or 2, if data nodes from one node group were restarted 256 times and applications were running traffic such that it would encounter `NDB` error 1204 (`Temporary failure, distribution changed`), the live node in the node group would crash, causing the cluster to crash as well. The crash occurred only when the error was encountered on the 256th restart; having the error on any previous or subsequent restart did not cause any problems. (Bug #50930)

- **Cluster API**: An issue internal to `ndb_mgm` could cause problems when trying to start a large number of data nodes at the same time. (Bug #51273)

References: See also Bug #51310.

Changes in MySQL Cluster NDB 7.0.12b (5.1.41-ndb-7.0.12b)

Bugs Fixed

- Setting `IndexMemory` [1819] greater than 2GB could cause data nodes to crash while starting. (Bug #51256)

Changes in MySQL Cluster NDB 7.0.12a (5.1.41-ndb-7.0.12a)

Bugs Fixed

- An initial restart of a data node configured with a large amount of memory could fail with a `Pointer too large` error. (Bug #51027)

  References: This bug was introduced by Bug #47818.

Changes in MySQL Cluster NDB 7.0.12 (5.1.41-ndb-7.0.12)

Functionality Added or Changed

- Numeric codes used in management server status update messages in the cluster logs have been replaced with text descriptions. (Bug #49627)

  References: See also Bug #44248.

Bugs Fixed

- `ndbmtd` started on a single-core machine could sometimes fail with a `Job Buffer Full` error when `MaxNoOfExecutionThreads` [1855] was set greater than `LockExecuteThreadToCPU` [1852]. Now a warning is logged when this occurs. (Bug #50582)

- When a primary key lookup on an `NDB` table containing one or more `BLOB` columns was executed in a transaction, a shared lock on any blob tables used by the `NDB` table was held for the duration of the transaction. (This did not occur for indexed or non-indexed `WHERE` conditions.)

  Now in such cases, the lock is released after all `BLOB` data has been read. (Bug #49190)

Changes in MySQL Cluster NDB 7.0.11b (5.1.41-ndb-7.0.11b)

Bugs Fixed

- Setting `IndexMemory` [1819] greater than 2GB could cause data nodes to crash while starting. (Bug #51256)

Changes in MySQL Cluster NDB 7.0.11a (5.1.41-ndb-7.0.11a)

Bugs Fixed

- An initial restart of a data node configured with a large amount of memory could fail with a `Pointer too large` error. (Bug #51027)

  References: This bug was introduced by Bug #47818.

Changes in MySQL Cluster NDB 7.0.11 (5.1.41-ndb-7.0.11)

Functionality Added or Changed

- **Important Change**: The maximum permitted value of the `ndb_autoincrement_prefetch_sz` [1921] system variable has been increased from 256 to 65536. (Bug #50621)

- Added multi-threaded ordered index building capability during system restarts or node restarts, controlled by the `BuildIndexThreads` [1854] data node configuration parameter (also introduced in this release).

Bugs Fixed

- `ndbmtd` was not built on Windows (`CMake` did not provide a build target for it). (Bug #49325)
- When attempting to join a running cluster whose management server had been started with the `--nowait-nodes` [1967] option and having SQL nodes with dynamically allocated node IDs, a second management server failed with spurious `INTERNAL ERROR: Found dynamic ports with value in config...` error messages. (Bug #49807)
- Under some circumstances, the `DBTC` kernel block could send an excessive number of commit and completion messages which could lead to a the job buffer filling up and node failure. This was especially likely to occur when using `ndbmtd` with a single data node. (Bug #45989)
- If a query on an `NDB` table compared a constant string value to a column, and the length of the string was greater than that of the column, condition pushdown did not work correctly. (The string was truncated to fit the column length before being pushed down.) Now in such cases, the condition is no longer pushed down. (Bug #49459)
- When performing a `DELETE` that included a left join from an `NDB` table, only the first matching row was deleted. (Bug #47054)
- Initial start of partitioned nodes did not work correctly. This issue was observed in MySQL Cluster NDB 7.0 only. (Bug #50661)
- The `CREATE NODEGROUP` client command in `ndb_mgm` could sometimes cause the forced shutdown of a data node. (Bug #50594)
- During Start Phases 1 and 2, the `STATUS` command sometimes (falsely) returned `Not Connected` for data nodes running `ndbmtd`. (Bug #47818)
- When setting the `LockPagesInMainMemory` [1832] configuration parameter failed, only the error `Failed to memlock pages...` was returned. Now in such cases the operating system's error code is also returned. (Bug #49724)
- Local query handler information was not reported or written to the cluster log correctly. This issue is thought to have been introduced in MySQL Cluster NDB 7.0.10. (Bug #50467)
- Online upgrades from MySQL Cluster NDB 7.0.9b to MySQL Cluster NDB 7.0.10 did not work correctly. Current MySQL Cluster NDB 7.0 users should upgrade directly to MySQL Cluster NDB 7.0.11 or later.

  This issue is not known to have affected MySQL Cluster NDB 6.3, and it should be possible to upgrade from MySQL Cluster NDB 6.3 to MySQL Cluster NDB 7.0.10 without problems. See Upgrade and Downgrade Compatibility: MySQL Cluster NDB 6.x, for more information. (Bug #50433)
- Dropping unique indexes in parallel while they were in use could cause node and cluster failures. (Bug #50118)
- Performing intensive inserts and deletes in parallel with a high scan load could a data node crashes due to a failure in the `DBACC` kernel block. This was because checking for when to perform bucket splits or merges considered the first 4 scans only. (Bug #48700)
- `mysqld` could sometimes crash during a commit while trying to handle NDB Error 4028 `Node failure caused abort of transaction`. (Bug #38577)
- When setting `LockPagesInMainMemory` [1832], the stated memory was not allocated when the node was started, but rather only when the memory was used by the data node process for other reasons. (Bug #37430)

- Trying to insert more rows than would fit into an NDB table caused data nodes to crash. Now in such situations, the insert fails gracefully with error 633 `Table fragment hash index has reached maximum possible size`. (Bug #34348)

Changes in MySQL Cluster NDB 7.0.10 (5.1.39-ndb-7.0.10)

Functionality Added or Changed

- The output from `ndb_config --configinfo` [1975] `--xml` [1976] now indicates, for each configuration parameter, the following restart type information:

  - Whether a system restart or a node restart is required when resetting that parameter;
  - Whether cluster nodes need to be restarted using the `--initial` option when resetting the parameter.

  (Bug #47366)

- This enhanced functionality is supported for upgrades from MySQL Cluster NDB 6.3 when the NDB engine version is 6.3.29 or later. (Bug #48528, Bug #49163)

- Added the `ndb_mgmd --nowait-nodes` [1967] option, which permits a cluster that is configured to use multiple management servers to be started using fewer than the number configured. This is most likely to be useful when a cluster is configured with two management servers and you wish to start the cluster using only one of them.

  See ndb_mgmd — The MySQL Cluster Management Server Daemon, for more information. (Bug #48669)

Bugs Fixed

- Node takeover during a system restart occurs when the REDO log for one or more data nodes is out of date, so that a node restart is invoked for that node or those nodes. If this happens while a `mysqld` process is attached to the cluster as an SQL node, the `mysqld` takes a global schema lock (a row lock), while trying to set up cluster-internal replication.

  However, this setup process could fail, causing the global schema lock to be held for an excessive length of time, which made the node restart hang as well. As a result, the mysqld failed to set up cluster-internal replication, which led to tables being read only, and caused one node to hang during the restart.

  Note

  This issue could actually occur in MySQL Cluster NDB 7.0 only, but the fix was also applied MySQL Cluster NDB 6.3, to keep the two codebases in alignment.

  (Bug #49560)

- Starting a `mysqld` process with `--ndb-nodeid` [1916] (either as a command-line option or by assigning it a value in `my.cnf`) caused the `mysqld` to get only the corresponding connection from the `[mysqld]` section in the `config.ini` file having the matching ID, even when connection pooling was enabled (that is, when the `mysqld` process was started with `--ndb-cluster-connection-pool` [1912] set greater than 1). (Bug #48405)

  References: See also Bug #27644, Bug #38590, Bug #41592.

- Attempting to create more than 11435 tables failed with Error 306 (`Out of fragment records in DIH`). (Bug #49156)

- If the master data node receiving a request from a newly started API or data node for a node ID died before the request has been handled, the management server waited (and kept a mutex) until

all handling of this node failure was complete before responding to any other connections, instead of responding to other connections as soon as it was informed of the node failure (that is, it waited until it had received a NF_COMPLETEREP signal rather than a NODE_FAILREP signal). On visible effect of this misbehavior was that it caused management client commands such as SHOW and ALL STATUS to respond with unnecessary slowness in such circumstances. (Bug #49207)

- Sending `SIGHUP` to a `mysqld` running with the `--ndbcluster` [1915] and `--log-bin` [1647] options caused the process to crash instead of refreshing its log files. (Bug #49515)

- When evaluating the options `--include-databases` [1999], `--include-tables` [2000], `--exclude-databases` [2001], and `--exclude-tables` [2001], the `ndb_restore` program overwrote the result of the database-level options with the result of the table-level options rather than merging these results together, sometimes leading to unexpected and unpredictable results.

  As part of the fix for this problem, the semantics of these options have been clarified; because of this, the rules governing their evaluation have changed slightly. These changes be summed up as follows:

  - All `--include-*` and `--exclude-*` options are now evaluated from right to left in the order in which they are passed to `ndb_restore`.
  - All `--include-*` and `--exclude-*` options are now cumulative.
  - In the event of a conflict, the first (rightmost) option takes precedence.

  For more detailed information and examples, see `ndb_restore` — Restore a MySQL Cluster Backup. (Bug #48907)

- When performing tasks that generated large amounts of I/O (such as when using `ndb_restore`), an internal memory buffer could overflow, causing data nodes to fail with signal 6.

  Subsequent analysis showed that this buffer was not actually required, so this fix removes it. (Bug #48861)

- Exhaustion of send buffer memory or long signal memory caused data nodes to crash. Now an appropriate error message is provided instead when this situation occurs. (Bug #48852)

- In some situations, when it was not possible for an SQL node to start a schema transaction (necessary, for instance, as part of an online `ALTER TABLE`), `NDBCLUSTER` did not correctly indicate the error to the MySQL server, which led `mysqld` to crash. (Bug #48841)

- When employing `NDB` native backup to back up and restore an empty `NDB` table that used a non-sequential `AUTO_INCREMENT` value, the `AUTO_INCREMENT` value was not restored correctly. (Bug #48005)

- `NDB` stores blob column data in a separate, hidden table that is not accessible from MySQL. If this table was missing for some reason (such as accidental deletion of the file corresponding to the hidden table) when making a MySQL Cluster native backup, ndb_restore crashed when attempting to restore the backup. Now in such cases, ndb_restore fails with the error message `Table table_name has blob column (column_name) with missing parts table in backup` instead. (Bug #47289)

- Under certain conditions, accounting of the number of free scan records in the local query handler could be incorrect, so that during node recovery or a local checkpoint operations, the LQH could find itself lacking a scan record that is expected to find, causing the node to crash. (Bug #48697)

  References: See also Bug #48564.

- The creation of an ordered index on a table undergoing DDL operations could cause a data node crash under certain timing-dependent conditions. (Bug #48604)

- When running many parallel scans, a local checkpoint (which performs a scan internally) could find itself not getting a scan record, which led to a data node crash. Now an extra scan record is reserved

for this purpose, and a problem with obtaining the scan record returns an appropriate error (error code 489, `Too many active scans`). (Bug #48564)

- During an LCP master takeover, when the newly elected master did not receive a `COPY_GCI` LCP protocol message but other nodes participating in the local checkpoint had received one, the new master could use an uninitialized variable, which caused it to crash. (Bug #48584)

- When using very large transactions containing many inserts, `ndbmtd` could fail with `Signal 11` without an easily detectable reason, due to an internal variable being unitialized in the event that the `LongMessageBuffer` [1825] was overloaded. Now, the variable is initialized in such cases, avoiding the crash, and an appropriate error message is generated. (Bug #48441)

  References: See also Bug #46914.

- `ndb_config --xml --configinfo` now indicates that parameters belonging in the `[SCI]`, `[SCI DEFAULT]`, `[SHM]`, and `[SHM DEFAULT]` sections of the `config.ini` file are deprecated or experimental, as appropriate. (Bug #47365)

- During a node restart, logging was enabled on a per-fragment basis as the copying of each fragment was completed but local checkpoints were not enabled until all fragments were copied, making it possible to run out of redo log file space (`NDB` error code 410) before the restart was complete. Now logging is enabled only after all fragments has been copied, just prior to enabling local checkpoints. (Bug #48474)

- The configuration check that each management server runs to verify that all connected `ndb_mgmd` processes have the same configuration could fail when a configuration change took place while this check was in progress. Now in such cases, the configuration check is rescheduled for a later time, after the change is complete. (Bug #48143)

- A data node crashing while restarting, followed by a system restart could lead to incorrect handling of redo log metadata, causing the system restart to fail with `Error while reading REDO log`. (Bug #48436)

- Creating an `NDB` table with an excessive number of large `BIT` columns caused the cluster to fail. Now, an attempt to create such a table is rejected with error 791 (`Too many total bits in bitfields`). (Bug #42046)

  References: See also Bug #42047.

- In MySQL Cluster NDB 7.0, `ndb_config` and `ndb_error_reporter` were printing warnings about management and data nodes running on the same host to `stdout` instead of `stderr`, as was the case in earlier MySQL Cluster release series. (Bug #44689, Bug #49160)

  References: See also Bug #25941.

- `DROP DATABASE` failed when there were stale temporary `NDB` tables in the database. This situation could occur if `mysqld` crashed during execution of a `DROP TABLE` statement after the table definition had been removed from `NDBCLUSTER` but before the corresponding `.ndb` file had been removed from the crashed SQL node's data directory. Now, when `mysqld` executes `DROP DATABASE`, it checks for these files and removes them if there are no corresponding table definitions for them found in `NDBCLUSTER`. (Bug #44529)

- When a long-running transaction lasting long enough to cause Error 410 (`REDO log files overloaded`) was later committed or rolled back, it could happen that `NDBCLUSTER` was not able to release the space used for the REDO log, so that the error condition persisted indefinitely.

  The most likely cause of such transactions is a bug in the application using MySQL Cluster. This fix should handle most cases where this might occur. (Bug #36500)

- Deprecation and usage information obtained from `ndb_config --configinfo` [1975] regarding the `PortNumber` [1810] and `ServerPort` [1814] configuration parameters was improved. (Bug #24584)

- **Disk Data**: Repeatedly creating and then dropping Disk Data tables could eventually lead to data node failures. (Bug #45794, Bug #48910)

- **Disk Data**: When running a write-intensive workload with a very large disk page buffer cache, CPU usage approached 100% during a local checkpoint of a cluster containing Disk Data tables. (Bug #49532)

- **Disk Data**: `NDBCLUSTER` failed to provide a valid error message it failed to commit schema transactions during an initial start if the cluster was configured using the `InitialLogFileGroup` [1859] parameter. (Bug #48517)

- **Disk Data**: In certain limited cases, it was possible when the cluster contained Disk Data tables for `ndbmtd` to crash during a system restart. (Bug #48498)

  References: See also Bug #47832.

- **Disk Data**: When a crash occurs due to a problem in Disk Data code, the currently active page list is printed to `stdout` (that is, in one or more `ndb_`*`nodeid`*`_out.log` files). One of these lists could contain an endless loop; this caused a printout that was effectively never-ending. Now in such cases, a maximum of 512 entries is printed from each list. (Bug #42431)

- **Disk Data**: When the `FileSystemPathUndoFiles` [1858] configuration parameter was set to an non-existent path, the data nodes shut down with the generic error code 2341 (`Internal program error`). Now in such cases, the error reported is error 2815 (`File not found`).

- **Cluster API**: When a DML operation failed due to a uniqueness violation on an `NDB` table having more than one unique index, it was difficult to determine which constraint caused the failure; it was necessary to obtain an `NdbError` object, then decode its `details` property, which in could lead to memory management issues in application code.

  To help solve this problem, a new API method `Ndb::getNdbErrorDetail()` is added, providing a well-formatted string containing more precise information about the index that caused the unque constraint violation. The following additional changes are also made in the NDB API:

  - Use of `NdbError.details` is now deprecated in favor of the new method.

  - The `NdbDictionary::listObjects()` method has been modified to provide more information.

  For more information, see `Ndb::getNdbErrorDetail()`, The `NdbError` Structure, and `Dictionary::listObjects()`. (Bug #48851)

- **Cluster API**: When using blobs, calling `getBlobHandle()` requires the full key to have been set using `equal()`, because `getBlobHandle()` must access the key for adding blob table operations. However, if `getBlobHandle()` was called without first setting all parts of the primary key, the application using it crashed. Now, an appropriate error code is returned instead. (Bug #28116, Bug #48973)

Changes in MySQL Cluster NDB 7.0.9b (5.1.39-ndb-7.0.9b)

Bugs Fixed

- Using a large number of small fragment log files could cause `NDBCLUSTER` to crash while trying to read them during a restart. This issue was first observed with 1024 fragment log files of 16 MB each. (Bug #48651)

Changes in MySQL Cluster NDB 7.0.9a (5.1.39-ndb-7.0.9a)

Bugs Fixed

- When the combined length of all names of tables using the `NDB` storage engine was greater than or equal to 1024 bytes, issuing the `START BACKUP` command in the `ndb_mgm` client caused the cluster to crash. (Bug #48531)

Changes in MySQL Cluster NDB 7.0.9 (5.1.39-ndb-7.0.9)

Functionality Added or Changed

- **Performance**: Significant improvements in redo log handling and other file system operations can yield a considerable reduction in the time required for restarts. While actual restart times observed in a production setting will naturally vary according to database size, hardware, and other conditions, our own preliminary testing shows that these optimizations can yield startup times that are faster than those typical of previous MySQL Cluster releases by a factor of 50 or more.

Bugs Fixed

- **Important Change**: The `--with-ndb-port-base` option for `configure` did not function correctly, and has been deprecated. Attempting to use this option produces the warning `Ignoring deprecated option --with-ndb-port-base`.

  Beginning with MySQL Cluster NDB 7.1.0, the deprecation warning itself is removed, and the `--with-ndb-port-base` option is simply handled as an unknown and invalid option if you try to use it. (Bug #47941)

  References: See also Bug #38502.

- For `UPDATE IGNORE` statements, batching of updates is now disabled. This is because such statements failed when batching of updates was employed if any updates violated a unique constraint, to the fact a unique constraint violation could not be handled without aborting the transaction. (Bug #48036)

- When an `UPDATE` statement was issued against an `NDB` table where an index was used to identify rows but no data was actually changed, the `NDB` storage returned zero found rows.

  For example, consider the table created and populated using these statements:

```
CREATE TABLE t1
(
    c1 INT NOT NULL,
    c2 INT NOT NULL,
    PRIMARY KEY(c1),
    KEY(c2)
)
ENGINE = NDB;

INSERT INTO t1 VALUES(1, 1);
```

  The following `UPDATE` statements, even though they did not change any rows, each still matched a row, but this was reported incorrectly in both cases, as shown here:

```
mysql> UPDATE t1 SET c2 = 1 WHERE c1 = 1;
Query OK, 0 rows affected (0.00 sec)
Rows matched: 0  Changed: 0  Warnings: 0

mysql> UPDATE t1 SET c1 = 1 WHERE c2 = 1;
Query OK, 0 rows affected (0.00 sec)
Rows matched: 0  Changed: 0  Warnings: 0
```

  Now in such cases, the number of rows matched is correct. (In the case of each of the example `UPDATE` statements just shown, this is displayed as Rows matched: 1, as it should be.)

  This issue could affect `UPDATE` statements involving any indexed columns in `NDB` tables, regardless of the type of index (including `KEY`, `UNIQUE KEY`, and `PRIMARY KEY`) or the number of columns covered by the index. (Bug #47955)

- After upgrading a MySQL Cluster containing tables having unique indexes from an NDB 6.3 release to an NDB 7.0 release, attempts to create new unique indexes failed with `inconsistent trigger` errors (error code `293`).

For more information (including a workaround for previous MySQL Cluster NDB 7.0 releases), see Upgrade and downgrade compatibility: MySQL Cluster NDB 7.x. (Bug #48416)

- When a data node failed to start due to inability to recreate or drop objects during schema restoration (for example: insufficient memory was available to the data node process on account of issues not directly related to MySQL Cluster on the host machine), the reason for the failure was not provided. Now is such cases, a more informative error message is logged. (Bug #48232)

- A table that was created following an upgrade from a MySQL Cluster NDB 6.3 release to MySQL Cluster NDB 7.0 (starting with version 6.4.0) or later was dropped by a system restart. This was due to a change in the format of `NDB` schema files and the fact that the upgrade of the format of existing `NDB` 6.3 schema files to the `NDB` 7.0 format failed to change the version number contained in the file; this meant that a system restart re-ran the upgrade routine, which interpreted the newly created table as an uncommitted table (which by definition ought not to be saved). Now the version number of upgraded `NDB` 6.3 schema files is set correctly during the upgrade process. (Bug #48227)

- In certain cases, performing very large inserts on `NDB` tables when using `ndbmtd` caused the memory allocations for ordered or unique indexes (or both) to be exceeded. This could cause aborted transactions and possibly lead to data node failures. (Bug #48037)

  References: See also Bug #48113.

- Performing a system restart of the cluster after having performed a table reorganization which added partitions caused the cluster to become inconsistent, possibly leading to a forced shutdown, in either of the following cases:

  1. When a local checkpoint was in progress but had not yet completed, new partitions were not restored; that is, data that was supposed to be moved could be lost instead, leading to an inconsistent cluster. This was due to an issue whereby the `DBDIH` kernel block did not save the new table definition and instead used the old one (the version having fewer partitions).

  2. When the most recent LCP had completed, ordered indexes and unlogged tables were still not saved (since these did not participate in the LCP). In this case, the cluster crashed during a subsequent system restart, due to the inconsistency between the main table and the ordered index.

  Now, `DBDIH` is forced in such cases to use the version of the table definition held by the `DBDICT` kernel block, which was (already) correct and up to date. (Bug #46585)

- `SHOW CREATE TABLE` did not display the `AUTO_INCREMENT` value for `NDB` tables having `AUTO_INCREMENT` columns. (Bug #47865)

- In some cases, `ndbmtd` could allocate more space for the undo buffer than was actually available, leading to a failure in the `LGMAN` kernel block and subsequent failure of the data node. (Bug #47966)

- Starting a data node with a very large amount of `DataMemory` [1817] (approximately 90G or more) could lead to crash of the node due to job buffer congestion. (Bug #47984)

- On Solaris, shutting down a management node failed when issuing the command to do so from a client connected to a different management node. (Bug #47948)

- After changing the value of `DiskSyncSize` [1842] to 4294967039 (the maximum) in the `config.ini` file and reloading the cluster configuration, the new value was displayed in the update information written into the cluster log as a signed number instead of unsigned. (Bug #47944)

  References: See also Bug #47932.

- On Solaris 10 for SPARC, `ndb_mgmd` failed to parse the `config.ini` file when the `DiskSyncSize` [1842] configuration parameter, whose permitted range of values is 32768 to 4294967039, was set equal to 4294967040 (which is also the value of the internal constant

MAX_INT_RNIL), nor could DiskSyncSize [1842] be set successfully any higher than the minimum value. (Bug #47932)

References: See also Bug #47944.

- Setting FragmentLogFileSize [1826] to a value greater than 256 MB led to errors when trying to read the redo log file. (Bug #47908)

- ndb_mgmd failed to close client connections that had timed out. After running for some time, a race condition could develop in the management server, due to ndb_mgmd having exhausted all of its file descriptors in this fashion. (Bug #45497)

  References: See also Bug #47712.

- An optimization in MySQL Cluster NDB 7.0 causes the DBDICT kernel block to copy several tables at a time when synchronizing the data dictionary to a newly started node; previously, this was done one table at a time. However, when NDB tables were sufficiently large and numerous, the internal buffer for storing them could fill up, causing a data node crash.

  In testing, it was found that having 100 NDB tables with 128 columns each was enough to trigger this issue. (Bug #47859)

- When starting a node and synchronizing tables, memory pages were allocated even for empty fragments. In certain situations, this could lead to insufficient memory. (Bug #47782)

- Under some circumstances, when a scan encountered an error early in processing by the DBTC kernel block (see The DBTC Block), a node could crash as a result. Such errors could be caused by applications sending incorrect data, or, more rarely, by a DROP TABLE operation executed in parallel with a scan. (Bug #47831)

- In some cases, the MySQL Server tried to use an error status whose value had never been set. The problem in the code that caused this, in hostname.cc, manifested when using debug builds of mysqld in MySQL Cluster replication.

  This fix brings MySQL Cluster's error handling in hostname.cc in line with what is implemented in MySQL 5.4. (Bug #47548)

- During an upgrade, newer nodes (NDB kernel block DBTUP) could in some cases try to use the long signal format for communication with older nodes (DBUTIL kernel block) that did not understand the newer format, causing older data nodes to fail after restarting. (Bug #47740)

- configure failed to honor the --with-zlib-dir option when trying to build MySQL Cluster from source. (Bug #47223)

- A very small race-condition between NODE_FAILREP and LQH_TRANSREQ signals when handling node failure could lead to operations (locks) not being taken over when they should have been, and subsequently becoming stale. This could lead to node restart failures, and applications getting into endless lock-conflicts with operations that were not released until the node was restarted. (Bug #47715)

  References: See also Bug #41297.

- ndbd was not built correctly when compiled using gcc 4.4.0. (The ndbd binary was built, but could not be started.) (Bug #46113)

- When starting a cluster with a great many tables, it was possible for MySQL client connections as well as the slave SQL thread to issue DML statements against MySQL Cluster tables before mysqld had finished connecting to the cluster and making all tables writeable. This resulted in Table ... is read only errors for clients and the Slave SQL thread.

This issue is fixed by introducing the `--ndb-wait-setup` [1919] option for the MySQL server. This provides a configurable maximum amount of time that `mysqld` waits for all `NDB` tables to become writeable, before enabling MySQL clients or the slave SQL thread to connect. (Bug #40679)

References: See also Bug #46955.

- When building MySQL Cluster, it was possible to configure the build using `--with-ndb-port` without supplying a port number. Now in such cases, `configure` fails with an error. (Bug #38502)

  References: See also Bug #47941.

- If a node failed while sending a fragmented long signal, the receiving node did not free long signal assembly resources that it had allocated for the fragments of the long signal that had already been received. (Bug #44607)

- Numeric configuration parameters set in `my.cnf` were interpreted as signed rather than unsigned values. The effect of this was that values of 2G or more were truncated with the warning `[MgmSrvr] Warning: option 'opt_name': signed value opt_value adjusted to 2147483647`. Now such parameter values are treated as unsigned, so that this truncation does not take place.

  This issue did not effect parameters set in `config.ini`. (Bug #44448)

- When a copying operation exhausted the available space on a data node while copying large `BLOB` columns, this could lead to failure of the data node and a `Table is full` error on the SQL node which was executing the operation. Examples of such operations could include an `ALTER TABLE` that changed an `INT` column to a `BLOB` column, or a bulk insert of `BLOB` data that failed due to running out of space or to a duplicate key error. (Bug #34583, Bug #48040)

  References: See also Bug #41674, Bug #45768.

- When the MySQL server SQL mode included `STRICT_TRANS_TABLES` [576], storage engine warnings and error codes specific to `NDB` were returned when errors occurred, instead of the MySQL server errors and error codes expected by some programming APIs (such as Connector/J) and applications. (Bug #35990)

- **Disk Data**: A local checkpoint of an empty fragment could cause a crash during a system restart which was based on that LCP. (Bug #47832)

  References: See also Bug #41915.

- **Disk Data**: Multi-threaded data nodes could in some cases attempt to access the same memory structure in parallel, in a non-safe manner. This could result in data node failure when running `ndbmtd` while using Disk Data tables. (Bug #44195)

  References: See also Bug #46507.

- **Cluster API**: If an NDB API program reads the same column more than once, it is possible exceed the maximum permissible message size, in which case the operation should be aborted due to NDB error 880 `Tried to read too much - too many getValue calls`, however due to a change introduced in MySQL Cluster NDB 6.3.18, the check for this was not done correctly, which instead caused a data node crash. (Bug #48266)

- **Cluster API**: The NDB API methods `Dictionary::listEvents()`, `Dictionary::listIndexes()`, `Dictionary::listObjects()`, and `NdbOperation::getErrorLine()` formerly had both `const` and non-`const` variants. The non-`const` versions of these methods have been removed. In addition, the `NdbOperation::getBlobHandle()` method has been re-implemented to provide consistent internal semantics. (Bug #47798)

- **Cluster API**: A duplicate read of a column caused NDB API applications to crash. (Bug #45282)

- **Cluster API**: The error handling shown in the example file `ndbapi_scan.cpp` included with the MySQL Cluster distribution was incorrect. (Bug #39573)

Changes in MySQL Cluster NDB 7.0.8a (5.1.37-ndb-7.0.8a)

Bugs Fixed

- The disconnection of an API or SQL node having a node ID greater than 49 caused a forced shutdown of the cluster. (Bug #47844)
- The error message text for `NDB` error code 410 (`REDO log files overloaded...`) was truncated. (Bug #23662)

Changes in MySQL Cluster NDB 7.0.8 (5.1.37-ndb-7.0.8)

Functionality Added or Changed

- A new option `--log-name` [1965] is added for `ndb_mgmd`. This option can be used to provide a name for the current node and then to identify it in messages written to the cluster log. For more information, see `ndb_mgmd` — The MySQL Cluster Management Server Daemon. (Bug #47643)
- `--config-dir` is now accepted by `ndb_mgmd` as an alias for the `--configdir` [1963] option. (Bug #42013)
- **Disk Data**: Two new columns have been added to the output of `ndb_desc` to make it possible to determine how much of the disk space allocated to a given table or fragment remains free. (This information is not available from the `INFORMATION_SCHEMA.FILES` table, since the `FILES` table applies only to Disk Data files.) For more information, see `ndb_desc` — Describe NDB Tables. (Bug #47131)

Bugs Fixed

- **Important Change**: Previously, the MySQL Cluster management node and data node programs, when run on Windows platforms, required the `--nodaemon` option to produce console output. Now, these programs run in the foreground when invoked from the command line on Windows, which is the same behavior that `mysqld.exe` displays on Windows. (Bug #45588)
- When reloading the management server configuration, only the last changed parameter was logged. (Bug #47036)
- Now, when started with `--initial` [1965] `--reload` [1966], `ndb_mgmd` tries to connect to and to copy the configuration of an existing `ndb_mgmd` process with a confirmed configuration. This works only if another management server is found, and the configuration files used by both management nodes are exactly the same.

  If no other management server is found, the local configuration file is read and used. With this change, it is now necessary when performing a rolling restart of a MySQL Cluster having multiple management nodes, to stop all `ndb_mgmd` processes, and when restarting them, to start the first of these with the `--reload` [1966] or `--initial` [1965] option (or both options), and then to start any remaining management nodes without using either of these two options. For more information, see Performing a Rolling Restart of a MySQL Cluster. (Bug #45495, Bug #46488, Bug #11753966, Bug #11754823)

  References: See also Bug #42015, Bug #11751233.
- The NDB kernel's parser (in `ndb/src/common/util/Parser.cpp`) did not interpret the backslash (“`\`”) character correctly. (Bug #47426)
- The following issues with error logs generated by `ndbmtd` were addressed:

  1. The version string was sometimes truncated, or even not shown, depending on the number of threads in use (the more threads, the worse the problem). Now the version string is shown in full, as well as the file names for all tracefiles (where available).

2. In the event of a crash, the thread number of the thread that crashed was not printed. Now this information is supplied, if available.

(Bug #47629)

- `mysqld` allocated an excessively large buffer for handling `BLOB` values due to overestimating their size. (For each row, enough space was allocated to accommodate *every* `BLOB` or `TEXT` column value in the result set.) This could adversely affect performance when using tables containing `BLOB` or `TEXT` columns; in a few extreme cases, this issue could also cause the host system to run out of memory unexpectedly. (Bug #47574)

  References: See also Bug #47572, Bug #47573.

- `NDBCLUSTER` uses a dynamically allocated buffer to store `BLOB` or `TEXT` column data that is read from rows in MySQL Cluster tables.

  When an instance of the `NDBCLUSTER` table handler was recycled (this can happen due to table definition cache pressure or to operations such as `FLUSH TABLES` or `ALTER TABLE`), if the last row read contained blobs of zero length, the buffer was not freed, even though the reference to it was lost. This resulted in a memory leak.

  For example, consider the table defined and populated as shown here:

  ```
  CREATE TABLE t (a INT PRIMARY KEY, b LONGTEXT) ENGINE=NDB;

  INSERT INTO t VALUES (1, REPEAT('F', 20000));
  INSERT INTO t VALUES (2, '');
  ```

  Now execute repeatedly a `SELECT` on this table, such that the zero-length `LONGTEXT` row is last, followed by a `FLUSH TABLES` statement (which forces the handler object to be re-used), as shown here:

  ```

  SELECT a, length(b) FROM bl ORDER BY a;
  FLUSH TABLES;
  ```

  Prior to the fix, this resulted in a memory leak proportional to the size of the stored `LONGTEXT` value each time these two statements were executed. (Bug #47573)

  References: See also Bug #47572, Bug #47574.

- Large transactions involving joins between tables containing `BLOB` columns used excessive memory. (Bug #47572)

  References: See also Bug #47573, Bug #47574.

- After an `NDB` table had an `ALTER ONLINE TABLE` operation performed on it in a MySQL Cluster running a MySQL Cluster NDB 6.3.x release, it could not be upgraded online to a MySQL Cluster NDB 7.0.x release. This issue was detected using MySQL Cluster NDB 6.3.20, but is likely to effect any MySQL Cluster NDB 6.3.x release supporting online DDL operations. (Bug #47542)

- When using multi-threaded data nodes (`ndbmtd`) with `NoOfReplicas` [1815] set to a value greater than 2, attempting to restart any of the data nodes caused a forced shutdown of the entire cluster. (Bug #47530)

- A variable was left uninitialized while a data node copied data from its peers as part of its startup routine; if the starting node died during this phase, this could lead a crash of the cluster when the node was later restarted. (Bug #47505)

- Handling of `LQH_TRANS_REQ` signals was done incorrectly in `DBLQH` when the transaction coordinator failed during a `LQH_TRANS_REQ` session. This led to incorrect handling of multiple node failures, particularly when using `ndbmtd`. (Bug #47476)

- When using `ndbmtd`, a parallel `DROP TABLE` operation could cause data nodes to have different views of which tables should be included in local checkpoints; this discrepancy could lead to a node failure during an LCP. (Bug #46873)

- During an online alter table operation, the new table definition was made available for users during the prepare-phase when it should only be exposed during and after a commit. This issue could affect NDB API applications, mysqld processes, or data node processes. (Bug #47375)

- Aborting an online add column operation (for example, due to resource problems on a single data node, but not others) could lead to a forced node shutdown. (Bug #47364)

- On Windows, `ndbd --initial [1954]` could hang in an endless loop while attempting to remove directories. (Bug #45402)

- When a data node restarts, it first runs the redo log until reaching the latest restorable global checkpoint; after this it scans the remainder of the redo log file, searching for entries that should be invalidated so they are not used in any subsequent restarts. (It is possible, for example, if restoring GCI number 25, that there might be entries belonging to GCI 26 in the redo log.) However, under certain rare conditions, during the invalidation process, the redo log files themselves were not always closed while scanning ahead in the redo log. In rare cases, this could lead to `MaxNoOfOpenFiles [1827]` being exceeded, causing a the data node to crash. (Bug #47171)

- Clients attempting to connect to the cluster during shutdown could sometimes cause the management server to crash. (Bug #47325)

- Using triggers on `NDB` tables caused `ndb_autoincrement_prefetch_sz [1921]` to be treated as having the NDB kernel's internal default value (32) and the value for this variable as set on the cluster's SQL nodes to be ignored. (Bug #46712)

- The size of the table descriptor pool used in the `DBTUP` kernel block was incorrect. This could lead to a data node crash when an LQH sent a `CREATE_TAB_REF` signal. (Bug #47215)

  References: See also Bug #44908.

- For very large values of `MaxNoOfTables [1829]` + `MaxNoOfAttributes [1828]`, the calculation for `StringMemory [1819]` could overflow when creating large numbers of tables, leading to `NDB` error 773 (`Out of string memory, please modify StringMemory config parameter`), even when `StringMemory [1819]` was set to `100` (100 percent). (Bug #47170)

- The default value for the `StringMemory [1819]` configuration parameter, unlike other MySQL Cluster configuration parameters, was not set in `ndb/src/mgmsrv/ConfigInfo.cpp`. (Bug #47166)

- Signals from a failed API node could be received after an `API_FAILREQ` signal (see Operations and Signals) has been received from that node, which could result in invalid states for processing subsequent signals. Now, all pending signals from a failing API node are processed before any `API_FAILREQ` signal is received. (Bug #47039)

  References: See also Bug #44607.

- When started with the `--initial [1965]` and `--reload [1966]` options, if `ndb_mgmd` could not find a configuration file or connect to another management server, it appeared to hang. Now, when trying to fetch its configuration from another management node, `ndb_mgmd` checks and signals (`Trying to get configuration from other mgmd(s)`) each 30 seconds that it has not yet done so. (Bug #42015)

  References: See also Bug #45495.

- When performing auto-discovery of tables on individual SQL nodes, `NDBCLUSTER` attempted to overwrite existing `MyISAM .frm` files and corrupted them.

Workaround. In the `mysql` client, create a new table (`t2`) with same definition as the corrupted table (`t1`). Use your system shell or file manager to rename the old `.MYD` file to the new file name (for example, `mv t1.MYD t2.MYD`). In the `mysql` client, repair the new table, drop the old one, and rename the new table using the old file name (for example, `RENAME TABLE t2 TO t1`).

(Bug #42614)

- When a data node received a `TAKE_OVERTCCONF` signal from the master before that node had received a `NODE_FAILREP`, a race condition could in theory result. (Bug #37688)

  References: See also Bug #25364, Bug #28717.

- Running an `ALTER TABLE` statement while an `NDB` backup was in progress caused `mysqld` to crash. (Bug #44695)

- Running `ndb_restore` with the `--print` or `--print_log` option could cause it to crash. (Bug #40428, Bug #33040)

- An insert on an `NDB` table was not always flushed properly before performing a scan. One way in which this issue could manifest was that `LAST_INSERT_ID()` [1036] sometimes failed to return correct values when using a trigger on an `NDB` table. (Bug #38034)

- For multi-threaded data nodes, insufficient fragment records were allocated in the `DBDIH` NDB kernel block, which could lead to error 306 when creating many tables; the number of fragment records allocated did not take into account the number of LQH instances. (Bug #44908)

- Some joins on large `NDB` tables having `TEXT` or `BLOB` columns could cause `mysqld` processes to leak memory. The joins did not need to reference the `TEXT` or `BLOB` columns directly for this issue to occur. (Bug #36701)

- On Mac OS X 10.5, commands entered in the management client failed and sometimes caused the client to hang, although management client commands invoked using the `--execute` [1970] (or `-e`) option from the system shell worked normally.

  For example, the following command failed with an error and hung until killed manually, as shown here:

  ```
  ndb_mgm> SHOW
  Warning, event thread startup failed, degraded printouts as result, errno=36
  ^C
  ```

  However, the same management client command, invoked from the system shell as shown here, worked correctly:

  ```
  shell> ndb_mgm -e "SHOW"
  ```

  (Bug #35751)

  References: See also Bug #34438.

- **Disk Data**: Calculation of free space for Disk Data table fragments was sometimes done incorrectly. This could lead to unnecessary allocation of new extents even when sufficient space was available in existing ones for inserted data. In some cases, this might also lead to crashes when restarting data nodes.

  Note

  This miscalculation was not reflected in the contents of the `INFORMATION_SCHEMA.FILES` table, as it applied to extents allocated to a fragment, and not to a file.

  (Bug #47072)

- **Cluster API**: In some circumstances, if an API node encountered a data node failure between the creation of a transaction and the start of a scan using that transaction, then any subsequent calls to `startTransaction()` and `closeTransaction()` could cause the same transaction to be started and closed repeatedly. (Bug #47329)

- **Cluster API**: Performing multiple operations using the same primary key within the same `NdbTransaction::execute()` call could lead to a data node crash.

  Note

  This fix does not make change the fact that performing multiple operations using the same primary key within the same `execute()` is not supported; because there is no way to determine the order of such operations, the result of such combined operations remains undefined.

  (Bug #44065)

  References: See also Bug #44015.

Changes in MySQL Cluster NDB 7.0.7 (5.1.35-ndb-7.0.7)

Functionality Added or Changed

- **Important Change**: The default value of the `DiskIOThreadPool` [1857] data node configuration parameter has changed from 8 to 2.

- On Solaris platforms, the MySQL Cluster management server and NDB API applications now use `CLOCK_REALTIME` as the default clock. (Bug #46183)

- A new option `--exclude-missing-columns` has been added for the `ndb_restore` program. In the event that any tables in the database or databases being restored to have fewer columns than the same-named tables in the backup, the extra columns in the backup's version of the tables are ignored. For more information, see `ndb_restore` — Restore a MySQL Cluster Backup. (Bug #43139)

- Formerly, node IDs were represented in the cluster log using a complex hexadecimal/binary encoding scheme. Now, node IDs are reported in the cluster log using numbers in standard decimal notation. (Bug #44248)

-

  Note

  This issue, originally resolved in MySQL 5.1.16, re-occurred due to a later (unrelated) change. The fix has been re-applied.

  (Bug #25984)

- Previously, it was possible to disable arbitration only by setting `ArbitrationRank` to 0 on all management and API nodes. A new data node configuration parameter `Arbitration` [1844] simplifies this task; to disable arbitration, you can now use `Arbitration = Disabled` in the `[ndbd default]` section of the `config.ini` file.

  It is now also possible to configure arbitration in such a way that the cluster waits until the time determined by `ArbitrationTimeout` [1844] passes for an external manager to perform arbitration instead of handling it internally. This can be done by setting `Arbitration = WaitExternal` in the `[ndbd default]` section of the `config.ini` file.

  The default value for the Arbitration parameter is `Default`, which permits arbitration to proceed normally, as determined by the `ArbitrationRank` settings for the management and API nodes.

  For more information, see Defining MySQL Cluster Data Nodes.

Bugs Fixed

- **Packaging**: The `pkg` installer for MySQL Cluster on Solaris did not perform a complete installation due to an invalid directory reference in the postinstall script. (Bug #41998)

- The output from `ndb_config --configinfo` [1975] `--xml` [1975] contained quote characters (`"`) within quoted XML attributes, causing it to be not well-formed. (Bug #46891)

- When using multi-threaded data node processes (`ndbmtd`), it was possible for LQH threads to continue running even after all `NDB` tables had been dropped. This meant that dropping the last remaining `NDB` table during a local checkpoint could cause multi-threaded data nodes to fail. (Bug #46890)

- During a global checkpoint, LQH threads could run unevenly, causing a circular buffer overflow by the Subscription Manager, which led to data node failure. (Bug #46782)

  References: See also Bug #46123, Bug #46723, Bug #45612.

- Killing MySQL Cluster nodes immediately following a local checkpoint could lead to a crash of the cluster when later attempting to perform a system restart.

  The exact sequence of events causing this issue was as follows:

  1. Local checkpoint occurs.
  2. Immediately following the LCP, kill the master data node.
  3. Kill the remaining data nodes within a few seconds of killing the master.
  4. Attempt to restart the cluster.

  (Bug #46412)

- Restarting the cluster following a local checkpoint and an online `ALTER TABLE` on a non-empty table caused data nodes to crash. (Bug #46651)

- A combination of index creation and drop operations (or creating and dropping tables having indexes) with node and system restarts could lead to a crash. (Bug #46552)

- Creating an index when the cluster had run out of table records could cause data nodes to crash. (Bug #46295)

- When combining an index scan and a delete with a primary key delete, the index scan and delete failed to initialize a flag properly. This could in rare circumstances cause a data node to crash. (Bug #46069)

- Following an upgrade from MySQL Cluster NDB 6.3.x to MySQL Cluster NDB 7.0.6, DDL and backup operations failed. (Bug #46494, Bug #46563)

- Full table scans failed to execute when the cluster contained more than 21 table fragments.

  Note

  The number of table fragments in the cluster can be calculated as the number of data nodes, times 8 (that is, times the value of the internal constant `MAX_FRAG_PER_NODE`), divided by the number of replicas. Thus, when `NoOfReplicas = 1` at least 3 data nodes were required to trigger this issue, and when `NoOfReplicas = 2` at least 4 data nodes were required to do so.

  (Bug #46490)

- `OPTIMIZE TABLE` on an `NDB` table could in some cases cause SQL and data nodes to crash. This issue was observed with both `ndbd` and `ndbmtd`. (Bug #45971)

- Ending a line in the `config.ini` file with an extra semicolon character (`;`) caused reading the file to fail with a parsing error. (Bug #46242)
- On Windows, the internal `basestring_vsprintf()` function did not return a POSIX-compliant value as expected, causing the management server to crash when trying to start a MySQL Cluster with more than 4 data nodes. (Bug #45733)
- The `AutoReconnect` [1867] configuration parameter for API nodes (including SQL nodes) has been added. This is intended to prevent API nodes from re-using allocated node IDs during cluster restarts. For more information, see Defining SQL and Other API Nodes in a MySQL Cluster.

  This fix also introduces two new methods of the NDB API `Ndb_cluster_connection` class: `set_auto_reconnect()` and `get_auto_reconnect()`. (Bug #45921)
- DML statements run during an upgrade from MySQL Cluster NDB 6.3 to NDB 7.0 were not handled correctly. (Bug #45917)
- The signals used by `ndb_restore` to send progress information about backups to the cluster log accessed the cluster transporter without using any locks. Because of this, it was theoretically possible that these signals could be interefered with by heartbeat signals if both were sent at the same time, causing the `ndb_restore` messages to be corrupted. (Bug #45646)
- Due to changes in the way that `NDBCLUSTER` handles schema changes (implementation of schema transactions) in MySQL Cluster NDB 7.0, it was not possible to create MySQL Cluster tables having more than 16 indexes using a single `CREATE TABLE` statement.

  This issue occurs only in MySQL Cluster NDB 7.0 releases prior to 7.0.7 (including releases numbered NDB 6.4.x).

  If you are not yet able to upgrade from an earlier MySQL Cluster NDB 7.0 release, you can work around this problem by creating the table without any indexes, then adding the indexes using a separate `CREATE INDEX` statement for each index. (Bug #45525)
- `storage/ndb/src/common/util/CMakeLists.txt` did not build the `BaseString-t` test program for Windows as the equivalent `storage/ndb/src/common/util/Makefile.am` does when building MySQL Cluster on Unix platforms. (Bug #45099)
- The warning message `Possible bug in Dbdih::execBLOCK_COMMIT_ORD ...` could sometimes appear in the cluster log. This warning is obsolete, and has been removed. (Bug #44563)
- `ALTER TABLE REORGANIZE PARTITION` could fail with Error 741 (`Unsupported alter table`) if the appropriate hash-map was not present. This could occur when adding nodes online; for example, when going from 2 data nodes to 3 data nodes with `NoOfReplicas=1`, or from 4 data nodes to 6 data nodes with `NoOfReplicas=2`. (Bug #44301)
- In some cases, `OPTIMIZE TABLE` on an `NDB` table did not free any `DataMemory` [1817]. (Bug #43683)
- Problems could arise when using `VARCHAR` columns whose size was greater than 341 characters and which used the `utf8_unicode_ci` collation. In some cases, this combination of conditions could cause certain queries and `OPTIMIZE TABLE` statements to crash `mysqld`. (Bug #45053)
- Previously, a `GCP STOP` event was written to the cluster log as an `INFO` event. Now it is logged as a `WARNING` event instead. (Bug #43853)
- Debugging code causing `ndbd` to use file compression on NTFS file systems failed with an error. (The code was removed.) This issue affected debug builds of MySQL Cluster on Windows platforms only. (Bug #44418)
- If the cluster crashed during the execution of a `CREATE LOGFILE GROUP` statement, the cluster could not be restarted afterward. (Bug #36702)

  References: See also Bug #34102.

- **Disk Data**: **Partitioning**: An `NDB` table created with a very large value for the `MAX_ROWS` option could—if this table was dropped and a new table with fewer partitions, but having the same table ID, was created—cause `ndbd` to crash when performing a system restart. This was because the server attempted to examine each partition whether or not it actually existed. (Bug #45154)

  References: See also Bug #58638.

- **Disk Data**: If the value set in the `config.ini` file for `FileSystemPathDD` [1857], `FileSystemPathDataFiles` [1858], or `FileSystemPathUndoFiles` [1858] was identical to the value set for `FileSystemPath` [1816], that parameter was ignored when starting the data node with `--initial` [1954] option. As a result, the Disk Data files in the corresponding directory were not removed when performing an initial start of the affected data node or data nodes. (Bug #46243)

Changes in MySQL Cluster NDB 7.0.6 (5.1.34-ndb-7.0.6)

Functionality Added or Changed

- The `ndb_config` utility program can now provide an offline dump of all MySQL Cluster configuration parameters including information such as default and permitted values, brief description, and applicable section of the `config.ini` file. A dump in text format is produced when running `ndb_config` with the new `--configinfo` option, and in XML format when the options `--configinfo --xml` are used together. For more information and examples, see `ndb_config` — Extract MySQL Cluster Configuration Information.

Bugs Fixed

- **Important Change**: **Partitioning**: User-defined partitioning of an `NDBCLUSTER` table without any primary key sometimes failed, and could cause `mysqld` to crash.

  Now, if you wish to create an `NDBCLUSTER` table with user-defined partitioning, the table must have an explicit primary key, and all columns listed in the partitioning expression must be part of the primary key. The hidden primary key used by the `NDBCLUSTER` storage engine is not sufficient for this purpose. However, if the list of columns is empty (that is, the table is defined using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

  This change does not effect the partitioning of tables using any storage engine other than `NDBCLUSTER`. (Bug #40709)

- **Important Change**: Previously, the configuration parameter `NoOfReplicas` [1815] had no default value. Now the default for `NoOfReplicas` [1815] is 2, which is the recommended value in most settings. (Bug #44746)

- **Important Note**: It was not possible to perform an online upgrade from any MySQL Cluster NDB 6.x release to MySQL Cluster NDB 7.0.5 or any to earlier MySQL Cluster NDB 7.0 release.

  With this fix, it is possible in MySQL Cluster NDB 7.0.6 and later to perform online upgrades from MySQL Cluster NDB 6.3.8 and later MySQL Cluster NDB 6.3 releases, or from MySQL Cluster NDB 7.0.5 or later MySQL Cluster NDB 7.0 releases. Online upgrades to MySQL Cluster NDB 7.0 releases previous to MySQL Cluster NDB 7.0.6 from earlier MySQL Cluster releases remain unsupported; online upgrades from MySQL Cluster NDB 7.0 releases previous to MySQL Cluster NDB 7.0.5 (including NDB 6.4.x beta releases) to later MySQL Cluster NDB 7.0 releases also remain unsupported. (Bug #44294)

- `ndb_config --xml` [1975] did not output any entries for the `HostName` parameter. In addition, the default listed for `MaxNoOfFiles` was outside the permitted range of values. (Bug #44749)

  References: See also Bug #44685, Bug #44746.

- The output of `ndb_config --xml` [1975] did not provide information about all sections of the configuration file. (Bug #44685)

  References: See also Bug #44746, Bug #44749.

- An internal NDB API buffer was not properly initialized. (Bug #44977)
- When a data node had written its GCI marker to the first page of a megabyte, and that node was later killed during restart after having processed that page (marker) but before completing a LCP, the data node could fail with file system errors. (Bug #44952)

  References: See also Bug #42564, Bug #44291.
- Repeated starting and stopping of data nodes could cause ndb_mgmd to fail. This issue was observed on Solaris/SPARC. (Bug #43974)
- When `ndb_config` could not find the file referenced by the `--config-file` option, it tried to read `my.cnf` instead, then failed with a misleading error message. (Bug #44846)
- When a data node was down so long that its most recent local checkpoint depended on a global checkpoint that was no longer restorable, it was possible for it to be unable to use optimized node recovery when being restarted later. (Bug #44844)

  References: See also Bug #26913.
- When restarting a data nodes, management and API nodes reconnecting to it failed to re-use existing ports that had already been dynamically allocated for communications with that data node. (Bug #44866)
- When using large numbers of configuration parameters, the management server took an excessive amount of time (several minutes or more) to load these from the configuration cache when starting. This problem occurred when there were more than 32 configuration parameters specified, and became progressively worse with each additional multiple of 32 configuration parameters. (Bug #44488)
- Online upgrades to MySQL Cluster NDB 7.0 from a MySQL Cluster NDB 6.3 release could fail due to changes in the handling of key lengths and unique indexes during node recovery. (Bug #44827)
- Building the MySQL Cluster NDB 7.0 tree failed when using the `icc` compiler. (Bug #44310)
- SSL connections to SQL nodes failed on big-endian platforms. (Bug #44295)
- An NDB internal timing function did not work correctly on Windows and could cause `mysqld` to fail on some AMD processors, or when running inside a virtual machine. (Bug #44276)
- A number of incorrectly formatted output strings in the source code caused compiler warnings. (Bug #43878)
- Use of `__builtin_expect()` had the side effect that compiler warnings about misuse of `=` (assignment) instead of `==` in comparisons were lost when building in debug mode. This is no longer employed when configuring the build with the `--with-debug` option. (Bug #44570)

  References: See also Bug #44567.
- Inspection of the code revealed that several assignment operators (`=`) were used in place of comparison operators (`==`) in `DbdihMain.cpp`. (Bug #44567)

  References: See also Bug #44570.
- It was possible for NDB API applications to insert corrupt data into the database, which could subquently lead to data node crashes. Now, stricter checking is enforced on input data for inserts and updates. (Bug #44132)
- `NDBCLUSTER` did not build correctly on Solaris 9 platforms. (Bug #39080)

  References: See also Bug #39036, Bug #39038.
- Signals providing node state information (`NODE_STATE_REP` and `CHANGE_NODE_STATE_REQ`) were not propagated to all blocks of `ndbmtd`. This could cause the following problems:

- Inconsistent redo logs when performing a graceful shutdown;
- Data nodes crashing when later restarting the cluster, data nodes needing to perform node recovery during the system restart, or both.

(Bug #44291)

References: See also Bug #42564.

- When trying to use a data node with an older version of the management server, the data node crashed on startup. (Bug #43699)
- In some cases, data node restarts during a system restart could fail due to insufficient redo log space. (Bug #43156)
- `ndb_restore` failed when trying to restore data on a big-endian machine from a backup file created on a little-endian machine. (Bug #44069)
- The output of `ndbd --help` did not provide clear information about the program's `--initial` and `--initial-start` options. (Bug #28905)
- It was theoretically possible for the value of a nonexistent column to be read as `NULL`, rather than causing an error. (Bug #27843)
- **Disk Data**: During a checkpoint, restore points are created for both the on-disk and in-memory parts of a Disk Data table. Under certain rare conditions, the in-memory restore point could include or exclude a row that should have been in the snapshot. This would later lead to a crash during or following recovery.

  This issue was somewhat more likely to be encountered when using `ndbmtd`. (Bug #41915)

  References: See also Bug #47832.

- **Disk Data**: This fix supercedes and improves on an earlier fix made for this bug in MySQL 5.1.18. (Bug #24521)

Changes in MySQL Cluster NDB 7.0.5 (5.1.32-ndb-7.0.5)

Functionality Added or Changed

- Two new server status variables `Ndb_scan_count` [1949] and `Ndb_pruned_scan_count` [1949] have been introduced. `Ndb_scan_count` [1949] gives the number of scans executed since the cluster was last started. `Ndb_pruned_scan_count` [1949] gives the number of scans for which `NDBCLUSTER` was able to use partition pruning. Together, these variables can be used to help determine in the MySQL server whether table scans are pruned by `NDBCLUSTER`. (Bug #44153)

Bugs Fixed

- **Important Note**: Due to problem discovered after the code freeze for this release, it is not possible to perform an online upgrade from any MySQL Cluster NDB 6.x release to MySQL Cluster NDB 7.0.5 or any earlier MySQL Cluster NDB 7.0 release.

  This issue is fixed in MySQL Cluster NDB 7.0.6 and later for upgrades from MySQL Cluster NDB 6.3.8 and later MySQL Cluster NDB 6.3 releases, or from MySQL Cluster NDB 7.0.5. (Bug #44294)

- **Cluster Replication**: If data node failed during an event creation operation, there was a slight risk that a surviving data node could send an invalid table reference back to NDB, causing the operation to fail with a false Error 723 (`No such table`). This could take place when a data node failed as a `mysqld` process was setting up MySQL Cluster Replication. (Bug #43754)
- **Cluster API**: The following issues occurred when performing an online (rolling) upgrade of a cluster to a version of MySQL Cluster that supports configuration caching from a version that does not:

1. When using multiple management servers, after upgrading and restarting one `ndb_mgmd`, any remaining management servers using the previous version of `ndb_mgmd` could not synchronize their configuration data.

2. The MGM API `ndb_mgm_get_configuration_nodeid()` function failed to obtain configuration data.

(Bug #43641)

- **Cluster API**: The following issues occurred when performing an online (rolling) upgrade of a cluster to a version of MySQL Cluster that supports configuration caching from a version that does not:

  1. When using multiple management servers, after upgrading and restarting one `ndb_mgmd`, any remaining management servers using the previous version of `ndb_mgmd` could not synchronize their configuration data.

  2. The MGM API `ndb_mgm_get_configuration_nodeid()` function failed to obtain configuration data.

  (Bug #43641)

- If the number of fragments per table rises above a certain threshold, the `DBDIH` kernel block's on-disk table-definition grows large enough to occupy 2 pages. However, in MySQL Cluster NDB 7.0 (including MySQL Cluster NDB 6.4 releases), only 1 page was actually written, causing table definitions stored on disk to be incomplete.

  This issue was not observed in MySQL Cluster release series prior to MySQL Cluster NDB 7.0. (Bug #44135)

- `TransactionDeadlockDetectionTimeout` [1841] values less than 100 were treated as 100. This could cause scans to time out unexpectedly. (Bug #44099)

- The file `ndberror.c` contained a C++-style comment, which caused builds to fail with some C compilers. (Bug #44036)

- The setting for `ndb_use_transactions` [1932] was ignored. This issue was only known to occur in MySQL Cluster NDB 6.4.3 and MySQL Cluster NDB 7.0.4. (Bug #43236)

- `ndb_restore` crashed when trying to restore a backup made to a MySQL Cluster running on a platform having different endianness from that on which the original backup was taken. (Bug #39540)

- PID files for the data and management node daemons were not removed following a normal shutdown. (Bug #37225)

- `ndb_restore --print_data` [1997] did not handle `DECIMAL` columns correctly. (Bug #37171)

- A race condition could occur when a data node failed to restart just before being included in the next global checkpoint. This could cause other data nodes to fail. (Bug #43888)

- When a data node process had been killed after allocating a node ID, but before making contact with any other data node processes, it was not possible to restart it due to a node ID allocation failure.

  This issue could effect either `ndbd` or `ndbmtd` processes. (Bug #43224)

  References: This bug was introduced by Bug #42973.

- Invoking the management client `START BACKUP` command from the system shell (for example, as `ndb_mgm -e "START BACKUP"`) did not work correctly, unless the backup ID was included when the command was invoked.

Now, the backup ID is no longer required in such cases, and the backup ID that is automatically generated is printed to stdout, similar to how this is done when invoking `START BACKUP` within the management client. (Bug #31754)

- When aborting an operation involving both an insert and a delete, the insert and delete were aborted separately. This was because the transaction coordinator did not know that the operations affected on same row, and, in the case of a committed-read (tuple or index) scan, the abort of the insert was performed first, then the row was examined after the insert was aborted but before the delete was aborted. In some cases, this would leave the row in a inconsistent state. This could occur when a local checkpoint was performed during a backup. This issue did not affect primary ley operations or scans that used locks (these are serialized).

  After this fix, for ordered indexes, all operations that follow the operation to be aborted are now also aborted.

- **Disk Data**: When using multi-threaded data nodes, `DROP TABLE` statements on Disk Data tables could hang. (Bug #43825)

- **Disk Data**: This fix completes one that was made for this issue in MySQL Cluster NDB-7.0.4, which did not rectify the problem in all cases. (Bug #43632)

- **Cluster API**: `BIT` columns created using the native NDB API format that were not created as nullable could still sometimes be overwritten, or cause other columns to be overwritten.

  This issue did not effect tables having `BIT` columns created using the mysqld format (always used by MySQL Cluster SQL nodes). (Bug #43802)

- **Cluster API**: If the largest offset of a `RecordSpecification` used for an `NdbRecord` object was for the `NULL` bits (and thus not a column), this offset was not taken into account when calculating the size used for the `RecordSpecification`. This meant that the space for the `NULL` bits could be overwritten by key or other information. (Bug #43891)

Changes in MySQL Cluster NDB 7.0.4 (5.1.32-ndb-7.0.4)

Functionality Added or Changed

- **Important Change**: The default values for a number of MySQL Cluster configuration parameters relating to memory usage and buffering have changed. These parameters include `RedoBuffer` [1846], `LongMessageBuffer` [1825], `BackupMemory` [1851], `BackupDataBufferSize` [1850], `BackupLogBufferSize` [1850], `BackupWriteSize` [1851], `BackupMaxWriteSize` [1852], `SendBufferMemory` [1870] (when applied to TCP transporters), and `ReceiveBufferMemory` [1871].

  For more information, see MySQL Cluster Configuration.

- When restoring from backup, `ndb_restore` now reports the last global checkpoint reached when the backup was taken. (Bug #37384)

Bugs Fixed

- **Cluster API**: Partition pruning did not work correctly for queries involving multiple range scans.

  As part of the fix for this issue, several improvements have been made in the NDB API, including the addition of a new `NdbScanOperation::getPruned()` method, a new variant of `NdbIndexScanOperation::setBound()`, and a new `PartitionSpec` data structure. (Bug #37934)

- **Cluster API**: Partition pruning did not work correctly for queries involving multiple range scans.

  As part of the fix for this issue, several improvements have been made in the NDB API, including the addition of a new `NdbScanOperation::getPruned()` method, a new variant of

`NdbIndexScanOperation::setBound()`, and a new `PartitionSpec` data structure. (Bug #37934)

- The management server failed to start correctly in daemon mode. (Bug #43559)
- Some queries using combinations of logical and comparison operators on an indexed column in the `WHERE` clause could fail with the error `Got error 4541 'IndexBound has no bound information' from NDBCLUSTER`. (Bug #42857)
- Following a `DROP NODEGROUP` command, the output of `SHOW` in the `ndb_mgm` cliently was not updated to reflect the fact that the data nodes affected by this command were no longer part of a node group. (Bug #43413)
- It was not possible to add new data nodes to the cluster online using multi-threaded data node processes (`ndbmtd`). (Bug #43108)
- `TimeBetweenLocalCheckpoints` [1839] was measured from the end of one local checkpoint to the beginning of the next, rather than from the beginning of one LCP to the beginning of the next. This meant that the time spent performing the LCP was not taken into account when determining the `TimeBetweenLocalCheckpoints` [1839] interval, so that LCPs were not started often enough, possibly causing data nodes to run out of redo log space prematurely. (Bug #43567)
- Using indexes containing variable-sized columns could lead to internal errors when the indexes were being built. (Bug #43226)
- When using `ndbmtd`, multiple data node failures caused the remaining data nodes to fail as well. (Bug #43109)
- **Disk Data**: When using multi-threaded data nodes, dropping a Disk Data table followed by a data node restart led to a crash. (Bug #43632)
- **Disk Data**: When using `ndbmtd`, repeated high-volume inserts (on the order of 10000 rows inserted at a time) on a Disk Data table would eventually lead to a data node crash. (Bug #41398)
- **Disk Data**: When a log file group had an undo log file whose size was too small, restarting data nodes failed with `Read underflow` errors.

  As a result of this fix, the minimum permitted `INTIAL_SIZE` for an undo log file is now `1M` (1 megabyte). (Bug #29574)
- **Cluster API**: Ordered index scans using `NdbRecord` formerly expressed a `BoundEQ` range as separate lower and upper bounds, resulting in 2 copies of the column values being sent to the NDB kernel.

  Now, when a range is specified by `NdbScanOperation::setBound()`, the passed pointers, key lengths, and inclusive bits are compared, and only one copy of the equal key columns is sent to the kernel. This makes such operations more efficient, as half the amount of `KeyInfo` is now sent for a `BoundEQ` range as before. (Bug #38793)
- **Cluster API**: When performing insert or write operations, `NdbRecord` permits key columns to be specified in both the key record and in the attribute record. Only one key column value for each key column should be sent to the NDB kernel, but this was not guaranteed. This is now ensured as follows: For insert and write operations, key column values are taken from the key record; for scan takeover update operations, key column values are taken from the attribute record. (Bug #42238)
- **Cluster API**: The default `NdbRecord` structures created by `NdbDictionary` could have overlapping null bits and data fields. (Bug #43590)

Changes in MySQL Cluster NDB 6.4.3 (5.1.32-ndb-6.4.3)

Functionality Added or Changed

- A new data node configuration parameter `MaxLCPStartDelay` [1828] has been introduced to facilitate parallel node recovery by causing a local checkpoint to be delayed while recovering nodes are synchronizing data dictionaries and other meta-information. For more information about this parameter, see Defining MySQL Cluster Data Nodes. (Bug #43053)

- New options are introduced for `ndb_restore` for determining which tables or databases should be restored:

  - `--include-tables` and `--include-databases` can be used to restore specific tables or databases.

  - `--exclude-tables` and `--exclude-databases` can be used to exclude the specified tables or databases from being restored.

  For more information about these options, see `ndb_restore` — Restore a MySQL Cluster Backup. (Bug #40429)

- **Disk Data**: It is now possible to specify default locations for Disk Data data files and undo log files, either together or separately, using the data node configuration parameters `FileSystemPathDD` [1857], `FileSystemPathDataFiles` [1858], and `FileSystemPathUndoFiles` [1858]. For information about these configuration parameters, see *Disk Data file system parameters*.

  It is also now possible to specify a log file group, tablespace, or both, that is created when the cluster is started, using the `InitialLogFileGroup` [1859] and `InitialTablespace` [1859] data node configuration parameters. For information about these configuration parameters, see *Disk Data object creation parameters*.

Bugs Fixed

- **Performance**: Updates of the `SYSTAB_0` system table to obtain a unique identifier did not use transaction hints for tables having no primary key. In such cases the NDB kernel used a cache size of 1. This meant that each insert into a table not having a primary key required an update of the corresponding `SYSTAB_0` entry, creating a potential performance bottleneck.

  With this fix, inserts on `NDB` tables without primary keys can be under some conditions be performed up to 100% faster than previously. (Bug #39268)

- **Important Note**: It is not possible in this release to install the `InnoDB` plugin if `InnoDB` support has been compiled into `mysqld`. (Bug #42610)

  References: This bug was introduced by Bug #29263.

- **Packaging**: Packages for MySQL Cluster were missing the `libndbclient.so` and `libndbclient.a` files. (Bug #42278)

- **Partitioning**: Executing `ALTER TABLE ... REORGANIZE PARTITION` on an `NDBCLUSTER` table having only one partition caused `mysqld` to crash. (Bug #41945)

  References: See also Bug #40389.

- If the cluster configuration cache file was larger than 32K, the management server would not start. (Bug #42543)

- In some cases, `NDB` did not check correctly whether tables had changed before trying to use the query cache. This could result in a crash of the debug MySQL server. (Bug #40464)

- When using `ndbmtd`, NDB kernel threads could hang while trying to start the data nodes with `LockPagesInMainMemory` [1832] set to 1. (Bug #43021)

- Backup IDs greater than 2^{31} were not handled correctly, causing negative values to be used in backup directory names and printouts. (Bug #43042)

- Given a MySQL Cluster containing no data (that is, whose data nodes had all been started using `--initial`, and into which no data had yet been imported) and having an empty backup directory, executing `START BACKUP` with a user-specified backup ID caused the data nodes to crash. (Bug #41031)

- When using multiple management servers and starting several API nodes (possibly including one or more SQL nodes) whose connectstrings listed the management servers in different order, it was possible for 2 API nodes to be assigned the same node ID. When this happened it was possible for an API node not to get fully connected, consequently producing a number of errors whose cause was not easily recognizable. (Bug #42973)

- Triggers on `NDBCLUSTER` tables caused such tables to become locked. (Bug #42751)

  References: See also Bug #16229, Bug #18135.

- `ndb_error_reporter` worked correctly only with GNU `tar`. (With other versions of `tar`, it produced empty archives.) (Bug #42753)

- When using multi-threaded data nodes, their `DataMemory` [1817] and `IndexMemory` [1819] usage as reported was multiplied by the number of local query handlers (worker threads), making it appear that much more memory was being used than was actually the case. (Bug #42215)

  References: See also Bug #42765.

- When using multi-threaded data nodes, `IndexMemory` [1819], `MaxNoOfLocalOperations` [1822], and `MaxNoOfLocalScans` [1824] were effectively multiplied by the number of local query handlers in use by each `ndbmtd` instance. (Bug #42765)

  References: See also Bug #42215.

- When performing more than 32 index or tuple scans on a single fragment, the scans could be left hanging. This caused unnecessary timeouts, and in addition could possibly lead to a hang of an LCP. (Bug #42559)

  References: This bug is a regression of Bug #42084.

- A data node failure that occurred between calls to `NdbIndexScanOperation::readTuples(SF_OrderBy)` and `NdbTransaction::execute()` was not correctly handled; a subsequent call to `nextResult()` caused a null pointer to be deferenced, leading to a segfault in `mysqld`. (Bug #42545)

- Issuing `SHOW GLOBAL STATUS LIKE 'NDB%'` before `mysqld` had connected to the cluster caused a segmentation fault. (Bug #42458)

- Data node failures that occurred before all data nodes had connected to the cluster were not handled correctly, leading to additional data node failures. (Bug #42422)

- When using `ndbmtd` for all data nodes, repeated failures of one data node during DML operations caused other data nodes to fail. (Bug #42450)

- **Disk Data**: Repeated insert and delete operations on disk-based tables could lead to failures in the NDB Tablespace Manager (`TSMAN` kernel block). (Bug #40344)

- **Disk Data**: Creating a Disk Data tablespace with a very large extent size caused the data nodes to fail. The issue was observed when using extent sizes of 100 MB and larger. (Bug #39096)

- **Disk Data**: It was not possible to add an in-memory column online to a table that used a table-level or column-level `STORAGE DISK` option. The same issue prevented `ALTER ONLINE TABLE ... REORGANIZE PARTITION` from working on Disk Data tables. (Bug #42549)

- **Disk Data**: Using a path or file name longer than 128 characters for Disk Data undo log files and tablespace data files caused a number of issues, including failures of `CREATE LOGFILE GROUP`,

`ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, and `ALTER TABLESPACE` statements, as well as crashes of management nodes and data nodes.

With this fix, the maximum length for path and file names used for Disk Data undo log files and tablespace data files is now the same as the maximum for the operating system. (Bug #31769, Bug #31770, Bug #31772)

- **Disk Data**: Trying to execute a `CREATE LOGFILE GROUP` statement using a value greater than `150M` for `UNDO_BUFFER_SIZE` caused data nodes to crash.

  As a result of this fix, the upper limit for `UNDO_BUFFER_SIZE` is now `600M`; attempting to set a higher value now fails gracefully with an error. (Bug #34102)

  References: See also Bug #36702.

- **Disk Data**: When attempting to create a tablespace that already existed, the error message returned was `Table or index with given name already exists`. (Bug #32662)

- **Disk Data**: Attempting to perform a system restart of the cluster where there existed a logfile group without and undo log files caused the data nodes to crash.

  Note

  While issuing a `CREATE LOGFILE GROUP` statement without an `ADD UNDOFILE` option fails with an error in the MySQL server, this situation could arise if an SQL node failed during the execution of a valid `CREATE LOGFILE GROUP` statement; it is also possible to create a logfile group without any undo log files using the NDB API.

  (Bug #17614)

- **Cluster API**: Some error messages from `ndb_mgmd` contained newline (`\n`) characters. This could break the MGM API protocol, which uses the newline as a line separator. (Bug #43104)

- **Cluster API**: When using an ordered index scan without putting all key columns in the read mask, this invalid use of the NDB API went undetected, which resulted in the use of uninitialized memory. (Bug #42591)

Changes in MySQL Cluster NDB 6.4.2 (5.1.31-ndb-6.4.2)

Bugs Fixed

- Connections using IPv6 were not handled correctly by `mysqld`. (Bug #42413)

  References: See also Bug #42412, Bug #38247.

- When a cluster backup failed with Error 1304 (Node *`node_id1`*: Backup request from *`node_id2`* failed to start), no clear reason for the failure was provided.

  As part of this fix, MySQL Cluster now retries backups in the event of sequence errors. (Bug #42354)

  References: See also Bug #22698.

- When using `ndbmtd`, setting `MaxNoOfExecutionThreads` to a value higher than the actual number of cores available and with insufficient `SharedGlobalMemory` [1856] caused the data nodes to crash.

  The fix for this issue changes the behavior of `ndbmtd` such that its internal job buffers no longer rely on `SharedGlobalMemory` [1856]. (Bug #42254)

- Issuing `SHOW ENGINE NDBCLUSTER STATUS` on an SQL node before the management server had connected to the cluster caused `mysqld` to crash. (Bug #42264)

Changes in MySQL Cluster NDB 6.4.1 (5.1.31-ndb-6.4.1)

Functionality Added or Changed

- **Important Change**: Formerly, when the management server failed to create a transporter for a data node connection, `net_write_timeout` [506] seconds elapsed before the data node was actually permitted to disconnect. Now in such cases the disconnection occurs immediately. (Bug #41965)

  References: See also Bug #41713.

- Formerly, when using MySQL Cluster Replication, records for "empty" epochs—that is, epochs in which no changes to `NDBCLUSTER` data or tables took place—were inserted into the `ndb_apply_status` and `ndb_binlog_index` tables on the slave even when `--log-slave-updates` [1628] was disabled. Beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.13 this was changed so that these "empty" epochs were no longer logged. However, it is now possible to re-enable the older behavior (and cause "empty" epochs to be logged) by using the `--ndb-log-empty-epochs` option. For more information, see Replication Slave Options and Variables.

  References: See also Bug #37472.

Bugs Fixed

- Trying to execute an `ALTER ONLINE TABLE ... ADD COLUMN` statement while inserting rows into the table caused `mysqld` to crash. (Bug #41905)

- When a data node connects to the management server, the node sends its node ID and transporter type; the management server then verifies that there is a transporter set up for that node and that it is in the correct state, and then sends back an acknowledgment to the connecting node. If the transporter was not in the correct state, no reply was sent back to the connecting node, which would then hang until a read timeout occurred (60 seconds). Now, if the transporter is not in the correct state, the management server acknowledges this promptly, and the node immediately disconnects. (Bug #41713)

  References: See also Bug #41965.

- When using `ndbmtd`, one thread could flood another thread, which would cause the system to stop with a `job buffer full` condition (currently implemented as an abort). This could be caused by committing or aborting a large transaction (50000 rows or more) on a single data node running `ndbmtd`. To prevent this from happening, the number of signals that can be accepted by the system threads is calculated before executing them, and only executing them if sufficient space is found. (Bug #42052)

- A maximum of 11 `TUP` scans were permitted in parallel. (Bug #42084)

- The management server could hang after attempting to halt it with the `STOP` command in the management client. (Bug #42056)

  References: See also Bug #40922.

- Issuing `EXIT` in the management client sometimes caused the client to hang. (Bug #40922)

- MySQL Cluster would not compile when using `libwrap`. This issue was known to occur only in MySQL Cluster NDB 6.4.0. (Bug #41918)

- In the event that a MySQL Cluster backup failed due to file permissions issues, conflicting reports were issued in the management client. (Bug #34526)

- If all data nodes were shut down, MySQL clients were unable to access `NDBCLUSTER` tables and data even after the data nodes were restarted, unless the MySQL clients themselves were restarted. (Bug #33626)

Changes in MySQL Cluster NDB 6.4.0 (5.1.30-ndb-6.4.0)

Functionality Added or Changed

- **Important Change**: MySQL Cluster now caches its configuration data. This means that, by default, the management server only reads the global configuration file (usually named `config.ini`) the first time that it is started, and does not automatically re-read the this file when restarted. This behavior can be controlled using new management server options (`--config-dir`, `--initial`, and `--reload`) that have been added for this purpose. For more information, see MySQL Cluster Configuration Files, and `ndb_mgmd` — The MySQL Cluster Management Server Daemon.

- It is now possible while in Single User Mode to restart all data nodes using `ALL RESTART` in the management client. Restarting of individual nodes while in Single User Mode remains not permitted. (Bug #31056)

- It is now possible when performing a cluster backup to determine whether the backup matches the state of the data when the backup began or when it ended, using the new `START BACKUP` options `SNAPSHOTSTART` and `SNAPSHOTEND` in the management client. See Using The MySQL Cluster Management Client to Create a Backup, for more information.

- A multi-threaded version of the MySQL Cluster data node daemon is now available. The multi-threaded `ndbmtd` binary is similar to `ndbd` and functions in much the same way, but is intended for use on machines with multiple CPU cores.

  For more information, see `ndbmtd` — The MySQL Cluster Data Node Daemon (Multi-Threaded).

- It is now possible to add data nodes to a MySQL Cluster online—that is, to a running MySQL Cluster without shutting it down.

  For information about the procedure for adding data nodes online, see Adding MySQL Cluster Data Nodes Online.

- **Cluster API**: Two new `Ndb_cluster_connection` methods have been added to help in diagnosing problems with NDB API client connections. The `get_latest_error()` method tells whether or not the latest connection attempt succeeded; if the attempt failed, `get_latest_error_msg()` provides an error message giving the reason.

Bugs Fixed

- API nodes disconnected too agressively from cluster when data nodes were being restarted. This could sometimes lead to the API node being unable to access the cluster at all during a rolling restart. (Bug #41462)

- When long signal buffer exhaustion in the `ndbd` process resulted in a signal being dropped, the usual handling mechanism did not take fragmented signals into account. This could result in a crash of the data node because the fragmented signal handling mechanism was not able to work with the missing fragments. (Bug #39235)

- Status messages shown in the management client when restarting a management node were inappropriate and misleading. Now, when restarting a management node, the messages displayed are as follows, where *`node_id`* is the management node's node ID:

  ```
  ndb_mgm> node_id RESTART
  Shutting down MGM node node_id for restart
  Node node_id is being restarted

  ndb_mgm>
  ```

  (Bug #29275)

- The failure of a master node during a DDL operation caused the cluster to be unavailable for further DDL operations until it was restarted; failures of nonmaster nodes during DLL operations caused the cluster to become completely inaccessible. (Bug #36718)

- A data node failure when `NoOfReplicas` [1815] was greater than 2 caused all cluster SQL nodes to crash. (Bug #18621)

Changes in the MySQL Cluster NDB 6.3 Series

This section contains unified change history highlights for all MySQL Cluster releases based on version 6.3 of the `NDBCLUSTER` storage engine through MySQL Cluster NDB 6.3.50. Included are all changelog entries in the categories *MySQL Cluster*, *Disk Data*, and *Cluster API*.

For an overview of features that were added in MySQL Cluster NDB 6.3, see MySQL Cluster Development in MySQL Cluster NDB 6.3.

- Changes in MySQL Cluster NDB 6.3.49 (5.1.61-ndb-6.3.49) [2470]
- Changes in MySQL Cluster NDB 6.3.47 (5.1.56-ndb-6.3.47) [2470]
- Changes in MySQL Cluster NDB 6.3.46 (5.1.56-ndb-6.3.46) [2471]
- Changes in MySQL Cluster NDB 6.3.45 (5.1.56-ndb-6.3.45) [2471]
- Changes in MySQL Cluster NDB 6.3.44 (5.1.56-ndb-6.3.44) [2471]
- Changes in MySQL Cluster NDB 6.3.43 (5.1.56-ndb-6.3.43) [2471]
- Changes in MySQL Cluster NDB 6.3.42 (5.1.51-ndb-6.3.42) [2472]
- Changes in MySQL Cluster NDB 6.3.41 (5.1.51-ndb-6.3.41) [2472]
- Changes in MySQL Cluster NDB 6.3.40 (5.1.51-ndb-6.3.40) [2472]
- Changes in MySQL Cluster NDB 6.3.39 (5.1.51-ndb-6.3.39) [2474]
- Changes in MySQL Cluster NDB 6.3.38 (5.1.47-ndb-6.3.38) [2475]
- Changes in MySQL Cluster NDB 6.3.37 (5.1.47-ndb-6.3.37) [2477]
- Changes in MySQL Cluster NDB 6.3.36 (5.1.47-ndb-6.3.36) [2477]
- Changes in MySQL Cluster NDB 6.3.35 (5.1.47-ndb-6.3.35) [2478]
- Changes in MySQL Cluster NDB 6.3.34 (5.1.44-ndb-6.3.34) [2479]
- Changes in MySQL Cluster NDB 6.3.33 (5.1.44-ndb-6.3.33) [2480]
- Changes in MySQL Cluster NDB 6.3.32 (5.1.41-ndb-6.3.32) [2482]
- Changes in MySQL Cluster NDB 6.3.31b (5.1.41-ndb-6.3.31b) [2483]
- Changes in MySQL Cluster NDB 6.3.31a (5.1.41-ndb-6.3.31a) [2483]
- Changes in MySQL Cluster NDB 6.3.31 (5.1.41-ndb-6.3.31) [2483]
- Changes in MySQL Cluster NDB 6.3.30 (5.1.39-ndb-6.3.30) [2484]
- Changes in MySQL Cluster NDB 6.3.29 (5.1.39-ndb-6.3.29) [2484]
- Changes in MySQL Cluster NDB 6.3.28b (5.1.39-ndb-6.3.28b) [2487]
- Changes in MySQL Cluster NDB 6.3.28a (5.1.39-ndb-6.3.28a) [2487]
- Changes in MySQL Cluster NDB 6.3.28 (5.1.39-ndb-6.3.28) [2487]
- Changes in MySQL Cluster NDB 6.3.27a (5.1.37-ndb-6.3.27a) [2490]
- Changes in MySQL Cluster NDB 6.3.27 (5.1.37-ndb-6.3.27) [2490]

- Changes in MySQL Cluster NDB 6.3.26 (5.1.35-ndb-6.3.26) [2492]
- Changes in MySQL Cluster NDB 6.3.25 (5.1.34-ndb-6.3.25) [2494]
- Changes in MySQL Cluster NDB 6.3.24 (5.1.32-ndb-6.3.24) [2496]
- Changes in MySQL Cluster NDB 6.3.23 (5.1.32-ndb-6.3.23) [2497]
- Changes in MySQL Cluster NDB 6.3.22 (5.1.31-ndb-6.3.22) [2499]
- Changes in MySQL Cluster NDB 6.3.21 (5.1.31-ndb-6.3.21) [2500]
- Changes in MySQL Cluster NDB 6.3.20 (5.1.30-ndb-6.3.20) [2501]
- Changes in MySQL Cluster NDB 6.3.19 (5.1.29-ndb-6.3.19) [2502]
- Changes in MySQL Cluster NDB 6.3.18 (5.1.28-ndb-6.3.18) [2504]
- Changes in MySQL Cluster NDB 6.3.17 (5.1.27-ndb-6.3.17) [2505]
- Changes in MySQL Cluster NDB 6.3.16 (5.1.24-ndb-6.3.16) [2506]
- Changes in MySQL Cluster NDB 6.3.15 (5.1.24-ndb-6.3.15) [2507]
- Changes in MySQL Cluster NDB 6.3.14 (5.1.24-ndb-6.3.14) [2507]
- Changes in MySQL Cluster NDB 6.3.13 (5.1.24-ndb-6.3.13) [2508]
- Changes in MySQL Cluster NDB 6.3.10 (5.1.23-ndb-6.3.10) [2509]
- Changes in MySQL Cluster NDB 6.3.9 (5.1.23-ndb-6.3.9) [2509]
- Changes in MySQL Cluster NDB 6.3.8 (5.1.23-ndb-6.3.8) [2510]
- Changes in MySQL Cluster NDB 6.3.7 (5.1.23-ndb-6.3.7) [2512]
- Changes in MySQL Cluster NDB 6.3.6 (5.1.22-ndb-6.3.6) [2512]
- Changes in MySQL Cluster NDB 6.3.5 (5.1.22-ndb-6.3.5) [2513]
- Changes in MySQL Cluster NDB 6.3.4 (5.1.22-ndb-6.3.4) [2513]
- Changes in MySQL Cluster NDB 6.3.3 (5.1.22-ndb-6.3.3) [2514]
- Changes in MySQL Cluster NDB 6.3.2 (5.1.22-ndb-6.3.2) [2514]
- Changes in MySQL Cluster NDB 6.3.0 (5.1.19-ndb-6.3.0) [2515]

Changes in MySQL Cluster NDB 6.3.49 (5.1.61-ndb-6.3.49)

Version 5.1.61-ndb-6.3.49 has no changelog entries.

Changes in MySQL Cluster NDB 6.3.47 (5.1.56-ndb-6.3.47)

Bugs Fixed

- When a failure of multiple data nodes during a local checkpoint (LCP) that took a long time to complete included the node designated as master, any new data nodes attempting to start before all ongoing LCPs were completed later crashed. This was due to the fact that node takeover by the new master cannot be completed until there are no pending local checkpoints. Long-running LCPs such as those which triggered this issue can occur when fragment sizes are sufficiently large (see MySQL Cluster Nodes, Node Groups, Replicas, and Partitions, for more information). Now in such cases, data nodes (other than the new master) are kept from restarting until the takeover is complete. (Bug #13323589)

- When deleting from multiple tables using a unique key in the `WHERE` condition, the wrong rows were deleted. In addition, `UPDATE` triggers failed when rows were changed by deleting from or updating multiple tables. (Bug #12718336, Bug #61705, Bug #12728221)

Changes in MySQL Cluster NDB 6.3.46 (5.1.56-ndb-6.3.46)

Bugs Fixed

- When replicating DML statements with `IGNORE` between clusters, the number of operations that failed due to nonexistent keys was expected to be no greater than the number of defined operations of any single type. Because the slave SQL thread defines operations of multiple types in batches together, code which relied on this assumption could cause `mysqld` to fail. (Bug #12859831)
- When failure handling of an API node takes longer than 300 seconds, extra debug information is included in the resulting output. In cases where the API node's node ID was greater than 48, these extra debug messages could lead to a crash, and confuing output otherwise. This was due to an attempt to provide information specific to data nodes for API nodes as well. (Bug #62208)
- In rare cases, a series of node restarts and crashes during restarts could lead to errors while reading the redo log. (Bug #62206)

Changes in MySQL Cluster NDB 6.3.45 (5.1.56-ndb-6.3.45)

Bugs Fixed

- When global checkpoint indexes were written with no intervening end-of-file or megabyte border markers, this could sometimes lead to a situation in which the end of the redo log was mistakenly regarded as being between these GCIs, so that if the restart of a data node took place before the start of the next redo log was overwritten, the node encountered an `Error while reading the REDO log`. (Bug #12653993, Bug #61500)

  References: See also Bug #56961.
- Error reporting has been improved for cases in which API nodes are unable to connect due to apparent unavailability of node IDs. (Bug #12598398)
- Error messages for `Failed to convert connection` transporter registration problems were inspecific. (Bug #12589691)
- Under certain rare circumstances, a data node process could fail with Signal 11 during a restart. This was due to uninitialized variables in the `QMGR` kernel block. (Bug #12586190)
- Handling of the `MaxNoOfTables` [1829] and `MaxNoOfAttributes` [1828] configuration parameters was not consistent in all parts of the `NDB` kernel, and were only strictly enforced by the `DBDICT` and `SUMA` kernel blocks. This could lead to problems when tables could be created but not replicated. Now these parameters are treated by `SUMA` and `DBDICT` as suggested maximums rather than hard limits, as they are elsewhere in the `NDB` kernel. (Bug #61684)
- **Cluster API**: Within a transaction, after creating, executing, and closing a scan, calling `NdbTransaction::refresh()` after creating and executing but not closing a second scan caused the application to crash. (Bug #12646659)

Changes in MySQL Cluster NDB 6.3.44 (5.1.56-ndb-6.3.44)

Bugs Fixed

- Two unused test files in `storage/ndb/test/sql` contained incorrect versions of the GNU Lesser General Public License. The files and the directory containing them have been removed. (Bug #11810156)

  References: See also Bug #11810224.

Changes in MySQL Cluster NDB 6.3.43 (5.1.56-ndb-6.3.43)

Bugs Fixed

- **Cluster API**: Performing interpreted operations using a unique index did not work correctly, because the interpret bit was kept when sending the lookup to the index table.

Changes in MySQL Cluster NDB 6.3.42 (5.1.51-ndb-6.3.42)

Bugs Fixed

- A scan with a pushed condition (filter) using the `CommittedRead` lock mode could hang for a short interval when it was aborted when just as it had decided to send a batch. (Bug #11932525)

- When aborting a multi-read range scan exactly as it was changing ranges in the local query handler, LQH could fail to detect it, leaving the scan hanging. (Bug #11929643)

- **Disk Data**: Limits imposed by the size of `SharedGlobalMemory` [1856] were not always enforced consistently with regard to Disk Data undo buffers and log files. This could sometimes cause a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement to fail for no apparent reason, or cause the log file group specified by `InitialLogFileGroup` [1859] not to be created when starting the cluster. (Bug #57317)

Changes in MySQL Cluster NDB 6.3.41 (5.1.51-ndb-6.3.41)

Functionality Added or Changed

- A new `--rewrite-database` [2003] option is added for `ndb_restore`, which makes it possible to restore to a database having a different name from that of the database in the backup.

  For more information, see `ndb_restore` — Restore a MySQL Cluster Backup. (Bug #54327)

Changes in MySQL Cluster NDB 6.3.40 (5.1.51-ndb-6.3.40)

Functionality Added or Changed

- Added the `--skip-broken-objects` [2003] option for `ndb_restore`. This option causes `ndb_restore` to ignore tables corrupted due to missing blob parts tables, and to continue reading from the backup file and restoring the remaining tables. (Bug #54613)

  References: See also Bug #51652.

Bugs Fixed

- Two related problems could occur with read-committed scans made in parallel with transactions combining multiple (concurrent) operations:

  1. When committing a multiple-operation transaction that contained concurrent insert and update operations on the same record, the commit arrived first for the insert and then for the update. If a read-committed scan arrived between these operations, it could thus read incorrect data; in addition, if the scan read variable-size data, it could cause the data node to fail.

  2. When rolling back a multiple-operation transaction having concurrent delete and insert operations on the same record, the abort arrived first for the delete operation, and then for the insert. If a read-committed scan arrived between the delete and the insert, it could incorrectly assume that the record should not be returned (in other words, the scan treated the insert as though it had not yet been committed).

  (Bug #59496)

- A row insert or update followed by a delete operation on the same row within the same transaction could in some cases lead to a buffer overflow. (Bug #59242)

  References: See also Bug #56524. This bug was introduced by Bug #35208.

- The FAIL_REP signal, used inside the NDB kernel to declare that a node has failed, now includes the node ID of the node that detected the failure. This information can be useful in debugging. (Bug #58904)
- When handling failures of multiple data nodes, an error in the construction of internal signals could cause the cluster's remaining nodes to crash. This issue was most likely to affect clusters with large numbers of data nodes. (Bug #58240)
- Trying to drop an index while it was being used to perform scan updates caused data nodes to crash. (Bug #58277, Bug #57057)
- The number of rows affected by a statement that used a WHERE clause having an IN [942] condition with a value list containing a great many elements, and that deleted or updated enough rows such that NDB processed them in batches, was not computed or reported correctly. (Bug #58040)
- In some circumstances, an SQL trigger on an NDB table could read stale data. (Bug #58538)
- A query having multiple predicates joined by OR in the WHERE clause and which used the sort_union access method (as shown using EXPLAIN) could return duplicate rows. (Bug #58280)
- During a node takeover, it was possible in some circumstances for one of the remaining nodes to send an extra transaction confirmation (LQH_TRANSCONF) signal to the DBTC kernel block, conceivably leading to a crash of the data node trying to take over as the new transaction coordinator. (Bug #58453)
- Some queries of the form SELECT ... WHERE *column* IN (*subquery*) against an NDB table could cause mysqld to hang in an endless loop. (Bug #58163)
- In some circumstances, it was possible for mysqld to begin a new multi-range read scan without having closed a previous one. This could lead to exhaustion of all scan operation objects, transaction objects, or lock objects (or some combination of these) in NDB, causing queries to fail with such errors as Lock wait timeout exceeded or Connect failure - out of connection objects. (Bug #57481)

  References: See also Bug #58750.
- Queries using *column* IS [NOT] NULL on a table with a unique index created with USING HASH on *column* always returned an empty result. (Bug #57032)
- With engine_condition_pushdown [473] enabled, a query using LIKE on an ENUM column of an NDB table failed to return any results. This issue is resolved by disabling engine_condition_pushdown [473] when performing such queries. (Bug #53360)
- A query using BETWEEN as part of a pushed-down WHERE condition could cause mysqld to hang or crash. (Bug #57735)
- When a slash character (/) was used as part of the name of an index on an NDB table, attempting to execute a TRUNCATE TABLE statement on the table failed with the error Index not found, and the table was rendered unusable. (Bug #38914)
- **Disk Data**: In certain cases, a race condition could occur when DROP LOGFILE GROUP removed the logfile group while a read or write of one of the effected files was in progress, which in turn could lead to a crash of the data node. (Bug #59502)
- **Disk Data**: A race condition could sometimes be created when DROP TABLESPACE was run concurrently with a local checkpoint; this could in turn lead to a crash of the data node. (Bug #59501)
- **Disk Data**: Performing what should have been an online drop of a multi-column index was actually performed offline. (Bug #55618)
- **Disk Data**: When at least one data node was not running, queries against the INFORMATION_SCHEMA.FILES table took an excessive length of time to complete because the

MySQL server waited for responses from any stopped nodes to time out. Now, in such cases, MySQL does not attempt to contact nodes which are not known to be running. (Bug #54199)

- **Cluster API**: Attempting to read the same value (using `getValue()`) more than 9000 times within the same transaction caused the transaction to hang when executed. Now when more reads are performed in this way than can be accommodated in a single transaction, the call to `execute()` fails with a suitable error. (Bug #58110)

Changes in MySQL Cluster NDB 6.3.39 (5.1.51-ndb-6.3.39)

Functionality Added or Changed

- **Important Change**: The `Id` configuration parameter used with MySQL Cluster management, data, and API nodes (including SQL nodes) is now deprecated, and the `NodeId` parameter (long available as a synonym for `Id` when configuring these types of nodes) should be used instead. `Id` continues to be supported for reasons of backward compatibility, but now generates a warning when used with these types of nodes, and is subject to removal in a future release of MySQL Cluster.

  This change affects the name of the configuration parameter only, establishing a clear preference for `NodeId` over `Id` in the `[mgmd]`, `[ndbd]`, `[mysql]`, and `[api]` sections of the MySQL Cluster global configuration (`config.ini`) file. The behavior of unique identifiers for management, data, and SQL and API nodes in MySQL Cluster has not otherwise been altered.

  The `Id` parameter as used in the `[computer]` section of the MySQL Cluster global configuration file is not affected by this change.

Bugs Fixed

- **Packaging**: MySQL Cluster RPM distributions did not include a `shared-compat` RPM for the MySQL Server, which meant that MySQL applications depending on `libmysqlclient.so.15` (MySQL 5.0 and earlier) no longer worked. (Bug #38596)

- The `LQHKEYREQ` request message used by the local query handler when checking the major schema version of a table, being only 16 bits wide, could cause this check to fail with an `Invalid schema version` error (`NDB` error code 1227). This issue occurred after creating and dropping (and re-creating) the same table 65537 times, then trying to insert rows into the table. (Bug #57896)

  References: See also Bug #57897.

- When a data node angel process failed to fork off a new worker process (to replace one that had failed), the failure was not handled. This meant that the angel process either transformed itself into a worker process, or itself failed. In the first case, the data node continued to run, but there was no longer any angel to restart it in the event of failure, even with `StopOnError` [1832] set to 0. (Bug #53456)

- An internal buffer overrun could cause a data node to fail. (Bug #57767)

- Data nodes compiled with `gcc` 4.5 or higher crashed during startup. (Bug #57761)

- Queries using `WHERE varchar_pk_column LIKE 'pattern%'` or `WHERE varchar_pk_column LIKE 'pattern_'` against an `NDB` table having a `VARCHAR` column as its primary key failed to return all matching rows. (Bug #56853)

- `ndb_restore` now retries failed transactions when replaying log entries, just as it does when restoring data. (Bug #57618)

- During a GCP takeover, it was possible for one of the data nodes not to receive a `SUB_GCP_COMPLETE_REP` signal, with the result that it would report itself as `GCP_COMMITTING` while the other data nodes reported `GCP_PREPARING`. (Bug #57522)

- A GCP stop is detected using 2 parameters which determine the maximum time that a global checkpoint or epoch can go unchanged; one of these controls this timeout for GCPs and one controls the timeout for epochs. Suppose the cluster is configured such that

`TimeBetweenEpochsTimeout` [1840] is 100 ms but `HeartbeatIntervalDbDb` [1836] is 1500 ms. A node failure can be signalled after 4 missed heartbeats—in this case, 6000 ms. However, this would exceed `TimeBetweenEpochsTimeout` [1840], causing false detection of a GCP. To prevent this from happening, the configured value for `TimeBetweenEpochsTimeout` [1840] is automatically adjusted, based on the values of `HeartbeatIntervalDbDb` [1836] and `ArbitrationTimeout` [1844].

The current issue arose when the automatic adjustment routine did not correctly take into consideration the fact that, during cascading node-failures, several intervals of length `4 * (HeartbeatIntervalDBDB + ArbitrationTimeout)` may elapse before all node failures have internally been resolved. This could cause false GCP detection in the event of a cascading node failure. (Bug #57322)

- Specifying a `WHERE` clause of the form *`range1 OR range2`* when selecting from an `NDB` table having a primary key on multiple columns could result in Error 4259 `Invalid set of range scan bounds` if *`range2`* started exactly where *`range1`* ended and the primary key definition declared the columns in a different order relative to the order in the table's column list. (Such a query should simply return all rows in the table, since any expression *`value < constant OR value >= constant`* is always true.)

  Example. Suppose `t` is an `NDB` table defined by the following `CREATE TABLE` statement:

  ```
  CREATE TABLE t (a, b, PRIMARY KEY (b, a)) ENGINE NDB;
  ```

  This issue could then be triggered by a query such as this one:

  ```
  SELECT * FROM t WHERE b < 8 OR b >= 8;
  ```

  In addition, the order of the ranges in the `WHERE` clause was significant; the issue was not triggered, for example, by the query `SELECT * FROM t WHERE b <= 8 OR b > 8`. (Bug #57396)

- **Disk Data**: Adding unique indexes to `NDB` Disk Data tables could take an extremely long time. This was particularly noticeable when using `ndb_restore --rebuild-indexes` [2002]. (Bug #57827)

- **Cluster API**: An application dropping a table at the same time that another application tried to set up a replication event on the same table could lead to a crash of the data node. The same issue could sometimes cause `NdbEventOperation::execute()` to hang. (Bug #57886)

- **Cluster API**: An NDB API client program under load could abort with an assertion error in `TransporterFacade::remove_from_cond_wait_queue`. (Bug #51775)

  References: See also Bug #32708.

Changes in MySQL Cluster NDB 6.3.38 (5.1.47-ndb-6.3.38)

Functionality Added or Changed

- `mysqldump` as supplied with MySQL Cluster now has an `--add-drop-trigger` [294] option which adds a `DROP TRIGGER IF EXISTS` statement before each dumped trigger definition. (Bug #55691)

  References: See also Bug #34325, Bug #11747863.

- **Cluster API**: The MGM API function `ndb_mgm_get_version()`, which was previously internal, has now been moved to the public API. This function can be used to get `NDB` storage engine and other version information from the management server. (Bug #51310)

  References: See also Bug #51273.

Bugs Fixed

- The text file `cluster_change_hist.txt` containing old MySQL Cluster changelog information was no longer being maintained, and so has been removed from the tree. (Bug #56116)

- Memory pages used for `DataMemory` [1817], once assigned to ordered indexes, were not ever freed, even after any rows that belonged to the corresponding indexes had been deleted. (Bug #56829)

- A data node can be shut down having completed and synchronized a given GCI *`x`*, while having written a great many log records belonging to the next GCI *`x`* + 1, as part of normal operations. However, when starting, completing, and synchronizing GCI *`x`* + 1, then the log records from original start must not be read. To make sure that this does not happen, the REDO log reader finds the last GCI to restore, scans forward from that point, and erases any log records that were not (and should never be) used.

  The current issue occurred because this scan stopped immediately as soon as it encountered an empty page. This was problematic because the REDO log is divided into several files; thus, it could be that there were log records in the beginning of the next file, even if the end of the previous file was empty. These log records were never invalidated; following a start or restart, they could be reused, leading to a corrupt REDO log. (Bug #56961)

- An error in program flow in `ndbd.cpp` could result in data node shutdown routines being called multiple times. (Bug #56890)

- In certain cases, `DROP DATABASE` could sometimes leave behind a cached table object, which caused problems with subsequent DDL operations. (Bug #56840)

- When distributing `CREATE TABLE` and `DROP TABLE` operations among several SQL nodes attached to a MySQL Cluster. the `LOCK_OPEN` lock normally protecting `mysqld`'s internal table list is released so that other queries or DML statements are not blocked. However, to make sure that other DDL is not executed simultaneously, a global schema lock (implemented as a row-level lock by `NDB`) is used, such that all operations that can modify the state of the `mysqld` internal table list also need to acquire this global schema lock. The `SHOW TABLE STATUS` statement did not acquire this lock. (Bug #56841)

- When multiple SQL nodes were connected to the cluster and one of them stopped in the middle of a DDL operation, the `mysqld` process issuing the DDL timed out with the error `distributing` *`tbl_name`* `timed out. Ignoring`. (Bug #56763)

- MySQL Cluster stores, for each row in each `NDB` table, a Global Checkpoint Index (GCI) which identifies the last committed transaction that modified the row. As such, a GCI can be thought of as a coarse-grained row version.

  Due to changes in the format used by `NDB` to store local checkpoints (LCPs) in MySQL Cluster NDB 6.3.11, it could happen that, following cluster shutdown and subsequent recovery, the GCI values for some rows could be changed unnecessarily; this could possibly, over the course of many node or system restarts (or both), lead to an inconsistent database. (Bug #56770)

- An online `ALTER TABLE ... ADD COLUMN` operation that changed the table schema such that the number of 32-bit words used for the bitmask allocated to each DML operation increased during a transaction in DML which was performed prior to DDL which was followed by either another DML operation or—if using replication—a commit, led to data node failure.

  This was because the data node did not take into account that the bitmask for the before-image was smaller than the current bitmask, which caused the node to crash. (Bug #56524)

  References: This bug is a regression of Bug #35208.

- The failure of a data node during some scans could cause other data nodes to fail. (Bug #54945)

- Exhausting the number of available commit-ack markers (controlled by the `MaxNoOfConcurrentTransactions` [1821] parameter) led to a data node crash. (Bug #54944)

- When running a `SELECT` on an `NDB` table with `BLOB` or `TEXT` columns, memory was allocated for the columns but was not freed until the end of the `SELECT`. This could cause problems with excessive

memory usage when dumping (using for example `mysqldump`) tables with such columns and having many rows, large column values, or both. (Bug #52313)

References: See also Bug #56488, Bug #50310.

Changes in MySQL Cluster NDB 6.3.37 (5.1.47-ndb-6.3.37)

Functionality Added or Changed

- **Important Change**: More finely grained control over restart-on-failure behavior is provided with two new data node configuration parameters `MaxStartFailRetries` [1863] and `StartFailRetryDelay` [1863]. `MaxStartFailRetries` [1863] limits the total number of retries made before giving up on starting the data node; `StartFailRetryDelay` [1863] sets the number of seconds between retry attempts.

  These parameters are used only if `StopOnError` [1832] is set to 0.

  For more information, see Defining MySQL Cluster Data Nodes. (Bug #54341)

Bugs Fixed

- Following a failure of the master data node, the new master sometimes experienced a race condition which caused the node to terminate with a **`GcpStop`** error. (Bug #56044)
- The warning `MaxNoOfExecutionThreads (#) > LockExecuteThreadToCPU count (#), this could cause contention` could be logged when running `ndbd`, even though the condition described can occur only when using `ndbmtd`. (Bug #54342)
- The graceful shutdown of a data node could sometimes cause transactions to be aborted unnecessarily. (Bug #18538)

  References: See also Bug #55641.

Changes in MySQL Cluster NDB 6.3.36 (5.1.47-ndb-6.3.36)

Functionality Added or Changed

- Added the `DictTrace` data node configuration parameter, for use in debugging `NDB` code. For more information, see Defining MySQL Cluster Data Nodes. (Bug #55963)

Bugs Fixed

- **Cluster API**: **Important Change**: The poll and select calls made by the MGM API were not interrupt-safe; that is, a signal caught by the process while waiting for an event on one or more sockets returned error -1 with `errno` set to `EINTR`. This caused problems with MGM API functions such as `ndb_logevent_get_next()` and `ndb_mgm_get_status2()`.

  To fix this problem, the internal `ndb_socket_poller::poll()` function has been made `EINTR`-safe.

  The old version of this function has been retained as `poll_unsafe()`, for use by those parts of NDB that do not need the `EINTR`-safe version of the function. (Bug #55906)
- When another data node failed, a given data node `DBTC` kernel block could time out while waiting for `DBDIH` to signal commits of pending transactions, leading to a crash. Now in such cases the timeout generates a prinout, and the data node continues to operate. (Bug #55715)
- An excessive number of timeout warnings (normally used only for debugging) were written to the data node logs. (Bug #53987)
- It was possible for a `DROP DATABASE` statement to remove `NDB` hidden blob tables without removing the parent tables, with the result that the tables, although hidden to MySQL clients, were still visible

in the output of `ndb_show_tables` but could not be dropped using `ndb_drop_table`. (Bug #54788)

- The `configure.js` option `WITHOUT_DYNAMIC_PLUGINS=TRUE` was ignored when building MySQL Cluster for Windows using `CMake`. Among the effects of this issue was that `CMake` attempted to build the `InnoDB` storage engine as a plugin (`.DLL` file) even though the `InnoDB Plugin` is not currently supported by MySQL Cluster. (Bug #54913)

- **Disk Data**: As an optimization when inserting a row to an empty page, the page is not read, but rather simply initialized. However, this optimzation was performed in all cases when an empty row was inserted, even though it should have been done only if it was the first time that the page had been used by a table or fragment. This is because, if the page had been in use, and then all records had been released from it, the page still needed to be read to learn its log sequence number (LSN).

  This caused problems only if the page had been flushed using an incorrect LSN and the data node failed before any local checkpoint was completed—which would remove any need to apply the undo log, hence the incorrect LSN was ignored.

  The user-visible result of the incorrect LSN was that it caused the data node to fail during a restart. It was perhaps also possible (although not conclusively proven) that this issue could lead to incorrect data. (Bug #54986)

- **Cluster API**: Calling `NdbTransaction::refresh()` did not update the timer for `TransactionInactiveTimeout` [1841]. (Bug #54724)

Changes in MySQL Cluster NDB 6.3.35 (5.1.47-ndb-6.3.35)

Functionality Added or Changed

- Restrictions on some types of mismatches in column definitions when restoring data using `ndb_restore` have been relaxed. These include the following types of mismatches:

  - Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
  - Different `STORAGE` settings (`MEMORY`, `DISK`)
  - Different default values
  - Different distribution key settings

  Now, when one of these types of mismatches in column definitions is encountered, `ndb_restore` no longer stops with an error; instead, it accepts the data and inserts it into the target table, while issuing a warning to the user.

  For more information, see `ndb_restore` — Restore a MySQL Cluster Backup. (Bug #54423)

  References: See also Bug #53810, Bug #54178, Bug #54242, Bug #54279.

- Introduced the `HeartbeatOrder` [1837] data node configuration parameter, which can be used to set the order in which heartbeats are transmitted between data nodes. This parameter can be useful in situations where multiple data nodes are running on the same host and a temporary disruption in connectivity between hosts would otherwise cause the loss of a node group, leading to failure of the cluster. (Bug #52182)

Bugs Fixed

- The disconnection of all API nodes (including SQL nodes) during an `ALTER TABLE` caused a memory leak. (Bug #54685)

- If a node shutdown (either in isolation or as part of a system shutdown) occurred directly following a local checkpoint, it was possible that this local checkpoint would not be used when restoring the cluster. (Bug #54611)

- A table having the maximum number of attributes permitted could not be backed up using the `ndb_mgm` client.

  Note

  The maximum number of attributes supported per table is not the same for all MySQL Cluster releases. See Limits Associated with Database Objects in MySQL Cluster, to determine the maximum that applies in the release which you are using.

  (Bug #54155)

- When performing an online alter table where 2 or more SQL nodes connected to the cluster were generating binary logs, an incorrect message could be sent from the data nodes, causing `mysqld` processes to crash. This problem was often difficult to detect, because restarting SQL node or data node processes could clear the error, and because the crash in `mysqld` did not occur until several minutes after the erroneous message was sent and received. (Bug #54168)

- During initial node restarts, initialization of the REDO log was always performed 1 node at a time, during start phase 4. Now this is done during start phase 2, so that the initialization can be performed in parallel, thus decreasing the time required for initial restarts involving multiple nodes. (Bug #50062)

- **Cluster API**: When using the NDB API, it was possible to rename a table with the same name as that of an existing table.

  Note

  This issue did not affect table renames executed using SQL on MySQL servers acting as MySQL Cluster API nodes.

  (Bug #54651)

- **Cluster API**: An excessive number of client connections, such that more than 1024 file descriptors, sockets, or both were open, caused NDB API applications to crash. (Bug #34303)

Changes in MySQL Cluster NDB 6.3.34 (5.1.44-ndb-6.3.34)

Functionality Added or Changed

- A `--wait-nodes` option has been added for `ndb_waiter`. When this option is used, the program waits only for the nodes having the listed IDs to reach the desired state. For more information, see `ndb_waiter` — Wait for MySQL Cluster to Reach a Given Status. (Bug #52323)

- Added the `--skip-unknown-objects` [2003] option for `ndb_restore`. This option causes `ndb_restore` to ignore any schema objects which it does not recognize. Currently, this is useful chiefly for restoring native backups made from a cluster running MySQL Cluster NDB 7.0 to a cluster running MySQL Cluster NDB 6.3.

Bugs Fixed

- **Cluster API**: **Incompatible Change**: The default behavior of the NDB API Event API has changed as follows:

  Previously, when creating an `Event`, DDL operations (alter and drop operations on tables) were automatically reported on any event operation that used this event, but as a result of this change, this is no longer the case. Instead, you must now invoke the event's `setReport()` method, with the new `EventReport` value `ER_DDL`, to get this behavior.

  For existing NDB API applications where you wish to retain the old behavior, you must update the code as indicated previously, then recompile, following an upgrade. Otherwise, DDL operations are no longer reported after upgrading `libndbnclient`.

For more information, see The `Event::EventReport` Type, and `Event::setReport()`. (Bug #53308)

- **Cluster API**: **Incompatible Change**: The default behavior of the NDB API Event API has changed as follows:

  Previously, when creating an `Event`, DDL operations (alter and drop operations on tables) were automatically reported on any event operation that used this event, but as a result of this change, this is no longer the case. Instead, you must now invoke the event's `setReport()` method, with the new `EventReport` value `ER_DDL`, to get this behavior.

  For existing NDB API applications where you wish to retain the old behavior, you must update the code as indicated previously, then recompile, following an upgrade. Otherwise, DDL operations are no longer reported after upgrading `libndbnclient`.

  For more information, see The `Event::EventReport` Type, and `Event::setReport()`. (Bug #53308)

- When attempting to create an `NDB` table on an SQL node that had not yet connected to a MySQL Cluster management server since the SQL node's last restart, the `CREATE TABLE` statement failed as expected, but with the unexpected Error 1495 `For the partitioned engine it is necessary to define all partitions`. (Bug #11747335, Bug #31853)

- Creating a Disk Data table, dropping it, then creating an in-memory table and performing a restart, could cause data node processes to fail with errors in the `DBTUP` kernel block if the new table's internal ID was the same as that of the old Disk Data table. This could occur because undo log handling during the restart did not check that the table having this ID was now in-memory only. (Bug #53935)

- An internal buffer allocator used by `NDB` has the form `alloc(wanted, minimum)` and attempts to allocate *`wanted`* pages, but is permitted to allocate a smaller number of pages, between *`wanted`* and *`minimum`*. However, this allocator could sometimes allocate fewer than *`minimum`* pages, causing problems with multi-threaded building of ordered indexes. (Bug #53580)

- A table created while `ndb_table_no_logging` [1930] was enabled was not always stored to disk, which could lead to a data node crash with `Error opening DIH schema files for table`. (Bug #53934)

- When compiled with support for `epoll` but this functionality is not available at runtime, MySQL Cluster tries to fall back to use the `select()` function in its place. However, an extra `ndbout_c()` call in the transporter registry code caused `ndbd` to fail instead. (Bug #53482)

- `NDB` truncated a column declared as `DECIMAL(65,0)` to a length of 64. Now such a column is accepted and handled correctly. In cases where the maximum length (65) is exceeded, `NDB` now raises an error instead of truncating. (Bug #53352)

- Setting `DataMemory` [1817] higher than 4G on 32-bit platforms caused `ndbd` to crash, instead of failing gracefully with an error. (Bug #52536, Bug #50928)

- When a watchdog shutdown occurred due to an error, the process was not terminated quickly enough, sometimes resulting in a hang. (To correct this, the internal `_exit()` function is now called in such situations, rather than `exit()`.) (Bug #53246)

- NDB did not distinguish correctly between table names differing only by lettercase when `lower_case_table_names` [492] was set to 0. (Bug #33158)

- `ndb_mgm -e "ALL STATUS"` erroneously reported that data nodes remained in start phase 0 until they had actually started.

Changes in MySQL Cluster NDB 6.3.33 (5.1.44-ndb-6.3.33)

Functionality Added or Changed

- **Cluster API**: It is now possible to determine, using the `ndb_desc` utility or the NDB API, which data nodes contain replicas of which partitions. For `ndb_desc`, a new `--extra-node-info` [1982] option is added to cause this information to be included in its output. A new method `Table::getFragmentNodes()` is added to the NDB API for obtaining this information programmatically. (Bug #51184)

- **Cluster API**: It is now possible to determine, using the `ndb_desc` utility or the NDB API, which data nodes contain replicas of which partitions. For `ndb_desc`, a new `--extra-node-info` [1982] option is added to cause this information to be included in its output. A new method `Table::getFragmentNodes()` is added to the NDB API for obtaining this information programmatically. (Bug #51184)

- Formerly, the `REPORT` and `DUMP` commands returned output to all `ndb_mgm` clients connected to the same MySQL Cluster. Now, these commands return their output only to the `ndb_mgm` client that actually issued the command. (Bug #40865)

Bugs Fixed

- If a node or cluster failure occurred while `mysqld` was scanning the `ndb.ndb_schema` table (which it does when attempting to connect to the cluster), insufficient error handling could lead to a crash by `mysqld` in certain cases. This could happen in a MySQL Cluster with a great many tables, when trying to restart data nodes while one or more `mysqld` processes were restarting. (Bug #52325)

- After running a mixed series of node and system restarts, a system restart could hang or fail altogether. This was caused by setting the value of the newest completed global checkpoint too low for a data node performing a node restart, which led to the node reporting incorrect GCI intervals for its first local checkpoint. (Bug #52217)

- When performing a complex mix of node restarts and system restarts, the node that was elected as master sometimes required optimized node recovery due to missing `REDO` information. When this happened, the node crashed with `Failure to recreate object ... during restart, error 721` (because the `DBDICT` restart code was run twice). Now when this occurs, node takeover is executed immediately, rather than being made to wait until the remaining data nodes have started. (Bug #52135)

  References: See also Bug #48436.

- The redo log protects itself from being filled up by periodically checking how much space remains free. If insufficient redo log space is available, it sets the state `TAIL_PROBLEM` which results in transactions being aborted with error code 410 (`out of redo log`). However, this state was not set following a node restart, which meant that if a data node had insufficient redo log space following a node restart, it could crash a short time later with `Fatal error due to end of REDO log`. Now, this space is checked during node restarts. (Bug #51723)

- The output of the `ndb_mgm` client `REPORT BACKUPSTATUS` command could sometimes contain errors due to uninitialized data. (Bug #51316)

- The `ndb_mgm` client sometimes inserted extra prompts within the output of the `REPORT MEMORYUSAGE` command. (Bug #50196)

- Issuing a command in the `ndb_mgm` client after it had lost its connection to the management server could cause the client to crash. (Bug #49219)

- A `GROUP BY` query against `NDB` tables sometimes did not use any indexes unless the query included a `FORCE INDEX` option. With this fix, indexes are used by such queries (where otherwise possible) even when `FORCE INDEX` is not specified. (Bug #50736)

- The `ndb_print_backup_file` utility failed to function, due to a previous internal change in the NDB code. (Bug #41512, Bug #48673)

- When the `MemReportFrequency` [1849] configuration parameter was set in `config.ini`, the `ndb_mgm` client `REPORT MEMORYUSAGE` command printed its output multiple times. (Bug #37632)

- `ndb_mgm -e "... REPORT ..."` did not write any output to `stdout`.

  The fix for this issue also prevents the cluster log from being flooded with `INFO` messages when `DataMemory` [1817] usage reaches 100%, and insures that when the usage is decreased, an appropriate message is written to the cluster log. (Bug #31542, Bug #44183, Bug #49782)

- **Disk Data**: Inserts of blob column values into a MySQL Cluster Disk Data table that exhausted the tablespace resulted in misleading `no such tuple` error messages rather than the expected error `tablespace full`.

  This issue appeared similar to Bug #48113, but had a different underlying cause. (Bug #52201)

- **Disk Data**: The error message returned after atttempting to execute `ALTER LOGFILE GROUP` on an nonexistent logfile group did not indicate the reason for the failure. (Bug #51111)

- **Cluster API**: When reading blob data with lock mode `LM_SimpleRead`, the lock was not upgraded as expected. (Bug #51034)

- **Cluster API**: A number of issues were corrected in the NDB API coding examples found in the `storage/ndb/ndbapi-examples` directory in the MySQL Cluster source tree. These included possible endless recursion in `ndbapi_scan.cpp` as well as problems running some of the examples on systems using Windows or Mac OS X due to the lettercase used for some table names. (Bug #30552, Bug #30737)

Changes in MySQL Cluster NDB 6.3.32 (5.1.41-ndb-6.3.32)

Functionality Added or Changed

- A new configuration parameter `HeartbeatThreadPriority` makes it possible to select between a first-in, first-out or round-round scheduling policy for management node and API node heartbeat threads, as well as to set the priority of these threads. See Defining a MySQL Cluster Management Server, or Defining SQL and Other API Nodes in a MySQL Cluster, for more information. (Bug #49617)

- **Disk Data**: The `ndb_desc` utility can now show the extent space and free extent space for subordinate `BLOB` and `TEXT` columns (stored in hidden `BLOB` tables by NDB). A `--blob-info` [1982] option has been added for this program that causes `ndb_desc` to generate a report for each subordinate `BLOB` table. For more information, see `ndb_desc` — Describe NDB Tables. (Bug #50599)

Bugs Fixed

- When one or more data nodes read their LCPs and applied undo logs significantly faster than others, this could lead to a race condition causing system restarts of data nodes to hang. This could most often occur when using both `ndbd` and `ndbmtd` processes for the data nodes. (Bug #51644)

- When deciding how to divide the REDO log, the `DBDIH` kernel block saved more than was needed to restore the previous local checkpoint, which could cause REDO log space to be exhausted prematurely (`NDB` error 410). (Bug #51547)

- DML operations can fail with `NDB` error 1220 (`REDO log files overloaded...`) if the opening and closing of REDO log files takes too much time. If this occurred as a GCI marker was being written in the REDO log while REDO log file 0 was being opened or closed, the error could persist until a GCP stop was encountered. This issue could be triggered when there was insufficient REDO log space (for example, with configuration parameter settings `NoOfFragmentLogFiles = 6` and `FragmentLogFileSize = 6M`) with a load including a very high number of updates. (Bug #51512)

  References: See also Bug #20904.

- A `SELECT` requiring a sort could fail with the error `Can't find record in 'table'` when run concurrently with a `DELETE` from the same table. (Bug #45687)
- During an online upgrade from MySQL Cluster NDB 6.2 to MySQL Cluster NDB 6.3, a sufficiently large amount of traffic with more than 1 DML operation per transaction could lead.an NDB 6.3 data node to crash an NDB 6.2 data node with an internal error in the `DBLQOH` kernel block. (Bug #51389)
- A side effect of the `ndb_restore --disable-indexes` [2002] and `--rebuild-indexes` [2002] options is to change the schema versions of indexes. When a `mysqld` later tried to drop a table that had been restored from backup using one or both of these options, the server failed to detect these changed indexes. This caused the table to be dropped, but the indexes to be left behind, leading to problems with subsequent backup and restore operations. (Bug #51374)
- `ndb_restore` crashed while trying to restore a corrupted backup, due to missing error handling. (Bug #51223)
- The `ndb_restore` message `Successfully created index `PRIMARY`...` was directed to `stderr` instead of `stdout`. (Bug #51037)
- When using `NoOfReplicas` [1815] equal to 1 or 2, if data nodes from one node group were restarted 256 times and applications were running traffic such that it would encounter `NDB` error 1204 (`Temporary failure, distribution changed`), the live node in the node group would crash, causing the cluster to crash as well. The crash occurred only when the error was encountered on the 256th restart; having the error on any previous or subsequent restart did not cause any problems. (Bug #50930)
- **Cluster API**: An issue internal to `ndb_mgm` could cause problems when trying to start a large number of data nodes at the same time. (Bug #51273)

  References: See also Bug #51310.

Changes in MySQL Cluster NDB 6.3.31b (5.1.41-ndb-6.3.31b)

Bugs Fixed

- Setting `IndexMemory` [1819] greater than 2GB could cause data nodes to crash while starting. (Bug #51256)

Changes in MySQL Cluster NDB 6.3.31a (5.1.41-ndb-6.3.31a)

Bugs Fixed

- An initial restart of a data node configured with a large amount of memory could fail with a `Pointer too large` error. (Bug #51027)

  References: This bug was introduced by Bug #47818.

Changes in MySQL Cluster NDB 6.3.31 (5.1.41-ndb-6.3.31)

Functionality Added or Changed

- **Important Change**: The maximum permitted value of the `ndb_autoincrement_prefetch_sz` [1921] system variable has been increased from 256 to 65536. (Bug #50621)

Bugs Fixed

- If a query on an `NDB` table compared a constant string value to a column, and the length of the string was greater than that of the column, condition pushdown did not work correctly. (The string was truncated to fit the column length before being pushed down.) Now in such cases, the condition is no longer pushed down. (Bug #49459)
- When performing a `DELETE` that included a left join from an `NDB` table, only the first matching row was deleted. (Bug #47054)

- During Start Phases 1 and 2, the `STATUS` command sometimes (falsely) returned `Not Connected` for data nodes running `ndbmtd`. (Bug #47818)
- When setting the `LockPagesInMainMemory` [1832] configuration parameter failed, only the error `Failed to memlock pages...` was returned. Now in such cases the operating system's error code is also returned. (Bug #49724)
- Dropping unique indexes in parallel while they were in use could cause node and cluster failures. (Bug #50118)
- Setting `BuildIndexThreads` [1854] greater than 1 with more than 31 ordered indexes caused node and system restarts to fail. (Bug #50266)
- Performing intensive inserts and deletes in parallel with a high scan load could a data node crashes due to a failure in the `DBACC` kernel block. This was because checking for when to perform bucket splits or merges considered the first 4 scans only. (Bug #48700)
- `mysqld` could sometimes crash during a commit while trying to handle NDB Error 4028 `Node failure caused abort of transaction`. (Bug #38577)
- When setting `LockPagesInMainMemory` [1832], the stated memory was not allocated when the node was started, but rather only when the memory was used by the data node process for other reasons. (Bug #37430)
- Trying to insert more rows than would fit into an `NDB` table caused data nodes to crash. Now in such situations, the insert fails gracefully with error 633 `Table fragment hash index has reached maximum possible size`. (Bug #34348)
- **Disk Data**: When a crash occurs due to a problem in Disk Data code, the currently active page list is printed to `stdout` (that is, in one or more `ndb_`*`nodeid`*`_out.log` files). One of these lists could contain an endless loop; this caused a printout that was effectively never-ending. Now in such cases, a maximum of 512 entries is printed from each list. (Bug #42431)

Changes in MySQL Cluster NDB 6.3.30 (5.1.39-ndb-6.3.30)

Functionality Added or Changed

- Added multi-threaded ordered index building capability during system restarts or node restarts, controlled by the `BuildIndexThreads` [1854] data node configuration parameter (also introduced in this release).

Changes in MySQL Cluster NDB 6.3.29 (5.1.39-ndb-6.3.29)

Functionality Added or Changed

- The output from `ndb_config --configinfo` [1975] `--xml` [1976] now indicates, for each configuration parameter, the following restart type information:
  - Whether a system restart or a node restart is required when resetting that parameter;
  - Whether cluster nodes need to be restarted using the `--initial` option when resetting the parameter.

  (Bug #47366)
- This enhanced functionality is supported for upgrades to MySQL Cluster NDB 7.0 when the `NDB` engine version is 7.0.10 or later. (Bug #48528, Bug #49163)

Bugs Fixed

- Node takeover during a system restart occurs when the REDO log for one or more data nodes is out of date, so that a node restart is invoked for that node or those nodes. If this happens while a `mysqld` process is attached to the cluster as an SQL node, the `mysqld` takes a global schema lock (a row lock), while trying to set up cluster-internal replication.

However, this setup process could fail, causing the global schema lock to be held for an excessive length of time, which made the node restart hang as well. As a result, the mysqld failed to set up cluster-internal replication, which led to tables being read only, and caused one node to hang during the restart.

Note

This issue could actually occur in MySQL Cluster NDB 7.0 only, but the fix was also applied MySQL Cluster NDB 6.3, to keep the two codebases in alignment.

(Bug #49560)

- If the master data node receiving a request from a newly started API or data node for a node ID died before the request has been handled, the management server waited (and kept a mutex) until all handling of this node failure was complete before responding to any other connections, instead of responding to other connections as soon as it was informed of the node failure (that is, it waited until it had received a NF_COMPLETEREP signal rather than a NODE_FAILREP signal). On visible effect of this misbehavior was that it caused management client commands such as SHOW and ALL STATUS to respond with unnecessary slowness in such circumstances. (Bug #49207)

- Sending `SIGHUP` to a `mysqld` running with the `--ndbcluster` [1915] and `--log-bin` [1647] options caused the process to crash instead of refreshing its log files. (Bug #49515)

- When evaluating the options `--include-databases` [1999], `--include-tables` [2000], `--exclude-databases` [2001], and `--exclude-tables` [2001], the `ndb_restore` program overwrote the result of the database-level options with the result of the table-level options rather than merging these results together, sometimes leading to unexpected and unpredictable results.

  As part of the fix for this problem, the semantics of these options have been clarified; because of this, the rules governing their evaluation have changed slightly. These changes be summed up as follows:

  - All `--include-*` and `--exclude-*` options are now evaluated from right to left in the order in which they are passed to `ndb_restore`.
  - All `--include-*` and `--exclude-*` options are now cumulative.
  - In the event of a conflict, the first (rightmost) option takes precedence.

  For more detailed information and examples, see `ndb_restore` — Restore a MySQL Cluster Backup. (Bug #48907)

- When performing tasks that generated large amounts of I/O (such as when using `ndb_restore`), an internal memory buffer could overflow, causing data nodes to fail with signal 6.

  Subsequent analysis showed that this buffer was not actually required, so this fix removes it. (Bug #48861)

- Exhaustion of send buffer memory or long signal memory caused data nodes to crash. Now an appropriate error message is provided instead when this situation occurs. (Bug #48852)

- When employing `NDB` native backup to back up and restore an empty `NDB` table that used a non-sequential `AUTO_INCREMENT` value, the `AUTO_INCREMENT` value was not restored correctly. (Bug #48005)

- `NDB` stores blob column data in a separate, hidden table that is not accessible from MySQL. If this table was missing for some reason (such as accidental deletion of the file corresponding to the hidden table) when making a MySQL Cluster native backup, ndb_restore crashed when attempting to restore the backup. Now in such cases, ndb_restore fails with the error message `Table table_name has blob column (column_name) with missing parts table in backup` instead. (Bug #47289)

- Under certain conditions, accounting of the number of free scan records in the local query handler could be incorrect, so that during node recovery or a local checkpoint operations, the LQH could find itself lacking a scan record that is expected to find, causing the node to crash. (Bug #48697)

  References: See also Bug #48564.

- The creation of an ordered index on a table undergoing DDL operations could cause a data node crash under certain timing-dependent conditions. (Bug #48604)

- When running many parallel scans, a local checkpoint (which performs a scan internally) could find itself not getting a scan record, which led to a data node crash. Now an extra scan record is reserved for this purpose, and a problem with obtaining the scan record returns an appropriate error (error code 489, `Too many active scans`). (Bug #48564)

- During an LCP master takeover, when the newly elected master did not receive a `COPY_GCI` LCP protocol message but other nodes participating in the local checkpoint had received one, the new master could use an uninitialized variable, which caused it to crash. (Bug #48584)

- `ndb_config --xml --configinfo` now indicates that parameters belonging in the `[SCI]`, `[SCI DEFAULT]`, `[SHM]`, and `[SHM DEFAULT]` sections of the `config.ini` file are deprecated or experimental, as appropriate. (Bug #47365)

- During a node restart, logging was enabled on a per-fragment basis as the copying of each fragment was completed but local checkpoints were not enabled until all fragments were copied, making it possible to run out of redo log file space (`NDB` error code 410) before the restart was complete. Now logging is enabled only after all fragments has been copied, just prior to enabling local checkpoints. (Bug #48474)

- Creating an `NDB` table with an excessive number of large `BIT` columns caused the cluster to fail. Now, an attempt to create such a table is rejected with error 791 (`Too many total bits in bitfields`). (Bug #42046)

  References: See also Bug #42047.

- `DROP DATABASE` failed when there were stale temporary `NDB` tables in the database. This situation could occur if `mysqld` crashed during execution of a `DROP TABLE` statement after the table definition had been removed from `NDBCLUSTER` but before the corresponding `.ndb` file had been removed from the crashed SQL node's data directory. Now, when `mysqld` executes `DROP DATABASE`, it checks for these files and removes them if there are no corresponding table definitions for them found in `NDBCLUSTER`. (Bug #44529)

- When a long-running transaction lasting long enough to cause Error 410 (`REDO log files overloaded`) was later committed or rolled back, it could happen that `NDBCLUSTER` was not able to release the space used for the REDO log, so that the error condition persisted indefinitely.

  The most likely cause of such transactions is a bug in the application using MySQL Cluster. This fix should handle most cases where this might occur. (Bug #36500)

- Deprecation and usage information obtained from `ndb_config --configinfo [1975]` regarding the `PortNumber` [1810] and `ServerPort` [1814] configuration parameters was improved. (Bug #24584)

- **Disk Data**: Repeatedly creating and then dropping Disk Data tables could eventually lead to data node failures. (Bug #45794, Bug #48910)

- **Disk Data**: When running a write-intensive workload with a very large disk page buffer cache, CPU usage approached 100% during a local checkpoint of a cluster containing Disk Data tables. (Bug #49532)

- **Disk Data**: When the `FileSystemPathUndoFiles` [1858] configuration parameter was set to an non-existent path, the data nodes shut down with the generic error code 2341 (`Internal program error`). Now in such cases, the error reported is error 2815 (`File not found`).

- **Cluster API**: When a DML operation failed due to a uniqueness violation on an `NDB` table having more than one unique index, it was difficult to determine which constraint caused the failure; it was necessary to obtain an `NdbError` object, then decode its `details` property, which in could lead to memory management issues in application code.

  To help solve this problem, a new API method `Ndb::getNdbErrorDetail()` is added, providing a well-formatted string containing more precise information about the index that caused the unque constraint violation. The following additional changes are also made in the NDB API:

  - Use of `NdbError.details` is now deprecated in favor of the new method.
  - The `NdbDictionary::listObjects()` method has been modified to provide more information.

  For more information, see `Ndb::getNdbErrorDetail()`, The `NdbError` Structure, and `Dictionary::listObjects()`. (Bug #48851)

- **Cluster API**: When using blobs, calling `getBlobHandle()` requires the full key to have been set using `equal()`, because `getBlobHandle()` must access the key for adding blob table operations. However, if `getBlobHandle()` was called without first setting all parts of the primary key, the application using it crashed. Now, an appropriate error code is returned instead. (Bug #28116, Bug #48973)

Changes in MySQL Cluster NDB 6.3.28b (5.1.39-ndb-6.3.28b)

Bugs Fixed

- Using a large number of small fragment log files could cause `NDBCLUSTER` to crash while trying to read them during a restart. This issue was first observed with 1024 fragment log files of 16 MB each. (Bug #48651)

Changes in MySQL Cluster NDB 6.3.28a (5.1.39-ndb-6.3.28a)

Bugs Fixed

- When the combined length of all names of tables using the `NDB` storage engine was greater than or equal to 1024 bytes, issuing the `START BACKUP` command in the `ndb_mgm` client caused the cluster to crash. (Bug #48531)

Changes in MySQL Cluster NDB 6.3.28 (5.1.39-ndb-6.3.28)

Functionality Added or Changed

- **Performance**: Significant improvements in redo log handling and other file system operations can yield a considerable reduction in the time required for restarts. While actual restart times observed in a production setting will naturally vary according to database size, hardware, and other conditions, our own preliminary testing shows that these optimizations can yield startup times that are faster than those typical of previous MySQL Cluster releases by a factor of 50 or more.

Bugs Fixed

- **Important Change**: The `--with-ndb-port-base` option for `configure` did not function correctly, and has been deprecated. Attempting to use this option produces the warning `Ignoring deprecated option --with-ndb-port-base`.

  Beginning with MySQL Cluster NDB 7.1.0, the deprecation warning itself is removed, and the `--with-ndb-port-base` option is simply handled as an unknown and invalid option if you try to use it. (Bug #47941)

  References: See also Bug #38502.

- For `UPDATE IGNORE` statements, batching of updates is now disabled. This is because such statements failed when batching of updates was employed if any updates violated a unique

constraint, to the fact a unique constraint violation could not be handled without aborting the transaction. (Bug #48036)

- When an `UPDATE` statement was issued against an `NDB` table where an index was used to identify rows but no data was actually changed, the `NDB` storage returned zero found rows.

  For example, consider the table created and populated using these statements:

  ```
  CREATE TABLE t1
  (
      c1 INT NOT NULL,
      c2 INT NOT NULL,
      PRIMARY KEY(c1),
      KEY(c2)
  )
  ENGINE = NDB;

  INSERT INTO t1 VALUES(1, 1);
  ```

  The following `UPDATE` statements, even though they did not change any rows, each still matched a row, but this was reported incorrectly in both cases, as shown here:

  ```
  mysql> UPDATE t1 SET c2 = 1 WHERE c1 = 1;
  Query OK, 0 rows affected (0.00 sec)
  Rows matched: 0  Changed: 0  Warnings: 0

  mysql> UPDATE t1 SET c1 = 1 WHERE c2 = 1;
  Query OK, 0 rows affected (0.00 sec)
  Rows matched: 0  Changed: 0  Warnings: 0
  ```

  Now in such cases, the number of rows matched is correct. (In the case of each of the example `UPDATE` statements just shown, this is displayed as Rows matched: 1, as it should be.)

  This issue could affect `UPDATE` statements involving any indexed columns in `NDB` tables, regardless of the type of index (including `KEY`, `UNIQUE KEY`, and `PRIMARY KEY`) or the number of columns covered by the index. (Bug #47955)

- In certain cases, performing very large inserts on `NDB` tables when using `ndbmtd` caused the memory allocations for ordered or unique indexes (or both) to be exceeded. This could cause aborted transactions and possibly lead to data node failures. (Bug #48037)

  References: See also Bug #48113.

- `SHOW CREATE TABLE` did not display the `AUTO_INCREMENT` value for `NDB` tables having `AUTO_INCREMENT` columns. (Bug #47865)

- Starting a data node with a very large amount of `DataMemory` [1817] (approximately 90G or more) could lead to crash of the node due to job buffer congestion. (Bug #47984)

- On Solaris, shutting down a management node failed when issuing the command to do so from a client connected to a different management node. (Bug #47948)

- Setting `FragmentLogFileSize` [1826] to a value greater than 256 MB led to errors when trying to read the redo log file. (Bug #47908)

- When starting a node and synchronizing tables, memory pages were allocated even for empty fragments. In certain situations, this could lead to insufficient memory. (Bug #47782)

- Under some circumstances, when a scan encountered an error early in processing by the `DBTC` kernel block (see The `DBTC` Block), a node could crash as a result. Such errors could be caused by applications sending incorrect data, or, more rarely, by a `DROP TABLE` operation executed in parallel with a scan. (Bug #47831)

- `configure` failed to honor the `--with-zlib-dir` option when trying to build MySQL Cluster from source. (Bug #47223)

- A very small race-condition between `NODE_FAILREP` and `LQH_TRANSREQ` signals when handling node failure could lead to operations (locks) not being taken over when they should have been, and subsequently becoming stale. This could lead to node restart failures, and applications getting into endless lock-conflicts with operations that were not released until the node was restarted. (Bug #47715)

  References: See also Bug #41297.

- `ndbd` was not built correctly when compiled using `gcc` 4.4.0. (The `ndbd` binary was built, but could not be started.) (Bug #46113)

- When starting a cluster with a great many tables, it was possible for MySQL client connections as well as the slave SQL thread to issue DML statements against MySQL Cluster tables before `mysqld` had finished connecting to the cluster and making all tables writeable. This resulted in `Table ... is read only` errors for clients and the Slave SQL thread.

  This issue is fixed by introducing the `--ndb-wait-setup` [1919] option for the MySQL server. This provides a configurable maximum amount of time that `mysqld` waits for all `NDB` tables to become writeable, before enabling MySQL clients or the slave SQL thread to connect. (Bug #40679)

  References: See also Bug #46955.

- When building MySQL Cluster, it was possible to configure the build using `--with-ndb-port` without supplying a port number. Now in such cases, `configure` fails with an error. (Bug #38502)

  References: See also Bug #47941.

- If a node failed while sending a fragmented long signal, the receiving node did not free long signal assembly resources that it had allocated for the fragments of the long signal that had already been received. (Bug #44607)

- When a copying operation exhausted the available space on a data node while copying large `BLOB` columns, this could lead to failure of the data node and a `Table is full` error on the SQL node which was executing the operation. Examples of such operations could include an `ALTER TABLE` that changed an `INT` column to a `BLOB` column, or a bulk insert of `BLOB` data that failed due to running out of space or to a duplicate key error. (Bug #34583, Bug #48040)

  References: See also Bug #41674, Bug #45768.

- When the MySQL server SQL mode included `STRICT_TRANS_TABLES` [576], storage engine warnings and error codes specific to `NDB` were returned when errors occurred, instead of the MySQL server errors and error codes expected by some programming APIs (such as Connector/J) and applications. (Bug #35990)

- **Disk Data**: A local checkpoint of an empty fragment could cause a crash during a system restart which was based on that LCP. (Bug #47832)

  References: See also Bug #41915.

- **Cluster API**: If an NDB API program reads the same column more than once, it is possible exceed the maximum permissible message size, in which case the operation should be aborted due to NDB error 880 `Tried to read too much - too many getValue calls`, however due to a change introduced in MySQL Cluster NDB 6.3.18, the check for this was not done correctly, which instead caused a data node crash. (Bug #48266)

- **Cluster API**: The NDB API methods `Dictionary::listEvents()`, `Dictionary::listIndexes()`, `Dictionary::listObjects()`, and `NdbOperation::getErrorLine()` formerly had both `const` and non-`const` variants. The non-`const` versions of these methods have been removed. In addition, the `NdbOperation::getBlobHandle()` method has been re-implemented to provide consistent internal semantics. (Bug #47798)

- **Cluster API**: A duplicate read of a column caused NDB API applications to crash. (Bug #45282)
- **Cluster API**: The error handling shown in the example file `ndbapi_scan.cpp` included with the MySQL Cluster distribution was incorrect. (Bug #39573)

Changes in MySQL Cluster NDB 6.3.27a (5.1.37-ndb-6.3.27a)

Bugs Fixed

- The disconnection of an API or SQL node having a node ID greater than 49 caused a forced shutdown of the cluster. (Bug #47844)
- The error message text for `NDB` error code 410 (`REDO log files overloaded...`) was truncated. (Bug #23662)

Changes in MySQL Cluster NDB 6.3.27 (5.1.37-ndb-6.3.27)

Functionality Added or Changed

- **Disk Data**: Two new columns have been added to the output of `ndb_desc` to make it possible to determine how much of the disk space allocated to a given table or fragment remains free. (This information is not available from the `INFORMATION_SCHEMA.FILES` table, since the `FILES` table applies only to Disk Data files.) For more information, see `ndb_desc` — Describe NDB Tables. (Bug #47131)

Bugs Fixed

- `mysqld` allocated an excessively large buffer for handling `BLOB` values due to overestimating their size. (For each row, enough space was allocated to accommodate *every* `BLOB` or `TEXT` column value in the result set.) This could adversely affect performance when using tables containing `BLOB` or `TEXT` columns; in a few extreme cases, this issue could also cause the host system to run out of memory unexpectedly. (Bug #47574)

  References: See also Bug #47572, Bug #47573.

- `NDBCLUSTER` uses a dynamically allocated buffer to store `BLOB` or `TEXT` column data that is read from rows in MySQL Cluster tables.

  When an instance of the `NDBCLUSTER` table handler was recycled (this can happen due to table definition cache pressure or to operations such as `FLUSH TABLES` or `ALTER TABLE`), if the last row read contained blobs of zero length, the buffer was not freed, even though the reference to it was lost. This resulted in a memory leak.

  For example, consider the table defined and populated as shown here:

  ```
  CREATE TABLE t (a INT PRIMARY KEY, b LONGTEXT) ENGINE=NDB;

  INSERT INTO t VALUES (1, REPEAT('F', 20000));
  INSERT INTO t VALUES (2, '');
  ```

  Now execute repeatedly a `SELECT` on this table, such that the zero-length `LONGTEXT` row is last, followed by a `FLUSH TABLES` statement (which forces the handler object to be re-used), as shown here:

  ```

  SELECT a, length(b) FROM bl ORDER BY a;
  FLUSH TABLES;
  ```

  Prior to the fix, this resulted in a memory leak proportional to the size of the stored `LONGTEXT` value each time these two statements were executed. (Bug #47573)

  References: See also Bug #47572, Bug #47574.

- Large transactions involving joins between tables containing `BLOB` columns used excessive memory. (Bug #47572)

  References: See also Bug #47573, Bug #47574.

- A variable was left uninitialized while a data node copied data from its peers as part of its startup routine; if the starting node died during this phase, this could lead a crash of the cluster when the node was later restarted. (Bug #47505)

- When a data node restarts, it first runs the redo log until reaching the latest restorable global checkpoint; after this it scans the remainder of the redo log file, searching for entries that should be invalidated so they are not used in any subsequent restarts. (It is possible, for example, if restoring GCI number 25, that there might be entries belonging to GCI 26 in the redo log.) However, under certain rare conditions, during the invalidation process, the redo log files themselves were not always closed while scanning ahead in the redo log. In rare cases, this could lead to `MaxNoOfOpenFiles` [1827] being exceeded, causing a the data node to crash. (Bug #47171)

- Using triggers on `NDB` tables caused `ndb_autoincrement_prefetch_sz` [1921] to be treated as having the NDB kernel's internal default value (32) and the value for this variable as set on the cluster's SQL nodes to be ignored. (Bug #46712)

- For very large values of `MaxNoOfTables` [1829] + `MaxNoOfAttributes` [1828], the calculation for `StringMemory` [1819] could overflow when creating large numbers of tables, leading to `NDB` error 773 (`Out of string memory, please modify StringMemory config parameter`), even when `StringMemory` [1819] was set to `100` (100 percent). (Bug #47170)

- The default value for the `StringMemory` [1819] configuration parameter, unlike other MySQL Cluster configuration parameters, was not set in `ndb/src/mgmsrv/ConfigInfo.cpp`. (Bug #47166)

- Signals from a failed API node could be received after an `API_FAILREQ` signal (see Operations and Signals) has been received from that node, which could result in invalid states for processing subsequent signals. Now, all pending signals from a failing API node are processed before any `API_FAILREQ` signal is received. (Bug #47039)

  References: See also Bug #44607.

- When performing auto-discovery of tables on individual SQL nodes, `NDBCLUSTER` attempted to overwrite existing `MyISAM .frm` files and corrupted them.

  Workaround. In the `mysql` client, create a new table (`t2`) with same definition as the corrupted table (`t1`). Use your system shell or file manager to rename the old `.MYD` file to the new file name (for example, `mv t1.MYD t2.MYD`). In the `mysql` client, repair the new table, drop the old one, and rename the new table using the old file name (for example, `RENAME TABLE t2 TO t1`).

  (Bug #42614)

- When a data node received a `TAKE_OVERTCCONF` signal from the master before that node had received a `NODE_FAILREP`, a race condition could in theory result. (Bug #37688)

  References: See also Bug #25364, Bug #28717.

- Running an `ALTER TABLE` statement while an `NDB` backup was in progress caused `mysqld` to crash. (Bug #44695)

- Running `ndb_restore` with the `--print` or `--print_log` option could cause it to crash. (Bug #40428, Bug #33040)

- An insert on an `NDB` table was not always flushed properly before performing a scan. One way in which this issue could manifest was that `LAST_INSERT_ID()` [1036] sometimes failed to return correct values when using a trigger on an `NDB` table. (Bug #38034)

- Some joins on large `NDB` tables having `TEXT` or `BLOB` columns could cause `mysqld` processes to leak memory. The joins did not need to reference the `TEXT` or `BLOB` columns directly for this issue to occur. (Bug #36701)

- On Mac OS X 10.5, commands entered in the management client failed and sometimes caused the client to hang, although management client commands invoked using the `--execute` [1970] (or `-e`) option from the system shell worked normally.

  For example, the following command failed with an error and hung until killed manually, as shown here:

  ```
  ndb_mgm> SHOW
  Warning, event thread startup failed, degraded printouts as result, errno=36
  ^C
  ```

  However, the same management client command, invoked from the system shell as shown here, worked correctly:

  ```
  shell> ndb_mgm -e "SHOW"
  ```

  (Bug #35751)

  References: See also Bug #34438.

- **Disk Data**: Calculation of free space for Disk Data table fragments was sometimes done incorrectly. This could lead to unnecessary allocation of new extents even when sufficient space was available in existing ones for inserted data. In some cases, this might also lead to crashes when restarting data nodes.

  Note

  This miscalculation was not reflected in the contents of the `INFORMATION_SCHEMA.FILES` table, as it applied to extents allocated to a fragment, and not to a file.

  (Bug #47072)

- **Cluster API**: In some circumstances, if an API node encountered a data node failure between the creation of a transaction and the start of a scan using that transaction, then any subsequent calls to `startTransaction()` and `closeTransaction()` could cause the same transaction to be started and closed repeatedly. (Bug #47329)

- **Cluster API**: Performing multiple operations using the same primary key within the same `NdbTransaction::execute()` call could lead to a data node crash.

  Note

  This fix does not make change the fact that performing multiple operations using the same primary key within the same `execute()` is not supported; because there is no way to determine the order of such operations, the result of such combined operations remains undefined.

  (Bug #44065)

  References: See also Bug #44015.

Changes in MySQL Cluster NDB 6.3.26 (5.1.35-ndb-6.3.26)

Functionality Added or Changed

- On Solaris platforms, the MySQL Cluster management server and NDB API applications now use `CLOCK_REALTIME` as the default clock. (Bug #46183)

- A new option `--exclude-missing-columns` has been added for the `ndb_restore` program. In the event that any tables in the database or databases being restored to have fewer columns than the same-named tables in the backup, the extra columns in the backup's version of the tables are ignored. For more information, see `ndb_restore` — Restore a MySQL Cluster Backup. (Bug #43139)

-

  Note

  This issue, originally resolved in MySQL 5.1.16, re-occurred due to a later (unrelated) change. The fix has been re-applied.

  (Bug #25984)

Bugs Fixed

- Killing MySQL Cluster nodes immediately following a local checkpoint could lead to a crash of the cluster when later attempting to perform a system restart.

  The exact sequence of events causing this issue was as follows:

  1. Local checkpoint occurs.
  2. Immediately following the LCP, kill the master data node.
  3. Kill the remaining data nodes within a few seconds of killing the master.
  4. Attempt to restart the cluster.

  (Bug #46412)

- Restarting the cluster following a local checkpoint and an online `ALTER TABLE` on a non-empty table caused data nodes to crash. (Bug #46651)

- When combining an index scan and a delete with a primary key delete, the index scan and delete failed to initialize a flag properly. This could in rare circumstances cause a data node to crash. (Bug #46069)

- Full table scans failed to execute when the cluster contained more than 21 table fragments.

  Note

  The number of table fragments in the cluster can be calculated as the number of data nodes, times 8 (that is, times the value of the internal constant `MAX_FRAG_PER_NODE`), divided by the number of replicas. Thus, when `NoOfReplicas = 1` at least 3 data nodes were required to trigger this issue, and when `NoOfReplicas = 2` at least 4 data nodes were required to do so.

  (Bug #46490)

- `OPTIMIZE TABLE` on an `NDB` table could in some cases cause SQL and data nodes to crash. This issue was observed with both `ndbd` and `ndbmtd`. (Bug #45971)

- Ending a line in the `config.ini` file with an extra semicolon character (`;`) caused reading the file to fail with a parsing error. (Bug #46242)

- The `AutoReconnect` [1867] configuration parameter for API nodes (including SQL nodes) has been added. This is intended to prevent API nodes from re-using allocated node IDs during cluster restarts. For more information, see Defining SQL and Other API Nodes in a MySQL Cluster.

  This fix also introduces two new methods of the NDB API `Ndb_cluster_connection` class: `set_auto_reconnect()` and `get_auto_reconnect()`. (Bug #45921)

- The signals used by `ndb_restore` to send progress information about backups to the cluster log accessed the cluster transporter without using any locks. Because of this, it was theoretically possible that these signals could be interefered with by heartbeat signals if both were sent at the same time, causing the `ndb_restore` messages to be corrupted. (Bug #45646)

- The warning message `Possible bug in Dbdih::execBLOCK_COMMIT_ORD ...` could sometimes appear in the cluster log. This warning is obsolete, and has been removed. (Bug #44563)

- In some cases, `OPTIMIZE TABLE` on an `NDB` table did not free any `DataMemory` [1817]. (Bug #43683)

- Problems could arise when using `VARCHAR` columns whose size was greater than 341 characters and which used the `utf8_unicode_ci` collation. In some cases, this combination of conditions could cause certain queries and `OPTIMIZE TABLE` statements to crash `mysqld`. (Bug #45053)

- An internal NDB API buffer was not properly initialized. (Bug #44977)

- When a data node had written its GCI marker to the first page of a megabyte, and that node was later killed during restart after having processed that page (marker) but before completing a LCP, the data node could fail with file system errors. (Bug #44952)

  References: See also Bug #42564, Bug #44291.

- If the cluster crashed during the execution of a `CREATE LOGFILE GROUP` statement, the cluster could not be restarted afterward. (Bug #36702)

  References: See also Bug #34102.

- **Disk Data**: **Partitioning**: An `NDB` table created with a very large value for the `MAX_ROWS` option could—if this table was dropped and a new table with fewer partitions, but having the same table ID, was created—cause `ndbd` to crash when performing a system restart. This was because the server attempted to examine each partition whether or not it actually existed. (Bug #45154)

  References: See also Bug #58638.

- **Disk Data**: If the value set in the `config.ini` file for `FileSystemPathDD` [1857], `FileSystemPathDataFiles` [1858], or `FileSystemPathUndoFiles` [1858] was identical to the value set for `FileSystemPath` [1816], that parameter was ignored when starting the data node with `--initial` [1954] option. As a result, the Disk Data files in the corresponding directory were not removed when performing an initial start of the affected data node or data nodes. (Bug #46243)

- **Disk Data**: During a checkpoint, restore points are created for both the on-disk and in-memory parts of a Disk Data table. Under certain rare conditions, the in-memory restore point could include or exclude a row that should have been in the snapshot. This would later lead to a crash during or following recovery. (Bug #41915)

  References: See also Bug #47832.

Changes in MySQL Cluster NDB 6.3.25 (5.1.34-ndb-6.3.25)

Functionality Added or Changed

- Two new server status variables `Ndb_scan_count` [1949] and `Ndb_pruned_scan_count` [1949] have been introduced. `Ndb_scan_count` [1949] gives the number of scans executed since the cluster was last started. `Ndb_pruned_scan_count` [1949] gives the number of scans for which `NDBCLUSTER` was able to use partition pruning. Together, these variables can be used to help determine in the MySQL server whether table scans are pruned by `NDBCLUSTER`. (Bug #44153)

- The `ndb_config` utility program can now provide an offline dump of all MySQL Cluster configuration parameters including information such as default and permitted values, brief description, and applicable section of the `config.ini` file. A dump in text format is produced when running

`ndb_config` with the new `--configinfo` option, and in XML format when the options `--configinfo --xml` are used together. For more information and examples, see `ndb_config` — Extract MySQL Cluster Configuration Information.

Bugs Fixed

- **Important Change**: **Partitioning**: User-defined partitioning of an `NDBCLUSTER` table without any primary key sometimes failed, and could cause `mysqld` to crash.

  Now, if you wish to create an `NDBCLUSTER` table with user-defined partitioning, the table must have an explicit primary key, and all columns listed in the partitioning expression must be part of the primary key. The hidden primary key used by the `NDBCLUSTER` storage engine is not sufficient for this purpose. However, if the list of columns is empty (that is, the table is defined using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

  This change does not effect the partitioning of tables using any storage engine other than `NDBCLUSTER`. (Bug #40709)

- **Important Change**: Previously, the configuration parameter `NoOfReplicas` [1815] had no default value. Now the default for `NoOfReplicas` [1815] is 2, which is the recommended value in most settings. (Bug #44746)

- **Packaging**: The `pkg` installer for MySQL Cluster on Solaris did not perform a complete installation due to an invalid directory reference in the postinstall script. (Bug #41998)

- `ndb_config --xml` [1975] did not output any entries for the `HostName` parameter. In addition, the default listed for `MaxNoOfFiles` was outside the permitted range of values. (Bug #44749)

  References: See also Bug #44685, Bug #44746.

- The output of `ndb_config --xml` [1975] did not provide information about all sections of the configuration file. (Bug #44685)

  References: See also Bug #44746, Bug #44749.

- When `ndb_config` could not find the file referenced by the `--config-file` option, it tried to read `my.cnf` instead, then failed with a misleading error message. (Bug #44846)

- When a data node was down so long that its most recent local checkpoint depended on a global checkpoint that was no longer restorable, it was possible for it to be unable to use optimized node recovery when being restarted later. (Bug #44844)

  References: See also Bug #26913.

- Inspection of the code revealed that several assignment operators (`=`) were used in place of comparison operators (`==`) in `DbdihMain.cpp`. (Bug #44567)

  References: See also Bug #44570.

- It was possible for NDB API applications to insert corrupt data into the database, which could subquently lead to data node crashes. Now, stricter checking is enforced on input data for inserts and updates. (Bug #44132)

- `NDBCLUSTER` did not build correctly on Solaris 9 platforms. (Bug #39080)

  References: See also Bug #39036, Bug #39038.

- When trying to use a data node with an older version of the management server, the data node crashed on startup. (Bug #43699)

- In some cases, data node restarts during a system restart could fail due to insufficient redo log space. (Bug #43156)

- `ndb_restore` failed when trying to restore data on a big-endian machine from a backup file created on a little-endian machine. (Bug #44069)
- The file `ndberror.c` contained a C++-style comment, which caused builds to fail with some C compilers. (Bug #44036)
- `ndb_restore --print_data [1997]` did not handle `DECIMAL` columns correctly. (Bug #37171)
- The output of `ndbd --help` did not provide clear information about the program's `--initial` and `--initial-start` options. (Bug #28905)
- It was theoretically possible for the value of a nonexistent column to be read as `NULL`, rather than causing an error. (Bug #27843)
- **Disk Data**: This fix supercedes and improves on an earlier fix made for this bug in MySQL 5.1.18. (Bug #24521)

Changes in MySQL Cluster NDB 6.3.24 (5.1.32-ndb-6.3.24)

Bugs Fixed

- **Cluster Replication**: If data node failed during an event creation operation, there was a slight risk that a surviving data node could send an invalid table reference back to NDB, causing the operation to fail with a false Error 723 (`No such table`). This could take place when a data node failed as a `mysqld` process was setting up MySQL Cluster Replication. (Bug #43754)
- **Cluster API**: Partition pruning did not work correctly for queries involving multiple range scans.

  As part of the fix for this issue, several improvements have been made in the NDB API, including the addition of a new `NdbScanOperation::getPruned()` method, a new variant of `NdbIndexScanOperation::setBound()`, and a new `PartitionSpec` data structure. (Bug #37934)
- **Cluster API**: Partition pruning did not work correctly for queries involving multiple range scans.

  As part of the fix for this issue, several improvements have been made in the NDB API, including the addition of a new `NdbScanOperation::getPruned()` method, a new variant of `NdbIndexScanOperation::setBound()`, and a new `PartitionSpec` data structure. (Bug #37934)
- `TransactionDeadlockDetectionTimeout [1841]` values less than 100 were treated as 100. This could cause scans to time out unexpectedly. (Bug #44099)
- `ndb_restore` crashed when trying to restore a backup made to a MySQL Cluster running on a platform having different endianness from that on which the original backup was taken. (Bug #39540)
- A race condition could occur when a data node failed to restart just before being included in the next global checkpoint. This could cause other data nodes to fail. (Bug #43888)
- When a data node process had been killed after allocating a node ID, but before making contact with any other data node processes, it was not possible to restart it due to a node ID allocation failure.

  This issue could effect either `ndbd` or `ndbmtd` processes. (Bug #43224)

  References: This bug was introduced by Bug #42973.
- Some queries using combinations of logical and comparison operators on an indexed column in the `WHERE` clause could fail with the error `Got error 4541 'IndexBound has no bound information' from NDBCLUSTER`. (Bug #42857)
- `TimeBetweenLocalCheckpoints [1839]` was measured from the end of one local checkpoint to the beginning of the next, rather than from the beginning of one LCP to the beginning of the next. This meant that the time spent performing the LCP was not taken into account when determining the

`TimeBetweenLocalCheckpoints` [1839] interval, so that LCPs were not started often enough, possibly causing data nodes to run out of redo log space prematurely. (Bug #43567)

- Using indexes containing variable-sized columns could lead to internal errors when the indexes were being built. (Bug #43226)

- When aborting an operation involving both an insert and a delete, the insert and delete were aborted separately. This was because the transaction coordinator did not know that the operations affected on same row, and, in the case of a committed-read (tuple or index) scan, the abort of the insert was performed first, then the row was examined after the insert was aborted but before the delete was aborted. In some cases, this would leave the row in a inconsistent state. This could occur when a local checkpoint was performed during a backup. This issue did not affect primary ley operations or scans that used locks (these are serialized).

  After this fix, for ordered indexes, all operations that follow the operation to be aborted are now also aborted.

- **Disk Data**: When a log file group had an undo log file whose size was too small, restarting data nodes failed with `Read underflow` errors.

  As a result of this fix, the minimum permitted `INTIAL_SIZE` for an undo log file is now `1M` (1 megabyte). (Bug #29574)

- **Cluster API**: `BIT` columns created using the native NDB API format that were not created as nullable could still sometimes be overwritten, or cause other columns to be overwritten.

  This issue did not effect tables having `BIT` columns created using the mysqld format (always used by MySQL Cluster SQL nodes). (Bug #43802)

- **Cluster API**: If the largest offset of a `RecordSpecification` used for an `NdbRecord` object was for the `NULL` bits (and thus not a column), this offset was not taken into account when calculating the size used for the `RecordSpecification`. This meant that the space for the `NULL` bits could be overwritten by key or other information. (Bug #43891)

- **Cluster API**: Ordered index scans using `NdbRecord` formerly expressed a `BoundEQ` range as separate lower and upper bounds, resulting in 2 copies of the column values being sent to the NDB kernel.

  Now, when a range is specified by `NdbScanOperation::setBound()`, the passed pointers, key lengths, and inclusive bits are compared, and only one copy of the equal key columns is sent to the kernel. This makes such operations more efficient, as half the amount of `KeyInfo` is now sent for a `BoundEQ` range as before. (Bug #38793)

- **Cluster API**: When performing insert or write operations, `NdbRecord` permits key columns to be specified in both the key record and in the attribute record. Only one key column value for each key column should be sent to the NDB kernel, but this was not guaranteed. This is now ensured as follows: For insert and write operations, key column values are taken from the key record; for scan takeover update operations, key column values are taken from the attribute record. (Bug #42238)

- **Cluster API**: The default `NdbRecord` structures created by `NdbDictionary` could have overlapping null bits and data fields. (Bug #43590)

Changes in MySQL Cluster NDB 6.3.23 (5.1.32-ndb-6.3.23)

Functionality Added or Changed

- A new data node configuration parameter `MaxLCPStartDelay` [1828] has been introduced to facilitate parallel node recovery by causing a local checkpoint to be delayed while recovering nodes are synchronizing data dictionaries and other meta-information. For more information about this parameter, see Defining MySQL Cluster Data Nodes. (Bug #43053)

Bugs Fixed

- **Performance**: Updates of the `SYSTAB_0` system table to obtain a unique identifier did not use transaction hints for tables having no primary key. In such cases the NDB kernel used a cache size of 1. This meant that each insert into a table not having a primary key required an update of the corresponding `SYSTAB_0` entry, creating a potential performance bottleneck.

  With this fix, inserts on `NDB` tables without primary keys can be under some conditions be performed up to 100% faster than previously. (Bug #39268)

- **Packaging**: Packages for MySQL Cluster were missing the `libndbclient.so` and `libndbclient.a` files. (Bug #42278)

- **Partitioning**: Executing `ALTER TABLE ... REORGANIZE PARTITION` on an `NDBCLUSTER` table having only one partition caused `mysqld` to crash. (Bug #41945)

  References: See also Bug #40389.

- In some cases, `NDB` did not check correctly whether tables had changed before trying to use the query cache. This could result in a crash of the debug MySQL server. (Bug #40464)

- When using `ndbmtd`, NDB kernel threads could hang while trying to start the data nodes with `LockPagesInMainMemory` [1832] set to 1. (Bug #43021)

- Backup IDs greater than 2^{31} were not handled correctly, causing negative values to be used in backup directory names and printouts. (Bug #43042)

- Given a MySQL Cluster containing no data (that is, whose data nodes had all been started using `--initial`, and into which no data had yet been imported) and having an empty backup directory, executing `START BACKUP` with a user-specified backup ID caused the data nodes to crash. (Bug #41031)

- When using multiple management servers and starting several API nodes (possibly including one or more SQL nodes) whose connectstrings listed the management servers in different order, it was possible for 2 API nodes to be assigned the same node ID. When this happened it was possible for an API node not to get fully connected, consequently producing a number of errors whose cause was not easily recognizable. (Bug #42973)

- Triggers on `NDBCLUSTER` tables caused such tables to become locked. (Bug #42751)

  References: See also Bug #16229, Bug #18135.

- `ndb_error_reporter` worked correctly only with GNU `tar`. (With other versions of `tar`, it produced empty archives.) (Bug #42753)

- **Disk Data**: Creating a Disk Data tablespace with a very large extent size caused the data nodes to fail. The issue was observed when using extent sizes of 100 MB and larger. (Bug #39096)

- **Disk Data**: It was not possible to add an in-memory column online to a table that used a table-level or column-level `STORAGE DISK` option. The same issue prevented `ALTER ONLINE TABLE ... REORGANIZE PARTITION` from working on Disk Data tables. (Bug #42549)

- **Disk Data**: Using a path or file name longer than 128 characters for Disk Data undo log files and tablespace data files caused a number of issues, including failures of `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, and `ALTER TABLESPACE` statements, as well as crashes of management nodes and data nodes.

  With this fix, the maximum length for path and file names used for Disk Data undo log files and tablespace data files is now the same as the maximum for the operating system. (Bug #31769, Bug #31770, Bug #31772)

- **Disk Data**: Trying to execute a `CREATE LOGFILE GROUP` statement using a value greater than `150M` for `UNDO_BUFFER_SIZE` caused data nodes to crash.

As a result of this fix, the upper limit for `UNDO_BUFFER_SIZE` is now `600M`; attempting to set a higher value now fails gracefully with an error. (Bug #34102)

References: See also Bug #36702.

- **Disk Data**: When attempting to create a tablespace that already existed, the error message returned was `Table or index with given name already exists`. (Bug #32662)
- **Disk Data**: Attempting to perform a system restart of the cluster where there existed a logfile group without and undo log files caused the data nodes to crash.

  Note

  While issuing a `CREATE LOGFILE GROUP` statement without an `ADD UNDOFILE` option fails with an error in the MySQL server, this situation could arise if an SQL node failed during the execution of a valid `CREATE LOGFILE GROUP` statement; it is also possible to create a logfile group without any undo log files using the NDB API.

  (Bug #17614)
- **Cluster API**: Some error messages from `ndb_mgmd` contained newline (`\n`) characters. This could break the MGM API protocol, which uses the newline as a line separator. (Bug #43104)
- **Cluster API**: When using an ordered index scan without putting all key columns in the read mask, this invalid use of the NDB API went undetected, which resulted in the use of uninitialized memory. (Bug #42591)

Changes in MySQL Cluster NDB 6.3.22 (5.1.31-ndb-6.3.22)

Functionality Added or Changed

- New options are introduced for `ndb_restore` for determining which tables or databases should be restored:
  - `--include-tables` and `--include-databases` can be used to restore specific tables or databases.
  - `--exclude-tables` and `--exclude-databases` can be used to exclude the specified tables or databases from being restored.

  For more information about these options, see `ndb_restore` — Restore a MySQL Cluster Backup. (Bug #40429)

Bugs Fixed

- When performing more than 32 index or tuple scans on a single fragment, the scans could be left hanging. This caused unnecessary timeouts, and in addition could possibly lead to a hang of an LCP. (Bug #42559)

  References: This bug is a regression of Bug #42084.
- A data node failure that occurred between calls to `NdbIndexScanOperation::readTuples(SF_OrderBy)` and `NdbTransaction::execute()` was not correctly handled; a subsequent call to `nextResult()` caused a null pointer to be deferenced, leading to a segfault in `mysqld`. (Bug #42545)
- Issuing `SHOW GLOBAL STATUS LIKE 'NDB%'` before `mysqld` had connected to the cluster caused a segmentation fault. (Bug #42458)
- Data node failures that occurred before all data nodes had connected to the cluster were not handled correctly, leading to additional data node failures. (Bug #42422)

- When a cluster backup failed with Error 1304 (Node *`node_id1`*: Backup request from *`node_id2`* failed to start), no clear reason for the failure was provided.

  As part of this fix, MySQL Cluster now retries backups in the event of sequence errors. (Bug #42354)

  References: See also Bug #22698.

- Issuing `SHOW ENGINE NDBCLUSTER STATUS` on an SQL node before the management server had connected to the cluster caused `mysqld` to crash. (Bug #42264)

Changes in MySQL Cluster NDB 6.3.21 (5.1.31-ndb-6.3.21)

Functionality Added or Changed

- **Important Change**: Formerly, when the management server failed to create a transporter for a data node connection, `net_write_timeout` [506] seconds elapsed before the data node was actually permitted to disconnect. Now in such cases the disconnection occurs immediately. (Bug #41965)

  References: See also Bug #41713.

- It is now possible while in Single User Mode to restart all data nodes using `ALL RESTART` in the management client. Restarting of individual nodes while in Single User Mode remains not permitted. (Bug #31056)

- Formerly, when using MySQL Cluster Replication, records for “empty” epochs—that is, epochs in which no changes to `NDBCLUSTER` data or tables took place—were inserted into the `ndb_apply_status` and `ndb_binlog_index` tables on the slave even when `--log-slave-updates` [1628] was disabled. Beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.13 this was changed so that these “empty” epochs were no longer logged. However, it is now possible to re-enable the older behavior (and cause “empty” epochs to be logged) by using the `--ndb-log-empty-epochs` option. For more information, see Replication Slave Options and Variables.

  References: See also Bug #37472.

Bugs Fixed

- Trying to execute an `ALTER ONLINE TABLE ... ADD COLUMN` statement while inserting rows into the table caused `mysqld` to crash. (Bug #41905)

- API nodes disconnected too agressively from cluster when data nodes were being restarted. This could sometimes lead to the API node being unable to access the cluster at all during a rolling restart. (Bug #41462)

- A maximum of 11 `TUP` scans were permitted in parallel. (Bug #42084)

- Issuing `EXIT` in the management client sometimes caused the client to hang. (Bug #40922)

- If the master node failed during a global checkpoint, it was possible in some circumstances for the new master to use an incorrect value for the global checkpoint index. This could occur only when the cluster used more than one node group. (Bug #41469)

- It was not possible to perform online upgrades from a MySQL Cluster NDB 6.2 release to MySQL Cluster NDB 6.3.8 or a later MySQL Cluster NDB 6.3 release. (Bug #41435)

- An abort path in the `DBLQH` kernel block failed to release a commit acknowledgment marker. This meant that, during node failure handling, the local query handler could be added multiple times to the marker record which could lead to additional node failures due an array overflow. (Bug #41296)

- During node failure handling (of a data node other than the master), there was a chance that the master was waiting for a `GCP_NODEFINISHED` signal from the failed node after having received it from all other data nodes. If this occurred while the failed node had a transaction that was still being committed in the current epoch, the master node could crash in the `DBTC` kernel block when

discovering that a transaction actually belonged to an epoch which was already completed. (Bug #41295)

- Cluster log files were opened twice by internal log-handling code, resulting in a resource leak. (Bug #41362)
- In the event that a MySQL Cluster backup failed due to file permissions issues, conflicting reports were issued in the management client. (Bug #34526)
- If all data nodes were shut down, MySQL clients were unable to access `NDBCLUSTER` tables and data even after the data nodes were restarted, unless the MySQL clients themselves were restarted. (Bug #33626)
- **Disk Data**: Starting a cluster under load such that Disk Data tables used most of the undo buffer could cause data node failures.

  The fix for this bug also corrected an issue in the `LGMAN` kernel block where the amount of free space left in the undo buffer was miscalculated, causing buffer overruns. This could cause records in the buffer to be overwritten, leading to problems when restarting data nodes. (Bug #28077)
- **Cluster API**: `mgmapi.h` contained constructs which only worked in C++, but not in C. (Bug #27004)

Changes in MySQL Cluster NDB 6.3.20 (5.1.30-ndb-6.3.20)

Functionality Added or Changed

- **Cluster API**: Two new `Ndb_cluster_connection` methods have been added to help in diagnosing problems with NDB API client connections. The `get_latest_error()` method tells whether or not the latest connection attempt succeeded; if the attempt failed, `get_latest_error_msg()` provides an error message giving the reason.

Bugs Fixed

- Statements of the form `UPDATE ... ORDER BY ... LIMIT` run against `NDBCLUSTER` tables failed to update all matching rows, or failed with the error `Can't find record in 'table_name'`. (Bug #40081)
- Issuing `SHOW TABLES` repeatedly could cause `NDBCLUSTER` tables to be dropped. (Bug #40854)
- Start phase reporting was inconsistent between the management client and the cluster log. (Bug #39667)
- If a transaction was aborted during the handling of a data node failure, this could lead to the later handling of an API node failure not being completed. (Bug #41214)
- Status messages shown in the management client when restarting a management node were inappropriate and misleading. Now, when restarting a management node, the messages displayed are as follows, where *`node_id`* is the management node's node ID:

  ```
  ndb_mgm> node_id RESTART
  Shutting down MGM node node_id for restart
  Node node_id is being restarted

  ndb_mgm>
  ```

  (Bug #29275)
- **Disk Data**: This improves on a previous fix for this issue that was made in MySQL Cluster 6.3.8. (Bug #37116)

  References: See also Bug #29186.
- **Cluster API**: When creating a scan using an `NdbScanFilter` object, it was possible to specify conditions against a `BIT` column, but the correct rows were not returned when the scan was executed.

As part of this fix, 4 new comparison operators have been implemented for use with scans on `BIT` columns:

- `COL_AND_MASK_EQ_MASK`
- `COL_AND_MASK_NE_MASK`
- `COL_AND_MASK_EQ_ZERO`
- `COL_AND_MASK_NE_ZERO`

For more information about these operators, see The `NdbScanFilter::BinaryCondition` Type.

Equivalent methods are now also defined for `NdbInterpretedCode`; for more information, see `NdbInterpretedCode` Bitwise Comparison Operations. (Bug #40535)

Changes in MySQL Cluster NDB 6.3.19 (5.1.29-ndb-6.3.19)

Functionality Added or Changed

- **Cluster API**: **Important Change**: MGM API applications exited without raising any errors if the connection to the management server was lost. The fix for this issue includes two changes:

  1. The MGM API now provides its own `SIGPIPE` handler to catch the “broken pipe” error that occurs when writing to a closed or reset socket. This means that MGM API now behaves the same as NDB API in this regard.

  2. A new function `ndb_mgm_set_ignore_sigpipe()` has been added to the MGM API. This function makes it possible to bypass the `SIGPIPE` handler provided by the MGM API.

  (Bug #40498)

- When performing an initial start of a data node, fragment log files were always created sparsely—that is, not all bytes were written. Now it is possible to override this behavior using the new `InitFragmentLogFiles` [1827] configuration parameter. (Bug #40847)

Bugs Fixed

- **Cluster API**: Failed operations on `BLOB` and `TEXT` columns were not always reported correctly to the originating SQL node. Such errors were sometimes reported as being due to timeouts, when the actual problem was a transporter overload due to insufficient buffer space. (Bug #39867, Bug #39879)

- **Cluster API**: Failed operations on `BLOB` and `TEXT` columns were not always reported correctly to the originating SQL node. Such errors were sometimes reported as being due to timeouts, when the actual problem was a transporter overload due to insufficient buffer space. (Bug #39867, Bug #39879)

- Memory leaks could occur in handling of strings used for storing cluster metadata and providing output to users. (Bug #38662)

- Undo logs and data files were created in 32K increments. Now these files are created in 512K increments, resulting in shorter creation times. (Bug #40815)

- A segfault in `Logger::Log` caused `ndbd` to hang indefinitely. This fix improves on an earlier one for this issue, first made in MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.17. (Bug #39180)

  References: See also Bug #38609.

- Redo log creation was very slow on some platforms, causing MySQL Cluster to start more slowly than necessary with some combinations of hardware and operating system. This was due to all write operations being synchronized to disk while creating a redo log file. Now this synchronization occurs only after the redo log has been created. (Bug #40734)

- Transaction failures took longer to handle than was necessary.

  When a data node acting as transaction coordinator (TC) failed, the surviving data nodes did not inform the API node initiating the transaction of this until the failure had been processed by all protocols. However, the API node needed only to know about failure handling by the transaction protocol—that is, it needed to be informed only about the TC takeover process. Now, API nodes (including MySQL servers acting as cluster SQL nodes) are informed as soon as the TC takeover is complete, so that it can carry on operating more quickly. (Bug #40697)

- Events logged after setting `ALL CLUSTERLOG STATISTICS=15` in the management client did not always include the node ID of the reporting node. (Bug #39839)

- It was theoretically possible for stale data to be read from `NDBCLUSTER` tables when the transaction isolation level was set to `ReadCommitted`. (Bug #40543)

- The `LockExecuteThreadToCPU` [1852] and `LockMaintThreadsToCPU` [1853] parameters did not work on Solaris. (Bug #40521)

- Restoring a MySQL Cluster from a dump made using `mysqldump` failed due to a spurious error: `Can't execute the given command because you have active locked tables or an active transaction`. (Bug #40346)

- `SET SESSION ndb_optimized_node_selection = 1` failed with an invalid warning message. (Bug #40457)

- A restarting data node could fail with an error in the `DBDIH` kernel block when a local or global checkpoint was started or triggered just as the node made a request for data from another data node. (Bug #40370)

- `O_DIRECT` was incorrectly disabled when making MySQL Cluster backups. (Bug #40205)

- The MySQL Query Cache did not function correctly with `NDBCLUSTER` tables containing `TEXT` columns. (Bug #39295)

- Heavy DDL usage caused the `mysqld` processes to hang due to a timeout error (`NDB` error code 266). (Bug #39885)

- Executing `EXPLAIN SELECT` on an `NDBCLUSTER` table could cause `mysqld` to crash. (Bug #39872)

- A duplicate key or other error raised when inserting into an `NDBCLUSTER` table caused the current transaction to abort, after which any SQL statement other than a `ROLLBACK` failed. With this fix, the `NDBCLUSTER` storage engine now performs an implicit rollback when a transaction is aborted in this way; it is no longer necessary to issue an explicit `ROLLBACK` statement, and the next statement that is issued automatically begins a new transaction.

  Note

  It remains necessary in such cases to retry the complete transaction, regardless of which statement caused it to be aborted.

  (Bug #32656)

  References: See also Bug #47654.

- Error messages for `NDBCLUSTER` error codes 1224 and 1227 were missing. (Bug #28496)

- **Disk Data**: Issuing concurrent `CREATE TABLESPACE`, `ALTER TABLESPACE`, `CREATE LOGFILE GROUP`, or `ALTER LOGFILE GROUP` statements on separate SQL nodes caused a resource leak that led to data node crashes when these statements were used again later. (Bug #40921)

- **Disk Data**: Disk-based variable-length columns were not always handled like their memory-based equivalents, which could potentially lead to a crash of cluster data nodes. (Bug #39645)

- **Disk Data**: `O_SYNC` was incorrectly disabled on platforms that do not support `O_DIRECT`. This issue was noted on Solaris but could have affected other platforms not having `O_DIRECT` capability. (Bug #34638)

- **Cluster API**: The MGM API function `ndb_mgm_listen_event()` ignored bind addresses.

  As part of this fix, it is now possible to specify bind addresses in connectstrings. See The MySQL Cluster Connectstring, for more information. (Bug #38473)

- **Cluster API**: It was not always possible to access parent objects directly from `NdbBlob`, `NdbOperation`, and `NdbScanOperation` objects. To alleviate this problem, a new `getNdbOperation()` method has been added to `NdbBlob` and new getNdbTransaction() methods have been added to `NdbOperation` and `NdbScanOperation`. In addition, a const variant of `NdbOperation::getErrorLine()` is now also available. (Bug #40242)

- **Cluster API**: `NdbScanOperation::getBlobHandle()` failed when used with incorrect column names or numbers. (Bug #40241)

- **Cluster API**: The MGM API reset error codes on management server handles before checking them. This meant that calling an MGM API function with a null handle caused applications to crash. (Bug #40455)

- **Cluster API**: The NDB API example programs included in MySQL Cluster source distributions failed to compile. (Bug #37491)

  References: See also Bug #40238.

Changes in MySQL Cluster NDB 6.3.18 (5.1.28-ndb-6.3.18)

Functionality Added or Changed

- It is no longer a requirement for database autodiscovery that an SQL node already be connected to the cluster at the time that a database is created on another SQL node. It is no longer necessary to issue `CREATE DATABASE` (or `CREATE SCHEMA`) statements on an SQL node joining the cluster after a database is created for the new SQL node to see the database and any `NDBCLUSTER` tables that it contains. (Bug #39612)

Bugs Fixed

- When a transaction included a multi-row insert to an `NDBCLUSTER` table that caused a constraint violation, the transaction failed to roll back. (Bug #395638)

- After a forced shutdown and initial restart of the cluster, it was possible for SQL nodes to retain `.frm` files corresponding to `NDBCLUSTER` tables that had been dropped, and thus to be unaware that these tables no longer existed. In such cases, attempting to re-create the tables using `CREATE TABLE IF NOT EXISTS` could fail with a spurious `Table ... doesn't exist` error. (Bug #37921)

- When restarting a data node, an excessively long shutdown message could cause the node process to crash. (Bug #38580)

- Starting the MySQL Server with the `--ndbcluster` [1915] option plus an invalid command-line option (for example, using `mysqld --ndbcluster --foobar`) caused it to hang while shutting down the binlog thread. (Bug #39635)

- Dropping and then re-creating a database on one SQL node caused other SQL nodes to hang. (Bug #39613)

- Unique identifiers in tables having no primary key were not cached. This fix has been observed to increase the efficiency of `INSERT` operations on such tables by as much as 50%. (Bug #39267)

- A statement of the form `DELETE FROM table WHERE primary_key=value` or `UPDATE table WHERE primary_key=value` where there was no row whose primary key column had the stated `value` appeared to succeed, with the server reporting that 1 row had been changed.

  This issue was only known to affect MySQL Cluster NDB 6.3.11 and later NDB 6.3 versions. (Bug #37153)

- Setting a low value of `MaxNoOfLocalScans` [1824] (< 100) and performing a large number of (certain) scans could cause the Transaction Coordinator to run out of scan fragment records, and then crash. Now when this resource is exhausted, the cluster returns Error 291 (`Out of scanfrag records in TC (increase MaxNoOfLocalScans)`) instead. (Bug #39549)

- Creating a unique index on an `NDBCLUSTER` table caused a memory leak in the `NDB` subscription manager (`SUMA`) which could lead to mysqld hanging, due to the fact that the resource shortage was not reported back to the `NDB` kernel correctly. (Bug #39518)

  References: See also Bug #39450.

- Embedded `libmysqld` with `NDB` did not drop table events. (Bug #39450)

- **Cluster API**: Passing a value greater than 65535 to `NdbInterpretedCode::add_val()` and `NdbInterpretedCode::sub_val()` caused these methods to have no effect. (Bug #39536)

Changes in MySQL Cluster NDB 6.3.17 (5.1.27-ndb-6.3.17)

Bugs Fixed

- **Packaging**: Support for the `InnoDB` storage engine was missing from the GPL source releases. An updated GPL source tarball `mysql-5.1.27-ndb-6.3.17-innodb.tar.gz` which includes code for building `InnoDB` can be found on the MySQL FTP site.

- `MgmtSrvr::allocNodeId()` left a mutex locked following an `Ambiguity for node if %d` error. (Bug #39158)

- An invalid path specification caused `mysql-test-run.pl` to fail. (Bug #39026)

- During transactional coordinator takeover (directly after node failure), the LQH finding an operation in the `LOG_COMMIT` state sent an `LQH_TRANS_CONF` signal twice, causing the TC to fail. (Bug #38930)

- An invalid memory access caused the management server to crash on Solaris Sparc platforms. (Bug #38628)

- A segfault in `Logger::Log` caused `ndbd` to hang indefinitely. (Bug #38609)

- `ndb_mgmd` failed to start on older Linux distributions (2.4 kernels) that did not support e-polling. (Bug #38592)

- `ndb_mgmd` sometimes performed unnecessary network I/O with the client. This in combination with other factors led to long-running threads that were attempting to write to clients that no longer existed. (Bug #38563)

- `ndb_restore` failed with a floating point exception due to a division by zero error when trying to restore certain data files. (Bug #38520)

- A failed connection to the management server could cause a resource leak in `ndb_mgmd`. (Bug #38424)

- Failure to parse configuration parameters could cause a memory leak in the NDB log parser. (Bug #38380)

- Renaming an `NDBCLUSTER` table on one SQL node, caused a trigger on this table to be deleted on another SQL node. (Bug #36658)

- Attempting to add a `UNIQUE INDEX` twice to an `NDBCLUSTER` table, then deleting rows from the table could cause the MySQL Server to crash. (Bug #35599)
- `ndb_restore` failed when a single table was specified. (Bug #33801)
- `GCP_COMMIT` did not wait for transaction takeover during node failure. This could cause `GCP_SAVE_REQ` to be executed too early. This could also cause (very rarely) replication to skip rows. (Bug #30780)
- **Cluster API**: Certain Multi-Range Read scans involving `IS NULL` and `IS NOT NULL` comparisons failed with an error in the `NDB` local query handler. (Bug #38204)
- **Cluster API**: Creating an `NdbScanFilter` object using an `NdbScanOperation` object that had not yet had its `readTuples()` method called resulted in a crash when later attempting to use the `NdbScanFilter`. (Bug #37986)
- **Cluster API**: Executing an `NdbRecord` interpreted delete created with an `ANYVALUE` option caused the transaction to abort. (Bug #37672)
- **Cluster API**: Support for Multi-Range Read index scans using the old API (using, for example, `NdbIndexScanOperation::setBound()` or `NdbIndexScanOperation::end_of_bound()`) were dropped in MySQL Cluster NDB 6.2. This functionality is restored in MySQL Cluster NDB 6.3 beginning with 6.3.17, but remains unavailable in MySQL Cluster NDB 6.2. Both MySQL Cluster NDB 6.2 and 6.3 support Multi-Range Read scans through the `NdbRecord` API. (Bug #38791)
- **Cluster API**: The `NdbScanOperation::readTuples()` method could be called multiple times without error. (Bug #38717)
- **Cluster API**: Problems with the public headers prevented `NDB` applications from being built with warnings turned on. (Bug #38177)

Changes in MySQL Cluster NDB 6.3.16 (5.1.24-ndb-6.3.16)

Functionality Added or Changed

- Event buffer lag reports are now written to the cluster log. (Bug #37427)
- Added the `--no-binlog` option for `ndb_restore`. When used, this option prevents information being written to SQL node binary logs from the restoration of a cluster backup. (Bug #30452)

Bugs Fixed

- **Cluster API**: Changing the system time on data nodes could cause MGM API applications to hang and the data nodes to crash. (Bug #35607)
- **Cluster API**: Changing the system time on data nodes could cause MGM API applications to hang and the data nodes to crash. (Bug #35607)
- Failure of a data node could sometimes cause mysqld to crash. (Bug #37628)
- `DELETE ... WHERE` *`unique_index_column=value`* deleted the wrong row from the table. (Bug #37516)
- If subscription was terminated while a node was down, the epoch was not properly acknowledged by that node. (Bug #37442)
- `libmysqld` failed to wait for the cluster binlog thread to terminate before exiting. (Bug #37429)
- In rare circumstances, a connection followed by a disconnection could give rise to a “stale” connection where the connection still existed but was not seen by the transporter. (Bug #37338)
- Queries against `NDBCLUSTER` tables were cached only if `autocommit` [461] was in use. (Bug #36692)

- **Cluster API**: When some operations succeeded and some failed following a call to `NdbTransaction::execute(Commit, AO_IgnoreOnError)`, a race condition could cause spurious occurrences of NDB API Error 4011 (`Internal error`). (Bug #37158)
- **Cluster API**: A buffer overrun in `NdbBlob::setValue()` caused erroneous results on Mac OS X. (Bug #31284)
- **Cluster API**: Creating a table on an SQL node, then starting an NDB API application that listened for events from this table, then dropping the table from an SQL node, prevented data node restarts. (Bug #32949, Bug #37279)

Changes in MySQL Cluster NDB 6.3.15 (5.1.24-ndb-6.3.15)

Bugs Fixed

- Under some circumstances, a failed `CREATE TABLE` could mean that subsequent `CREATE TABLE` statements caused node failures. (Bug #37092)
- A fail attempt to create an `NDB` table could in some cases lead to resource leaks or cluster failures. (Bug #37072)
- Attempting to create a native backup of `NDB` tables having a large number of `NULL` columns and data could lead to node failures. (Bug #37039)
- In certain rare situations, `ndb_size.pl` could fail with the error `Can't use string ("value") as a HASH ref while "strict refs" in use`. (Bug #43022)
- Where column values to be compared in a query were of the `VARCHAR` or `VARBINARY` types, `NDBCLUSTER` passed a value padded to the full size of the column, which caused unnecessary data to be sent to the data nodes. This also had the effect of wasting CPU and network bandwidth, and causing condition pushdown to be disabled where it could (and should) otherwise have been applied. (Bug #35393)
- Checking of API node connections was not efficiently handled. (Bug #36843)
- Attempting to delete a nonexistent row from a table containing a `TEXT` or `BLOB` column within a transaction caused the transaction to fail. (Bug #36756)

  References: See also Bug #36851.
- If the combined total of tables and indexes in the cluster was greater than 4096, issuing `START BACKUP` caused data nodes to fail. (Bug #36044)
- When dropping a table failed for any reason (such as when in single user mode) then the corresponding `.ndb` file was still removed.
- **Cluster API**: Ordered index scans were not pruned correctly where a partitioning key was specified with an EQ-bound. (Bug #36950)
- **Cluster API**: When an insert operation involving `BLOB` data was attempted on a row which already existed, no duplicate key error was correctly reported and the transaction is incorrectly aborted. In some cases, the existing row could also become corrupted. (Bug #36851)

  References: See also Bug #26756.
- **Cluster API**: `NdbApi.hpp` depended on `ndb_global.h`, which was not actually installed, causing the compilation of programs that used `NdbApi.hpp` to fail. (Bug #35853)

Changes in MySQL Cluster NDB 6.3.14 (5.1.24-ndb-6.3.14)

Bugs Fixed

- A race condition caused by a failure in epoll handling could cause data nodes to fail. (Bug #36537)

- Under certain rare circumstances, the failure of the new master node while attempting a node takeover would cause takeover errors to repeat without being resolved. (Bug #36199, Bug #36246, Bug #36247, Bug #36276)
- When more than one SQL node connected to the cluster at the same time, creation of the `mysql.ndb_schema` table failed on one of them with an explicit `Table exists` error, which was not necessary. (Bug #35943)
- `mysqld` failed to start after running `mysql_upgrade`. (Bug #35708)
- `SET GLOBAL ndb_extra_logging` caused `mysqld` to crash. (Bug #36547)
- Notification of a cascading master node failures could sometimes not be transmitted correctly (that is, transmission of the `NF_COMPLETEREP` signal could fail), leading to transactions hanging and timing out (`NDB` error 4012), scans hanging, and failure of the management server process. (Bug #32645)
- `NDB` error 1427 (`Api node died, when SUB_START_REQ reached node`) was incorrectly classified as a schema error rather than a temporary error.
- If an API node disconnected and then reconnected during Start Phase 8, then the connection could be “blocked”—that is, the `QMGR` kernel block failed to detect that the API node was in fact connected to the cluster, causing issues with the `NDB` Subscription Manager (`SUMA`).
- **Cluster API**: Accessing the debug version of `libndbclient` using `dlopen()` resulted in a segmentation fault. (Bug #35927)
- **Cluster API**: Attempting to pass a nonexistent column name to the `equal()` and `setValue()` methods of `NdbOperation` caused NDB API applications to crash. Now the column name is checked, and an error is returned in the event that the column is not found. (Bug #33747)

Changes in MySQL Cluster NDB 6.3.13 (5.1.24-ndb-6.3.13)

Bugs Fixed

- **Important Change**: `mysqld_safe` now traps Signal 13 (`SIGPIPE`) so that this signal no longer kills the MySQL server process. (Bug #33984)
- Node or system restarts could fail due an unitialized variable in the `DTUP` kernel block. This issue was found in MySQL Cluster NDB 6.3.11. (Bug #35797)
- It was not possible to determine the value used for the `--ndb-cluster-connection-pool` option in the `mysql` client. Now this value is reported as a system status variable. (Bug #35573)
- If an error occurred while executing a statement involving a `BLOB` or `TEXT` column of an `NDB` table, a memory leak could result. (Bug #35593)
- The `ndb_waiter` utility wrongly calculated timeouts. (Bug #35435)
- A `SELECT` on a table with a nonindexed, large `VARCHAR` column which resulted in condition pushdown on this column could cause `mysqld` to crash. (Bug #35413)
- `ndb_restore` incorrectly handled some data types when applying log files from backups. (Bug #35343)
- In some circumstances, a stopped data node was handled incorrectly, leading to redo log space being exhausted following an initial restart of the node, or an initial or partial restart of the cluster (the wrong CGI might be used in such cases). This could happen, for example, when a node was stopped following the creation of a new table, but before a new LCP could be executed. (Bug #35241)
- `SELECT ... LIKE ...` queries yielded incorrect results when used on `NDB` tables. As part of this fix, condition pushdown of such queries has been disabled; re-enabling it is expected to be done as part of a later, permanent fix for this issue. (Bug #35185)
- `ndb_mgmd` reported errors to `STDOUT` rather than to `STDERR`. (Bug #35169)

- Nested Multi-Range Read scans failed when the second Multi-Range Read released the first read's unprocessed operations, sometimes leading to an SQL node crash. (Bug #35137)
- In some situations, a problem with synchronizing checkpoints between nodes could cause a system restart or a node restart to fail with `Error 630 during restore of TX`. (Bug #34756)

  References: This bug is a regression of Bug #34033.
- When a secondary index on a `DECIMAL` column was used to retrieve data from an `NDB` table, no results were returned even if the target table had a matched value in the column that was defined with the secondary index. (Bug #34515)
- An `UPDATE` on an `NDB` table that set a new value for a unique key column could cause subsequent queries to fail. (Bug #34208)
- If a data node in one node group was placed in the “not started” state (using *`node_id`* `RESTART -n`), it was not possible to stop a data node in a different node group. (Bug #34201)
- Numerous `NDBCLUSTER` test failures occurred in builds compiled using `icc` on IA64 platforms. (Bug #31239)
- A node failure during an initial node restart followed by another node start could cause the master data node to fail, because it incorrectly gave the node permission to start even if the invalidated node's LCP was still running. (Bug #34702)
- `REPLACE` statements did not work correctly with `NDBCLUSTER` tables when all columns were not explicitly listed. (Bug #22045)
- If a `START BACKUP` command was issued while `ndb_restore` was running, the backup being restored could be overwritten. (Bug #26498)
- `CREATE TABLE` and `ALTER TABLE` statements using `ENGINE=NDB` or `ENGINE=NDBCLUSTER` caused `mysqld` to fail on Solaris 10 for x86 platforms. (Bug #19911)
- **Cluster API**: Closing a scan before it was executed caused the application to segfault. (Bug #36375)
- **Cluster API**: Scans having no bounds set were handled incorrectly. (Bug #35876)
- **Cluster API**: Using NDB API applications from older MySQL Cluster versions with `libndbclient` from newer ones caused the cluster to fail. (Bug #36124)
- **Cluster API**: Some ordered index scans could return tuples out of order. (Bug #35908)
- **Cluster API**: `NdbScanFilter::getNdbOperation()`, which was inadvertently removed in MySQL Cluster NDB 6.3.11, has been restored. (Bug #35854)

Changes in MySQL Cluster NDB 6.3.10 (5.1.23-ndb-6.3.10)

Bugs Fixed

- Due to the reduction of the number of local checkpoints from 3 to 2 in MySQL Cluster NDB 6.3.8, a data node using ndbd from MySQL Cluster NDB 6.3.8 or later started using a file system from an earlier version could incorrectly invalidate local checkpoints too early during the startup process, causing the node to fail. (Bug #34596)

Changes in MySQL Cluster NDB 6.3.9 (5.1.23-ndb-6.3.9)

Bugs Fixed

- When configured with `NDB` support, MySQL failed to compile using `gcc` 4.3 on 64bit FreeBSD systems. (Bug #34169)
- When configured with `NDB` support, MySQL failed to compile on 64bit FreeBSD systems. (Bug #34046)

- Cluster failures could sometimes occur when performing more than three parallel takeovers during node restarts or system restarts. This affected MySQL Cluster NDB 6.3.*x* releases only. (Bug #34445)
- Upgrades of a cluster using while a `DataMemory` [1817] setting in excess of 16 GB caused data nodes to fail. (Bug #34378)
- Performing many SQL statements on `NDB` tables while in `autocommit` [461] mode caused a memory leak in `mysqld`. (Bug #34275)
- In certain rare circumstances, a race condition could occur between an aborted insert and a delete leading a data node crash. (Bug #34260)
- Multi-table updates using ordered indexes during handling of node failures could cause other data nodes to fail. (Bug #34216)
- The failure of a DDL statement could sometimes lead to node failures when attempting to execute subsequent DDL statements. (Bug #34160)
- Extremely long `SELECT` statements (where the text of the statement was in excess of 50000 characters) against `NDB` tables returned empty results. (Bug #34107)
- Statements executing multiple inserts performed poorly on `NDB` tables having `AUTO_INCREMENT` columns. (Bug #33534)
- The `ndb_waiter` utility polled `ndb_mgmd` excessively when obtaining the status of cluster data nodes. (Bug #32025)

  References: See also Bug #32023.
- Transaction atomicity was sometimes not preserved between reads and inserts under high loads. (Bug #31477)
- Having tables with a great many columns could cause Cluster backups to fail. (Bug #30172)
- **Cluster Replication**: **Disk Data**: Statements violating unique keys on Disk Data tables (such as attempting to insert `NULL` into a `NOT NULL` column) could cause data nodes to fail. When the statement was executed from the binlog, this could also result in failure of the slave cluster. (Bug #34118)
- **Disk Data**: Updating in-memory columns of one or more rows of Disk Data table, followed by deletion of these rows and re-insertion of them, caused data node failures. (Bug #33619)

Changes in MySQL Cluster NDB 6.3.8 (5.1.23-ndb-6.3.8)

Functionality Added or Changed

- **Cluster API**: **Important Change**: Because `NDB_LE_MemoryUsage.page_size_kb` shows memory page sizes in bytes rather than kilobytes, it has been renamed to `page_size_bytes`. The name `page_size_kb` is now deprecated and thus subject to removal in a future release, although it currently remains supported for reasons of backward compatibility. See The `Ndb_logevent_type` Type, for more information about `NDB_LE_MemoryUsage`. (Bug #30271)
- `OPTIMIZE TABLE` can now be interrupted. This can be done, for example, by killing the SQL thread performing the `OPTIMIZE` operation.
- Persistence of `NDB` tables can now be controlled using the session variables `ndb_table_temporary` [1931] and `ndb_table_no_logging` [1930]. `ndb_table_no_logging` [1930] causes `NDB` tables not to be checkpointed to disk. `ndb_table_temporary` [1931] has the same effect; in addition, when `ndb_table_temporary` [1931] is used, no `NDB` table schema files are created.

- Node recovery can now be done in parallel, rather than sequentially, which can result in much faster recovery times.
- The `mysqld` option `--ndb-batch-size` has been added. This enables control of the size of batches used for running transactions.
- Now only 2 local checkpoints are stored, rather than 3 as in previous MySQL Cluster versions. This lowers disk space requirements and reduces the size and number of redo log files needed.
- `ndb_restore` now supports basic *attribute promotion*; that is, data from a column of a given type can be restored to a column using a "larger" type. For example, Cluster backup data taken from a `SMALLINT` column can be restored to a `MEDIUMINT`, `INT`, or `BIGINT` column.

  For more information, see `ndb_restore` — Restore a MySQL Cluster Backup.

Bugs Fixed

- **Disk Data**: **Important Change**: It is no longer possible on 32-bit systems to issue statements appearing to create Disk Data log files or data files greater than 4 GB in size. (Trying to create log files or data files larger than 4 GB on 32-bit systems led to unrecoverable data node failures; such statements now fail with `NDB` error 1515.) (Bug #29186)
- **Replication**: The code implementing heartbeats did not check for possible errors in some circumstances; this kept the dump thread hanging while waiting for heartbeats loop even though the slave was no longer connected. (Bug #33332)
- Some tuple scans caused the wrong memory page to be accessed, leading to invalid results. This issue could affect both in-memory and Disk Data tables. (Bug #33739)
- Issuing an `INSERT ... ON DUPLICATE KEY UPDATE` concurrently with or following a `TRUNCATE TABLE` statement on an `NDB` table failed with `NDB` error 4350 `Transaction already aborted`. (Bug #29851)
- The server failed to reject properly the creation of an `NDB` table having an unindexed `AUTO_INCREMENT` column. (Bug #30417)
- A failure to initialize an internal variable led to sporadic crashes during cluster testing. (Bug #33715)
- A race condition could occur (very rarely) when the release of a GCI was followed by a data node failure. (Bug #33793)
- `DROP TABLE` did not free all data memory. This bug was observed in MySQL Cluster NDB 6.3.7 only. (Bug #33802)
- A periodic failure to flush the send buffer by the `NDB` TCP transporter could cause a unnecessary delay of 10 ms between operations. (Bug #34005)
- High numbers of insert operations, delete operations, or both could cause `NDB` error 899 (`Rowid already allocated`) to occur unnecessarily. (Bug #34033)
- Under some circumstances, a recovering data node did not use its own data, instead copying data from another node even when this was not required. This in effect bypassed the optimized node recovery protocol and caused recovery times to be unnecessarily long. (Bug #26913)
- It was possible in `config.ini` to define cluster nodes having node IDs greater than the maximum permitted value. (Bug #28298)
- The Cluster backup process could not detect when there was no more disk space and instead continued to run until killed manually. Now the backup fails with an appropriate error when disk space is exhausted. (Bug #28647)
- **Cluster API**: When reading a `BIT(64)` value using `NdbOperation:getValue()`, 12 bytes were written to the buffer rather than the expected 8 bytes. (Bug #33750)

- **Cluster API**: Transactions containing inserts or reads would hang during `NdbTransaction::execute()` calls made from NDB API applications built against a MySQL Cluster version that did not support micro-GCPs accessing a later version that supported micro-GCPs. This issue was observed while upgrading from MySQL Cluster NDB 6.1.23 to MySQL Cluster NDB 6.2.10 when the API application built against the earlier version attempted to access a data node already running the later version, even after disabling micro-GCPs by setting `TimeBetweenEpochs` [1840] equal to 0. (Bug #33895)

Changes in MySQL Cluster NDB 6.3.7 (5.1.23-ndb-6.3.7)

Functionality Added or Changed

- It is now possible to cause statements occurring within the same transaction to be run as a batch by setting the session variable `transaction_allow_batching` [1932] to `1` or `ON`.

  Note

  To use this feature, `autocommit` [461] must be disabled.

- `OPTIMIZE TABLE` is now supported for `NDBCLUSTER` tables, subject to the following limitations:

  - Only in-memory tables are supported. `OPTIMIZE` still has no effect on Disk Data tables.
  - Only variable-length columns are supported. However, you can force columns defined using fixed-length data types to be dynamic using the `ROW_FORMAT` or `COLUMN_FORMAT` option with a `CREATE TABLE` or `ALTER TABLE` statement.

  Memory reclaimed from an `NDB` table using `OPTIMIZE` is generally available to the cluster, and not confined to the table from which it was recovered, unlike the case with memory freed using `DELETE`.

  The performance of `OPTIMIZE` on `NDB` tables can be regulated by adjusting the value of the `ndb_optimization_delay` system variable.

- Compressed local checkpoints and backups are now supported, resulting in a space savings of 50% or more over uncompressed LCPs and backups. Compression of these can be enabled in the `config.ini` file using the two new data node configuration parameters `CompressedLCP` [1834] and `CompressedBackup` [1834], respectively.

Bugs Fixed

- **Partitioning**: When partition pruning on an `NDB` table resulted in an ordered index scan spanning only one partition, any descending flag for the scan was wrongly discarded, causing `ORDER BY DESC` to be treated as `ORDER BY ASC`, `MAX()` to be handled incorrectly, and similar problems. (Bug #33061)
- When all data and SQL nodes in the cluster were shut down abnormally (that is, other than by using `STOP` in the cluster management client), `ndb_mgm` used excessive amounts of CPU. (Bug #33237)
- When using micro-GCPs, if a node failed while preparing for a global checkpoint, the master node would use the wrong GCI. (Bug #32922)
- Under some conditions, performing an `ALTER TABLE` on an `NDBCLUSTER` table failed with a `Table is full` error, even when only 25% of `DataMemory` [1817] was in use and the result should have been a table using less memory (for example, changing a `VARCHAR(100)` column to `VARCHAR(80)`). (Bug #32670)

Changes in MySQL Cluster NDB 6.3.6 (5.1.22-ndb-6.3.6)

Functionality Added or Changed

- The output of the `ndb_mgm` client `SHOW` and `STATUS` commands now indicates when the cluster is in single user mode. (Bug #27999)

- Introduced the `Ndb_execute_count` [1948] status variable, which measures the number of round trips made by queries to the `NDB` kernel.
- Batched operations are now better supported for `DELETE` and `UPDATE`. (`UPDATE WHERE...` and multiple `DELETE`.)
- Unnecessary reads when performing a primary key or unique key update have been reduced, and in some cases, eliminated. (It is almost never necessary to read a record prior to an update, the lone exception to this being when a primary key is updated, since this requires a delete followed by an insert, which must be prepared by reading the record.) Depending on the number of primary key and unique key lookups that are performed per transaction, this can yield a considerable improvement in performance.

Bugs Fixed

- The `NDB` management client command *`node_id`* `REPORT MEMORY` provided no output when *`node_id`* was the node ID of a management or API node. Now, when this occurs, the management client responds with `Node` *`node_id`*`: is not a data node`. (Bug #29485)
- `ndb_restore` displayed incorrect backup file version information. This meant (for example) that, when attempting to restore a backup made from a MySQL 5.1.22 cluster to a MySQL Cluster NDB 6.3.3 cluster, the restore process failed with the error `Restore program older than backup version. Not supported. Use new restore program.` (Bug #31723)
- Following an upgrade, `ndb_mgmd` would fail with an *`ArbitrationError`*. (Bug #31690)
- The `NDB` storage engine code was not safe for strict-alias optimization in `gcc` 4.2.1. (Bug #31761)
- An error with an `if` statement in `sql/ha_ndbcluster.cc` could potentially lead to an infinite loop in case of failure when working with `AUTO_INCREMENT` columns in `NDB` tables. (Bug #31810)
- An insert or update with combined range and equality constraints failed when run against an `NDB` table with the error `Got unknown error from NDB`. An example of such a statement would be `UPDATE t1 SET b = 5 WHERE a IN (7,8) OR a >= 10;`. (Bug #31874)
- Performing `DELETE` operations after a data node had been shut down could lead to inconsistent data following a restart of the node. (Bug #26450)
- `UPDATE IGNORE` could sometimes fail on `NDB` tables due to the use of unitialized data when checking for duplicate keys to be ignored. (Bug #25817)

Changes in MySQL Cluster NDB 6.3.5 (5.1.22-ndb-6.3.5)

Bugs Fixed

- A query against a table with `TEXT` or `BLOB` columns that would return more than a certain amount of data failed with `Got error 4350 'Transaction already aborted' from NDBCLUSTER`. (Bug #31482)

  References: This bug was introduced by Bug #29102.

Changes in MySQL Cluster NDB 6.3.4 (5.1.22-ndb-6.3.4)

Functionality Added or Changed

- **Incompatible Change**: The `--ndb_optimized_node_selection` startup option for `mysqld` now permits a wider range of values and corresponding behaviors for SQL nodes when selecting a transaction coordinator.

  You should be aware that the default value and behavior as well as the value type used for this option have changed, and that you may need to update the setting used for this option in your `my.cnf` file prior to upgrading `mysqld`. See Server System Variables, for more information.

- **Incompatible Change**: The `--ndb_optimized_node_selection` startup option for `mysqld` now permits a wider range of values and corresponding behaviors for SQL nodes when selecting a transaction coordinator.

  You should be aware that the default value and behavior as well as the value type used for this option have changed, and that you may need to update the setting used for this option in your `my.cnf` file prior to upgrading `mysqld`. See Server System Variables, for more information.

Bugs Fixed

- It was possible in some cases for a node group to be “lost” due to missed local checkpoints following a system restart. (Bug #31525)
- A node failure during a local checkpoint could lead to a subsequent failure of the cluster during a system restart. (Bug #31257)
- An interpreted program of sufficient size and complexity could cause all cluster data nodes to shut down due to buffer overruns. (Bug #29390)
- `ndb_mgm --help` did not display any information about the `-a` option. (Bug #29509)
- `NDB` tables having names containing nonalphanumeric characters (such as “`$`”) were not discovered correctly. (Bug #31470)
- A cluster restart could sometimes fail due to an issue with table IDs. (Bug #30975)
- Transaction timeouts were not handled well in some circumstances, leading to excessive number of transactions being aborted unnecessarily. (Bug #30379)
- In some cases, the cluster managment server logged entries multiple times following a restart of `ndb_mgmd`. (Bug #29565)
- The cluster log was formatted inconsistently and contained extraneous newline characters. (Bug #25064)

Changes in MySQL Cluster NDB 6.3.3 (5.1.22-ndb-6.3.3)

Functionality Added or Changed

- Mapping of `NDB` error codes to MySQL storage engine error codes has been improved. (Bug #28423)

Bugs Fixed

- **Partitioning**: `EXPLAIN PARTITIONS` reported partition usage by queries on `NDB` tables according to the standard MySQL hash function than the hash function used in the `NDB` storage engine. (Bug #29550)
- Attempting to restore a backup made on a cluster host using one endian to a machine using the other endian could cause the cluster to fail. (Bug #29674)
- Restoring a backup made on a cluster host using one endian to a machine using the other endian failed for `BLOB` and `DATETIME` columns. (Bug #27543, Bug #30024)
- The description of the `--print` option provided in the output from `ndb_restore --help` was incorrect. (Bug #27683)

Changes in MySQL Cluster NDB 6.3.2 (5.1.22-ndb-6.3.2)

Functionality Added or Changed

- A new cluster management server startup option `--bind-address` [1962] makes it possible to restrict management client connections to `ndb_mgmd` to a single host and port. For more information, see `ndb_mgmd` — The MySQL Cluster Management Server Daemon.

- It is now possible to control whether fixed-width or variable-width storage is used for a given column of an NDB table by means of the COLUMN_FORMAT specifier as part of the column's definition in a CREATE TABLE or ALTER TABLE statement.

  It is also possible to control whether a given column of an NDB table is stored in memory or on disk, using the STORAGE specifier as part of the column's definition in a CREATE TABLE or ALTER TABLE statement.

  For permitted values and other information about COLUMN_FORMAT and STORAGE, see CREATE TABLE Syntax.

- Online ADD COLUMN, ADD INDEX, and DROP INDEX operations can now be performed explicitly for NDB tables—that is, without copying or locking of the affected tables—using ALTER ONLINE TABLE. Indexes can also be created and dropped online using CREATE INDEX and DROP INDEX, respectively, using the ONLINE keyword.

  You can force operations that would otherwise be performed online to be done offline using the OFFLINE keyword.

  Renaming of tables and columns for NDB and MyISAM tables is performed in place without table copying.

  For more information, see ALTER TABLE Online Operations, CREATE INDEX Syntax, and DROP INDEX Syntax.

Bugs Fixed

- When an NDB event was left behind but the corresponding table was later recreated and received a new table ID, the event could not be dropped. (Bug #30877)

- When creating an NDB table with a column that has COLUMN_FORMAT = DYNAMIC, but the table itself uses ROW_FORMAT=FIXED, the table is considered dynamic, but any columns for which the row format is unspecified default to FIXED. Now in such cases the server issues the warning `Row format FIXED incompatible with dynamic attribute column_name`. (Bug #30276)

- An insufficiently descriptive and potentially misleading Error 4006 (`Connect failure - out of connection objects...`) was produced when either of the following two conditions occurred:

  1. There were no more transaction records in the transaction coordinator

  2. An NDB object in the NDB API was initialized with insufficient parallelism

  Separate error messages are now generated for each of these two cases. (Bug #11313)

Changes in MySQL Cluster NDB 6.3.0 (5.1.19-ndb-6.3.0)

Functionality Added or Changed

- A new configuration parameter ODirect [1833] causes NDB to attempt using O_DIRECT writes for LCP, backups, and redo logs, often lowering CPU usage.

- Reporting functionality has been significantly enhanced in this release:

  - A new configuration parameter BackupReportFrequency [1851] now makes it possible to cause the management client to provide status reports at regular intervals as well as for such reports to be written to the cluster log (depending on cluster event logging levels).

  - A new REPORT command has been added in the cluster management client. REPORT BackupStatus enables you to obtain a backup status report at any time during a backup. REPORT MemoryUsage reports the current data memory and index memory used by each data node. For more about the REPORT command, see Commands in the MySQL Cluster Management Client.

- `ndb_restore` now provides running reports of its progress when restoring a backup. In addition, a complete report status report on the backup is written to the cluster log.

Changes in the MySQL Cluster NDB 6.2 Series

This section contains unified change history highlights for all MySQL Cluster releases based on version 6.2 of the `NDBCLUSTER` storage engine through MySQL Cluster NDB 6.2.19. Included are all changelog entries in the categories *MySQL Cluster*, *Disk Data*, and *Cluster API*.

For an overview of features that were added in MySQL Cluster NDB 6.2, see MySQL Cluster Development in MySQL Cluster NDB 6.2.

- Changes in MySQL Cluster NDB 6.2.18 (5.1.34-ndb-6.2.18) [2516]
- Changes in MySQL Cluster NDB 6.2.17 (5.1.32-ndb-6.2.17) [2518]
- Changes in MySQL Cluster NDB 6.2.16 (5.1.28-ndb-6.2.16) [2523]
- Changes in MySQL Cluster NDB 6.2.14 (5.1.23-ndb-6.2.14) [2524]
- Changes in MySQL Cluster NDB 6.2.13 (5.1.23-ndb-6.2.13) [2525]
- Changes in MySQL Cluster NDB 6.2.12 (5.1.23-ndb-6.2.12) [2526]
- Changes in MySQL Cluster NDB 6.2.11 (5.1.23-ndb-6.2.11) [2526]
- Changes in MySQL Cluster NDB 6.2.10 (5.1.23-ndb-6.2.10) [2527]
- Changes in MySQL Cluster NDB 6.2.9 (5.1.22-ndb-6.2.9) [2527]
- Changes in MySQL Cluster NDB 6.2.8 (5.1.22-ndb-6.2.8) [2528]
- Changes in MySQL Cluster NDB 6.2.7 (5.1.22-ndb-6.2.7) [2528]
- Changes in MySQL Cluster NDB 6.2.6 (5.1.22-ndb-6.2.6) [2529]
- Changes in MySQL Cluster NDB 6.2.5 (5.1.22-ndb-6.2.5) [2529]
- Changes in MySQL Cluster NDB 6.2.4 (5.1.19-ndb-6.2.4) [2531]
- Changes in MySQL Cluster NDB 6.2.3 (5.1.19-ndb-6.2.3) [2531]
- Changes in MySQL Cluster NDB 6.2.2 (5.1.18-ndb-6.2.2) [2533]
- Changes in MySQL Cluster NDB 6.2.1 (5.1.18-ndb-6.2.1) [2533]
- Changes in MySQL Cluster NDB 6.2.0 (5.1.16-ndb-6.2.0) [2533]

Changes in MySQL Cluster NDB 6.2.18 (5.1.34-ndb-6.2.18)

Bugs Fixed

- **Important Change**: **Partitioning**: User-defined partitioning of an `NDBCLUSTER` table without any primary key sometimes failed, and could cause `mysqld` to crash.

  Now, if you wish to create an `NDBCLUSTER` table with user-defined partitioning, the table must have an explicit primary key, and all columns listed in the partitioning expression must be part of the primary key. The hidden primary key used by the `NDBCLUSTER` storage engine is not sufficient for this purpose. However, if the list of columns is empty (that is, the table is defined using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

  This change does not effect the partitioning of tables using any storage engine other than `NDBCLUSTER`. (Bug #40709)

- An internal NDB API buffer was not properly initialized. (Bug #44977)
- When a data node had written its GCI marker to the first page of a megabyte, and that node was later killed during restart after having processed that page (marker) but before completing a LCP, the data node could fail with file system errors. (Bug #44952)

  References: See also Bug #42564, Bug #44291.
- Inspection of the code revealed that several assignment operators (`=`) were used in place of comparison operators (`==`) in `DbdihMain.cpp`. (Bug #44567)

  References: See also Bug #44570.
- It was possible for NDB API applications to insert corrupt data into the database, which could subquently lead to data node crashes. Now, stricter checking is enforced on input data for inserts and updates. (Bug #44132)
- When trying to use a data node with an older version of the management server, the data node crashed on startup. (Bug #43699)
- In some cases, data node restarts during a system restart could fail due to insufficient redo log space. (Bug #43156)
- `TransactionDeadlockDetectionTimeout` [1841] values less than 100 were treated as 100. This could cause scans to time out unexpectedly. (Bug #44099)
- The file `ndberror.c` contained a C++-style comment, which caused builds to fail with some C compilers. (Bug #44036)
- `ndb_restore --print_data` [1997] did not handle `DECIMAL` columns correctly. (Bug #37171)
- A race condition could occur when a data node failed to restart just before being included in the next global checkpoint. This could cause other data nodes to fail. (Bug #43888)
- Some queries using combinations of logical and comparison operators on an indexed column in the `WHERE` clause could fail with the error `Got error 4541 'IndexBound has no bound information' from NDBCLUSTER`. (Bug #42857)
- Using indexes containing variable-sized columns could lead to internal errors when the indexes were being built. (Bug #43226)
- The output of `ndbd --help` did not provide clear information about the program's `--initial` and `--initial-start` options. (Bug #28905)
- It was theoretically possible for the value of a nonexistent column to be read as `NULL`, rather than causing an error. (Bug #27843)
- When aborting an operation involving both an insert and a delete, the insert and delete were aborted separately. This was because the transaction coordinator did not know that the operations affected on same row, and, in the case of a committed-read (tuple or index) scan, the abort of the insert was performed first, then the row was examined after the insert was aborted but before the delete was aborted. In some cases, this would leave the row in a inconsistent state. This could occur when a local checkpoint was performed during a backup. This issue did not affect primary ley operations or scans that used locks (these are serialized).

  After this fix, for ordered indexes, all operations that follow the operation to be aborted are now also aborted.
- **Disk Data**: **Partitioning**: An `NDB` table created with a very large value for the `MAX_ROWS` option could—if this table was dropped and a new table with fewer partitions, but having the same table ID, was created—cause `ndbd` to crash when performing a system restart. This was because the server attempted to examine each partition whether or not it actually existed. (Bug #45154)

References: See also Bug #58638.

- **Disk Data**: During a checkpoint, restore points are created for both the on-disk and in-memory parts of a Disk Data table. Under certain rare conditions, the in-memory restore point could include or exclude a row that should have been in the snapshot. This would later lead to a crash during or following recovery. (Bug #41915)

  References: See also Bug #47832.

- **Disk Data**: When a log file group had an undo log file whose size was too small, restarting data nodes failed with `Read underflow` errors.

  As a result of this fix, the minimum permitted `INTIAL_SIZE` for an undo log file is now `1M` (1 megabyte). (Bug #29574)

- **Disk Data**: This fix supercedes and improves on an earlier fix made for this bug in MySQL 5.1.18. (Bug #24521)

- **Cluster API**: If the largest offset of a `RecordSpecification` used for an `NdbRecord` object was for the `NULL` bits (and thus not a column), this offset was not taken into account when calculating the size used for the `RecordSpecification`. This meant that the space for the `NULL` bits could be overwritten by key or other information. (Bug #43891)

- **Cluster API**: Ordered index scans using `NdbRecord` formerly expressed a `BoundEQ` range as separate lower and upper bounds, resulting in 2 copies of the column values being sent to the NDB kernel.

  Now, when a range is specified by `NdbScanOperation::setBound()`, the passed pointers, key lengths, and inclusive bits are compared, and only one copy of the equal key columns is sent to the kernel. This makes such operations more efficient, as half the amount of `KeyInfo` is now sent for a `BoundEQ` range as before. (Bug #38793)

- **Cluster API**: When performing insert or write operations, `NdbRecord` permits key columns to be specified in both the key record and in the attribute record. Only one key column value for each key column should be sent to the NDB kernel, but this was not guaranteed. This is now ensured as follows: For insert and write operations, key column values are taken from the key record; for scan takeover update operations, key column values are taken from the attribute record. (Bug #42238)

- **Cluster API**: The default `NdbRecord` structures created by `NdbDictionary` could have overlapping null bits and data fields. (Bug #43590)

Changes in MySQL Cluster NDB 6.2.17 (5.1.32-ndb-6.2.17)

Functionality Added or Changed

- **Important Change**: Formerly, when the management server failed to create a transporter for a data node connection, `net_write_timeout` [506] seconds elapsed before the data node was actually permitted to disconnect. Now in such cases the disconnection occurs immediately. (Bug #41965)

  References: See also Bug #41713.

- **Disk Data**: It is now possible to specify default locations for Disk Data data files and undo log files, either together or separately, using the data node configuration parameters `FileSystemPathDD` [1857], `FileSystemPathDataFiles` [1858], and `FileSystemPathUndoFiles` [1858]. For information about these configuration parameters, see *Disk Data file system parameters*.

  It is also now possible to specify a log file group, tablespace, or both, that is created when the cluster is started, using the `InitialLogFileGroup` [1859] and `InitialTablespace` [1859] data node configuration parameters. For information about these configuration parameters, see *Disk Data object creation parameters*.

Bugs Fixed

- **Performance**: Updates of the `SYSTAB_0` system table to obtain a unique identifier did not use transaction hints for tables having no primary key. In such cases the NDB kernel used a cache size of 1. This meant that each insert into a table not having a primary key required an update of the corresponding `SYSTAB_0` entry, creating a potential performance bottleneck.

  With this fix, inserts on `NDB` tables without primary keys can be under some conditions be performed up to 100% faster than previously. (Bug #39268)

- **Packaging**: Packages for MySQL Cluster were missing the `libndbclient.so` and `libndbclient.a` files. (Bug #42278)

- **Partitioning**: Executing `ALTER TABLE ... REORGANIZE PARTITION` on an `NDBCLUSTER` table having only one partition caused `mysqld` to crash. (Bug #41945)

  References: See also Bug #40389.

- **Cluster API**: Failed operations on `BLOB` and `TEXT` columns were not always reported correctly to the originating SQL node. Such errors were sometimes reported as being due to timeouts, when the actual problem was a transporter overload due to insufficient buffer space. (Bug #39867, Bug #39879)

- **Cluster API**: Failed operations on `BLOB` and `TEXT` columns were not always reported correctly to the originating SQL node. Such errors were sometimes reported as being due to timeouts, when the actual problem was a transporter overload due to insufficient buffer space. (Bug #39867, Bug #39879)

- In some cases, `NDB` did not check correctly whether tables had changed before trying to use the query cache. This could result in a crash of the debug MySQL server. (Bug #40464)

- Trying to execute an `ALTER ONLINE TABLE ... ADD COLUMN` statement while inserting rows into the table caused `mysqld` to crash. (Bug #41905)

- When using `ndbmtd`, NDB kernel threads could hang while trying to start the data nodes with `LockPagesInMainMemory` [1832] set to 1. (Bug #43021)

- Backup IDs greater than 2^{31} were not handled correctly, causing negative values to be used in backup directory names and printouts. (Bug #43042)

- Given a MySQL Cluster containing no data (that is, whose data nodes had all been started using `--initial`, and into which no data had yet been imported) and having an empty backup directory, executing `START BACKUP` with a user-specified backup ID caused the data nodes to crash. (Bug #41031)

- When using multiple management servers and starting several API nodes (possibly including one or more SQL nodes) whose connectstrings listed the management servers in different order, it was possible for 2 API nodes to be assigned the same node ID. When this happened it was possible for an API node not to get fully connected, consequently producing a number of errors whose cause was not easily recognizable. (Bug #42973)

- Triggers on `NDBCLUSTER` tables caused such tables to become locked. (Bug #42751)

  References: See also Bug #16229, Bug #18135.

- `ndb_error_reporter` worked correctly only with GNU `tar`. (With other versions of `tar`, it produced empty archives.) (Bug #42753)

- API nodes disconnected too agressively from cluster when data nodes were being restarted. This could sometimes lead to the API node being unable to access the cluster at all during a rolling restart. (Bug #41462)

- When performing more than 32 index or tuple scans on a single fragment, the scans could be left hanging. This caused unnecessary timeouts, and in addition could possibly lead to a hang of an LCP. (Bug #42559)

  References: This bug is a regression of Bug #42084.

- A data node failure that occurred between calls to `NdbIndexScanOperation::readTuples(SF_OrderBy)` and `NdbTransaction::execute()` was not correctly handled; a subsequent call to `nextResult()` caused a null pointer to be deferenced, leading to a segfault in `mysqld`. (Bug #42545)

- Issuing `SHOW GLOBAL STATUS LIKE 'NDB%'` before `mysqld` had connected to the cluster caused a segmentation fault. (Bug #42458)

- Data node failures that occurred before all data nodes had connected to the cluster were not handled correctly, leading to additional data node failures. (Bug #42422)

- When a cluster backup failed with Error 1304 (Node *`node_id1`*: Backup request from *`node_id2`* failed to start), no clear reason for the failure was provided.

  As part of this fix, MySQL Cluster now retries backups in the event of sequence errors. (Bug #42354)

  References: See also Bug #22698.

- Issuing `SHOW ENGINE NDBCLUSTER STATUS` on an SQL node before the management server had connected to the cluster caused `mysqld` to crash. (Bug #42264)

- A maximum of 11 `TUP` scans were permitted in parallel. (Bug #42084)

- Issuing `EXIT` in the management client sometimes caused the client to hang. (Bug #40922)

- If the master node failed during a global checkpoint, it was possible in some circumstances for the new master to use an incorrect value for the global checkpoint index. This could occur only when the cluster used more than one node group. (Bug #41469)

- Start phase reporting was inconsistent between the management client and the cluster log. (Bug #39667)

- An abort path in the `DBLQH` kernel block failed to release a commit acknowledgment marker. This meant that, during node failure handling, the local query handler could be added multiple times to the marker record which could lead to additional node failures due an array overflow. (Bug #41296)

- During node failure handling (of a data node other than the master), there was a chance that the master was waiting for a `GCP_NODEFINISHED` signal from the failed node after having received it from all other data nodes. If this occurred while the failed node had a transaction that was still being committed in the current epoch, the master node could crash in the `DBTC` kernel block when discovering that a transaction actually belonged to an epoch which was already completed. (Bug #41295)

- If a transaction was aborted during the handling of a data node failure, this could lead to the later handling of an API node failure not being completed. (Bug #41214)

- Memory leaks could occur in handling of strings used for storing cluster metadata and providing output to users. (Bug #38662)

- A segfault in `Logger::Log` caused `ndbd` to hang indefinitely. This fix improves on an earlier one for this issue, first made in MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.17. (Bug #39180)

  References: See also Bug #38609.

- Redo log creation was very slow on some platforms, causing MySQL Cluster to start more slowly than necessary with some combinations of hardware and operating system. This was due to all write

operations being synchronized to disk while creating a redo log file. Now this synchronization occurs only after the redo log has been created. (Bug #40734)

- Transaction failures took longer to handle than was necessary.

  When a data node acting as transaction coordinator (TC) failed, the surviving data nodes did not inform the API node initiating the transaction of this until the failure had been processed by all protocols. However, the API node needed only to know about failure handling by the transaction protocol—that is, it needed to be informed only about the TC takeover process. Now, API nodes (including MySQL servers acting as cluster SQL nodes) are informed as soon as the TC takeover is complete, so that it can carry on operating more quickly. (Bug #40697)

- Events logged after setting `ALL CLUSTERLOG STATISTICS=15` in the management client did not always include the node ID of the reporting node. (Bug #39839)

- It was theoretically possible for stale data to be read from `NDBCLUSTER` tables when the transaction isolation level was set to `ReadCommitted`. (Bug #40543)

- Restoring a MySQL Cluster from a dump made using `mysqldump` failed due to a spurious error: `Can't execute the given command because you have active locked tables or an active transaction`. (Bug #40346)

- `O_DIRECT` was incorrectly disabled when making MySQL Cluster backups. (Bug #40205)

- The MySQL Query Cache did not function correctly with `NDBCLUSTER` tables containing `TEXT` columns. (Bug #39295)

- In the event that a MySQL Cluster backup failed due to file permissions issues, conflicting reports were issued in the management client. (Bug #34526)

- A duplicate key or other error raised when inserting into an `NDBCLUSTER` table caused the current transaction to abort, after which any SQL statement other than a `ROLLBACK` failed. With this fix, the `NDBCLUSTER` storage engine now performs an implicit rollback when a transaction is aborted in this way; it is no longer necessary to issue an explicit `ROLLBACK` statement, and the next statement that is issued automatically begins a new transaction.

  Note

  It remains necessary in such cases to retry the complete transaction, regardless of which statement caused it to be aborted.

  (Bug #32656)

  References: See also Bug #47654.

- Error messages for `NDBCLUSTER` error codes 1224 and 1227 were missing. (Bug #28496)

- **Disk Data**: Creating a Disk Data tablespace with a very large extent size caused the data nodes to fail. The issue was observed when using extent sizes of 100 MB and larger. (Bug #39096)

- **Disk Data**: It was not possible to add an in-memory column online to a table that used a table-level or column-level `STORAGE DISK` option. The same issue prevented `ALTER ONLINE TABLE ... REORGANIZE PARTITION` from working on Disk Data tables. (Bug #42549)

- **Disk Data**: Creation of a tablespace data file whose size was greater than 4 GB failed silently on 32-bit platforms. (Bug #37116)

  References: See also Bug #29186.

- **Disk Data**: Issuing concurrent `CREATE TABLESPACE`, `ALTER TABLESPACE`, `CREATE LOGFILE GROUP`, or `ALTER LOGFILE GROUP` statements on separate SQL nodes caused a resource leak that led to data node crashes when these statements were used again later. (Bug #40921)

- **Disk Data**: Disk-based variable-length columns were not always handled like their memory-based equivalents, which could potentially lead to a crash of cluster data nodes. (Bug #39645)

- **Disk Data**: Using a path or file name longer than 128 characters for Disk Data undo log files and tablespace data files caused a number of issues, including failures of `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, and `ALTER TABLESPACE` statements, as well as crashes of management nodes and data nodes.

  With this fix, the maximum length for path and file names used for Disk Data undo log files and tablespace data files is now the same as the maximum for the operating system. (Bug #31769, Bug #31770, Bug #31772)

- **Disk Data**: Trying to execute a `CREATE LOGFILE GROUP` statement using a value greater than `150M` for `UNDO_BUFFER_SIZE` caused data nodes to crash.

  As a result of this fix, the upper limit for `UNDO_BUFFER_SIZE` is now `600M`; attempting to set a higher value now fails gracefully with an error. (Bug #34102)

  References: See also Bug #36702.

- **Disk Data**: When attempting to create a tablespace that already existed, the error message returned was `Table or index with given name already exists`. (Bug #32662)

- **Disk Data**: `O_SYNC` was incorrectly disabled on platforms that do not support `O_DIRECT`. This issue was noted on Solaris but could have affected other platforms not having `O_DIRECT` capability. (Bug #34638)

- **Disk Data**: Starting a cluster under load such that Disk Data tables used most of the undo buffer could cause data node failures.

  The fix for this bug also corrected an issue in the `LGMAN` kernel block where the amount of free space left in the undo buffer was miscalculated, causing buffer overruns. This could cause records in the buffer to be overwritten, leading to problems when restarting data nodes. (Bug #28077)

- **Disk Data**: Attempting to perform a system restart of the cluster where there existed a logfile group without and undo log files caused the data nodes to crash.

  Note

  While issuing a `CREATE LOGFILE GROUP` statement without an `ADD UNDOFILE` option fails with an error in the MySQL server, this situation could arise if an SQL node failed during the execution of a valid `CREATE LOGFILE GROUP` statement; it is also possible to create a logfile group without any undo log files using the NDB API.

  (Bug #17614)

- **Cluster API**: Some error messages from `ndb_mgmd` contained newline (`\n`) characters. This could break the MGM API protocol, which uses the newline as a line separator. (Bug #43104)

- **Cluster API**: When using an ordered index scan without putting all key columns in the read mask, this invalid use of the NDB API went undetected, which resulted in the use of uninitialized memory. (Bug #42591)

- **Cluster API**: It was not always possible to access parent objects directly from `NdbBlob`, `NdbOperation`, and `NdbScanOperation` objects. To alleviate this problem, a new `getNdbOperation()` method has been added to `NdbBlob` and new getNdbTransaction() methods have been added to `NdbOperation` and `NdbScanOperation`. In addition, a const variant of `NdbOperation::getErrorLine()` is now also available. (Bug #40242)

- **Cluster API**: `NdbScanOperation::getBlobHandle()` failed when used with incorrect column names or numbers. (Bug #40241)

- **Cluster API**: The MGM API reset error codes on management server handles before checking them. This meant that calling an MGM API function with a null handle caused applications to crash. (Bug #40455)

- **Cluster API**: The NDB API example programs included in MySQL Cluster source distributions failed to compile. (Bug #37491)

  References: See also Bug #40238.

- **Cluster API**: `mgmapi.h` contained constructs which only worked in C++, but not in C. (Bug #27004)

Changes in MySQL Cluster NDB 6.2.16 (5.1.28-ndb-6.2.16)

Functionality Added or Changed

- It is no longer a requirement for database autodiscovery that an SQL node already be connected to the cluster at the time that a database is created on another SQL node. It is no longer necessary to issue `CREATE DATABASE` (or `CREATE SCHEMA`) statements on an SQL node joining the cluster after a database is created for the new SQL node to see the database and any `NDBCLUSTER` tables that it contains. (Bug #39612)

Bugs Fixed

- After a forced shutdown and initial restart of the cluster, it was possible for SQL nodes to retain `.frm` files corresponding to `NDBCLUSTER` tables that had been dropped, and thus to be unaware that these tables no longer existed. In such cases, attempting to re-create the tables using `CREATE TABLE IF NOT EXISTS` could fail with a spurious `Table ... doesn't exist` error. (Bug #37921)

- When restarting a data node, an excessively long shutdown message could cause the node process to crash. (Bug #38580)

- Starting the MySQL Server with the `--ndbcluster` [1915] option plus an invalid command-line option (for example, using `mysqld --ndbcluster --foobar`) caused it to hang while shutting down the binlog thread. (Bug #39635)

- Heavy DDL usage caused the `mysqld` processes to hang due to a timeout error (`NDB` error code 266). (Bug #39885)

- Executing `EXPLAIN SELECT` on an `NDBCLUSTER` table could cause `mysqld` to crash. (Bug #39872)

- Dropping and then re-creating a database on one SQL node caused other SQL nodes to hang. (Bug #39613)

- Unique identifiers in tables having no primary key were not cached. This fix has been observed to increase the efficiency of `INSERT` operations on such tables by as much as 50%. (Bug #39267)

- Setting a low value of `MaxNoOfLocalScans` [1824] (< 100) and performing a large number of (certain) scans could cause the Transaction Coordinator to run out of scan fragment records, and then crash. Now when this resource is exhausted, the cluster returns Error 291 (`Out of scanfrag records in TC (increase MaxNoOfLocalScans)`) instead. (Bug #39549)

- Creating a unique index on an `NDBCLUSTER` table caused a memory leak in the `NDB` subscription manager (`SUMA`) which could lead to mysqld hanging, due to the fact that the resource shortage was not reported back to the `NDB` kernel correctly. (Bug #39518)

  References: See also Bug #39450.

- `MgmtSrvr::allocNodeId()` left a mutex locked following an `Ambiguity for node if %d` error. (Bug #39158)

- An invalid path specification caused `mysql-test-run.pl` to fail. (Bug #39026)

- During transactional coordinator takeover (directly after node failure), the LQH finding an operation in the LOG_COMMIT state sent an LQH_TRANS_CONF signal twice, causing the TC to fail. (Bug #38930)
- An invalid memory access caused the management server to crash on Solaris Sparc platforms. (Bug #38628)
- A segfault in Logger::Log caused ndbd to hang indefinitely. (Bug #38609)
- ndb_mgmd failed to start on older Linux distributions (2.4 kernels) that did not support e-polling. (Bug #38592)
- ndb_mgmd sometimes performed unnecessary network I/O with the client. This in combination with other factors led to long-running threads that were attempting to write to clients that no longer existed. (Bug #38563)
- ndb_restore failed with a floating point exception due to a division by zero error when trying to restore certain data files. (Bug #38520)
- A failed connection to the management server could cause a resource leak in ndb_mgmd. (Bug #38424)
- Failure to parse configuration parameters could cause a memory leak in the NDB log parser. (Bug #38380)
- Renaming an NDBCLUSTER table on one SQL node, caused a trigger on this table to be deleted on another SQL node. (Bug #36658)
- Attempting to add a UNIQUE INDEX twice to an NDBCLUSTER table, then deleting rows from the table could cause the MySQL Server to crash. (Bug #35599)
- ndb_restore failed when a single table was specified. (Bug #33801)
- GCP_COMMIT did not wait for transaction takeover during node failure. This could cause GCP_SAVE_REQ to be executed too early. This could also cause (very rarely) replication to skip rows. (Bug #30780)
- **Cluster API**: Certain Multi-Range Read scans involving IS NULL and IS NOT NULL comparisons failed with an error in the NDB local query handler. (Bug #38204)
- **Cluster API**: Creating an NdbScanFilter object using an NdbScanOperation object that had not yet had its readTuples() method called resulted in a crash when later attempting to use the NdbScanFilter. (Bug #37986)
- **Cluster API**: Executing an NdbRecord interpreted delete created with an ANYVALUE option caused the transaction to abort. (Bug #37672)
- **Cluster API**: Passing a value greater than 65535 to NdbInterpretedCode::add_val() and NdbInterpretedCode::sub_val() caused these methods to have no effect. (Bug #39536)
- **Cluster API**: The NdbScanOperation::readTuples() method could be called multiple times without error. (Bug #38717)
- **Cluster API**: Problems with the public headers prevented NDB applications from being built with warnings turned on. (Bug #38177)
- **Cluster API**: Accessing the debug version of libndbclient using dlopen() resulted in a segmentation fault. (Bug #35927)

Changes in MySQL Cluster NDB 6.2.14 (5.1.23-ndb-6.2.14)

Functionality Added or Changed

- Added the MaxBufferedEpochs [1840] data node configuration parameter, which controls the maximum number of unprocessed epochs by which a subscribing node can lag. Subscribers which exceed this number are disconnected and forced to reconnect.

See Defining MySQL Cluster Data Nodes, for more information.

Bugs Fixed

- **Incompatible Change**: The `UPDATE` statement permitted `NULL` to be assigned to `NOT NULL` columns (the implicit default value for the column data type was assigned). This was changed so that on error occurs.

  This change was reverted, because the original report was determined not to be a bug: Assigning `NULL` to a `NOT NULL` column in an `UPDATE` statement should produce an error only in strict SQL mode and set the column to the implicit default with a warning otherwise, which was the original behavior. See Data Type Default Values, and Bug #39265. (Bug #33699)

- **Incompatible Change**: Previously, the parser accepted the ODBC `{ OJ ... LEFT OUTER JOIN ...}` syntax for writing left outer joins. The parser now permits `{ OJ ... }` to be used to write other types of joins, such as `INNER JOIN` or `RIGHT OUTER JOIN`. This helps with compatibility with some third-party applications, but is not official ODBC syntax.

  A consequence of this change is that the parser no longer permits nested `{ OJ ... }` constructs (which are not legal ODBC syntax, anyway). Queries that use such constructs should be rewritten. For example, this query is now produces an error:

```
SELECT * FROM
   {OJ
      {OJ a LEFT OUTER JOIN b ON a.a1=b.a1}
      LEFT OUTER JOIN c ON b.b1 = c.b1};
```

  That can be replaced by any of the following rewrites:

```
SELECT * FROM
    {OJ a LEFT OUTER JOIN b
          LEFT OUTER JOIN c ON b.b1 = c.b1 ON a.a1=b.a1};

SELECT * FROM
   {OJ a LEFT OUTER JOIN b ON a.a1=b.a1
         LEFT OUTER JOIN c ON b.b1 = c.b1};

SELECT * FROM
     a LEFT OUTER JOIN b ON a.a1=b.a1 LEFT OUTER JOIN c ON b.b1 = c.b1;
```

  The first two are legal according to ODBC, and you nest the joins inside a single `{ OJ ...}` clause. The third is standard SQL syntax, without ODBC decoration. It can be used with parentheses to emphasize the evaluation order:

```
SELECT * FROM
     ((a LEFT OUTER JOIN b ON a.a1=b.a1)
         LEFT OUTER JOIN c ON b.b1 = c.b1);
```

  (Bug #28317)

- **Cluster API**: Closing a scan before it was executed caused the application to segfault. (Bug #36375)

- **Cluster API**: Scans having no bounds set were handled incorrectly. (Bug #35876)

- **Cluster API**: Using NDB API applications from older MySQL Cluster versions with `libndbclient` from newer ones caused the cluster to fail. (Bug #36124)

Changes in MySQL Cluster NDB 6.2.13 (5.1.23-ndb-6.2.13)

Bugs Fixed

- A node failure during an initial node restart followed by another node start could cause the master data node to fail, because it incorrectly gave the node permission to start even if the invalidated node's LCP was still running. (Bug #34702)

Changes in MySQL Cluster NDB 6.2.12 (5.1.23-ndb-6.2.12)

Bugs Fixed

- When configured with NDB support, MySQL failed to compile using gcc 4.3 on 64bit FreeBSD systems. (Bug #34169)
- Upgrades of a cluster using while a DataMemory [1817] setting in excess of 16 GB caused data nodes to fail. (Bug #34378)
- Performing many SQL statements on NDB tables while in autocommit [461] mode caused a memory leak in mysqld. (Bug #34275)
- In certain rare circumstances, a race condition could occur between an aborted insert and a delete leading a data node crash. (Bug #34260)
- Multi-table updates using ordered indexes during handling of node failures could cause other data nodes to fail. (Bug #34216)
- The failure of a DDL statement could sometimes lead to node failures when attempting to execute subsequent DDL statements. (Bug #34160)
- Extremely long SELECT statements (where the text of the statement was in excess of 50000 characters) against NDB tables returned empty results. (Bug #34107)
- Statements executing multiple inserts performed poorly on NDB tables having AUTO_INCREMENT columns. (Bug #33534)
- The ndb_waiter utility polled ndb_mgmd excessively when obtaining the status of cluster data nodes. (Bug #32025)

  References: See also Bug #32023.
- Transaction atomicity was sometimes not preserved between reads and inserts under high loads. (Bug #31477)
- Having tables with a great many columns could cause Cluster backups to fail. (Bug #30172)
- **Cluster Replication**: **Disk Data**: Statements violating unique keys on Disk Data tables (such as attempting to insert NULL into a NOT NULL column) could cause data nodes to fail. When the statement was executed from the binlog, this could also result in failure of the slave cluster. (Bug #34118)
- **Disk Data**: Updating in-memory columns of one or more rows of Disk Data table, followed by deletion of these rows and re-insertion of them, caused data node failures. (Bug #33619)

Changes in MySQL Cluster NDB 6.2.11 (5.1.23-ndb-6.2.11)

Functionality Added or Changed

- **Cluster API**: **Important Change**: Because NDB_LE_MemoryUsage.page_size_kb shows memory page sizes in bytes rather than kilobytes, it has been renamed to page_size_bytes. The name page_size_kb is now deprecated and thus subject to removal in a future release, although it currently remains supported for reasons of backward compatibility. See The Ndb_logevent_type Type, for more information about NDB_LE_MemoryUsage. (Bug #30271)

Bugs Fixed

- Some tuple scans caused the wrong memory page to be accessed, leading to invalid results. This issue could affect both in-memory and Disk Data tables. (Bug #33739)
- Issuing an INSERT ... ON DUPLICATE KEY UPDATE concurrently with or following a TRUNCATE TABLE statement on an NDB table failed with NDB error 4350 Transaction already aborted. (Bug #29851)

- The server failed to reject properly the creation of an `NDB` table having an unindexed `AUTO_INCREMENT` column. (Bug #30417)
- A race condition could occur (very rarely) when the release of a GCI was followed by a data node failure. (Bug #33793)
- A periodic failure to flush the send buffer by the `NDB` TCP transporter could cause a unnecessary delay of 10 ms between operations. (Bug #34005)
- High numbers of insert operations, delete operations, or both could cause `NDB` error 899 (`Rowid already allocated`) to occur unnecessarily. (Bug #34033)
- It was possible in `config.ini` to define cluster nodes having node IDs greater than the maximum permitted value. (Bug #28298)
- The Cluster backup process could not detect when there was no more disk space and instead continued to run until killed manually. Now the backup fails with an appropriate error when disk space is exhausted. (Bug #28647)
- **Cluster API**: When reading a `BIT(64)` value using `NdbOperation:getValue()`, 12 bytes were written to the buffer rather than the expected 8 bytes. (Bug #33750)
- **Cluster API**: Transactions containing inserts or reads would hang during `NdbTransaction::execute()` calls made from NDB API applications built against a MySQL Cluster version that did not support micro-GCPs accessing a later version that supported micro-GCPs. This issue was observed while upgrading from MySQL Cluster NDB 6.1.23 to MySQL Cluster NDB 6.2.10 when the API application built against the earlier version attempted to access a data node already running the later version, even after disabling micro-GCPs by setting `TimeBetweenEpochs` [1840] equal to 0. (Bug #33895)

Changes in MySQL Cluster NDB 6.2.10 (5.1.23-ndb-6.2.10)

Bugs Fixed

- **Partitioning**: When partition pruning on an `NDB` table resulted in an ordered index scan spanning only one partition, any descending flag for the scan was wrongly discarded, causing `ORDER BY DESC` to be treated as `ORDER BY ASC`, `MAX()` to be handled incorrectly, and similar problems. (Bug #33061)
- When all data and SQL nodes in the cluster were shut down abnormally (that is, other than by using `STOP` in the cluster management client), `ndb_mgm` used excessive amounts of CPU. (Bug #33237)
- When using micro-GCPs, if a node failed while preparing for a global checkpoint, the master node would use the wrong GCI. (Bug #32922)
- Under some conditions, performing an `ALTER TABLE` on an `NDBCLUSTER` table failed with a `Table is full` error, even when only 25% of `DataMemory` [1817] was in use and the result should have been a table using less memory (for example, changing a `VARCHAR(100)` column to `VARCHAR(80)`). (Bug #32670)

Changes in MySQL Cluster NDB 6.2.9 (5.1.22-ndb-6.2.9)

Functionality Added or Changed

- Added the `ndb_mgm` client command `DUMP 8011`, which dumps all subscribers to the cluster log. See `DUMP 8011`, for more information.

Bugs Fixed

- The failure of a master node could lead to subsequent failures in local checkpointing. (Bug #32160)
- High numbers of API nodes on a slow or congested network could cause connection negotiation to time out prematurely, leading to the following issues:

- Excessive retries
- Excessive CPU usage
- Partially connected API nodes

(Bug #32359)

- A local checkpoint could sometimes be started before the previous LCP was restorable from a global checkpoint. (Bug #32519)
- Adding a new `TINYTEXT` column to an `NDB` table which used `COLUMN_FORMAT = DYNAMIC`, and when binary logging was enabled, caused all cluster `mysqld` processes to crash. (Bug #30213)
- After adding a new column of one of the `TEXT` or `BLOB` types to an `NDB` table which used `COLUMN_FORMAT = DYNAMIC`, it was no longer possible to access or drop the table using SQL. (Bug #30205)
- A restart of the cluster failed when more than 1 REDO phase was in use. (Bug #22696)

Changes in MySQL Cluster NDB 6.2.8 (5.1.22-ndb-6.2.8)

Functionality Added or Changed

- The output of the `ndb_mgm` client `SHOW` and `STATUS` commands now indicates when the cluster is in single user mode. (Bug #27999)

Bugs Fixed

- The `NDB` management client command *`node_id`* `REPORT MEMORY` provided no output when *`node_id`* was the node ID of a management or API node. Now, when this occurs, the management client responds with `Node` *`node_id`*`: is not a data node`. (Bug #29485)
- In a cluster running in diskless mode and with arbitration disabled, the failure of a data node during an insert operation caused other data node to fail. (Bug #31980)
- Following an upgrade, `ndb_mgmd` would fail with an *`ArbitrationError`*. (Bug #31690)
- The `NDB` storage engine code was not safe for strict-alias optimization in `gcc` 4.2.1. (Bug #31761)
- An error with an `if` statement in `sql/ha_ndbcluster.cc` could potentially lead to an infinite loop in case of failure when working with `AUTO_INCREMENT` columns in `NDB` tables. (Bug #31810)
- An insert or update with combined range and equality constraints failed when run against an `NDB` table with the error `Got unknown error from NDB`. An example of such a statement would be `UPDATE t1 SET b = 5 WHERE a IN (7,8) OR a >= 10;`. (Bug #31874)
- Performing `DELETE` operations after a data node had been shut down could lead to inconsistent data following a restart of the node. (Bug #26450)
- `UPDATE IGNORE` could sometimes fail on `NDB` tables due to the use of unitialized data when checking for duplicate keys to be ignored. (Bug #25817)

Changes in MySQL Cluster NDB 6.2.7 (5.1.22-ndb-6.2.7)

Bugs Fixed

- It was possible in some cases for a node group to be “lost” due to missed local checkpoints following a system restart. (Bug #31525)
- A node failure during a local checkpoint could lead to a subsequent failure of the cluster during a system restart. (Bug #31257)

- `ndb_mgm --help` did not display any information about the `-a` option. (Bug #29509)
- `NDB` tables having names containing nonalphanumeric characters (such as "`$`") were not discovered correctly. (Bug #31470)
- A cluster restart could sometimes fail due to an issue with table IDs. (Bug #30975)
- Transaction timeouts were not handled well in some circumstances, leading to excessive number of transactions being aborted unnecessarily. (Bug #30379)
- In some cases, the cluster managment server logged entries multiple times following a restart of `ndb_mgmd`. (Bug #29565)
- The cluster log was formatted inconsistently and contained extraneous newline characters. (Bug #25064)

Changes in MySQL Cluster NDB 6.2.6 (5.1.22-ndb-6.2.6)

Functionality Added or Changed

- Mapping of `NDB` error codes to MySQL storage engine error codes has been improved. (Bug #28423)

Bugs Fixed

- **Partitioning**: `EXPLAIN PARTITIONS` reported partition usage by queries on `NDB` tables according to the standard MySQL hash function than the hash function used in the `NDB` storage engine. (Bug #29550)
- When an `NDB` event was left behind but the corresponding table was later recreated and received a new table ID, the event could not be dropped. (Bug #30877)
- Attempting to restore a backup made on a cluster host using one endian to a machine using the other endian could cause the cluster to fail. (Bug #29674)
- Restoring a backup made on a cluster host using one endian to a machine using the other endian failed for `BLOB` and `DATETIME` columns. (Bug #27543, Bug #30024)
- The description of the `--print` option provided in the output from `ndb_restore --help` was incorrect. (Bug #27683)
- An insufficiently descriptive and potentially misleading Error 4006 (`Connect failure - out of connection objects...`) was produced when either of the following two conditions occurred:

  1. There were no more transaction records in the transaction coordinator
  2. An `NDB` object in the NDB API was initialized with insufficient parallelism

  Separate error messages are now generated for each of these two cases. (Bug #11313)

Changes in MySQL Cluster NDB 6.2.5 (5.1.22-ndb-6.2.5)

Functionality Added or Changed

- The following improvements have been made in the `ndb_size.pl` utility:
  - The script can now be used with multiple databases; lists of databases and tables can also be excluded from analysis.
  - Schema name information has been added to index table calculations.
  - The database name is now an optional parameter, the exclusion of which causes all databases to be examined.
  - If selecting from `INFORMATION_SCHEMA` fails, the script now attempts to fall back to `SHOW TABLES`.

- A `--real_table_name` option has been added; this designates a table to handle unique index size calculations.
- The report title has been amended to cover cases where more than one database is being analyzed.

Support for a `--socket` option was also added.

For more information, see `ndb_size.pl` — NDBCLUSTER Size Requirement Estimator. (Bug #28683, Bug #28253)

- A new cluster management server startup option `--bind-address` [1962] makes it possible to restrict management client connections to `ndb_mgmd` to a single host and port. For more information, see `ndb_mgmd` — The MySQL Cluster Management Server Daemon.
- It is now possible to control whether fixed-width or variable-width storage is used for a given column of an `NDB` table by means of the `COLUMN_FORMAT` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

  It is also possible to control whether a given column of an `NDB` table is stored in memory or on disk, using the `STORAGE` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

  For permitted values and other information about `COLUMN_FORMAT` and `STORAGE`, see `CREATE TABLE` Syntax.
- Online `ADD COLUMN`, `ADD INDEX`, and `DROP INDEX` operations can now be performed explicitly for `NDB` tables—that is, without copying or locking of the affected tables—using `ALTER ONLINE TABLE`. Indexes can also be created and dropped online using `CREATE INDEX` and `DROP INDEX`, respectively, using the `ONLINE` keyword.

  You can force operations that would otherwise be performed online to be done offline using the `OFFLINE` keyword.

  Renaming of tables and columns for `NDB` and `MyISAM` tables is performed in place without table copying.

  For more information, see `ALTER TABLE` Online Operations, `CREATE INDEX` Syntax, and `DROP INDEX` Syntax.

Bugs Fixed

- Reads on `BLOB` columns were not locked when they needed to be to guarantee consistency. (Bug #29102)

  References: See also Bug #31482.
- Using the `--ndb-cluster-connection-pool` option for `mysqld` caused DDL statements to be executed twice. (Bug #30598)
- A query using joins between several large tables and requiring unique index lookups failed to complete, eventually returning `Unknown Error` after a very long period of time. This occurred due to inadequate handling of instances where the Transaction Coordinator ran out of `TransactionBufferMemory` [1823], when the cluster should have returned NDB error code 4012 (`Request ndbd time-out`). (Bug #28804)
- When handling `BLOB` columns, the addition of read locks to the lock queue was not handled correctly. (Bug #30764)
- Discovery of `NDB` tables did not work correctly with `INFORMATION_SCHEMA`. (Bug #30667)
- A file system close operation could fail during a node or system restart. (Bug #30646)

- `ndb_size.pl` failed on tables with `FLOAT` columns whose definitions included commas (for example, `FLOAT(6,2)`). (Bug #29228)

- When creating an `NDB` table with a column that has `COLUMN_FORMAT = DYNAMIC`, but the table itself uses `ROW_FORMAT=FIXED`, the table is considered dynamic, but any columns for which the row format is unspecified default to `FIXED`. Now in such cases the server issues the warning `Row format FIXED incompatible with dynamic attribute column_name`. (Bug #30276)

- An attempt to perform a `SELECT ... FROM INFORMATION_SCHEMA.TABLES` whose result included information about `NDB` tables for which the user had no privileges crashed the MySQL Server on which the query was performed. (Bug #26793)

- **Cluster API**: A call to `CHECK_TIMEDOUT_RET()` in `mgmapi.cpp` should have been a call to `DBUG_CHECK_TIMEDOUT_RET()`. (Bug #30681)

Changes in MySQL Cluster NDB 6.2.4 (5.1.19-ndb-6.2.4)

Bugs Fixed

- Replica redo logs were inconsistently handled during a system restart. (Bug #29354)

- When restarting a data node, queries could hang during that node's start phase 5, and continue only after the node had entered phase 6. (Bug #29364)

- **Disk Data**: Disk data meta-information that existed in `ndbd` might not be visible to `mysqld`. (Bug #28720)

- **Disk Data**: Performing Disk Data schema operations during a node restart could cause forced shutdowns of other data nodes. (Bug #29501)

- **Disk Data**: The number of free extents was incorrectly reported for some tablespaces. (Bug #28642)

Changes in MySQL Cluster NDB 6.2.3 (5.1.19-ndb-6.2.3)

Functionality Added or Changed

- **Important Change**: The `TimeBetweenWatchdogCheckInitial` [1835] configuration parameter was added to enable setting of a separate watchdog timeout for memory allocation during startup of the data nodes. (Bug #28899)

- **Cluster API**: **Important Change**: A new `NdbRecord` object has been added to the `NDB` API. This object provides mapping to a record stored in `NDB`.

- `auto_increment_increment` [1622] and `auto_increment_offset` [1624] are now supported for `NDB` tables. (Bug #26342)

- A new memory allocator has been implemented for the `NDB` kernel, which allocates memory to tables 32K page by 32K page rather than allocating it in variable-sized chunks as previously. This removes much of the memory overhead that was associated with the old memory allocator.

- A new data node configuration parameter `BackupReportFrequency` [1851] now makes it possible to cause the management client to provide status reports at regular intervals as well as for such reports to be written to the cluster log (depending on cluster event logging levels).

- `ndb_restore` now provides running reports of its progress when restoring a backup. In addition, a complete report status report on the backup is written to the cluster log.

- A new configuration parameter `ODirect` [1833] causes `NDB` to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering CPU usage.

- Reporting functionality has been significantly enhanced in this release:

- A new configuration parameter `BackupReportFrequency` [1851] now makes it possible to cause the management client to provide status reports at regular intervals as well as for such reports to be written to the cluster log (depending on cluster event logging levels).
- A new `REPORT` command has been added in the cluster management client. `REPORT BackupStatus` enables you to obtain a backup status report at any time during a backup. `REPORT MemoryUsage` reports the current data memory and index memory used by each data node. For more about the `REPORT` command, see Commands in the MySQL Cluster Management Client.
- `ndb_restore` now provides running reports of its progress when restoring a backup. In addition, a complete report status report on the backup is written to the cluster log.

- A `REPORT BackupStatus` command has been added in the cluster management client. This command enables you to obtain a backup status report at any time during a backup. For more about this command, see Commands in the MySQL Cluster Management Client.

Bugs Fixed

- Having large amounts of memory locked caused swapping to disk. (Bug #28751)
- When shutting down `mysqld`, the `NDB` binlog process was not shut down before log cleanup began. (Bug #28949)
- Setting `InitialNoOfOpenFiles` [1827] equal to `MaxNoOfOpenFiles` [1827] caused an error. This was due to the fact that the actual value of `MaxNoOfOpenFiles` [1827] as used by the cluster was offset by 1 from the value set in `config.ini`. (Bug #28749)
- It is now possible to set the maximum size of the allocation unit for table memory using the `MaxAllocate` [1825] configuration parameter. (Bug #29044)
- A corrupt schema file could cause a `File already open` error. (Bug #28770)
- `ndb_error_reporter` now preserves timestamps on files. (Bug #29074)
- The wrong data pages were sometimes invalidated following a global checkpoint. (Bug #29067)
- LCP files were not removed following an initial system restart. (Bug #28726)
- A race condition could result when nonmaster nodes (in addition to the master node) tried to update active status due to a local checkpoint (that is, between `NODE_FAILREP` and `COPY_GCIREQ` events). Now only the master updates the active status. (Bug #28717)
- An invalid comparison made during `REDO` validation that could lead to an `Error while reading REDO log` condition. (Bug #29118)
- Memory corruption could occur due to a problem in the `DBTUP` kernel block. (Bug #29229)
- Attempting to restore a `NULL` row to a `VARBINARY` column caused `ndb_restore` to fail. (Bug #29103)
- If at least 2 files were involved in `REDO` invalidation, then file 0 of page 0 was not updated and so pointed to an invalid part of the redo log. (Bug #29057)
- In the event that two data nodes in the same node group and participating in a GCP crashed before they had written their respective `P0.sysfile` files, `QMGR` could refuse to start, issuing an invalid `Insufficient nodes for restart` error instead. (Bug #29167)
- `UPDATE IGNORE` statements involving the primary keys of multiple tables could result in data corruption. (Bug #28719)
- A query having a large `IN(...)` [942] or `NOT IN(...)` list in the `WHERE` condition on an `NDB` table could cause `mysqld` to crash. (Bug #29185)

- When a node failed to respond to a `COPY_GCI` signal as part of a global checkpoint, the master node was killed instead of the node that actually failed. (Bug #29331)
- A fast global checkpoint under high load with high usage of the redo buffer caused data nodes to fail. (Bug #28653)
- The management client's response to `START BACKUP WAIT COMPLETED` did not include the backup ID. (Bug #27640)
- **Disk Data**: When dropping a page, the stack's bottom entry could sometime be left “cold” rather than “hot”, violating the rules for stack pruning. (Bug #29176)
- **Disk Data**: Repeated `INSERT` and `DELETE` operations on a Disk Data table having one or more large `VARCHAR` columns could cause data nodes to fail. (Bug #20612)
- **Disk Data**: When loading data into a cluster following a version upgrade, the data nodes could forcibly shut down due to page and buffer management failures (that is, `ndbrequire` failures in `PGMAN`). (Bug #28525)
- **Cluster API**: An invalid error code could be set on transaction objects by `BLOB` handling code. (Bug #28724)
- **Cluster API**: The timeout set using the MGM API `ndb_mgm_set_timeout()` function was incorrectly interpreted as seconds rather than as milliseconds. (Bug #29063)

Changes in MySQL Cluster NDB 6.2.2 (5.1.18-ndb-6.2.2)

Functionality Added or Changed

- Added the `mysqld` option `--ndb-cluster-connection-pool` that enables a single MySQL server to use multiple connections to the cluster. This enables scaling out using multiple MySQL clients per SQL node instead of or in addition to using multiple SQL nodes with the cluster.

  For more information about this option, see MySQL Server Options and Variables for MySQL Cluster.
- New cluster management client `DUMP` commands were added to aid in tracking transactions, scan operations, and locks. See `DUMP 2350`, `DUMP 2352`, and `DUMP 2550`, for more information.

Changes in MySQL Cluster NDB 6.2.1 (5.1.18-ndb-6.2.1)

Bugs Fixed

- Multiple operations involving deletes followed by reads were not handled correctly.

  Note

  This issue could also affect MySQL Cluster Replication.

  (Bug #28276)
- **Cluster API**: Using `NdbBlob::writeData()` to write data in the middle of an existing blob value (that is, updating the value) could overwrite some data past the end of the data to be changed. (Bug #27018)

Changes in MySQL Cluster NDB 6.2.0 (5.1.16-ndb-6.2.0)

Functionality Added or Changed

- An `--ndb-wait-connected` [1919] option has been added for `mysqld`. When used, it causes `mysqld` wait a specified amount of time to be connected to the cluster before accepting client connections.

- **Cluster API**: It is now possible to iterate over all existing `NDB` objects using three new methods of the `Ndb_cluster_connection` class:
  - `lock_ndb_objects()`
  - `get_next_ndb_object()`
  - `unlock_ndb_objects()`
- **Cluster API**: The `Ndb::startTransaction()` method now provides an alternative interface for starting a transaction.

Changes in the MySQL Cluster NDB 6.1 Series

This section contains unified change history highlights for all MySQL Cluster releases based on version 6.1 of the `NDBCLUSTER` storage engine through MySQL Cluster NDB 5.1.15-ndb-6.1.23. Included are all changelog entries in the categories *MySQL Cluster*, *Disk Data*, and *Cluster API*.

For an overview of features that were added in MySQL Cluster NDB 6.1, see MySQL Cluster Development in MySQL Cluster NDB 6.1.

Note

MySQL Cluster NDB 6.1 is no longer being developed or maintained, and the information presented in this section should be considered to be of historical interest only. If you are using MySQL Cluster NDB 6.1, you should upgrade as soon as possible to the most recent version of MySQL Cluster NDB 6.2 or later MySQL Cluster release series.

- Changes in MySQL Cluster NDB 6.1.23 (5.1.15-ndb-6.1.23) [2535]
- Changes in MySQL Cluster NDB 6.1.22 (5.1.15-ndb-6.1.22) [2535]
- Changes in MySQL Cluster NDB 6.1.21 (5.1.15-ndb-6.1.21) [2535]
- Changes in MySQL Cluster NDB 6.1.19 (5.1.15-ndb-6.1.19) [2535]
- Changes in MySQL Cluster NDB 6.1.18 (5.1.15-ndb-6.1.18) [2535]
- Changes in MySQL Cluster NDB 6.1.17 (5.1.15-ndb-6.1.17) [2535]
- Changes in MySQL Cluster NDB 6.1.16 (5.1.15-ndb-6.1.16) [2535]
- Changes in MySQL Cluster NDB 6.1.15 (5.1.15-ndb-6.1.15) [2536]
- Changes in MySQL Cluster NDB 6.1.14 (5.1.15-ndb-6.1.14) [2536]
- Changes in MySQL Cluster NDB 6.1.13 (5.1.15-ndb-6.1.13) [2536]
- Changes in MySQL Cluster NDB 6.1.12 (5.1.15-ndb-6.1.12) [2536]
- Changes in MySQL Cluster NDB 6.1.11 (5.1.15-ndb-6.1.11) [2536]
- Changes in MySQL Cluster NDB 6.1.10 (5.1.15-ndb-6.1.10) [2536]
- Changes in MySQL Cluster NDB 6.1.9 (5.1.15-ndb-6.1.9) [2537]
- Changes in MySQL Cluster NDB 6.1.8 (5.1.15-ndb-6.1.8) [2537]
- Changes in MySQL Cluster NDB 6.1.7 (5.1.15-ndb-6.1.7) [2537]
- Changes in MySQL Cluster NDB 6.1.6 (5.1.15-ndb-6.1.6) [2538]
- Changes in MySQL Cluster NDB 6.1.5 (5.1.15-ndb-6.1.5) [2539]

- Changes in MySQL Cluster NDB 6.1.4 (5.1.15-ndb-6.1.4) [2540]
- Changes in MySQL Cluster NDB 6.1.3 (5.1.15-ndb-6.1.3) [2540]
- Changes in MySQL Cluster NDB 6.1.2 (5.1.15-ndb-6.1.2) [2541]
- Changes in MySQL Cluster NDB 6.1.1 (5.1.15-ndb-6.1.1) [2541]
- Changes in MySQL Cluster NDB 6.1.0 (5.1.14-ndb-6.1.0) [2541]

Changes in MySQL Cluster NDB 6.1.23 (5.1.15-ndb-6.1.23)

Bugs Fixed

- The `NDB` storage engine code was not safe for strict-alias optimization in `gcc` 4.2.1. (Bug #31761)

Changes in MySQL Cluster NDB 6.1.22 (5.1.15-ndb-6.1.22)

Bugs Fixed

- It was possible in some cases for a node group to be “lost” due to missed local checkpoints following a system restart. (Bug #31525)

Changes in MySQL Cluster NDB 6.1.21 (5.1.15-ndb-6.1.21)

Bugs Fixed

- A node failure during a local checkpoint could lead to a subsequent failure of the cluster during a system restart. (Bug #31257)
- A cluster restart could sometimes fail due to an issue with table IDs. (Bug #30975)

Changes in MySQL Cluster NDB 6.1.19 (5.1.15-ndb-6.1.19)

Functionality Added or Changed

- Whenever a TCP send buffer is over 80% full, temporary error 1218 (`Send Buffers overloaded in NDB kernel`) is now returned. See SendBufferMemory [1870] for more information.

Changes in MySQL Cluster NDB 6.1.18 (5.1.15-ndb-6.1.18)

Bugs Fixed

- When restarting a data node, queries could hang during that node's start phase 5, and continue only after the node had entered phase 6. (Bug #29364)
- **Disk Data**: Disk data meta-information that existed in `ndbd` might not be visible to `mysqld`. (Bug #28720)
- **Disk Data**: The number of free extents was incorrectly reported for some tablespaces. (Bug #28642)

Changes in MySQL Cluster NDB 6.1.17 (5.1.15-ndb-6.1.17)

Bugs Fixed

- Replica redo logs were inconsistently handled during a system restart. (Bug #29354)

Changes in MySQL Cluster NDB 6.1.16 (5.1.15-ndb-6.1.16)

Bugs Fixed

- The wrong data pages were sometimes invalidated following a global checkpoint. (Bug #29067)
- An invalid comparison made during `REDO` validation that could lead to an `Error while reading REDO log` condition. (Bug #29118)

- If at least 2 files were involved in `REDO` invalidation, then file 0 of page 0 was not updated and so pointed to an invalid part of the redo log. (Bug #29057)
- When a node failed to respond to a `COPY_GCI` signal as part of a global checkpoint, the master node was killed instead of the node that actually failed. (Bug #29331)
- **Disk Data**: When dropping a page, the stack's bottom entry could sometime be left “cold” rather than “hot”, violating the rules for stack pruning. (Bug #29176)

Changes in MySQL Cluster NDB 6.1.15 (5.1.15-ndb-6.1.15)

Bugs Fixed

- Memory corruption could occur due to a problem in the `DBTUP` kernel block. (Bug #29229)

Changes in MySQL Cluster NDB 6.1.14 (5.1.15-ndb-6.1.14)

Bugs Fixed

- In the event that two data nodes in the same node group and participating in a GCP crashed before they had written their respective `P0.sysfile` files, `QMGR` could refuse to start, issuing an invalid `Insufficient nodes for restart` error instead. (Bug #29167)

Changes in MySQL Cluster NDB 6.1.13 (5.1.15-ndb-6.1.13)

Bugs Fixed

- **Cluster API**: `NdbApi.hpp` depended on `ndb_global.h`, which was not actually installed, causing the compilation of programs that used `NdbApi.hpp` to fail. (Bug #35853)

Changes in MySQL Cluster NDB 6.1.12 (5.1.15-ndb-6.1.12)

Functionality Added or Changed

- New cluster management client `DUMP` commands were added to aid in tracking transactions, scan operations, and locks. See `DUMP 2350`, `DUMP 2352`, and `DUMP 2550`.

Bugs Fixed

- It is now possible to set the maximum size of the allocation unit for table memory using the `MaxAllocate` [1825] configuration parameter. (Bug #29044)

Changes in MySQL Cluster NDB 6.1.11 (5.1.15-ndb-6.1.11)

Functionality Added or Changed

- **Important Change**: The `TimeBetweenWatchdogCheckInitial` [1835] configuration parameter was added to enable setting of a separate watchdog timeout for memory allocation during startup of the data nodes. (Bug #28899)
- A new configuration parameter `ODirect` [1833] causes `NDB` to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering CPU usage.

Bugs Fixed

- Having large amounts of memory locked caused swapping to disk. (Bug #28751)
- LCP files were not removed following an initial system restart. (Bug #28726)
- **Disk Data**: Repeated `INSERT` and `DELETE` operations on a Disk Data table having one or more large `VARCHAR` columns could cause data nodes to fail. (Bug #20612)

Changes in MySQL Cluster NDB 6.1.10 (5.1.15-ndb-6.1.10)

Functionality Added or Changed

- Some unneeded printouts in the `ndbd` out file were removed.
- A new `times` printout was added in the `ndbd` watchdog thread.

Bugs Fixed

- Setting `InitialNoOfOpenFiles` [1827] equal to `MaxNoOfOpenFiles` [1827] caused an error. This was due to the fact that the actual value of `MaxNoOfOpenFiles` [1827] as used by the cluster was offset by 1 from the value set in `config.ini`. (Bug #28749)
- A corrupt schema file could cause a `File already open` error. (Bug #28770)
- A regression in the heartbeat monitoring code could lead to node failure under high load. This issue affected MySQL 5.1.19 and MySQL Cluster NDB 6.1.10 only. (Bug #28783)
- A race condition could result when nonmaster nodes (in addition to the master node) tried to update active status due to a local checkpoint (that is, between `NODE_FAILREP` and `COPY_GCIREQ` events). Now only the master updates the active status. (Bug #28717)
- A fast global checkpoint under high load with high usage of the redo buffer caused data nodes to fail. (Bug #28653)
- **Disk Data**: When loading data into a cluster following a version upgrade, the data nodes could forcibly shut down due to page and buffer management failures (that is, `ndbrequire` failures in `PGMAN`). (Bug #28525)

Changes in MySQL Cluster NDB 6.1.9 (5.1.15-ndb-6.1.9)

Bugs Fixed

- When an API node sent more than 1024 signals in a single batch, `NDB` would process only the first 1024 of these, and then hang. (Bug #28443)
- **Disk Data**: The cluster backup process scanned in `ACC` index order, which had bad effects for disk data. (Bug #28593)

Changes in MySQL Cluster NDB 6.1.8 (5.1.15-ndb-6.1.8)

Bugs Fixed

- Local checkpoint files relating to dropped `NDB` tables were not removed. (Bug #28348)
- Repeated insertion of data generated by `mysqldump` into `NDB` tables could eventually lead to failure of the cluster. (Bug #27437)
- **Disk Data**: Extremely large inserts into Disk Data tables could lead to data node failure in some circumstances. (Bug #27942)
- **Cluster API**: In a multi-operation transaction, a delete operation followed by the insertion of an implicit `NULL` failed to overwrite an existing value. (Bug #20535)

Changes in MySQL Cluster NDB 6.1.7 (5.1.15-ndb-6.1.7)

Functionality Added or Changed

- **Cluster Replication**: **Incompatible Change**: The schema for the `ndb_apply_status` table in the `mysql` system database has changed. When upgrading to this release from a previous MySQL Cluster NDB 6.x or mainline MySQL 5.1 release, you must drop the `mysql.ndb_apply_status` table, then restart the server for the table to be re-created with the new schema.

  See MySQL Cluster Replication Schema and Tables, for additional information.

Bugs Fixed

- An `INSERT` followed by a delete `DELETE` on the same `NDB` table caused a memory leak. (Bug #27756)

  References: This bug was introduced by Bug #20612.

- The cluster waited 30 seconds instead of 30 milliseconds before reading table statistics. (Bug #28093)

- Under some circumstances, a node restart could fail to update the Global Checkpoint Index (GCI). (Bug #28023)

- Under certain rare circumstances, `ndbd` could get caught in an infinite loop when one transaction took a read lock and then a second transaction attempted to obtain a write lock on the same tuple in the lock queue. (Bug #28073)

- Under certain rare circumstances performing a `DROP TABLE` or `TRUNCATE TABLE` on an `NDB` table could cause a node failure or forced cluster shutdown. (Bug #27581)

- Memory usage of a `mysqld` process grew even while idle. (Bug #27560)

- Performing a delete followed by an insert during a local checkpoint could cause a `Rowid already allocated` error. (Bug #27205)

- **Cluster Replication**: **Disk Data**: An issue with replication of Disk Data tables could in some cases lead to node failure. (Bug #28161)

- **Disk Data**: When restarting a data node following the creation of a large number of Disk Data objects (approximately 200 such objects), the cluster could not assign a node ID to the restarting node. (Bug #25741)

- **Disk Data**: Changing a column specification or issuing a `TRUNCATE TABLE` statement on a Disk Data table caused the table to become an in-memory table.

  This fix supersedes an incomplete fix that was made for this issue in MySQL 5.1.15. (Bug #24667, Bug #25296)

- **Disk Data**: Changes to a Disk Data table made as part of a transaction could not be seen by the client performing the changes until the transaction had been committed. (Bug #27757)

- **Cluster API**: An issue with the way in which the `Dictionary::listEvents()` method freed resources could sometimes lead to memory corruption. (Bug #27663)

Changes in MySQL Cluster NDB 6.1.6 (5.1.15-ndb-6.1.6)

Functionality Added or Changed

- **Cluster Replication**: **Incompatible Change**: The schema for the `ndb_apply_status` table in the `mysql` system database has changed. When upgrading to this release from a previous MySQL Cluster NDB 6.x or mainline MySQL 5.1 release, you must drop the `mysql.ndb_apply_status` table, then restart the server for the table to be re-created with the new schema.

  See MySQL Cluster Replication Schema and Tables, for additional information.

Bugs Fixed

- A data node failing while another data node was restarting could leave the cluster in an inconsistent state. In certain rare cases, this could lead to a race condition and the eventual forced shutdown of the cluster. (Bug #27466)

- `mysqld` processes would sometimes crash under high load.

Note

This fix improves on and replaces a fix for this bug that was made in MySQL Cluster NDB 6.1.5.

(Bug #26825)

- When a data node was taking over as the master node, a race condition could sometimes occur as the node was assuming responsibility for handling of global checkpoints. (Bug #27283)
- It was not possible to set `LockPagesInMainMemory` [1832] equal to `0`. (Bug #27291)
- A race condition could sometimes occur if the node acting as master failed while node IDs were still being allocated during startup. (Bug #27286)
- `mysqld` could crash shortly after a data node failure following certain DML operations. (Bug #27169)
- The same failed request from an API node could be handled by the cluster multiple times, resulting in reduced performance. (Bug #27087)
- The failure of a data node while restarting could cause other data nodes to hang or crash. (Bug #27003)
- **Disk Data**: `DROP INDEX` on a Disk Data table did not always move data from memory into the tablespace. (Bug #25877)
- **Cluster API**: An issue with the way in which the `Dictionary::listEvents()` method freed resources could sometimes lead to memory corruption. (Bug #27663)
- **Cluster API**: A delete operation using a scan followed by an insert using a scan could cause a data node to fail. (Bug #27203)

Changes in MySQL Cluster NDB 6.1.5 (5.1.15-ndb-6.1.5)

Functionality Added or Changed

- **Cluster Replication**: **Incompatible Change**: The schema for the `ndb_apply_status` table in the `mysql` system database has changed. When upgrading to this release from a previous MySQL Cluster NDB 6.x or mainline MySQL 5.1 release, you must drop the `mysql.ndb_apply_status` table, then restart the server for the table to be re-created with the new schema.

  See MySQL Cluster Replication Schema and Tables, for additional information.

Bugs Fixed

- An infinite loop in an internal logging function could cause trace logs to fill up with `Unknown Signal type` error messages and thus grow to unreasonable sizes. (Bug #26720)
- `mysqld` processes would sometimes crash under high load.

Note

This fix was reverted in MySQL Cluster NDB 6.1.6.

(Bug #26825)

- Creating a table on one SQL node while in single user mode caused other SQL nodes to crash. (Bug #26997)
- **Disk Data**: When creating a log file group, setting `INITIAL_SIZE` to less than `UNDO_BUFFER_SIZE` caused data nodes to crash. (Bug #25743)

Changes in MySQL Cluster NDB 6.1.4 (5.1.15-ndb-6.1.4)

Functionality Added or Changed

- An `--ndb-wait-connected` [1919] option has been added for `mysqld`. When used, it causes `mysqld` wait a specified amount of time to be connected to the cluster before accepting client connections.
- **Cluster API**: It is now possible to iterate over all existing `NDB` objects using three new methods of the `Ndb_cluster_connection` class:
  - `lock_ndb_objects()`
  - `get_next_ndb_object()`
  - `unlock_ndb_objects()`
- **Cluster API**: It is now possible to specify the transaction coordinator when starting a transaction. See `Ndb::startTransaction()`, for more information.

Bugs Fixed

- An inadvertent use of unaligned data caused `ndb_restore` to fail on some 64-bit platforms, including Sparc and Itanium-2. (Bug #26739)
- Using only the `--print_data` [1997] option (and no other options) with `ndb_restore` caused `ndb_restore` to fail. (Bug #26741)

  References: This bug was introduced by Bug #14612.

Changes in MySQL Cluster NDB 6.1.3 (5.1.15-ndb-6.1.3)

Functionality Added or Changed

- The `ndb_show_tables` utility now displays information about table events. See `ndb_show_tables` — Display List of NDB Tables, for more information.
- The `ndbd_redo_log_reader` utility is now part of the default build. For more information, see `ndbd_redo_log_reader` — Check and Print Content of Cluster Redo Log.
- **Cluster API**: A new `listEvents()` method has been added to the `Dictionary` class.

Bugs Fixed

- An invalid pointer was returned following a `FSCLOSECONF` signal when accessing the REDO logs during a node restart or system restart. (Bug #26515)
- No appropriate error message was provided when there was insufficient REDO log file space for the cluster to start. (Bug #25801)
- The message `Error 0 in readAutoIncrementValue(): no Error` was written to the error log whenever `SHOW TABLE STATUS` was performed on a Cluster table that did not have an `AUTO_INCREMENT` column.

  Note

  This improves on and supersedes an earlier fix that was made for this issue in MySQL 5.1.12.

  (Bug #21033)
- The **`InvalidUndoBufferSize`** error used the same error code (`763`) as the **`IncompatibleVersions`** error. **`InvalidUndoBufferSize`** now uses its own error code (`779`). (Bug #26490)

- Under some circumstances, following the restart of a management node, all data nodes would connect to it normally, but some of them subsequently failed to log any events to the management node. (Bug #26293)
- The `LockPagesInMainMemory` [1832] parameter was not read until after distributed communication had already started between cluster nodes. When the value of this parameter was `1`, this could sometimes result in data node failure due to missed heartbeats. (Bug #26454)
- Takeover for local checkpointing due to multiple failures of master nodes was sometimes incorrectly handled. (Bug #26457)
- The failure of a data node when restarting it with `--initial` could lead to failures of subsequent data node restarts. (Bug #26481)
- A memory allocation failure in `SUMA` (the cluster Subscription Manager) could cause the cluster to crash. (Bug #25239)
- **Disk Data**: Use of a tablespace whose `INITIAL_SIZE` was greater than 1 GB could cause the cluster to crash. (Bug #26487)
- **Disk Data**: A memory overflow could occur with tables having a large amount of data stored on disk, or with queries using a very high degree of parallelism on Disk Data tables. (Bug #26514)

Changes in MySQL Cluster NDB 6.1.2 (5.1.15-ndb-6.1.2)

Bugs Fixed

- Using node IDs greater than 48 could sometimes lead to incorrect memory access and a subsequent forced shutdown of the cluster. (Bug #26267)

Changes in MySQL Cluster NDB 6.1.1 (5.1.15-ndb-6.1.1)

Functionality Added or Changed

- A single cluster can now support up to 255 API nodes, including MySQL servers acting as SQL nodes. See Issues Exclusive to MySQL Cluster, for more information.

Bugs Fixed

- A memory leak could cause problems during a node or cluster shutdown or failure. (Bug #25997)
- **Cluster API**: **Disk Data**: A delete and a read performed in the same operation could cause one or more data nodes to crash. This could occur when the operation affected more than 5 columns concurrently, or when one or more of the columns was of the `VARCHAR` type and was stored on disk. (Bug #25794)
- **Cluster API**: **Disk Data**: A delete and a read performed in the same operation could cause one or more data nodes to crash. This could occur when the operation affected more than 5 columns concurrently, or when one or more of the columns was of the `VARCHAR` type and was stored on disk. (Bug #25794)

Changes in MySQL Cluster NDB 6.1.0 (5.1.14-ndb-6.1.0)

Functionality Added or Changed

- A new configuration parameter `MemReportFrequency` [1849] enables additional control of data node memory usage. Previously, only warnings at predetermined percentages of memory allocation were given; setting this parameter enables that behavior to be overridden.

Bugs Fixed

- When a data node was shut down using the management client `STOP` command, a connection event (`NDB_LE_Connected`) was logged instead of a disconnection event (`NDB_LE_Disconnected`). (Bug #22773)

- `SELECT` statements with a `BLOB` or `TEXT` column in the selected column list and a `WHERE` condition including a primary key lookup on a `VARCHAR` primary key produced empty result sets. (Bug #19956)
- **Disk Data**: `MEDIUMTEXT` columns of Disk Data tables were stored in memory rather than on disk, even if the columns were not indexed. (Bug #25001)
- **Disk Data**: When restoring from backup a cluster containing any Disk Data tables with hidden primary keys, a node failure resulted which could lead to a crash of the cluster. (Bug #24166)
- **Disk Data**: Repeated `CREATE`, `DROP`, or `TRUNCATE TABLE` in various combinations with system restarts between these operations could lead to the eventual failure of a system restart. (Bug #21948)
- **Disk Data**: Performing a node restart with a newly dropped Disk Data table could lead to failure of the node during the restart. (Bug #24917)
- **Disk Data**: Extents that should have been available for re-use following a `DROP TABLE` operation were not actually made available again until after the cluster had performed a local checkpoint. (Bug #17605)
- **Cluster API**: A unique index lookup on a nonexistent tuple could lead to a data node timeout (error 4012). (Bug #25059)
- **Cluster API**: Invoking the `NdbTransaction::execute()` method using execution type `Commit` and abort option `AO_IgnoreError` could lead to a crash of the transaction coordinator (`DBTC`). (Bug #25090)
- **Cluster API**: When using the `NdbTransaction::execute()` method, a very long timeout (greater than 5 minutes) could result if the last data node being polled was disconnected from the cluster. (Bug #24949)
- **Cluster API**: Due to an error in the computation of table fragment arrays, some transactions were not executed from the correct starting point. (Bug #24914)

Chapter 18. Partitioning

This chapter discusses MySQL's implementation of *user-defined partitioning*. You can determine whether your MySQL Server supports partitioning by means of a `SHOW VARIABLES` statement such as this one:

```
mysql> SHOW VARIABLES LIKE '%partition%';

+-------------------+-------+
| Variable_name     | Value |
+-------------------+-------+
| have_partitioning | YES   |
+-------------------+-------+
1 row in set (0.00 sec)
```

Note

Prior to MySQL 5.1.6, this variable was named `have_partition_engine`. (Bug #16718)

You can also check the output of the `SHOW PLUGINS` statement, as shown here:

```
mysql> SHOW PLUGINS;
+------------+----------+----------------+---------+---------+
| Name       | Status   | Type           | Library | License |
+------------+----------+----------------+---------+---------+
| binlog     | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| partition  | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| ARCHIVE    | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| BLACKHOLE  | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| CSV        | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| FEDERATED  | DISABLED | STORAGE ENGINE | NULL    | GPL     |
| MEMORY     | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| InnoDB     | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| MRG_MYISAM | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| MyISAM     | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| ndbcluster | DISABLED | STORAGE ENGINE | NULL    | GPL     |
+------------+----------+----------------+---------+---------+
11 rows in set (0.00 sec)
```

If you do not see the have_partitioning [480] variable with the value YES listed in the output of an appropriate SHOW VARIABLES statement, or if you do not see the partition plugin listed with the value ACTIVE for the Status column in the output of SHOW PLUGINS (show in bold text in the example just given), then your version of MySQL was not built with partitioning support.

MySQL 5.1 Community binaries provided by Oracle include partitioning support. For information about partitioning support offered in commercial MySQL Server binaries, see *MySQL Enterprise Server 5.1* on the MySQL Web site at http://www.mysql.com/products/enterprise/server.html.

If you are compiling MySQL 5.1 from source, the build must be configured using --with-partition to enable partitioning. Using --with-plugins=max to configure the build includes this option automatically.

If your MySQL binary is built with partitioning support, nothing further needs to be done to enable it (for example, no special entries are required in your my.cnf file).

If you want to disable partitioning support, you can start the MySQL Server with the --skip-partition [443] option, in which case the value of have_partitioning [480] is DISABLED. However, if you do this, you cannot access any partitioned tables until the server is once again restarted without the --skip-partition [443] option.

An introduction to partitioning and partitioning concepts may be found in Overview of Partitioning in MySQL.

MySQL supports several types of partitioning, which are discussed in Partitioning Types, as well as subpartitioning, which is described in Subpartitioning.

Methods of adding, removing, and altering partitions in existing partitioned tables are covered in Partition Management.

Table maintenance commands for use with partitioned tables are discussed in Maintenance of Partitions.

Beginning with MySQL 5.1.6, the PARTITIONS table in the INFORMATION_SCHEMA database provides information about partitions and partitioned tables. See The INFORMATION_SCHEMA PARTITIONS Table, for more information; for some examples of queries against this table, see How MySQL Partitioning Handles NULL.

Important

Partitioned tables created with MySQL versions prior to 5.1.6 cannot be read by a 5.1.6 or later MySQL Server. In addition, the INFORMATION_SCHEMA.TABLES table cannot be used if such tables are present on a 5.1.6 server. Beginning with MySQL 5.1.7, a suitable warning message is generated instead, to alert the user that incompatible partitioned tables have been found by the server.

If you are using partitioned tables which were created in MySQL 5.1.5 or earlier, be sure to see Changes in MySQL 5.1.6 (2006-02-01) for more information and suggested workarounds *before* upgrading to MySQL 5.1.6 or later.

For known issues with partitioning in MySQL 5.1, see Restrictions and Limitations on Partitioning.

You may also find the following resources to be useful when working with partitioned tables.

Additional Resources. Other sources of information about user-defined partitioning in MySQL include the following:

- MySQL Partitioning Forum

  This is the official discussion forum for those interested in or experimenting with MySQL Partitioning technology. It features announcements and updates from MySQL developers and others. It is monitored by members of the Partitioning Development and Documentation Teams.

- Mikael Ronström's Blog

  MySQL Partitioning Architect and Lead Developer Mikael Ronström frequently posts articles here concerning his work with MySQL Partitioning and MySQL Cluster.

- PlanetMySQL

  A MySQL news site featuring MySQL-related blogs, which should be of interest to anyone using my MySQL. We encourage you to check here for links to blogs kept by those working with MySQL Partitioning, or to have your own blog added to those covered.

MySQL 5.1 binaries are available from http://dev.mysql.com/downloads/mysql/5.1.html. However, for the latest partitioning bugfixes and feature additions, you can obtain the source from our Bazaar repository. To enable partitioning, you need to compile the server using the `--with-partition` option. For more information about building MySQL, see Installing MySQL from Source. If you have problems compiling a partitioning-enabled MySQL 5.1 build, check the MySQL Partitioning Forum and ask for assistance there if you do not find a solution to your problem already posted.

Overview of Partitioning in MySQL

This section provides a conceptual overview of partitioning in MySQL 5.1.

For information on partitioning restrictions and feature limitations, see Restrictions and Limitations on Partitioning.

The SQL standard does not provide much in the way of guidance regarding the physical aspects of data storage. The SQL language itself is intended to work independently of any data structures or media underlying the schemas, tables, rows, or columns with which it works. Nonetheless, most advanced database management systems have evolved some means of determining the physical location to be used for storing specific pieces of data in terms of the file system, hardware or even both. In MySQL, the `InnoDB` storage engine has long supported the notion of a tablespace, and the MySQL Server, even prior to the introduction of partitioning, could be configured to employ different physical directories for storing different databases (see Using Symbolic Links, for an explanation of how this is done).

Partitioning takes this notion a step further, by enabling you to distribute portions of individual tables across a file system according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a *partitioning function*, which in MySQL can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function. The function is selected according to the partitioning type specified by the user, and takes as its parameter the value of a user-supplied expression. This expression can be a column value, a function acting on one or more column values, or a set of one or more column values, depending on the type of partitioning that is used.

In the case of `RANGE`, `LIST`, and [`LINEAR`] `HASH` partitioning, the value of the partitioning column is passed to the partitioning function, which returns an integer value representing the number of the partition in which that particular record should be stored. This function must be nonconstant and nonrandom. It may not contain any queries, but may use an SQL expression that is valid in MySQL, as long as that expression returns either `NULL` or an integer *`intval`* such that

```
-MAXVALUE <= intval <= MAXVALUE
```

(`MAXVALUE` is used to represent the least upper bound for the type of integer in question. `-MAXVALUE` represents the greatest lower bound.)

For [`LINEAR`] `KEY`, the partitioning expression consists of a list of one or more columns, and the partitioning function is supplied by MySQL.

For more information about permitted partitioning column types and partitioning functions, see Partitioning Types, as well as `CREATE TABLE` Syntax, which provides partitioning syntax descriptions

and additional examples. For information about restrictions on partitioning functions, see Partitioning Limitations Relating to Functions.

This is known as *horizontal partitioning*—that is, different rows of a table may be assigned to different physical partitions. MySQL 5.1 does not support *vertical partitioning*, in which different columns of a table are assigned to different physical partitions. There are not at this time any plans to introduce vertical partitioning into MySQL 5.1.

For information about determining whether your MySQL Server binary supports user-defined partitioning, see Chapter 18, *Partitioning*.

For creating partitioned tables, you can use most storage engines that are supported by your MySQL server; the MySQL partitioning engine runs in a separate layer and can interact with any of these. In MySQL 5.1, all partitions of the same partitioned table must use the same storage engine; for example, you cannot use `MyISAM` for one partition and `InnoDB` for another. However, there is nothing preventing you from using different storage engines for different partitioned tables on the same MySQL server or even in the same database.

MySQL partitioning cannot be used with the `MERGE` or `CSV` storage engines. Beginning with MySQL 5.1.15, `FEDERATED` tables also cannot be partitioned (Bug #22451). Prior to MySQL 5.1.6, it was also not feasible to create a partitioned table using the `BLACKHOLE` storage engine (Bug #14524). See Partitioning Limitations Relating to Storage Engines.

Partitioning by `KEY` or `LINEAR KEY` is possible with `NDBCLUSTER`, but other types of user-defined partitioning are not supported for tables using this storage engine. In addition, an `NDBCLUSTER` table that employs user-defined partitioning must have an explicit primary key, and any columns referenced in the table's partitioning expression must be part of the primary key. However, if no columns are listed in the `PARTITION BY KEY` or `PARTITION BY LINEAR KEY` clause of the `CREATE TABLE` or `ALTER TABLE` statement used to create or modify a user-partitioned `NDBCLUSTER` table, then the table is not required to have an explicit primary key. For more information, see Noncompliance with SQL Syntax in MySQL Cluster.

To employ a particular storage engine for a partitioned table, it is necessary only to use the `[STORAGE] ENGINE` option just as you would for a nonpartitioned table. However, you should keep in mind that `[STORAGE] ENGINE` (and other table options) need to be listed *before* any partitioning options are used in a `CREATE TABLE` statement. This example shows how to create a table that is partitioned by hash into 6 partitions and which uses the `InnoDB` storage engine:

```
CREATE TABLE ti (id INT, amount DECIMAL(7,2), tr_date DATE)
    ENGINE=INNODB
    PARTITION BY HASH( MONTH(tr_date) )
    PARTITIONS 6;
```

Each `PARTITION` clause can include a `[STORAGE] ENGINE` option, but in MySQL 5.1 this has no effect.

Important

Partitioning applies to all data and indexes of a table; you cannot partition only the data and not the indexes, or *vice versa*, nor can you partition only a portion of the table.

Data and indexes for each partition can be assigned to a specific directory using the `DATA DIRECTORY` and `INDEX DIRECTORY` options for the `PARTITION` clause of the `CREATE TABLE` statement used to create the partitioned table.

Prior to MySQL 5.1.18, these options were permitted even when the `NO_DIR_IN_CREATE` [573] server SQL mode was in effect (Bug #24633).

The `DATA DIRECTORY` and `INDEX DIRECTORY` options have no effect when defining partitions for tables using the `InnoDB` storage engine.

`DATA DIRECTORY` and `INDEX DIRECTORY` are not supported for individual partitions or subpartitions on Windows. Beginning with MySQL 5.1.24, these options are ignored on Windows, except that a warning is generated (Bug #30459)-

In addition, `MAX_ROWS` and `MIN_ROWS` can be used to determine the maximum and minimum numbers of rows, respectively, that can be stored in each partition. The `MAX_ROWS` option can be useful for causing MySQL Cluster tables to be created with extra partitions, thus allowing for greater storage of hash indexes. See the documentation for the `DataMemory` [1817] data node configuration parameter, as well as MySQL Cluster Nodes, Node Groups, Replicas, and Partitions, for more information.

Some advantages of partitioning are listed here:

- Partitioning makes it possible to store more data in one table than can be held on a single disk or file system partition.
- Data that loses its usefulness can often be easily removed from a partitioned table by dropping the partition (or partitions) containing only that data. Conversely, the process of adding new data can in some cases be greatly facilitated by adding one or more new partitions for storing specifically that data.
- Some queries can be greatly optimized in virtue of the fact that data satisfying a given `WHERE` clause can be stored only on one or more partitions, which automatically excluding any remaining partitions from the search. Because partitions can be altered after a partitioned table has been created, you can reorganize your data to enhance frequent queries that may not have been often used when the partitioning scheme was first set up. This ability to exclude non-matching partitions (and thus any rows they contain) is often referred to as *partition pruning*, and was implemented in MySQL 5.1.6. For more information, see Partition Pruning.

Other benefits usually associated with partitioning include those in the following list. These features are not currently implemented in MySQL Partitioning, but are high on our list of priorities.

- Queries involving aggregate functions such as `SUM()` [1047] and `COUNT()` [1045] can easily be parallelized. A simple example of such a query might be `SELECT salesperson_id, COUNT(orders) as order_total FROM sales GROUP BY salesperson_id;`. By "parallelized," we mean that the query can be run simultaneously on each partition, and the final result obtained merely by summing the results obtained for all partitions.
- Achieving greater query throughput in virtue of spreading data seeks over multiple disks.

Be sure to check this section and chapter frequently for updates as MySQL Partitioning development continues.

Partitioning Types

This section discusses the types of partitioning which are available in MySQL 5.1. These include the types listed here:

- **`RANGE` partitioning.** This type of partitioning assigns rows to partitions based on column values falling within a given range. See `RANGE` Partitioning.
- **`LIST` partitioning.** Similar to partitioning by `RANGE`, except that the partition is selected based on columns matching one of a set of discrete values. See `LIST` Partitioning.
- **`HASH` partitioning.** With this type of partitioning, a partition is selected based on the value returned by a user-defined expression that operates on column values in rows to be inserted into the table. The function may consist of any expression valid in MySQL that yields a nonnegative integer value. An extension to this type, `LINEAR HASH`, is also available. See `HASH` Partitioning.
- **`KEY` partitioning.** This type of partitioning is similar to partitioning by `HASH`, except that only one or more columns to be evaluated are supplied, and the MySQL server provides its own hashing

function. These columns can contain other than integer values, since the hashing function supplied by MySQL guarantees an integer result regardless of the column data type. An extension to this type, `LINEAR KEY`, is also available. See `KEY` Partitioning.

A very common use of database partitioning is to segregate data by date. Some database systems support explicit date partitioning, which MySQL does not implement in 5.1. However, it is not difficult in MySQL to create partitioning schemes based on `DATE`, `TIME`, or `DATETIME` columns, or based on expressions making use of such columns.

When partitioning by `KEY` or `LINEAR KEY`, you can use a `DATE`, `TIME`, or `DATETIME` column as the partitioning column without performing any modification of the column value. For example, this table creation statement is perfectly valid in MySQL:

```
CREATE TABLE members (
    firstname VARCHAR(25) NOT NULL,
    lastname VARCHAR(25) NOT NULL,
    username VARCHAR(16) NOT NULL,
    email VARCHAR(35),
    joined DATE NOT NULL
)
PARTITION BY KEY(joined)
PARTITIONS 6;
```

MySQL's other partitioning types, however, require a partitioning expression that yields an integer value or `NULL`. If you wish to use date-based partitioning by `RANGE`, `LIST`, `HASH`, or `LINEAR HASH`, you can simply employ a function that operates on a `DATE`, `TIME`, or `DATETIME` column and returns such a value, as shown here:

```
CREATE TABLE members (
    firstname VARCHAR(25) NOT NULL,
    lastname VARCHAR(25) NOT NULL,
    username VARCHAR(16) NOT NULL,
    email VARCHAR(35),
    joined DATE NOT NULL
)
PARTITION BY RANGE( YEAR(joined) ) (
    PARTITION p0 VALUES LESS THAN (1960),
    PARTITION p1 VALUES LESS THAN (1970),
    PARTITION p2 VALUES LESS THAN (1980),
    PARTITION p3 VALUES LESS THAN (1990),
    PARTITION p4 VALUES LESS THAN MAXVALUE
);
```

Additional examples of partitioning using dates may be found in the following sections of this chapter:

- `RANGE` Partitioning
- `HASH` Partitioning
- `LINEAR HASH` Partitioning

For more complex examples of date-based partitioning, see the following sections:

- Partition Pruning
- Subpartitioning

MySQL partitioning is optimized for use with the `TO_DAYS()` [994] and `YEAR()` [997] functions. However, you can use other date and time functions that return an integer or `NULL`, such as `WEEKDAY()` [997], `DAYOFYEAR()` [987], or `MONTH()` [989]. See Date and Time Functions, for more information about such functions.

It is important to remember—regardless of the type of partitioning that you use—that partitions are always numbered automatically and in sequence when created, starting with `0`. When a new row is

inserted into a partitioned table, it is these partition numbers that are used in identifying the correct partition. For example, if your table uses 4 partitions, these partitions are numbered `0`, `1`, `2`, and `3`. For the `RANGE` and `LIST` partitioning types, it is necessary to ensure that there is a partition defined for each partition number. For `HASH` partitioning, the user function employed must return an integer value greater than `0`. For `KEY` partitioning, this issue is taken care of automatically by the hashing function which the MySQL server employs internally.

Names of partitions generally follow the rules governing other MySQL identifiers, such as those for tables and databases. However, you should note that partition names are not case-sensitive. For example, the following `CREATE TABLE` statement fails as shown:

```
mysql> CREATE TABLE t2 (val INT)
    -> PARTITION BY LIST(val)(
    ->     PARTITION mypart VALUES IN (1,3,5),
    ->     PARTITION MyPart VALUES IN (2,4,6)
    -> );
ERROR 1488 (HY000): Duplicate partition name mypart
```

Failure occurs because MySQL sees no difference between the partition names `mypart` and `MyPart`.

When you specify the number of partitions for the table, this must be expressed as a positive, nonzero integer literal with no leading zeros, and may not be an expression such as `0.8E+01` or `6-2`, even if it evaluates to an integer value. (Beginning with MySQL 5.1.12, decimal fractions are no longer truncated, but instead are prohibited entirely.)

In the sections that follow, we do not necessarily provide all possible forms for the syntax that can be used for creating each partition type; this information may be found in `CREATE TABLE` Syntax.

`RANGE` Partitioning

A table that is partitioned by range is partitioned in such a way that each partition contains rows for which the partitioning expression value lies within a given range. Ranges should be contiguous but not overlapping, and are defined using the `VALUES LESS THAN` operator. For the next few examples, suppose that you are creating a table such as the following to hold personnel records for a chain of 20 video stores, numbered 1 through 20:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
);
```

This table can be partitioned by range in a number of ways, depending on your needs. One way would be to use the `store_id` column. For instance, you might decide to partition the table 4 ways by adding a `PARTITION BY RANGE` clause as shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
    PARTITION p0 VALUES LESS THAN (6),
    PARTITION p1 VALUES LESS THAN (11),
    PARTITION p2 VALUES LESS THAN (16),
    PARTITION p3 VALUES LESS THAN (21)
);
```

In this partitioning scheme, all rows corresponding to employees working at stores 1 through 5 are stored in partition `p0`, to those employed at stores 6 through 10 are stored in partition `p1`, and so on. Note that each partition is defined in order, from lowest to highest. This is a requirement of the `PARTITION BY RANGE` syntax; you can think of it as being analogous to a series of `if ... elseif ...` statements in C or Java in this regard.

It is easy to determine that a new row containing the data `(72, 'Michael', 'Widenius', '1998-06-25', NULL, 13)` is inserted into partition `p2`, but what happens when your chain adds a 21st store? Under this scheme, there is no rule that covers a row whose `store_id` is greater than 20, so an error results because the server does not know where to place it. You can keep this from occurring by using a "catchall" `VALUES LESS THAN` clause in the `CREATE TABLE` statement that provides for all values greater than the highest value explicitly named:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
    PARTITION p0 VALUES LESS THAN (6),
    PARTITION p1 VALUES LESS THAN (11),
    PARTITION p2 VALUES LESS THAN (16),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

Note

Another way to avoid an error when no matching value is found is to use the `IGNORE` keyword as part of the `INSERT` statement. For an example, see `LIST` Partitioning. Also see `INSERT` Syntax, for general information about `IGNORE`.

`MAXVALUE` represents an integer value that is always greater than the largest possible integer value (in mathematical language, it serves as a *least upper bound*). Now, any rows whose `store_id` column value is greater than or equal to 16 (the highest value defined) are stored in partition `p3`. At some point in the future—when the number of stores has increased to 25, 30, or more—you can use an `ALTER TABLE` statement to add new partitions for stores 21-25, 26-30, and so on (see Partition Management, for details of how to do this).

In much the same fashion, you could partition the table based on employee job codes—that is, based on ranges of `job_code` column values. For example—assuming that two-digit job codes are used for regular (in-store) workers, three-digit codes are used for office and support personnel, and four-digit codes are used for management positions—you could create the partitioned table using the following statement:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
)
PARTITION BY RANGE (job_code) (
    PARTITION p0 VALUES LESS THAN (100),
    PARTITION p1 VALUES LESS THAN (1000),
    PARTITION p2 VALUES LESS THAN (10000)
);
```

In this instance, all rows relating to in-store workers would be stored in partition `p0`, those relating to office and support staff in `p1`, and those relating to managers in partition `p2`.

It is also possible to use an expression in `VALUES LESS THAN` clauses. However, MySQL must be able to evaluate the expression's return value as part of a `LESS THAN` (`<`) comparison.

Rather than splitting up the table data according to store number, you can use an expression based on one of the two `DATE` columns instead. For example, let us suppose that you wish to partition based on the year that each employee left the company; that is, the value of `YEAR(separated)` [997]. An example of a `CREATE TABLE` statement that implements such a partitioning scheme is shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY RANGE ( YEAR(separated) ) (
    PARTITION p0 VALUES LESS THAN (1991),
    PARTITION p1 VALUES LESS THAN (1996),
    PARTITION p2 VALUES LESS THAN (2001),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

In this scheme, for all employees who left before 1991, the rows are stored in partition `p0`; for those who left in the years 1991 through 1995, in `p1`; for those who left in the years 1996 through 2000, in `p2`; and for any workers who left after the year 2000, in `p3`.

Beginning with MySQL 5.1.43, it is also possible to partition a table by `RANGE` based on the value of a `TIMESTAMP` column, using the `UNIX_TIMESTAMP()` [995] function, as shown in this example:

```
CREATE TABLE quarterly_report_status (
    report_id INT NOT NULL,
    report_status VARCHAR(20) NOT NULL,
    report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
)
PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) (
    PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),
    PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),
    PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),
    PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-10-01 00:00:00') ),
    PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),
    PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),
    PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),
    PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),
    PARTITION p8 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),
    PARTITION p9 VALUES LESS THAN (MAXVALUE)
);
```

Also beginning with MySQL 5.1.43, any other expressions involving `TIMESTAMP` values are not permitted. (See Bug #42849.)

Note

It is also possible in MySQL 5.1.43 and later to use `UNIX_TIMESTAMP(`*`timestamp_column`*`)` [995] as a partitioning expression for tables that are partitioned by `LIST`. However, it is usually not practical to do so.

Range partitioning is particularly useful when one or more of the following conditions is true:

- You want or need to delete “old” data. If you are using the partitioning scheme shown immediately above, you can simply use `ALTER TABLE employees DROP PARTITION p0;` to delete all rows relating to employees who stopped working for the firm prior to 1991. (See `ALTER TABLE` Syntax, and Partition Management, for more information.) For a table with a great many rows, this can be much more efficient than running a `DELETE` query such as `DELETE FROM employees WHERE YEAR(separated) <= 1990;`.

- You want to use a column containing date or time values, or containing values arising from some other series.
- You frequently run queries that depend directly on the column used for partitioning the table. For example, when executing a query such as `EXPLAIN PARTITIONS SELECT COUNT(*) FROM employees WHERE separated BETWEEN '2000-01-01' AND '2000-12-31' GROUP BY store_id;`, MySQL can quickly determine that only partition `p2` needs to be scanned because the remaining partitions cannot contain any records satisfying the `WHERE` clause. See Partition Pruning, for more information about how this is accomplished.

LIST Partitioning

List partitioning in MySQL is similar to range partitioning in many ways. As in partitioning by `RANGE`, each partition must be explicitly defined. The chief difference between the two types of partitioning is that, in list partitioning, each partition is defined and selected based on the membership of a column value in one of a set of value lists, rather than in one of a set of contiguous ranges of values. This is done by using `PARTITION BY LIST(expr)` where *`expr`* is a column value or an expression based on a column value and returning an integer value, and then defining each partition by means of a `VALUES IN (value_list)`, where *`value_list`* is a comma-separated list of integers.

Note

In MySQL 5.1, it is possible to match against only a list of integers (and possibly `NULL`—see How MySQL Partitioning Handles `NULL`) when partitioning by `LIST`.

Unlike the case with partitions defined by range, list partitions do not need to be declared in any particular order. For more detailed syntactical information, see `CREATE TABLE` Syntax.

For the examples that follow, we assume that the basic definition of the table to be partitioned is provided by the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
);
```

(This is the same table used as a basis for the examples in `RANGE` Partitioning.)

Suppose that there are 20 video stores distributed among 4 franchises as shown in the following table.

Region	Store ID Numbers
North	3, 5, 6, 9, 17
East	1, 2, 10, 11, 19, 20
West	4, 12, 13, 14, 18
Central	7, 8, 15, 16

To partition this table in such a way that rows for stores belonging to the same region are stored in the same partition, you could use the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
```

```
    store_id INT
)
PARTITION BY LIST(store_id) (
    PARTITION pNorth VALUES IN (3,5,6,9,17),
    PARTITION pEast VALUES IN (1,2,10,11,19,20),
    PARTITION pWest VALUES IN (4,12,13,14,18),
    PARTITION pCentral VALUES IN (7,8,15,16)
);
```

This makes it easy to add or drop employee records relating to specific regions to or from the table. For instance, suppose that all stores in the West region are sold to another company. All rows relating to employees working at stores in that region can be deleted with an `ALTER TABLE employees DROP PARTITION pWest` statement, which can be executed much more efficiently than the equivalent `DELETE` statement (`DELETE FROM employees WHERE store_id IN (4,12,13,14,18)`). However, the `ALTER TABLE ... DROP PARTITION` statement also removes the partition itself from the definition for the table, and you must execute an `ALTER TABLE ... ADD PARTITION` statement to restore the table's original partitioning scheme. (This problem is resolved in MySQL 5.5, which adds the `ALTER TABLE ... TRUNCATE PARTITION` statement for removing all rows from a given partition without affecting the table definition.)

As with `RANGE` partitioning, it is possible to combine `LIST` partitioning with partitioning by hash or key to produce a composite partitioning (subpartitioning). See Subpartitioning.

Unlike the case with `RANGE` partitioning, there is no “catch-all” such as `MAXVALUE`; all expected values for the partitioning expression should be covered in `PARTITION ... VALUES IN (...)` clauses. An `INSERT` statement containing an unmatched partitioning column value fails with an error, as shown in this example:

```
mysql> CREATE TABLE h2 (
    ->   c1 INT,
    ->   c2 INT
    -> )
    -> PARTITION BY LIST(c1) (
    ->   PARTITION p0 VALUES IN (1, 4, 7),
    ->   PARTITION p1 VALUES IN (2, 5, 8)
    -> );
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO h2 VALUES (3, 5);
ERROR 1525 (HY000): Table has no partition for value 3
```

When inserting multiple rows using a single `INSERT` statement, any rows coming before the row containing the unmatched value are inserted, but any coming after it are not:

```
mysql> SELECT * FROM h2;
Empty set (0.00 sec)

mysql> INSERT INTO h2 VALUES (4, 7), (3, 5), (6, 0);
ERROR 1525 (HY000): Table has no partition for value 3
mysql> SELECT * FROM h2;
+------+------+
| c1   | c2   |
+------+------+
|    4 |    7 |
+------+------+
1 row in set (0.00 sec)
```

You can cause this type of error to be ignored by using the `IGNORE` keyword. If you do so, rows containing unmatched partitioning column values are not inserted, but any rows with matching values *are* inserted, and no errors are reported:

```
mysql> TRUNCATE h2;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM h2;
Empty set (0.00 sec)
```

```
mysql> INSERT IGNORE INTO h2 VALUES (2, 5), (6, 10), (7, 5), (3, 1), (1, 9);
Query OK, 3 rows affected (0.00 sec)
Records: 5  Duplicates: 2  Warnings: 0

mysql> SELECT * FROM h2;
+------+------+
| c1   | c2   |
+------+------+
|    7 |    5 |
|    1 |    9 |
|    2 |    5 |
+------+------+
3 rows in set (0.00 sec)
```

HASH Partitioning

Partitioning by HASH is used primarily to ensure an even distribution of data among a predetermined number of partitions. With range or list partitioning, you must specify explicitly into which partition a given column value or set of column values is to be stored; with hash partitioning, MySQL takes care of this for you, and you need only specify a column value or expression based on a column value to be hashed and the number of partitions into which the partitioned table is to be divided.

To partition a table using HASH partitioning, it is necessary to append to the CREATE TABLE statement a PARTITION BY HASH (*expr*) clause, where *expr* is an expression that returns an integer. This can simply be the name of a column whose type is one of MySQL's integer types. In addition, you will most likely want to follow this with a PARTITIONS *num* clause, where *num* is a positive integer representing the number of partitions into which the table is to be divided.

For example, the following statement creates a table that uses hashing on the store_id column and is divided into 4 partitions:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY HASH(store_id)
PARTITIONS 4;
```

If you do not include a PARTITIONS clause, the number of partitions defaults to 1.

Using the PARTITIONS keyword without a number following it results in a syntax error.

You can also use an SQL expression that returns an integer for *expr*. For instance, you might want to partition based on the year in which an employee was hired. This can be done as shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY HASH( YEAR(hired) )
PARTITIONS 4;
```

expr must return a nonconstant, nonrandom integer value (in other words, it should be varying but deterministic), and must not contain any prohibited constructs as described in Restrictions and Limitations on Partitioning. You should also keep in mind that this expression is evaluated each time a row is inserted or updated (or possibly deleted); this means that very complex expressions may give

rise to performance issues, particularly when performing operations (such as batch inserts) that affect a great many rows at one time.

The most efficient hashing function is one which operates upon a single table column and whose value increases or decreases consistently with the column value, as this allows for “pruning” on ranges of partitions. That is, the more closely that the expression varies with the value of the column on which it is based, the more efficiently MySQL can use the expression for hash partitioning.

For example, where `date_col` is a column of type `DATE`, then the expression `TO_DAYS(date_col)` [994] is said to vary directly with the value of `date_col`, because for every change in the value of `date_col`, the value of the expression changes in a consistent manner. The variance of the expression `YEAR(date_col)` [997] with respect to `date_col` is not quite as direct as that of `TO_DAYS(date_col)` [994], because not every possible change in `date_col` produces an equivalent change in `YEAR(date_col)` [997]. Even so, `YEAR(date_col)` [997] is a good candidate for a hashing function, because it varies directly with a portion of `date_col` and there is no possible change in `date_col` that produces a disproportionate change in `YEAR(date_col)` [997].

By way of contrast, suppose that you have a column named `int_col` whose type is `INT`. Now consider the expression `POW(5-int_col,3) + 6` [975]. This would be a poor choice for a hashing function because a change in the value of `int_col` is not guaranteed to produce a proportional change in the value of the expression. Changing the value of `int_col` by a given amount can produce by widely different changes in the value of the expression. For example, changing `int_col` from `5` to `6` produces a change of `-1` in the value of the expression, but changing the value of `int_col` from `6` to `7` produces a change of `-7` in the expression value.

In other words, the more closely the graph of the column value *versus* the value of the expression follows a straight line as traced by the equation `y=cx` where *`c`* is some nonzero constant, the better the expression is suited to hashing. This has to do with the fact that the more nonlinear an expression is, the more uneven the distribution of data among the partitions it tends to produce.

In theory, pruning is also possible for expressions involving more than one column value, but determining which of such expressions are suitable can be quite difficult and time-consuming. For this reason, the use of hashing expressions involving multiple columns is not particularly recommended.

When `PARTITION BY HASH` is used, MySQL determines which partition of *`num`* partitions to use based on the modulus of the result of the user function. In other words, for an expression *`expr`*, the partition in which the record is stored is partition number *`N`*, where *`N = MOD(expr, num)`*. Suppose that table `t1` is defined as follows, so that it has 4 partitions:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
    PARTITION BY HASH( YEAR(col3) )
    PARTITIONS 4;
```

If you insert a record into `t1` whose `col3` value is `'2005-09-15'`, then the partition in which it is stored is determined as follows:

```
MOD(YEAR('2005-09-01'),4)
=  MOD(2005,4)
=  1
```

MySQL 5.1 also supports a variant of `HASH` partitioning known as *linear hashing* which employs a more complex algorithm for determining the placement of new rows inserted into the partitioned table. See `LINEAR HASH` Partitioning, for a description of this algorithm.

The user function is evaluated each time a record is inserted or updated. It may also—depending on the circumstances—be evaluated when records are deleted.

Note

If a table to be partitioned has a `UNIQUE` key, then any columns supplied as arguments to the `HASH` user function or to the `KEY`'s *`column_list`* must be part of that key.

LINEAR HASH Partitioning

MySQL also supports linear hashing, which differs from regular hashing in that linear hashing utilizes a linear powers-of-two algorithm whereas regular hashing employs the modulus of the hashing function's value.

Syntactically, the only difference between linear-hash partitioning and regular hashing is the addition of the `LINEAR` keyword in the `PARTITION BY` clause, as shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY LINEAR HASH( YEAR(hired) )
PARTITIONS 4;
```

Given an expression *`expr`*, the partition in which the record is stored when linear hashing is used is partition number *`N`* from among *`num`* partitions, where *`N`* is derived according to the following algorithm:

1. Find the next power of 2 greater than *`num`*. We call this value *`V`*; it can be calculated as:

   ```
   V = POWER(2, CEILING(LOG(2, num)))
   ```

   (Suppose that *`num`* is 13. Then `LOG(2,13)` [974] is 3.7004397181411. `CEILING(3.7004397181411)` [972] is 4, and *`V`* = `POWER(2,4)` [975], which is 16.)

2. Set *`N`* = *`F`*(*`column_list`*) & (*`V`* - 1).

3. While *`N`* >= *`num`*:

   - Set *`V`* = CEIL(*`V`* / 2)
   - Set *`N`* = *`N`* & (*`V`* - 1)

Suppose that the table `t1`, using linear hash partitioning and having 6 partitions, is created using this statement:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
    PARTITION BY LINEAR HASH( YEAR(col3) )
    PARTITIONS 6;
```

Now assume that you want to insert two records into `t1` having the `col3` column values `'2003-04-14'` and `'1998-10-19'`. The partition number for the first of these is determined as follows:

```
V = POWER(2, CEILING( LOG(2,6) )) = 8
N = YEAR('2003-04-14') & (8 - 1)
   = 2003 & 7
   = 3

(3 >= 6 is FALSE: record stored in partition #3)
```

The number of the partition where the second record is stored is calculated as shown here:

```
V = 8
N = YEAR('1998-10-19') & (8-1)
  = 1998 & 7
  = 6

(6 >= 6 is TRUE: additional step required)
```

```
N = 6 & CEILING(8 / 2)
  = 6 & 3
  = 2

(2 >= 6 is FALSE: record stored in partition #2)
```

The advantage in partitioning by linear hash is that the adding, dropping, merging, and splitting of partitions is made much faster, which can be beneficial when dealing with tables containing extremely large amounts (terabytes) of data. The disadvantage is that data is less likely to be evenly distributed between partitions as compared with the distribution obtained using regular hash partitioning.

KEY Partitioning

Partitioning by key is similar to partitioning by hash, except that where hash partitioning employs a user-defined expression, the hashing function for key partitioning is supplied by the MySQL server. MySQL Cluster uses `MD5()` [1030] for this purpose; for tables using other storage engines, the server employs its own internal hashing function which is based on the same algorithm as `PASSWORD()` [1030].

The syntax rules for `CREATE TABLE ... PARTITION BY KEY` are similar to those for creating a table that is partitioned by hash. The major differences are listed here:

- `KEY` is used rather than `HASH`.
- `KEY` takes only a list of one or more column names. Beginning with MySQL 5.1.5, the column or columns used as the partitioning key must comprise part or all of the table's primary key, if the table has one.

  Beginning with MySQL 5.1.6, `KEY` takes a list of zero or more column names. Where no column name is specified as the partitioning key, the table's primary key is used, if there is one. For example, the following `CREATE TABLE` statement is valid in MySQL 5.1.6 or later:

  ```
  CREATE TABLE k1 (
      id INT NOT NULL PRIMARY KEY,
      name VARCHAR(20)
  )
  PARTITION BY KEY()
  PARTITIONS 2;
  ```

  If there is no primary key but there is a unique key, then the unique key is used for the partitioning key:

  ```
  CREATE TABLE k1 (
      id INT NOT NULL,
      name VARCHAR(20),
      UNIQUE KEY (id)
  )
  PARTITION BY KEY()
  PARTITIONS 2;
  ```

  However, if the unique key column were not defined as `NOT NULL`, then the previous statement would fail.

  In both of these cases, the partitioning key is the `id` column, even though it is not shown in the output of `SHOW CREATE TABLE` or in the `PARTITION_EXPRESSION` column of the `INFORMATION_SCHEMA.PARTITIONS` table.

  Unlike the case with other partitioning types, columns used for partitioning by `KEY` are not restricted to integer or `NULL` values. For example, the following `CREATE TABLE` statement is valid:

  ```
  CREATE TABLE tm1 (
      s1 CHAR(32) PRIMARY KEY
  )
  PARTITION BY KEY(s1)
  PARTITIONS 10;
  ```

The preceding statement would *not* be valid, were a different partitioning type to be specified. (In this case, simply using `PARTITION BY KEY()` would also be valid and have the same effect as `PARTITION BY KEY(s1)`, since `s1` is the table's primary key.)

For additional information about this issue, see Restrictions and Limitations on Partitioning.

Note

Also beginning with MySQL 5.1.6, tables using the `NDBCLUSTER` storage engine are implicitly partitioned by `KEY`, again using the table's primary key as the partitioning key. In the event that the MySQL Cluster table has no explicit primary key, the “hidden” primary key generated by the `NDBCLUSTER` storage engine for each MySQL Cluster table is used as the partitioning key.

Beginning with MySQL Cluster NDB 6.2.18, MySQL Cluster NDB 6.3.25, and MySQL Cluster NDB 7.0.6, if you define an explicit partitioning scheme for an `NDBCLUSTER` table, the table must have an explicit primary key, and any columns used in the partitioning expression must be part of this key. However, if the table uses an “empty” partitioning expression—that is, `PARTITION BY KEY()` with no column references—then no explicit primary key is required.

You can observe this partitioning using the `ndb_desc` utility (with the `-p` option).

Important

For a key-partitioned table using any MySQL storage engine other than `NDBCLUSTER`, you cannot execute an `ALTER TABLE DROP PRIMARY KEY`, as doing so generates the error `ERROR 1466 (HY000): Field in list of fields for partition function not found in table`. This is not an issue for MySQL Cluster tables which are partitioned by `KEY`; in such cases, the table is reorganized using the “hidden” primary key as the table's new partitioning key. See Chapter 17, *MySQL Cluster NDB 6.1 - 7.1*.

It is also possible to partition a table by linear key. Here is a simple example:

```
CREATE TABLE tk (
    col1 INT NOT NULL,
    col2 CHAR(5),
    col3 DATE
)
PARTITION BY LINEAR KEY (col1)
PARTITIONS 3;
```

Using `LINEAR` has the same effect on `KEY` partitioning as it does on `HASH` partitioning, with the partition number being derived using a powers-of-two algorithm rather than modulo arithmetic. See `LINEAR HASH` Partitioning, for a description of this algorithm and its implications.

Subpartitioning

Subpartitioning—also known as *composite partitioning*—is the further division of each partition in a partitioned table. Consider the following `CREATE TABLE` statement:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) )
    SUBPARTITIONS 2 (
        PARTITION p0 VALUES LESS THAN (1990),
        PARTITION p1 VALUES LESS THAN (2000),
        PARTITION p2 VALUES LESS THAN MAXVALUE
    );
```

Table `ts` has 3 `RANGE` partitions. Each of these partitions—`p0`, `p1`, and `p2`—is further divided into 2 subpartitions. In effect, the entire table is divided into `3 * 2 = 6` partitions. However, due to the action of the `PARTITION BY RANGE` clause, the first 2 of these store only those records with a value less than 1990 in the `purchased` column.

In MySQL 5.1, it is possible to subpartition tables that are partitioned by `RANGE` or `LIST`. Subpartitions may use either `HASH` or `KEY` partitioning. This is also known as *composite partitioning*.

Note

`SUBPARTITION BY HASH` and `SUBPARTITION BY KEY` generally follow the same syntax rules as `PARTITION BY HASH` and `PARTITION BY KEY`, respectively. An exception to this is that `SUBPARTITION BY KEY` (unlike `PARTITION BY KEY`) does not currently support a default column, so the column used for this purpose must be specified, even if the table has an explicit primary key. This is a known issue which we are working to address; see Issues with subpartitions, for more information and an example.

It is also possible to define subpartitions explicitly using `SUBPARTITION` clauses to specify options for individual subpartitions. For example, a more verbose fashion of creating the same table `ts` as shown in the previous example would be:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990) (
            SUBPARTITION s0,
            SUBPARTITION s1
        ),
        PARTITION p1 VALUES LESS THAN (2000) (
            SUBPARTITION s2,
            SUBPARTITION s3
        ),
        PARTITION p2 VALUES LESS THAN MAXVALUE (
            SUBPARTITION s4,
            SUBPARTITION s5
        )
    );
```

Some syntactical items of note are listed here:

- Each partition must have the same number of subpartitions.
- If you explicitly define any subpartitions using `SUBPARTITION` on any partition of a partitioned table, you must define them all. In other words, the following statement will fail:

  ```
  CREATE TABLE ts (id INT, purchased DATE)
      PARTITION BY RANGE( YEAR(purchased) )
      SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
          PARTITION p0 VALUES LESS THAN (1990) (
              SUBPARTITION s0,
              SUBPARTITION s1
          ),
          PARTITION p1 VALUES LESS THAN (2000),
          PARTITION p2 VALUES LESS THAN MAXVALUE (
              SUBPARTITION s2,
              SUBPARTITION s3
          )
      );
  ```

  This statement would still fail even if it included a `SUBPARTITIONS 2` clause.

- Each `SUBPARTITION` clause must include (at a minimum) a name for the subpartition. Otherwise, you may set any desired option for the subpartition or allow it to assume its default setting for that option.

- In MySQL 5.1.7 and earlier, names of subpartitions were required to be unique within each partition, but did not have to be unique within the table as a whole. Beginning with MySQL 5.1.8, subpartition names must be unique across the entire table. For example, the following `CREATE TABLE` statement is valid in MySQL 5.1.8 and later:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990) (
            SUBPARTITION s0,
            SUBPARTITION s1
        ),
        PARTITION p1 VALUES LESS THAN (2000) (
            SUBPARTITION s2,
            SUBPARTITION s3
        ),
        PARTITION p2 VALUES LESS THAN MAXVALUE (
            SUBPARTITION s4,
            SUBPARTITION s5
        )
    );
```

  (The previous statement is also valid for versions of MySQL prior to 5.1.8.)

Subpartitions can be used with especially large tables to distribute data and indexes across many disks. Suppose that you have 6 disks mounted as `/disk0`, `/disk1`, `/disk2`, and so on. Now consider the following example:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990) (
            SUBPARTITION s0
                DATA DIRECTORY = '/disk0/data'
                INDEX DIRECTORY = '/disk0/idx',
            SUBPARTITION s1
                DATA DIRECTORY = '/disk1/data'
                INDEX DIRECTORY = '/disk1/idx'
        ),
        PARTITION p1 VALUES LESS THAN (2000) (
            SUBPARTITION s2
                DATA DIRECTORY = '/disk2/data'
                INDEX DIRECTORY = '/disk2/idx',
            SUBPARTITION s3
                DATA DIRECTORY = '/disk3/data'
                INDEX DIRECTORY = '/disk3/idx'
        ),
        PARTITION p2 VALUES LESS THAN MAXVALUE (
            SUBPARTITION s4
                DATA DIRECTORY = '/disk4/data'
                INDEX DIRECTORY = '/disk4/idx',
            SUBPARTITION s5
                DATA DIRECTORY = '/disk5/data'
                INDEX DIRECTORY = '/disk5/idx'
        )
    );
```

In this case, a separate disk is used for the data and for the indexes of each `RANGE`. Many other variations are possible; another example might be:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE(YEAR(purchased))
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990) (
            SUBPARTITION s0a
                DATA DIRECTORY = '/disk0'
                INDEX DIRECTORY = '/disk1',
            SUBPARTITION s0b
                DATA DIRECTORY = '/disk2'
                INDEX DIRECTORY = '/disk3'
```

```
        ),
        PARTITION p1 VALUES LESS THAN (2000) (
            SUBPARTITION s1a
                DATA DIRECTORY = '/disk4/data'
                INDEX DIRECTORY = '/disk4/idx',
            SUBPARTITION s1b
                DATA DIRECTORY = '/disk5/data'
                INDEX DIRECTORY = '/disk5/idx'
        ),
        PARTITION p2 VALUES LESS THAN MAXVALUE (
            SUBPARTITION s2a,
            SUBPARTITION s2b
        )
    );
```

Here, the storage is as follows:

- Rows with `purchased` dates from before 1990 take up a vast amount of space, so are split up 4 ways, with a separate disk dedicated to the data and to the indexes for each of the two subpartitions (`s0a` and `s0b`) making up partition `p0`. In other words:
  - The data for subpartition `s0a` is stored on `/disk0`.
  - The indexes for subpartition `s0a` are stored on `/disk1`.
  - The data for subpartition `s0b` is stored on `/disk2`.
  - The indexes for subpartition `s0b` are stored on `/disk3`.
- Rows containing dates ranging from 1990 to 1999 (partition `p1`) do not require as much room as those from before 1990. These are split between 2 disks (`/disk4` and `/disk5`) rather than 4 disks as with the legacy records stored in `p0`:
  - Data and indexes belonging to `p1`'s first subpartition (`s1a`) are stored on `/disk4`—the data in `/disk4/data`, and the indexes in `/disk4/idx`.
  - Data and indexes belonging to `p1`'s second subpartition (`s1b`) are stored on `/disk5`—the data in `/disk5/data`, and the indexes in `/disk5/idx`.
- Rows reflecting dates from the year 2000 to the present (partition `p2`) do not take up as much space as required by either of the two previous ranges. Currently, it is sufficient to store all of these in the default location.

  In future, when the number of purchases for the decade beginning with the year 2000 grows to a point where the default location no longer provides sufficient space, the corresponding rows can be moved using an `ALTER TABLE ... REORGANIZE PARTITION` statement. See Partition Management, for an explanation of how this can be done.

Beginning with MySQL 5.1.18, the `DATA DIRECTORY` and `INDEX DIRECTORY` options are not permitted in partition definitions when the `NO_DIR_IN_CREATE` [573] server SQL mode is in effect. However, this not true when defining subpartitions; this is a known issue which is fixed in MySQL 5.5 (Bug #42954).

How MySQL Partitioning Handles `NULL`

Partitioning in MySQL does nothing to disallow `NULL` as the value of a partitioning expression, whether it is a column value or the value of a user-supplied expression. Even though it is permitted to use `NULL` as the value of an expression that must otherwise yield an integer, it is important to keep in mind that `NULL` is not a number. Beginning with MySQL 5.1.8, the partitioning implementation treats `NULL` as being less than any non-`NULL` value, just as `ORDER BY` does.

This means that treatment of `NULL` varies between partitioning of different types, and may produce behavior which you do not expect if you are not prepared for it. This being the case, we discuss in

this section how each MySQL partitioning type handles NULL values when determining the partition in which a row should be stored, and provide examples for each.

Handling of NULL with RANGE partitioning. If you insert a row into a table partitioned by RANGE such that the column value used to determine the partition is NULL, the row is inserted into the lowest partition. Consider these two tables in a database named p, created as follows:

```
mysql> CREATE TABLE t1 (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> )
    -> PARTITION BY RANGE(c1) (
    ->     PARTITION p0 VALUES LESS THAN (0),
    ->     PARTITION p1 VALUES LESS THAN (10),
    ->     PARTITION p2 VALUES LESS THAN MAXVALUE
    -> );
Query OK, 0 rows affected (0.09 sec)

mysql> CREATE TABLE t2 (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> )
    -> PARTITION BY RANGE(c1) (
    ->     PARTITION p0 VALUES LESS THAN (-5),
    ->     PARTITION p1 VALUES LESS THAN (0),
    ->     PARTITION p2 VALUES LESS THAN (10),
    ->     PARTITION p3 VALUES LESS THAN MAXVALUE
    -> );
Query OK, 0 rows affected (0.09 sec)
```

You can see the partitions created by these two CREATE TABLE statements using the following query against the PARTITIONS table in the INFORMATION_SCHEMA database:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
     >   FROM INFORMATION_SCHEMA.PARTITIONS
     >   WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+----------------+------------+----------------+-------------+
| t1         | p0             |          0 |              0 |           0 |
| t1         | p1             |          0 |              0 |           0 |
| t1         | p2             |          0 |              0 |           0 |
| t2         | p0             |          0 |              0 |           0 |
| t2         | p1             |          0 |              0 |           0 |
| t2         | p2             |          0 |              0 |           0 |
| t2         | p3             |          0 |              0 |           0 |
+------------+----------------+------------+----------------+-------------+
7 rows in set (0.00 sec)
```

(For more information about this table, see The INFORMATION_SCHEMA PARTITIONS Table.) Now let us populate each of these tables with a single row containing a NULL in the column used as the partitioning key, and verify that the rows were inserted using a pair of SELECT statements:

```
mysql> INSERT INTO t1 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM t1;
+------+--------+
| id   | name   |
+------+--------+
| NULL | mothra |
+------+--------+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
+------+--------+
| id   | name   |
```

```
+------+--------+
| NULL | mothra |
+------+--------+
1 row in set (0.00 sec)
```

You can see which partitions are used to store the inserted rows by rerunning the previous query against INFORMATION_SCHEMA.PARTITIONS and inspecting the output:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
    >   FROM INFORMATION_SCHEMA.PARTITIONS
    >   WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+----------------+------------+----------------+-------------+
| t1         | p0             |          1 |             20 |          20 |
| t1         | p1             |          0 |              0 |           0 |
| t1         | p2             |          0 |              0 |           0 |
| t2         | p0             |          1 |             20 |          20 |
| t2         | p1             |          0 |              0 |           0 |
| t2         | p2             |          0 |              0 |           0 |
| t2         | p3             |          0 |              0 |           0 |
+------------+----------------+------------+----------------+-------------+
7 rows in set (0.01 sec)
```

You can also demonstrate that these rows were stored in the lowest partition of each table by dropping these partitions, and then re-running the SELECT statements:

```
mysql> ALTER TABLE t1 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> ALTER TABLE t2 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> SELECT * FROM t1;
Empty set (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

Important

Prior to MySQL 5.1.8, RANGE partitioning treated a partitioning expression value of NULL as 0 with respect to determining placement. (The only way to circumvent this behavior was to design tables so as not to permit nulls, usually by declaring columns NOT NULL.) If you have a RANGE partitioning scheme that depends on this earlier behavior, you must re-implement it when upgrading to MySQL 5.1.8 or later. (Bug #15447)

NULL is also treated in this way for partitioning expressions that use SQL functions. Suppose that we define a table using a CREATE TABLE statement such as this one:

```
CREATE TABLE tndate (
    id INT,
    dt DATE
)
PARTITION BY RANGE( YEAR(dt) ) (
    PARTITION p0 VALUES LESS THAN (1990),
    PARTITION p1 VALUES LESS THAN (2000),
    PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

As with other MySQL functions, YEAR(NULL) [997] returns NULL. A row with a dt column value of NULL is treated as though the partitioning expression evaluated to a value less than any other value, and so is inserted into partition p0.

Handling of NULL with LIST partitioning. A table that is partitioned by LIST admits NULL values if and only if one of its partitions is defined using that value-list that contains NULL. The converse of

this is that a table partitioned by LIST which does not explicitly use NULL in a value list rejects rows resulting in a NULL value for the partitioning expression, as shown in this example:

```
mysql> CREATE TABLE ts1 (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> )
    -> PARTITION BY LIST(c1) (
    ->     PARTITION p0 VALUES IN (0, 3, 6),
    ->     PARTITION p1 VALUES IN (1, 4, 7),
    ->     PARTITION p2 VALUES IN (2, 5, 8)
    -> );
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO ts1 VALUES (9, 'mothra');
ERROR 1504 (HY000): Table has no partition for value 9

mysql> INSERT INTO ts1 VALUES (NULL, 'mothra');
ERROR 1504 (HY000): Table has no partition for value NULL
```

Only rows having a c1 value between 0 and 8 inclusive can be inserted into ts1. NULL falls outside this range, just like the number 9. We can create tables ts2 and ts3 having value lists containing NULL, as shown here:

```
mysql> CREATE TABLE ts2 (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> )
    -> PARTITION BY LIST(c1) (
    ->     PARTITION p0 VALUES IN (0, 3, 6),
    ->     PARTITION p1 VALUES IN (1, 4, 7),
    ->     PARTITION p2 VALUES IN (2, 5, 8),
    ->     PARTITION p3 VALUES IN (NULL)
    -> );
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE ts3 (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> )
    -> PARTITION BY LIST(c1) (
    ->     PARTITION p0 VALUES IN (0, 3, 6),
    ->     PARTITION p1 VALUES IN (1, 4, 7, NULL),
    ->     PARTITION p2 VALUES IN (2, 5, 8)
    -> );
Query OK, 0 rows affected (0.01 sec)
```

When defining value lists for partitioning, you can (and should) treat NULL just as you would any other value. For example, both VALUES IN (NULL) and VALUES IN (1, 4, 7, NULL) are valid, as are VALUES IN (1, NULL, 4, 7), VALUES IN (NULL, 1, 4, 7), and so on. You can insert a row having NULL for column c1 into each of the tables ts2 and ts3:

```
mysql> INSERT INTO ts2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO ts3 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)
```

By issuing the appropriate query against INFORMATION_SCHEMA.PARTITIONS, you can determine which partitions were used to store the rows just inserted (we assume, as in the previous examples, that the partitioned tables were created in the p database):

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
     >   FROM INFORMATION_SCHEMA.PARTITIONS
     >   WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 'ts_';
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+----------------+------------+----------------+-------------+
| ts2        | p0             |          0 |              0 |           0 |
```

```
| ts2        | p1             |            0 |               0 |            0 |
| ts2        | p2             |            0 |               0 |            0 |
| ts2        | p3             |            1 |              20 |           20 |
| ts3        | p0             |            0 |               0 |            0 |
| ts3        | p1             |            1 |              20 |           20 |
| ts3        | p2             |            0 |               0 |            0 |
+------------+----------------+------------+-----------------+--------------+
7 rows in set (0.01 sec)
```

As shown earlier in this section, you can also verify which partitions were used for storing the rows by deleting these partitions and then performing a SELECT.

Handling of NULL with HASH and KEY partitioning. NULL is handled somewhat differently for tables partitioned by HASH or KEY. In these cases, any partition expression that yields a NULL value is treated as though its return value were zero. We can verify this behavior by examining the effects on the file system of creating a table partitioned by HASH and populating it with a record containing appropriate values. Suppose that you have a table th (also in the p database) created using the following statement:

```
mysql> CREATE TABLE th (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> )
    -> PARTITION BY HASH(c1)
    -> PARTITIONS 2;
Query OK, 0 rows affected (0.00 sec)
```

The partitions belonging to this table can be viewed using the query shown here:

```
mysql> SELECT TABLE_NAME,PARTITION_NAME,TABLE_ROWS,AVG_ROW_LENGTH,DATA_LENGTH
     >   FROM INFORMATION_SCHEMA.PARTITIONS
     >   WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME ='th';
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+----------------+------------+----------------+-------------+
| th         | p0             |          0 |              0 |           0 |
| th         | p1             |          0 |              0 |           0 |
+------------+----------------+------------+----------------+-------------+
2 rows in set (0.00 sec)
```

Note that TABLE_ROWS for each partition is 0. Now insert two rows into th whose c1 column values are NULL and 0, and verify that these rows were inserted, as shown here:

```
mysql> INSERT INTO th VALUES (NULL, 'mothra'), (0, 'gigan');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM th;
+------+---------+
| c1   | c2      |
+------+---------+
| NULL | mothra  |
+------+---------+
|    0 | gigan   |
+------+---------+
2 rows in set (0.01 sec)
```

Recall that for any integer *N*, the value of NULL MOD *N* is always NULL. For tables that are partitioned by HASH or KEY, this result is treated for determining the correct partition as 0. Checking the INFORMATION_SCHEMA.PARTITIONS table once again, we can see that both rows were inserted into partition p0:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
     >   FROM INFORMATION_SCHEMA.PARTITIONS
     >   WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME ='th';
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+----------------+------------+----------------+-------------+
| th         | p0             |          2 |             20 |          20 |
```

```
| th         | p1             |          0 |              0 |           0 |
+------------+----------------+------------+----------------+-------------+
2 rows in set (0.00 sec)
```

If you repeat this example using `PARTITION BY KEY` in place of `PARTITION BY HASH` in the definition of the table, you can verify easily that `NULL` is also treated like 0 for this type of partitioning.

Partition Management

MySQL 5.1 provides a number of ways to modify partitioned tables. It is possible to add, drop, redefine, merge, or split existing partitions. All of these actions can be carried out using the partitioning extensions to the `ALTER TABLE` statement `ALTER TABLE` Syntax. There are also ways to obtain information about partitioned tables and partitions. We discuss these topics in the sections that follow.

- For information about partition management in tables partitioned by `RANGE` or `LIST`, see Management of `RANGE` and `LIST` Partitions.
- For a discussion of managing `HASH` and `KEY` partitions, see Management of `HASH` and `KEY` Partitions.
- See Obtaining Information About Partitions, for a discussion of mechanisms provided in MySQL 5.1 for obtaining information about partitioned tables and partitions.
- For a discussion of performing maintenance operations on partitions, see Maintenance of Partitions.

Note

In MySQL 5.1, all partitions of a partitioned table must have the same number of subpartitions, and it is not possible to change the subpartitioning once the table has been created.

The statement `ALTER TABLE ... PARTITION BY ...` is available and is functional beginning with MySQL 5.1.6; previously in MySQL 5.1, this was accepted as valid syntax, but the statement did nothing.

To change a table's partitioning scheme, it is necessary only to use the `ALTER TABLE` statement with a *`partition_options`* clause. This clause has the same syntax as that as used with `CREATE TABLE` for creating a partitioned table, and always begins with the keywords `PARTITION BY`. Suppose that you have a table partitioned by range using the following `CREATE TABLE` statement:

```
CREATE TABLE trb3 (id INT, name VARCHAR(50), purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990),
        PARTITION p1 VALUES LESS THAN (1995),
        PARTITION p2 VALUES LESS THAN (2000),
        PARTITION p3 VALUES LESS THAN (2005)
    );
```

To repartition this table so that it is partitioned by key into two partitions using the `id` column value as the basis for the key, you can use this statement:

```
ALTER TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;
```

This has the same effect on the structure of the table as dropping the table and re-creating it using `CREATE TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;`.

In MySQL 5.1.7 and earlier MySQL 5.1 releases, `ALTER TABLE ... ENGINE = ...` removed all partitioning from the affected table. Beginning with MySQL 5.1.8, this statement changes only the storage engine used by the table, and leaves the table's partitioning scheme intact. As of MySQL 5.1.8, use `ALTER TABLE ... REMOVE PARTITIONING` to remove a table's partitioning. See `ALTER TABLE` Syntax.

Important

Only a single PARTITION BY, ADD PARTITION, DROP PARTITION, REORGANIZE PARTITION, or COALESCE PARTITION clause can be used in a given ALTER TABLE statement. If you (for example) wish to drop a partition and reorganize a table's remaining partitions, you must do so in two separate ALTER TABLE statements (one using DROP PARTITION and then a second one using REORGANIZE PARTITIONS).

Management of RANGE and LIST Partitions

Range and list partitions are very similar with regard to how the adding and dropping of partitions are handled. For this reason we discuss the management of both sorts of partitioning in this section. For information about working with tables that are partitioned by hash or key, see Management of HASH and KEY Partitions. Dropping a RANGE or LIST partition is more straightforward than adding one, so we discuss this first.

Dropping a partition from a table that is partitioned by either RANGE or by LIST can be accomplished using the ALTER TABLE statement with a DROP PARTITION clause. Here is a very basic example, which supposes that you have already created a table which is partitioned by range and then populated with 10 records using the following CREATE TABLE and INSERT statements:

```
mysql> CREATE TABLE tr (id INT, name VARCHAR(50), purchased DATE)
    ->     PARTITION BY RANGE( YEAR(purchased) ) (
    ->         PARTITION p0 VALUES LESS THAN (1990),
    ->         PARTITION p1 VALUES LESS THAN (1995),
    ->         PARTITION p2 VALUES LESS THAN (2000),
    ->         PARTITION p3 VALUES LESS THAN (2005)
    ->     );
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO tr VALUES
    ->     (1, 'desk organiser', '2003-10-15'),
    ->     (2, 'CD player', '1993-11-05'),
    ->     (3, 'TV set', '1996-03-10'),
    ->     (4, 'bookcase', '1982-01-10'),
    ->     (5, 'exercise bike', '2004-05-09'),
    ->     (6, 'sofa', '1987-06-05'),
    ->     (7, 'popcorn maker', '2001-11-22'),
    ->     (8, 'aquarium', '1992-08-04'),
    ->     (9, 'study desk', '1984-09-16'),
    ->     (10, 'lava lamp', '1998-12-25');
Query OK, 10 rows affected (0.01 sec)
```

You can see which items should have been inserted into partition p2 as shown here:

```
mysql> SELECT * FROM tr
    -> WHERE purchased BETWEEN '1995-01-01' AND '1999-12-31';
+------+-----------+------------+
| id   | name      | purchased  |
+------+-----------+------------+
|    3 | TV set    | 1996-03-10 |
|   10 | lava lamp | 1998-12-25 |
+------+-----------+------------+
2 rows in set (0.00 sec)
```

To drop the partition named p2, execute the following command:

```
mysql> ALTER TABLE tr DROP PARTITION p2;
Query OK, 0 rows affected (0.03 sec)
```

Note

The NDBCLUSTER storage engine does not support ALTER TABLE ... DROP PARTITION. It does, however, support the other partitioning-related extensions to ALTER TABLE that are described in this chapter.

It is very important to remember that, *when you drop a partition, you also delete all the data that was stored in that partition*. You can see that this is the case by re-running the previous SELECT query:

```
mysql> SELECT * FROM tr WHERE purchased
    -> BETWEEN '1995-01-01' AND '1999-12-31';
Empty set (0.00 sec)
```

Because of this, the requirement was added in MySQL 5.1.10 that you have the DROP [626] privilege for a table before you can execute ALTER TABLE ... DROP PARTITION on that table.

If you wish to drop all data from all partitions while preserving the table definition and its partitioning scheme, use the TRUNCATE TABLE statement. (See TRUNCATE TABLE Syntax.)

If you intend to change the partitioning of a table *without* losing data, use ALTER TABLE ... REORGANIZE PARTITION instead. See below or in ALTER TABLE Syntax, for information about REORGANIZE PARTITION.

If you now execute a SHOW CREATE TABLE statement, you can see how the partitioning makeup of the table has been changed:

```
mysql> SHOW CREATE TABLE tr\G
*************************** 1. row ***************************
       Table: tr
Create Table: CREATE TABLE `tr` (
  `id` int(11) default NULL,
  `name` varchar(50) default NULL,
  `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE ( YEAR(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.01 sec)
```

When you insert new rows into the changed table with purchased column values between '1995-01-01' and '2004-12-31' inclusive, those rows will be stored in partition p3. You can verify this as follows:

```
mysql> INSERT INTO tr VALUES (11, 'pencil holder', '1995-07-12');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM tr WHERE purchased
    -> BETWEEN '1995-01-01' AND '2004-12-31';
+------+---------------+------------+
| id   | name          | purchased  |
+------+---------------+------------+
|   11 | pencil holder | 1995-07-12 |
|    1 | desk organiser | 2003-10-15 |
|    5 | exercise bike | 2004-05-09 |
|    7 | popcorn maker | 2001-11-22 |
+------+---------------+------------+
4 rows in set (0.00 sec)

mysql> ALTER TABLE tr DROP PARTITION p3;
Query OK, 0 rows affected (0.03 sec)

mysql> SELECT * FROM tr WHERE purchased
    -> BETWEEN '1995-01-01' AND '2004-12-31';
Empty set (0.00 sec)
```

Note that the number of rows dropped from the table as a result of ALTER TABLE ... DROP PARTITION is not reported by the server as it would be by the equivalent DELETE query.

Dropping LIST partitions uses exactly the same ALTER TABLE ... DROP PARTITION syntax as used for dropping RANGE partitions. However, there is one important difference in the effect this has on your use of the table afterward: You can no longer insert into the table any rows having any of the

values that were included in the value list defining the deleted partition. (See LIST Partitioning, for an example.)

To add a new range or list partition to a previously partitioned table, use the ALTER TABLE ... ADD PARTITION statement. For tables which are partitioned by RANGE, this can be used to add a new range to the end of the list of existing partitions. Suppose that you have a partitioned table containing membership data for your organization, which is defined as follows:

```
CREATE TABLE members (
    id INT,
    fname VARCHAR(25),
    lname VARCHAR(25),
    dob DATE
)
PARTITION BY RANGE( YEAR(dob) ) (
    PARTITION p0 VALUES LESS THAN (1970),
    PARTITION p1 VALUES LESS THAN (1980),
    PARTITION p2 VALUES LESS THAN (1990)
);
```

Suppose further that the minimum age for members is 16. As the calendar approaches the end of 2005, you realize that you will soon be admitting members who were born in 1990 (and later in years to come). You can modify the members table to accommodate new members born in the years 1990 to 1999 as shown here:

```
ALTER TABLE ADD PARTITION (PARTITION p3 VALUES LESS THAN (2000));
```

Important

With tables that are partitioned by range, you can use ADD PARTITION to add new partitions to the high end of the partitions list only. Trying to add a new partition in this manner between or before existing partitions will result in an error as shown here:

```
mysql> ALTER TABLE members
    >     ADD PARTITION (
    >     PARTITION p3 VALUES LESS THAN (1960));
ERROR 1463 (HY000): VALUES LESS THAN value must be strictly »
   increasing for each partition
```

In a similar fashion, you can add new partitions to a table that is partitioned by LIST. Suppose a table tt is defined using the following CREATE TABLE statement:

```
CREATE TABLE tt (
    id INT,
    data INT
)
PARTITION BY LIST(data) (
    PARTITION p0 VALUES IN (5, 10, 15),
    PARTITION p1 VALUES IN (6, 12, 18)
);
```

You can add a new partition in which to store rows having the data column values 7, 14, and 21 as shown:

```
ALTER TABLE tt ADD PARTITION (PARTITION p2 VALUES IN (7, 14, 21));
```

Note that you *cannot* add a new LIST partition encompassing any values that are already included in the value list of an existing partition. If you attempt to do so, an error will result:

```
mysql> ALTER TABLE tt ADD PARTITION
    >     (PARTITION np VALUES IN (4, 8, 12));
ERROR 1465 (HY000): Multiple definition of same constant »
                    in list partitioning
```

Because any rows with the data column value 12 have already been assigned to partition p1, you cannot create a new partition on table tt that includes 12 in its value list. To accomplish this, you could

drop p1, and add np and then a new p1 with a modified definition. However, as discussed earlier, this would result in the loss of all data stored in p1—and it is often the case that this is not what you really want to do. Another solution might appear to be to make a copy of the table with the new partitioning and to copy the data into it using CREATE TABLE ... SELECT ..., then drop the old table and rename the new one, but this could be very time-consuming when dealing with a large amounts of data. This also might not be feasible in situations where high availability is a requirement.

Beginning with MySQL 5.1.6, you can add multiple partitions in a single ALTER TABLE ... ADD PARTITION statement as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  hired DATE NOT NULL
)
PARTITION BY RANGE( YEAR(hired) ) (
  PARTITION p1 VALUES LESS THAN (1991),
  PARTITION p2 VALUES LESS THAN (1996),
  PARTITION p3 VALUES LESS THAN (2001),
  PARTITION p4 VALUES LESS THAN (2005)
);

ALTER TABLE employees ADD PARTITION (
    PARTITION p5 VALUES LESS THAN (2010),
    PARTITION p6 VALUES LESS THAN MAXVALUE
);
```

Fortunately, MySQL's partitioning implementation provides ways to redefine partitions without losing data. Let us look first at a couple of simple examples involving RANGE partitioning. Recall the members table which is now defined as shown here:

```
mysql> SHOW CREATE TABLE members\G
*************************** 1. row ***************************
       Table: members
Create Table: CREATE TABLE `members` (
  `id` int(11) default NULL,
  `fname` varchar(25) default NULL,
  `lname` varchar(25) default NULL,
  `dob` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE ( YEAR(dob) ) (
  PARTITION p0 VALUES LESS THAN (1970) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1980) ENGINE = MyISAM,
  PARTITION p2 VALUES LESS THAN (1990) ENGINE = MyISAM.
  PARTITION p3 VALUES LESS THAN (2000) ENGINE = MyISAM
)
```

Suppose that you would like to move all rows representing members born before 1960 into a separate partition. As we have already seen, this cannot be done using ALTER TABLE ... ADD PARTITION. However, you can use another partition-related extension to ALTER TABLE to accomplish this:

```
ALTER TABLE members REORGANIZE PARTITION p0 INTO (
    PARTITION s0 VALUES LESS THAN (1960),
    PARTITION s1 VALUES LESS THAN (1970)
);
```

In effect, this command splits partition p0 into two new partitions s0 and s1. It also moves the data that was stored in p0 into the new partitions according to the rules embodied in the two PARTITION ... VALUES ... clauses, so that s0 contains only those records for which YEAR(dob) [997] is less than 1960 and s1 contains those rows in which YEAR(dob) [997] is greater than or equal to 1960 but less than 1970.

A REORGANIZE PARTITION clause may also be used for merging adjacent partitions. You can return the members table to its previous partitioning as shown here:

```
ALTER TABLE members REORGANIZE PARTITION s0,s1 INTO (
```

```
    PARTITION p0 VALUES LESS THAN (1970)
);
```

No data is lost in splitting or merging partitions using REORGANIZE PARTITION. In executing the above statement, MySQL moves all of the records that were stored in partitions s0 and s1 into partition p0.

The general syntax for REORGANIZE PARTITION is shown here:

```
ALTER TABLE tbl_name
    REORGANIZE PARTITION partition_list
    INTO (partition_definitions);
```

Here, *tbl_name* is the name of the partitioned table, and *partition_list* is a comma-separated list of names of one or more existing partitions to be changed. *partition_definitions* is a comma-separated list of new partition definitions, which follow the same rules as for the *partition_definitions* list used in CREATE TABLE (see CREATE TABLE Syntax). It should be noted that you are not limited to merging several partitions into one, or to splitting one partition into many, when using REORGANIZE PARTITION. For example, you can reorganize all four partitions of the members table into two, as follows:

```
ALTER TABLE members REORGANIZE PARTITION p0,p1,p2,p3 INTO (
    PARTITION m0 VALUES LESS THAN (1980),
    PARTITION m1 VALUES LESS THAN (2000)
);
```

You can also use REORGANIZE PARTITION with tables that are partitioned by LIST. Let us return to the problem of adding a new partition to the list-partitioned tt table and failing because the new partition had a value that was already present in the value-list of one of the existing partitions. We can handle this by adding a partition that contains only nonconflicting values, and then reorganizing the new partition and the existing one so that the value which was stored in the existing one is now moved to the new one:

```
ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8));
ALTER TABLE tt REORGANIZE PARTITION p1,np INTO (
    PARTITION p1 VALUES IN (6, 18),
    PARTITION np VALUES in (4, 8, 12)
);
```

Here are some key points to keep in mind when using ALTER TABLE ... REORGANIZE PARTITION to repartition tables that are partitioned by RANGE or LIST:

- The PARTITION clauses used to determine the new partitioning scheme are subject to the same rules as those used with a CREATE TABLE statement.

  Most importantly, you should remember that the new partitioning scheme cannot have any overlapping ranges (applies to tables partitioned by RANGE) or sets of values (when reorganizing tables partitioned by LIST).

  Note

  Prior to MySQL 5.1.4, you could not reuse the names of existing partitions in the INTO clause, even when those partitions were being dropped or redefined. See Changes in MySQL 5.1.4 (2005-12-21), for more information.

- The combination of partitions in the *partition_definitions* list should account for the same range or set of values overall as the combined partitions named in the *partition_list*.

  For instance, in the members table used as an example in this section, partitions p1 and p2 together cover the years 1980 through 1999. Therefore, any reorganization of these two partitions should cover the same range of years overall.

- For tables partitioned by RANGE, you can reorganize only adjacent partitions; you cannot skip over range partitions.

For instance, you could not reorganize the `members` table used as an example in this section using a statement beginning with `ALTER TABLE members REORGANIZE PARTITION p0,p2 INTO ...` because `p0` covers the years prior to 1970 and `p2` the years from 1990 through 1999 inclusive, and thus the two are not adjacent partitions.

- You cannot use `REORGANIZE PARTITION` to change the table's partitioning type; that is, you cannot (for example) change `RANGE` partitions to `HASH` partitions or *vice versa*. You also cannot use this command to change the partitioning expression or column. To accomplish either of these tasks without dropping and re-creating the table, you can use `ALTER TABLE ... PARTITION BY ...`. For example:

```
ALTER TABLE members
    PARTITION BY HASH( YEAR(dob) )
    PARTITIONS 8;
```

Management of HASH and KEY Partitions

Tables which are partitioned by hash or by key are very similar to one another with regard to making changes in a partitioning setup, and both differ in a number of ways from tables which have been partitioned by range or list. For that reason, this section addresses the modification of tables partitioned by hash or by key only. For a discussion of adding and dropping of partitions of tables that are partitioned by range or list, see Management of `RANGE` and `LIST` Partitions.

You cannot drop partitions from tables that are partitioned by `HASH` or `KEY` in the same way that you can from tables that are partitioned by `RANGE` or `LIST`. However, you can merge `HASH` or `KEY` partitions using the `ALTER TABLE ... COALESCE PARTITION` statement. Suppose that you have a table containing data about clients, which is divided into twelve partitions. The `clients` table is defined as shown here:

```
CREATE TABLE clients (
    id INT,
    fname VARCHAR(30),
    lname VARCHAR(30),
    signed DATE
)
PARTITION BY HASH( MONTH(signed) )
PARTITIONS 12;
```

To reduce the number of partitions from twelve to eight, execute the following `ALTER TABLE` command:

```
mysql> ALTER TABLE clients COALESCE PARTITION 4;
Query OK, 0 rows affected (0.02 sec)
```

`COALESCE` works equally well with tables that are partitioned by `HASH`, `KEY`, `LINEAR HASH`, or `LINEAR KEY`. Here is an example similar to the previous one, differing only in that the table is partitioned by `LINEAR KEY`:

```
mysql> CREATE TABLE clients_lk (
    ->     id INT,
    ->     fname VARCHAR(30),
    ->     lname VARCHAR(30),
    ->     signed DATE
    -> )
    -> PARTITION BY LINEAR KEY(signed)
    -> PARTITIONS 12;
Query OK, 0 rows affected (0.03 sec)

mysql> ALTER TABLE clients_lk COALESCE PARTITION 4;
Query OK, 0 rows affected (0.06 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

Note that the number following `COALESCE PARTITION` is the number of partitions to merge into the remainder—in other words, it is the number of partitions to remove from the table.

If you attempt to remove more partitions than the table has, the result is an error like the one shown:

```
mysql> ALTER TABLE clients COALESCE PARTITION 18;
ERROR 1478 (HY000): Cannot remove all partitions, use DROP TABLE instead
```

To increase the number of partitions for the `clients` table from 12 to 18. use `ALTER TABLE ... ADD PARTITION` as shown here:

```
ALTER TABLE clients ADD PARTITION PARTITIONS 6;
```

Maintenance of Partitions

A number of table and partition maintenance tasks can be carried out using SQL statements intended for such purposes on partitioned tables in MySQL 5.1.

Table maintenance of partitioned tables can be accomplished using the statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE`, which are supported for partitioned tables as of MySQL 5.1.27.

Also beginning with MySQL 5.1.27, you can use a number of extensions to `ALTER TABLE` for performing operations of this type on one or more partitions directly, as described in the following list:

- **Rebuilding partitions.** Rebuilds the partition; this has the same effect as dropping all records stored in the partition, then reinserting them. This can be useful for purposes of defragmentation.

  Example:

  ```
  ALTER TABLE t1 REBUILD PARTITION p0, p1;
  ```

- **Optimizing partitions.** If you have deleted a large number of rows from a partition or if you have made many changes to a partitioned table with variable-length rows (that is, having `VARCHAR`, `BLOB`, or `TEXT` columns), you can use `ALTER TABLE ... OPTIMIZE PARTITION` to reclaim any unused space and to defragment the partition data file.

  Example:

  ```
  ALTER TABLE t1 OPTIMIZE PARTITION p0, p1;
  ```

  Using `OPTIMIZE PARTITION` on a given partition is equivalent to running `CHECK PARTITION`, `ANALYZE PARTITION`, and `REPAIR PARTITION` on that partition.

- **Analyzing partitions.** This reads and stores the key distributions for partitions.

  Example:

  ```
  ALTER TABLE t1 ANALYZE PARTITION p3;
  ```

- **Repairing partitions.** This repairs corrupted partitions.

  Example:

  ```
  ALTER TABLE t1 REPAIR PARTITION p0,p1;
  ```

- **Checking partitions.** You can check partitions for errors in much the same way that you can use `CHECK TABLE` with nonpartitioned tables.

  Example:

  ```
  ALTER TABLE trb3 CHECK PARTITION p1;
  ```

  This command will tell you if the data or indexes in partition `p1` of table `t1` are corrupted. If this is the case, use `ALTER TABLE ... REPAIR PARTITION` to repair the partition.

Each of the statements in the list just shown also supports the keyword `ALL` in place of the list of partition names. Using `ALL` causes the statement to act on all partitions in the table.

Note

The statements `ALTER TABLE ... ANALYZE PARTITION`, `ALTER TABLE ... CHECK PARTITION`, `ALTER TABLE ... OPTIMIZE PARTITION`, and `ALTER TABLE ... REPAIR PARTITION` were originally introduced in MySQL 5.1.5, but did not work properly and were disabled in MySQL 5.1.24. They were re-introduced in MySQL 5.1.27. (Bug #20129) The use of these partitioning-specific `ALTER TABLE` statements with tables which are not partitioned is not supported; beginning with MySQL 5.1.31, it is expressly not permitted. (Bug #39434)

`ALTER TABLE ... REBUILD PARTITION` was also introduced in MySQL 5.1.5.

The use of `mysqlcheck` and `myisamchk` is not supported with partitioned tables.

Obtaining Information About Partitions

This section discusses obtaining information about existing partitions, which can be done in a number of ways. Methods of obtaining such information include the following:

- Using the `SHOW CREATE TABLE` statement to view the partitioning clauses used in creating a partitioned table.
- Using the `SHOW TABLE STATUS` statement to determine whether a table is partitioned.
- Querying the `INFORMATION_SCHEMA.PARTITIONS` table.
- Using the statement `EXPLAIN PARTITIONS SELECT` to see which partitions are used by a given `SELECT`.

As discussed elsewhere in this chapter, `SHOW CREATE TABLE` includes in its output the `PARTITION BY` clause used to create a partitioned table. For example:

```
mysql> SHOW CREATE TABLE trb3\G
*************************** 1. row ***************************
       Table: trb3
Create Table: CREATE TABLE `trb3` (
  `id` int(11) default NULL,
  `name` varchar(50) default NULL,
  `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE (YEAR(purchased)) (
  PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
  PARTITION p2 VALUES LESS THAN (2000) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.00 sec)
```

Note

In early MySQL 5.1 releases, the `PARTITIONS` clause was not shown for tables partitioned by `HASH` or `KEY`. This issue was fixed in MySQL 5.1.6.

`SHOW TABLE STATUS` works with partitioned tables. Beginning with MySQL 5.1.9, its output is the same as that for nonpartitioned tables, except that the `Create_options` column contains the string `partitioned`. In MySQL 5.1.8 and earlier, the `Engine` column always contained the value `PARTITION`; beginning with MySQL 5.1.9, this column contains the name of the storage engine used by all partitions of the table. (See `SHOW TABLE STATUS` Syntax, for more information about this statement.)

You can also obtain information about partitions from `INFORMATION_SCHEMA`, which contains a `PARTITIONS` table. See The `INFORMATION_SCHEMA PARTITIONS` Table.

Beginning with MySQL 5.1.5, it is possible to determine which partitions of a partitioned table are involved in a given `SELECT` query using `EXPLAIN PARTITIONS`. The `PARTITIONS` keyword adds a `partitions` column to the output of `EXPLAIN` listing the partitions from which records would be matched by the query.

Suppose that you have a table `trb1` created and populated as follows:

```
CREATE TABLE trb1 (id INT, name VARCHAR(50), purchased DATE)
    PARTITION BY RANGE(id)
    (
        PARTITION p0 VALUES LESS THAN (3),
        PARTITION p1 VALUES LESS THAN (7),
        PARTITION p2 VALUES LESS THAN (9),
        PARTITION p3 VALUES LESS THAN (11)
    );

INSERT INTO trb1 VALUES
    (1, 'desk organiser', '2003-10-15'),
    (2, 'CD player', '1993-11-05'),
    (3, 'TV set', '1996-03-10'),
    (4, 'bookcase', '1982-01-10'),
    (5, 'exercise bike', '2004-05-09'),
    (6, 'sofa', '1987-06-05'),
    (7, 'popcorn maker', '2001-11-22'),
    (8, 'aquarium', '1992-08-04'),
    (9, 'study desk', '1984-09-16'),
    (10, 'lava lamp', '1998-12-25');
```

You can see which partitions are used in a query such as `SELECT * FROM trb1;`, as shown here:

```
mysql> EXPLAIN PARTITIONS SELECT * FROM trb1\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: trb1
   partitions: p0,p1,p2,p3
         type: ALL
possible_keys: NULL
          key: NULL
      key_len: NULL
          ref: NULL
         rows: 10
        Extra: Using filesort
```

In this case, all four partitions are searched. However, when a limiting condition making use of the partitioning key is added to the query, you can see that only those partitions containing matching values are scanned, as shown here:

```
mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: trb1
   partitions: p0,p1
         type: ALL
possible_keys: NULL
          key: NULL
      key_len: NULL
          ref: NULL
         rows: 10
        Extra: Using where
```

`EXPLAIN PARTITIONS` provides information about keys used and possible keys, just as with the standard `EXPLAIN SELECT` statement:

```
mysql> ALTER TABLE trb1 ADD PRIMARY KEY (id);
Query OK, 10 rows affected (0.03 sec)
Records: 10  Duplicates: 0  Warnings: 0
```

```
mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: trb1
   partitions: p0,p1
         type: range
possible_keys: PRIMARY
          key: PRIMARY
      key_len: 4
          ref: NULL
         rows: 7
        Extra: Using where
```

You should take note of the following restrictions and limitations on `EXPLAIN PARTITIONS`:

- You cannot use the `PARTITIONS` and `EXTENDED` keywords together in the same `EXPLAIN ... SELECT` statement. Attempting to do so produces a syntax error.
- If `EXPLAIN PARTITIONS` is used to examine a query against a nonpartitioned table, no error is produced, but the value of the `partitions` column is always `NULL`.

As of MySQL 5.1.28, the `rows` column of `EXPLAIN PARTITIONS` output always displays the total number of rows in the table. Previously, this was the number of matching rows (see Bug #35745).

See also `EXPLAIN` Syntax.

Partition Pruning

This section discusses an optimization known as *partition pruning*, which was implemented for partitioned tables in MySQL 5.1.6. The core concept behind partition pruning is relatively simple, and can be described as “Do not scan partitions where there can be no matching values”. Suppose that you have a partitioned table `t1` defined by this statement:

```
CREATE TABLE t1 (
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    region_code TINYINT UNSIGNED NOT NULL,
    dob DATE NOT NULL
)
PARTITION BY RANGE( region_code ) (
    PARTITION p0 VALUES LESS THAN (64),
    PARTITION p1 VALUES LESS THAN (128),
    PARTITION p2 VALUES LESS THAN (192),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

Consider the case where you wish to obtain results from a query such as this one:

```
SELECT fname, lname, region_code, dob
    FROM t1
    WHERE region_code > 125 AND region_code < 130;
```

It is easy to see that none of the rows which ought to be returned will be in either of the partitions `p0` or `p3`; that is, we need to search only in partitions `p1` and `p2` to find matching rows. By doing so, it is possible to expend much less time and effort in finding matching rows than would be required to scan all partitions in the table. This “cutting away” of unneeded partitions is known as *pruning*. When the optimizer can make use of partition pruning in performing a query, execution of the query can be an order of magnitude faster than the same query against a nonpartitioned table containing the same column definitions and data.

The query optimizer can perform pruning whenever a `WHERE` condition can be reduced to either one of the following two cases:

- *`partition_column = constant`*

- *`partition_column IN (constant1, constant2, ..., constantN)`*

In the first case, the optimizer simply evaluates the partitioning expression for the value given, determines which partition contains that value, and scans only this partition. In many cases, the equal sign can be replaced with another arithmetic comparison, including `<`, `>`, `<=`, `>=`, and `<>`. Some queries using `BETWEEN` in the `WHERE` clause can also take advantage of partition pruning. See the examples later in this section.

In the second case, the optimizer evaluates the partitioning expression for each value in the list, creates a list of matching partitions, and then scans only the partitions in this partition list.

Pruning can also be applied to short ranges, which the optimizer can convert into equivalent lists of values. For instance, in the previous example, the `WHERE` clause can be converted to `WHERE region_code IN (126, 127, 128, 129)`. Then the optimizer can determine that the first three values in the list are found in partition `p1`, the remaining three values in partition `p2`, and that the other partitions contain no relevant values and so do not need to be searched for matching rows.

This type of optimization can be applied whenever the partitioning expression consists of an equality or a range which can be reduced to a set of equalities, or when the partitioning expression represents an increasing or decreasing relationship. Pruning can also be applied for tables partitioned on a `DATE` or `DATETIME` column when the partitioning expression uses the `YEAR()` [997] or `TO_DAYS()` [994] function.

Suppose that table `t2`, defined as shown here, is partitioned on a `DATE` column:

```
CREATE TABLE t2 (
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    region_code TINYINT UNSIGNED NOT NULL,
    dob DATE NOT NULL
)
PARTITION BY RANGE( YEAR(dob) ) (
    PARTITION d0 VALUES LESS THAN (1970),
    PARTITION d1 VALUES LESS THAN (1975),
    PARTITION d2 VALUES LESS THAN (1980),
    PARTITION d3 VALUES LESS THAN (1985),
    PARTITION d4 VALUES LESS THAN (1990),
    PARTITION d5 VALUES LESS THAN (2000),
    PARTITION d6 VALUES LESS THAN (2005),
    PARTITION d7 VALUES LESS THAN MAXVALUE
);
```

The following queries on `t2` can make of use partition pruning:

```
SELECT * FROM t2 WHERE dob = '1982-06-23';

SELECT * FROM t2 WHERE dob BETWEEN '1991-02-15' AND '1997-04-25';

SELECT * FROM t2 WHERE dob >= '1984-06-21' AND dob <= '1999-06-21'
```

In the case of the last query, the optimizer can also act as follows:

1. *Find the partition containing the low end of the range*.

   `YEAR('1984-06-21')` [997] yields the value `1984`, which is found in partition `d3`.

2. *Find the partition containing the high end of the range*.

   `YEAR('1999-06-21')` [997] evaluates to `1999`, which is found in partition `d5`.

3. *Scan only these two partitions and any partitions that may lie between them*.

   In this case, this means that only partitions `d3`, `d4`, and `d5` are scanned. The remaining partitions may be safely ignored (and are ignored).

Important

Invalid `DATE` and `DATETIME` values referenced in the `WHERE` clause of a query on a partitioned table are treated as `NULL`. This means that a query such as `SELECT * FROM partitioned_table WHERE date_column < '2008-12-00'` does not return any values (see Bug #40972).

So far, we have looked only at examples using `RANGE` partitioning, but pruning can be applied with other partitioning types as well.

Consider a table that is partitioned by `LIST`, where the partitioning expression is increasing or decreasing, such as the table `t3` shown here. (In this example, we assume for the sake of brevity that the `region_code` column is limited to values between 1 and 10 inclusive.)

```
CREATE TABLE t3 (
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    region_code TINYINT UNSIGNED NOT NULL,
    dob DATE NOT NULL
)
PARTITION BY LIST(region_code) (
    PARTITION r0 VALUES IN (1, 3),
    PARTITION r1 VALUES IN (2, 5, 8),
    PARTITION r2 VALUES IN (4, 9),
    PARTITION r3 VALUES IN (6, 7, 10)
);
```

For a query such as `SELECT * FROM t3 WHERE region_code BETWEEN 1 AND 3`, the optimizer determines in which partitions the values 1, 2, and 3 are found (`r0` and `r1`) and skips the remaining ones (`r2` and `r3`).

For tables that are partitioned by `HASH` or `KEY`, partition pruning is also possible in cases in which the `WHERE` clause uses a simple `=` relation against a column used in the partitioning expression. Consider a table created like this:

```
CREATE TABLE t4 (
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    region_code TINYINT UNSIGNED NOT NULL,
    dob DATE NOT NULL
)
PARTITION BY KEY(region_code)
PARTITIONS 8;
```

Any query, such as this one, that compares a column value with a constant can be pruned:

```
SELECT * FROM t4 WHERE region_code = 7;
```

Pruning can also be employed for short ranges, because the optimizer can turn such conditions into `IN` relations. For example, using the same table `t4` as defined previously, queries such as these can be pruned:

```
SELECT * FROM t4 WHERE region_code > 2 AND region_code < 6;

SELECT * FROM t4 WHERE region_code BETWEEN 3 AND 5;
```

In both these cases, the `WHERE` clause is transformed by the optimizer into `WHERE region_code IN (3, 4, 5)`.

Important

This optimization is used only if the range size is smaller than the number of partitions. Consider this query:

```
SELECT * FROM t4 WHERE region_code BETWEEN 4 AND 12;
```

> The range in the `WHERE` clause covers 9 values (4, 5, 6, 7, 8, 9, 10, 11, 12), but `t4` has only 8 partitions. This means that the previous query cannot be pruned.

Pruning can be used only on integer columns of tables partitioned by `HASH` or `KEY`. For example, this query on table `t4` cannot use pruning because `dob` is a `DATE` column:

```
SELECT * FROM t4 WHERE dob >= '2001-04-14' AND dob <= '2005-10-15';
```

However, if the table stores year values in an `INT` column, then a query having `WHERE year_col >= 2001 AND year_col <= 2005` can be pruned.

For a table that is partitioned by `KEY`, has a composite primary key, and uses a composite partitioning key, it is possible to perform pruning for queries meeting the following two criteria:

- The query must have a `WHERE` clause of the form `pkcol1 = c1 AND pkcol2 = c2 AND ... pkcolN = cN`, where `pkcol1` ... `pkcolN` are the partitioning key columns and `c1` ... `cN` are constant values.
- All columns of the partitioning key must be referenced in the `WHERE` clause.

For example, suppose a table named `cities` is created as shown here:

```
CREATE TABLE cities (
    id INT NOT NULL AUTO_INCREMENT,
    name CHAR(35) NOT NULL DEFAULT '',
    country_code CHAR(3) NOT NULL DEFAULT '',
    district CHAR(20) NOT NULL DEFAULT '',
    population INT NOT NULL DEFAULT 0,
    PRIMARY KEY (ID, Population)
)
PARTITION BY KEY ()
PARTITIONS 8;
```

(Note that `PARTITION BY KEY()` is equivalent in this case to `PARTITION BY KEY(id, population)`.)

Only a query that references both the `id` and `population` columns of this table can be pruned, as shown here:

```
mysql> SELECT * FROM cities WHERE id = 101;
+-----+------------+--------------+----------+------------+
| id  | name       | country_code | district | population |
+-----+------------+--------------+----------+------------+
| 101 | Godoy Cruz | ARG          | Mendoza  |     206998 |
+-----+------------+--------------+----------+------------+
1 row in set (0.00 sec)

mysql> SELECT * FROM cities WHERE population = 206998;
+-----+------------+--------------+----------+------------+
| id  | name       | country_code | district | population |
+-----+------------+--------------+----------+------------+
| 101 | Godoy Cruz | ARG          | Mendoza  |     206998 |
+-----+------------+--------------+----------+------------+
1 row in set (0.00 sec)

mysql> EXPLAIN PARTITIONS SELECT * FROM cities WHERE id = 101\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: cities
   partitions: p0,p1,p2,p3,p4,p5,p6,p7
         type: ref
possible_keys: PRIMARY
          key: PRIMARY
      key_len: 4
          ref: const
         rows: 6
        Extra:
```

```
1 row in set (0.00 sec)

mysql> EXPLAIN PARTITIONS SELECT * FROM cities WHERE population = 206998\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: cities
   partitions: p0,p1,p2,p3,p4,p5,p6,p7
         type: ALL
possible_keys: NULL
          key: NULL
      key_len: NULL
          ref: NULL
         rows: 1973
        Extra: Using where
1 row in set (0.00 sec)

mysql> EXPLAIN PARTITIONS SELECT * FROM cities WHERE id = 101 AND population = 206998\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: cities
   partitions: p2
         type: const
possible_keys: PRIMARY
          key: PRIMARY
      key_len: 8
          ref: const,const
         rows: 1
        Extra:
1 row in set (0.00 sec)
```

This limitation on pruning with composite partitioning keys is removed in MySQL 5.5.

Restrictions and Limitations on Partitioning

This section discusses current restrictions and limitations on MySQL partitioning support.

Prohibited constructs. Beginning with MySQL 5.1.12, the following constructs are not permitted in partitioning expressions:

- Stored procedures, stored functions, UDFs, or plugins.
- Declared variables or user variables.

For a list of SQL functions which are permitted in partitioning expressions, see Partitioning Limitations Relating to Functions.

Arithmetic and logical operators. Use of the arithmetic operators + [969], - [969], and * [970] is permitted in partitioning expressions. However, the result must be an integer value or `NULL` (except in the case of `[LINEAR] KEY` partitioning, as discussed elsewhere in this chapter; see Partitioning Types, for more information).

Beginning with MySQL 5.1.23, the `DIV` [970] operator is also supported, and the / [970] operator is not permitted. (Bug #30188, Bug #33182)

Beginning with MySQL 5.1.12, the bit operators | [1025], & [1025], ^ [1026], << [1026], >> [1026], and ~ [1026] are not permitted in partitioning expressions.

Server SQL mode. Tables employing user-defined partitioning do not preserve the SQL mode in effect at the time that they were created. As discussed in Server SQL Modes, the results of many MySQL functions and operators may change according to the server SQL mode. Therefore, a change in the SQL mode at any time after the creation of partitioned tables may lead to major changes in the behavior of such tables, and could easily lead to corruption or loss of data. For these reasons, *it is strongly recommended that you never change the server SQL mode after creating partitioned tables*.

Examples. The following examples illustrate some changes in behavior of partitioned tables due to a change in the server SQL mode:

1. **Error handling.** Suppose that you create a partitioned table whose partitioning expression is one such as *`column`* `DIV 0` or *`column`* `MOD 0`, as shown here:

```
mysql> CREATE TABLE tn (c1 INT)
    ->     PARTITION BY LIST(1 DIV c1) (
    ->       PARTITION p0 VALUES IN (NULL),
    ->       PARTITION p1 VALUES IN (1)
    -> );
Query OK, 0 rows affected (0.05 sec)
```

   The default behavior for MySQL is to return `NULL` for the result of a division by zero, without producing any errors:

```
mysql> SELECT @@sql_mode;
+------------+
| @@sql_mode |
+------------+
|            |
+------------+
1 row in set (0.00 sec)

mysql> INSERT INTO tn VALUES (NULL), (0), (1);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0
```

   However, changing the server SQL mode to treat division by zero as an error and to enforce strict error handling causes the same `INSERT` statement to fail, as shown here:

```
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO tn VALUES (NULL), (0), (1);
ERROR 1365 (22012): Division by 0
```

2. **Table accessibility.** Sometimes a change in the server SQL mode can make partitioned tables unusable. The following `CREATE TABLE` statement can be executed successfully only if the `NO_UNSIGNED_SUBTRACTION` [574] mode is in effect:

```
mysql> SELECT @@sql_mode;
+------------+
| @@sql_mode |
+------------+
|            |
+------------+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
    ->   PARTITION BY RANGE(c1 - 10) (
    ->     PARTITION p0 VALUES LESS THAN (-5),
    ->     PARTITION p1 VALUES LESS THAN (0),
    ->     PARTITION p2 VALUES LESS THAN (5),
    ->     PARTITION p3 VALUES LESS THAN (10),
    ->     PARTITION p4 VALUES LESS THAN (MAXVALUE)
    -> );
ERROR 1563 (HY000): Partition constant is out of partition function domain

mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@sql_mode;
+-------------------------+
| @@sql_mode              |
+-------------------------+
| NO_UNSIGNED_SUBTRACTION |
+-------------------------+
1 row in set (0.00 sec)
```

```
mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
    ->   PARTITION BY RANGE(c1 - 10) (
    ->     PARTITION p0 VALUES LESS THAN (-5),
    ->     PARTITION p1 VALUES LESS THAN (0),
    ->     PARTITION p2 VALUES LESS THAN (5),
    ->     PARTITION p3 VALUES LESS THAN (10),
    ->     PARTITION p4 VALUES LESS THAN (MAXVALUE)
    -> );
Query OK, 0 rows affected (0.05 sec)
```

If you remove the `NO_UNSIGNED_SUBTRACTION` [574] server SQL mode after creating `tu`, you may no longer be able to access this table:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM tu;
ERROR 1563 (HY000): Partition constant is out of partition function domain
mysql> INSERT INTO tu VALUES (20);
ERROR 1563 (HY000): Partition constant is out of partition function domain
```

Server SQL modes also impact replication of partitioned tables. Differing SQL modes on master and slave can lead to partitioning expressions being evaluated differently; this can cause the distribution of data among partitions to be different in the master's and slave's copies of a given table, and may even cause inserts into partitioned tables that succeed on the master to fail on the slave. For best results, you should always use the same server SQL mode on the master and on the slave.

Performance considerations. Some affects of partitioning operations on performance are given in the following list:

- **File system operations.** Partitioning and repartitioning operations (such as `ALTER TABLE` with `PARTITION BY ...`, `REORGANIZE PARTITIONS`, or `REMOVE PARTITIONING`) depend on file system operations for their implementation. This means that the speed of these operations is affected by such factors as file system type and characteristics, disk speed, swap space, file handling efficiency of the operating system, and MySQL server options and variables that relate to file handling. In particular, you should make sure that `large_files_support` [486] is enabled and that `open_files_limit` [508] is set properly. For partitioned tables using the `MyISAM` storage engine, increasing `myisam_max_sort_file_size` [501] may improve performance; partitioning and repartitioning operations involving `InnoDB` tables may be made more efficient by enabling `innodb_file_per_table` [1367].

  See also Maximum number of partitions.

- **Table locks.** The process executing a partitioning operation on a table takes a write lock on the table. Reads from such tables are relatively unaffected; pending `INSERT` and `UPDATE` operations are performed as soon as the partitioning operation has completed.

- **Storage engine.** Partitioning operations, queries, and update operations generally tend to be faster with `MyISAM` tables than with `InnoDB` or `NDB` tables.

- **Use of indexes and partition pruning.** As with nonpartitioned tables, proper use of indexes can speed up queries on partitioned tables significantly. In addition, designing partitioned tables and queries on these tables to take advantage of *partition pruning* can improve performance dramatically. See Partition Pruning, for more information.

- **Performance with `LOAD DATA`.** Prior to MySQL 5.1.23, `LOAD DATA` performed very poorly when importing into partitioned tables. The statement now uses buffering to improve performance; however, the buffer uses 130 KB memory per partition to achieve this. (Bug #26527)

Maximum number of partitions.
The maximum possible number of partitions for a given table (that does not use the `NDB` storage engine) is 1024. This number includes subpartitions.

The maximum possible number of user-defined partitions for a table using the NDBCLUSTER storage engine is determined according to the version of the MySQL Cluster software being used, the number of data nodes, and other factors. See NDB and user-defined partitioning, for more information.

If, when creating tables with a large number of partitions (but less than the maximum), you encounter an error message such as `Got error ... from storage engine: Out of resources when opening file`, you may be able to address the issue by increasing the value of the open_files_limit [508] system variable. However, this is dependent on the operating system, and may not be possible or advisable on all platforms; see `'File' Not Found` and Similar Errors, for more information. In some cases, using large numbers (hundreds) of partitions may also not be advisable due to other concerns, so using more partitions does not automatically lead to better results.

See also File system operations.

Foreign keys not supported.
Partitioned tables do not support foreign keys. More specifically, this means that the following two statements are true:

1. Definitions of tables employing user-defined partitioning may not contain foreign key references to other tables.

2. No table definition may contain a foreign key reference to a partitioned table.

The scope of these restrictions includes tables that use the InnoDB storage engine.

`ALTER TABLE ... ORDER BY`. An `ALTER TABLE ... ORDER BY column` statement run against a partitioned table causes ordering of rows only within each partition.

`FULLTEXT` indexes.
Partitioned tables do not support FULLTEXT indexes or searches. This includes partitioned tables employing the MyISAM storage engine.

Spatial columns. Columns with spatial data types such as POINT or GEOMETRY cannot be used in partitioned tables.

Temporary tables.
As of MySQL 5.1.8, temporary tables cannot be partitioned. (Bug #17497)

Log tables. Beginning with MySQL 5.1.20, it is no longer possible to partition the log tables; beginning with that version, an `ALTER TABLE ... PARTITION BY ...` statement on such a table fails with an error. (Bug #27816)

Data type of partitioning key.
A partitioning key must be either an integer column or an expression that resolves to an integer. The column or expression value may also be NULL. (See How MySQL Partitioning Handles NULL.)

The lone exception to this restriction occurs when partitioning by [LINEAR] KEY, where it is possible to use columns of other types as partitioning keys, because MySQL's internal key-hashing functions produce the correct data type from these types. For example, the following CREATE TABLE statement is valid:

```
CREATE TABLE tkc (c1 CHAR)
PARTITION BY KEY(c1)
PARTITIONS 4;
```

This exception does *not* apply to BLOB or TEXT column types.

Subqueries.
A partitioning key may not be a subquery, even if that subquery resolves to an integer value or NULL.

Issues with subpartitions.

Subpartitions must use HASH or KEY partitioning. Only RANGE and LIST partitions may be subpartitioned; HASH and KEY partitions cannot be subpartitioned.

Currently, SUBPARTITION BY KEY requires that the subpartitioning column or columns be specified explicitly, unlike the case with PARTITION BY KEY, where it can be omitted (in which case the table's primary key column is used by default). Consider the table created by this statement:

```
CREATE TABLE ts (
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    name VARCHAR(30)
);
```

You can create a table having the same columns, partitioned by KEY, using a statement such as this one:

```
CREATE TABLE ts (
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    name VARCHAR(30)
)
PARTITION BY KEY()
PARTITIONS 4;
```

The previous statement is treated as though it had been written like this, with the table's primary key column used as the partitioning column:

```
CREATE TABLE ts (
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    name VARCHAR(30)
)
PARTITION BY KEY(id)
PARTITIONS 4;
```

However, the following statement that attempts to create a subpartitioned table using the default column as the subpartitioning column fails, and the column must be specified for the statement to succeed, as shown here:

```
mysql> CREATE TABLE ts (
    ->     id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    ->     name VARCHAR(30)
    -> )
    -> PARTITION BY RANGE(id)
    -> SUBPARTITION BY KEY()
    -> SUBPARTITIONS 4
    -> (
    ->     PARTITION p0 VALUES LESS THAN (100),
    ->     PARTITION p1 VALUES LESS THAN (MAXVALUE)
    -> );
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that
corresponds to your MySQL server version for the right syntax to use near ')

mysql> CREATE TABLE ts (
    ->     id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    ->     name VARCHAR(30)
    -> )
    -> PARTITION BY RANGE(id)
    -> SUBPARTITION BY KEY(id)
    -> SUBPARTITIONS 4
    -> (
    ->     PARTITION p0 VALUES LESS THAN (100),
    ->     PARTITION p1 VALUES LESS THAN (MAXVALUE)
    -> );
Query OK, 0 rows affected (0.07 sec)
```

This is a known issue (see Bug #51470).

Query cache not supported.

The query cache is not supported for partitioned tables. Beginning with MySQL 5.1.63, the query cache is automatically disabled for queries involving partitioned tables, and cannot be enabled for such queries. (Bug #53775)

Key cache not supported.
Caching is not supported for partitioned tables. The `CACHE INDEX` and `LOAD INDEX INTO CACHE` statements, when you attempt to use them on tables having user-defined partitioning, fail with the errors `The storage engine for the table doesn't support assign_to_keycache` and `The storage engine for the table doesn't support preload_keys`, respectively. This issue is fixed in MySQL 5.5.

`DELAYED` option not supported. Use of `INSERT DELAYED` to insert rows into a partitioned table is not supported. Beginning with MySQL 5.1.23, attempting to do so fails with an error (see Bug #31210).

`DATA DIRECTORY` and `INDEX DIRECTORY` options. `DATA DIRECTORY` and `INDEX DIRECTORY` are subject to the following restrictions when used with partitioned tables:

- Beginning with MySQL 5.1.23, table-level `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored (see Bug #32091).
- On Windows, the `DATA DIRECTORY` and `INDEX DIRECTORY` options are not supported for individual partitions or subpartitions (Bug #30459).

Repairing and rebuilding partitioned tables. The statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE` are supported for partitioned tables beginning with MySQL 5.1.27. (See Bug #20129.)

In addition, you can use `ALTER TABLE ... REBUILD PARTITION` to rebuild one or more partitions of a partitioned table; `ALTER TABLE ... REORGANIZE PARTITION` also causes partitions to be rebuilt. Both of these statements were added in MySQL 5.1.5. See `ALTER TABLE` Syntax, for more information about these two statements.

`mysqlcheck` and `myisamchk` are not supported with partitioned tables.

Partitioning Keys, Primary Keys, and Unique Keys

This section discusses the relationship of partitioning keys with primary keys and unique keys. The rule governing this relationship can be expressed as follows: All columns used in the partitioning expression for a partitioned table must be part of every unique key that the table may have.

In other words, *every unique key on the table must use every column in the table's partitioning expression*. (This also includes the table's primary key, since it is by definition a unique key. This particular case is discussed later in this section.) For example, each of the following table creation statements is invalid:

```
CREATE TABLE t1 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1),
    UNIQUE KEY (col3)
)
PARTITION BY HASH(col1 + col3)
```

```
PARTITIONS 4;
```

In each case, the proposed table would have at least one unique key that does not include all columns used in the partitioning expression.

Each of the following statements is valid, and represents one way in which the corresponding invalid table creation statement could be made to work:

```
CREATE TABLE t1 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col2, col3)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

This example shows the error produced in such cases:

```
mysql> CREATE TABLE t3 (
    ->     col1 INT NOT NULL,
    ->     col2 DATE NOT NULL,
    ->     col3 INT NOT NULL,
    ->     col4 INT NOT NULL,
    ->     UNIQUE KEY (col1, col2),
    ->     UNIQUE KEY (col3)
    -> )
    -> PARTITION BY HASH(col1 + col3)
    -> PARTITIONS 4;
ERROR 1491 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

The `CREATE TABLE` statement fails because both `col1` and `col3` are included in the proposed partitioning key, but neither of these columns is part of both of unique keys on the table. This shows one possible fix for the invalid table definition:

```
mysql> CREATE TABLE t3 (
    ->     col1 INT NOT NULL,
    ->     col2 DATE NOT NULL,
    ->     col3 INT NOT NULL,
    ->     col4 INT NOT NULL,
    ->     UNIQUE KEY (col1, col2, col3),
    ->     UNIQUE KEY (col3)
    -> )
    -> PARTITION BY HASH(col3)
    -> PARTITIONS 4;
Query OK, 0 rows affected (0.05 sec)
```

In this case, the proposed partitioning key `col3` is part of both unique keys, and the table creation statement succeeds.

The following table cannot be partitioned at all, because there is no way to include in a partitioning key any columns that belong to both unique keys:

```
CREATE TABLE t4 (
    col1 INT NOT NULL,
    col2 INT NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
```

```
    UNIQUE KEY (col1, col3),
    UNIQUE KEY (col2, col4)
);
```

Since every primary key is by definition a unique key, this restriction also includes the table's primary key, if it has one. For example, the next two statements are invalid:

```
CREATE TABLE t5 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t6 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col3),
    UNIQUE KEY(col2)
)
PARTITION BY HASH( YEAR(col2) )
PARTITIONS 4;
```

In both cases, the primary key does not include all columns referenced in the partitioning expression. However, both of the next two statements are valid:

```
CREATE TABLE t7 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;

CREATE TABLE t8 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2, col4),
    UNIQUE KEY(col2, col1)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;
```

If a table has no unique keys—this includes having no primary key—then this restriction does not apply, and you may use any column or columns in the partitioning expression as long as the column type is compatible with the partitioning type.

For the same reason, you cannot later add a unique key to a partitioned table unless the key includes all columns used by the table's partitioning expression. Consider the partitioned table created as shown here:

```
mysql> CREATE TABLE t_no_pk (c1 INT, c2 INT)
    ->     PARTITION BY RANGE(c1) (
    ->         PARTITION p0 VALUES LESS THAN (10),
    ->         PARTITION p1 VALUES LESS THAN (20),
    ->         PARTITION p2 VALUES LESS THAN (30),
    ->         PARTITION p3 VALUES LESS THAN (40)
    ->     );
Query OK, 0 rows affected (0.12 sec)
```

It is possible to add a primary key to `t_no_pk` using either of these `ALTER TABLE` statements:

```
#  possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1);
Query OK, 0 rows affected (0.13 sec)
Records: 0  Duplicates: 0  Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.10 sec)
Records: 0  Duplicates: 0  Warnings: 0

#  use another possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1, c2);
Query OK, 0 rows affected (0.12 sec)
Records: 0  Duplicates: 0  Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.09 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

However, the next statement fails, because `c1` is part of the partitioning key, but is not part of the proposed primary key:

```
#  fails with error 1503
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c2);
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

Since `t_no_pk` has only `c1` in its partitioning expression, attempting to adding a unique key on `c2` alone fails. However, you can add a unique key that uses both `c1` and `c2`.

These rules also apply to existing nonpartitioned tables that you wish to partition using `ALTER TABLE ... PARTITION BY`. Consider a table `np_pk` created as shown here:

```
mysql> CREATE TABLE np_pk (
    ->     id INT NOT NULL AUTO_INCREMENT,
    ->     name VARCHAR(50),
    ->     added DATE,
    ->     PRIMARY KEY (id)
    -> );
Query OK, 0 rows affected (0.08 sec)
```

The following `ALTER TABLE` statement fails with an error, because the `added` column is not part of any unique key in the table:

```
mysql> ALTER TABLE np_pk
    ->     PARTITION BY HASH( TO_DAYS(added) )
    ->     PARTITIONS 4;
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

However, this statement using the `id` column for the partitioning column is valid, as shown here:

```
mysql> ALTER TABLE np_pk
    ->     PARTITION BY HASH(id)
    ->     PARTITIONS 4;
Query OK, 0 rows affected (0.11 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

In the case of `np_pk`, the only column that may be used as part of a partitioning expression is `id`; if you wish to partition this table using any other column or columns in the partitioning expression, you must first modify the table, either by adding the desired column or columns to the primary key, or by dropping the primary key altogether.

Partitioning Limitations Relating to Storage Engines

The following limitations apply to the use of storage engines with user-defined partitioning of tables.

`MERGE` storage engine. User-defined partitioning and the `MERGE` storage engine are not compatible. Tables using the `MERGE` storage engine cannot be partitioned. Partitioned tables cannot be merged.

`FEDERATED` storage engine. Partitioning of `FEDERATED` tables is not supported. Beginning with MySQL 5.1.15, it is not possible to create partitioned `FEDERATED` tables at all.

`CSV` storage engine. Partitioned tables using the `CSV` storage engine are not supported. Starting with MySQL 5.1.12, it is not possible to create partitioned `CSV` tables at all.

`BLACKHOLE` storage engine. Prior to MySQL 5.1.6, tables using the `BLACKHOLE` storage engine also could not be partitioned.

`InnoDB` storage engine. `ALTER TABLE ... OPTIMIZE PARTITION` does not work correctly with partitioned tables that use the `InnoDB` storage engine. Use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead. For more information, see `ALTER TABLE` Partition Operations.

`NDBCLUSTER` storage engine (MySQL Cluster). Partitioning by `KEY` (including `LINEAR KEY`) is the only type of partitioning supported for the `NDBCLUSTER` storage engine. Beginning with MySQL 5.1.12, it is not possible to create a MySQL Cluster table using any partitioning type other than [`LINEAR`] `KEY`, and attempting to do so fails with an error.

In addition, the maximum number of partitions that can be defined for an `NDBCLUSTER` table depends on the number of data nodes and node groups in the cluster, the version of the MySQL Cluster software in use, and other factors. See `NDB` and user-defined partitioning, for more information.

Beginning with MySQL Cluster NDB 6.2.18, MySQL Cluster NDB 6.3.25, and MySQL Cluster NDB 7.0.6, `CREATE TABLE` and `ALTER TABLE` statements that would cause a user-partitioned `NDBCLUSTER` table not to meet either or both of the following two requirements are not permitted, and fail with an error (Bug #40709):

1. The table must have an explicit primary key.

2. All columns listed in the table's partitioning expression must be part of the primary key.

Exception. If a user-partitioned `NDBCLUSTER` table is created using an empty column-list (that is, using `PARTITION BY KEY()` or `PARTITION BY LINEAR KEY()`), then no explicit primary key is required.

Upgrading partitioned tables. When performing an upgrade, tables which are partitioned by `KEY` and which use any storage engine other than `NDBCLUSTER` must be dumped and reloaded.

Same storage engine for all partitions. All partitions of a partitioned table must use the same storage engine and it must be the same storage engine used by the table as a whole. In addition, if one does not specify an engine on the table level, then one must do either of the following when creating or altering a partitioned table:

- Do *not* specify any engine for *any* partition or subpartition
- Specify the engine for *all* partitions or subpartitions

Partitioning Limitations Relating to Functions

This section discusses limitations in MySQL Partitioning relating specifically to functions used in partitioning expressions.

Beginning with MySQL 5.1.12, only the MySQL functions shown in the following table are supported in partitioning expressions.

`ABS()` [971]	`CEILING()` [972] (see `CEILING()` and `FLOOR()`)	`DAY()` [986]
`DAYOFMONTH()` [986]	`DAYOFWEEK()` [987]	`DAYOFYEAR()` [987]

DATEDIFF() [982]	EXTRACT() [987] (see EXTRACT() function with WEEK specifier)	FLOOR() [973] (see CEILING() and FLOOR())
HOUR() [988]	MICROSECOND() [989]	MINUTE() [989]
MOD() [975]	MONTH() [989]	QUARTER() [990]
SECOND() [991]	TIME_TO_SEC() [994]	TO_DAYS() [994]
UNIX_TIMESTAMP() [995] (permitted in MySQL 5.1.43 and later, with TIMESTAMP columns)	WEEKDAY() [997]	YEAR() [997]
	YEARWEEK() [997]	

In MySQL 5.1, partition pruning is supported only for the TO_DAYS() [994] and YEAR() [997] functions. See Partition Pruning, for more information.

CEILING() and FLOOR(). Each of these functions returns an integer only if it is passed an argument of an exact numeric type, such as one of the INT types or DECIMAL. This means, for example, that the following CREATE TABLE statement fails with an error, as shown here:

```
mysql> CREATE TABLE t (c FLOAT) PARTITION BY LIST( FLOOR(c) )(
    ->     PARTITION p0 VALUES IN (1,3,5),
    ->     PARTITION p1 VALUES IN (2,4,6)
    -> );
ERROR 1490 (HY000): The PARTITION function returns the wrong type
```

EXTRACT() function with WEEK specifier. The value returned by the EXTRACT() [987] function, when used as EXTRACT(WEEK FROM *col*) [987], depends on the value of the default_week_format [470] system variable. For this reason, beginning with MySQL 5.1.55, EXTRACT() [987] is longer permitted as a partitioning function when it specifies the unit as WEEK. (Bug #54483)

See Mathematical Functions, for more information about the return types of these functions, as well as Numeric Types.

Partitioning and Table-Level Locking

For storage engines such as MyISAM that actually execute table-level locks when executing DML or DDL statements, such a statement affecting a partitioned table imposes a lock on the table as a whole; that is, all partitions are locked until the statement was finished. For example, a SELECT from a partitioned MyISAM table causes a lock on the entire table.

In practical terms, what this means is that the statements discussed later in this section tend to execute more slowly as the number of partitions increases. This limitation is greatly reduced in MySQL 5.6, with the introduction of *partition lock pruning* in MySQL 5.6.6.

This is not true for statements effecting partitioned tables using storage engines such as InnoDB, that employ row-level locking and do not actually perform (or need to perform) the locks prior to partition pruning.

The next few paragraphs discuss the effects of MySQL statements on partitioned tables using storage engines that employ table-level locks.

DML statements

SELECT statements lock the entire table. SELECT statements containing unions or joins lock all tables named in the union or join.

UPDATE also locks the entire table.

REPLACE and INSERT (including INSERT ... ON DUPLICATE KEY UPDATE) lock the entire table.

`INSERT ... SELECT` locks both the source table and the target table.

Note

`INSERT DELAYED` is not supported for partitioned tables.

A `LOAD DATA` statement on a partitioned table locks the entire table.

A trigger on a partitioned table, once activated, locks the entire table.

DDL statements

`CREATE VIEW` causes a lock on any partitioned table from which it reads.

`ALTER TABLE` locks the affected partitioned table.

Other statements

`LOCK TABLES` locks all partitions of a partioned table.

Evaluating the *`expr`* in a `CALL stored_procedure(`*`expr`*`)` statement locks all partitions of any partitioned table referenced by *`expr`*.

`ALTER TABLE` also takes a metadata lock on the table level.

This chapter discusses stored programs and views, which are database objects defined in terms of SQL code that is stored on the server for later execution.

Stored programs include these objects:

- Stored routines, that is, stored procedures and functions. A stored procedure is invoked using the `CALL` statement. A procedure does not have a return value but can modify its parameters for later inspection by the caller. It can also generate result sets to be returned to the client program. A stored function is used much like a built-in function. you invoke it in an expression and it returns a value during expression evaluation.
- Triggers. A trigger is a named database object that is associated with a table and that is activated when a particular event occurs for the table, such as an insert or update.
- Events. An event is a task that the server runs according to schedule.

Views are stored queries that when referenced produce a result set. A view acts as a virtual table.

This chapter describes how to use stored programs and views. The following sections provide additional information about SQL syntax for statements related to these objects:

- For each object type, there are `CREATE`, `ALTER`, and `DROP` statements that control which objects exist and how they are defined. See Data Definition Statements.
- The `CALL` statement is used to invoke stored procedures. See `CALL` Syntax.
- Stored program definitions include a body that may use compound statements, loops, conditionals, and declared variables. See MySQL Compound-Statement Syntax.

Defining Stored Programs

Each stored program contains a body that consists of an SQL statement. This statement may be a compound statement made up of several statements separated by semicolon (`;`) characters. For example, the following stored procedure has a body made up of a `BEGIN ... END` block that contains a `SET` statement and a `REPEAT` loop that itself contains another `SET` statement:

```
CREATE PROCEDURE dorepeat(p1 INT)
BEGIN
  SET @x = 0;
  REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
END;
```

If you use the `mysql` client program to define a stored program containing semicolon characters, a problem arises. By default, `mysql` itself recognizes the semicolon as a statement delimiter, so you must redefine the delimiter temporarily to cause `mysql` to pass the entire stored program definition to the server.

To redefine the `mysql` delimiter, use the `delimiter` command. The following example shows how to do this for the `dorepeat()` procedure just shown. The delimiter is changed to `//` to enable the entire definition to be passed to the server as a single statement, and then restored to `;` before invoking the procedure. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself.

```
mysql> delimiter //

mysql> CREATE PROCEDURE dorepeat(p1 INT)
    -> BEGIN
    ->   SET @x = 0;
    ->   REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
    -> END
    -> //
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;

mysql> CALL dorepeat(1000);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x;
+------+
| @x   |
+------+
| 1001 |
+------+
1 row in set (0.00 sec)
```

You can redefine the delimiter to a string other than `//`, and the delimiter can consist of a single character or multiple characters. You should avoid the use of the backslash (“`\`”) character because that is the escape character for MySQL.

The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
    -> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+----------------+
| hello('world') |
+----------------+
| Hello, world!  |
+----------------+
1 row in set (0.00 sec)
```

Using Stored Routines (Procedures and Functions)

Stored routines (procedures and functions) are supported in MySQL 5.1. A stored routine is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored routine instead.

Stored routines require the `proc` table in the `mysql` database. This table is created during the MySQL 5.1 installation procedure. If you are upgrading to MySQL 5.1 from an earlier version, be sure to update your grant tables to make sure that the `proc` table exists. See `mysql_upgrade` — Check and Upgrade MySQL Tables.

Stored routines can be particularly useful in certain situations:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures and functions for all common operations. This provides a consistent and secure environment, and routines can ensure that each operation is properly logged. In such a setup, applications and users would have no access to the database tables directly, but can only execute specific stored routines.

Stored routines can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored routines also enable you to have libraries of functions in the database server. This is a feature shared by modern application languages that enable such design internally (for example, by using classes). Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored routines, which is also used by IBM's DB2. All syntax described here is supported and any limitations and extensions are documented where appropriate.

Additional Resources

- You may find the Stored Procedures User Forum of use when working with stored procedures and functions.
- For answers to some commonly asked questions regarding stored routines in MySQL, see MySQL 5.1 FAQ: Stored Procedures and Functions.
- There are some restrictions on the use of stored routines. See Restrictions on Stored Programs.
- Binary logging for stored routines takes place as described in Binary Logging of Stored Programs.

Stored Routine Syntax

A stored routine is either a procedure or a function. Stored routines are created with the `CREATE PROCEDURE` and `CREATE FUNCTION` statements (see `CREATE PROCEDURE` and `CREATE FUNCTION` Syntax). A procedure is invoked using a `CALL` statement (see `CALL` Syntax), and can only pass back values using output variables. A function can be called from inside a statement just like any other function (that is, by invoking the function's name), and can return a scalar value. The body of a stored routine can use compound statements (see MySQL Compound-Statement Syntax).

Stored routines can be dropped with the `DROP PROCEDURE` and `DROP FUNCTION` statements (see `DROP PROCEDURE` and `DROP FUNCTION` Syntax), and altered with the `ALTER PROCEDURE` and `ALTER FUNCTION` statements (see `ALTER PROCEDURE` Syntax).

A stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are not permitted.
- You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure `p` or function `f` that is associated with the `test` database, you can say `CALL test.p()` or `test.f()`.
- When a database is dropped, all stored routines associated with it are dropped as well.

Stored functions cannot be recursive.

Recursion in stored procedures is permitted but disabled by default. To enable recursion, set the `max_sp_recursion_depth` [499] server system variable to a value greater than zero. Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth` [499], it may be necessary to increase thread stack size by increasing the value of `thread_stack` [532] at server startup. See Server System Variables, for more information.

MySQL supports a very useful extension that enables the use of regular `SELECT` statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple `SELECT` statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1. The client should also specify the `CLIENT_MULTI_RESULTS` option when it connects. For C programs, this can be done with the `mysql_real_connect()` C API function. See `mysql_real_connect()`, and C API Support for Multiple Statement Execution.

Stored Routines and MySQL Privileges

The MySQL grant system takes stored routines into account as follows:

- The `CREATE ROUTINE` [626] privilege is needed to create stored routines.
- The `ALTER ROUTINE` [626] privilege is needed to alter or drop stored routines. This privilege is granted automatically to the creator of a routine if necessary, and dropped from the creator when the routine is dropped.
- The `EXECUTE` [626] privilege is required to execute stored routines. However, this privilege is granted automatically to the creator of a routine if necessary (and dropped from the creator when the routine is dropped). Also, the default `SQL SECURITY` characteristic for a routine is `DEFINER`, which enables users who have access to the database with which the routine is associated to execute the routine.
- If the `automatic_sp_privileges` [462] system variable is 0, the `EXECUTE` [626] and `ALTER ROUTINE` [626] privileges are not automatically granted to and dropped from the routine creator.
- The creator of a routine is the account used to execute the `CREATE` statement for it. This might not be the same as the account named as the `DEFINER` in the routine definition.

The server manipulates the `mysql.proc` table in response to statements that create, alter, or drop stored routines. It is not supported that the server will notice manual manipulation of this table.

Stored Routine Metadata

Metadata about stored routines can be obtained as follows:

- Query the `ROUTINES` table of the `INFORMATION_SCHEMA` database. See The `INFORMATION_SCHEMA ROUTINES` Table.
- Use the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements to see routine definitions. See `SHOW CREATE PROCEDURE` Syntax.

- Use the SHOW PROCEDURE STATUS and SHOW FUNCTION STATUS statements to see routine characteristics. See SHOW PROCEDURE STATUS Syntax.
- INFORMATION_SCHEMA does not have a PARAMETERS table until MySQL 5.5, so applications that need to acquire routine parameter information at runtime must use workarounds such as parsing the output of SHOW CREATE statements or the param_list column of the mysql.proc table. param_list contents can be processed from within a stored routine, unlike the output from SHOW.

Stored Procedures, Functions, Triggers, and LAST_INSERT_ID()

Within the body of a stored routine (procedure or function) or a trigger, the value of LAST_INSERT_ID() [1036] changes the same way as for statements executed outside the body of these kinds of objects (see Information Functions). The effect of a stored routine or trigger upon the value of LAST_INSERT_ID() [1036] that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of LAST_INSERT_ID() [1036], the changed value is seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements do not see a changed value.

Using Triggers

A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Some uses for triggers are to perform checks of values to be inserted into a table or to perform calculations on values involved in an update.

A trigger is defined to activate when an INSERT, DELETE, or UPDATE statement executes for the associated table. A trigger can be set to activate either before or after the triggering statement. For example, you can have a trigger activate before each row that is inserted into a table or after each row that is updated.

Important

MySQL triggers are activated by SQL statements *only*. They are not activated by changes in views, nor by changes to tables made by APIs that do not transmit SQL statements to the MySQL Server. This means that:

- Triggers are not activated by changes in INFORMATION_SCHEMA tables, because these tables are actually views.
- Triggers are not activated by updates made using the NDB API.

To use triggers if you have upgraded to MySQL 5.1 from an older release that did not support triggers, you should upgrade your grant tables so that they contain the trigger-related privileges. See mysql_upgrade — Check and Upgrade MySQL Tables.

The following discussion describes the syntax for creating and dropping triggers, and shows some examples of how to use them.

Additional Resources

- You may find the Triggers User Forum of use when working with views.
- For answers to some commonly asked questions regarding triggers in MySQL, see MySQL 5.1 FAQ: Triggers.
- There are some restrictions on the use of triggers; see Restrictions on Stored Programs.

- Binary logging for triggers takes place as described in Binary Logging of Stored Programs.

Trigger Syntax

To create a trigger or drop a trigger, use the `CREATE TRIGGER` or `DROP TRIGGER` statement. The syntax for these statements is described in `CREATE TRIGGER` Syntax, and `DROP TRIGGER` Syntax.

Here is a simple example that associates a trigger with a table for `INSERT` statements. The trigger acts as an accumulator, summing the values inserted into one of the columns of the table.

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
Query OK, 0 rows affected (0.03 sec)

mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
    -> FOR EACH ROW SET @sum = @sum + NEW.amount;
Query OK, 0 rows affected (0.06 sec)
```

The `CREATE TRIGGER` statement creates a trigger named `ins_sum` that is associated with the `account` table. It also includes clauses that specify the trigger activation time, the triggering event, and what to do with the trigger activates:

- The keyword `BEFORE` indicates the trigger action time. In this case, the trigger should activate before each row inserted into the table. The other permissible keyword here is `AFTER`.
- The keyword `INSERT` indicates the event that activates the trigger. In the example, `INSERT` statements cause trigger activation. You can also create triggers for `DELETE` and `UPDATE` statements.
- The statement following `FOR EACH ROW` defines the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering statement In the example, the triggered statement is a simple `SET` that accumulates the values inserted into the `amount` column. The statement refers to the column as `NEW.amount` which means “the value of the `amount` column to be inserted into the new row.”

To use the trigger, set the accumulator variable to zero, execute an `INSERT` statement, and then see what value the variable has afterward:

```
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
+-----------------------+
| Total amount inserted |
+-----------------------+
| 1852.48               |
+-----------------------+
```

In this case, the value of `@sum` after the `INSERT` statement has executed is `14.98 + 1937.50 - 100`, or `1852.48`.

To destroy the trigger, use a `DROP TRIGGER` statement. You must specify the schema name if the trigger is not in the default schema:

```
mysql> DROP TRIGGER test.ins_sum;
```

Triggers for a table are also dropped if you drop the table.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

In addition to the requirement that trigger names be unique for a schema, there are other limitations on the types of triggers you can create. In particular, you cannot have two triggers for a table that have the same activation time and activation event. For example, you cannot define two `BEFORE INSERT` triggers or two `AFTER UPDATE` triggers for a table. This should rarely be a significant limitation,

because it is possible to define a trigger that executes multiple statements by using the `BEGIN ... END` compound statement construct after `FOR EACH ROW`. (An example appears later in this section.)

The `OLD` and `NEW` keywords enable you to access columns in the rows affected by a trigger. (`OLD` and `NEW` are not case sensitive.) In an `INSERT` trigger, only `NEW.col_name` can be used; there is no old row. In a `DELETE` trigger, only `OLD.col_name` can be used; there is no new row. In an `UPDATE` trigger, you can use `OLD.col_name` to refer to the columns of a row before it is updated and `NEW.col_name` to refer to the columns of the row after it is updated.

A column named with `OLD` is read only. You can refer to it (if you have the `SELECT` privilege), but not modify it. A column named with `NEW` can be referred to if you have the `SELECT` [627] privilege for it. In a `BEFORE` trigger, you can also change its value with `SET NEW.col_name = value` if you have the `UPDATE` [628] privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or that are used to update a row.

In a `BEFORE` trigger, the `NEW` value for an `AUTO_INCREMENT` column is 0, not the automatically generated sequence number that will be generated when the new record actually is inserted.

`OLD` and `NEW` are MySQL extensions to triggers.

By using the `BEGIN ... END` construct, you can define a trigger that executes multiple statements. Within the `BEGIN` block, you also can use other syntax that is permitted within stored routines such as conditionals and loops. However, just as for stored routines, if you use the `mysql` program to define a trigger that executes multiple statements, it is necessary to redefine the `mysql` statement delimiter so that you can use the `;` statement delimiter within the trigger definition. The following example illustrates these points. It defines an `UPDATE` trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a `BEFORE` trigger because the value needs to be checked before it is used to update the row:

```
mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
    -> FOR EACH ROW
    -> BEGIN
    ->     IF NEW.amount < 0 THEN
    ->         SET NEW.amount = 0;
    ->     ELSEIF NEW.amount > 100 THEN
    ->         SET NEW.amount = 100;
    ->     END IF;
    -> END;//
mysql> delimiter ;
```

It can be easier to define a stored procedure separately and then invoke it from the trigger using a simple `CALL` statement. This is also advantageous if you want to invoke the same routine from within several triggers.

There are some limitations on what can appear in statements that a trigger executes when activated:

- The trigger cannot use the `CALL` statement to invoke stored procedures that return data to the client or that use dynamic SQL. (Stored procedures are permitted to return data to the trigger through `OUT` or `INOUT` parameters.)
- The trigger cannot use statements that explicitly or implicitly begin or end a transaction such as `START TRANSACTION`, `COMMIT`, or `ROLLBACK`.

MySQL handles errors during trigger execution as follows:

- If a `BEFORE` trigger fails, the operation on the corresponding row is not performed.
- A `BEFORE` trigger is activated by the *attempt* to insert or modify the row, regardless of whether the attempt subsequently succeeds.
- An `AFTER` trigger is executed only if the `BEFORE` trigger (if any) and the row operation both execute successfully.

- An error during either a `BEFORE` or `AFTER` trigger results in failure of the entire statement that caused trigger invocation.
- For transactional tables, failure of a statement should cause rollback of all changes performed by the statement. Failure of a trigger causes the statement to fail, so trigger failure also causes rollback. For nontransactional tables, such rollback cannot be done, so although the statement fails, any changes performed prior to the point of the error remain in effect.

Trigger Metadata

Metadata about triggers can be obtained as follows:

- Query the `TRIGGERS` table of the `INFORMATION_SCHEMA` database. See The `INFORMATION_SCHEMA TRIGGERS` Table.
- Use the `SHOW TRIGGERS` statement. See `SHOW TRIGGERS` Syntax.

Using the Event Scheduler

The *MySQL Event Scheduler* manages the scheduling and execution of events: Tasks that run according to schedule. Event support was added in MySQL 5.1.6. The following discussion covers the Event Scheduler and is divided into the following sections:

- Event Scheduler Overview, provides an introduction to and conceptual overview of MySQL Events.
- Event Syntax, discusses the SQL statements for creating, altering, and dropping MySQL Events.
- Event Metadata, shows how to obtain information about events and how this information is stored by the MySQL Server.
- The Event Scheduler and MySQL Privileges, discusses the privileges required to work with events and the ramifications that events have with regard to privileges when executing.

Stored routines require the `event` table in the `mysql` database. This table is created during the MySQL 5.1 installation procedure. If you are upgrading to MySQL 5.1 from an earlier version, be sure to update your grant tables to make sure that the `event` table exists. See `mysql_upgrade` — Check and Upgrade MySQL Tables.

Additional Resources

- You may find the MySQL Event Scheduler User Forum of use when working with scheduled events.
- There are some restrictions on the use of events; see Restrictions on Stored Programs.
- Binary logging for events takes place as described in Binary Logging of Stored Programs.

Event Scheduler Overview

MySQL Events are tasks that run according to a schedule. Therefore, we sometimes refer to them as *scheduled* events. When you create an event, you are creating a named database object containing one or more SQL statements to be executed at one or more regular intervals, beginning and ending at a specific date and time. Conceptually, this is similar to the idea of the Unix `crontab` (also known as a "cron job") or the Windows Task Scheduler.

Scheduled tasks of this type are also sometimes known as "temporal triggers", implying that these are objects that are triggered by the passage of time. While this is essentially correct, we prefer to use the term *events* to avoid confusion with triggers of the type discussed in Using Triggers. Events should more specifically not be confused with "temporary triggers". Whereas a trigger is a database object whose statements are executed in response to a specific type of event that occurs on a given table, a (scheduled) event is an object whose statements are executed in response to the passage of a specified time interval.

While there is no provision in the SQL Standard for event scheduling, there are precedents in other database systems, and you may notice some similarities between these implementations and that found in the MySQL Server.

MySQL Events have the following major features and properties:

- In MySQL 5.1.12 and later, an event is uniquely identified by its name and the schema to which it is assigned. (Previously, an event was also unique to its definer.)
- An event performs a specific action according to a schedule. This action consists of an SQL statement, which can be a compound statement in a `BEGIN ... END` block if desired (see MySQL Compound-Statement Syntax). An event's timing can be either *one-time* or *recurrent*. A one-time event executes one time only. A recurrent event repeats its action at a regular interval, and the schedule for a recurring event can be assigned a specific start day and time, end day and time, both, or neither. (By default, a recurring event's schedule begins as soon as it is created, and continues indefinitely, until it is disabled or dropped.)

  If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the `GET_LOCK()` [1040] function, or row or table locking.
- Users can create, modify, and drop scheduled events using SQL statements intended for these purposes. Syntactically invalid event creation and modification statements fail with an appropriate error message. *A user may include statements in an event's action which require privileges that the user does not actually have*. The event creation or modification statement succeeds but the event's action fails. See The Event Scheduler and MySQL Privileges for details.
- Many of the properties of an event can be set or modified using SQL statements. These properties include the event's name, timing, persistence (that is, whether it is preserved following the expiration of its schedule), status (enabled or disabled), action to be performed, and the schema to which it is assigned. See `ALTER EVENT` Syntax.

  The default definer of an event is the user who created the event, unless the event has been altered, in which case the definer is the user who issued the last `ALTER EVENT` statement affecting that event. An event can be modified by any user having the `EVENT` [626] privilege on the database for which the event is defined. (Prior to MySQL 5.1.12, only an event's definer, or a user having privileges on the `mysql.event` table, could modify a given event.) See The Event Scheduler and MySQL Privileges.
- An event's action statement may include most SQL statements permitted within stored routines. For restrictions, see Restrictions on Stored Programs.

Event Scheduler Configuration

Events are executed by a special *event scheduler thread*; when we refer to the Event Scheduler, we actually refer to this thread. When running, the event scheduler thread and its current state can be seen by users having the `PROCESS` [627] privilege in the output of `SHOW PROCESSLIST`, as shown in the discussion that follows.

The global `event_scheduler` [474] system variable determines whether the Event Scheduler is enabled and running on the server. Beginning with MySQL 5.1.12, it has one of these 3 values, which affect event scheduling as described here:

- `OFF`: The Event Scheduler is stopped. The event scheduler thread does not run, is not shown in the output of `SHOW PROCESSLIST`, and no scheduled events are executed. `OFF` is the default value for `event_scheduler` [474].

  When the Event Scheduler is stopped (`event_scheduler` [474] is `OFF`), it can be started by setting the value of `event_scheduler` [474] to `ON`. (See next item.)

- `ON`: The Event Scheduler is started; the event scheduler thread runs and executes all scheduled events.

  When the Event Scheduler is `ON`, the event scheduler thread is listed in the output of `SHOW PROCESSLIST` as a daemon process, and its state is represented as shown here:

```
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
     Id: 1
   User: root
   Host: localhost
     db: NULL
Command: Query
   Time: 0
  State: NULL
   Info: show processlist
*************************** 2. row ***************************
     Id: 2
   User: event_scheduler
   Host: localhost
     db: NULL
Command: Daemon
   Time: 3
  State: Waiting for next activation
   Info: NULL
2 rows in set (0.00 sec)
```

  Event scheduling can be stopped by setting the value of `event_scheduler` [474] to `OFF`.

- `DISABLED`: This value renders the Event Scheduler nonoperational. When the Event Scheduler is `DISABLED`, the event scheduler thread does not run (and so does not appear in the output of `SHOW PROCESSLIST`). In addition, the Event Scheduler state cannot be changed at runtime.

If the Event Scheduler status has not been set to `DISABLED`, `event_scheduler` [474] can be toggled between `ON` and `OFF` (using `SET`). It is also possible to use `0` for `OFF`, and `1` for `ON` when setting this variable. Thus, any of the following 4 statements can be used in the `mysql` client to turn on the Event Scheduler:

```
SET GLOBAL event_scheduler = ON;
SET @@global.event_scheduler = ON;
SET GLOBAL event_scheduler = 1;
SET @@global.event_scheduler = 1;
```

Similarly, any of these 4 statements can be used to turn off the Event Scheduler:

```
SET GLOBAL event_scheduler = OFF;
SET @@global.event_scheduler = OFF;
SET GLOBAL event_scheduler = 0;
SET @@global.event_scheduler = 0;
```

Although `ON` and `OFF` have numeric equivalents, the value displayed for `event_scheduler` [474] by `SELECT` or `SHOW VARIABLES` is always one of `OFF`, `ON`, or `DISABLED`. *`DISABLED` has no numeric equivalent*. For this reason, `ON` and `OFF` are usually preferred over `1` and `0` when setting this variable.

Note that attempting to set `event_scheduler` [474] without specifying it as a global variable causes an error:

```
mysql< SET @@event_scheduler = OFF;
ERROR 1229 (HY000): Variable 'event_scheduler' is a GLOBAL
variable and should be set with SET GLOBAL
```

Important

It is possible to set the Event Scheduler to `DISABLED` only at server startup. If `event_scheduler` [474] is `ON` or `OFF`, you cannot set it to `DISABLED` at runtime. Also, if the Event Scheduler is set to `DISABLED` at startup, you cannot change the value of `event_scheduler` [474] at runtime.

To disable the event scheduler, use one of the following two methods:

- As a command-line option when starting the server:

```
--event-scheduler=DISABLED
```

- In the server configuration file (`my.cnf`, or `my.ini` on Windows systems), include the line where it will be read by the server (for example, in a `[mysqld]` section):

```
event_scheduler=DISABLED
```

To enable the Event Scheduler, restart the server without the `--event-scheduler=DISABLED` [427] command-line option, or after removing or commenting out the line containing `event-scheduler=DISABLED` [427] in the server configuration file, as appropriate. Alternatively, you can use `ON` (or `1`) or `OFF` (or `0`) in place of the `DISABLED` value when starting the server.

Note

You can issue event-manipulation statements when `event_scheduler` [474] is set to `DISABLED`. No warnings or errors are generated in such cases (provided that the statements are themselves valid). However, scheduled events cannot execute until this variable is set to `ON` (or `1`). Once this has been done, the event scheduler thread executes all events whose scheduling conditions are satisfied.

In MySQL 5.1.11, `event_scheduler` [474] behaved as follows: this variable could take one of the values `0` (or `OFF`), `1` (or `ON`), or `2`. Setting it to `0` turned event scheduling off, so that the event scheduler thread did not run; the `event_scheduler` [474] variable could not be set to this value while the server was running. Setting it to `1` so that the event scheduler thread ran and executed scheduled events. In this state, the event scheduler thread appeared to be sleeping when viewed with `SHOW PROCESSLIST`. When `event_scheduler` [474] was set to `2` (which was the default value), the Event Scheduler was considered to be “suspended”; the event scheduler thread ran and could be seen in the output of `SHOW PROCESSLIST` (where `Suspended` was displayed in the `State` column), but did not execute any scheduled events. The value of `event_scheduler` [474] could be changed only between `1` (or `ON`) and `2` while the server was running. Setting it to `0` (or `OFF`) required a server restart, as did changing its value from `0` (or `OFF`) to `1` (or `ON`) or `2`.

Prior to MySQL 5.1.11, `event_scheduler` [474] could take one of only the 2 values `0`|`OFF` or `1`|`ON`, and the default value was `0`|`OFF`. It was also possible to start and stop the event scheduler thread while the MySQL server was running.

For more information concerning the reasons for these changes in behavior, see Bug #17619.

Beginning with MySQL 5.1.17, starting the MySQL server with the `--skip-grant-tables` [443] option causes `event_scheduler` [474] to be set to `DISABLED`, overriding any other value set either on the command line or in the `my.cnf` or `my.ini` file (Bug #26807).

For SQL statements used to create, alter, and drop events, see Event Syntax.

MySQL 5.1.6 and later provides an `EVENTS` table in the `INFORMATION_SCHEMA` database. This table can be queried to obtain information about scheduled events which have been defined on the server. See Event Metadata, and The `INFORMATION_SCHEMA EVENTS` Table, for more information.

For information regarding event scheduling and the MySQL privilege system, see The Event Scheduler and MySQL Privileges.

Event Syntax

MySQL 5.1.6 and later provides several SQL statements for working with scheduled events:

- New events are defined using the `CREATE EVENT` statement. See `CREATE EVENT` Syntax.

- The definition of an existing event can be changed by means of the `ALTER EVENT` statement. See `ALTER EVENT` Syntax.
- When a scheduled event is no longer wanted or needed, it can be deleted from the server by its definer using the `DROP EVENT` statement. See `DROP EVENT` Syntax. Whether an event persists past the end of its schedule also depends on its `ON COMPLETION` clause, if it has one. See `CREATE EVENT` Syntax.

  An event can be dropped by any user having the `EVENT` [626] privilege for the database on which the event is defined. Prior to MySQL 5.1.12, a user other than the definer required privileges on the `mysql.event` table. See The Event Scheduler and MySQL Privileges.

Event Metadata

Metadata about events can be obtained as follows:

- Query the `event` table of the `mysql` database.
- Query the `EVENTS` table of the `INFORMATION_SCHEMA` database. See The `INFORMATION_SCHEMA EVENTS` Table.
- Use the `SHOW CREATE EVENT` statement. See `SHOW CREATE EVENT` Syntax.
- Use the `SHOW EVENTS` statement. See `SHOW EVENTS` Syntax.

Event Scheduler Time Representation

Each session in MySQL has a session time zone (STZ). This is the session `time_zone` [533] value that is initialized from the server's global `time_zone` [533] value when the session begins but may be changed during the session.

The session time zone that is current when a `CREATE EVENT` or `ALTER EVENT` statement executes is used to interpret times specified in the event definition. This becomes the event time zone (ETZ); that is, the time zone that is used for event scheduling and is in effect within the event as it executes.

For representation of event information in the `mysql.event` table, the `execute_at`, `starts`, and `ends` times are converted to UTC and stored along with the event time zone. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. The `last_executed` time is also stored in UTC.

If you select information from `mysql.event`, the times just mentioned are retrieved as UTC values. These times can also be obtained by selecting from the `INFORMATION_SCHEMA.EVENTS` table or from `SHOW EVENTS`, but they are reported as ETZ values. Other times available from these sources indicate when an event was created or last altered; these are displayed as STZ values. The following table summarizes representation of event times.

Value	`mysql.event`	`INFORMATION_SCHEMA.EVENTS`	`SHOW EVENTS`
Execute at	UTC	ETZ	ETZ
Starts	UTC	ETZ	ETZ
Ends	UTC	ETZ	ETZ
Last executed	UTC	ETZ	n/a
Created	STZ	STZ	n/a
Last altered	STZ	STZ	n/a

The preceding table applies for MySQL 5.1.17 and up. Prior to MySQL 5.1.17, the event time zone is not stored in the `mysql.event` table or available from `INFORMATION_SCHEMA.EVENTS` or `SHOW`

EVENTS. Times that are displayed using ETZ from 5.1.17 and up are displayed in UTC before 5.1.17, as shown in the following table.

Value	mysql.event	INFORMATION_SCHEMA.EVENTS	SHOW EVENTS
Execute at	UTC	UTC	UTC
Starts	UTC	UTC	UTC
Ends	UTC	UTC	UTC
Last executed	UTC	UTC	n/a
Created	STZ	STZ	n/a
Last altered	STZ	STZ	n/a

Event Scheduler Status

The Event Scheduler writes information about event execution that terminates with an error or warning to the MySQL Server's error log. See The Event Scheduler and MySQL Privileges for an example. (Before MySQL 5.1.31, the Event Scheduler also logged messages when events started execution and terminated successfully.)

Information about the state of the Event Scheduler for debugging and troubleshooting purposes can be obtained as follows:

- In debugging builds of MySQL 5.1.11, you can use the SHOW SCHEDULER STATUS statement; see SHOW SCHEDULER STATUS Syntax. This statement was removed in MySQL 5.1.12. We intend to implement an SQL statement providing similar functionality in a future MySQL release.
- Beginning with MySQL 5.1.12, event scheduler status information can be obtained by running mysqladmin debug (see mysqladmin — Client for Administering a MySQL Server); after running this command, the server's error log contains output relating to the Event Scheduler, similar to what is shown here:

```
Events status:
LLA = Last Locked At  LUA = Last Unlocked At
WOC = Waiting On Condition  DL = Data Locked

Event scheduler status:
State      : INITIALIZED
Thread id  : 0
LLA        : init_scheduler:313
LUA        : init_scheduler:318
WOC        : NO
Workers    : 0
Executed   : 0
Data locked: NO

Event queue status:
Element count   : 1
Data locked     : NO
Attempting lock : NO
LLA             : init_queue:148
LUA             : init_queue:168
WOC             : NO
Next activation : 0000-00-00 00:00:00
```

In statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For frequently executed events, it is possible for this to result in many logged messages. For example, for SELECT ... INTO *var_list* statements, if the query returns no rows, a warning with error code 1329 occurs (No data), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (Result consisted of more than one row). For either condition, you can avoid having the warnings be logged by declaring a condition handler; see

`DECLARE ... HANDLER` Syntax. For statements that may retrieve multiple rows, another strategy is to use `LIMIT 1` to limit the result set to a single row.

The Event Scheduler and MySQL Privileges

To enable or disable the execution of scheduled events, it is necessary to set the value of the global `event_scheduler` [474] system variable. This requires the `SUPER` [628] privilege.

MySQL 5.1.6 introduces a privilege governing the creation, modification, and deletion of events, the `EVENT` [626] privilege. This privilege can be bestowed using `GRANT`. For example, this `GRANT` statement confers the `EVENT` [626] privilege for the schema named `myschema` on the user `jon@ghidora`:

```
GRANT EVENT ON myschema.* TO jon@ghidora;
```

(We assume that this user account already exists, and that we wish for it to remain unchanged otherwise.)

To grant this same user the `EVENT` [626] privilege on all schemas, use the following statement:

```
GRANT EVENT ON *.* TO jon@ghidora;
```

The `EVENT` [626] privilege has global or schema-level scope. Therefore, trying to grant it on a single table results in an error as shown:

```
mysql> GRANT EVENT ON myschema.mytable TO jon@ghidora;
ERROR 1144 (42000): Illegal GRANT/REVOKE command; please
consult the manual to see which privileges can be used
```

It is important to understand that an event is executed with the privileges of its definer, and that it cannot perform any actions for which its definer does not have the requisite privileges. For example, suppose that `jon@ghidora` has the `EVENT` [626] privilege for `myschema`. Suppose also that this user has the `SELECT` [627] privilege for `myschema`, but no other privileges for this schema. It is possible for `jon@ghidora` to create a new event such as this one:

```
CREATE EVENT e_store_ts
    ON SCHEDULE
      EVERY 10 SECOND
    DO
      INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
```

The user waits for a minute or so, and then performs a `SELECT * FROM mytable;` query, expecting to see several new rows in the table. Instead, the table is empty. Since the user does not have the `INSERT` [627] privilege for the table in question, the event has no effect.

If you inspect the MySQL error log (*`hostname`*`.err`), you can see that the event is executing, but the action it is attempting to perform fails, as indicated by `RetCode=0`:

```
060209 22:39:44 [Note]     EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:39:44 [Note]     EVEX EXECUTED event newdb.e  [EXPR:10]. RetCode=0
060209 22:39:54 [Note]     EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:39:54 [Note]     EVEX EXECUTED event newdb.e  [EXPR:10]. RetCode=0
060209 22:40:04 [Note]     EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:40:04 [Note]     EVEX EXECUTED event newdb.e  [EXPR:10]. RetCode=0
```

Since this user very likely does not have access to the error log, it is possible to verify whether the event's action statement is valid by executing it directly:

```
mysql> INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
ERROR 1142 (42000): INSERT command denied to user
'jon'@'ghidora' for table 'mytable'
```

Inspection of the `INFORMATION_SCHEMA.EVENTS` table shows that `e_store_ts` exists and is enabled, but its `LAST_EXECUTED` column is `NULL`:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
     >     WHERE EVENT_NAME='e_store_ts'
     >     AND EVENT_SCHEMA='myschema'\G
*************************** 1. row ***************************
   EVENT_CATALOG: NULL
    EVENT_SCHEMA: myschema
      EVENT_NAME: e_store_ts
         DEFINER: jon@ghidora
      EVENT_BODY: SQL
EVENT_DEFINITION: INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP())
      EVENT_TYPE: RECURRING
      EXECUTE_AT: NULL
  INTERVAL_VALUE: 5
  INTERVAL_FIELD: SECOND
        SQL_MODE: NULL
          STARTS: 0000-00-00 00:00:00
            ENDS: 0000-00-00 00:00:00
          STATUS: ENABLED
   ON_COMPLETION: NOT PRESERVE
         CREATED: 2006-02-09 22:36:06
    LAST_ALTERED: 2006-02-09 22:36:06
   LAST_EXECUTED: NULL
   EVENT_COMMENT:
1 row in set (0.00 sec)
```

Note

Prior to MySQL 5.1.12, there was no `EVENT_DEFINITION` column, and `EVENT_BODY` contained the SQL statement or statements to be executed. See The `INFORMATION_SCHEMA EVENTS` Table, for more information.

To rescind the `EVENT` [626] privilege, use the `REVOKE` statement. In this example, the `EVENT` [626] privilege on the schema `myschema` is removed from the `jon@ghidora` user account:

```
REVOKE EVENT ON myschema.* FROM jon@ghidora;
```

Important

Revoking the `EVENT` [626] privilege from a user does not delete or disable any events that may have been created by that user.

An event is not migrated or dropped as a result of renaming or dropping the user who created it.

Suppose that the user `jon@ghidora` has been granted the `EVENT` [626] and `INSERT` [627] privileges on the `myschema` schema. This user then creates the following event:

```
CREATE EVENT e_insert
    ON SCHEDULE
      EVERY 7 SECOND
    DO
      INSERT INTO myschema.mytable;
```

After this event has been created, `root` revokes the `EVENT` [626] privilege for `jon@ghidora`. However, `e_insert` continues to execute, inserting a new row into `mytable` each seven seconds. The same would be true if `root` had issued either of these statements:

- `DROP USER jon@ghidora;`
- `RENAME USER jon@ghidora TO someotherguy@ghidora;`

You can verify that this is true by examining the `mysql.event` table (discussed later in this section) or the `INFORMATION_SCHEMA.EVENTS` table (see The `INFORMATION_SCHEMA EVENTS` Table) before and after issuing a `DROP USER` or `RENAME USER` statement.

Event definitions are stored in the `mysql.event` table, which was added in MySQL 5.1.6. To drop an event created by another user account, the MySQL `root` user (or another user with the necessary

privileges) can delete rows from this table. For example, to remove the event `e_insert` shown previously, `root` can use the following statement:

```
DELETE FROM mysql.event
    WHERE db = 'myschema'
      AND definer = 'jon@ghidora'
      AND name = 'e_insert';
```

It is very important to match the event name, database schema name, and user account when deleting rows from the `mysql.event` table. This is because the same user can create different events of the same name in different schemas.

Note

The namespace for scheduled events changed in MySQL 5.1.12. Prior to that MySQL version, different users could create different events having the same name in the same database; in MySQL 5.1.12 and later, that is no longer the case. When upgrading to MySQL 5.1.12 or later from MySQL 5.1.11 or earlier, it is extremely important to make sure that no events in the same database share the same name, *prior to performing the upgrade*.

Users' `EVENT` [626] privileges are stored in the `Event_priv` columns of the `mysql.user` and `mysql.db` tables. In both cases, this column holds one of the values 'Y' or 'N'. 'N' is the default. `mysql.user.Event_priv` is set to 'Y' for a given user only if that user has the global `EVENT` [626] privilege (that is, if the privilege was bestowed using `GRANT EVENT ON *.*`). For a schema-level `EVENT` [626] privilege, `GRANT` creates a row in `mysql.db` and sets that row's `Db` column to the name of the schema, the `User` column to the name of the user, and the `Event_priv` column to 'Y'. There should never be any need to manipulate these tables directly, since the `GRANT EVENT` and `REVOKE EVENT` statements perform the required operations on them.

MySQL 5.1.6 introduces five status variables providing counts of event-related operations (but *not* of statements executed by events; see Restrictions on Stored Programs). These are:

- `Com_create_event`: The number of `CREATE EVENT` statements executed since the last server restart.
- `Com_alter_event`: The number of `ALTER EVENT` statements executed since the last server restart.
- `Com_drop_event`: The number of `DROP EVENT` statements executed since the last server restart.
- `Com_show_create_event`: The number of `SHOW CREATE EVENT` statements executed since the last server restart.
- `Com_show_events`: The number of `SHOW EVENTS` statements executed since the last server restart.

You can view current values for all of these at one time by running the statement `SHOW STATUS LIKE '%event%';`.

Using Views

Views (including updatable views) are available in MySQL Server 5.1. Views are stored queries that when invoked produce a result set. A view acts as a virtual table.

To use views if you have upgraded to MySQL 5.1 from an older release that did not support views, you should upgrade your grant tables so that they contain the view-related privileges. See `mysql_upgrade` — Check and Upgrade MySQL Tables.

The following discussion describes the syntax for creating and dropping views, and shows some examples of how to use them.

Additional Resources

- You may find the Views User Forum of use when working with views.
- For answers to some commonly asked questions regarding views in MySQL, see MySQL 5.1 FAQ: Views.
- There are some restrictions on the use of views; see Restrictions on Views.

View Syntax

The `CREATE VIEW` statement creates a new view (see `CREATE VIEW` Syntax). To alter the definition of a view or drop a view, use `ALTER VIEW` (see `ALTER VIEW` Syntax), or `DROP VIEW` (see `DROP VIEW` Syntax).

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50), (5, 60);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+------+-------+-------+
| qty  | price | value |
+------+-------+-------+
|    3 |    50 |   150 |
|    5 |    60 |   300 |
+------+-------+-------+
mysql> SELECT * FROM v WHERE qty = 5;
+------+-------+-------+
| qty  | price | value |
+------+-------+-------+
|    5 |    60 |   300 |
+------+-------+-------+
```

View Processing Algorithms

The optional `ALGORITHM` clause for `CREATE VIEW` or `ALTER VIEW` is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`. The default algorithm is `UNDEFINED` if no `ALGORITHM` clause is present.

For `MERGE`, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.

For `TEMPTABLE`, the results from the view are retrieved into a temporary table, which then is used to execute the statement.

For `UNDEFINED`, MySQL chooses which algorithm to use. It prefers `MERGE` over `TEMPTABLE` if possible, because `MERGE` is usually more efficient and because a view cannot be updatable if a temporary table is used.

A reason to choose `TEMPTABLE` explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the `MERGE` algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be `UNDEFINED` for three reasons:

- No `ALGORITHM` clause is present in the `CREATE VIEW` statement.

- The `CREATE VIEW` statement has an explicit `ALGORITHM = UNDEFINED` clause.
- `ALGORITHM = MERGE` is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to `UNDEFINED`.

As mentioned earlier, `MERGE` is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the `MERGE` algorithm works. The examples assume that there is a view `v_merge` that has this definition:

```
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 1: Suppose that we issue this statement:

```
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

- `v_merge` becomes `t`
- `*` becomes `vc1, vc2`, which corresponds to `c1, c2`
- The view `WHERE` clause is added

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 2: Suppose that we issue this statement:

```
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that `vc1 < 100` becomes `c1 < 100` and the view `WHERE` clause is added to the statement `WHERE` clause using an `AND` [944] connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence). The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a `WHERE` clause of this form:

```
WHERE (select WHERE) AND (view WHERE)
```

If the `MERGE` algorithm cannot be used, a temporary table must be used instead. `MERGE` cannot be used if the view contains any of the following constructs:

- Aggregate functions (`SUM()` [1047], `MIN()` [1047], `MAX()` [1046], `COUNT()` [1045], and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `LIMIT`
- `UNION` or `UNION ALL`
- Subquery in the select list
- Refers only to literal values (in this case, there is no underlying table)

Updatable and Insertable Views

Some views are updatable. That is, you can use them in statements such as `UPDATE`, `DELETE`, or `INSERT` to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions (`SUM()` [1047], `MIN()` [1047], `MAX()` [1046], `COUNT()` [1045], and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `UNION` or `UNION ALL`
- Subquery in the select list
- Certain joins (see additional join discussion later in this section)
- Nonupdatable view in the `FROM` clause
- A subquery in the `WHERE` clause that refers to a table in the `FROM` clause
- Refers only to literal values (in this case, there is no underlying table to update)
- Uses `ALGORITHM = TEMPTABLE` (use of a temporary table always makes a view nonupdatable)
- Multiple references to any column of a base table.

With respect to insertability (being updatable with `INSERT` statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.
- The view must contain all columns in the base table that do not have a default value.
- The view columns must be simple column references and not derived columns. A derived column is one that is not a simple column reference but is derived from an expression. These are examples of derived columns:

```
3.14159
col1 + 3
UPPER(col2)
col3 / col4
(subquery)
```

A view that has a mix of simple column references and derived columns is not insertable, but it can be updatable if you update only those columns that are not derived. Consider this view:

```
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because `col2` is derived from an expression. But it is updatable if the update does not try to update `col2`. This update is permissible:

```
UPDATE v SET col1 = 0;
```

This update is not permissible because it attempts to update a derived column:

```
UPDATE v SET col2 = 0;
```

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the `MERGE` algorithm. For this to work, the view must use an inner join (not an outer join or a

UNION). Also, only a single table in the view definition can be updated, so the SET clause must name only columns from one of the tables in the view. Views that use UNION ALL are not permitted even though they might be theoretically updatable, because the implementation uses temporary tables to process them.

For a multiple-table updatable view, INSERT can work if it inserts into a single table. DELETE is not supported.

INSERT DELAYED is not supported for views.

If a table contains an AUTO_INCREMENT column, inserting into an insertable view on the table that does not include the AUTO_INCREMENT column does not change the value of LAST_INSERT_ID() [1036], because the side effects of inserting default values into columns not part of the view should not be visible.

The WITH CHECK OPTION clause can be given for an updatable view to prevent inserts or updates to rows except those for which the WHERE clause in the *select_statement* is true.

In a WITH CHECK OPTION clause for an updatable view, the LOCAL and CASCADED keywords determine the scope of check testing when the view is defined in terms of another view. The LOCAL keyword restricts the CHECK OPTION only to the view being defined. CASCADED causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is CASCADED. Consider the definitions for the following table and set of views:

```
mysql> CREATE TABLE t1 (a INT);
mysql> CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
    -> WITH CHECK OPTION;
mysql> CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
    -> WITH LOCAL CHECK OPTION;
mysql> CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
    -> WITH CASCADED CHECK OPTION;
```

Here the v2 and v3 views are defined in terms of another view, v1. v2 has a LOCAL check option, so inserts are tested only against the v2 check. v3 has a CASCADED check option, so inserts are tested not only against its own check, but against those of underlying views. The following statements illustrate these differences:

```
mysql> INSERT INTO v2 VALUES (2);
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

MySQL sets a flag, called the view updatability flag, at CREATE VIEW time. The flag is set to YES (true) if UPDATE and DELETE (and similar operations) are legal for the view. Otherwise, the flag is set to NO (false). The IS_UPDATABLE column in the INFORMATION_SCHEMA.VIEWS table displays the status of this flag. It means that the server always knows whether a view is updatable. If the view is not updatable, statements such UPDATE, DELETE, and INSERT are illegal and will be rejected. (Note that even if a view is updatable, it might not be possible to insert into it, as described elsewhere in this section.)

The updatability of views may be affected by the value of the updatable_views_with_limit [537] system variable. See Server System Variables.

View Metadata

Metadata about views can be obtained as follows:

- Query the VIEWS table of the INFORMATION_SCHEMA database. See The INFORMATION_SCHEMA VIEWS Table.
- Use the SHOW CREATE VIEW statement. See SHOW CREATE VIEW Syntax.

Access Control for Stored Programs and Views

Stored programs and views are defined prior to use and, when referenced, execute within a security context that determines their privileges. These privileges are controlled by their `DEFINER` attribute, and, if there is one, their `SQL SECURITY` characteristic.

All stored programs (procedures, functions, triggers, and events) and views can have a `DEFINER` attribute that names a MySQL account. If the `DEFINER` attribute is omitted from a stored program or view definition, the default account is the user who creates the object.

In addition, stored routines (procedures and functions) and views can have a `SQL SECURITY` characteristic with a value of `DEFINER` or `INVOKER` to specify whether the object executes in definer or invoker context. If the `SQL SECURITY` characteristic is omitted, the default is definer context.

Triggers and events have no `SQL SECURITY` characteristic and always execute in definer context. The server invokes these objects automatically as necessary, so there is no invoking user.

Definer and invoker security contexts differ as follows:

- A stored program or view that executes in definer security context executes with the privileges of the account named by its `DEFINER` attribute. These privileges may be entirely different from those of the invoking user. The invoker must have appropriate privileges to reference the object (for example, `EXECUTE` [626] to call a stored procedure or `SELECT` [627] to select from a view), but when the object executes, the invoker's privileges are ignored and only the `DEFINER` account privileges matter. If this account has few privileges, the object is correspondingly limited in the operations it can perform. If the `DEFINER` account is highly privileged (such as a `root` account), the object can perform powerful operations *no matter who invokes it.*
- A stored routine or view that executes in invoker security context can perform only operations for which the invoker has privileges. The `DEFINER` attribute can be specified but has no effect for objects that execute in invoker context.

Consider the following stored procedure:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p1()
SQL SECURITY DEFINER
BEGIN
  UPDATE t1 SET counter = counter + 1;
END;
```

Any user who has the `EXECUTE` [626] privilege for `p1` can invoke it with a `CALL` statement. However, when `p1` executes, it does so in `DEFINER` security context and thus executes with the privileges of `'admin'@'localhost'`, the account named in the `DEFINER` attribute. This account must have the `EXECUTE` [626] privilege for `p1` as well as the `UPDATE` [628] privilege for the table `t1`. Otherwise, the procedure fails.

Now consider this stored procedure, which is identical to `p1` except that its `SQL SECURITY` characteristic is `INVOKER`:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p2()
SQL SECURITY INVOKER
BEGIN
  UPDATE t1 SET counter = counter + 1;
END;
```

`p2`, unlike `p1`, executes in `INVOKER` security context. The `DEFINER` attribute is irrelevant and `p2` executes with the privileges of the invoking user. `p2` fails if the invoker lacks the `EXECUTE` [626] privilege for `p2` or the `UPDATE` [628] privilege for the table `t1`.

MySQL uses the following rules to control which accounts a user can specify in an object `DEFINER` attribute:

- You can specify a DEFINER value other than your own account only if you have the SUPER [628] privilege.
- If you do not have the SUPER [628] privilege, the only legal user value is your own account, either specified literally or by using CURRENT_USER [1033]. You cannot set the definer to some other account.

To minimize the risk potential for stored program and view creation and use, follow these guidelines:

- For a stored routine or view, use SQL SECURITY INVOKER in the object definition when possible so that it can be used only by users with permissions appropriate for the operations performed by the object.
- If you create definer-context stored programs or views while using an account that has the SUPER [628] privilege, specify an explicit DEFINER attribute that names an account possessing only the privileges required for the operations performed by the object. Specify a highly privileged DEFINER account only when absolutely necessary.
- Administrators can prevent users from specifying highly privileged DEFINER accounts by not granting them the SUPER [628] privilege.
- Definer-context objects should be written keeping in mind that they may be able to access data for which the invoking user has no privileges. In some cases, you can prevent reference to these objects by not granting unauthorized users particular privileges:
  - A stored procedure or function cannot be referenced by a user who does not have the EXECUTE [626] privilege for it.
  - A view cannot be referenced by a user who does not have the appropriate privilege for it (SELECT [627] to select from it, INSERT [627] to insert into it, and so forth).

  However, no such control exists for triggers because users do not reference them directly. A trigger always executes in DEFINER context and is activated by access to the table with which it is associated, even ordinary table accesses by users with no special privileges. If the DEFINER account is highly privileged, the trigger can perform sensitive or dangerous operations. This remains true if the SUPER [628] and TRIGGER [628] privileges needed to create the trigger are revoked from the account of the user who created it. Administrators should be especially careful about granting users that combination of privileges.

Binary Logging of Stored Programs

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of “events” that describe the modifications. The binary log has two important purposes:

- For replication, the binary log is used on master replication servers as a record of the statements to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See Replication Implementation.
- Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See Using Backups for Recovery.

However, there are certain binary logging issues that apply with respect to stored programs (stored procedures and functions, triggers, and events), if logging occurs at the statement level:

- In some cases, it is possible that a statement will affect different sets of rows on a master and a slave.
- Replicated statements executed on a slave are processed by the slave SQL thread, which has full privileges. It is possible for a procedure to follow different execution paths on master and slave

servers, so a user can write a routine containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges.

- If a stored program that modifies data is nondeterministic, it is not repeatable. This can result in different data on a master and slave, or cause restored data to differ from the original data.

This section describes how MySQL 5.1 handles binary logging for stored programs. It states the current conditions that the implementation places on the use of stored programs, and what you can do to avoid problems. It also provides additional information about the reasons for these conditions.

In general, the issues described here result when binary logging occurs at the SQL statement level. If you use row-based binary logging, the log contains changes made to individual rows as a result of executing SQL statements. When routines or triggers execute, row changes are logged, not the statements that make the changes. For stored procedures, this means that the `CALL` statement is not logged. For stored functions, row changes made within the function are logged, not the function invocation. For triggers, row changes made by the trigger are logged. On the slave side, only the row changes are seen, not the stored program invocation. For general information about row-based logging, see Replication Formats.

Unless noted otherwise, the remarks here assume that you have enabled binary logging by starting the server with the `--log-bin` [1647] option. (See The Binary Log.) If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery.

The current conditions on the use of stored functions in MySQL 5.1 can be summarized as follows. These conditions do not apply to stored procedures or Event Scheduler events and they do not apply unless binary logging is enabled.

- To create or alter a stored function, you must have the `SUPER` [628] privilege, in addition to the `CREATE ROUTINE` [626] or `ALTER ROUTINE` [626] privilege that is normally required. (Depending on the `DEFINER` value in the function definition, `SUPER` [628] might be required regardless of whether binary logging is enabled. See `CREATE PROCEDURE` and `CREATE FUNCTION` Syntax.)

- When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication.

  By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

  This function is deterministic (and does not modify data), so it is safe:

```
CREATE FUNCTION f1(i INT)
RETURNS INT
DETERMINISTIC
READS SQL DATA
BEGIN
  RETURN i;
END;
```

  This function uses `UUID()` [1042], which is not deterministic, so the function also is not deterministic and is not safe:

```
CREATE FUNCTION f2()
RETURNS CHAR(36) CHARACTER SET utf8
BEGIN
  RETURN UUID();
END;
```

  This function modifies data, so it may not be safe:

```
CREATE FUNCTION f3(p_id INT)
```

```
RETURNS INT
BEGIN
  UPDATE t SET modtime = NOW() WHERE id = p_id;
  RETURN ROW_COUNT();
END;
```

Assessment of the nature of a function is based on the “honesty” of the creator: MySQL does not check that a function declared `DETERMINISTIC` is free of statements that produce nondeterministic results.

- Although it is possible to create a deterministic stored function without specifying `DETERMINISTIC`, you cannot as of MySQL 5.1.15 execute this function using statement-based binary logging. To execute such a function, you must use row-based or mixed binary logging. Alternatively, if you explicitly specify `DETERMINISTIC` in the function definition, you can use any kind of logging, including statement-based logging.

- To relax the preceding conditions on function creation (that you must have the `SUPER` [628] privilege and that a function must be declared deterministic or to not modify data), set the global `log_bin_trust_function_creators` [488] system variable to 1. By default, this variable has a value of 0, but you can change it like this:

  ```
  mysql> SET GLOBAL log_bin_trust_function_creators = 1;
  ```

  You can also set this variable by using the `--log-bin-trust-function-creators=1` [1648] option when starting the server.

  If binary logging is not enabled, `log_bin_trust_function_creators` [488] does not apply. `SUPER` [628] is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- For information about built-in functions that may be unsafe for replication (and thus cause stored functions that use them to be unsafe as well), see Replication Features and Issues.

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: `CREATE TRIGGER` does not have an optional `DETERMINISTIC` characteristic, so triggers are assumed to be always deterministic. However, this assumption might in some cases be invalid. For example, the `UUID()` [1042] function is nondeterministic (and does not replicate). You should be careful about using such functions in triggers.

Triggers can update tables, so error messages similar to those for stored functions occur with `CREATE TRIGGER` if you do not have the required privileges. On the slave side, the slave uses the trigger `DEFINER` attribute to determine which user is considered to be the creator of the trigger.

The rest of this section provides additional detail about the logging implementation and its implications. You need not read it unless you are interested in the background on the rationale for the current logging-related conditions on stored routine use. This discussion applies only for statement-based logging, and not for row-based logging, with the exception of the first item: `CREATE` and `DROP` statements are logged as statements regardless of the logging mode.

- The server writes `CREATE EVENT`, `CREATE PROCEDURE`, `CREATE FUNCTION`, `ALTER EVENT`, `ALTER PROCEDURE`, `ALTER FUNCTION`, `DROP EVENT`, `DROP PROCEDURE`, and `DROP FUNCTION` statements to the binary log.

- A stored function invocation is logged as a `SELECT` statement if the function changes data and occurs within a statement that would not otherwise be logged. This prevents nonreplication of data changes that result from use of stored functions in nonlogged statements. For example, `SELECT` statements are not written to the binary log, but a `SELECT` might invoke a stored function that makes changes. To handle this, a `SELECT` *`func_name`*`()` statement is written to the binary log when the given function makes a change. Suppose that the following statements are executed on the master:

  ```
  CREATE FUNCTION f1(a INT) RETURNS INT
  BEGIN
    IF (a < 3) THEN
  ```

```
    INSERT INTO t2 VALUES (a);
  END IF;
  RETURN 0;
END;

CREATE TABLE t1 (a INT);
INSERT INTO t1 VALUES (1),(2),(3);

SELECT f1(a) FROM t1;
```

When the `SELECT` statement executes, the function `f1()` is invoked three times. Two of those invocations insert a row, and MySQL logs a `SELECT` statement for each of them. That is, MySQL writes the following statements to the binary log:

```
SELECT f1(1);
SELECT f1(2);
```

The server also logs a `SELECT` statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the `SELECT` statement to the log along with the expected error code. On the slave, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

Note: Before MySQL 5.1.7, you will see these `SELECT func_name()` statements logged as `DO func_name()`. The change to `SELECT` was made because use of `DO` was found to yield insufficient control over error code checking.

- Logging stored function invocations rather than the statements executed by a function has a security implication for replication, which arises from two factors:
  - It is possible for a function to follow different execution paths on master and slave servers.
  - Statements executed on a slave are processed by the slave SQL thread which has full privileges.

  The implication is that although a user must have the `CREATE ROUTINE` [626] privilege to create a function, the user can write a function containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges. For example, if the master and slave servers have server ID values of 1 and 2, respectively, a user on the master server could create and invoke an unsafe function `unsafe_func()` as follows:

```
mysql> delimiter //
mysql> CREATE FUNCTION unsafe_func () RETURNS INT
    -> BEGIN
    ->   IF @@server_id=2 THEN dangerous_statement; END IF;
    ->   RETURN 1;
    -> END;
    -> //
mysql> delimiter ;
mysql> INSERT INTO t VALUES(unsafe_func());
```

The `CREATE FUNCTION` and `INSERT` statements are written to the binary log, so the slave will execute them. Because the slave SQL thread has full privileges, it will execute the dangerous statement. Thus, the function invocation has different effects on the master and slave and is not replication-safe.

To guard against this danger for servers that have binary logging enabled, stored function creators must have the `SUPER` [628] privilege, in addition to the usual `CREATE ROUTINE` [626] privilege that is required. Similarly, to use `ALTER FUNCTION`, you must have the `SUPER` [628] privilege in addition to the `ALTER ROUTINE` [626] privilege. Without the `SUPER` [628] privilege, an error will occur:

```
ERROR 1419 (HY000): You do not have the SUPER privilege and
binary logging is enabled (you *might* want to use the less safe
log_bin_trust_function_creators variable)
```

If you do not want to require function creators to have the `SUPER` [628] privilege (for example, if all users with the `CREATE ROUTINE` [626] privilege on your system are experienced

application developers), set the global `log_bin_trust_function_creators` [488] system variable to 1. You can also set this variable by using the `--log-bin-trust-function-creators=1` [1648] option when starting the server. If binary logging is not enabled, `log_bin_trust_function_creators` [488] does not apply. `SUPER` [628] is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- If a function that performs updates is nondeterministic, it is not repeatable. This can have two undesirable effects:
  - It will make a slave different from the master.
  - Restored data will be different from the original data.

  To deal with these problems, MySQL enforces the following requirement: On a master server, creation and alteration of a function is refused unless you declare the function to be deterministic or to not modify data. Two sets of function characteristics apply here:

  - The `DETERMINISTIC` and `NOT DETERMINISTIC` characteristics indicate whether a function always produces the same result for given inputs. The default is `NOT DETERMINISTIC` if neither characteristic is given. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.
  - The `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` characteristics provide information about whether the function reads or writes data. Either `NO SQL` or `READS SQL DATA` indicates that a function does not change data, but you must specify one of these explicitly because the default is `CONTAINS SQL` if no characteristic is given.

  By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

  If you set `log_bin_trust_function_creators` [488] to 1, the requirement that functions be deterministic or not modify data is dropped.

- Stored procedure calls are logged at the statement level rather than at the `CALL` level. That is, the server does not log the `CALL` statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the master will be observed on slave servers. This prevents problems that could result from a procedure having different execution paths on different machines.

  In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because statement execution within procedures is not quite the same as in nonprocedure context:

  - A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:

```
NAME_CONST(var_name, var_value)
```

    `var_name` is the local variable name, and *`var_value`* is a constant indicating the value that the variable has at the time the statement is logged. `NAME_CONST()` [1042] has a value of *`var_value`*, and a “name” of *`var_name`*. Thus, if you invoke this function directly, you get a result like this:

```
mysql> SELECT NAME_CONST('myname', 14);
+--------+
| myname |
+--------+
|     14 |
+--------+
```

`NAME_CONST()` [1042] enables a logged standalone statement to be executed on a slave with the same effect as the original statement that was executed on the master within a stored procedure.

The use of `NAME_CONST()` [1042] can result in a problem for `CREATE TABLE ... SELECT` statements when the source column expressions refer to local variables. Converting these references to `NAME_CONST()` [1042] expressions can result in column names that are different on the master and slave servers, or names that are too long to be legal column identifiers. A workaround is to supply aliases for columns that refer to local variables. Consider this statement when `myvar` has a value of 1:

```
CREATE TABLE t1 SELECT myvar;
```

That will be rewritten as follows:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1);
```

To ensure that the master and slave tables have the same column names, write the statement like this:

```
CREATE TABLE t1 SELECT myvar AS myvar;
```

The rewritten statement becomes:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1) AS myvar;
```

- A statement to be logged might contain references to user-defined variables. To handle this, MySQL writes a `SET` statement to the binary log to make sure that the variable exists on the slave with the same value as on the master. For example, if a statement refers to a variable `@my_var`, that statement will be preceded in the binary log by the following statement, where *`value`* is the value of `@my_var` on the master:

  ```
  SET @my_var = value;
  ```

- Procedure calls can occur within a committed or rolled-back transaction. Transactional context is accounted for so that the transactional aspects of procedure execution are replicated correctly. That is, the server logs those statements within the procedure that actually execute and modify data, and also logs `BEGIN`, `COMMIT`, and `ROLLBACK` statements as necessary. For example, if a procedure updates only transactional tables and is executed within a transaction that is rolled back, those updates are not logged. If the procedure occurs within a committed transaction, `BEGIN` and `COMMIT` statements are logged with the updates. For a procedure that executes within a rolled-back transaction, its statements are logged using the same rules that would apply if the statements were executed in standalone fashion:

  - Updates to transactional tables are not logged.
  - Updates to nontransactional tables are logged because rollback does not cancel them.
  - Updates to a mix of transactional and nontransactional tables are logged surrounded by `BEGIN` and `ROLLBACK` so that slaves will make the same changes and rollbacks as on the master.

- A stored procedure call is *not* written to the binary log at the statement level if the procedure is invoked from within a stored function. In that case, the only thing logged is the statement that invokes the function (if it occurs within a statement that is logged) or a `DO` statement (if it occurs within a statement that is not logged). For this reason, care should be exercised in the use of stored functions that invoke a procedure, even if the procedure is otherwise safe in itself.

Chapter 20. INFORMATION_SCHEMA Tables

Table of Contents

The INFORMATION_SCHEMA CHARACTER_SETS Table 2624
The INFORMATION_SCHEMA COLLATIONS Table 2624
The INFORMATION_SCHEMA COLLATION_CHARACTER_SET_APPLICABILITY Table 2624

The INFORMATION_SCHEMA FILES Table 2647
The INFORMATION_SCHEMA ndb_transid_mysql_connection_map Table 2652
Extensions to SHOW Statements 2653

INFORMATION_SCHEMA provides access to database *metadata*, information about the MySQL server such as the name of a database or table, the data type of a column, or access privileges. Other terms that are sometimes used for this information are *data dictionary* and *system catalog*.

Usage Notes for the INFORMATION_SCHEMA Database

INFORMATION_SCHEMA is a database within each MySQL instance, the place that stores information about all the other databases that the MySQL server maintains. The INFORMATION_SCHEMA database contains several read-only tables. They are actually views, not base tables, so there are no files associated with them, and you cannot set triggers on them. Also, there is no database directory with that name.

Although you can select INFORMATION_SCHEMA as the default database with a USE statement, you can only read the contents of tables, not perform INSERT, UPDATE, or DELETE operations on them.

Example

Here is an example of a statement that retrieves information from INFORMATION_SCHEMA:

```
mysql> SELECT table_name, table_type, engine
    -> FROM information_schema.tables
    -> WHERE table_schema = 'db5'
    -> ORDER BY table_name;
```

```
+------------+------------+--------+
| table_name | table_type | engine |
+------------+------------+--------+
| fk         | BASE TABLE | InnoDB |
| fk2        | BASE TABLE | InnoDB |
| goto       | BASE TABLE | MyISAM |
| into       | BASE TABLE | MyISAM |
| k          | BASE TABLE | MyISAM |
| kurs       | BASE TABLE | MyISAM |
| loop       | BASE TABLE | MyISAM |
| pk         | BASE TABLE | InnoDB |
| t          | BASE TABLE | MyISAM |
| t2         | BASE TABLE | MyISAM |
| t3         | BASE TABLE | MyISAM |
| t7         | BASE TABLE | MyISAM |
| tables     | BASE TABLE | MyISAM |
| v          | VIEW       | NULL   |
| v2         | VIEW       | NULL   |
| v3         | VIEW       | NULL   |
| v56        | VIEW       | NULL   |
+------------+------------+--------+
17 rows in set (0.01 sec)
```

Explanation: The statement requests a list of all the tables in database `db5`, showing just three pieces of information: the name of the table, its type, and its storage engine.

Character Set Considerations

The definition for character columns (for example, `TABLES.TABLE_NAME`) is generally `VARCHAR(N) CHARACTER SET utf8` where *`N`* is at least 64. MySQL uses the default collation for this character set (`utf8_general_ci`) for all searches, sorts, comparisons, and other string operations on such columns.

Because some MySQL objects are represented as files, searches in `INFORMATION_SCHEMA` string columns can be affected by file system case sensitivity. For more information, see Collation and `INFORMATION_SCHEMA` Searches.

`INFORMATION_SCHEMA` as Alternative to `SHOW` Statements

The `SELECT ... FROM INFORMATION_SCHEMA` statement is intended as a more consistent way to provide access to the information provided by the various `SHOW` statements that MySQL supports (`SHOW DATABASES`, `SHOW TABLES`, and so forth). Using `SELECT` has these advantages, compared to `SHOW`:

- It conforms to Codd's rules, because all access is done on tables.
- You can use the familiar syntax of the `SELECT` statement, and only need to learn some table and column names.
- The implementor need not worry about adding keywords.
- You can filter, sort, concatenate, and transform the results from `INFORMATION_SCHEMA` queries into whatever format your application needs, such as a data structure or a text representation to parse.
- This technique is more interoperable with other database systems. For example, Oracle Database users are familiar with querying tables in the Oracle data dictionary.

Because `SHOW` is familiar and widely used, the `SHOW` statements remain as an alternative. In fact, along with the implementation of `INFORMATION_SCHEMA`, there are enhancements to `SHOW` as described in Extensions to `SHOW` Statements.

Privileges

Each MySQL user has the right to access these tables, but can see only the rows in the tables that correspond to objects for which the user has the proper access privileges. In some cases (for example,

the ROUTINE_DEFINITION column in the INFORMATION_SCHEMA.ROUTINES table), users who have insufficient privileges see NULL. These restrictions do not apply for InnoDB tables; you can see them with only the PROCESS [627] privilege.

The same privileges apply to selecting information from INFORMATION_SCHEMA and viewing the same information through SHOW statements. In either case, you must have some privilege on an object to see information about it.

Performance Considerations

INFORMATION_SCHEMA queries that search for information from more than one database might take a long time and impact performance. To check the efficiency of a query, you can use EXPLAIN. For information about using EXPLAIN output to tune INFORMATION_SCHEMA queries, see INFORMATION_SCHEMA Optimization.

Standards Considerations

The implementation for the INFORMATION_SCHEMA table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 *Schemata*. Our intent is approximate compliance with SQL:2003 core feature F021 *Basic information schema*.

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation, and added columns that are MySQL-specific. One such column is the ENGINE column in the INFORMATION_SCHEMA.TABLES table.

Although other DBMSs use a variety of names, like syscat or system, the standard name is INFORMATION_SCHEMA.

To avoid using any name that is reserved in the standard or in DB2, SQL Server, or Oracle, we changed the names of some columns marked “MySQL extension”. (For example, we changed COLLATION to TABLE_COLLATION in the TABLES table.) See the list of reserved words near the end of this article: http://web.archive.org/web/20070409075643rn_1/www.dbazine.com/db2/db2-disarticles/gulutzan5.

Conventions in the INFORMATION_SCHEMA Reference Sections

The following sections describe each of the tables and columns in INFORMATION_SCHEMA. For each column, there are three pieces of information:

- “INFORMATION_SCHEMA Name” indicates the name for the column in the INFORMATION_SCHEMA table. This corresponds to the standard SQL name unless the “Remarks” field says “MySQL extension.”
- “SHOW Name” indicates the equivalent field name in the closest SHOW statement, if there is one.
- “Remarks” provides additional information where applicable. If this field is NULL, it means that the value of the column is always NULL. If this field says “MySQL extension,” the column is a MySQL extension to standard SQL.

Many sections indicate what SHOW statement is equivalent to a SELECT that retrieves information from INFORMATION_SCHEMA. For SHOW statements that display information for the default database if you omit a FROM *db_name* clause, you can often select information for the default database by adding an AND TABLE_SCHEMA = SCHEMA() condition to the WHERE clause of a query that retrieves information from an INFORMATION_SCHEMA table.

For information about INFORMATION_SCHEMA tables specific to the NDB storage engine (MySQL Cluster), see INFORMATION_SCHEMA Tables for MySQL Cluster.

For answers to questions that are often asked concerning the INFORMATION_SCHEMA database, see MySQL 5.1 FAQ: INFORMATION_SCHEMA.

The INFORMATION_SCHEMA CHARACTER_SETS Table

The CHARACTER_SETS table provides information about available character sets.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CHARACTER_SET_NAME	Charset	
DEFAULT_COLLATE_NAME	Default collation	
DESCRIPTION	Description	MySQL extension
MAXLEN	Maxlen	MySQL extension

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
  [WHERE CHARACTER_SET_NAME LIKE 'wild']

SHOW CHARACTER SET
  [LIKE 'wild']
```

The INFORMATION_SCHEMA COLLATIONS Table

The COLLATIONS table provides information about collations for each character set.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
COLLATION_NAME	Collation	
CHARACTER_SET_NAME	Charset	MySQL extension
ID	Id	MySQL extension
IS_DEFAULT	Default	MySQL extension
IS_COMPILED	Compiled	MySQL extension
SORTLEN	Sortlen	MySQL extension

- COLLATION_NAME is the collation name.
- CHARACTER_SET_NAME is the name of the character set with which the collation is associated.
- ID is the collation ID.
- IS_DEFAULT indicates whether the collation is the default for its character set.
- IS_COMPILED indicates whether the character set is compiled into the server.
- SORTLEN is related to the amount of memory required to sort strings expressed in the character set.

Collation information is also available from the SHOW COLLATION statement. The following statements are equivalent:

```
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
  [WHERE COLLATION_NAME LIKE 'wild']

SHOW COLLATION
  [LIKE 'wild']
```

The INFORMATION_SCHEMA COLLATION_CHARACTER_SET_APPLICABILITY Table

The COLLATION_CHARACTER_SET_APPLICABILITY table indicates what character set is applicable for what collation. The columns are equivalent to the first two display fields that we get from SHOW COLLATION.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
COLLATION_NAME	Collation	
CHARACTER_SET_NAME	Charset	

The INFORMATION_SCHEMA COLUMNS Table

The COLUMNS table provides information about columns in tables.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME	Field	
ORDINAL_POSITION		see notes
COLUMN_DEFAULT	Default	
IS_NULLABLE	Null	
DATA_TYPE	Type	
CHARACTER_MAXIMUM_LENGTH	Type	
CHARACTER_OCTET_LENGTH		
NUMERIC_PRECISION	Type	
NUMERIC_SCALE	Type	
CHARACTER_SET_NAME		
COLLATION_NAME	Collation	
COLUMN_TYPE	Type	MySQL extension
COLUMN_KEY	Key	MySQL extension
EXTRA	Extra	MySQL extension
PRIVILEGES	Privileges	MySQL extension
COLUMN_COMMENT	Comment	MySQL extension

Notes:

- In SHOW, the Type display includes values from several different COLUMNS columns.
- ORDINAL_POSITION is necessary because you might want to say ORDER BY ORDINAL_POSITION. Unlike SHOW, SELECT does not have automatic ordering.
- CHARACTER_OCTET_LENGTH should be the same as CHARACTER_MAXIMUM_LENGTH, except for multi-byte character sets.
- CHARACTER_SET_NAME can be derived from Collation. For example, if you say SHOW FULL COLUMNS FROM t, and you see in the Collation column a value of latin1_swedish_ci, the character set is what is before the first underscore: latin1.

The following statements are nearly equivalent:

```
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT
  FROM INFORMATION_SCHEMA.COLUMNS
  WHERE table_name = 'tbl_name'
  [AND table_schema = 'db_name']
  [AND column_name LIKE 'wild']

SHOW COLUMNS
  FROM tbl_name
```

```
  [FROM db_name]
  [LIKE 'wild']
```

The INFORMATION_SCHEMA COLUMN_PRIVILEGES Table

The COLUMN_PRIVILEGES table provides information about column privileges. This information comes from the mysql.columns_priv grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		'user_name'@'host_name' value
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME		
PRIVILEGE_TYPE		
IS_GRANTABLE		

Notes:

- In the output from SHOW FULL COLUMNS, the privileges are all in one field and in lowercase, for example, select,insert,update,references. In COLUMN_PRIVILEGES, there is one privilege per row, in uppercase.
- PRIVILEGE_TYPE can contain one (and only one) of these values: SELECT [627], INSERT [627], UPDATE [628], REFERENCES [627].
- If the user has GRANT OPTION [627] privilege, IS_GRANTABLE should be YES. Otherwise, IS_GRANTABLE should be NO. The output does not list GRANT OPTION [627] as a separate privilege.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES

SHOW GRANTS ...
```

The INFORMATION_SCHEMA ENGINES Table

The PLUGINS table provides information about storage engines.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
ENGINE	Engine	MySQL extension
SUPPORT	Support	MySQL extension
COMMENT	Comment	MySQL extension
TRANSACTIONS	Transactions	MySQL extension
XA	XA	MySQL extension
SAVEPOINTS	Savepoints	MySQL extension

Notes:

- The ENGINES table is a nonstandard table. It was added in MySQL 5.1.5.

See also SHOW ENGINES Syntax.

The INFORMATION_SCHEMA EVENTS Table

The EVENTS table provides information about scheduled events, which are discussed in Using the Event Scheduler. The SHOW Name values correspond to column names of the SHOW EVENTS statement.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
EVENT_CATALOG		NULL, MySQL extension
EVENT_SCHEMA	Db	MySQL extension
EVENT_NAME	Name	MySQL extension
DEFINER	Definer	MySQL extension
TIME_ZONE	Time zone	MySQL extension
EVENT_BODY		MySQL extension
EVENT_DEFINITION		MySQL extension
EVENT_TYPE	Type	MySQL extension
EXECUTE_AT	Execute at	MySQL extension
INTERVAL_VALUE	Interval value	MySQL extension
INTERVAL_FIELD	Interval field	MySQL extension
SQL_MODE		MySQL extension
STARTS	Starts	MySQL extension
ENDS	Ends	MySQL extension
STATUS	Status	MySQL extension
ON_COMPLETION		MySQL extension
CREATED		MySQL extension
LAST_ALTERED		MySQL extension
LAST_EXECUTED		MySQL extension
EVENT_COMMENT		MySQL extension
ORIGINATOR	Originator	MySQL extension
CHARACTER_SET_CLIENT	character_set_client	MySQL extension
COLLATION_CONNECTION	collation_connection	MySQL extension
DATABASE_COLLATION	Database Collation	MySQL extension

Notes:

- The EVENTS table is a nonstandard table. It was added in MySQL 5.1.6.
- EVENT_CATALOG: The value of this column is always NULL.
- EVENT_SCHEMA: The name of the schema (database) to which this event belongs.
- EVENT_NAME: The name of the event.
- DEFINER: The account of the user who created the event, in *'user_name'@'host_name'* format.
- TIME_ZONE: The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is SYSTEM.

  This column was added in MySQL 5.1.17. See Changes in MySQL 5.1.17 (2007-04-04), for important information if you are using the Event Scheduler and are upgrading to MySQL 5.1.17 or later from an earlier version.
- EVENT_BODY: The language used for the statements in the event's DO clause; in MySQL 5.1, this is always SQL.

This column was added in MySQL 5.1.12. It is not to be confused with the column of the same name (now named EVENT_DEFINITION) that existed in earlier MySQL versions.

- EVENT_DEFINITION: The text of the SQL statement making up the event's DO clause; in other words, the statement executed by this event.

  Note

  Prior to MySQL 5.1.12, this column was named EVENT_BODY.

- EVENT_TYPE: The event repetition type, either ONE TIME (transient) or RECURRING (repeating).

- EXECUTE_AT: For a one-time event, this is the DATETIME value specified in the AT clause of the CREATE EVENT statement used to create the event, or of the last ALTER EVENT statement that modified the event. The value shown in this column reflects the addition or subtraction of any INTERVAL value included in the event's AT clause. For example, if an event is created using ON SCHEDULE AT CURRENT_TIMESTAMP + '1:6' DAY_HOUR, and the event was created at 2006-02-09 14:05:30, the value shown in this column would be '2006-02-10 20:05:30'.

  If the event's timing is determined by an EVERY clause instead of an AT clause (that is, if the event is recurring), the value of this column is NULL.

- INTERVAL_VALUE: For recurring events, this column contains the numeric portion of the event's EVERY clause.

  For a one-time event (that is, an event whose timing is determined by an AT clause), this column is NULL.

- INTERVAL_FIELD: For recurring events, this column contains the units portion of the EVERY clause governing the timing of the event. Thus, this column contains a value such as 'YEAR', 'QUARTER', 'DAY', and so on.

  Note

  In early MySQL 5.1 releases, this value was prefixed with 'INTERVAL_', and was displayed as 'INTERVAL_YEAR', 'INTERVAL_QUARTER', 'INTERVAL_DAY', and so on.

  For a one-time event (that is, an event whose timing is determined by an AT clause), this column is NULL.

- SQL_MODE: The SQL mode in effect at the time the event was created or altered.

- STARTS: For a recurring event whose definition includes a STARTS clause, this column contains the corresponding DATETIME value. As with the EXECUTE_AT column, this value resolves any expressions used.

  If there is no STARTS clause affecting the timing of the event, this column is NULL. (Prior to MySQL 5.1.8, it contained 0000-00-00 00:00:00 in such cases.)

- ENDS: For a recurring event whose definition includes a ENDS clause, this column contains the corresponding DATETIME value. As with the EXECUTE_AT column, this value resolves any expressions used.

  If there is no ENDS clause affecting the timing of the event, this column is NULL.

- STATUS: One of the three values ENABLED, DISABLED, or SLAVESIDE_DISABLED.

  SLAVESIDE_DISABLED was added to the list of possible values for this column in MySQL 5.1.18. This value indicates that the creation of the event occurred on another MySQL server acting as a

replication master and was replicated to the current MySQL server which is acting as a slave, but the event is not presently being executed on the slave. See Replication of Invoked Features, for more information.

- ON_COMPLETION: One of the two values PRESERVE or NOT PRESERVE.
- CREATED: The date and time when the event was created. This is a DATETIME value.
- LAST_ALTERED: The date and time when the event was last modified. This is a DATETIME value. If the event has not been modified since its creation, this column holds the same value as the CREATED column.
- LAST_EXECUTED: The date and time when the event last executed. A DATETIME value. If the event has never executed, this column is NULL.

  Before MySQL 5.1.23, LAST_EXECUTED indicates when event finished executing. As of 5.1.23, LAST_EXECUTED instead indicates when the event started. As a result, the ENDS column is never less than LAST_EXECUTED.
- EVENT_COMMENT: The text of a comment, if the event has one. If not, the value of this column is an empty string.
- ORIGINATOR: The server ID of the MySQL server on which the event was created; used in replication. The default value is 0. This column was added in MySQL 5.1.18.
- CHARACTER_SET_CLIENT is the session value of the character_set_client [464] system variable when the event was created. COLLATION_CONNECTION is the session value of the collation_connection [466] system variable when the event was created. DATABASE_COLLATION is the collation of the database with which the event is associated. These columns were added in MySQL 5.1.21.

Example: Suppose that the user jon@ghidora creates an event named e_daily, and then modifies it a few minutes later using an ALTER EVENT statement, as shown here:

```
DELIMITER |

CREATE EVENT e_daily
    ON SCHEDULE
      EVERY 1 DAY
    COMMENT 'Saves total number of sessions then clears the table each day'
    DO
      BEGIN
        INSERT INTO site_activity.totals (time, total)
          SELECT CURRENT_TIMESTAMP, COUNT(*)
            FROM site_activity.sessions;
        DELETE FROM site_activity.sessions;
      END |

DELIMITER ;

ALTER EVENT e_daily
    ENABLED;
```

(Note that comments can span multiple lines.)

This user can then run the following SELECT statement, and obtain the output shown:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
     > WHERE EVENT_NAME = 'e_daily'
     > AND EVENT_SCHEMA = 'myschema'\G
*************************** 1. row ***************************
       EVENT_CATALOG: NULL
        EVENT_SCHEMA: test
          EVENT_NAME: e_daily
             DEFINER: paul@localhost
          TIME_ZONE: SYSTEM
```

```
          EVENT_BODY: SQL
    EVENT_DEFINITION: BEGIN
        INSERT INTO site_activity.totals (time, total)
          SELECT CURRENT_TIMESTAMP, COUNT(*)
            FROM site_activity.sessions;
        DELETE FROM site_activity.sessions;
      END
          EVENT_TYPE: RECURRING
          EXECUTE_AT: NULL
      INTERVAL_VALUE: 1
      INTERVAL_FIELD: DAY
             SQL_MODE:
               STARTS: 2008-09-03 12:13:39
                 ENDS: NULL
               STATUS: ENABLED
       ON_COMPLETION: NOT PRESERVE
             CREATED: 2008-09-03 12:13:39
        LAST_ALTERED: 2008-09-03 12:13:39
       LAST_EXECUTED: NULL
       EVENT_COMMENT: Saves total number of sessions then clears the
                      table each day
          ORIGINATOR: 1
CHARACTER_SET_CLIENT: latin1
COLLATION_CONNECTION: latin1_swedish_ci
  DATABASE_COLLATION: latin1_swedish_ci
```

Times in the EVENTS table are displayed using the event time zone or the current session time zone. Prior to MySQL 5.1.17, some of the times are displayed in UTC rather than the event time zone. For details, see Event Metadata.

See also SHOW EVENTS Syntax.

The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables

The GLOBAL_STATUS and SESSION_STATUS tables provide information about server status variables. Their contents correspond to the information produced by the SHOW GLOBAL STATUS and SHOW SESSION STATUS statements (see SHOW STATUS Syntax).

INFORMATION_SCHEMA Name	SHOW Name	Remarks
VARIABLE_NAME	Variable_name	
VARIABLE_VALUE	Value	

Notes:

- The GLOBAL_STATUS and SESSION_STATUS tables were added in MySQL 5.1.12.
- Beginning with MySQL 5.1.19, the VARIABLE_VALUE column for each of these tables is defined as VARCHAR(20480). Previously, this column had the data type DECIMAL(22,7), but was changed to avoid loss of data when working with status variables whose values were strings (Bug #26994).

The INFORMATION_SCHEMA GLOBAL_VARIABLES and SESSION_VARIABLES Tables

The GLOBAL_VARIABLES and SESSION_VARIABLES tables provide information about server status variables. Their contents correspond to the information produced by the SHOW GLOBAL VARIABLES and SHOW SESSION VARIABLES statements (see SHOW VARIABLES Syntax).

INFORMATION_SCHEMA Name	SHOW Name	Remarks
VARIABLE_NAME	Variable_name	

INFORMATION_SCHEMA Name	SHOW Name	Remarks
VARIABLE_VALUE	Value	

Notes:

- The GLOBAL_VARIABLES and SESSION_VARIABLES tables were added in MySQL 5.1.12.
- Beginning with MySQL 5.1.19, the VARIABLE_VALUE column for each of these tables is defined as VARCHAR(20480). Previously, this column had the data type LONGTEXT; this was changed to make these tables consistent with the GLOBAL_STATUS and SESSION_STATUS tables, whose definitions had been changed in that version (see The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables).

The INFORMATION_SCHEMA KEY_COLUMN_USAGE Table

The KEY_COLUMN_USAGE table describes which key columns have constraints.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CONSTRAINT_CATALOG		NULL
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
TABLE_CATALOG		
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME		
ORDINAL_POSITION		
POSITION_IN_UNIQUE_CONSTRAINT		
REFERENCED_TABLE_SCHEMA		
REFERENCED_TABLE_NAME		
REFERENCED_COLUMN_NAME		

Notes:

- If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.
- The value of ORDINAL_POSITION is the column's position within the constraint, not the column's position within the table. Column positions are numbered beginning with 1.
- The value of POSITION_IN_UNIQUE_CONSTRAINT is NULL for unique and primary-key constraints. For foreign-key constraints, it is the ordinal position in key of the table that is being referenced.

  Suppose that there are two tables name t1 and t3 that have the following definitions:

```
CREATE TABLE t1
(
    s1 INT,
    s2 INT,
    s3 INT,
    PRIMARY KEY(s3)
) ENGINE=InnoDB;

CREATE TABLE t3
(
    s1 INT,
    s2 INT,
```

```
    s3 INT,
    KEY(s1),
    CONSTRAINT CO FOREIGN KEY (s2) REFERENCES t1(s3)
) ENGINE=InnoDB;
```

For those two tables, the KEY_COLUMN_USAGE table has two rows:

- One row with CONSTRAINT_NAME = 'PRIMARY', TABLE_NAME = 't1', COLUMN_NAME = 's3', ORDINAL_POSITION = 1, POSITION_IN_UNIQUE_CONSTRAINT = NULL.
- One row with CONSTRAINT_NAME = 'CO', TABLE_NAME = 't3', COLUMN_NAME = 's2', ORDINAL_POSITION = 1, POSITION_IN_UNIQUE_CONSTRAINT = 1.

The INFORMATION_SCHEMA PARTITIONS Table

The PARTITIONS table provides information about table partitions. See Chapter 18, *Partitioning*, for more information about partitioning tables.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		MySQL extension
TABLE_SCHEMA		MySQL extension
TABLE_NAME		MySQL extension
PARTITION_NAME		MySQL extension
SUBPARTITION_NAME		MySQL extension
PARTITION_ORDINAL_POSITION		MySQL extension
SUBPARTITION_ORDINAL_POSITION		MySQL extension
PARTITION_METHOD		MySQL extension
SUBPARTITION_METHOD		MySQL extension
PARTITION_EXPRESSION		MySQL extension
SUBPARTITION_EXPRESSION		MySQL extension
PARTITION_DESCRIPTION		MySQL extension
TABLE_ROWS		MySQL extension
AVG_ROW_LENGTH		MySQL extension
DATA_LENGTH		MySQL extension
MAX_DATA_LENGTH		MySQL extension
INDEX_LENGTH		MySQL extension
DATA_FREE		MySQL extension
CREATE_TIME		MySQL extension
UPDATE_TIME		MySQL extension
CHECK_TIME		MySQL extension
CHECKSUM		MySQL extension
PARTITION_COMMENT		MySQL extension
NODEGROUP		MySQL extension
TABLESPACE_NAME		MySQL extension

Notes:

- The PARTITIONS table is a nonstandard table. It was added in MySQL 5.1.6.

  Each record in this table corresponds to an individual partition or subpartition of a partitioned table.

- TABLE_CATALOG: This column is always NULL.
- TABLE_SCHEMA: This column contains the name of the database to which the table belongs.
- TABLE_NAME: This column contains the name of the table containing the partition.
- PARTITION_NAME: The name of the partition.
- SUBPARTITION_NAME: If the PARTITIONS table record represents a subpartition, then this column contains the name of subpartition; otherwise it is NULL.
- PARTITION_ORDINAL_POSITION: All partitions are indexed in the same order as they are defined, with 1 being the number assigned to the first partition. The indexing can change as partitions are added, dropped, and reorganized; the number shown is this column reflects the current order, taking into account any indexing changes.
- SUBPARTITION_ORDINAL_POSITION: Subpartitions within a given partition are also indexed and reindexed in the same manner as partitions are indexed within a table.
- PARTITION_METHOD: One of the values RANGE, LIST, HASH, LINEAR HASH, KEY, or LINEAR KEY; that is, one of the available partitioning types as discussed in Partitioning Types.
- SUBPARTITION_METHOD: One of the values HASH, LINEAR HASH, KEY, or LINEAR KEY; that is, one of the available subpartitioning types as discussed in Subpartitioning.
- PARTITION_EXPRESSION: This is the expression for the partitioning function used in the CREATE TABLE or ALTER TABLE statement that created the table's current partitioning scheme.

  For example, consider a partitioned table created in the test database using this statement:

```
CREATE TABLE tp (
    c1 INT,
    c2 INT,
    c3 VARCHAR(25)
)
PARTITION BY HASH(c1 + c2)
PARTITIONS 4;
```

  The PARTITION_EXPRESSION column in a PARTITIONS table record for a partition from this table displays c1 + c2, as shown here:

```
mysql> SELECT DISTINCT PARTITION_EXPRESSION
    >     FROM INFORMATION_SCHEMA.PARTITIONS
    >     WHERE TABLE_NAME='tp' AND TABLE_SCHEMA='test';
+----------------------+
| PARTITION_EXPRESSION |
+----------------------+
| c1 + c2              |
+----------------------+
1 row in set (0.09 sec)
```

- SUBPARTITION_EXPRESSION: This works in the same fashion for the subpartitioning expression that defines the subpartitioning for a table as PARTITION_EXPRESSION does for the partitioning expression used to define a table's partitioning.

  If the table has no subpartitions, then this column is NULL.
- PARTITION_DESCRIPTION: This column is used for RANGE and LIST partitions. For a RANGE partition, it contains the value set in the partition's VALUES LESS THAN clause, which can be either an integer or MAXVALUE. For a LIST partition, this column contains the values defined in the partition's VALUES IN clause, which is a comma-separated list of integer values.

  For partitions whose PARTITION_METHOD is other than RANGE or LIST, this column is always NULL.
- TABLE_ROWS: The number of table rows in the partition.

For partitioned InnoDB tables, the row count given in the TABLE_ROWS column is only an estimated value used in SQL optimization, and may not always be exact.

Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, TABLE_ROWS shows correct information for NDB tables. Previously, for partitions of NDB tables, the TABLE_ROWS column value was always 0.

For NDB tables, you can also obtain this information using the ndb_desc utility.

- AVG_ROW_LENGTH: The average length of the rows stored in this partition or subpartition, in bytes.

  This is the same as DATA_LENGTH divided by TABLE_ROWS.

  Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, AVG_ROW_LENGTH includes statistics for partitions of NDB tables, whether the tables use implicit or explicit partitioning. (Previously the value of this column was always 0 for partitions of NDB tables.)

  You can also obtain equivalent information using the ndb_desc utility.

- DATA_LENGTH: The total length of all rows stored in this partition or subpartition, in bytes—that is, the total number of bytes stored in the partition or subpartition.

  Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, DATA_LENGTH shows correct information for in-memory data in NDB tables. Previously, for partitions of NDB tables, the DATA_LENGTH column value was always 0.

  For NDB tables, you can also obtain this information using the ndb_desc utility.

- MAX_DATA_LENGTH: The maximum number of bytes that can be stored in this partition or subpartition.

  Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, MAX_DATA_LENGTH shows the space allocated for the disk part of a MySQL Cluster Disk Data table or fragment. (Previously, for partitions of NDB tables, the MAX_DATA_LENGTH column value was always NULL.)

  For NDB tables, you can also obtain this information using the ndb_desc utility.

- INDEX_LENGTH: The length of the index file for this partition or subpartition, in bytes.

  For partitions of NDB tables, whether the tables use implicit or explicit partitioning, the INDEX_LENGTH column value is always 0. However, you can obtain equivalent information using the ndb_desc utility.

- DATA_FREE: The number of bytes allocated to the partition or subpartition but not used.

  For MySQL Cluster Disk Data tables, beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, DATA_FREE shows the space allocated on disk for, but not used by, a Disk Data table or fragment on disk. (Previously, for partitions of NDB tables, the value of this column was always 0.)

  For NDB tables, you can also obtain this information using the ndb_desc utility.

- CREATE_TIME: The time of the partition's or subpartition's creation.

- UPDATE_TIME: The time that the partition or subpartition was last modified.

- CHECK_TIME: The last time that the table to which this partition or subpartition belongs was checked.

Note

Some storage engines do not update this time; for tables using these storage engines, this value is always NULL.

- CHECKSUM: The checksum value, if any; otherwise, this column is NULL.
- PARTITION_COMMENT: This column contains the text of any comment made for the partition.

  In MySQL 5.1, the display width of this column is 80 characters, and partition comments which exceed this length are truncated to fit. This issue is fixed in MySQL 5.6. (Bug #11748924, Bug #37728)

  The default value for this column is an empty string.
- NODEGROUP: This is the nodegroup to which the partition belongs. This is relevant only to MySQL Cluster tables; otherwise the value of this column is always 0.
- TABLESPACE_NAME: This column contains the name of the tablespace to which the partition belongs. Currently, the value of this column is always DEFAULT.
-

  Important

  If any partitioned tables created in a MySQL version prior to MySQL 5.1.6 are present following an upgrade to MySQL 5.1.6 or later, it is not possible to SELECT from, SHOW, or DESCRIBE the PARTITIONS table. See Changes in MySQL 5.1.6 (2006-02-01) *before* upgrading from MySQL 5.1.5 or earlier to MySQL 5.1.6 or later.
- A nonpartitioned table has one record in INFORMATION_SCHEMA.PARTITIONS; however, the values of the PARTITION_NAME, SUBPARTITION_NAME, PARTITION_ORDINAL_POSITION, SUBPARTITION_ORDINAL_POSITION, PARTITION_METHOD, SUBPARTITION_METHOD, PARTITION_EXPRESSION, SUBPARTITION_EXPRESSION, and PARTITION_DESCRIPTION columns are all NULL. (The PARTITION_COMMENT column in this case is blank.)

  In MySQL 5.1, there is also only one record in the PARTITIONS table for a table using the NDBCLUSTER storage engine. The same columns are also NULL (or empty) as for a nonpartitioned table.

The INFORMATION_SCHEMA PLUGINS Table

The PLUGINS table provides information about server plugins.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
PLUGIN_NAME	Name	MySQL extension
PLUGIN_VERSION		MySQL extension
PLUGIN_STATUS	Status	MySQL extension
PLUGIN_TYPE	Type	MySQL extension
PLUGIN_TYPE_VERSION		MySQL extension
PLUGIN_LIBRARY	Library	MySQL extension
PLUGIN_LIBRARY_VERSION		MySQL extension
PLUGIN_AUTHOR		MySQL extension
PLUGIN_DESCRIPTION		MySQL extension
PLUGIN_LICENSE		MySQL extension

Notes:

- The PLUGINS table is a nonstandard table. It was added in MySQL 5.1.5.
- PLUGIN_NAME is the name used to refer to the plugin in statements such as INSTALL PLUGIN and UNINSTALL PLUGIN.
- PLUGIN_VERSION is the version from the plugin's general type descriptor.

- PLUGIN_STATUS indicates the plugin status, one of ACTIVE, INACTIVE, DISABLED, or DELETED.
- PLUGIN_TYPE indicates the type of plugin, such as STORAGE ENGINE or INFORMATION_SCHEMA.
- PLUGIN_TYPE_VERSION is the version from the plugin's type-specific descriptor.
- PLUGIN_LIBRARY is the name of the plugin shared object file. This is the name used to refer to the plugin file in statements such as INSTALL PLUGIN and UNINSTALL PLUGIN. This file is located in the directory named by the plugin_dir [510] system variable. If the library name is NULL, the plugin is compiled in and cannot be uninstalled with UNINSTALL PLUGIN.
- PLUGIN_LIBRARY_VERSION indicates the plugin API interface version.
- PLUGIN_AUTHOR names the plugin author.
- PLUGIN_DESCRIPTION provides a short description of the plugin.
- PLUGIN_LICENSE indicates how the plugin is licensed; for example, GPL. This column was added in MySQL 5.1.12.

For plugins installed with INSTALL PLUGIN, the PLUGIN_NAME and PLUGIN_LIBRARY values are also registered in the mysql.plugin table.

These statements are equivalent:

```
SELECT
  PLUGIN_NAME, PLUGIN_STATUS, PLUGIN_TYPE,
  PLUGIN_LIBRARY, PLUGIN_LICENSE
FROM INFORMATION_SCHEMA.PLUGINS;

SHOW PLUGINS;
```

For information about plugin data structures that form the basis of the information in the PLUGINS table, see The MySQL Plugin API.

Plugin information is also available using the SHOW PLUGINS statement. See SHOW PLUGINS Syntax.

The INFORMATION_SCHEMA PROCESSLIST Table

The PROCESSLIST table provides information about which threads are running.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
ID	Id	MySQL extension
USER	User	MySQL extension
HOST	Host	MySQL extension
DB	db	MySQL extension
COMMAND	Command	MySQL extension
TIME	Time	MySQL extension
STATE	State	MySQL extension
INFO	Info	MySQL extension

For an extensive description of the table columns, see SHOW PROCESSLIST Syntax.

Notes:

- The PROCESSLIST table is a nonstandard table. It was added in MySQL 5.1.7.
- Like the output from the corresponding SHOW statement, the PROCESSLIST table will only show information about your own threads, unless you have the PROCESS [627] privilege, in which case you will see information about other threads, too. As an anonymous user, you cannot see any rows at all.

- If an SQL statement refers to INFORMATION_SCHEMA.PROCESSLIST, then MySQL will populate the entire table once, when statement execution begins, so there is read consistency during the statement. There is no read consistency for a multi-statement transaction, though.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST

SHOW FULL PROCESSLIST
```

The INFORMATION_SCHEMA PROFILING Table

The PROFILING table provides statement profiling information. Its contents correspond to the information produced by the SHOW PROFILES and SHOW PROFILE statements (see SHOW PROFILES Syntax). The table is empty unless the profiling [511] session variable is set to 1.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
QUERY_ID	Query_ID	
SEQ		
STATE	Status	
DURATION	Duration	
CPU_USER	CPU_user	
CPU_SYSTEM	CPU_system	
CONTEXT_VOLUNTARY	Context_voluntary	
CONTEXT_INVOLUNTARY	Context_involuntary	
BLOCK_OPS_IN	Block_ops_in	
BLOCK_OPS_OUT	Block_ops_out	
MESSAGES_SENT	Messages_sent	
MESSAGES_RECEIVED	Messages_received	
PAGE_FAULTS_MAJOR	Page_faults_major	
PAGE_FAULTS_MINOR	Page_faults_minor	
SWAPS	Swaps	
SOURCE_FUNCTION	Source_function	
SOURCE_FILE	Source_file	
SOURCE_LINE	Source_line	

Notes:

- The PROFILING table was added in MySQL 5.1.24 but contains no information unless the SHOW PROFILE feature is enabled. The SHOW PROFILE feature is not included in binary distributions by default until MySQL 5.1.28.
- QUERY_ID is a numeric statement identifier.
- SEQ is a sequence number indicating the display order for rows with the same QUERY_ID value.
- STATE is the profiling state to which the row measurements apply.
- DURATION indicates how long statement execution remained in the given state, in seconds.
- CPU_USER and CPU_SYSTEM indicate user and system CPU use, in seconds.
- CONTEXT_VOLUNTARY and CONTEXT_INVOLUNTARY indicate how many voluntary and involuntary context switches occurred.

- BLOCK_OPS_IN and BLOCK_OPS_OUT indicate the number of block input and output operations.
- MESSAGES_SENT and MESSAGES_RECEIVED indicate the number of communication messages sent and received.
- PAGE_FAULTS_MAJOR and PAGE_FAULTS_MINOR indicate the number of major and minor page faults.
- SWAPS indicates how many swaps occurred.
- SOURCE_FUNCTION, SOURCE_FILE, and SOURCE_LINE provide information indicating where in the source code the profiled state executes.

The INFORMATION_SCHEMA REFERENTIAL_CONSTRAINTS Table

The REFERENTIAL_CONSTRAINTS table provides information about foreign keys.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CONSTRAINT_CATALOG		NULL
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
UNIQUE_CONSTRAINT_CATALOG		NULL
UNIQUE_CONSTRAINT_SCHEMA		
UNIQUE_CONSTRAINT_NAME		
MATCH_OPTION		
UPDATE_RULE		
DELETE_RULE		
TABLE_NAME		
REFERENCED_TABLE_NAME		

Notes:

- The REFERENTIAL_CONSTRAINTS table was added in MySQL 5.1.10. The REFERENCED_TABLE_NAME column was added in MySQL 5.1.16.
- TABLE_NAME has the same value as TABLE_NAME in INFORMATION_SCHEMA.TABLE_CONSTRAINTS.
- CONSTRAINT_SCHEMA and CONSTRAINT_NAME identify the foreign key.
- UNIQUE_CONSTRAINT_SCHEMA, UNIQUE_CONSTRAINT_NAME, and REFERENCED_TABLE_NAME identify the referenced key. (Note: Before MySQL 5.1.16, UNIQUE_CONSTRAINT_NAME incorrectly named the referenced table, not the constraint.)
- The only valid value at this time for MATCH_OPTION is NONE.
- The possible values for UPDATE_RULE or DELETE_RULE are CASCADE, SET NULL, SET DEFAULT, RESTRICT, NO ACTION.

The INFORMATION_SCHEMA ROUTINES Table

The ROUTINES table provides information about stored routines (both procedures and functions). The ROUTINES table does not include user-defined functions (UDFs).

The column named "mysql.proc name" indicates the mysql.proc table column that corresponds to the INFORMATION_SCHEMA.ROUTINES table column, if any.

INFORMATION_SCHEMA Name	mysql.proc Name	Remarks
SPECIFIC_NAME	specific_name	
ROUTINE_CATALOG		NULL
ROUTINE_SCHEMA	db	
ROUTINE_NAME	name	
ROUTINE_TYPE	type	{PROCEDURE|FUNCTION}
DTD_IDENTIFIER		data type descriptor
ROUTINE_BODY		SQL
ROUTINE_DEFINITION	body or body_utf8	see Notes
EXTERNAL_NAME		NULL
EXTERNAL_LANGUAGE	language	NULL
PARAMETER_STYLE		SQL
IS_DETERMINISTIC	is_deterministic	
SQL_DATA_ACCESS	sql_data_access	
SQL_PATH		NULL
SECURITY_TYPE	security_type	
CREATED	created	
LAST_ALTERED	modified	
SQL_MODE	sql_mode [526]	MySQL extension
ROUTINE_COMMENT	comment	MySQL extension
DEFINER	definer	MySQL extension
CHARACTER_SET_CLIENT		MySQL extension
COLLATION_CONNECTION		MySQL extension
DATABASE_COLLATION		MySQL extension

Notes:

- MySQL calculates EXTERNAL_LANGUAGE thus:
  - If mysql.proc.language='SQL', EXTERNAL_LANGUAGE is NULL
  - Otherwise, EXTERNAL_LANGUAGE is what is in mysql.proc.language. However, we do not have external languages yet, so it is always NULL.
- ROUTINE_DEFINITION is what is in mysql.proc.body_utf8 as of MySQL 5.1.21, mysql.proc.body before 5.1.21.
- CHARACTER_SET_CLIENT is the session value of the character_set_client [464] system variable when the routine was created. COLLATION_CONNECTION is the session value of the collation_connection [466] system variable when the routine was created. DATABASE_COLLATION is the collation of the database with which the routine is associated. These columns were added in MySQL 5.1.21.

The INFORMATION_SCHEMA SCHEMATA Table

A schema is a database, so the SCHEMATA table provides information about databases.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CATALOG_NAME		NULL
SCHEMA_NAME		Database

INFORMATION_SCHEMA Name	SHOW Name	Remarks
DEFAULT_CHARACTER_SET_NAME		
DEFAULT_COLLATION_NAME		
SQL_PATH		NULL

The following statements are equivalent:

```
SELECT SCHEMA_NAME AS `Database`
  FROM INFORMATION_SCHEMA.SCHEMATA
  [WHERE SCHEMA_NAME LIKE 'wild']

SHOW DATABASES
  [LIKE 'wild']
```

The INFORMATION_SCHEMA SCHEMA_PRIVILEGES Table

The SCHEMA_PRIVILEGES table provides information about schema (database) privileges. This information comes from the mysql.db grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		'user_name'@'host_name' value, MySQL extension
TABLE_CATALOG		NULL, MySQL extension
TABLE_SCHEMA		MySQL extension
PRIVILEGE_TYPE		MySQL extension
IS_GRANTABLE		MySQL extension

Notes:

- This is a nonstandard table. It takes its values from the mysql.db table.

The INFORMATION_SCHEMA STATISTICS Table

The STATISTICS table provides information about table indexes.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		= Database
TABLE_NAME	Table	
NON_UNIQUE	Non_unique	
INDEX_SCHEMA		= Database
INDEX_NAME	Key_name	
SEQ_IN_INDEX	Seq_in_index	
COLUMN_NAME	Column_name	
COLLATION	Collation	
CARDINALITY	Cardinality	
SUB_PART	Sub_part	MySQL extension
PACKED	Packed	MySQL extension
NULLABLE	Null	MySQL extension
INDEX_TYPE	Index_type	MySQL extension
COMMENT	Comment	MySQL extension

Notes:

- There is no standard table for indexes. The preceding list is similar to what SQL Server 2000 returns for `sp_statistics`, except that we replaced the name `QUALIFIER` with `CATALOG` and we replaced the name `OWNER` with `SCHEMA`.

  Clearly, the preceding table and the output from `SHOW INDEX` are derived from the same parent. So the correlation is already close.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS
  WHERE table_name = 'tbl_name'
  AND table_schema = 'db_name'

SHOW INDEX
  FROM tbl_name
  FROM db_name
```

The INFORMATION_SCHEMA TABLES Table

The `TABLES` table provides information about tables in databases.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA	Table_...	
TABLE_NAME	Table_...	
TABLE_TYPE		
ENGINE	Engine	MySQL extension
VERSION	Version	The version number of the table's `.frm` file, MySQL extension
ROW_FORMAT	Row_format	MySQL extension
TABLE_ROWS	Rows	MySQL extension
AVG_ROW_LENGTH	Avg_row_length	MySQL extension
DATA_LENGTH	Data_length	MySQL extension
MAX_DATA_LENGTH	Max_data_length	MySQL extension
INDEX_LENGTH	Index_length	MySQL extension
DATA_FREE	Data_free	MySQL extension
AUTO_INCREMENT	Auto_increment	MySQL extension
CREATE_TIME	Create_time	MySQL extension
UPDATE_TIME	Update_time	MySQL extension
CHECK_TIME	Check_time	MySQL extension
TABLE_COLLATION	Collation	MySQL extension
CHECKSUM	Checksum	MySQL extension
CREATE_OPTIONS	Create_options	MySQL extension
TABLE_COMMENT	Comment	MySQL extension

Notes:

- `TABLE_SCHEMA` and `TABLE_NAME` are a single field in a `SHOW` display, for example `Table_in_db1`.

- TABLE_TYPE should be BASE TABLE or VIEW. Currently, the TABLES table does not list TEMPORARY tables.
- For partitioned tables, beginning with MySQL 5.1.9, the ENGINE column shows the name of the storage engine used by all partitions. (Previously, this column showed PARTITION for such tables.)
- The TABLE_ROWS column is NULL if the table is in the INFORMATION_SCHEMA database.

  For InnoDB tables, the row count is only a rough estimate used in SQL optimization. (This is also true if the InnoDB table is partitioned.)
- Prior to MySQL 5.1.12, MySQL Cluster allocated storage for variable-width columns in 10-page extents of 32 kilobytes each; thus, the DATA_LENGTH for such columns was reported in increments of 320 KB. Beginning with MySQL 5.1.12, the DATA_LENGTH column reflects the true amount of storage for variable-width columns of NDB tables. (Bug #18413)

  For NDB tables, DATA_LENGTH includes data stored in main memory only; the MAX_DATA_LENGTH and DATA_FREE columns apply to Disk Data.
- Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, for MySQL Cluster Disk Data tables, MAX_DATA_LENGTH shows the space allocated for the disk part of a Disk Data table or fragment. (In-memory data resource usage is reported by the DATA_LENGTH column.)
- Beginning with MySQL 5.1.28, the DATA_FREE column shows the free space in bytes for InnoDB tables.

  Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, DATA_FREE shows the space allocated on disk for, but not used by, a Disk Data table or fragment on disk. (In-memory data resource usage is reported by the DATA_LENGTH column.)
- We have nothing for the table's default character set. TABLE_COLLATION is close, because collation names begin with a character set name.
- Beginning with MySQL 5.1.9, the CREATE_OPTIONS column shows partitioned if the table is partitioned.

The following statements are equivalent:

```
SELECT table_name FROM INFORMATION_SCHEMA.TABLES
  WHERE table_schema = 'db_name'
  [AND table_name LIKE 'wild']

SHOW TABLES
  FROM db_name
  [LIKE 'wild']
```

The INFORMATION_SCHEMA TABLE_CONSTRAINTS Table

The TABLE_CONSTRAINTS table describes which tables have constraints.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CONSTRAINT_CATALOG		NULL
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
TABLE_SCHEMA		
TABLE_NAME		
CONSTRAINT_TYPE		

Notes:

- The CONSTRAINT_TYPE value can be UNIQUE, PRIMARY KEY, or FOREIGN KEY.

- The UNIQUE and PRIMARY KEY information is about the same as what you get from the Key_name field in the output from SHOW INDEX when the Non_unique field is 0.
- The CONSTRAINT_TYPE column can contain one of these values: UNIQUE, PRIMARY KEY, FOREIGN KEY, CHECK. This is a CHAR (not ENUM) column. The CHECK value is not available until we support CHECK.

The INFORMATION_SCHEMA TABLE_PRIVILEGES Table

The TABLE_PRIVILEGES table provides information about table privileges. This information comes from the mysql.tables_priv grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		*'user_name'@'host_name'* value
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
PRIVILEGE_TYPE		
IS_GRANTABLE		

Notes:

- PRIVILEGE_TYPE can contain one (and only one) of these values: SELECT [627], INSERT [627], UPDATE [628], REFERENCES [627], ALTER [626], INDEX [627], DROP [626], CREATE VIEW [626].

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES

SHOW GRANTS ...
```

The INFORMATION_SCHEMA TRIGGERS Table

The TRIGGERS table provides information about triggers. You must have the TRIGGER [628] privilege to access this table (prior to MySQL 5.1.23, you must have the SUPER [628] privilege). You can see results only for databases and tables for which you have the TRIGGER [628] privilege, or (prior to MySQL 5.1.23) if you have the SUPER [628] privilege).

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TRIGGER_CATALOG		NULL
TRIGGER_SCHEMA		
TRIGGER_NAME	Trigger	
EVENT_MANIPULATION	Event	
EVENT_OBJECT_CATALOG		NULL
EVENT_OBJECT_SCHEMA		
EVENT_OBJECT_TABLE	Table	
ACTION_ORDER		0
ACTION_CONDITION		NULL
ACTION_STATEMENT	Statement	
ACTION_ORIENTATION		ROW
ACTION_TIMING	Timing	
ACTION_REFERENCE_OLD_TABLE		NULL

INFORMATION_SCHEMA Name	SHOW Name	Remarks
ACTION_REFERENCE_NEW_TABLE		NULL
ACTION_REFERENCE_OLD_ROW		OLD
ACTION_REFERENCE_NEW_ROW		NEW
CREATED		NULL (0)
SQL_MODE		MySQL extension
DEFINER		MySQL extension
CHARACTER_SET_CLIENT		MySQL extension
COLLATION_CONNECTION		MySQL extension
DATABASE_COLLATION		MySQL extension

Notes:

- The TRIGGER_SCHEMA and TRIGGER_NAME columns contain the name of the database in which the trigger occurs and the trigger name, respectively.
- The EVENT_MANIPULATION column contains one of the values 'INSERT', 'DELETE', or 'UPDATE'.
- As noted in Using Triggers, every trigger is associated with exactly one table. The EVENT_OBJECT_SCHEMA and EVENT_OBJECT_TABLE columns contain the database in which this table occurs, and the table's name.
- The ACTION_ORDER column contains the ordinal position of the trigger's action within the list of all similar triggers on the same table. Currently, this value is always 0, because it is not possible to have more than one trigger with the same EVENT_MANIPULATION and ACTION_TIMING on the same table.
- The ACTION_STATEMENT column contains the statement to be executed when the trigger is invoked. This is the same as the text displayed in the Statement column of the output from SHOW TRIGGERS. Note that this text uses UTF-8 encoding.
- The ACTION_ORIENTATION column always contains the value 'ROW'.
- The ACTION_TIMING column contains one of the two values 'BEFORE' or 'AFTER'.
- The columns ACTION_REFERENCE_OLD_ROW and ACTION_REFERENCE_NEW_ROW contain the old and new column identifiers, respectively. This means that ACTION_REFERENCE_OLD_ROW always contains the value 'OLD' and ACTION_REFERENCE_NEW_ROW always contains the value 'NEW'.
- The SQL_MODE column shows the server SQL mode that was in effect at the time when the trigger was created (and thus which remains in effect for this trigger whenever it is invoked, *regardless of the current server SQL mode*). The possible range of values for this column is the same as that of the sql_mode [526] system variable. See Server SQL Modes.
- The DEFINER column was added in MySQL 5.1.2. DEFINER indicates who defined the trigger.
- CHARACTER_SET_CLIENT is the session value of the character_set_client [464] system variable when the trigger was created. COLLATION_CONNECTION is the session value of the collation_connection [466] system variable when the trigger was created. DATABASE_COLLATION is the collation of the database with which the trigger is associated. These columns were added in MySQL 5.1.21.
- The following columns currently always contain NULL: TRIGGER_CATALOG, EVENT_OBJECT_CATALOG, ACTION_CONDITION, ACTION_REFERENCE_OLD_TABLE, ACTION_REFERENCE_NEW_TABLE, and CREATED.

Example, using the ins_sum trigger defined in Using Triggers:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.TRIGGERS\G
*************************** 1. row ***************************
             TRIGGER_CATALOG: NULL
              TRIGGER_SCHEMA: test
                TRIGGER_NAME: ins_sum
          EVENT_MANIPULATION: INSERT
        EVENT_OBJECT_CATALOG: NULL
         EVENT_OBJECT_SCHEMA: test
          EVENT_OBJECT_TABLE: account
                ACTION_ORDER: 0
            ACTION_CONDITION: NULL
            ACTION_STATEMENT: SET @sum = @sum + NEW.amount
          ACTION_ORIENTATION: ROW
               ACTION_TIMING: BEFORE
ACTION_REFERENCE_OLD_TABLE: NULL
ACTION_REFERENCE_NEW_TABLE: NULL
  ACTION_REFERENCE_OLD_ROW: OLD
  ACTION_REFERENCE_NEW_ROW: NEW
                   CREATED: NULL
                  SQL_MODE:
                   DEFINER: me@localhost
```

See also SHOW TRIGGERS Syntax.

The INFORMATION_SCHEMA USER_PRIVILEGES Table

The USER_PRIVILEGES table provides information about global privileges. This information comes from the mysql.user grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		*'user_name'@'host_name'* value, MySQL extension
TABLE_CATALOG		NULL, MySQL extension
PRIVILEGE_TYPE		MySQL extension
IS_GRANTABLE		MySQL extension

Notes:

- This is a nonstandard table. It takes its values from the mysql.user table.

The INFORMATION_SCHEMA VIEWS Table

The VIEWS table provides information about views in databases. You must have the SHOW VIEW [628] privilege to access this table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
VIEW_DEFINITION		
CHECK_OPTION		
IS_UPDATABLE		
DEFINER		
SECURITY_TYPE		
CHARACTER_SET_CLIENT		MySQL extension
COLLATION_CONNECTION		MySQL extension

Notes:

- The VIEW_DEFINITION column has most of what you see in the Create Table field that SHOW CREATE VIEW produces. Skip the words before SELECT and skip the words WITH CHECK OPTION. Suppose that the original statement was:

```
CREATE VIEW v AS
  SELECT s2,s1 FROM t
  WHERE s1 > 5
  ORDER BY s1
  WITH CHECK OPTION;
```

  Then the view definition looks like this:

```
SELECT s2,s1 FROM t WHERE s1 > 5 ORDER BY s1
```

- The CHECK_OPTION column has a value of NONE, CASCADE, or LOCAL.
- MySQL sets a flag, called the view updatability flag, at CREATE VIEW time. The flag is set to YES (true) if UPDATE and DELETE (and similar operations) are legal for the view. Otherwise, the flag is set to NO (false). The IS_UPDATABLE column in the VIEWS table displays the status of this flag. It means that the server always knows whether a view is updatable. If the view is not updatable, statements such UPDATE, DELETE, and INSERT are illegal and will be rejected. (Note that even if a view is updatable, it might not be possible to insert into it; for details, refer to CREATE VIEW Syntax.)
- The DEFINER column indicates who defined the view. SECURITY_TYPE has a value of DEFINER or INVOKER.
- CHARACTER_SET_CLIENT is the session value of the character_set_client [464] system variable when the view was created. COLLATION_CONNECTION is the session value of the collation_connection [466] system variable when the view was created. These columns were added in MySQL 5.1.21.

MySQL lets you use different sql_mode [526] settings to tell the server the type of SQL syntax to support. For example, you might use the ANSI [577] SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (||), in your queries. If you then create a view that concatenates items, you might worry that changing the sql_mode [526] setting to a value different from ANSI [577] could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a CONCAT() [951] function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as col1;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT VIEW_DEFINITION FROM INFORMATION_SCHEMA.VIEWS
    -> WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 'v';
+---------------------------------+
| VIEW_DEFINITION                 |
+---------------------------------+
| select concat('a','b') AS `col1` |
+---------------------------------+
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of sql_mode [526] will not affect the results from the view. However an additional consequence is that comments prior to SELECT are stripped from the definition by the server.

INFORMATION_SCHEMA Tables for MySQL Cluster

The following sections provide information about INFORMATION_SCHEMA tables which are specific to MySQL Cluster. The FILES table was added in MySQL Server 5.1.6 as part of MySQL Cluster data-on-disk support (it is available in standard MySQL 5.5 but is not used there). The ndb_transid_mysql_connection_map table was added as part of additions made to MySQL

Cluster's ndbinfo information database in MySQL Cluster NDB 7.1.17; it is implemented as an INFORMATION_SCHEMA plugin available only in MySQL Cluster binaries or source, and does not exist in MySQL Server 5.1.

Additional statistical and other data about MySQL Cluster transactions, operations, threads, blocks, and other aspects of performance can be obtained from the tables in the ndbinfo database. Information about these tables, see The ndbinfo MySQL Cluster Information Database.

The INFORMATION_SCHEMA FILES Table

The FILES table provides information about the files in which MySQL NDB Disk Data tables are stored.

Note

This table provides information about Disk Data *files* only; you cannot use it for determining disk space allocation or availability for individual NDB tables. However, beginning with MySQL Cluster NDB 6.3.27 and MySQL Cluster NDB 7.0.8, it is possible to see how much space is allocated for each NDB table having data stored on disk, as well as how much remains available for storage of of data on disk for that table, using ndb_desc. For more information, see ndb_desc — Describe NDB Tables.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
FILE_ID		MySQL extension

INDEX_LENGTH		MySQL extension
DATA_FREE		MySQL extension
CREATE_TIME		MySQL extension
UPDATE_TIME		MySQL extension
CHECK_TIME		MySQL extension
CHECKSUM		MySQL extension
STATUS		MySQL extension
EXTRA		MySQL extension

Notes:

- FILE_ID column values are auto-generated.
- FILE_NAME is the name of an UNDO log file created by CREATE LOGFILE GROUP or ALTER LOGFILE GROUP, or of a data file created by CREATE TABLESPACE or ALTER TABLESPACE.
- FILE_TYPE is one of the values UNDOFILE or DATAFILE.

  Beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.32, MySQL Cluster NDB 7.0.13, and MySQL Cluster NDB 7.1.2, this column can also have the value TABLESPACE.
- TABLESPACE_NAME is the name of the tablespace with which the file is associated.
- Currently, the value of the TABLESPACE_CATALOG column is always NULL.
- TABLE_NAME is the name of the Disk Data table with which the file is associated, if any.
- The LOGFILE_GROUP_NAME column gives the name of the log file group to which the log file or data file belongs.
- For an UNDO log file, the LOGFILE_GROUP_NUMBER contains the auto-generated ID number of the log file group to which the log file belongs.
- For a MySQL Cluster Disk Data log file or data file, the value of the ENGINE column is always NDB or NDBCLUSTER.
- For a MySQL Cluster Disk Data log file or data file, the value of the FULLTEXT_KEYS column is always empty.
- The FREE EXTENTS column displays the number of extents which have not yet been used by the file. The TOTAL EXTENTS column show the total number of extents allocated to the file.

  The difference between these two columns is the number of extents currently in use by the file:

```
SELECT TOTAL_EXTENTS - FREE_EXTENTS AS extents_used
    FROM INFORMATION_SCHEMA.FILES
    WHERE FILE_NAME = 'myfile.dat';
```

  You can approximate the amount of disk space in use by the file by multiplying this difference by the value of the EXTENT_SIZE column, which gives the size of an extent for the file in bytes:

```
SELECT (TOTAL_EXTENTS - FREE_EXTENTS) * EXTENT_SIZE AS bytes_used
    FROM INFORMATION_SCHEMA.FILES
    WHERE FILE_NAME = 'myfile.dat';
```

Similarly, you can estimate the amount of space that remains available in a given file by multiplying FREE_EXTENTS by EXTENT_SIZE:

```
SELECT FREE_EXTENTS * EXTENT_SIZE AS bytes_free
    FROM INFORMATION_SCHEMA.FILES
    WHERE FILE_NAME = 'myfile.dat';
```

Important

The byte values produced by the preceding queries are approximations only, and their precision is inversely proportional to the value of EXTENT_SIZE. That is, the larger EXTENT_SIZE becomes, the less accurate the approximations are.

It is also important to remember that once an extent is used, it cannot be freed again without dropping the data file of which it is a part. This means that deletes from a Disk Data table do *not* release disk space.

The extent size can be set in a CREATE TABLESPACE statement. See CREATE TABLESPACE Syntax, for more information.

- The INITIAL_SIZE column shows the size in bytes of the file. This is the same value that was used in the INITIAL_SIZE clause of the CREATE LOGFILE GROUP, ALTER LOGFILE GROUP, CREATE TABLESPACE, or ALTER TABLESPACE statement used to create the file.

  For MySQL Cluster Disk Data files, the value of the MAXIMUM_SIZE column is always the same as INITIAL_SIZE, and the AUTOEXTEND_SIZE column is always empty.

- The CREATION_TIME column shows the date and time when the file was created. The LAST_UPDATE_TIME column displays the date and time when the file was last modified. The LAST_ACCESSED column provides the date and time when the file was last accessed by the server.

  Currently, the values of these columns are as reported by the operating system, and are not supplied by the NDB storage engine. Where no value is provided by the operating system, these columns display 0000-00-00 00:00:00.

- For MySQL Cluster Disk Data files, the value of the RECOVER_TIME and TRANSACTION_COUNTER columns is always 0.

- For MySQL Cluster Disk Data files, the following columns are always NULL:

  - VERSION
  - ROW_FORMAT
  - TABLE_ROWS
  - AVG_ROW_LENGTH
  - DATA_LENGTH
  - MAX_DATA_LENGTH
  - INDEX_LENGTH
  - DATA_FREE
  - CREATE_TIME
  - UPDATE_TIME
  - CHECK_TIME

  - CHECKSUM

- For MySQL Cluster Disk Data files, the value of the STATUS column is always NORMAL.
- For MySQL Cluster Disk Data files, the EXTRA column shows which data node the file belongs to, as each data node has its own copy of the file. Suppose that you use this statement on a MySQL Cluster with four data nodes:

```
CREATE LOGFILE GROUP mygroup
    ADD UNDOFILE 'new_undo.dat'
    INITIAL_SIZE 2G
    ENGINE NDB;
```

  After running the CREATE LOGFILE GROUP statement successfully, you should see a result similar to the one shown here for this query against the FILES table:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_TYPE, EXTRA
    ->     FROM INFORMATION_SCHEMA.FILES
    ->     WHERE FILE_NAME = 'new_undo.dat';
+--------------------+-------------+----------------+
| LOGFILE_GROUP_NAME | FILE_TYPE   | EXTRA          |
+--------------------+-------------+----------------+
| mygroup            | UNDO FILE   | CLUSTER_NODE=3 |
| mygroup            | UNDO FILE   | CLUSTER_NODE=4 |
| mygroup            | UNDO FILE   | CLUSTER_NODE=5 |
| mygroup            | UNDO FILE   | CLUSTER_NODE=6 |
+--------------------+-------------+----------------+
4 rows in set (0.01 sec)
```

- The FILES table is a nonstandard table. It was added in MySQL 5.1.6.
- Beginning with MySQL 5.1.14, an additional row is present in the FILES table following the creation of a logfile group. This row has NULL for the value of the FILE_NAME column. For this row, the value of the FILE_ID column is always 0, that of the FILE_TYPE column is always UNDO FILE, and that of the STATUS column is always NORMAL. Currently, the value of the ENGINE column is always NDBCLUSTER.

  The FREE_EXTENTS column in this row shows the total number of free extents available to all undo files belonging to a given log file group whose name and number are shown in the LOGFILE_GROUP_NAME and LOGFILE_GROUP_NUMBER columns, respectively.

  Suppose there are no existing log file groups on your MySQL Cluster, and you create one using the following statement:

```
mysql> CREATE LOGFILE GROUP lg1
    ->   ADD UNDOFILE 'undofile.dat'
    ->   INITIAL_SIZE = 16M
    ->   UNDO_BUFFER_SIZE = 1M
    ->   ENGINE = NDB;
Query OK, 0 rows affected (3.81 sec)
```

  You can now see this NULL row when you query the FILES table:

```
mysql> SELECT DISTINCT
    ->   FILE_NAME AS File,
    ->   FREE_EXTENTS AS Free,
    ->   TOTAL_EXTENTS AS Total,
    ->   EXTENT_SIZE AS Size,
    ->   INITIAL_SIZE AS Initial
    ->   FROM INFORMATION_SCHEMA.FILES;
+-------------+---------+---------+------+----------+
| File        | Free    | Total   | Size | Initial  |
+-------------+---------+---------+------+----------+
| undofile.dat |    NULL | 4194304 |    4 | 16777216 |
| NULL         | 4184068 |    NULL |    4 |     NULL |
+-------------+---------+---------+------+----------+
2 rows in set (0.01 sec)
```

The total number of free extents available for undo logging is always somewhat less than the sum of the TOTAL_EXTENTS column values for all undo files in the log file group due to overhead required for maintaining the undo files. This can be seen by adding a second undo file to the log file group, then repeating the previous query against the FILES table:

```
mysql> ALTER LOGFILE GROUP lg1
    ->   ADD UNDOFILE 'undofile02.dat'
    ->   INITIAL_SIZE = 4M
    ->   ENGINE = NDB;
Query OK, 0 rows affected (1.02 sec)

mysql> SELECT DISTINCT
    ->   FILE_NAME AS File,
    ->   FREE_EXTENTS AS Free,
    ->   TOTAL_EXTENTS AS Total,
    ->   EXTENT_SIZE AS Size,
    ->   INITIAL_SIZE AS Initial
    ->   FROM INFORMATION_SCHEMA.FILES;
+----------------+---------+---------+------+----------+
| File           | Free    | Total   | Size | Initial  |
+----------------+---------+---------+------+----------+
| undofile.dat   |    NULL | 4194304 |    4 | 16777216 |
| undofile02.dat |    NULL | 1048576 |    4 |  4194304 |
| NULL           | 5223944 |    NULL |    4 |     NULL |
+----------------+---------+---------+------+----------+
3 rows in set (0.01 sec)
```

The amount of free space in bytes which is available for undo logging by Disk Data tables using this log file group can be approximated by multiplying the number of free extents by the initial size:

```
mysql> SELECT
    ->   FREE_EXTENTS AS 'Free Extents',
    ->   FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
    ->   FROM INFORMATION_SCHEMA.FILES
    ->   WHERE LOGFILE_GROUP_NAME = 'lg1'
    ->   AND FILE_NAME IS NULL;
+--------------+------------+
| Free Extents | Free Bytes |
+--------------+------------+
|      5223944 |   20895776 |
+--------------+------------+
1 row in set (0.02 sec)
```

If you create a MySQL Cluster Disk Data table and then insert some rows into it, you can see approximately how much space remains for undo logging afterward, for example:

```
mysql> CREATE TABLESPACE ts1
    ->   ADD DATAFILE 'data1.dat'
    ->   USE LOGFILE GROUP lg1
    ->   INITIAL_SIZE 512M
    ->   ENGINE = NDB;
Query OK, 0 rows affected (8.71 sec)

mysql> CREATE TABLE dd (
    ->   c1 INT NOT NULL PRIMARY KEY,
    ->   c2 INT,
    ->   c3 DATE
    ->   )
    ->   TABLESPACE ts1 STORAGE DISK
    ->   ENGINE = NDB;
Query OK, 0 rows affected (2.11 sec)

mysql> INSERT INTO dd VALUES
    ->   (NULL, 1234567890, '2007-02-02'),
    ->   (NULL, 1126789005, '2007-02-03'),
    ->   (NULL, 1357924680, '2007-02-04'),
    ->   (NULL, 1642097531, '2007-02-05');
Query OK, 4 rows affected (0.01 sec)
```

```
mysql> SELECT
    ->   FREE_EXTENTS AS 'Free Extents',
    ->   FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
    ->   FROM INFORMATION_SCHEMA.FILES
    ->   WHERE LOGFILE_GROUP_NAME = 'lg1'
    ->   AND FILE_NAME IS NULL;
+--------------+------------+
| Free Extents | Free Bytes |
+--------------+------------+
|      5207565 |   20830260 |
+--------------+------------+
1 row in set (0.01 sec)
```

- Beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.32, MySQL Cluster NDB 7.0.13, and MySQL Cluster NDB 7.1.2, an additional row is present in the FILES table for any tablespace, whether or not any data files are associated with the tablespace. This row has NULL for the value of the FILE_NAME column. For this row, the value of the FILE_ID column is always 0, that of the FILE_TYPE column is always TABLESPACE, and that of the STATUS column is always NORMAL. Currently, the value of the ENGINE column is always NDBCLUSTER.
- There are no SHOW statements associated with the FILES table.
- For additional information, and examples of creating and dropping MySQL Cluster Disk Data objects, see MySQL Cluster Disk Data Tables.

The INFORMATION_SCHEMA ndb_transid_mysql_connection_map Table

The ndb_transid_mysql_connection_map table provides a mapping between NDB transactions, NDB transaction coordinators, and MySQL Servers attached to a MySQL Cluster as API nodes. This information is used when populating the server_operations and server_transactions tables of the ndbinfo MySQL Cluster information database.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
mysql_connection_id		MySQL Server connection ID
node_id		Transaction coordinator node ID
ndb_transid		NDB transaction ID

The mysql_connection_id is the same as the connection or session ID shown in the output of SHOW PROCESSLIST.

There are no SHOW statements associated with this table.

This is a nonstandard table, added in MySQL Cluster NDB 7.1.17. It is implemented as an INFORMATION_SCHEMA plugin; you can verify that it is supported by checking the output of SHOW PLUGINS. If ndb_transid_mysql_connection_map support is present, the output from this statement includes a plugin having this name and of type INFORMATION SCHEMA, as shown here (using emphasized text):

```
mysql> SHOW PLUGINS;
+----------------------------------+--------+--------------------+---------+---------+
| Name                             | Status | Type               | Library | License |
+----------------------------------+--------+--------------------+---------+---------+
| binlog                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| mysql_native_password            | ACTIVE | AUTHENTICATION     | NULL    | GPL     |
| mysql_old_password               | ACTIVE | AUTHENTICATION     | NULL    | GPL     |
| CSV                              | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| MEMORY                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| MRG_MYISAM                       | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| MyISAM                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| PERFORMANCE_SCHEMA               | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| BLACKHOLE                        | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ARCHIVE                          | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
```

```
| ndbcluster                          | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ndbinfo                             | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ndb_transid_mysql_connection_map    | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| InnoDB                              | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| INNODB_TRX                          | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_LOCKS                        | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_LOCK_WAITS                   | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMP                          | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMP_RESET                    | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMPMEM                       | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMPMEM_RESET                 | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| partition                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
+-------------------------------------+--------+--------------------+---------+---------+
22 rows in set (0.00 sec)
```

Although the names of this table and its columns are displayed using lowercase, you can use uppercase or lowercase when referring to them in SQL statements.

For this table to be created, the MySQL Server must be a binary that wass supplied with the MySQL Cluster distribution, or one that was built from the MySQL Cluster sources with NDB storage engine support enabled. It is not available in the standard MySQL 5.1 Server.

Extensions to SHOW Statements

Some extensions to SHOW statements accompany the implementation of INFORMATION_SCHEMA:

- SHOW can be used to get information about the structure of INFORMATION_SCHEMA itself.
- Several SHOW statements accept a WHERE clause that provides more flexibility in specifying which rows to display.

INFORMATION_SCHEMA is an information database, so its name is included in the output from SHOW DATABASES. Similarly, SHOW TABLES can be used with INFORMATION_SCHEMA to obtain a list of its tables:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA;
+---------------------------------------+
| Tables_in_INFORMATION_SCHEMA          |
+---------------------------------------+
| CHARACTER_SETS                        |
| COLLATIONS                            |
| COLLATION_CHARACTER_SET_APPLICABILITY |
| COLUMNS                               |
| COLUMN_PRIVILEGES                     |
| ENGINES                               |

| TRIGGERS                              |
| USER_PRIVILEGES                       |
| VIEWS                                 |
+---------------------------------------+
27 rows in set (0.00 sec)
```

SHOW COLUMNS and DESCRIBE can display information about the columns in individual INFORMATION_SCHEMA tables.

SHOW statements that accept a LIKE [959] clause to limit the rows displayed also permit a WHERE clause that specifies more general conditions that selected rows must satisfy:

```
SHOW CHARACTER SET
SHOW COLLATION
SHOW COLUMNS
SHOW DATABASES
SHOW FUNCTION STATUS
SHOW INDEX
SHOW OPEN TABLES
SHOW PROCEDURE STATUS
SHOW STATUS
SHOW TABLE STATUS
SHOW TABLES
SHOW TRIGGERS
SHOW VARIABLES
```

The WHERE clause, if present, is evaluated against the column names displayed by the SHOW statement. For example, the SHOW CHARACTER SET statement produces these output columns:

```
mysql> SHOW CHARACTER SET;
+----------+-----------------------------+---------------------+--------+
| Charset  | Description                 | Default collation   | Maxlen |
+----------+-----------------------------+---------------------+--------+
| big5     | Big5 Traditional Chinese    | big5_chinese_ci     |      2 |
| dec8     | DEC West European           | dec8_swedish_ci     |      1 |
| cp850    | DOS West European           | cp850_general_ci    |      1 |
| hp8      | HP West European            | hp8_english_ci      |      1 |
| koi8r    | KOI8-R Relcom Russian       | koi8r_general_ci    |      1 |
| latin1   | cp1252 West European        | latin1_swedish_ci   |      1 |
| latin2   | ISO 8859-2 Central European | latin2_general_ci   |      1 |
...
```

To use a WHERE clause with SHOW CHARACTER SET, you would refer to those column names. As an example, the following statement displays information about character sets for which the default collation contains the string 'japanese':

```
mysql> SHOW CHARACTER SET WHERE `Default collation` LIKE '%japanese%';
+---------+---------------------------+---------------------+--------+
| Charset | Description               | Default collation   | Maxlen |
+---------+---------------------------+---------------------+--------+
| ujis    | EUC-JP Japanese           | ujis_japanese_ci    |      3 |
| sjis    | Shift-JIS Japanese        | sjis_japanese_ci    |      2 |
| cp932   | SJIS for Windows Japanese | cp932_japanese_ci   |      2 |
| eucjpms | UJIS for Windows Japanese | eucjpms_japanese_ci |      3 |
+---------+---------------------------+---------------------+--------+
```

This statement displays the multi-byte character sets:

```
mysql> SHOW CHARACTER SET WHERE Maxlen > 1;
+---------+---------------------------+---------------------+--------+
| Charset | Description               | Default collation   | Maxlen |
+---------+---------------------------+---------------------+--------+
| big5    | Big5 Traditional Chinese  | big5_chinese_ci     |      2 |
| ujis    | EUC-JP Japanese           | ujis_japanese_ci    |      3 |
| sjis    | Shift-JIS Japanese        | sjis_japanese_ci    |      2 |
| euckr   | EUC-KR Korean             | euckr_korean_ci     |      2 |
| gb2312  | GB2312 Simplified Chinese | gb2312_chinese_ci   |      2 |
| gbk     | GBK Simplified Chinese    | gbk_chinese_ci      |      2 |
| utf8    | UTF-8 Unicode             | utf8_general_ci     |      3 |
| ucs2    | UCS-2 Unicode             | ucs2_general_ci     |      2 |
| cp932   | SJIS for Windows Japanese | cp932_japanese_ci   |      2 |
| eucjpms | UJIS for Windows Japanese | eucjpms_japanese_ci |      3 |
+---------+---------------------------+---------------------+--------+
```

MySQL Connectors provide connectivity to the MySQL server for client programs. APIs provide low-level access to the MySQL protocol and MySQL resources. Both Connectors and the APIs enable you to connect and execute MySQL statements from another language or environment, including Java (JDBC), ODBC, Perl, Python, PHP, Ruby, and native C and embedded MySQL instances.

Note

Connector version numbers do not correlate with MySQL Server version numbers. See also Table 21.2, “MySQL Connector Versions and MySQL Server Versions”.

A number of connectors are developed by MySQL:

- Connector/ODBC provides driver support for connecting to a MySQL server using the Open Database Connectivity (ODBC) API. Support is available for ODBC connectivity from Windows, Unix and Mac OS X platforms.
- Connector/Net enables developers to create .NET applications that use data stored in a MySQL database. Connector/Net implements a fully functional ADO.NET interface and provides support for use with ADO.NET aware tools. Applications that want to use Connector/Net can be written in any of the supported .NET languages.

  The MySQL Visual Studio Plugin works with Connector/Net and Visual Studio 2005. The plugin is a MySQL DDEX Provider, which means that you can use the schema and data manipulation tools within Visual Studio to create and edit objects within a MySQL database.
- Connector/J provides driver support for connecting to MySQL from a Java application using the standard Java Database Connectivity (JDBC) API.
- Connector/Python provides driver support for connecting to MySQL from a Python program using an API that is compliant with the Python DB API version 2.0. No additional Python modules or MySQL client libraries are required.
- Connector/C++ is a tool that enables easy deployment and management of MySQL server and database through your C++ application.
- Connector/C is a standalone replacement for the MySQL Client Library (`libmysql`).
- Connector/OpenOffice.org is a tool that enables OpenOffice.org applications to connect to MySQL server.

There are two direct access methods for using MySQL natively within a C application:

- The C API provides low-level access to the MySQL protocol through the `libmysql` client library; this is the primary method used to connect to an instance of the MySQL server, and is used both by MySQL command line clients and many of the APIs also detailed in this section. MySQL Connector/C can now also be used for this purpose.
- `libmysqld` is an embedded MySQL server library that enables you to embed an instance of the MySQL server into your C applications.

If you need to access MySQL from a C application, or build an interface to MySQL for a language not supported by the Connectors or APIs in this chapter, the C API is where you would start. A number of programmers utilities are available to help with the process, and also covered in this section.

The remaining APIs provide an interface to MySQL from specific application languages. These solutions are not developed or supported by MySQL. Basic information on their usage and abilities is provided here for reference purposes only.

All the language APIs are developed using one of two methods, using `libmysql` or by building a *native driver*. The two solutions offer different benefits:

- Using *`libmysql`* offers complete compatibility with MySQL as it uses the same libraries as the MySQL client applications. However, the feature set is limited to the implementation and interfaces exposed through `libmysql` and the performance may be lower as data is copied between the native language, and the MySQL API components. MySQL Connector/C is a possible alternative to using `libmysql`.
- *Native drivers* are an implementation of the MySQL network protocol entirely within the host language or environment. Native drivers are fast, as there is less copying of data between components, and they can offer advanced functionality not available through the standard MySQL API. Native drivers are also easier to build and deploy, as you do not need a copy of the MySQL client libraries to build the native driver components.

A list of many of the libraries and interfaces available for MySQL are shown in the table. See Table 21.1, “MySQL APIs and Interfaces”.

Table 21.1. MySQL APIs and Interfaces

Environment	API	Type	Notes
Ada	MySQL Bindings for GNU Ada	`libmysql`	See MySQL Bindings for GNU Ada
C	Connector/C	Replacement for `libmysql`	See MySQL Connector/C.
C++	Connector/C++	`libmysql`	See MySQL Connector/C++.
	MySQL++	`libmysql`	See MySQL++ Web site.
	MySQL wrapped	`libmysql`	See MySQL wrapped.
Cocoa	MySQL-Cocoa	`libmysql`	Compatible with the Objective-C Cocoa environment. See http://mysql-cocoa.sourceforge.net/
D	MySQL for D	`libmysql`	See MySQL for D.
Eiffel	Eiffel MySQL	`libmysql`	See MySQL Eiffel Wrapper.
Erlang	`erlang-mysql-driver`	`libmysql`	See `erlang-mysql-driver`.
Haskell	Haskell MySQL Bindings	Native Driver	See Brian O'Sullivan's pure Haskell MySQL bindings.
	`hsql-mysql`	`libmysql`	See MySQL driver for Haskell .
Java/ JDBC	Connector/J	Native Driver	See MySQL Connector/J.
Kaya	MyDB	`libmysql`	See MyDB.
Lua	LuaSQL	`libmysql`	See LuaSQL.
.NET/ Mono	Connector/Net	Native Driver	See MySQL Connector/Net.
Objective Caml	MySQL Bindings for OBjective Caml	`libmysql`	See MySQL Bindings for Objective Caml.
Octave	Database bindings for GNU Octave	`libmysql`	See Database bindings for GNU Octave.
ODBC	Connector/ODBC	`libmysql`	See MySQL Connector/ODBC.
OpenOffice	MySQL Connector/OpenOffice.org	`libmysql`	Direct connectivity, without using JDBC/ODBC. See MySQL Connector/ OpenOffice.org.
Perl	`DBI`/`DBD::mysql`	`libmysql`	See MySQL Perl API.

Environment	API	Type	Notes
	`Net::MySQL`	Native Driver	See `Net::MySQL` at CPAN
PHP	`mysql`, `ext/mysql` interface (deprecated)	`libmysql`	See Original MySQL API (`Mysql`).
	`mysqli`, `ext/mysqli` interface	`libmysql`	See MySQL Improved Extension (`Mysqli`).
	`PDO_MYSQL`	`libmysql`	See MySQL Functions (PDO_MYSQL) (`MySQL (PDO)`).
	PDO mysqlnd	Native Driver	
Python	Connector/Python	Native Driver	See MySQL Connector/Python.
	MySQLdb	`libmysql`	See MySQL Python API.
Ruby	MySQL/Ruby	`libmysql`	Uses `libmysql`. See The MySQL/Ruby API.
	Ruby/MySQL	Native Driver	See The Ruby/MySQL API.
Scheme	`Myscsh`	`libmysql`	See `Myscsh`.
SPL	`sql_mysql`	`libmysql`	See `sql_mysql` for SPL.
Tcl	MySQLtcl	`libmysql`	See MySQL Tcl API.

Table 21.2. MySQL Connector Versions and MySQL Server Versions

Connector	Connector version	MySQL Server version
Connector/C++	1.0.5 GA	5.6, 5.5, 5.4, 5.1
Connector/J	5.1.8	5.6, 5.5, 5.4, 5.1, 5.0, 4.1
Connector/Net	6.5	5.6, 5.5, 5.4, 5.1, 5.0
Connector/Net	6.4	5.6, 5.5, 5.4, 5.1, 5.0
Connector/Net	6.3	5.6, 5.5, 5.4, 5.1, 5.0
Connector/Net	6.2 (No longer supported)	5.6, 5.5, 5.4, 5.1, 5.0
Connector/Net	6.1 (No longer supported)	5.6, 5.5, 5.4, 5.1, 5.0
Connector/Net	6.0 (No longer supported)	5.6, 5.5, 5.4, 5.1, 5.0
Connector/Net	5.2 (No longer supported)	5.6, 5.5, 5.4, 5.1, 5.0
Connector/Net	1.0 (No longer supported)	5.0, 4.0
Connector/ODBC	5.1	5.6, 5.5, 5.4, 5.1, 5.0, 4.1.1+
Connector/ODBC	3.51 (Unicode not supported)	5.6, 5.5, 5.4, 5.1, 5.0, 4.1
Connector/OpenOffice.org	1.0 GA	5.6, 5.5, 5.4, 5.1, 5.0

MySQL Connector/ODBC

The MySQL Connector/ODBC is the name for the family of MySQL ODBC drivers (previously called MyODBC drivers) that provide access to a MySQL database using the industry standard Open Database Connectivity (ODBC) API. This reference covers Connector/ODBC 5.2, which includes the

functionality of the Unicode driver and the ANSI driver, which formerly were split between Connector/ODBC 5.1 and Connector/ODBC 3.51.

MySQL Connector/ODBC provides both driver-manager based and native interfaces to the MySQL database, with full support for MySQL functionality, including stored procedures, transactions and, with Connector/ODBC 5.1 and higher, full Unicode compliance.

For more information on the ODBC API standard and how to use it, refer to http://support.microsoft.com/kb/110093.

The application development section of the ODBC API reference assumes a good working knowledge of C, general DBMS, and a familiarity with MySQL. For more information about MySQL functionality and its syntax, refer to http://dev.mysql.com/doc/.

Typically, you need to install Connector/ODBC only on Windows machines. For Unix and Mac OS X, you can use the native MySQL network or named pipes to communicate with your MySQL database. You may need Connector/ODBC for Unix or Mac OS X if you have an application that requires an ODBC interface to communicate with the database. Applications that require ODBC to communicate with MySQL include ColdFusion, Microsoft Office, and Filemaker Pro.

Key connector/ODBC topics include:

- The configuration options: Connector/ODBC Connection Parameters.
- An example that connects to a MySQL database from a Windows host: Step-by-step Guide to Connecting to a MySQL Database through Connector/ODBC.
- An example that uses Microsoft Access as an interface to a MySQL database: Using Connector/ODBC with Microsoft Access.
- General tips and notes, including how to obtain the last auto-increment ID: Connector/ODBC General Functionality.
- Application-specific usage tips and notes: Connector/ODBC Application-Specific Tips.
- A FAQ (Frequently Asked Questions) list: Connector/ODBC Errors and Resolutions (FAQ).
- Additional Connector/ODBC support options: Connector/ODBC Support.

Connector/ODBC Versions

These are the versions of Connector/ODBC that are currently available:

- Connector/ODBC 5.2, currently in beta status, upgrades the ANSI driver of Connector/ODBC 3.51 to the 5.x code base. It also includes new features, such as enabling server-side prepared statements by default. At installation time, you can choose the Unicode driver for the broadest compatibility with data sources using various character sets, or the ANSI driver for optimal performance with a more limited range of character sets. It works with MySQL versions 4.1.1 and higher.
- Connector/ODBC 5.1, currently in GA status, is a partial rewrite of the of the 3.51 code base, and is designed to work with MySQL versions 4.1.1 and newer.

  Connector/ODBC 5.1 also includes the following changes and improvements over the 3.51 release:

  - Improved support on Windows 64-bit platforms.
  - Full Unicode support at the driver level. This includes support for the `SQL_WCHAR` data type, and support for Unicode login, password and DSN configurations. For more information, see Microsoft Knowledgebase Article #716246.

- Support for the `SQL_NUMERIC_STRUCT` data type, which provides easier access to the precise definition of numeric values. For more information, see Microsoft Knowledgebase Article #714556
- Native Windows setup library. This replaces the Qt library based interface for configuring DSN information within the ODBC Data Sources application.
- Support for the ODBC descriptor, which improves the handling and metadata of columns and parameter data. For more information, see Microsoft Knowledgebase Article #716339.

- Connector/ODBC 3.51 is the current release of the 32-bit ODBC driver, also known as the MySQL ODBC 3.51 driver. Connector/ODBC 3.51 has support for ODBC 3.5x specification level 1 (complete core API + level 2 features) to continue to provide all functionality of ODBC for accessing MySQL.

  With MySQL Connector/ODBC 5.2 (currently in beta status) now offering both ANSI and Unicode drivers, you should expect to upgrade relatively soon after 5.2 becomes generally available.

The manual for versions of Connector/ODBC older than 5.2 can be located in the corresponding binary or source distribution. Please note that versions of Connector/ODBC earlier than the 3.51 revision were not fully compliant with the ODBC specification.

Note

From this section onward, the primary focus of this guide is the Connector/ODBC 5.2 driver.

Note

Version numbers for MySQL products are formatted as X.X.X. However, Windows tools (Control Panel, properties display) may show the version numbers as XX.XX.XX. For example, the official MySQL formatted version number 5.0.9 may be displayed by Windows tools as 5.00.09. The two versions are the same; only the number display format is different.

Connector/ODBC Introduction

ODBC (Open Database Connectivity) provides a way for client programs to access a wide range of databases or data sources. ODBC is a standardized API that enables connections to SQL database servers. It was developed according to the specifications of the SQL Access Group and defines a set of function calls, error codes, and data types that can be used to develop database-independent applications. ODBC usually is used when database independence or simultaneous access to different data sources is required.

For more information about ODBC, refer to http://support.microsoft.com/kb/110093.

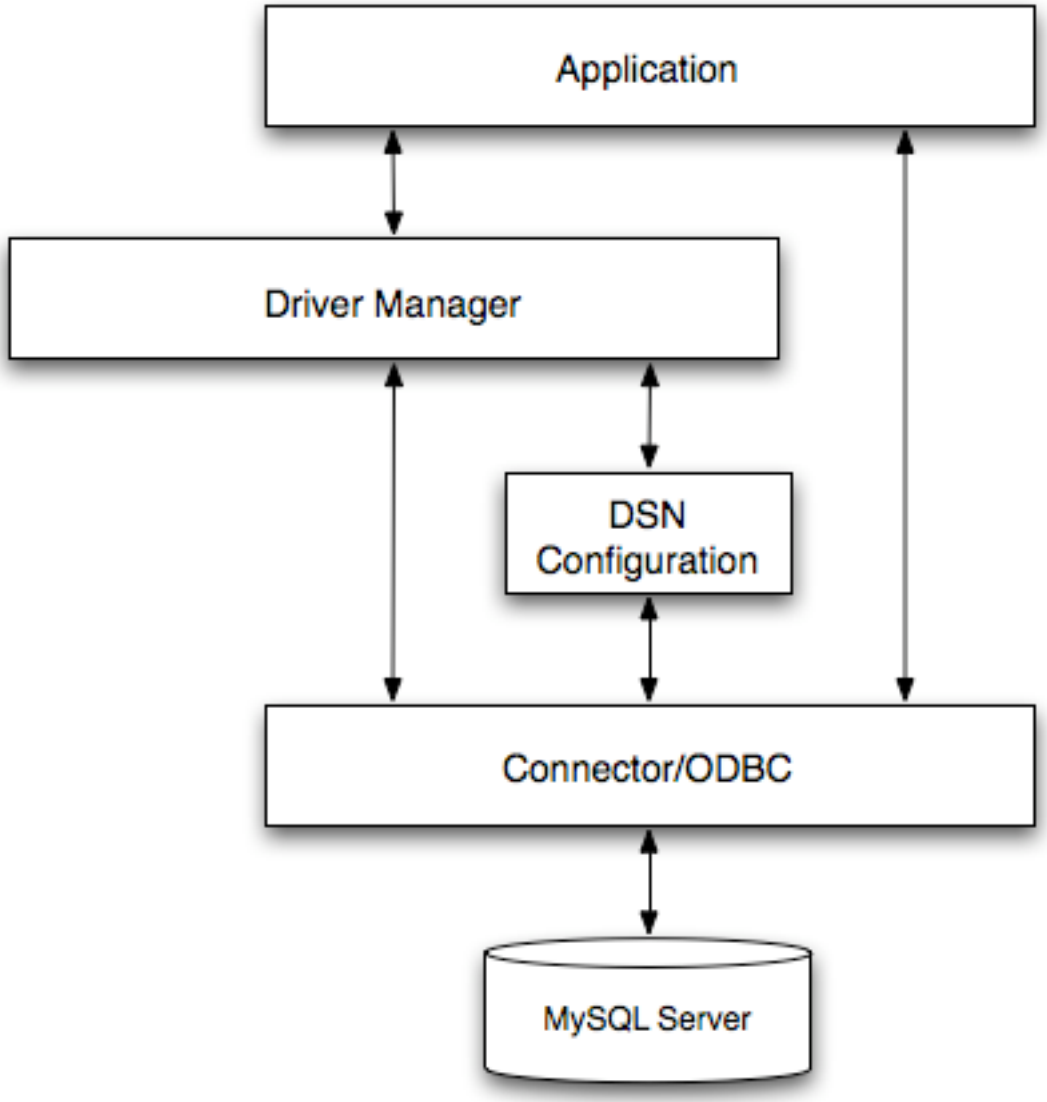
General Information About ODBC and Connector/ODBC

Open Database Connectivity (ODBC) is a widely accepted application-programming interface (API) for database access. It is based on the Call-Level Interface (CLI) specifications from X/Open and ISO/IEC for database APIs and uses Structured Query Language (SQL) as its database access language.

A survey of ODBC functions supported by Connector/ODBC is given at Connector/ODBC API Reference. For general information about ODBC, see http://support.microsoft.com/kb/110093.

Connector/ODBC Architecture

The Connector/ODBC architecture is based on five components, as shown in the following diagram:



- **Application:**

  The Application uses the ODBC API to access the data from the MySQL server. The ODBC API in turn communicates with the Driver Manager. The Application communicates with the Driver Manager using the standard ODBC calls. The Application does not care where the data is stored, how it is stored, or even how the system is configured to access the data. It needs to know only the Data Source Name (DSN).

  A number of tasks are common to all applications, no matter how they use ODBC. These tasks are:

  - Selecting the MySQL server and connecting to it.
  - Submitting SQL statements for execution.
  - Retrieving results (if any).
  - Processing errors.
  - Committing or rolling back the transaction enclosing the SQL statement.
  - Disconnecting from the MySQL server.

Because most data access work is done with SQL, the primary tasks for applications that use ODBC are submitting SQL statements and retrieving any results generated by those statements.

- **Driver manager:**

  The Driver Manager is a library that manages communication between application and driver or drivers. It performs the following tasks:

  - Resolves Data Source Names (DSN). The DSN is a configuration string that identifies a given database driver, database, database host and optionally authentication information that enables an ODBC application to connect to a database using a standardized reference.

    Because the database connectivity information is identified by the DSN, any ODBC compliant application can connect to the data source using the same DSN reference. This eliminates the need to separately configure each application that needs access to a given database; instead you instruct the application to use a pre-configured DSN.

  - Loading and unloading of the driver required to access a specific database as defined within the DSN. For example, if you have configured a DSN that connects to a MySQL database then the driver manager will load the Connector/ODBC driver to enable the ODBC API to communicate with the MySQL host.

  - Processes ODBC function calls or passes them to the driver for processing.

- **Connector/ODBC Driver:**

  The Connector/ODBC driver is a library that implements the functions supported by the ODBC API. It processes ODBC function calls, submits SQL requests to MySQL server, and returns results back to the application. If necessary, the driver modifies an application's request so that the request conforms to syntax supported by MySQL.

- **DSN Configuration:**

  The ODBC configuration file stores the driver and database information required to connect to the server. It is used by the Driver Manager to determine which driver to be loaded according to the definition in the DSN. The driver uses this to read connection parameters based on the DSN specified. For more information, Configuring Connector/ODBC.

- **MySQL Server:**

  The MySQL database where the information is stored. The database is used as the source of the data (during queries) and the destination for data (during inserts and updates).

ODBC Driver Managers

An ODBC Driver Manager is a library that manages communication between the ODBC-aware application and any drivers. Its main functionality includes:

- Resolving Data Source Names (DSN).
- Driver loading and unloading.
- Processing ODBC function calls or passing them to the driver.

Both Windows and Mac OS X include ODBC driver managers with the operating system. Most ODBC Driver Manager implementations also include an administration application that makes the configuration of DSN and drivers easier. Examples and information on these managers, including Unix ODBC driver managers, are listed below:

- Microsoft Windows ODBC Driver Manager (`odbc32.dll`), http://support.microsoft.com/kb/110093.

- Mac OS X includes `ODBC Administrator`, a GUI application that provides a simpler configuration mechanism for the Unix iODBC Driver Manager. You can configure DSN and driver information either through ODBC Administrator or through the iODBC configuration files. This also means that you can test ODBC Administrator configurations using the `iodbctest` command. http://www.apple.com.
- `unixODBC` Driver Manager for Unix (`libodbc.so`). See http://www.unixodbc.org, for more information. The `unixODBC` Driver Manager includes the Connector/ODBC driver 3.51 in the installation package, starting with version `unixODBC` 2.1.2.
- `iODBC` ODBC Driver Manager for Unix (`libiodbc.so`), see http://www.iodbc.org, for more information.

Connector/ODBC Installation

This section explains where to download Connector/ODBC, and how to run the installer, copy the files manually, or build from source.

Where to Get Connector/ODBC

You can get a copy of the latest version of Connector/ODBC binaries and sources from our Web site at http://dev.mysql.com/downloads/connector/odbc/.

For more information about Connector/ODBC, visit http://www.mysql.com/products/myodbc/.

For more information about licensing, visit http://www.mysql.com/company/legal/licensing/.

Choosing Unicode or ANSI Driver

Connector/ODBC offers the flexibility to handle data using any character set through its **Unicode-enabled** driver, or the maximum raw speed for a more limited range of character sets through its **ANSI** driver. Some users postponed their upgrade to Connector/ODBC 5.1, remaining with the older 3.51 version to keep this performance edge. As of Connector/ODBC 5.2, both kinds of drivers are available based on the 5.x code base: you can choose either a Unicode-enabled driver or an ANSI driver on the download page. The Unicode-enabled driver, recommended for most users, has no special qualifier in the download filename. The ANSI driver includes `-ansi-` in the download filename.

Note

You can install either the Unicode driver on a Windows system, or the ANSI driver, or both. The drivers are distinguished in the list of installed software and in the names of libraries and directories by a `w` (for “wide characters”) for the Unicode driver, and `a` in the ANSI driver.

Choosing Binary or Source Installation Method

You can install the Connector/ODBC drivers using two different methods:

- The **binary installation** is the easiest and most straightforward method of installation. You receive all the necessary libraries and other files pre-built, with an installer program or batch script to perform all necessary copying and configuration.
- The **source installation** method is intended for platforms where a binary installation package is not available, or in situations where you want to customize or modify the installation process or Connector/ODBC drivers before installation.

  If a binary distribution is not available for a particular platform, and you build the driver from the original source code, you can contribute the binaries you create to MySQL by sending a mail message to `<myodbc@lists.mysql.com>`, so that it becomes available for other users.

Supported Platforms

Connector/ODBC can be used on all major platforms supported by MySQL. You can install it on:

- Windows 95, 98, Me, NT, 2000, XP, 2003, Vista and 7.
- All Unix-like Operating Systems, including: AIX, Amiga, BSDI, DEC, FreeBSD, HP-UX 10/11, Linux, NetBSD, OpenBSD, OS/2, SGI Irix, Solaris, SunOS, SCO OpenServer, SCO UnixWare, Tru64 Unix.
- Mac OS X and Mac OS X Server.

Note

On all non-Windows platforms except Mac OS X, the driver is built against `unixODBC` and is expecting a 2-byte `SQLWCHAR`, not 4 bytes as `iODBC` is using. For this reason, the binaries are **only** compatible with `unixODBC`; recompile the driver against `iODBC` to use them together. For further information, see ODBC Driver Managers.

For further instructions:

Platform	Binary	Source
Windows	Installation Instructions	Build Instructions
Unix/Linux	Installation Instructions	Build Instructions
Mac OS X	Installation Instructions	

Installing Connector/ODBC on Windows

Before installing the Connector/ODBC drivers on Windows, ensure that your Microsoft Data Access Components (MDAC) are up to date. You can obtain the latest version from the Microsoft Data Access and Storage Web site.

There are different distribution types to use when installing for Windows. The software that is installed is identical in each case, only the installation method is different.

- The **zipped installer** consists of a zipped package containing a standalone installation application. To install from this package, unzip the installer, and then run the installation application.

  The **MSI installer** is an installation file that can be used with the installer included in Windows 2000, Windows XP and Windows Server 2003.

  See Installing the Windows Connector/ODBC Driver Using an Installer for the steps to complete the installation with either of these installers.

- The **zipped DLL** package contains DLL files that must be manually installed. See Installing the Windows Connector/ODBC Driver using the Zipped DLL Package for the steps to complete this type of installation.

Note

An OLEDB/ODBC driver for Windows 64-bit is available from Microsoft Downloads.

Installing the Windows Connector/ODBC Driver Using an Installer

The zipped or MSI installer packages offer a very simple method for installing the Connector/ODBC drivers. If you have downloaded the zipped installer, extract the installer application. The basic installation process is identical for both installers.

Follow these steps to complete the installation:

1. Double-click the standalone installer that you extracted, or the MSI file you downloaded.
2. The MySQL Connector/ODBC Setup Wizard starts. Click the Next button to begin the installation process.
3. Choose the installation type. The **Typical** installation provides the standard files needed to connect to a MySQL database using ODBC. The **Complete** option installs all the available files, including debug and utility components. Oracle recommends choosing one of these two options to complete the installation. If you choose one of these methods, click Next, then proceed to step 5.

   You can also choose a **Custom** installation, where you select the individual components to install. If you choose this method, click Next, then proceed to step 4.
4. If you have chosen a custom installation, use the pop-ups to select which components to install, then click Next to install the necessary files.
5. Once the files are copied to their final locations, the installation is complete. Click Finish to exit the installer.

Now that the installation is complete, configure your ODBC connections using Configuring Connector/ODBC.

Installing the Windows Connector/ODBC Driver using the Zipped DLL Package

If you have downloaded the zipped DLL package:

1. Unzip the installation files.
2. Run the included batch file to perform an installation to the default locations.
3. Alternatively, install the individual files required for Connector/ODBC operation manually.

Note

The following instructions only work for 32-bit Windows systems. If you have a 64-bit Windows system, use the MSI installer, which installs both the 32-bit and 64-bit drivers to the correct locations.

To install using the **batch file**:

1. Unzip the Connector/ODBC zipped DLL package.
2. Open a command prompt.
3. Change to the directory created when you unzipped the Connector/ODBC zipped DLL package.
4. Run `Install.bat`:

```
C:\> Install.bat
```

   This copies the necessary files into the default location, and then registers the Connector/ODBC driver with the Windows ODBC manager.

Note

Changing or adding a new DSN (data source name) may be accomplished using either the GUI, or from the command-line using `myodbc-installer.exe` with Connector/ODBC 5.x, or `myodbc3i.exe` with Connector/ODBC 3.51,

Although Oracle recommends installing these files in the standard location, you can also copy the files by hand to an alternative location - for example, to run or test different versions of the Connector/ODBC driver on the same machine. To **copy the files** to a location of your choice, use the following steps:

1. Unzip the Connector/ODBC zipped DLL package.
2. Open a command prompt.
3. Change to the directory created when you unzipped the Connector/ODBC zipped DLL package.
4. Copy the library files to a suitable directory. The default location is the default Windows system directory `\Windows\System32`:

```
C:\> copy lib\myodbc5S.dll \Windows\System32
C:\> copy lib\myodbc5S.lib \Windows\System32

If installing the Unicode-enabled driver:
C:\> copy lib\myodbc5w.dll \Windows\System32
C:\> copy lib\myodbc5w.lib \Windows\System32

If installing the ANSI driver:
C:\> copy lib\myodbc5a.dll \Windows\System32
C:\> copy lib\myodbc5a.lib \Windows\System32
```

5. Copy the Connector/ODBC tools. These must be placed in a directory that is in the system `%PATH%`. The default is to install these into the Windows system directory `\Windows\System32`:

```
C:\> copy bin\myodbc3i.exe \Windows\System32
C:\> copy bin\myodbc3m.exe \Windows\System32
C:\> copy bin\myodbc3c.exe \Windows\System32
```

6. Optionally, copy the help files. For these files to be accessible through the help system, they must be installed in the Windows system directory:

```
C:\> copy doc\*.hlp \Windows\System32
```

7. Finally, register the Connector/ODBC driver with the ODBC manager:

```
For Unicode-enabled driver:
C:\> myodbc3i -a -d -t"MySQL ODBC 5.2 Driver;\
  DRIVER=myodbc5w.dll;SETUP=myodbc5S.dll"

For ANSI driver:
C:\> myodbc3i -a -d -t"MySQL ODBC 5.2 Driver;\
  DRIVER=myodbc5a.dll;SETUP=myodbc5S.dll"
```

   If you installed these files into a non-default location, change the references to the DLL files and command location in the above statement

Installing Connector/ODBC on Unix

There are two methods available for installing Connector/ODBC on Unix from a binary distribution. For most Unix environments, you will use the **tarball** distribution. For Linux systems, there is also an **RPM** distribution available.

Note

To install Connector/ODBC 5.x on Unix requires unixODBC 2.2.12 or later to be installed.

Installing Connector/ODBC from a Binary Tarball Distribution

To install the driver from a tarball distribution (`.tar.gz` file), download the latest version of the driver for your operating system and follow these steps that demonstrate the process using the Linux version of the tarball, substituting the appropriate file and directory names based on the package you download:

```
shell> su root
shell> gunzip mysql-connector-odbc-5.2.2-i686-pc-linux.tar.gz
shell> tar xvf mysql-connector-odbc-5.2.2-i686-pc-linux.tar
shell> cd mysql-connector-odbc-5.2.2-i686-pc-linux
```

Read the installation instructions in the `INSTALL` file and execute these commands.

Then see Configuring a Connector/ODBC DSN on Unix to configure the DSN for Connector/ODBC. For more information, refer to the `INSTALL` file that comes with your distribution.

Installing Connector/ODBC from an RPM Distribution

To install or upgrade Connector/ODBC from an RPM distribution on Linux, simply download the RPM distribution of the latest version of Connector/ODBC and follow the instructions below. Use `su root` to become `root`, then install the RPM file.

If you are installing for the first time:

```
shell> su root
shell> rpm -ivh mysql-connector-odbc-5.2.2.i386.rpm
```

If the driver exists, upgrade it like this:

```
shell> su root
shell> rpm -Uvh mysql-connector-odbc-5.2.2.i386.rpm
```

If there is any dependency error for MySQL client library, `libmysqlclient`, simply ignore it by supplying the `--nodeps` option, and then make sure the MySQL client shared library is in the path or set through `LD_LIBRARY_PATH`.

This installs the driver libraries and related documents to `/usr/local/lib` and `/usr/share/doc/MyODBC`, respectively. See Configuring a Connector/ODBC DSN on Unix for the post-installation configuration steps.

To **uninstall** the driver, become `root` and execute an `rpm` command:

```
shell> su root
shell> rpm -e mysql-connector-odbc
```

Installing Connector/ODBC on Mac OS X

Mac OS X is based on the FreeBSD operating system, and you can normally use the MySQL network port for connecting to MySQL servers on other hosts. Installing the Connector/ODBC driver lets you connect to MySQL databases on any platform through the ODBC interface. If your application requires an ODBC interface, install the Connector/ODBC driver. Applications that require or can use ODBC (and therefore the Connector/ODBC driver) include ColdFusion, Filemaker Pro, 4th Dimension and many other applications.

Mac OS X includes its own ODBC manager, based on the `iODBC` manager. Mac OS X includes an administration tool that provides easier administration of ODBC drivers and configuration, updating the underlying `iODBC` configuration files.

For Connector/ODBC 5.x, the package is provided as a compressed tar archive that you manually install.

In either case, the driver is designed to work with the iODBC driver manager included with Mac OS X.

To install Connector/ODBC 5.x:

1. Download the installation file for the appropriate level of OS X (10.5 or higher).
2. Extract the archive:

   ```
   shell> tar xvzf mysql-connector-odbc-5.x.y-osx10.z-x86-(32|64)bit.tar.gz
   ```

3. The directory created contains the subdirectories, `lib`, `bin`, and `test`. Copy the contents of `lib` and `bin` to a suitable location such as `/usr/local`:

```
shell> sudo cp bin/* /usr/local/bin
shell> sudo cp lib/* /usr/local/lib
```

4. Finally, register the driver with iODBC using the `myodbc3i` tool you just installed:

```
shell> myodbc3i -a -d -t"MySQL ODBC 3.51 Driver;Driver=/usr/local/lib/libmyodbc3.so;Setup=/usr/local
```

To verify the installed drivers, either use the ODBC Administrator application or the `myodbc3i` utility:

```
shell> myodbc3i -q -d
```

Building Connector/ODBC from a Source Distribution on Windows

You only need to build Connector/ODBC from source on Windows to modify the source or installation location. If you are unsure whether to install from source, please use the binary installation detailed in Installing Connector/ODBC on Windows.

Building Connector/ODBC from source on Windows requires a number of different tools and packages:

- MDAC, Microsoft Data Access SDK from http://support.microsoft.com/kb/110093.
- Suitable C compiler, such as Microsoft Visual C++ or the C compiler included with Microsoft Visual Studio.

  Microsoft Visual Studio 7 and 8 are preferred, and well-tested.
- Connector/ODBC 5.2: `cmake`.
- MySQL client libraries and include files from MySQL 4.0.0 or higher. (Preferably MySQL 4.0.16 or higher). This is required because Connector/ODBC uses calls and structures that exist only starting from this version of the library. To get the client libraries and include files, visit http://dev.mysql.com/downloads/.

Build Steps

Set the environment variables for the Visual Studio toolchain. Visual Studio includes a batch file to set these for you, and installs a **Start** menu shortcut that opens a command prompt with these variables set.

Set `MYSQL_DIR` to the MySQL server installation path, while using the short-style file names. For example:

```
C:\> set MYSQL_DIR=C:\PROGRA~1\MySQL\MYSQLS~1.0
```

Build Connector/ODBC using the `cmake` command-line tool by executing the following from the source root directory (in a command prompt window):

```
C:\> cmake -G "Visual Studio 8 2005"
```

This produces a project file that you can open with Visual Studio, or build from the command line with either of the following commands:

```
C:\> devenv.com MySQL_Connector_ODBC.sln /build Release
C:\> devenv.com MySQL_Connector_ODBC.sln /build RelWithDebInfo
```

To compile a debug build, set the `cmake` build type so that the correct versions of the MySQL client libraries are used:

```
C:\> cmake -G "Visual Studio 8 2005" -DCMAKE_BUILD_TYPE=Debug
C:\> devenv.com MySQL_Connector_ODBC.sln /build Debug
```

Upon completion, the executables are in the `bin/` and `lib/` subdirectories.

See Installing the Windows Connector/ODBC Driver using the Zipped DLL Package for the `copy` commands to complete the installation.

Building Connector/ODBC from a Source Distribution on Unix

Note

Connector/5.2 uses `cmake` for build, rather than `autoconf` and its `configure` command.

You need the following tools to build MySQL from source on Unix:

- A working ANSI C++ compiler. GCC 4.2.1 or later, Sun Studio 10 or later, Visual Studio 2008 or later, and many current vendor-supplied compilers are known to work.
- `cmake`.
- MySQL client libraries and include files from MySQL 4.0.0 or higher. (Preferably MySQL 4.0.16 or higher). This is required because Connector/ODBC uses calls and structures that exist only starting from this version of the library. To get the client libraries and include files, visit http://dev.mysql.com/downloads/.

  If you have built your own MySQL server or client libraries from source using the GNU autotools, use the `--enable-thread-safe-client` option to `configure` when the libraries were built. No special option is needed if you configure with `cmake`.

  Also, ensure that the `libmysqlclient` library was built and installed as a shared library.
- A compatible ODBC manager must be installed. Connector/ODBC is known to work with the `iODBC` and `unixODBC` managers. See ODBC Driver Managers for more information.
- If you are using a character set that is not compiled into the MySQL client library, install the MySQL character definitions from the `charsets` directory into *`SHAREDIR`* (by default, `/usr/local/mysql/share/mysql/charsets`). These should be in place if you have installed the MySQL server on the same machine. See Character Set Support for more information on character set support.

Once you have all the required files, unpack the source files to a separate directory, then run `configure` and build the library using `make`.

Typical `cmake` Options

`iODBC` is the default ODBC library used by Connector/ODBC. Alternatively, `unixODBC` may be used by passing in the appropriate option to `cmake`. For example:

```
shell> cmake -G "Unix Makefiles" -DWITH_UNIXODBC=1
```

When you run `cmake`, you might add options to the command line. Here are some examples:

- `-DODBC_INCLUDES=`*`dir_name`*: Used when the ODBC include directory is not found within the system `$PATH`.
- `-DODBC_LIB_DIR=`*`dir_name`*: Used when the ODBC library directory is not found within the system `$PATH`.
- `-DWITH_UNIXODBC=`*`1`*: Enables unixODBC support.

Additional configure Options

There are a number of other options that you need, or want, to set when configuring the Connector/ODBC driver before it is built.

- To link the driver with MySQL thread safe client libraries `libmysqlclient_r.so` or `libmysqlclient_r.a`, specify the following `configure` option:

```
--enable-thread-safe
```

and can be disabled (default) using

```
--disable-thread-safe
```

This option enables the building of the driver thread-safe library `libmyodbc3_r.so` from by linking with MySQL thread-safe client library `libmysqlclient_r.so`. (The extensions are OS-dependent.)

If the compilation with the thread-safe option fails, it may be because the correct thread-libraries on the system could not be located. Set the value of `LIBS` to point to the correct thread library for your system.

```
LIBS="-lpthread" ./configure ..
```

- You can enable or disable the shared and static versions of Connector/ODBC using these options:

```
--enable-shared[=yes|no]
--disable-shared
--enable-static[=yes|no]
--disable-static
```

- By default, all the binary distributions are built as non-debug versions (configured with `--without-debug`).

  To enable debugging information, build the driver from a source distribution with the proper configuration option to enable debugging support. See MySQL Source-Configuration Options.

- This option is available only for source trees that have been obtained from the Subversion repository. This option does not apply to the packaged source distributions.

  By default, the driver is built with the `--without-docs` option. If you would like the documentation to be built, then execute `configure` with:

```
--with-docs
```

Build Steps for Unix

To build the driver libraries, execute `make`:

```
shell> make
```

If any errors occur, correct them and continue the build process. If you are not able to build, then send a detailed email to `<myodbc@lists.mysql.com>` for further assistance.

Building Shared Libraries

On most platforms, MySQL does not build or support `.so` (shared) client libraries by default. This is based on our experience of problems when building shared libraries.

In cases like this, you have to download the MySQL distribution and configure it with these options:

```
--without-server --enable-shared
```

To build shared driver libraries, specify the `--enable-shared` option for `configure`. By default, `configure` does not enable this option.

If you have configured with the `--disable-shared` option, you can build the `.so` file from the static libraries using the following commands:

```
shell> cd mysql-connector-odbc-3.51.01
shell> make
shell> cd driver
shell> CC=/usr/bin/gcc \
```

```
          $CC -bundle -flat_namespace -undefined error \
          -o .libs/libmyodbc3-3.51.01.so \
          catalog.o connect.o cursor.o dll.o error.o execute.o \
          handle.o info.o misc.o myodbc3.o options.o prepare.o \
          results.o transact.o utility.o \
          -L/usr/local/mysql/lib/mysql/ \
          -L/usr/local/iodbc/lib/ \
          -lz -lc -lmysqlclient -liodbcinst
```

Make sure to change `-liodbcinst` to `-lodbcinst` if you are using `unixODBC` instead of `iODBC`, and configure the library paths accordingly.

This builds and places the `libmyodbc3-3.51.01.so` file in the `.libs` directory. Copy this file to the Connector/ODBC library installation directory (`/usr/local/lib`, or the `lib` directory under the installation directory that you supplied with the `--prefix` option).

```
shell> cd .libs
shell> cp libmyodbc3-3.51.01.so /usr/local/lib
shell> cd /usr/local/lib
shell> ln -s libmyodbc3-3.51.01.so libmyodbc3.so
```

To build the thread-safe driver library:

```
shell> CC=/usr/bin/gcc \
          $CC -bundle -flat_namespace -undefined error
          -o .libs/libmyodbc3_r-3.51.01.so
          catalog.o connect.o cursor.o dll.o error.o execute.o
          handle.o info.o misc.o myodbc3.o options.o prepare.o
          results.o transact.o utility.o
          -L/usr/local/mysql/lib/mysql/
          -L/usr/local/iodbc/lib/
          -lz -lc -lmysqlclient_r -liodbcinst
```

Installing Driver Libraries

To install the driver libraries, execute the following command:

```
shell> make install
```

That command installs one of the following sets of libraries:

For Connector/ODBC 3.51:

- `libmyodbc3.so`
- `libmyodbc3-3.51.01.so`, where 3.51.01 is the version of the driver
- `libmyodbc3.a`

For thread-safe Connector/ODBC 3.51:

- `libmyodbc3_r.so`
- `libmyodbc3-3_r.51.01.so`
- `libmyodbc3_r.a`

For more information on build process, refer to the `INSTALL` file that comes with the source distribution. Note that if you are trying to use the `make` from Sun, you may end up with errors. On the other hand, GNU `gmake` should work fine on all platforms.

Testing Connector/ODBC on Unix

To run the basic samples provided in the distribution with the libraries that you built, use the following command:

```
shell> make test
```

Before running the tests, create the DSN 'myodbc3' in `odbc.ini` and set the environment variable `ODBCINI` to the correct `odbc.ini` file; and MySQL server is running. You can find a sample `odbc.ini` with the driver distribution.

You can even modify the `samples/run-samples` script to pass the desired DSN, UID, and PASSWORD values as the command-line arguments to each sample.

Building Connector/ODBC from Source on Mac OS X

To build the driver on Mac OS X (Darwin), make use of the following `configure` example:

```
shell> ./configure --prefix=/usr/local
          --with-unixODBC=/usr/local
          --with-mysql-path=/usr/local/mysql
          --disable-shared
          --enable-gui=no
          --host=powerpc-apple
```

The command assumes that the `unixODBC` and MySQL are installed in the default locations. If not, configure accordingly.

On Mac OS X, `--enable-shared` builds `.dylib` files by default. You can build `.so` files like this:

```
shell> make
shell> cd driver
shell> CC=/usr/bin/gcc \
          $CC -bundle -flat_namespace -undefined error
          -o .libs/libmyodbc3-3.51.01.so *.o
          -L/usr/local/mysql/lib/
          -L/usr/local/iodbc/lib
          -liodbcinst -lmysqlclient -lz -lc
```

To build the thread-safe driver library:

```
shell> CC=/usr/bin/gcc \
          $CC -bundle -flat_namespace -undefined error
          -o .libs/libmyodbc3-3.51.01.so *.o
          -L/usr/local/mysql/lib/
          -L/usr/local/iodbc/lib
          -liodbcinst -lmysqlclienti_r -lz -lc -lpthread
```

Make sure to change the `-liodbcinst` to `-lodbcinst` in case of using `unixODBC` instead of `iODBC` and configure the libraries path accordingly.

In Apple's version of GCC, both `cc` and `gcc` are actually symbolic links to `gcc3`.

Copy this library to the `$prefix/lib` directory and symlink to `libmyodbc3.so`.

You can cross-check the output shared-library properties using this command:

```
shell> otool -LD .libs/libmyodbc3-3.51.01.so
```

Installing Connector/ODBC from the Development Source Tree

Caution

Read this section only if you are interested in helping us test our new code. To just get MySQL Connector/ODBC up and running on your system, use a standard release distribution.

To obtain the most recent development source tree, first download and install Bazaar from the Bazaar VCS Web site. Bazaar is supported by any platform that supports Python, and is therefore compatible with any Linux, Unix, Windows or Mac OS X host. Instructions for downloading and installing Bazaar on the different platforms are available on the Bazaar Web site.

Building from the source trees requires the following tools:

- `autoconf` 2.52 (or newer).

- `automake` 1.4 (or newer).
- `libtool` 1.4 (or newer).
- `m4`.

The most recent development source tree is available from our public Subversion trees at http://dev.mysql.com/tech-resources/sources.html.

To check out out the Connector/ODBC sources, change to the directory where you want the copy of the Connector/ODBC tree to be stored, then use the following command:

```
shell> bzr branch lp:myodbc
```

You should now have a copy of the entire Connector/ODBC source tree in the directory `connector-odbc3`. To build from this source tree on Unix or Linux, follow these steps:

```
shell> cd myodbc
shell> aclocal
shell> autoheader
shell> libtoolize -c -f
shell> autoconf
shell> automake;
shell> ./configure  # Add your favorite options here
shell> make
```

When the build is done, run `make install` to install the Connector/ODBC driver on your system.

If you have gotten to the `make` stage and the distribution does not compile, please report it to `<myodbc@lists.mysql.com>`.

On Windows, make use of Windows Makefiles `WIN-Makefile` and `WIN-Makefile_debug` in building the driver. For more information, see Building Connector/ODBC from a Source Distribution on Windows.

After the initial checkout operation to get the source tree, run `bzr pull` periodically to update your source according to the latest version.

Configuring Connector/ODBC

Before you connect to a MySQL database using the Connector/ODBC driver, you configure an ODBC Data Source Name (DSN). The DSN associates the various configuration parameters required to communicate with a database to a specific name. You use the DSN in an application to communicate with the database, rather than specifying individual parameters within the application itself. DSN information can be user-specific, system-specific, or provided in a special file. ODBC data source names are configured in different ways, depending on your platform and ODBC driver.

Overview of Connector/ODBC Data Source Names

A Data Source Name associates the configuration parameters for communicating with a specific database. Generally, a DSN consists of the following parameters:

- Name
- Host Name
- Database Name
- Login
- Password

In addition, different ODBC drivers, including Connector/ODBC, may accept additional driver-specific options and parameters.

There are three types of DSN:

- A *System DSN* is a global DSN definition that is available to any user and application on a particular system. A System DSN can normally only be configured by a systems administrator, or by a user who has specific permissions that let them create System DSNs.
- A *User DSN* is specific to an individual user, and can be used to store database connectivity information that the user regularly uses.
- A *File DSN* uses a simple file to define the DSN configuration. File DSNs can be shared between users and machines and are therefore more practical when installing or deploying DSN information as part of an application across many machines.

DSN information is stored in different locations depending on your platform and environment.

Connector/ODBC Connection Parameters

You can specify the parameters in the following tables for Connector/ODBC when configuring a DSN:

- Table 21.3, “Connector/ODBC DSN Configuration Options”
- Table 21.4, “Connector/ODBC Option Flags”

Users on Windows can use the Options and Advanced panels when configuring a DSN to set these parameters; see the table for information on which options relate to which fields and check boxes. On Unix and Mac OS X, use the parameter name and value as the keyword/value pair in the DSN configuration. Alternatively, you can set these parameters within the `InConnectionString` argument in the `SQLDriverConnect()` call.

Table 21.3. Connector/ODBC DSN Configuration Options

Parameter	Default Value	Comment
`user`	ODBC	The user name used to connect to MySQL.
`uid`	ODBC	Synonymous with `user`. Added in 3.51.16.
`server`	`localhost`	The host name of the MySQL server.
`database`		The default database.
`option`	0	Options that specify how Connector/ODBC works. See below.
`port`	3306	The TCP/IP port to use if `server` is not `localhost`.
`initstmt`		Initial statement. A statement to execute when connecting to MySQL. In version 3.51 the parameter is called `stmt`. Note, the driver supports the initial statement being executed only at the time of the initial connection.
`password`		The password for the `user` account on `server`.
`pwd`		Synonymous with `password`. Added in 3.51.16.
`socket` [523]		The Unix socket file or Windows named pipe to connect to if `server` is `localhost`.
`sslca`		The path to a file with a list of trust SSL CAs. Added in 3.51.16.
`sslcapath`		The path to a directory that contains trusted SSL CA certificates in PEM format. Added in 3.51.16.
`sslcert`		The name of the SSL certificate file to use for establishing a secure connection. Added in 3.51.16.
`sslcipher`		A list of permissible ciphers to use for SSL encryption. The cipher list has the same format as the `openssl ciphers` command. Added in 3.51.16.
`sslkey`		The name of the SSL key file to use for establishing a secure connection. Added in 3.51.16.
`charset`		The character set to use for the connection. Added in 3.51.17.

Parameter	Default Value	Comment
sslverify		If set to 1, the SSL certificate will be verified when used with the MySQL connection. If not set, then the default behavior is to ignore SSL certificate verification.
readtimeout		The timeout in seconds for attempts to read from the server. Each attempt uses this timeout value and there are retries if necessary, so the total effective timeout value is three times the option value. You can set the value so that a lost connection can be detected earlier than the TCP/IP Close_Wait_Timeout value of 10 minutes. This option works only for TCP/IP connections, and only for Windows prior to MySQL 5.1.12. Corresponds to the MYSQL_OPT_READ_TIMEOUT option of the MySQL Client Library. This option was added in Connector/ODBC 3.51.27.
writetimeout		The timeout in seconds for attempts to write to the server. Each attempt uses this timeout value and there are net_retry_count retries if necessary, so the total effective timeout value is net_retry_count times the option value. This option works only for TCP/IP connections, and only for Windows prior to MySQL 5.1.12. Corresponds to the MYSQL_OPT_WRITE_TIMEOUT option of the MySQL Client Library. This option was added in Connector/ODBC 3.51.27.
interactive		Enables the CLIENT_INTERACTIVE connection option of mysql_real_connect.
prefetch	0	When set to a non-zero value *N*, causes all queries in the connection to return *N* rows at a time rather than the entire result set. Useful for queries against very large tables where it is not practical to retrieve the whole result set at once. You can scroll through the result set, *N* records at a time. This option works only with forward-only cursors. It does not work when the FLAG_MULTI_STATEMENTS flag is set. It can be used in combination with the FLAG_NO_CACHE option. Its behavior in ADO applications is undefined: the prefetching might or might not occur.
no_ssps	0	In Connector/ODBC 5.2, by default, server-side prepared statements are used. When this option is set to a non-zero value, prepared statements are emulated on the client side, which is the same behavior as in 5.1 and 3.51. Added in 5.2.

Note

The SSL configuration parameters can also be automatically loaded from a my.ini or my.cnf file. See Using Option Files.

The option argument is used to tell Connector/ODBC that the client is not 100% ODBC-compliant. On Windows, you normally select options by toggling the check boxes in the connection screen, but you can also select them in the option argument. The following options are listed in the order in which they appear in the Connector/ODBC connect screen.

Table 21.4. Connector/ODBC Option Flags

Flag Name	GUI Option	Constant Value	Description
FLAG_FIELD_LENGTH	Do not Optimize Column Width		The client cannot handle that Connector/ODBC returns the real width of a column. This option was removed in 3.51.18.

Flag Name	GUI Option	Constant Value	Description
FLAG_FOUND_ROWS	Return Matching Rows	2	The client cannot handle that MySQL returns the true value of affected rows. If this flag is set, MySQL returns “found rows” instead. You must have MySQL 3.21.14 or newer for this to work.
FLAG_DEBUG	Trace Driver Calls To myodbc.log		Make a debug log in C:\myodbc.log on Windows, or /tmp/myodbc.log on Unix variants. This option was removed in Connector/ODBC 3.51.18.
FLAG_BIG_PACKETS	Allow Big Results	8	Do not set any packet limit for results and bind parameters. Without this option, parameter binding will be truncated to 255 characters.
FLAG_NO_PROMPT	Do not Prompt Upon Connect	16	Do not prompt for questions even if driver would like to prompt.
FLAG_DYNAMIC_CURSOR	Enable Dynamic Cursor	32	Enable or disable the dynamic cursor support.
FLAG_NO_SCHEMA	Ignore # in Table Name	64	Ignore use of database name in *db_name.tbl_name.col_name*.
FLAG_NO_DEFAULT_CURSOR	User Manager Cursors	128	Force use of ODBC manager cursors (experimental).
FLAG_NO_LOCALE	Do not Use Set Locale	256	Disable the use of extended fetch (experimental).
FLAG_PAD_SPACE	Pad Char To Full Length	512	Pad CHAR columns to full column length.
FLAG_FULL_COLUMN_NAMES	Return Table Names for SQLDescribeCol	1024	SQLDescribeCol() returns fully qualified column names.
FLAG_COMPRESSED_PROTO	Use Compressed Protocol	2048	Use the compressed client/server protocol.
FLAG_IGNORE_SPACE	Ignore Space After Function Names	4096	Tell server to ignore space after function name and before “(” (needed by PowerBuilder). This makes all function names keywords.
FLAG_NAMED_PIPE	Force Use of Named Pipes	8192	Connect with named pipes to a mysqld server running on NT.
FLAG_NO_BIGINT	Change BIGINT Columns to Int	16384	Change BIGINT columns to INT columns (some applications cannot handle BIGINT).
FLAG_NO_CATALOG	No Catalog	32768	Forces results from the catalog functions, such as SQLTables, to always return NULL and the driver to report that catalogs are not supported.

Flag Name	GUI Option	Constant Value	Description
FLAG_USE_MYCNF	Read Options From my.cnf	65536	Read parameters from the [client] and [odbc] groups from my.cnf.
FLAG_SAFE	Safe	131072	Add some extra safety checks.
FLAG_NO_TRANSACTIONS	Disable transactions	262144	Disable transactions.
FLAG_LOG_QUERY	Save queries to myodbc.sql	524288	Enable query logging to c:\myodbc.sql(/tmp/myodbc.sql) file. (Enabled only in debug mode.)
FLAG_NO_CACHE	Do not Cache Result (forward only cursors)	1048576	Do not cache the results locally in the driver, instead read from server (mysql_use_result()). This works only for forward-only cursors. This option is very important in dealing with large tables when you do not want the driver to cache the entire result set.
FLAG_FORWARD_CURSOR	Force Use Of Forward Only Cursors	2097152	Force the use of Forward-only cursor type. In case of applications setting the default static/dynamic cursor type, and one wants the driver to use noncache result sets, then this option ensures the forward-only cursor behavior.
FLAG_AUTO_RECONNECT	Enable auto-reconnect.	4194304	Enables auto-reconnection functionality. Do not use this option with transactions, since an auto-reconnection during a incomplete transaction may cause corruption. Note that an auto-reconnected connection will not inherit the same settings and environment as the original. This option was added in Connector/ODBC 3.51.13.
FLAG_AUTO_IS_NULL	Flag Auto Is Null	8388608	When FLAG_AUTO_IS_NULL is set, the driver does not change the default value of sql_auto_is_null [524], leaving it at 1, so you get the MySQL default, not the SQL standard behavior. When FLAG_AUTO_IS_NULL is not set, the driver changes the default value of SQL_AUTO_IS_NULL to 0 after connecting, so you get the SQL standard, not the MySQL default behavior.

Flag Name	GUI Option	Constant Value	Description
			Thus, omitting the flag disables the compatibility option and forces SQL standard behavior. See `IS NULL` [940]. This option was added in Connector/ODBC 3.51.13.
`FLAG_ZERO_DATE_TO_MIN`	Return SQL_NULL_DATA for zero date	16777216	Translates zero dates (`XXXX-00-00`) into the minimum date values supported by ODBC, `XXXX-01-01`. This resolves an issue where some statements will not work because the date returned and the minimum ODBC date value are incompatible. This option was added in Connector/ODBC 3.51.17.
`FLAG_MIN_DATE_TO_ZERO`	Bind minimal date as zero date	33554432	Translates the minimum ODBC date value (`XXXX-01-01`) to the zero date format supported by MySQL (`XXXX-00-00`). This resolves an issue where some statements will not work because the date returned and the minimum ODBC date value are incompatible. This option was added in Connector/ODBC 3.51.17.
`FLAG_MULTI_STATEMENTS`	Allow multiple statements	67108864	Enables support for batched statements. This option was added in Connector/ODBC 3.51.18.
`FLAG_COLUMN_SIZE_S32`	Limit column size to 32-bit value	134217728	Limits the column size to a signed 32-bit value to prevent problems with larger column sizes in applications that do not support them. This option is automatically enabled when working with ADO applications. This option was added in Connector/ODBC 3.51.22.
`FLAG_NO_BINARY_RESULT`	Always handle binary function results as character data	268435456	When set this option disables charset 63 for columns with an empty `org_table`. This option was added in Connector/ODBC 3.51.26.
`FLAG_DFLT_BIGINT_BIND_STR`		536870912	Causes `BIGINT` parameters to be bound as strings. Microsoft Access treats `BIGINT` as a string on linked tables. The value is read correctly, but bound as a string. This option is used

Flag Name	GUI Option	Constant Value	Description
			automatically if the driver is used by Microsoft Access.
FLAG_NO_INFORMATION_SCHEMA		1073741824	Tells catalog functions not to use INFORMATION_SCHEMA, but rather use legacy algorithms. The trade-off here is usually speed for information quality. Using INFORMATION_SCHEMA is often slow, but the information obtained is more complete.

To select multiple options, add together their values, using the numbers from the Constant Value column in the table.

Note

In MySQL Connector/ODBC 5.2, you can use the flag name directly as a parameter in the connection string, by specifying the flag name without the FLAG_ prefix. So, in addition to using the options parameter with various flags set, you can use the flags directly as parameters. For example, FIELD_LENGTH, FOUND_ROWS and DEBUG could all be used as parameters.

The following table shows some recommended option values for various configurations.

Configuration	Option Value
Microsoft Access, Visual Basic	3
Driver trace generation (Debug mode)	4
Microsoft Access (with improved DELETE queries)	35
Large tables with too many rows	2049
Sybase PowerBuilder	135168
Query log generation (Debug mode)	524288
Generate driver trace as well as query log (Debug mode)	524292
Large tables with no-cache results	3145731

Configuring a Connector/ODBC DSN on Windows

The ODBC Data Source Administrator within Windows lets you create DSNs, check driver installation and configure ODBC systems such as tracing (used for debugging) and connection pooling.

Different editions and versions of Windows store the ODBC Data Source Administrator in different locations depending on the version of Windows that you are using.

To open the ODBC Data Source Administrator in Windows Server 2003:

Tip

To identify whether a DSN was created using the 32-bit or the 64-bit driver, include the driver being used within the DSN identifier. This will help you to identify the right DSN to use with applications such as Excel that are only compatible with the 32-bit driver. For example, you might add Using32bitCODBC to the DSN identifier for the 32-bit interface and Using64bitCODBC for those using the 64-bit Connector/ODBC driver.

1. On the Start menu, choose Administrative Tools, and then click Data Sources (ODBC).

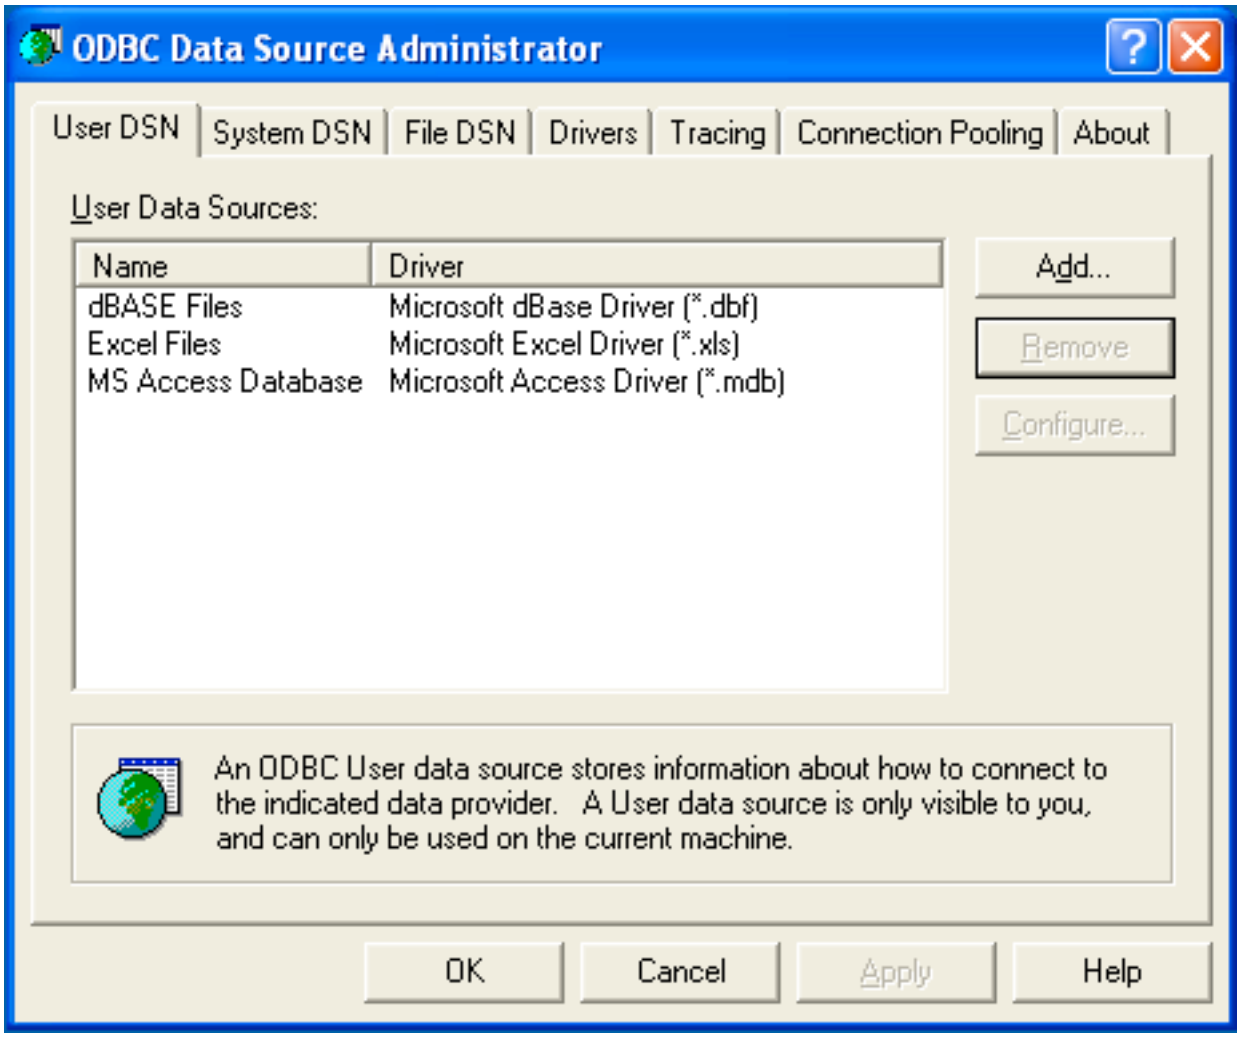
To open the ODBC Data Source Administrator in Windows 2000 Server or Windows 2000 Professional:

1. On the Start menu, choose Settings, and then click Control Panel.
2. In Control Panel, click Administrative Tools.
3. In Administrative Tools, click Data Sources (ODBC).

To open the ODBC Data Source Administrator on Windows XP:

1. On the Start menu, click Control Panel.
2. In the Control Panel when in Category View click Performance and Maintenance and then click Administrative Tools.. If you are viewing the Control Panel in Classic View, click Administrative Tools.
3. In Administrative Tools, click Data Sources (ODBC).

Irrespective of your Windows version, you should be presented the ODBC Data Source Administrator window:



Within Windows XP, you can add the Administrative Tools folder to your Start menu to make it easier to locate the ODBC Data Source Administrator. To do this:

1. Right-click the Start menu.
2. Select Properties.

3. Click Customize....
4. Select the Advanced tab.
5. Within `Start menu items`, within the `System Administrative Tools` section, select `Display on the All Programs menu`.

Within both Windows Server 2003 and Windows XP, consider permanently adding the `ODBC Data Source Administrator` to your Start menu. To do this, locate the `Data Sources (ODBC)` icon using the methods shown, then right-click on the icon and then choose Pin to Start Menu.

The interfaces for the 3.51 and 5.x versions of the Connector/ODBC driver are different, although the fields and information that you need to enter remain the same.

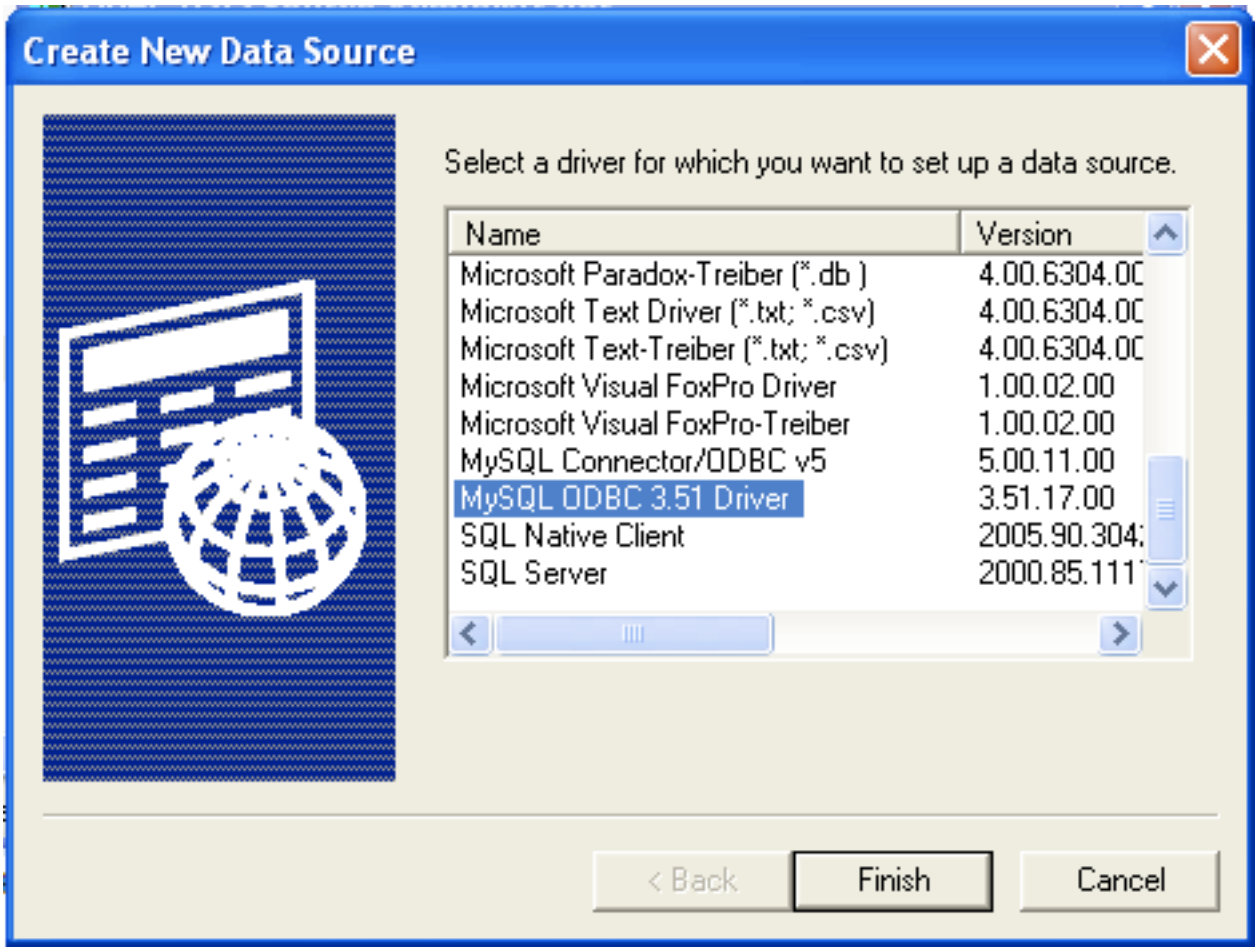
To configure a DSN using Connector/ODBC 5.2, see Configuring a Connector/ODBC 5.x DSN on Windows.

Configuring a Connector/ODBC 5.x DSN on Windows

Due to the native Unicode support within Connector/ODBC, you do not need to specify the initial character set to be used with your connection.

To add or configure a Connector/ODBC 5.x DSN on Windows, use either the command-line, or the `ODBC Data Source Administrator` GUI.

1. Open the `ODBC Data Source Administrator`.
2. To create a System DSN (which will be available to all users), select the **System DSN** tab. To create a User DSN, which will be unique only to the current user, click the Add... button.
3. Select the ODBC driver for this DSN.



Select `MySQL ODBC 5.x Driver` for the appropriate level of Connector/ODBC, then click Finish.

4. You now need to configure the specific fields for the DSN you are creating through the `Connection Parameters` dialog.

   In the **Data Source Name** box, enter the name of the data source to access. It can be any valid name that you choose.

5. In the **Description** box, enter some text to help identify the connection.

6. In the **Server** field, enter the name of the MySQL server host to access. By default, it is `localhost`.

7. In the **User** field, enter the user name to use for this connection.

8. In the **Password** field, enter the corresponding password for this connection.

9. The **Database** pop-up should automatically populate with the list of databases that the user has permissions to access.

10. To communicate over a different TCP/IP port than the default (3306), change the value of the **Port**.

11. Click OK to save the DSN.

To verify the connection using the parameters you have entered, click the Test button. If the connection could be made successfully, you will be notified with a `Success; connection was made!` dialog.

You can configure a number of options for a specific DSN by using the Details button.

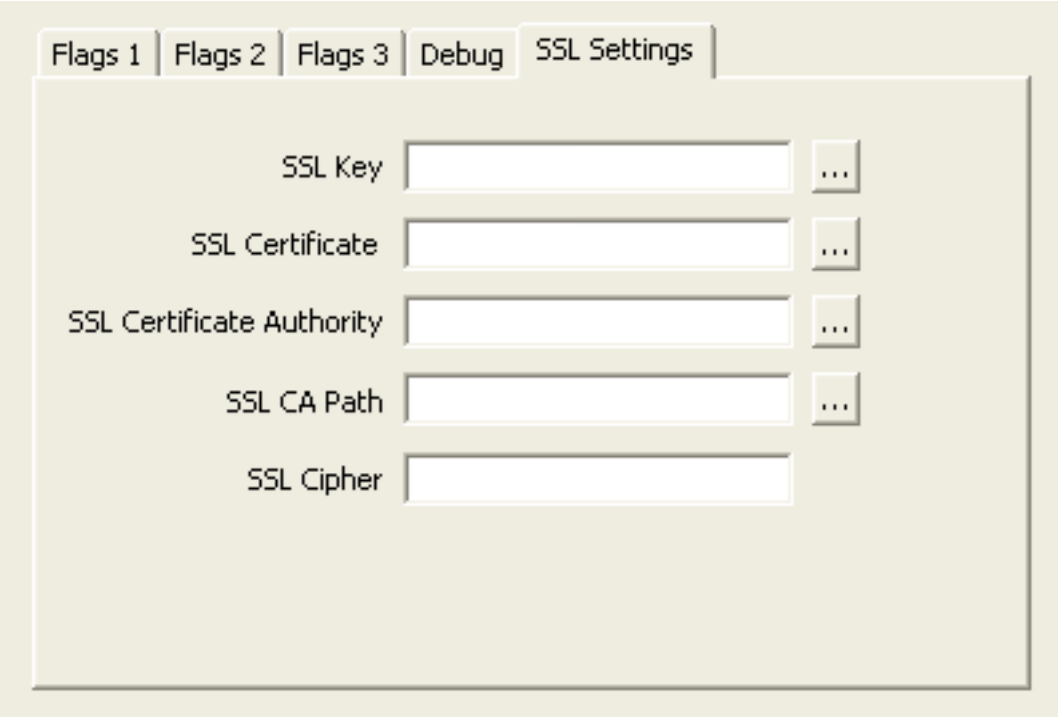
Help

The **Details** button opens a tabbed display where you set additional options:

- **Flags 1**, **Flags 2**, and **Flags 3** enable you to select the additional flags for the DSN connection. For more information on these flags, see Connector/ODBC Connection Parameters.
- **Debug** lets you turn on ODBC debugging to record the queries you execute through the DSN to the `myodbc.sql` file. For more information, see Getting an ODBC Trace File.
- **SSL Settings** configures the additional options required for using the Secure Sockets Layer (SSL) when communicating with MySQL server. Note that you must also enable SSL and configure the MySQL server with suitable certificates to communicate over SSL.



The Advanced tab lets you configure Connector/ODBC connection parameters. Refer to Connector/ODBC Connection Parameters, for information about the meaning of these options.

Configuring a Connector/ODBC 5.x DSN on Windows, Using the Command Line

Use `myodbc-installer.exe` when configuring Connector/ODBC 5.1 or later from the command-line.

Execute `myodbc-installer.exe` without arguments to view a list of available options.

Troubleshooting ODBC Connection Problems

This section answers Connector/ODBC connection-related questions.

- **While configuring a Connector/ODBC DSN, a `Could Not Load Translator or Setup Library` error occurs**

  For more information, refer to MS KnowledgeBase Article(Q260558). Also, make sure you have the latest valid `ctl3d32.dll` in your system directory.

- On Windows, the default `myodbc5w.dll` (Unicode) or `myodbc5a.dll` (ANSI) is compiled for optimal performance. To debug Connector/ODBC (for example, to enable tracing), instead use `myodbc5d.dll`. To install this file, copy `myodbc5d.dll` over the installed `myodbc5w.dll` or `myodbc5a.dll` file. Make sure to revert back to the release version of the driver DLL once you are done with the debugging, because the debug version may cause performance issues.

Configuring a Connector/ODBC DSN on Mac OS X

To configure a DSN on Mac OS X, you can either use the command-line utility (`myodbc-installer` with connector/ODBC 5.1, or `myodbc3i` with connector/OCBC 3.51), edit the `odbc.ini` file within the `Library/ODBC` directory of the user, or use the ODBC Administrator GUI. If you have Mac OS X 10.2 or earlier, refer to Configuring a Connector/ODBC DSN on Unix. Select whether to create a User DSN or a System DSN. When adding a System DSN, you might need to authenticate with the system. Click the padlock and enter a user and password with administrator privileges.

For correct operation of ODBC Administrator, ensure that the `/Library/ODBC/odbc.ini` file used to set up ODBC connectivity and DSNs are writable by the `admin` group. If this file is not writable by this group, then the ODBC Administrator may fail, or may appear to work but not generate the correct entry.

Warning

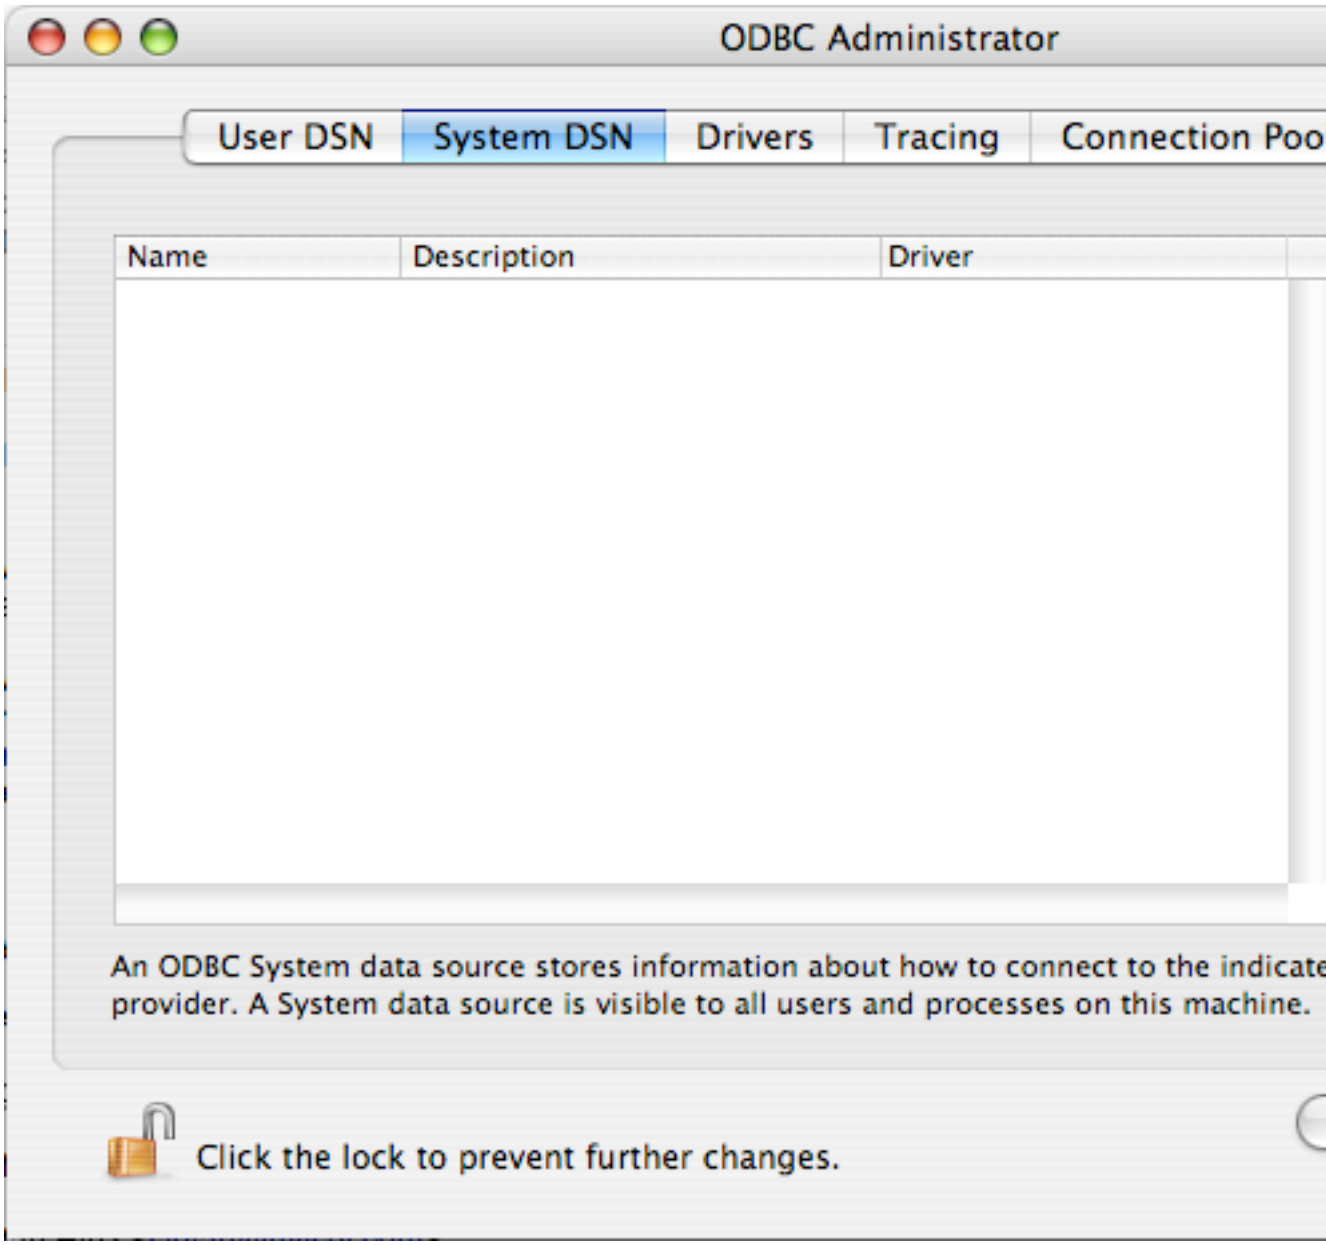
There are known issues with the OS X ODBC Administrator and Connector/ODBC that may prevent you from creating a DSN using this method. In this case, use the command line or edit the `odbc.ini` file directly. Note that existing DSNs or those that you create using the `myodbc3i` or `myodbc-installer` tool can still be checked and edited using ODBC Administrator.

To create a DSN using the `myodbc3i` utility, you need only specify the DSN type and the DSN connection string. For example:

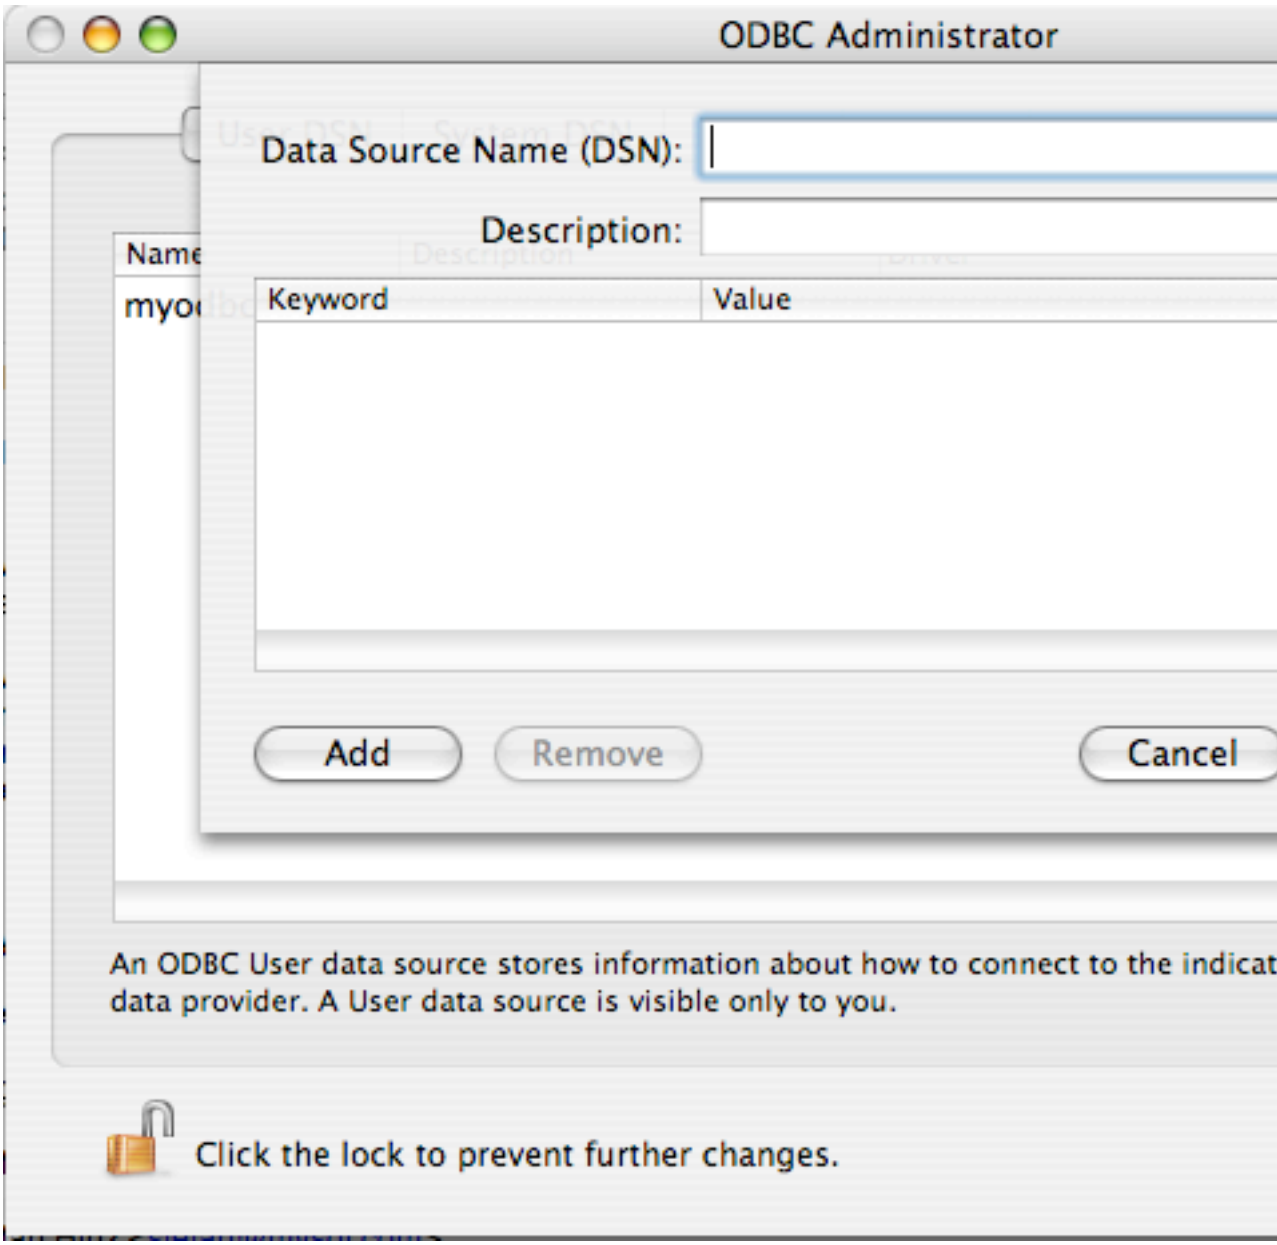
```
shell> myodbc3i -a -s -t"DSN=mydb;DRIVER=MySQL ODBC 3.51 Driver;SERVER=mysql;USER=username;PASSWORD=pas
```

To use ODBC Administrator:

1. Open the ODBC Administrator from the `Utilities` folder in the `Applications` folder.



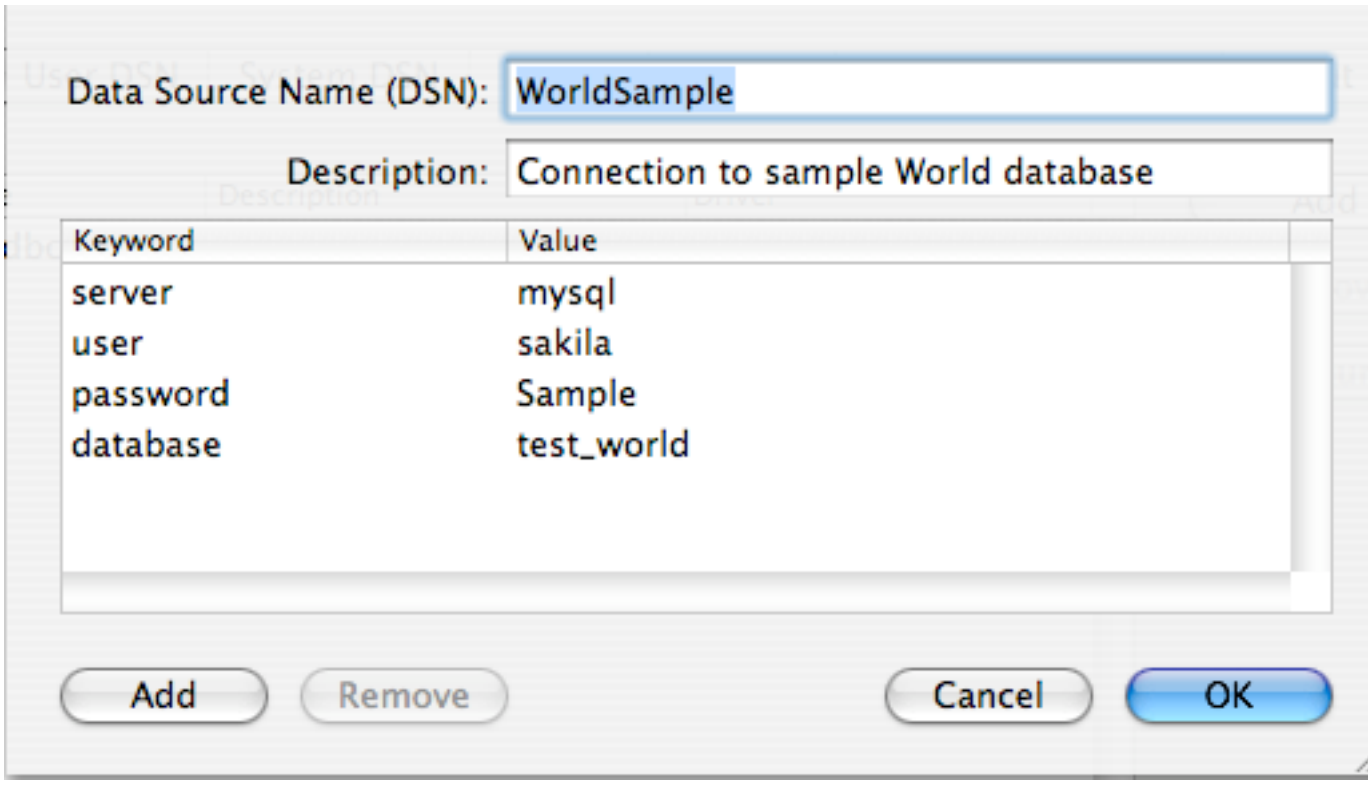
2. On the User DSN or System DSN panel, click Add.
3. Select the Connector/ODBC driver and click OK.
4. You will be presented with the `Data Source Name` dialog. Enter the `Data Source Name` and an optional `Description` for the DSN.



5. Click Add to add a new keyword/value pair to the panel. Configure at least four pairs to specify the `server`, `username`, `password` and `database` connection parameters. See Connector/ODBC Connection Parameters.

6. Click OK to add the DSN to the list of configured data source names.

A completed DSN configuration may look like this:



You can configure other ODBC options in your DSN by adding further keyword/value pairs and setting the corresponding values. See Connector/ODBC Connection Parameters.

Configuring a Connector/ODBC DSN on Unix

On `Unix`, you configure DSN entries directly in the `odbc.ini` file. Here is a typical `odbc.ini` file that configures `myodbc3` as the DSN name for Connector/ODBC 3.51:

```
;
;  odbc.ini configuration for Connector/ODBC and Connector/ODBC 3.51 drivers
;

[ODBC Data Sources]
myodbc3     = MyODBC 3.51 Driver DSN

[myodbc3]
Driver       = /usr/local/lib/libmyodbc3.so
Description  = Connector/ODBC 3.51 Driver DSN
SERVER       = localhost
PORT         =
USER         = root
Password     =
Database     = test
OPTION       = 3
SOCKET       =

[Default]
Driver       = /usr/local/lib/libmyodbc3.so
Description  = Connector/ODBC 3.51 Driver DSN
SERVER       = localhost
PORT         =
USER         = root
Password     =
Database     = test
OPTION       = 3
SOCKET       =
```

Refer to the Connector/ODBC Connection Parameters, for the list of connection parameters that can be supplied.

Note

If you are using `unixODBC`, you can use the following tools to set up the DSN:

- `ODBCConfig` GUI tool (HOWTO: ODBCConfig)
- `odbcinst`

In some cases when using `unixODBC`, you might get this error:

```
Data source name not found and no default driver specified
```

If this happens, make sure the `ODBCINI` and `ODBCSYSINI` environment variables are pointing to the right `odbc.ini` file. For example, if your `odbc.ini` file is located in `/usr/local/etc`, set the environment variables like this:

```
export ODBCINI=/usr/local/etc/odbc.ini
export ODBCSYSINI=/usr/local/etc
```

Connecting Without a Predefined DSN

You can connect to the MySQL server using `SQLDriverConnect`, by specifying the `DRIVER` name field. Here are the connection strings for Connector/ODBC using DSN-Less connections:

For Connector/ODBC 3.51:

```
ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};\
                    SERVER=localhost;\
                    DATABASE=test;\
                    USER=venu;\
                    PASSWORD=venu;\
                    OPTION=3;"
```

If your programming language converts backslash followed by whitespace to a space, it is preferable to specify the connection string as a single long string, or to use a concatenation of multiple strings that does not add spaces in between. For example:

```
ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};"
                    "SERVER=localhost;"
                    "DATABASE=test;"
                    "USER=venu;"
                    "PASSWORD=venu;"
                    "OPTION=3;"
```

Note. On Mac OS X, you might need to specify the full path to the Connector/ODBC driver library.

Refer to Connector/ODBC Connection Parameters for the list of connection parameters that can be supplied.

ODBC Connection Pooling

Connection pooling enables the ODBC driver to re-use existing connections to a given database from a pool of connections, instead of opening a new connection each time the database is accessed. By enabling connection pooling you can improve the overall performance of your application by lowering the time taken to open a connection to a database in the connection pool.

For more information about connection pooling: http://support.microsoft.com/default.aspx?scid=kb;EN-US;q169470.

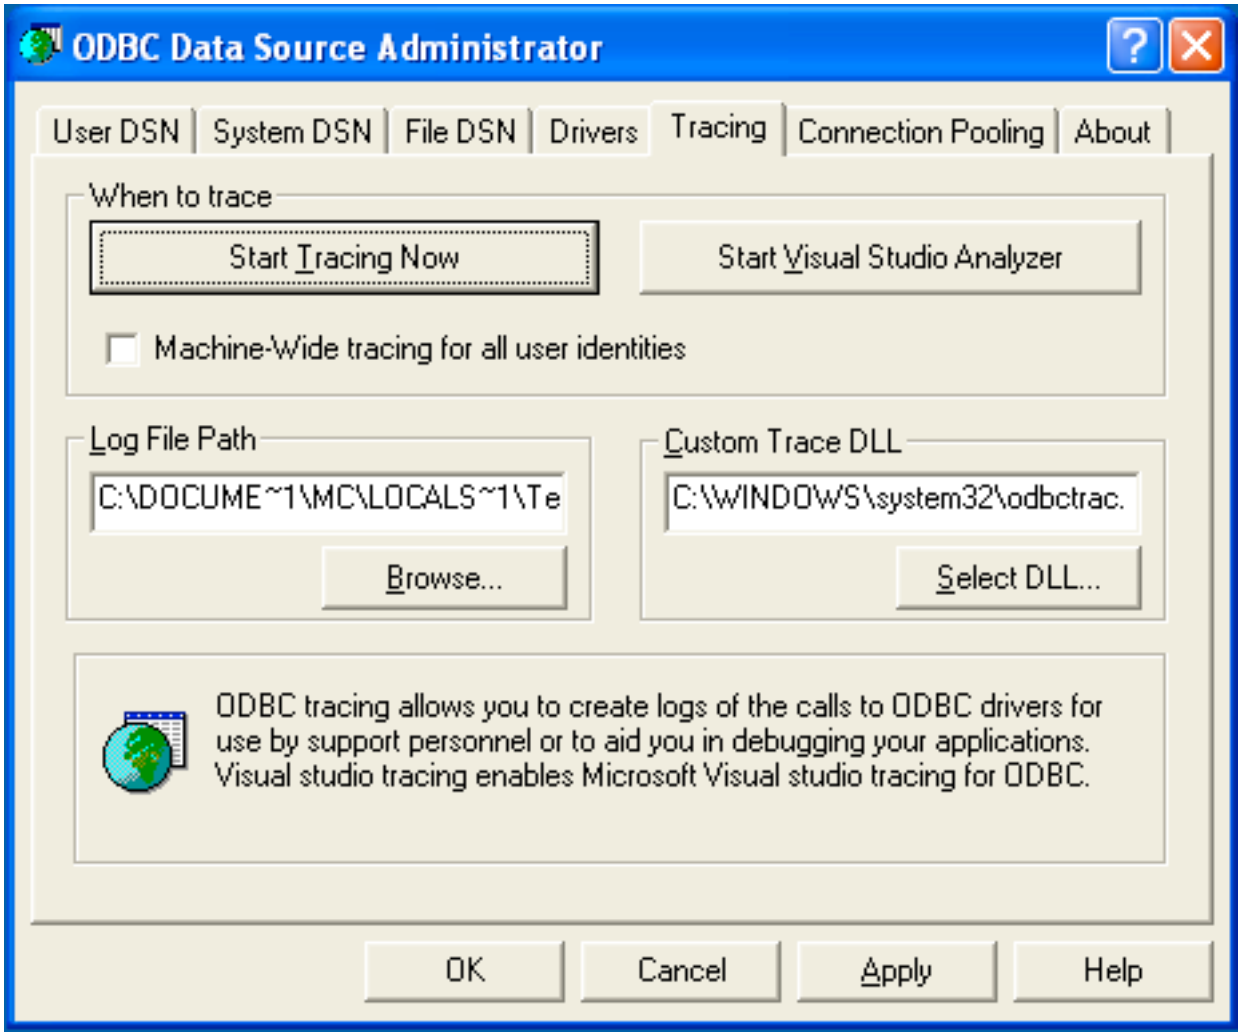
Getting an ODBC Trace File

If you encounter difficulties or problems with Connector/ODBC, start by making a log file from the `ODBC Manager` and Connector/ODBC. This is called *tracing*, and is enabled through the ODBC Manager. The procedure for this differs for Windows, Mac OS X and Unix.

Enabling ODBC Tracing on Windows

To enable the trace option on Windows:

1. The `Tracing` tab of the ODBC Data Source Administrator dialog box lets you configure the way ODBC function calls are traced.



2. When you activate tracing from the `Tracing` tab, the `Driver Manager` logs all ODBC function calls for all subsequently run applications.

3. ODBC function calls from applications running before tracing is activated are not logged. ODBC function calls are recorded in a log file you specify.

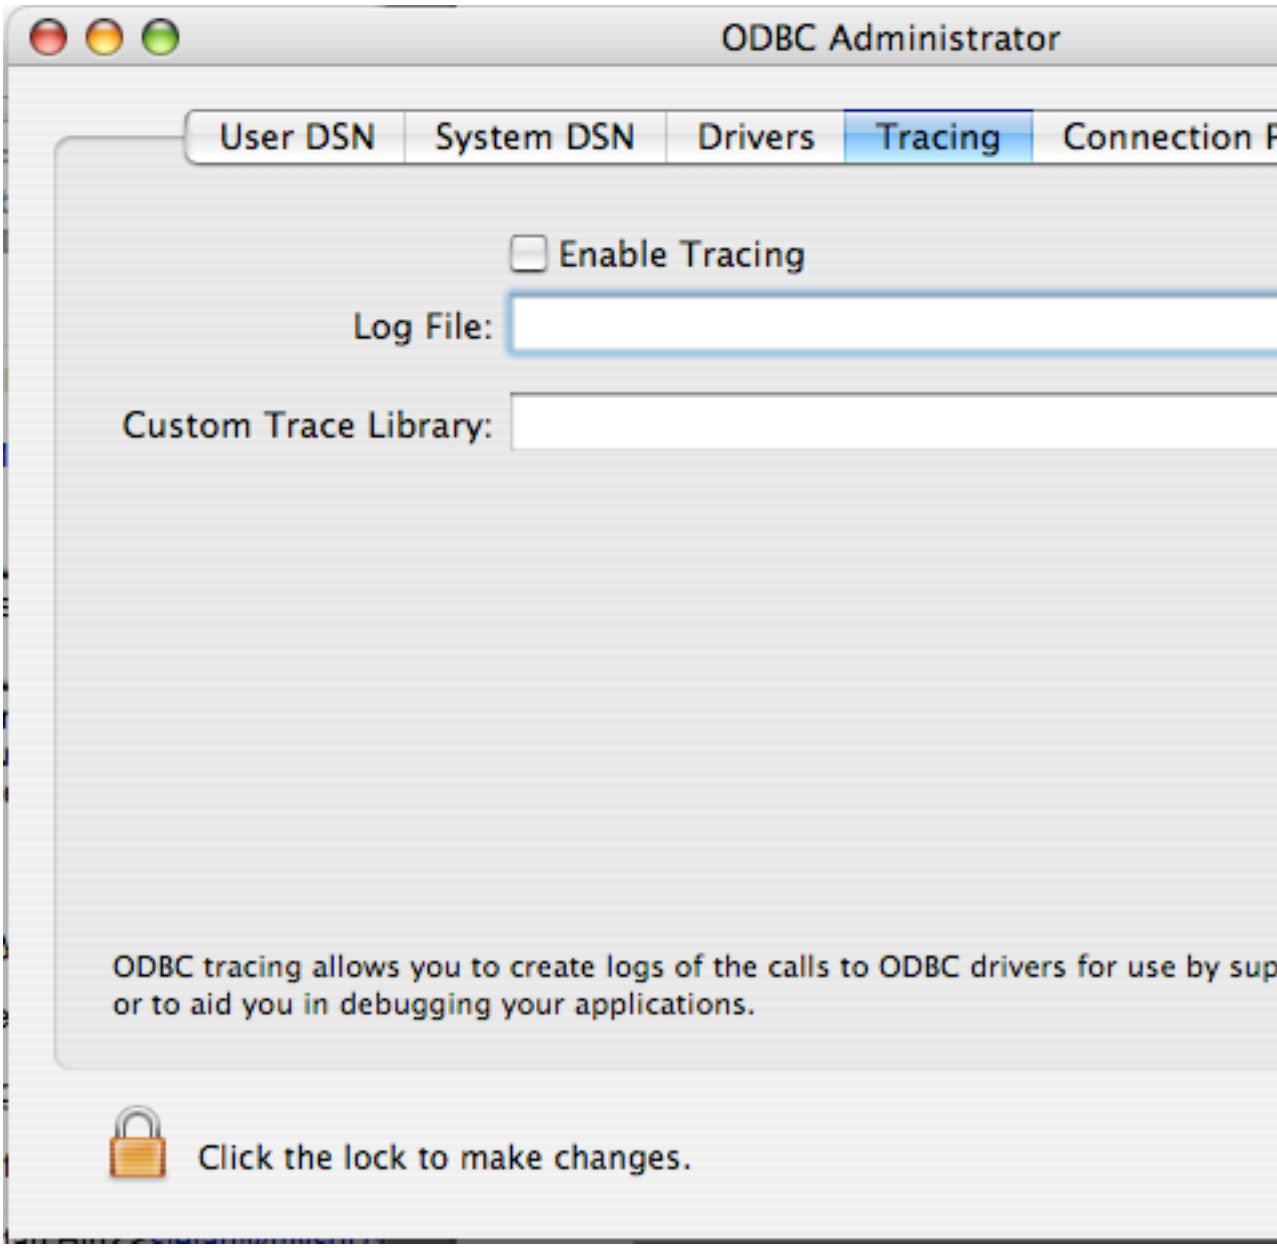
4. Tracing ceases only after you click `Stop Tracing Now`. Remember that while tracing is on, the log file continues to increase in size and that tracing affects the performance of all your ODBC applications.

Enabling ODBC Tracing on Mac OS X

To enable the trace option on Mac OS X 10.3 or later, use the `Tracing` tab within ODBC Administrator .

1. Open the ODBC Administrator.

2. Select the `Tracing` tab.



3. Select the `Enable Tracing` check box.
4. Enter the location to save the Tracing log. To append information to an existing log file, click the Choose... button.

Enabling ODBC Tracing on Unix

To enable the trace option on Mac OS X 10.2 (or earlier) or Unix, add the `trace` option to the ODBC configuration:

1. On Unix, explicitly set the `Trace` option in the `ODBC.INI` file.

   Set the tracing `ON` or `OFF` by using `TraceFile` and `Trace` parameters in `odbc.ini` as shown below:

```
TraceFile  = /tmp/odbc.trace
Trace      = 1
```

`TraceFile` specifies the name and full path of the trace file and `Trace` is set to `ON` or `OFF`. You can also use `1` or `YES` for `ON` and `0` or `NO` for `OFF`. If you are using `ODBCConfig` from `unixODBC`, then follow the instructions for tracing `unixODBC` calls at HOWTO-ODBCConfig.

Enabling a Connector/ODBC Log

To generate a Connector/ODBC log, do the following:

1. Within Windows, enable the `Trace Connector/ODBC` option flag in the Connector/ODBC connect/configure screen. The log is written to file `C:\myodbc.log`. If the trace option is not remembered when you are going back to the above screen, it means that you are not using the `myodbcd.dll` driver, see Troubleshooting ODBC Connection Problems.

   On Mac OS X, Unix, or if you are using a DSN-less connection, either supply `OPTION=4` in the connection string, or set the corresponding keyword/value pair in the DSN.

2. Start your application and try to get it to fail. Then check the Connector/ODBC trace file to find out what could be wrong.

If you need help determining what is wrong, see Connector/ODBC Community Support.

Connector/ODBC Examples

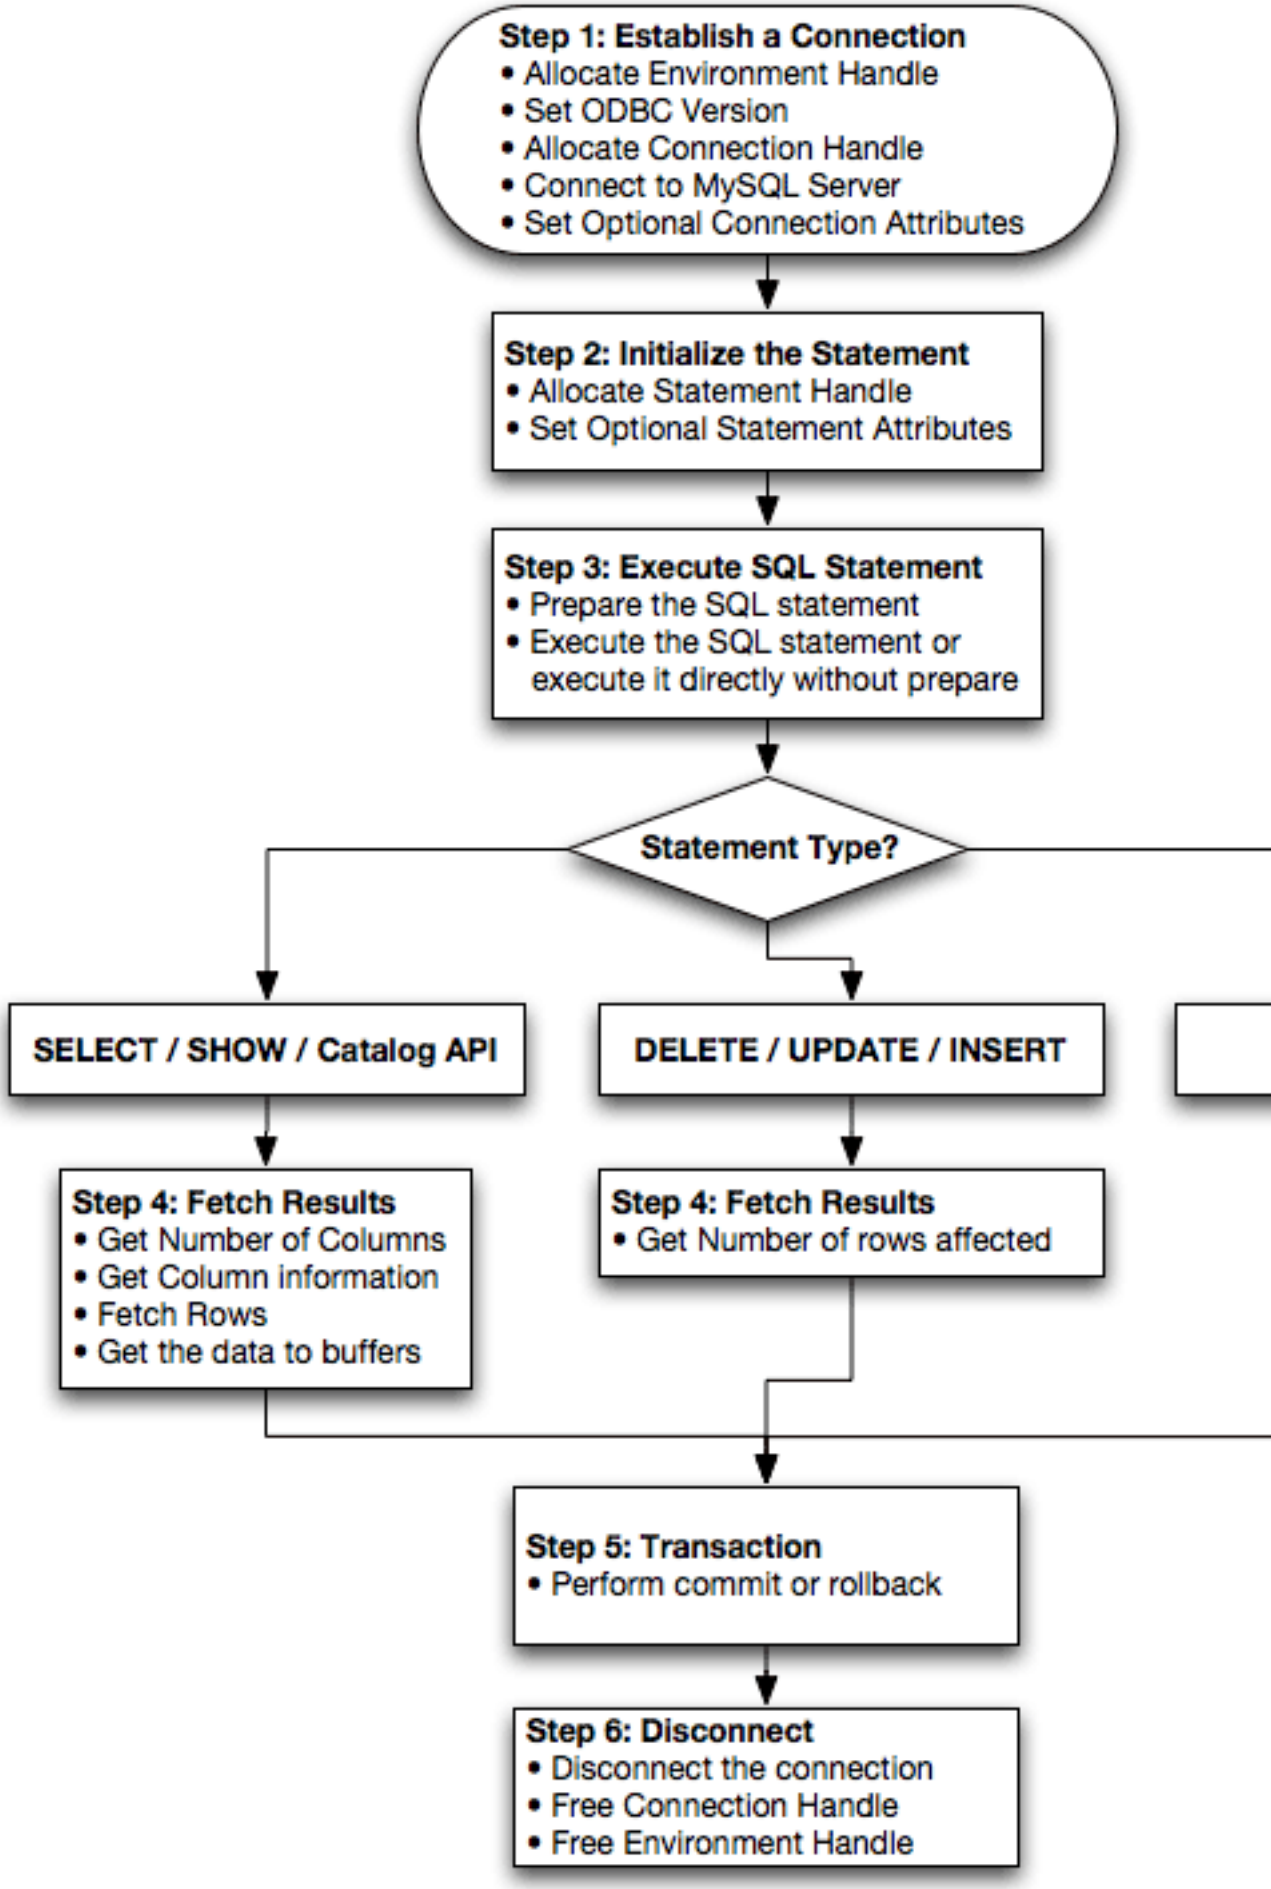
Once you have configured a DSN to provide access to a database, how you access and use that connection is dependent on the application or programming language. As ODBC is a standardized interface, any application or language that supports ODBC can use the DSN and connect to the configured database.

Basic Connector/ODBC Application Steps

Interacting with a MySQL server from an applications using the Connector/ODBC typically involves the following operations:

- Configure the Connector/ODBC DSN.
- Connect to MySQL server.
- Initialization operations.
- Execute SQL statements.
- Retrieve results.
- Perform transactions.
- Disconnect from the server.

Most applications use some variation of these steps. The basic application steps are shown in the following diagram:



Step 1: Establish a Connection
• Allocate Environment Handle
• Set ODBC Version
• Allocate Connection Handle
• Connect to MySQL Server
• Set Optional Connection Attributes
Step 2: Initialize the Statement
• Allocate Statement Handle
• Set Optional Statement Attributes
Step 3: Execute SQL Statement
• Prepare the SQL statement
• Execute the SQL statement or execute it directly without prepare
Statement Type?
SELECT / SHOW / Catalog API
DELETE / UPDATE / INSERT
Step 4: Fetch Results
• Get Number of Columns
• Get Column information
• Fetch Rows
• Get the data to buffers
Step 4: Fetch Results
• Get Number of rows affected
Step 5: Transaction
• Perform commit or rollback
Step 6: Disconnect
• Disconnect the connection
• Free Connection Handle
• Free Environment Handle

Step-by-step Guide to Connecting to a MySQL Database through Connector/ODBC

A typical situation where you would install Connector/ODBC is to access a database on a Linux or Unix host from a Windows machine.

As an example of the process required to set up access between two machines, the steps below take you through the basic steps. These instructions assume that you connect to system ALPHA from system BETA with a user name and password of `myuser` and `mypassword`.

On system ALPHA (the MySQL server) follow these steps:

1. Start the MySQL server.
2. Use `GRANT` to set up an account with a user name of `myuser` that can connect from system BETA using a password of `myuser` to the database `test`:

   ```
   GRANT ALL ON test.* to 'myuser'@'BETA' IDENTIFIED BY 'mypassword';
   ```

   For more information about MySQL privileges, refer to MySQL User Account Management.

On system BETA (the Connector/ODBC client), follow these steps:

1. Configure a Connector/ODBC DSN using parameters that match the server, database and authentication information that you have just configured on system ALPHA.

Parameter	Value	Comment
DSN	remote_test	A name to identify the connection.
SERVER	ALPHA	The address of the remote server.
DATABASE	test	The name of the default database.
USER	myuser	The user name configured for access to this database.
PASSWORD	mypassword	The password for `myuser`.

2. Using an ODBC-capable application, such as Microsoft Office, connect to the MySQL server using the DSN you have just created. If the connection fails, use tracing to examine the connection process. See Getting an ODBC Trace File, for more information.

Connector/ODBC and Third-Party ODBC Tools

Once you have configured your Connector/ODBC DSN, you can access your MySQL database through any application that supports the ODBC interface, including programming languages and third-party applications. This section contains guides and help on using Connector/ODBC with various ODBC-compatible tools and applications, including Microsoft Word, Microsoft Excel and Adobe/Macromedia ColdFusion.

Connector/ODBC has been tested with the following applications.

Publisher	Application	Notes
Adobe	ColdFusion	Formerly Macromedia ColdFusion
Borland	C++ Builder	
	Builder 4	
	Delphi	
Business Objects	Crystal Reports	
Claris	Filemaker Pro	
Corel	Paradox	

Publisher	Application	Notes
Computer Associates	Visual Objects	Also known as CAVO
	AllFusion ERwin Data Modeler	
Gupta	Team Developer	Previously known as Centura Team Developer; Gupta SQL/Windows
Gensym	G2-ODBC Bridge	
Inline	iHTML	
Lotus	Notes	Versions 4.5 and 4.6
Microsoft	Access	
	Excel	
	Visio Enterprise	
	Visual C++	
	Visual Basic	
	ODBC.NET	Using C#, Visual Basic, C++
	FoxPro	
	Visual Interdev	
OpenOffice.org	OpenOffice.org	
Perl	DBD::ODBC	
Pervasive Software	DataJunction	
Sambar Technologies	Sambar Server	
SPSS	SPSS	
SoftVelocity	Clarion	
SQLExpress	SQLExpress for Xbase++	
Sun	StarOffice	
SunSystems	Vision	
Sybase	PowerBuilder	
	PowerDesigner	
theKompany.com	Data Architect	

If you know of any other applications that work with Connector/ODBC, please send mail to <myodbc@lists.mysql.com> about them.

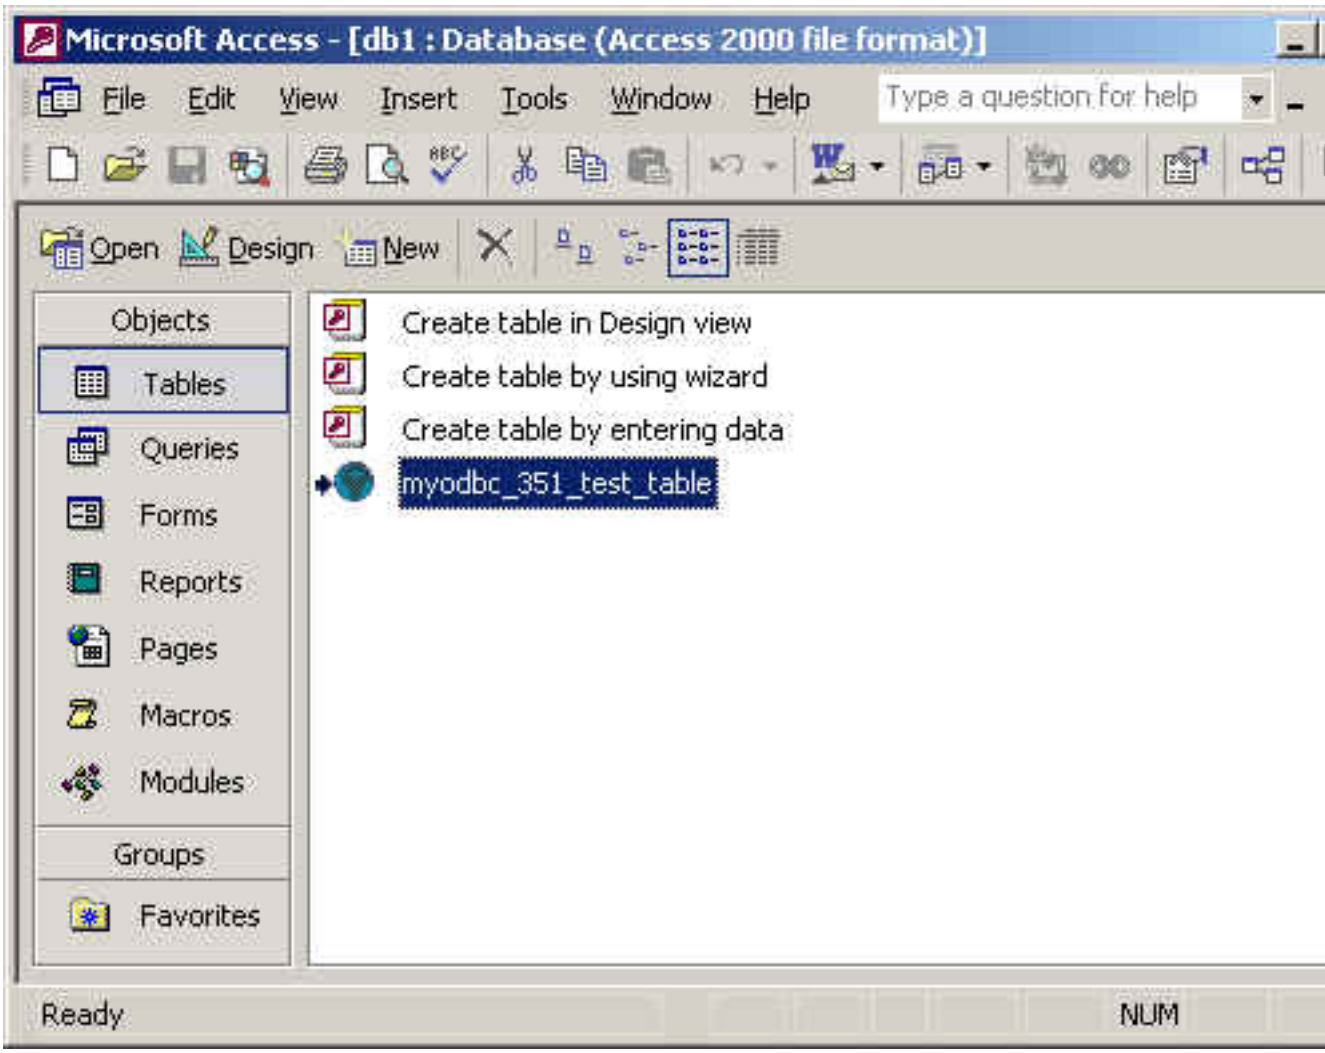
Using Connector/ODBC with Microsoft Access

You can use MySQL database with Microsoft Access using Connector/ODBC. The MySQL database can be used as an import source, an export source, or as a linked table for direct use within an Access application, so you can use Access as the front-end interface to a MySQL database.

Exporting Access Data to MySQL

To export a table of data from an Access database to MySQL, follow these instructions:

1. When you open an Access database or an Access project, a Database window appears. It displays shortcuts for creating new database objects and opening existing objects.



2. Click the name of the `table` or `query` to export, and then in the `File` menu, select `Export`.

3. In the `Export Object Type` *`Object name`* `To` dialog box, in the `Save As Type` box, select `ODBC Databases ()` as shown here:

4. In the `Export` dialog box, enter a name for the file (or use the suggested name), and then select `OK`.

5. The Select Data Source dialog box is displayed; it lists the defined data sources for any ODBC drivers installed on your computer. Click either the File Data Source or Machine Data Source tab, and then double-click the Connector/ODBC or Connector/ODBC 3.51 data source to export to. To define a new data source for Connector/ODBC, please Configuring a Connector/ODBC DSN on Windows.

Note

Ensure that the information that you are exporting to the MySQL table is valid for the corresponding MySQL data types. Values that are outside of the supported range of the MySQL data type but valid within Access may trigger an “overflow” error during the export.

Microsoft Access connects to the MySQL Server through this data source and exports new tables and or data.

Importing MySQL Data to Access

To import a table or tables from MySQL to Access, follow these instructions:

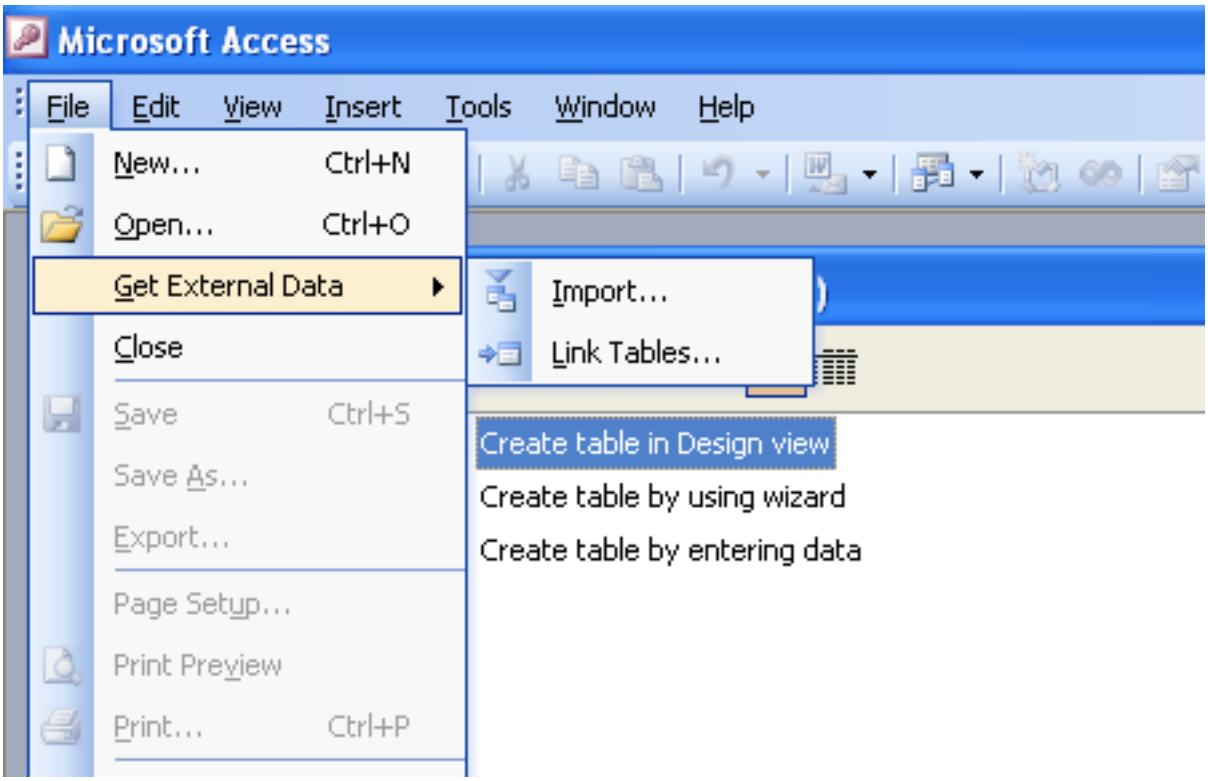
1. Open a database, or switch to the Database window for the open database.
2. To import tables, on the `File` menu, point to `Get External Data`, and then click `Import`.
3. In the `Import` dialog box, in the Files Of Type box, select **ODBC Databases ()**. The Select Data Source dialog box lists the defined data sources **The Select Data Source** dialog box is displayed; it lists the defined data source names.
4. If the ODBC data source that you selected requires you to log on, enter your login ID and password (additional information might also be required), and then click `OK`.
5. Microsoft Access connects to the MySQL server through `ODBC data source` and displays the list of tables that you can `import`.
6. Click each table to `import`, and then click `OK`.

Using Microsoft Access as a Front-end to MySQL

You can use Microsoft Access as a front end to a MySQL database by linking tables within your Microsoft Access database to tables that exist within your MySQL database. When a query is requested on a table within Access, ODBC is used to execute the queries on the MySQL database instead.

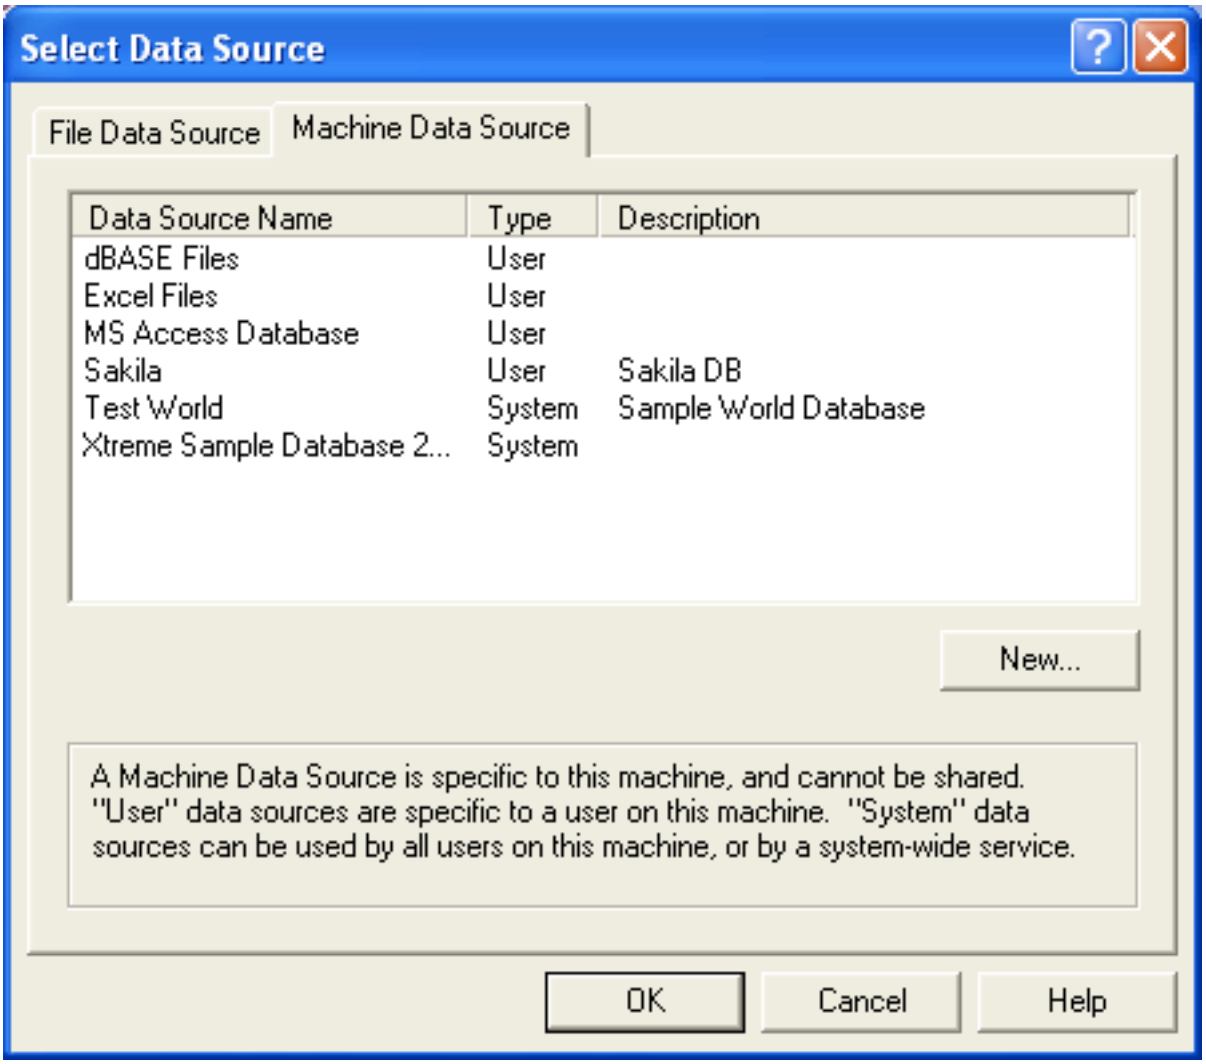
To create a linked table:

1. Open the Access database that you want to link to MySQL.
2. From the File, choose Get External Data->Link Tables.

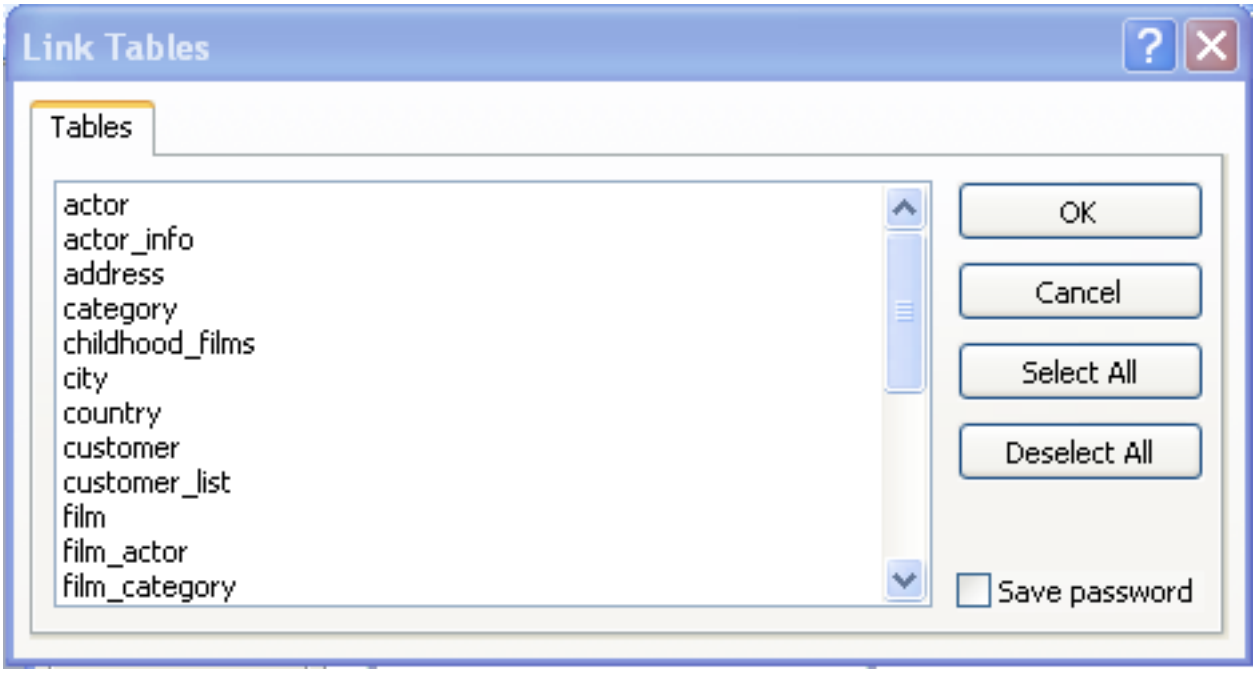


3. From the browser, choose **ODBC Databases ()** from the **Files of type** pop-up.

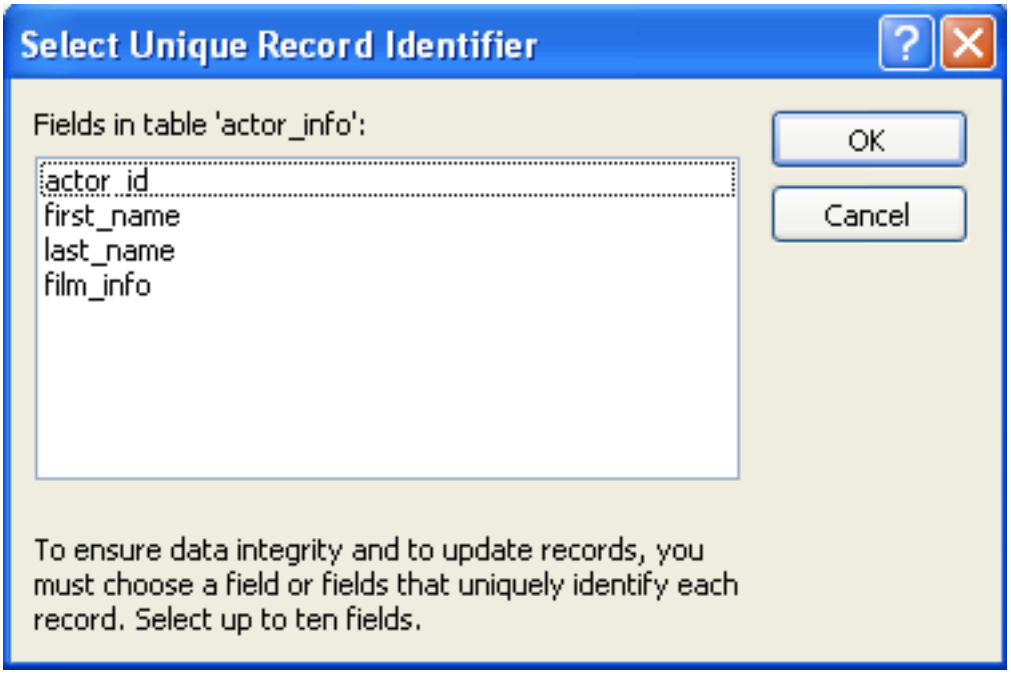
4. In the **Select Data Source** window, choose an existing DSN, either from a **File Data Source** or **Machine Data Source**.You can also create a new DSN using the New... button. For more information on creating a DSN see Configuring a Connector/ODBC DSN on Windows.



5. In the **Link Tables** dialog, select one or more tables from the MySQL database. A link will be created to each table that you select from this list.



6. If Microsoft Access is unable to determine the unique record identifier for a table automatically then it may ask you to confirm the column, or combination of columns, to be used to uniquely identify each row from the source table. Select the columns to use and click OK.



Once the process has been completed, you can now build interfaces and queries to the linked tables just as you would for any Access database.

Use the following procedure to view or to refresh links when the structure or location of a linked table has changed. The Linked Table Manager lists the paths to all currently linked tables.

To view or refresh links:

1. Open the database that contains links to MySQL tables.
2. On the `Tools` menu, point to `Add-ins` (`Database Utilities` in Access 2000 or newer), and then click `Linked Table Manager`.
3. Select the check box for the tables whose links you want to refresh.
4. Click OK to refresh the links.

Microsoft Access confirms a successful refresh or, if the table wasn't found, displays the `Select New Location of` <table name> dialog box in which you can specify its the table's new location. If several selected tables have moved to the new location that you specify, the Linked Table Manager searches that location for all selected tables, and updates all links in one step.

To change the path for a set of linked tables:

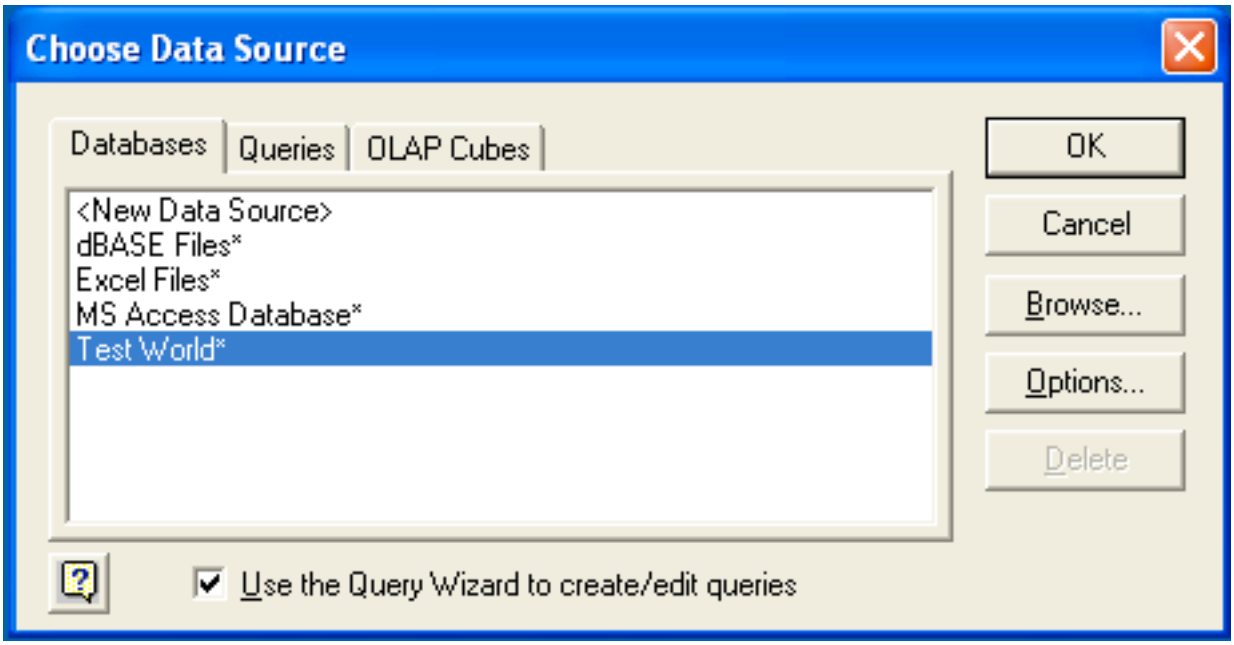
1. Open the database that contains links to tables.
2. On the `Tools` menu, point to `Add-ins` (`Database Utilities` in Access 2000 or newer), and then click `Linked Table Manager`.
3. Select the `Always Prompt For A New Location` check box.
4. Select the check box for the tables whose links you want to change, and then click `OK`.
5. In the `Select New Location of` <table name> dialog box, specify the new location, click `Open`, and then click `OK`.

Using Connector/ODBC with Microsoft Word or Excel

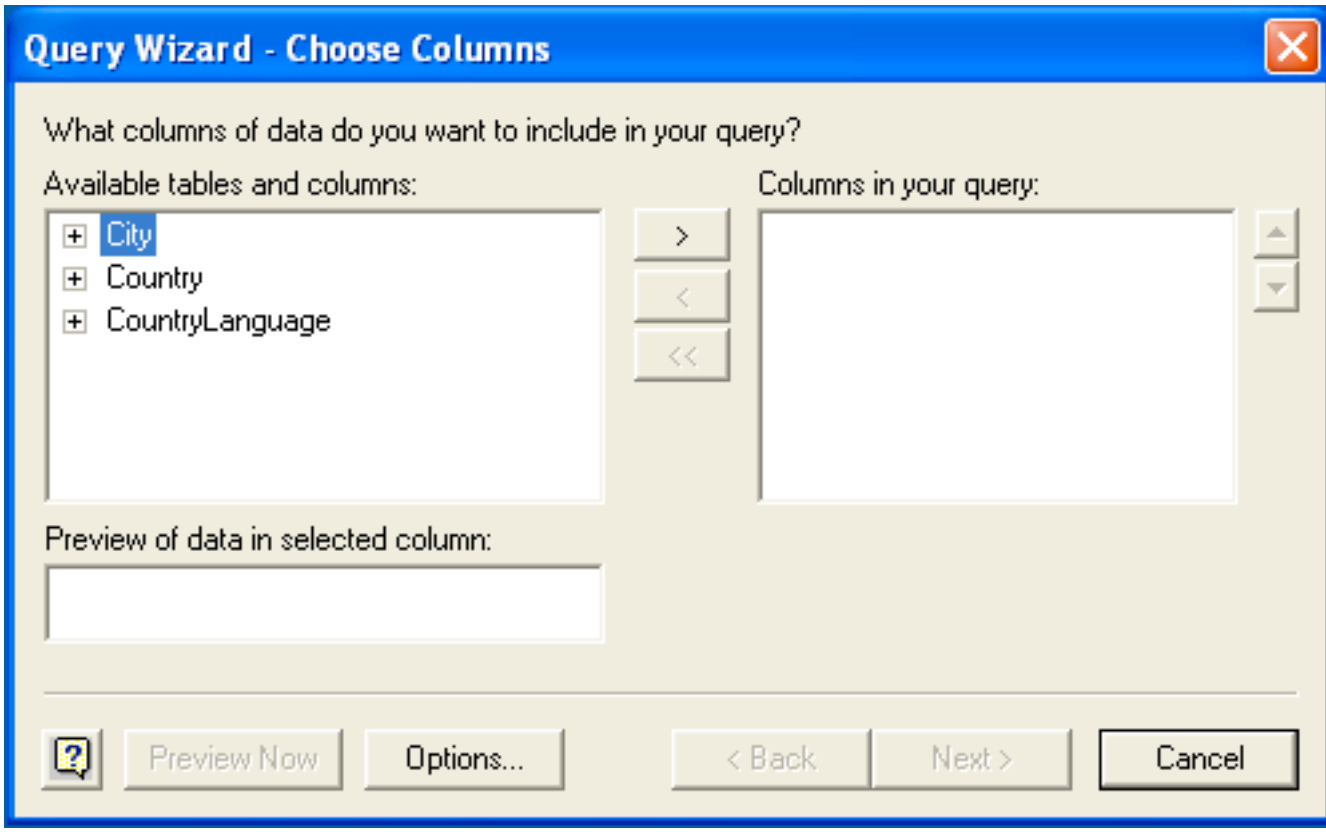
You can use Microsoft Word and Microsoft Excel to access information from a MySQL database using Connector/ODBC. Within Microsoft Word, this facility is most useful when importing data for mailmerge, or for tables and data to be included in reports. Within Microsoft Excel, you can execute queries on your MySQL server and import the data directly into an Excel Worksheet, presenting the data as a series of rows and columns.

With both applications, data is accessed and imported into the application using Microsoft Query, which lets you execute a query though an ODBC source. You use Microsoft Query to build the SQL statement to be executed, selecting the tables, fields, selection criteria and sort order. For example, to insert information from a table in the World test database into an Excel spreadsheet, using the DSN samples shown in Configuring Connector/ODBC:

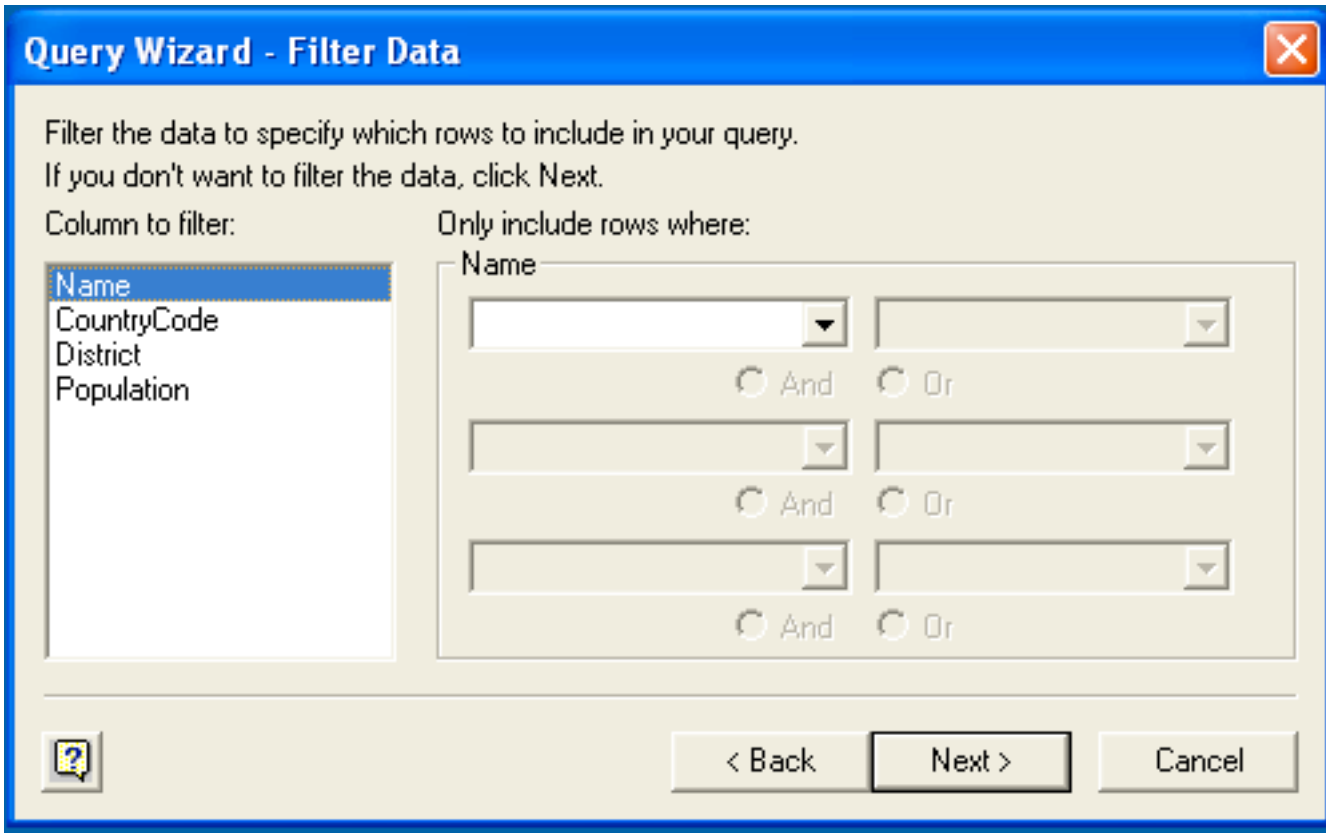
1. Create a new Worksheet.
2. From the `Data` menu, choose `Import External Data`, and then select `New Database Query`.
3. Microsoft Query will start. First, you need to choose the data source, by selecting an existing Data Source Name.



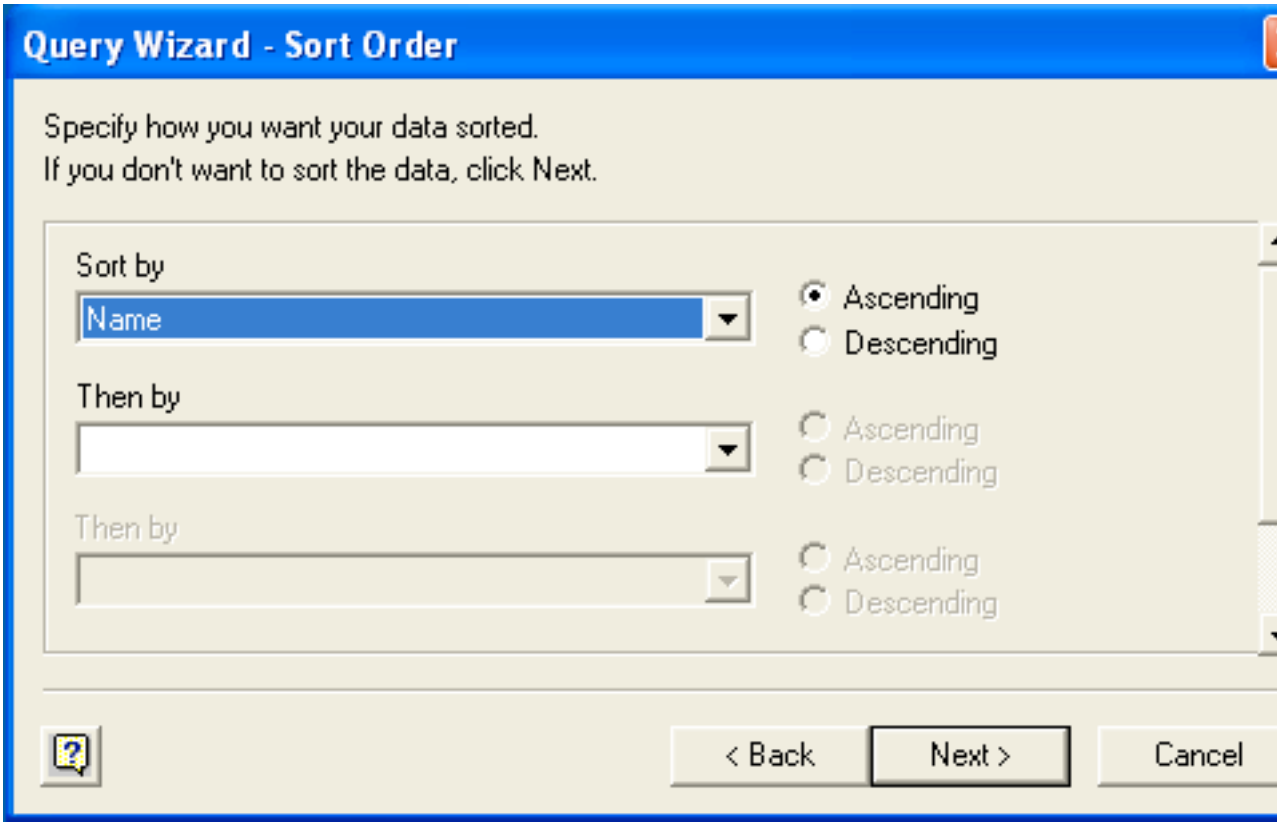
4. Within the `Query Wizard`, choose the columns to import. The list of tables available to the user configured through the DSN is shown on the left, the columns that will be added to your query are shown on the right. The columns you choose are equivalent to those in the first section of a `SELECT` query. Click Next to continue.



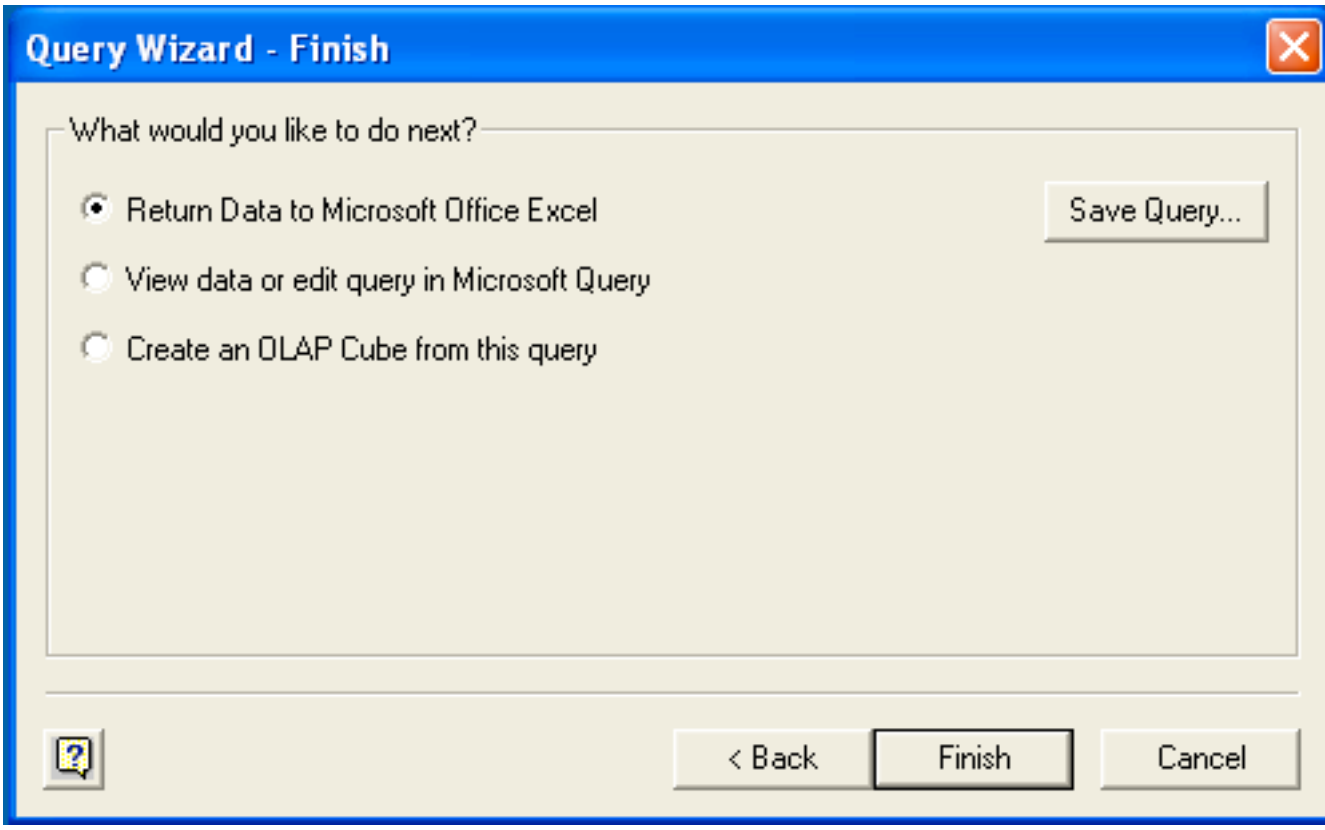
5. You can filter rows from the query (the equivalent of a `WHERE` clause) using the `Filter Data` dialog. Click Next to continue.



6. Select an (optional) sort order for the data. This is equivalent to using a `ORDER BY` clause in your SQL query. You can select up to three fields for sorting the information returned by the query. Click Next to continue.



7. Select the destination for your query. You can select to return the data Microsoft Excel, where you can choose a worksheet and cell where the data will be inserted; you can continue to view the query and results within Microsoft Query, where you can edit the SQL query and further filter and sort the information returned; or you can create an OLAP Cube from the query, which can then be used directly within Microsoft Excel. Click Finish.



The same process can be used to import data into a Word document, where the data will be inserted as a table. This can be used for mail merge purposes (where the field data is read from a Word table), or where you want to include data and reports within a report or other document.

Using Connector/ODBC with Crystal Reports

Crystal Reports can use an ODBC DSN to connect to a database from which you to extract data and information for reporting purposes.

Note

There is a known issue with certain versions of Crystal Reports where the application is unable to open and browse tables and fields through an ODBC connection. Before using Crystal Reports with MySQL, please ensure that you have update to the latest version, including any outstanding service packs and hotfixes. For more information on this issue, see the Business) Objects Knowledgebase for more information.

For example, to create a simple crosstab report within Crystal Reports XI, follow these steps:

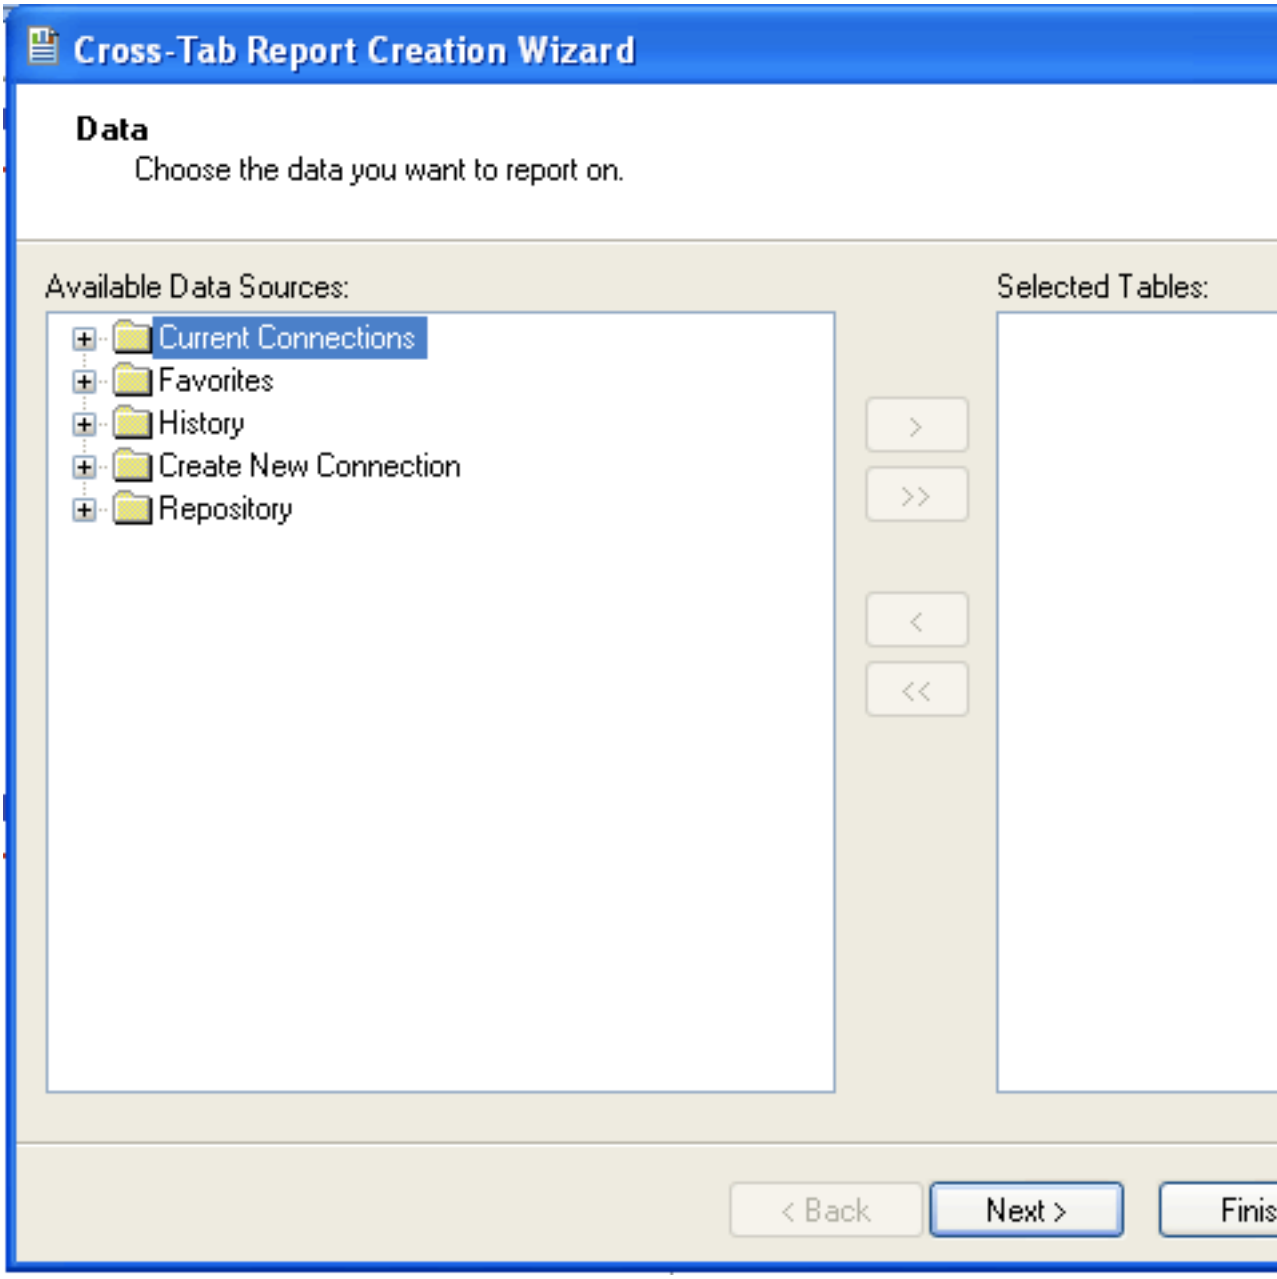
1. Create a DSN using the `Data Sources (ODBC)` tool. You can either specify a complete database, including user name and password, or you can build a basic DSN and use Crystal Reports to set the user name and password.

   For the purposes of this example, a DSN that provides a connection to an instance of the MySQL Sakila sample database has been created.

2. Open Crystal Reports and create a new project, or an open an existing reporting project into which you want to insert data from your MySQL data source.

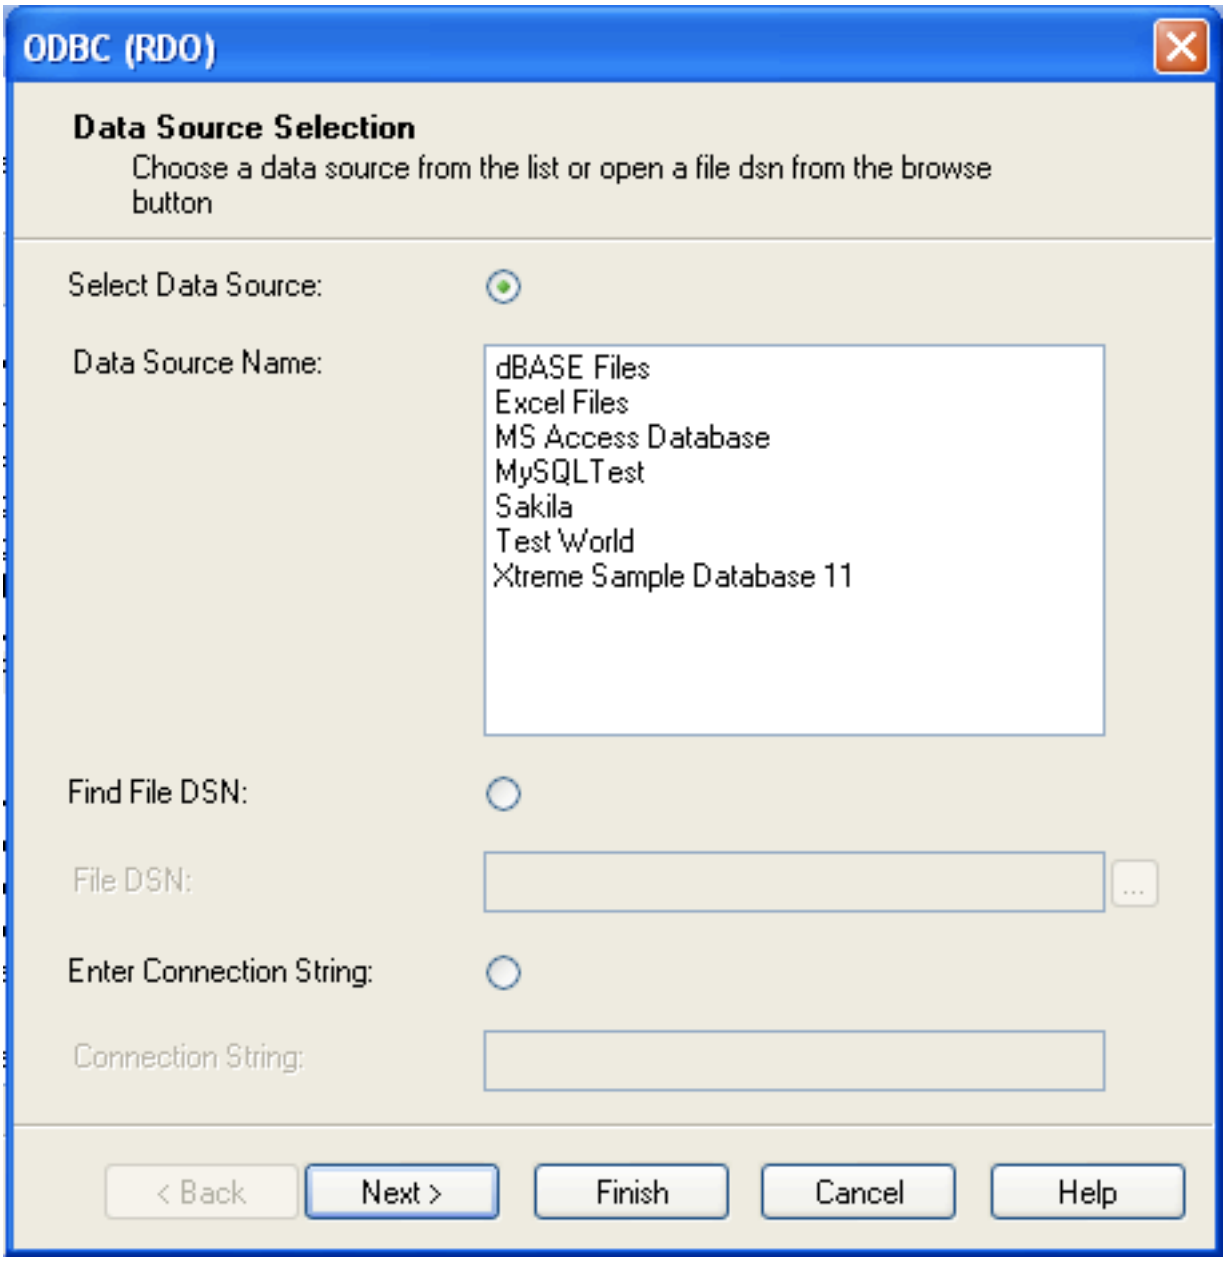
3. Start the Cross-Tab Report Wizard, either by clicking the option on the Start Page. Expand the **Create New Connection** folder, then expand the **ODBC (RDO)** folder to obtain a list of ODBC data sources.

You will be asked to select a data source.



4. When you first expand the **ODBC (RDO)** folder you will be presented the Data Source Selection screen. From here you can select either a pre-configured DSN, open a file-based DSN or enter and manual connection string. For this example, the **Sakila** DSN will be used.

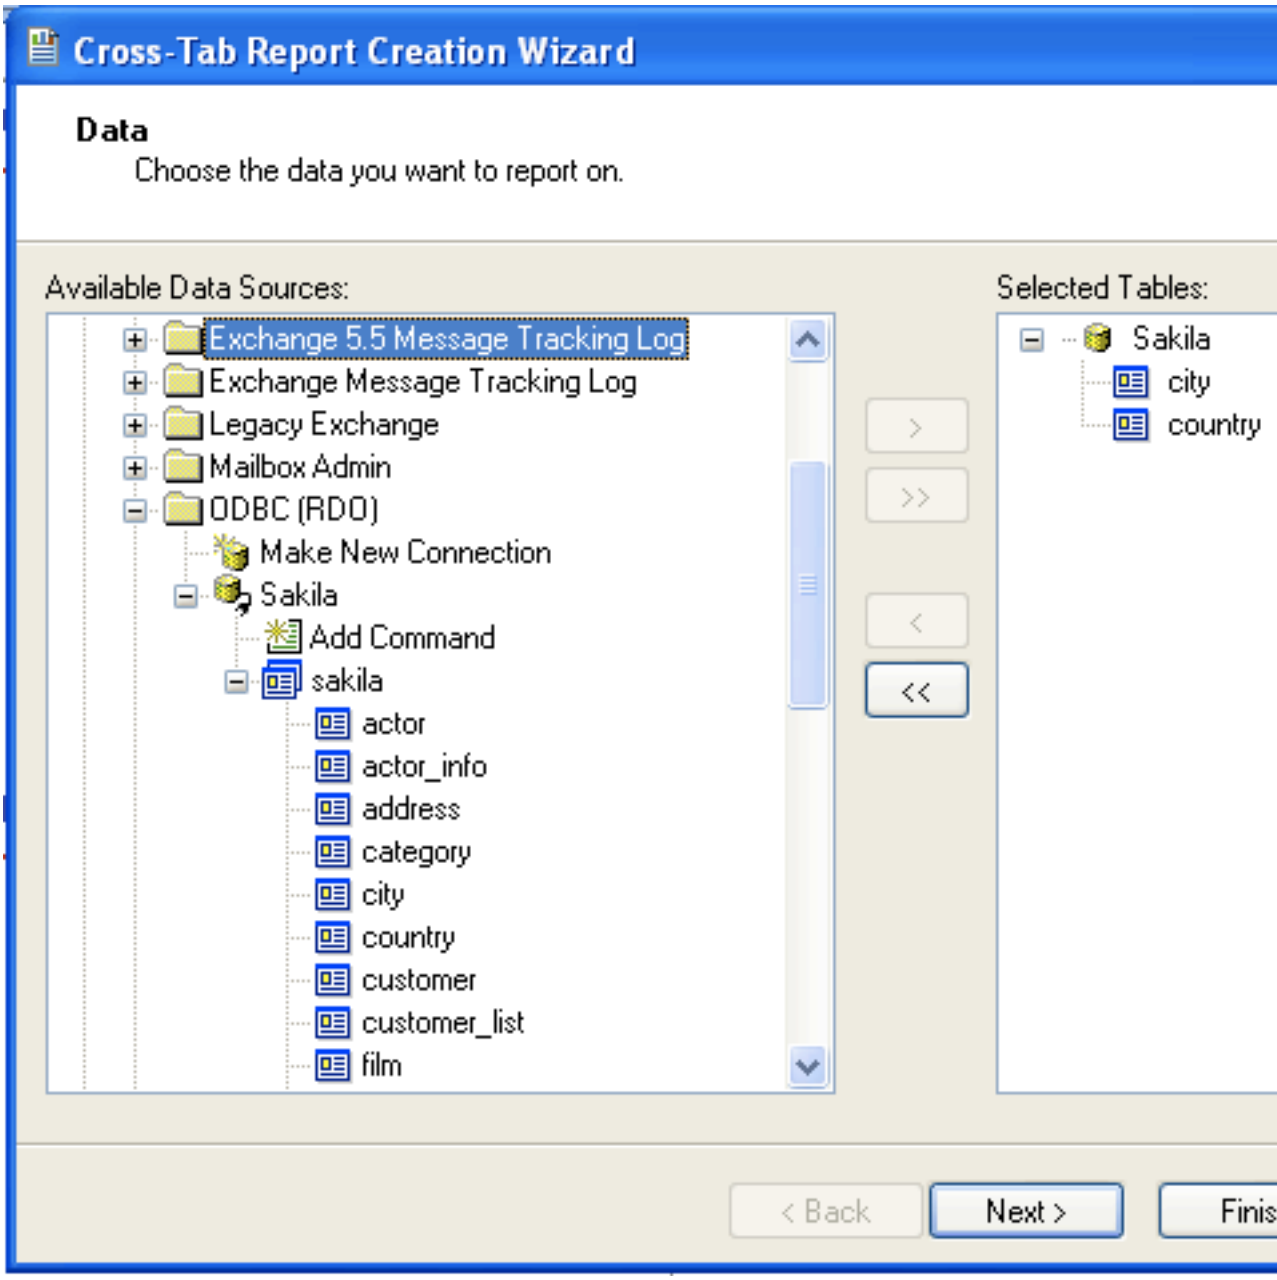
   If the DSN contains a user name/password combination, or you want to use different authentication credentials, click Next to enter the user name and password that you want to use. Otherwise, click Finish to continue the data source selection wizard.



5. You will be returned the Cross-Tab Report Creation Wizard. You now need to select the database and tables that you want to include in your report. For our example, we will expand the selected Sakila database. Click the `city` table and use the > button to add the table to the report. Then repeat the action with the `country` table. Alternatively you can select multiple tables and add them to the report.

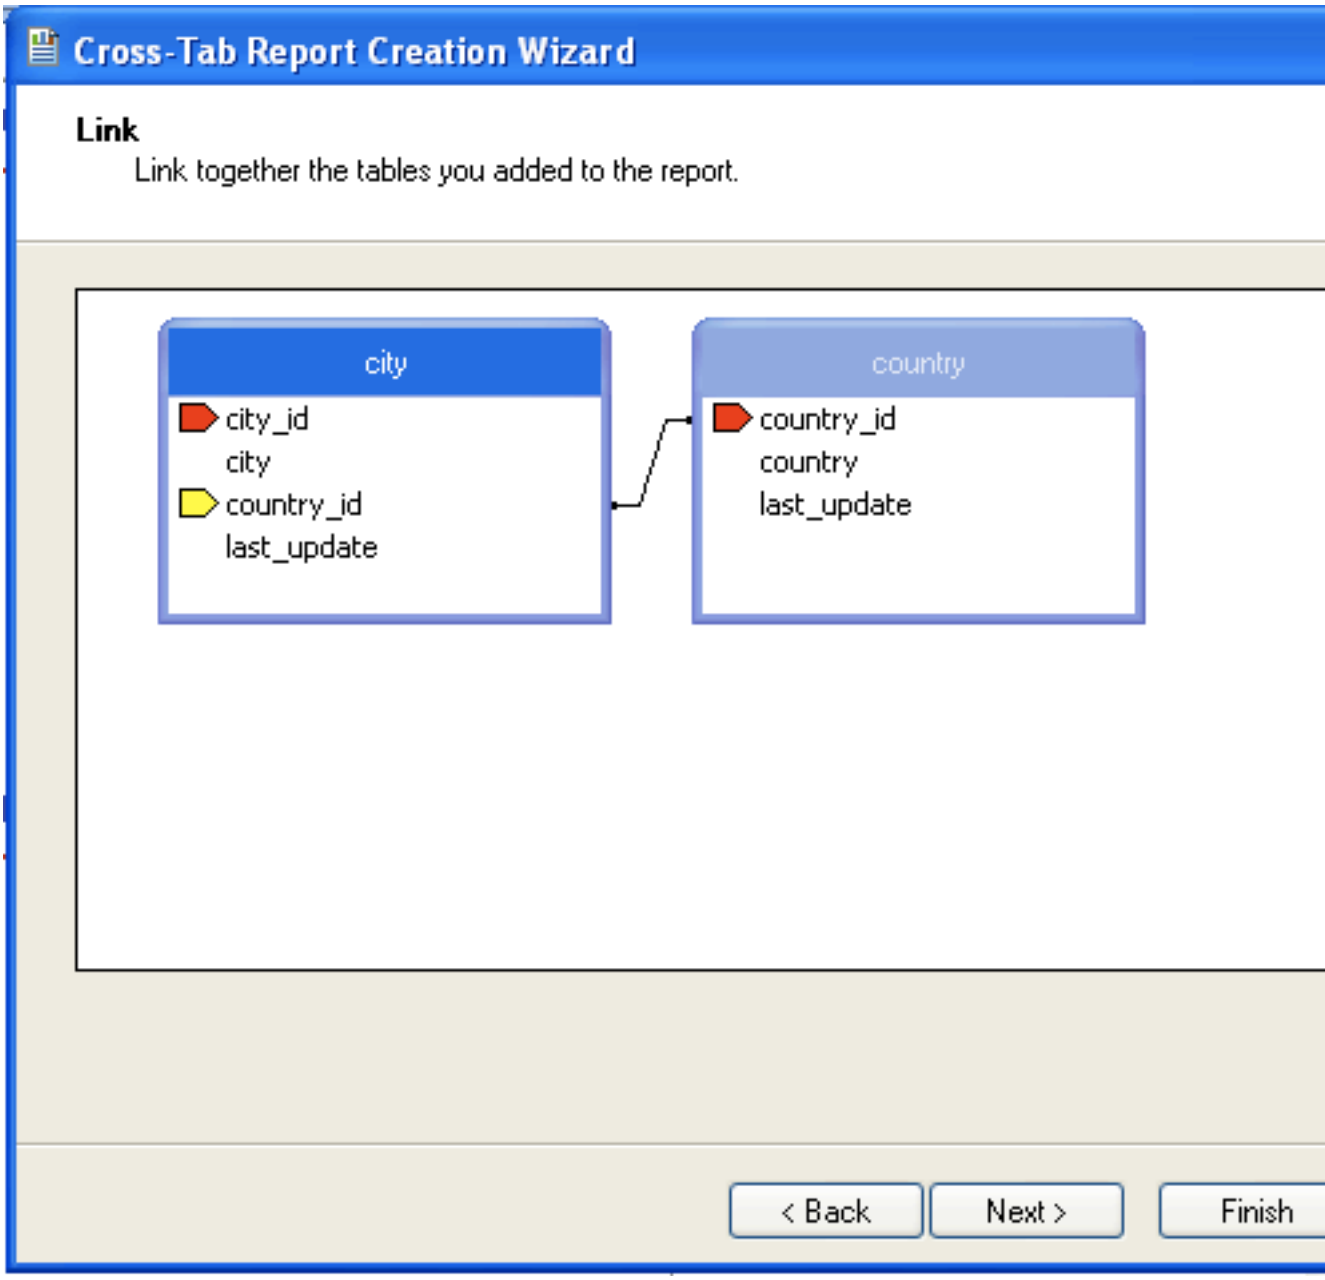
   Finally, you can select the parent **Sakila** resource and add of the tables to the report.

   Once you have selected the tables you want to include, click Next to continue.



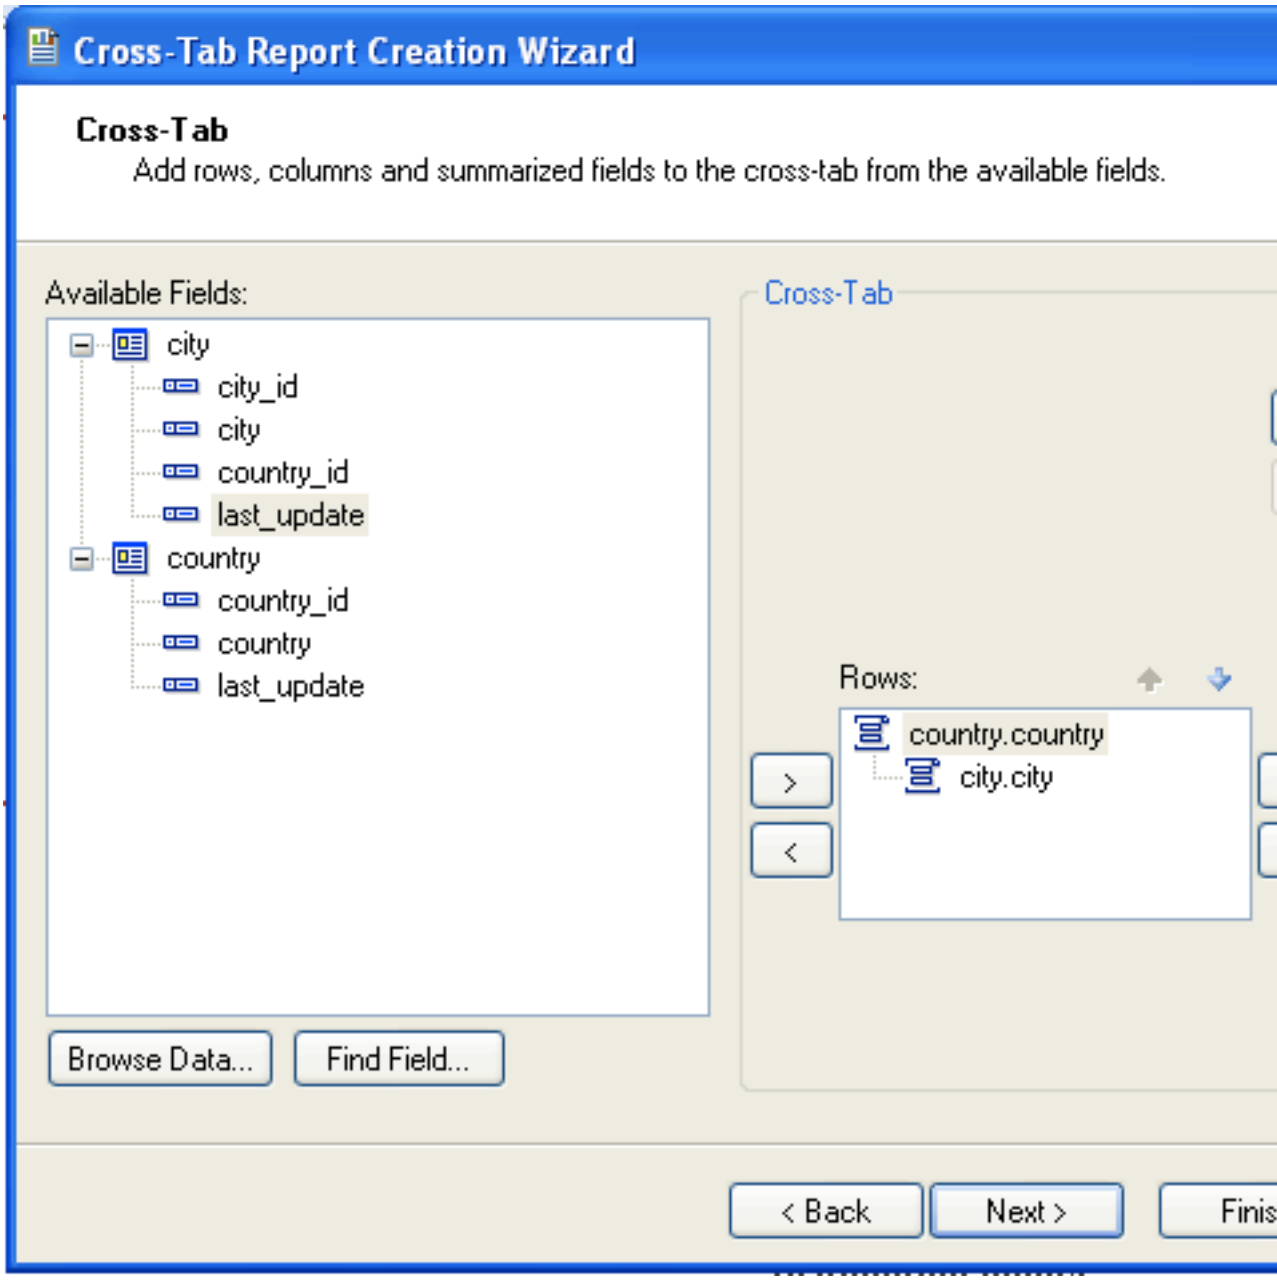
6. Crystal Reports will now read the table definitions and automatically identify the links between the tables. The identification of links between tables enables Crystal Reports to automatically lookup and summarize information based on all the tables in the database according to your query. If Crystal Reports is unable to perform the linking itself, you can manually create the links between fields in the tables you have selected.

   Click Next to continue the process.



7. You can now select the columns and rows that to include within the Cross-Tab report. Drag and drop or use the > buttons to add fields to each area of the report. In the example shown, we will report on cities, organized by country, incorporating a count of the number of cities within each country. If you want to browse the data, select a field and click the Browse Data... button.

   Click Next to create a graph of the results. Since we are not creating a graph from this data, click Finish to generate the report.



8. The finished report will be shown, a sample of the output from the Sakila sample database is shown below.

		Total
Total		600
Afghanistan	Total	1
	Kabul	1
Algeria	Total	3
	Batna	1
	Bchar	1
	Skikda	1
American Samoa	Total	1
	Tafuna	1
Angola	Total	2
	Benguela	1
	Namibe	1
Anguilla	Total	1
	South Hill	1
Argentina	Total	13
	Almirante Brow	1

Once the ODBC connection has been opened within Crystal Reports, you can browse and add any fields within the available tables into your reports.

Connector/ODBC Programming

With a suitable ODBC Manager and the Connector/ODBC driver installed, any programming language or environment that can support ODBC can connect to a MySQL database through Connector/ODBC.

This includes, but is not limited to, Microsoft support languages (including Visual Basic, C# and interfaces such as ODBC.NET), Perl (through the DBI module, and the DBD::ODBC driver).

Using Connector/ODBC with Visual Basic Using ADO, DAO and RDO

This section contains simple examples of the use of Connector/ODBC with ADO, DAO and RDO.

ADO: `rs.addNew`, `rs.delete`, and `rs.update`

The following ADO (ActiveX Data Objects) example creates a table `my_ado` and demonstrates the use of `rs.addNew`, `rs.delete`, and `rs.update`.

```
Private Sub myodbc_ado_Click()

Dim conn As ADODB.Connection
Dim rs As ADODB.Recordset
Dim fld As ADODB.Field
Dim sql As String

'connect to MySQL server using Connector/ODBC
Set conn = New ADODB.Connection
conn.ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};"_
& "SERVER=localhost;"_
& " DATABASE=test;"_
& "UID=venu;PWD=venu; OPTION=3"

conn.Open

'create table
conn.Execute "DROP TABLE IF EXISTS my_ado"
conn.Execute "CREATE TABLE my_ado(id int not null primary key, name varchar(20)," _
& "txt text, dt date, tm time, ts timestamp)"

'direct insert
conn.Execute "INSERT INTO my_ado(id,name,txt) values(1,100,'venu')"
conn.Execute "INSERT INTO my_ado(id,name,txt) values(2,200,'MySQL')"
conn.Execute "INSERT INTO my_ado(id,name,txt) values(3,300,'Delete')"

Set rs = New ADODB.Recordset
rs.CursorLocation = adUseServer

'fetch the initial table ..
rs.Open "SELECT * FROM my_ado", conn
Debug.Print rs.RecordCount
rs.MoveFirst
Debug.Print String(50, "-") & "Initial my_ado Result Set " & String(50, "-")
For Each fld In rs.Fields
Debug.Print fld.Name,
Next
Debug.Print

Do Until rs.EOF
For Each fld In rs.Fields
Debug.Print fld.Value,
Next
rs.MoveNext
Debug.Print
Loop
rs.Close

'rs insert
rs.Open "select * from my_ado", conn, adOpenDynamic, adLockOptimistic
rs.AddNew
rs!Name = "Monty"
rs!txt = "Insert row"
rs.Update
rs.Close

'rs update
rs.Open "SELECT * FROM my_ado"
rs!Name = "update"
rs!txt = "updated-row"
rs.Update
rs.Close

'rs update second time..
rs.Open "SELECT * FROM my_ado"
rs!Name = "update"
rs!txt = "updated-second-time"
```

```
rs.Update
rs.Close

'rs delete
rs.Open "SELECT * FROM my_ado"
rs.MoveNext
rs.MoveNext
rs.Delete
rs.Close

'fetch the updated table ..
rs.Open "SELECT * FROM my_ado", conn
Debug.Print rs.RecordCount
rs.MoveFirst
Debug.Print String(50, "-") & "Updated my_ado Result Set " & String(50, "-")
For Each fld In rs.Fields
Debug.Print fld.Name,
Next
Debug.Print

Do Until rs.EOF
For Each fld In rs.Fields
Debug.Print fld.Value,
Next
rs.MoveNext
Debug.Print
Loop
rs.Close
conn.Close
End Sub
```

DAO: `rs.addNew`, `rs.update`, and Scrolling

The following DAO (Data Access Objects) example creates a table `my_dao` and demonstrates the use of `rs.addNew`, `rs.update`, and result set scrolling.

```
Private Sub myodbc_dao_Click()

Dim ws As Workspace
Dim conn As Connection
Dim queryDef As queryDef
Dim str As String

'connect to MySQL using MySQL ODBC 3.51 Driver
Set ws = DBEngine.CreateWorkspace("", "venu", "venu", dbUseODBC)
str = "odbc;DRIVER={MySQL ODBC 3.51 Driver};"_
& "SERVER=localhost;"_
& " DATABASE=test;"_
& "UID=venu;PWD=venu; OPTION=3"
Set conn = ws.OpenConnection("test", dbDriverNoPrompt, False, str)

'Create table my_dao
Set queryDef = conn.CreateQueryDef("", "drop table if exists my_dao")
queryDef.Execute

Set queryDef = conn.CreateQueryDef("", "create table my_dao(Id INT AUTO_INCREMENT PRIMARY KEY, " _
& "Ts TIMESTAMP(14) NOT NULL, Name varchar(20), Id2 INT)")
queryDef.Execute

'Insert new records using rs.addNew
Set rs = conn.OpenRecordset("my_dao")
Dim i As Integer

For i = 10 To 15
rs.AddNew
rs!Name = "insert record" & i
rs!Id2 = i
rs.Update
Next i
rs.Close

'rs update..
```

```
Set rs = conn.OpenRecordset("my_dao")
rs.Edit
rs!Name = "updated-string"
rs.Update
rs.Close

'fetch the table back...
Set rs = conn.OpenRecordset("my_dao", dbOpenDynamic)
str = "Results:"
rs.MoveFirst
While Not rs.EOF
str = " " & rs!Id & " , " & rs!Name & ", " & rs!Ts & ", " & rs!Id2
Debug.Print "DATA:" & str
rs.MoveNext
Wend

'rs Scrolling
rs.MoveFirst
str = " FIRST ROW: " & rs!Id & " , " & rs!Name & ", " & rs!Ts & ", " & rs!Id2
Debug.Print str

rs.MoveLast
str = " LAST ROW: " & rs!Id & " , " & rs!Name & ", " & rs!Ts & ", " & rs!Id2
Debug.Print str

rs.MovePrevious
str = " LAST-1 ROW: " & rs!Id & " , " & rs!Name & ", " & rs!Ts & ", " & rs!Id2
Debug.Print str

'free all resources
rs.Close
queryDef.Close
conn.Close
ws.Close

End Sub
```

RDO: `rs.addNew` and `rs.update`

The following RDO (Remote Data Objects) example creates a table `my_rdo` and demonstrates the use of `rs.addNew` and `rs.update`.

```
Dim rs As rdoResultset
Dim cn As New rdoConnection
Dim cl As rdoColumn
Dim SQL As String

'cn.Connect = "DSN=test;"
cn.Connect = "DRIVER={MySQL ODBC 3.51 Driver};"_
& "SERVER=localhost;"_
& " DATABASE=test;"_
& "UID=venu;PWD=venu; OPTION=3"

cn.CursorDriver = rdUseOdbc
cn.EstablishConnection rdDriverPrompt

'drop table my_rdo
SQL = "drop table if exists my_rdo"
cn.Execute SQL, rdExecDirect

'create table my_rdo
SQL = "create table my_rdo(id int, name varchar(20))"
cn.Execute SQL, rdExecDirect

'insert - direct
SQL = "insert into my_rdo values (100,'venu')"
cn.Execute SQL, rdExecDirect

SQL = "insert into my_rdo values (200,'MySQL')"
cn.Execute SQL, rdExecDirect
```

```
'rs insert
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.AddNew
rs!id = 300
rs!Name = "Insert1"
rs.Update
rs.Close

'rs insert
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.AddNew
rs!id = 400
rs!Name = "Insert 2"
rs.Update
rs.Close

'rs update
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.Edit
rs!id = 999
rs!Name = "updated"
rs.Update
rs.Close

'fetch back...
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
Do Until rs.EOF
For Each cl In rs.rdoColumns
Debug.Print cl.Value,
Next
rs.MoveNext
Debug.Print
Loop
Debug.Print "Row count="; rs.RowCount

'close
rs.Close
cn.Close

End Sub
```

Using Connector/ODBC with .NET

This section contains simple examples that demonstrate the use of Connector/ODBC drivers with ODBC.NET.

Using Connector/ODBC with ODBC.NET and C# (C sharp)

The following sample creates a table `my_odbc_net` and demonstrates its use in C#.

```
/**
 * @sample    : mycon.cs
 * @purpose   : Demo sample for ODBC.NET using Connector/ODBC
 * @author    : Venu, <myodbc@lists.mysql.com>
 *
 * (C) Copyright MySQL AB, 1995-2006
 *
 **/

/* build command
 *
 *  csc /t:exe
 *      /out:mycon.exe mycon.cs
 *      /r:Microsoft.Data.Odbc.dll
 */

using Console = System.Console;
using Microsoft.Data.Odbc;
```

```
namespace myodbc3
{
  class mycon
  {
    static void Main(string[] args)
    {
      try
        {
          //Connection string for Connector/ODBC 3.51
          string MyConString = "DRIVER={MySQL ODBC 3.51 Driver};" +
            "SERVER=localhost;" +
            "DATABASE=test;" +
            "UID=venu;" +
            "PASSWORD=venu;" +
            "OPTION=3";

          //Connect to MySQL using Connector/ODBC
          OdbcConnection MyConnection = new OdbcConnection(MyConString);
          MyConnection.Open();

          Console.WriteLine("\n !!! success, connected successfully !!!\n");

          //Display connection information
          Console.WriteLine("Connection Information:");
          Console.WriteLine("\tConnection String:" +
                            MyConnection.ConnectionString);
          Console.WriteLine("\tConnection Timeout:" +
                            MyConnection.ConnectionTimeout);
          Console.WriteLine("\tDatabase:" +
                            MyConnection.Database);
          Console.WriteLine("\tDataSource:" +
                            MyConnection.DataSource);
          Console.WriteLine("\tDriver:" +
                            MyConnection.Driver);
          Console.WriteLine("\tServerVersion:" +
                            MyConnection.ServerVersion);

          //Create a sample table
          OdbcCommand MyCommand =
            new OdbcCommand("DROP TABLE IF EXISTS my_odbc_net",
                            MyConnection);
          MyCommand.ExecuteNonQuery();
          MyCommand.CommandText =
            "CREATE TABLE my_odbc_net(id int, name varchar(20), idb bigint)";
          MyCommand.ExecuteNonQuery();

          //Insert
          MyCommand.CommandText =
            "INSERT INTO my_odbc_net VALUES(10,'venu', 300)";
          Console.WriteLine("INSERT, Total rows affected:" +
                            MyCommand.ExecuteNonQuery());;

          //Insert
          MyCommand.CommandText =
            "INSERT INTO my_odbc_net VALUES(20,'mysql',400)";
          Console.WriteLine("INSERT, Total rows affected:" +
                            MyCommand.ExecuteNonQuery());

          //Insert
          MyCommand.CommandText =
            "INSERT INTO my_odbc_net VALUES(20,'mysql',500)";
          Console.WriteLine("INSERT, Total rows affected:" +
                            MyCommand.ExecuteNonQuery());

          //Update
          MyCommand.CommandText =
            "UPDATE my_odbc_net SET id=999 WHERE id=20";
          Console.WriteLine("Update, Total rows affected:" +
                            MyCommand.ExecuteNonQuery());

          //COUNT(*)
```

```
          MyCommand.CommandText =
            "SELECT COUNT(*) as TRows FROM my_odbc_net";
          Console.WriteLine("Total Rows:" +
                            MyCommand.ExecuteScalar());

          //Fetch
          MyCommand.CommandText = "SELECT * FROM my_odbc_net";
          OdbcDataReader MyDataReader;
          MyDataReader =  MyCommand.ExecuteReader();
          while (MyDataReader.Read())
            {
              if(string.Compare(MyConnection.Driver,"myodbc3.dll") == 0) {
                //Supported only by Connector/ODBC 3.51
                Console.WriteLine("Data:" + MyDataReader.GetInt32(0) + " " +
                                  MyDataReader.GetString(1) + " " +
                                  MyDataReader.GetInt64(2));
              }
              else {
                //BIGINTs not supported by Connector/ODBC
                Console.WriteLine("Data:" + MyDataReader.GetInt32(0) + " " +
                                  MyDataReader.GetString(1) + " " +
                                  MyDataReader.GetInt32(2));
              }
            }

          //Close all resources
          MyDataReader.Close();
          MyConnection.Close();
        }
      catch (OdbcException MyOdbcException) //Catch any ODBC exception ..
        {
          for (int i=0; i < MyOdbcException.Errors.Count; i++)
            {
              Console.Write("ERROR #" + i + "\n" +
                            "Message: " +
                            MyOdbcException.Errors[i].Message + "\n" +
                            "Native: " +
                            MyOdbcException.Errors[i].NativeError.ToString() + "\n" +
                            "Source: " +
                            MyOdbcException.Errors[i].Source + "\n" +
                            "SQL: " +
                            MyOdbcException.Errors[i].SQLState + "\n");
            }
        }
    }
  }
}

Using Connector/ODBC with ODBC.NET and Visual Basic

The following sample creates a table `my_vb_net` and demonstrates the use in VB.

```
' @sample    : myvb.vb
' @purpose   : Demo sample for ODBC.NET using Connector/ODBC
' @author    : Venu, <myodbc@lists.mysql.com>
'
' (C) Copyright MySQL AB, 1995-2006
'
'

'
' build command
'
' vbc /target:exe
'     /out:myvb.exe
'     /r:Microsoft.Data.Odbc.dll
'     /r:System.dll
'     /r:System.Data.dll
'

Imports Microsoft.Data.Odbc
Imports System
```

```
Module myvb
  Sub Main()
    Try

      'Connector/ODBC 3.51 connection string
      Dim MyConString As String = "DRIVER={MySQL ODBC 3.51 Driver};" & _
      "SERVER=localhost;" & _
      "DATABASE=test;" & _
      "UID=venu;" & _
      "PASSWORD=venu;" & _
      "OPTION=3;"

      'Connection
      Dim MyConnection As New OdbcConnection(MyConString)
      MyConnection.Open()

      Console.WriteLine("Connection State::" & MyConnection.State.ToString)

      'Drop
      Console.WriteLine("Dropping table")
      Dim MyCommand As New OdbcCommand()
      MyCommand.Connection = MyConnection
      MyCommand.CommandText = "DROP TABLE IF EXISTS my_vb_net"
      MyCommand.ExecuteNonQuery()

      'Create
      Console.WriteLine("Creating....")
      MyCommand.CommandText = "CREATE TABLE my_vb_net(id int, name varchar(30))"
      MyCommand.ExecuteNonQuery()

      'Insert
      MyCommand.CommandText = "INSERT INTO my_vb_net VALUES(10,'venu')"
      Console.WriteLine("INSERT, Total rows affected:" & _
      MyCommand.ExecuteNonQuery())

      'Insert
      MyCommand.CommandText = "INSERT INTO my_vb_net VALUES(20,'mysql')"
      Console.WriteLine("INSERT, Total rows affected:" & _
      MyCommand.ExecuteNonQuery())

      'Insert

```

Connector/ODBC Reference

This section provides reference material for the Connector/ODBC API, showing supported functions and methods, supported MySQL column types and the corresponding native type in Connector/ODBC, and the error codes returned by Connector/ODBC when a fault occurs.

Connector/ODBC API Reference

This section summarizes ODBC routines, categorized by functionality.

For the complete ODBC API reference, please refer to the ODBC Programmer's Reference at http://msdn.microsoft.com/en-us/library/ms714177.aspx.

An application can call `SQLGetInfo` function to obtain conformance information about Connector/ODBC. To obtain information about support for a specific function in the driver, an application can call `SQLGetFunctions`.

Note

For backward compatibility, the Connector/ODBC driver supports all deprecated functions.

The following tables list Connector/ODBC API calls grouped by task:

Connecting to a Data Source

Function Name	Connector/ODBC Supports?	Standard	Purpose
`SQLAllocHandle`	Yes	ISO 92	Obtains an environment, connection, statement, or descriptor handle.
`SQLConnect`	Yes	ISO 92	Connects to a specific driver by data source name, user ID, and password.
`SQLDriverConnect`	Yes	ODBC	Connects to a specific driver by connection string or requests that the Driver Manager and driver display connection dialog boxes for the user.
`SQLAllocEnv`	Yes	Deprecated	Obtains an environment handle allocated from driver.
`SQLAllocConnect`	Yes	Deprecated	Obtains a connection handle

Obtaining information about a driver and data source

Function Name	Connector/ODBC Supports?	Standard	Purpose
SQLDataSources	No	ISO 92	Returns the list of available data sources, handled by the Driver Manager
SQLDrivers	No	ODBC	Returns the list of installed drivers and their attributes, handles by Driver Manager
SQLGetInfo	Yes	ISO 92	Returns information about a specific driver and data source.
SQLGetFunctions	Yes	ISO 92	Returns supported driver functions.
SQLGetTypeInfo	Yes	ISO 92	Returns information about supported data types.

Setting and retrieving driver attributes

Function Name	Connector/ODBC Supports?	Standard	Purpose
SQLSetConnectAttr	Yes	ISO 92	Sets a connection attribute.
SQLGetConnectAttr	Yes	ISO 92	Returns the value of a connection attribute.
SQLSetConnectOption	Yes	Deprecated	Sets a connection option
SQLGetConnectOption	Yes	Deprecated	Returns the value of a connection option
SQLSetEnvAttr	Yes	ISO 92	Sets an environment attribute.
SQLGetEnvAttr	Yes	ISO 92	Returns the value of an environment attribute.
SQLSetStmtAttr	Yes	ISO 92	Sets a statement attribute.
SQLGetStmtAttr	Yes	ISO 92	Returns the value of a statement attribute.
SQLSetStmtOption	Yes	Deprecated	Sets a statement option
SQLGetStmtOption	Yes	Deprecated	Returns the value of a statement option

Preparing SQL Requests

Function Name	Connector/ODBC Supports?	Standard	Purpose
SQLAllocStmt	Yes	Deprecated	Allocates a statement handle
SQLPrepare	Yes	ISO 92	Prepares an SQL statement for later execution.
SQLBindParameter	Yes	ODBC	Assigns storage for a parameter in an SQL statement. Connector/ODBC 5.2 adds support for “out” and “inout” parameters, through the SQL_PARAM_OUTPUT or SQL_PARAM_INPUT_OUTPUT type specifiers. (“Out” and “inout” parameters are not supported for LONGTEXT and LONGBLOB columns.)
SQLGetCursorName	Yes	ISO 92	Returns the cursor name associated with a statement handle.
SQLSetCursorName	Yes	ISO 92	Specifies a cursor name.
SQLSetScrollOptions	Yes	ODBC	Sets options that control cursor behavior.

Submitting Requests

Function Name	Connector/ODBC Supports?	Standard	Purpose
SQLExecute	Yes	ISO 92	Executes a prepared statement.
SQLExecDirect	Yes	ISO 92	Executes a statement
SQLNativeSql	Yes	ODBC	Returns the text of an SQL statement as translated by the driver.
SQLDescribeParam	Yes	ODBC	Returns the description for a specific parameter in a statement.
SQLNumParams	Yes	ISO 92	Returns the number of parameters in a statement.
SQLParamData	Yes	ISO 92	Used in conjunction with SQLPutData to supply parameter data at execution time. (Useful for long data values.)
SQLPutData	Yes	ISO 92	Sends part or all of a data value for a parameter. (Useful for long data values.)

Retrieving results and information about results

Function Name	Connector/ODBC Supports?	Standard	Purpose
SQLRowCount	Yes	ISO 92	Returns the number of rows affected by an insert, update, or delete request.
SQLNumResultCols	Yes	ISO 92	Returns the number of columns in the result set.
SQLDescribeCol	Yes	ISO 92	Describes a column in the result set.
SQLColAttribute	Yes	ISO 92	Describes attributes of a column in the result set.
SQLColAttributes	Yes	Deprecated	Describes attributes of a column in the result set.
SQLFetch	Yes	ISO 92	Returns multiple result rows.
SQLFetchScroll	Yes	ISO 92	Returns scrollable result rows.
SQLExtendedFetch	Yes	Deprecated	Returns scrollable result rows.
SQLSetPos	Yes	ODBC	Positions a cursor within a fetched block of data and enables an application to refresh data in the rowset or to update or delete data in the result set.
SQLBulkOperations	Yes	ODBC	Performs bulk insertions and bulk bookmark operations, including update, delete, and fetch by bookmark.

Retrieving error or diagnostic information

Function Name	Connector/ODBC Supports?	Standard	Purpose
SQLError	Yes	Deprecated	Returns additional error or status information
SQLGetDiagField	Yes	ISO 92	Returns additional diagnostic information (a single field of the diagnostic data structure).
SQLGetDiagRec	Yes	ISO 92	Returns additional diagnostic information (multiple fields of the diagnostic data structure).

Obtaining information about the data source's system tables (catalog functions) item

Function Name	Connector/ODBC Supports?	Standard	Purpose
SQLColumnPrivileges	Yes	ODBC	Returns a list of columns and associated privileges for one or more tables.
SQLColumns	Yes	X/Open	Returns the list of column names in specified tables.
SQLForeignKeys	Yes	ODBC	Returns a list of column names that make up foreign keys, if they exist for a specified table.
SQLPrimaryKeys	Yes	ODBC	Returns the list of column names that make up the primary key for a table.
SQLSpecialColumns	Yes	X/Open	Returns information about the optimal set of columns that uniquely identifies a row in a specified table, or the columns that are automatically updated when any value in the row is updated by a transaction.
SQLStatistics	Yes	ISO 92	Returns statistics about a single table and the list of indexes associated with the table.
SQLTablePrivileges	Yes	ODBC	Returns a list of tables and the privileges associated with each table.
SQLTables	Yes	X/Open	Returns the list of table names stored in a specific data source.

Performing Transactions

Function Name	Connector/ODBC Supports?	Standard	Purpose
SQLTransact	Yes	Deprecated	Commits or rolls back a transaction
SQLEndTran	Yes	ISO 92	Commits or rolls back a transaction.

Terminating a Statement

Function Name	Connector/ODBC Supports?	Standard	Purpose
SQLFreeStmt	Yes	ISO 92	Ends statement processing, discards pending results, and, optionally, frees all resources associated with the statement handle.
SQLCloseCursor	Yes	ISO 92	Closes a cursor that has been opened on a statement handle.
SQLCancel	Yes	ISO 92	Cancels an SQL statement.

Terminating a Connection

Function Name	Connector/ODBC Supports?	Standard	Purpose
SQLDisconnect	Yes	ISO 92	Closes the connection.

Function Name	Connector/ODBC Supports?	Standard	Purpose
SQLFreeHandle	Yes	ISO 92	Releases an environment, connection, statement, or descriptor handle.
SQLFreeConnect	Yes	Deprecated	Releases connection handle.
SQLFreeEnv	Yes	Deprecated	Releases an environment handle.

Connector/ODBC Data Types

The following table illustrates how driver maps the server data types to default SQL and C data types.

Native Value	SQL Type	C Type
bigint unsigned	SQL_BIGINT	SQL_C_UBIGINT
bigint	SQL_BIGINT	SQL_C_SBIGINT
bit	SQL_BIT	SQL_C_BIT
bit	SQL_CHAR	SQL_C_CHAR
blob	SQL_LONGVARBINARY	SQL_C_BINARY
bool	SQL_CHAR	SQL_C_CHAR
char	SQL_CHAR	SQL_C_CHAR
date	SQL_DATE	SQL_C_DATE
datetime	SQL_TIMESTAMP	SQL_C_TIMESTAMP
decimal	SQL_DECIMAL	SQL_C_CHAR
double precision	SQL_DOUBLE	SQL_C_DOUBLE
double	SQL_FLOAT	SQL_C_DOUBLE
enum	SQL_VARCHAR	SQL_C_CHAR
float	SQL_REAL	SQL_C_FLOAT
int unsigned	SQL_INTEGER	SQL_C_ULONG
int	SQL_INTEGER	SQL_C_SLONG
integer unsigned	SQL_INTEGER	SQL_C_ULONG
integer	SQL_INTEGER	SQL_C_SLONG
long varbinary	SQL_LONGVARBINARY	SQL_C_BINARY
long varchar	SQL_LONGVARCHAR	SQL_C_CHAR
longblob	SQL_LONGVARBINARY	SQL_C_BINARY
longtext	SQL_LONGVARCHAR	SQL_C_CHAR
mediumblob	SQL_LONGVARBINARY	SQL_C_BINARY
mediumint unsigned	SQL_INTEGER	SQL_C_ULONG
mediumint	SQL_INTEGER	SQL_C_SLONG
mediumtext	SQL_LONGVARCHAR	SQL_C_CHAR
numeric	SQL_NUMERIC	SQL_C_CHAR
real	SQL_FLOAT	SQL_C_DOUBLE
set	SQL_VARCHAR	SQL_C_CHAR
smallint unsigned	SQL_SMALLINT	SQL_C_USHORT
smallint	SQL_SMALLINT	SQL_C_SSHORT
text	SQL_LONGVARCHAR	SQL_C_CHAR

Native Value	SQL Type	C Type
time	SQL_TIME	SQL_C_TIME
timestamp [533]	SQL_TIMESTAMP	SQL_C_TIMESTAMP
tinyblob	SQL_LONGVARBINARY	SQL_C_BINARY
tinyint unsigned	SQL_TINYINT	SQL_C_UTINYINT
tinyint	SQL_TINYINT	SQL_C_STINYINT
tinytext	SQL_LONGVARCHAR	SQL_C_CHAR
varchar	SQL_VARCHAR	SQL_C_CHAR
year	SQL_SMALLINT	SQL_C_SHORT

Connector/ODBC Error Codes

The following tables lists the error codes returned by the driver apart from the server errors.

Native Code	SQLSTATE 2	SQLSTATE 3	Error Message
500	01000	01000	General warning
501	01004	01004	String data, right truncated
502	01S02	01S02	Option value changed
503	01S03	01S03	No rows updated/deleted
504	01S04	01S04	More than one row updated/deleted
505	01S06	01S06	Attempt to fetch before the result set returned the first row set
506	07001	07002	SQLBindParameter not used for all parameters
507	07005	07005	Prepared statement not a cursor-specification
508	07009	07009	Invalid descriptor index
509	08002	08002	Connection name in use
510	08003	08003	Connection does not exist
511	24000	24000	Invalid cursor state
512	25000	25000	Invalid transaction state
513	25S01	25S01	Transaction state unknown
514	34000	34000	Invalid cursor name
515	S1000	HY000	General driver defined error
516	S1001	HY001	Memory allocation error
517	S1002	HY002	Invalid column number
518	S1003	HY003	Invalid application buffer type
519	S1004	HY004	Invalid SQL data type
520	S1009	HY009	Invalid use of null pointer
521	S1010	HY010	Function sequence error
522	S1011	HY011	Attribute can not be set now
523	S1012	HY012	Invalid transaction operation code
524	S1013	HY013	Memory management error
525	S1015	HY015	No cursor name available
526	S1024	HY024	Invalid attribute value

Native Code	SQLSTATE 2	SQLSTATE 3	Error Message
527	S1090	HY090	Invalid string or buffer length
528	S1091	HY091	Invalid descriptor field identifier
529	S1092	HY092	Invalid attribute/option identifier
530	S1093	HY093	Invalid parameter number
531	S1095	HY095	Function type out of range
532	S1106	HY106	Fetch type out of range
533	S1117	HY117	Row value out of range
534	S1109	HY109	Invalid cursor position
535	S1C00	HYC00	Optional feature not implemented
0	21S01	21S01	Column count does not match value count
0	23000	23000	Integrity constraint violation
0	42000	42000	Syntax error or access violation
0	42S02	42S02	Base table or view not found
0	42S12	42S12	Index not found
0	42S21	42S21	Column already exists
0	42S22	42S22	Column not found
0	08S01	08S01	Communication link failure

Connector/ODBC Notes and Tips

Here are some common notes and tips for using Connector/ODBC within different environments, applications and tools. The notes provided here are based on the experiences of Connector/ODBC developers and users.

Connector/ODBC General Functionality

This section provides help with common queries and areas of functionality in MySQL and how to use them with Connector/ODBC.

Obtaining Auto-Increment Values

Obtaining the value of column that uses `AUTO_INCREMENT` after an `INSERT` statement can be achieved in a number of different ways. To obtain the value immediately after an `INSERT`, use a `SELECT` query with the `LAST_INSERT_ID()` [1036] function.

For example, using Connector/ODBC you would execute two separate statements, the `INSERT` statement and the `SELECT` query to obtain the auto-increment value.

```
INSERT INTO tbl (auto,text) VALUES(NULL,'text');
SELECT LAST_INSERT_ID();
```

If you do not require the value within your application, but do require the value as part of another `INSERT`, the entire process can be handled by executing the following statements:

```
INSERT INTO tbl (auto,text) VALUES(NULL,'text');
INSERT INTO tbl2 (id,text) VALUES(LAST_INSERT_ID(),'text');
```

Certain ODBC applications (including Delphi and Access) may have trouble obtaining the auto-increment value using the previous examples. In this case, try the following statement as an alternative:

```
SELECT * FROM tbl WHERE auto IS NULL;
```

This alternative method requires that `sql_auto_is_null` [524] variable is not set to 0. See Server System Variables.

See also How to Get the Unique ID for the Last Inserted Row.

Dynamic Cursor Support

Support for the `dynamic cursor` is provided in Connector/ODBC 3.51, but dynamic cursors are not enabled by default. You can enable this function within Windows by selecting the `Enable Dynamic Cursor` check box within the ODBC Data Source Administrator.

On other platforms, you can enable the dynamic cursor by adding `32` to the `OPTION` value when creating the DSN.

Connector/ODBC Performance

The Connector/ODBC driver has been optimized to provide very fast performance. If you experience problems with the performance of Connector/ODBC, or notice a large amount of disk activity for simple queries, there are a number of aspects to check:

- Ensure that `ODBC Tracing` is not enabled. With tracing enabled, a lot of information is recorded in the tracing file by the ODBC Manager. You can check, and disable, tracing within Windows using the Tracing panel of the ODBC Data Source Administrator. Within Mac OS X, check the Tracing panel of ODBC Administrator. See Getting an ODBC Trace File.
- Make sure you are using the standard version of the driver, and not the debug version. The debug version includes additional checks and reporting measures.
- Disable the Connector/ODBC driver trace and query logs. These options are enabled for each DSN, so make sure to examine only the DSN that you are using in your application. Within Windows, you can disable the Connector/ODBC and query logs by modifying the DSN configuration. Within Mac OS X and Unix, ensure that the driver trace (option value 4) and query logging (option value 524288) are not enabled.

Setting ODBC Query Timeout in Windows

For more information on how to set the query timeout on Microsoft Windows when executing queries through an ODBC connection, read the Microsoft knowledgebase document at http://support.microsoft.com/default.aspx?scid=kb%3Ben-us%3B153756.

Connector/ODBC Application-Specific Tips

Most programs should work with Connector/ODBC, but for each of those listed here, there are specific notes and tips to improve or enhance the way you work with Connector/ODBC and these applications.

With all applications, ensure that you are using the latest Connector/ODBC drivers, ODBC Manager and any supporting libraries and interfaces used by your application. For example, on Windows, using the latest version of Microsoft Data Access Components (MDAC) will improve the compatibility with ODBC in general, and with the Connector/ODBC driver.

Using Connector/ODBC with Microsoft Applications

The majority of Microsoft applications have been tested with Connector/ODBC, including Microsoft Office, Microsoft Access and the various programming languages supported within ASP and Microsoft Visual Studio.

Microsoft Access

To improve the integration between Microsoft Access and MySQL through Connector/ODBC:

- For all versions of Access, enable the Connector/ODBC `Return matching rows` option. For Access 2.0, also enable the `Simulate ODBC 1.0` option.
- Include a `TIMESTAMP` column in all tables that you want to be able to update. For maximum portability, do not use a length specification in the column declaration (which is unsupported within MySQL in versions earlier than 4.1).
- Include a primary key in each MySQL table you want to use with Access. If not, new or updated rows may show up as `#DELETED#`.
- Use only `DOUBLE` float fields. Access fails when comparing with single-precision floats. The symptom usually is that new or updated rows may show up as `#DELETED#` or that you cannot find or update rows.
- If you are using Connector/ODBC to link to a table that has a `BIGINT` column, the results are displayed as `#DELETED#`. The work around solution is:
  - Have one more dummy column with `TIMESTAMP` as the data type.
  - Select the `Change BIGINT columns to INT` option in the connection dialog in ODBC DSN Administrator.
  - Delete the table link from Access and re-create it.

  Old records may still display as `#DELETED#`, but newly added/updated records are displayed properly.
- If you still get the error `Another user has changed your data` after adding a `TIMESTAMP` column, the following trick may help you:

  Do not use a `table` data sheet view. Instead, create a form with the fields you want, and use that `form` data sheet view. Set the `DefaultValue` property for the `TIMESTAMP` column to `NOW()` [990]. Consider hiding the `TIMESTAMP` column from view so your users are not confused.
- In some cases, Access may generate SQL statements that MySQL cannot understand. You can fix this by selecting `"Query|SQLSpecific|Pass-Through"` from the Access menu.
- On Windows NT, Access reports `BLOB` columns as `OLE OBJECTS`. If you want to have `MEMO` columns instead, change `BLOB` columns to `TEXT` with `ALTER TABLE`.
- Access cannot always handle the MySQL `DATE` column properly. If you have a problem with these, change the columns to `DATETIME`.
- If you have in Access a column defined as `BYTE`, Access tries to export this as `TINYINT` instead of `TINYINT UNSIGNED`. This gives you problems if you have values larger than 127 in the column.
- If you have very large (long) tables in Access, it might take a very long time to open them. Or you might run low on virtual memory and eventually get an `ODBC Query Failed` error and the table cannot open. To deal with this, select the following options:
  - Return Matching Rows (2)
  - Allow BIG Results (8).

  These add up to a value of 10 (`OPTION=10`).

Some external articles and tips that may be useful when using Access, ODBC and Connector/ODBC:

- Optimizing Access ODBC Applications
  - Optimizing for Client/Server Performance

- Tips for Converting Applications to Using ODBCDirect
- Tips for Optimizing Queries on Attached SQL Tables

- For a list of tools that can be used with Access and ODBC data sources, refer to http://www.mysql.com/portal/software/convertors/ section for list of available tools.

Microsoft Excel and Column Types

If you have problems importing data into Microsoft Excel, particularly numeric, date, and time values, this is probably because of a bug in Excel, where the column type of the source data is used to determine the data type when that data is inserted into a cell within the worksheet. The result is that Excel incorrectly identifies the content and this affects both the display format and the data when it is used within calculations.

To address this issue, use the `CONCAT()` [951] function in your queries. The use of `CONCAT()` [951] forces Excel to treat the value as a string, which Excel will then parse and usually correctly identify the embedded information.

However, even with this option, some data may be incorrectly formatted, even though the source data remains unchanged. Use the `Format Cells` option within Excel to change the format of the displayed information.

Microsoft Visual Basic

To be able to update a table, you must define a primary key for the table.

Visual Basic with ADO cannot handle big integers. This means that some queries like `SHOW PROCESSLIST` do not work properly. The fix is to use `OPTION=16384` in the ODBC connect string or to select the `Change BIGINT columns to INT` option in the Connector/ODBC connect screen. You may also want to select the `Return matching rows` option.

Microsoft Visual InterDev

If you have a `BIGINT` in your result, you may get the error `[Microsoft][ODBC Driver Manager] Driver does not support this parameter`. Try selecting the `Change BIGINT columns to INT` option in the Connector/ODBC connect screen.

Visual Objects

Select the `Don't optimize column widths` option.

Microsoft ADO

When you are coding with the ADO API and Connector/ODBC, you need to pay attention to some default properties that aren't supported by the MySQL server. For example, using the `CursorLocation Property` as `adUseServer` returns a result of –1 for the `RecordCount Property`. To have the right value, you need to set this property to `adUseClient`, as shown in the VB code here:

```
Dim myconn As New ADODB.Connection
Dim myrs As New Recordset
Dim mySQL As String
Dim myrows As Long

myconn.Open "DSN=MyODBCsample"
mySQL = "SELECT * from user"
myrs.Source = mySQL
Set myrs.ActiveConnection = myconn
myrs.CursorLocation = adUseClient
myrs.Open
myrows = myrs.RecordCount
```

```
myrs.Close
myconn.Close
```

Another workaround is to use a `SELECT COUNT(*)` statement for a similar query to get the correct row count.

To find the number of rows affected by a specific SQL statement in ADO, use the `RecordsAffected` property in the ADO execute method. For more information on the usage of execute method, refer to http://msdn.microsoft.com/library/default.asp?url=/library/en-us/ado270/htm/mdmthcnnexecute.asp.

For information, see ActiveX Data Objects(ADO) Frequently Asked Questions.

Using Connector/ODBC with Active Server Pages (ASP)

Select the `Return matching rows` option in the DSN.

For more information about how to access MySQL through ASP using Connector/ODBC, refer to the following articles:

- Using MyODBC To Access Your MySQL Database Via ASP
- ASP and MySQL at DWAM.NT

A Frequently Asked Questions list for ASP can be found at http://support.microsoft.com/default.aspx?scid=/Support/ActiveServer/faq/data/adofaq.asp.

Using Connector/ODBC with Visual Basic (ADO, DAO and RDO) and ASP

Some articles that may help with Visual Basic and ASP:

- MySQL BLOB columns and Visual Basic 6 by Mike Hillyer (`<mike@openwin.org>`).
- How to map Visual basic data type to MySQL types by Mike Hillyer (`<mike@openwin.org>`).

Using Connector/ODBC with Borland Applications

With all Borland applications where the Borland Database Engine (BDE) is used, follow these steps to improve compatibility:

- Update to BDE 3.2 or newer.
- Enable the `Don't optimize column widths` option in the DSN.
- Enabled the `Return matching rows` option in the DSN.

Using Connector/ODBC with Borland Builder 4

When you start a query, you can use the `Active` property or the `Open` method. Note that `Active` starts by automatically issuing a `SELECT * FROM ...` query. That may not be a good thing if your tables are large.

Using Connector/ODBC with Delphi

Also, here is some potentially useful Delphi code that sets up both an ODBC entry and a BDE entry for Connector/ODBC. The BDE entry requires a BDE Alias Editor that is free at a Delphi Super Page near you. (Thanks to Bryan Brunton `<bryan@flesherfab.com>` for this):

```
fReg:= TRegistry.Create;
fReg.OpenKey('\Software\ODBC\ODBC.INI\DocumentsFab', True);
fReg.WriteString('Database', 'Documents');
fReg.WriteString('Description', ' ');
fReg.WriteString('Driver', 'C:\WINNT\System32\myodbc.dll');
```

```
fReg.WriteString('Flag', '1');
fReg.WriteString('Password', '');
fReg.WriteString('Port', ' ');
fReg.WriteString('Server', 'xmark');
fReg.WriteString('User', 'winuser');
fReg.OpenKey('\Software\ODBC\ODBC.INI\ODBC Data Sources', True);
fReg.WriteString('DocumentsFab', 'MySQL');
fReg.CloseKey;
fReg.Free;

Memo1.Lines.Add('DATABASE NAME=');
Memo1.Lines.Add('USER NAME=');
Memo1.Lines.Add('ODBC DSN=DocumentsFab');
Memo1.Lines.Add('OPEN MODE=READ/WRITE');
Memo1.Lines.Add('BATCH COUNT=200');
Memo1.Lines.Add('LANGDRIVER=');
Memo1.Lines.Add('MAX ROWS=-1');
Memo1.Lines.Add('SCHEMA CACHE DIR=');
Memo1.Lines.Add('SCHEMA CACHE SIZE=8');
Memo1.Lines.Add('SCHEMA CACHE TIME=-1');
Memo1.Lines.Add('SQLPASSTHRU MODE=SHARED AUTOCOMMIT');
Memo1.Lines.Add('SQLQRYMODE=');
Memo1.Lines.Add('ENABLE SCHEMA CACHE=FALSE');
Memo1.Lines.Add('ENABLE BCD=FALSE');
Memo1.Lines.Add('ROWSET SIZE=20');
Memo1.Lines.Add('BLOBS TO CACHE=64');
Memo1.Lines.Add('BLOB SIZE=32');

AliasEditor.Add('DocumentsFab','MySQL',Memo1.Lines);
```

Using Connector/ODBC with C++ Builder

Tested with BDE 3.0. The only known problem is that when the table schema changes, query fields are not updated. BDE, however, does not seem to recognize primary keys, only the index named `PRIMARY`, although this has not been a problem.

Using Connector/ODBC with ColdFusion

The following information is taken from the ColdFusion documentation:

Use the following information to configure ColdFusion Server for Linux to use the `unixODBC` driver with Connector/ODBC for MySQL data sources. You can download Connector/ODBC at http://dev.mysql.com/downloads/connector/odbc/.

ColdFusion version 4.5.1 lets you use the ColdFusion Administrator to add the MySQL data source. However, the driver is not included with ColdFusion version 4.5.1. Before the MySQL driver appears in the ODBC data sources drop-down list, build and copy the Connector/ODBC driver to `/opt/coldfusion/lib/libmyodbc.so`.

The Contrib directory contains the program `mydsn-xxx.zip` which lets you build and remove the DSN registry file for the Connector/ODBC driver on ColdFusion applications.

For more information and guides on using ColdFusion and Connector/ODBC, see the following external sites:

- Troubleshooting Data Sources and Database Connectivity for Unix Platforms.

Using Connector/ODBC with OpenOffice.org

Open Office (http://www.openoffice.org) How-to: MySQL + OpenOffice. How-to: OpenOffice + MyODBC + unixODBC.

Using Connector/ODBC with Sambar Server

Sambar Server (http://www.sambarserver.info) How-to: MyODBC + SambarServer + MySQL.

Using Connector/ODBC with Pervasive Software DataJunction

You have to change it to output `VARCHAR` rather than `ENUM`, as it exports the latter in a manner that causes MySQL problems.

Using Connector/ODBC with SunSystems Vision

Select the `Return matching rows` option.

Connector/ODBC Errors and Resolutions (FAQ)

The following section details some common errors and their suggested fix or alternative solution. If you are still experiencing problems, use the Connector/ODBC mailing list; see Connector/ODBC Community Support.

Many problems can be resolved by upgrading your Connector/ODBC drivers to the latest available release. On Windows, make sure that you have the latest versions of the Microsoft Data Access Components (MDAC) installed.

64-Bit Windows and ODBC Data Source Administrator

I have installed Connector/ODBC on Windows XP x64 Edition or Windows Server 2003 R2 x64. The installation completed successfully, but the Connector/ODBC driver does not appear in `ODBC Data Source Administrator`.

This is not a bug, but is related to the way Windows x64 editions operate with the ODBC driver. On Windows x64 editions, the Connector/ODBC driver is installed in the `%SystemRoot%\SysWOW64` folder. However, the default `ODBC Data Source Administrator` that is available through the `Administrative Tools` or `Control Panel` in Windows x64 Editions is located in the `%SystemRoot%\system32` folder, and only searches this folder for ODBC drivers.

On Windows x64 editions, use the ODBC administration tool located at `%SystemRoot%\SysWOW64\odbcad32.exe`, this will correctly locate the installed Connector/ODBC drivers and enable you to create a Connector/ODBC DSN.

This issue was originally reported as Bug #20301.

Error 10061 (Cannot connect to server)

When connecting or using the Test button in `ODBC Data Source Administrator` I get error 10061 (Cannot connect to server)

This error can be raised by a number of different issues, including server problems, network problems, and firewall and port blocking problems. For more information, see `Can't connect to [local] MySQL server`.

"Transactions are not enabled" Error

The following error is reported when using transactions: `Transactions are not enabled`

This error indicates that you are trying to use transactions with a MySQL table that does not support transactions. Transactions are supported within MySQL when using the `InnoDB` database engine, which is the default storage engine in MySQL 5.5 and higher. In versions of MySQL before MySQL 5.1, you may also use the `BDB` engine.

Check the following before continuing:

- Verify that your MySQL server supports a transactional database engine. Use `SHOW ENGINES` to obtain a list of the available engine types.

- Verify that the tables you are updating use a transactional database engine.
- Ensure that you have not enabled the `disable transactions` option in your DSN.

#DELETED# Records Reported by Access

Access reports records as `#DELETED#` when inserting or updating records in linked tables.

If the inserted or updated records are shown as `#DELETED#` in Access, then:

- If you are using Access 2000, get and install the newest (version 2.6 or higher) Microsoft MDAC (`Microsoft Data Access Components`) from http://support.microsoft.com/kb/110093. This fixes a bug in Access that when you export data to MySQL, the table and column names aren't specified.

  Also, get and apply the Microsoft Jet 4.0 Service Pack 5 (SP5), which can be found at http://support.microsoft.com/default.aspx?scid=kb;EN-US;q239114. This fixes some cases where columns are marked as `#DELETED#` in Access.
- For all versions of Access, enable the Connector/ODBC `Return matching rows` option. For Access 2.0, also enable the `Simulate ODBC 1.0` option.
- Include a `TIMESTAMP` in all tables that you want to be able to update.
- Include a primary key in the table. If not, new or updated rows may show up as `#DELETED#`.
- Use only `DOUBLE` float fields. Access fails when comparing with single-precision floats. The symptom usually is that new or updated rows may show up as `#DELETED#` or that you cannot find or update rows.
- If you are using Connector/ODBC to link to a table that has a `BIGINT` column, the results are displayed as `#DELETED`. The work around solution is:
  - Have one more dummy column with `TIMESTAMP` as the data type.
  - Select the `Change BIGINT columns to INT` option in the connection dialog in ODBC DSN Administrator.
  - Delete the table link from Access and re-create it.

  Old records still display as `#DELETED#`, but newly added/updated records are displayed properly.

Write Conflicts or Row Location Errors

How do I handle Write Conflicts or Row Location errors?

If you see the following errors, select the `Return Matching Rows` option in the DSN configuration dialog, or specify `OPTION=2`, as the connection parameter:

```
Write Conflict. Another user has changed your data.

Row cannot be located for updating. Some values may have been changed
since it was last read.
```

Importing from Access 97

Exporting data from Access 97 to MySQL reports a `Syntax Error`.

This error is specific to Access 97 and versions of Connector/ODBC earlier than 3.51.02. Update to the latest version of the Connector/ODBC driver to resolve this problem.

Importing from Microsoft DTS

Exporting data from Microsoft DTS to MySQL reports a `Syntax Error`.

This error occurs only with MySQL tables using the `TEXT` or `VARCHAR` data types. You can fix this error by upgrading your Connector/ODBC driver to version 3.51.02 or higher.

SQL_NO_DATA Exception from ODBC.NET

Using ODBC.NET with Connector/ODBC, while fetching empty string (0 length), it starts giving the `SQL_NO_DATA` exception.

You can get the patch that addresses this problem from http://support.microsoft.com/default.aspx?scid=kb;EN-US;q319243.

Error with SELECT COUNT(*)

Using `SELECT COUNT(*) FROM tbl_name` within Visual Basic and ASP returns an error.

This error occurs because the `COUNT(*)` [1045] expression is returning a `BIGINT`, and ADO cannot make sense of a number this big. Select the `Change BIGINT columns to INT` option (option value 16384).

Multiple-Step Operation Error

Using the `AppendChunk()` or `GetChunk()` ADO methods, the `Multiple-step operation generated errors. Check each status value` error is returned.

The `GetChunk()` and `AppendChunk()` methods from ADO do not work as expected when the cursor location is specified as `adUseServer`. On the other hand, you can overcome this error by using `adUseClient`.

A simple example can be found from http://www.dwam.net/iishelp/ado/docs/adomth02_4.htm

Modified Record Error

Access returns `Another user had modified the record that you have modified` while editing records on a Linked Table.

In most cases, this can be solved by doing one of the following things:

- Add a primary key for the table if one doesn't exist.
- Add a timestamp column if one doesn't exist.
- Only use double-precision float fields. Some programs may fail when they compare single-precision floats.

If these strategies do not help, start by making a log file from the ODBC manager (the log you get when requesting logs from ODBCADMIN) and a Connector/ODBC log to help you figure out why things go wrong. For instructions, see Getting an ODBC Trace File.

Direct Application Linking Under Unix or Linux

When linking an application directly to the Connector/ODBC library under Unix or Linux, the application crashes.

Connector/ODBC under Unix or Linux is not compatible with direct application linking. To connect to an ODBC source, use a driver manager, such as `iODBC` or `unixODBC`.

Microsoft Office and DATE or TIMESTAMP Columns

Applications in the Microsoft Office suite cannot update tables that have `DATE` or `TIMESTAMP` columns.

This is a known issue with Connector/ODBC. Ensure that the field has a default value (rather than `NULL`) and that the default value is nonzero (that is, something other than `0000-00-00 00:00:00`).

INFORMATION_SCHEMA Database

When connecting Connector/ODBC 5.x to a MySQL 4.x server, the error `1044 Access denied for user 'xxx'@'%' to database 'information_schema'` is returned.

Connector/ODBC 5.x is designed to work with MySQL 5.0 or later, taking advantage of the `INFORMATION_SCHEMA` database to determine data definition information. Support for MySQL 4.1 is planned for the final release.

S1T00 Error

When calling `SQLTables`, the error `S1T00` is returned, but I cannot find this in the list of error numbers for Connector/ODBC.

The `S1T00` error indicates that a general timeout has occurred within the ODBC system and is not a MySQL error. Typically it indicates that the connection you are using is stale, the server is too busy to accept your request or that the server has gone away.

"Table does not exist" Error in Access 2000

When linking to tables in Access 2000 and generating links to tables programmatically, rather than through the table designer interface, you may get errors about tables not existing.

There is a known issue with a specific version of the `msjet40.dll` that exhibits this issue. The version affected is 4.0.9025.0. Reverting to an older version will enable you to create the links. If you have recently updated your version, check your `WINDOWS` directory for the older version of the file and copy it to the drivers directory.

Batched Statements

When I try to use batched statements, the execution of the batched statements fails.

Batched statement support was added in 3.51.18. Support for batched statements is not enabled by default. Enable option `FLAG_MULTI_STATEMENTS`, value 67108864, or select the **Allow multiple statements** flag within a GUI configuration.

Packet Errors with ADODB and Excel

When connecting to a MySQL server using ADODB and Excel, occasionally the application fails to communicate with the server and the error `Got an error reading communication packets` appears in the error log.

This error may be related to Keyboard Logger 1.1 from PanteraSoft.com, which is known to interfere with the network communication between MySQL Connector/ODBC and MySQL.

Outer Join Error

When using some applications to access a MySQL server using Connector/ODBC and outer joins, an error is reported regarding the Outer Join Escape Sequence.

This is a known issue with MySQL Connector/ODBC which is not correctly parsing the "Outer Join Escape Sequence", as per the specs at Microsoft ODBC Specs. Currently, Connector/ODBC will return a value > 0 when asked for `SQL_OJ_CAPABILITIES` even though no parsing takes place in the driver to handle the outer join escape sequence.

Hebrew/CJK Characters

I can correctly store extended characters in the database (Hebrew/CJK) using Connector/ODBC 5.1, but when I retrieve the data, the text is not formatted correctly and I get garbled characters.

When using ASP and UTF8 characters, add the following to your ASP files to ensure that the data returned is correctly encoded:

```
Response.CodePage = 65001
Response.CharSet = "utf-8"
```

Duplicate Entry in Installed Programs List

I have a duplicate MySQL Connector/ODBC entry within my **Installed Programs** list, but I cannot delete one of them.

This problem can occur when you upgrade an existing Connector/ODBC installation, rather than removing and then installing the updated version.

Warning

To fix the problem, use any working uninstallers to remove existing installations; then may have to edit the contents of the registry. Make sure you have a backup of your registry information before attempting any editing of the registry contents.

Values Truncated to 255 Characters

When submitting queries with parameter binding using `UPDATE`, my field values are being truncated to 255 characters.

Ensure that the `FLAG_BIG_PACKETS` option is set for your connection. This removes the 255 character limitation on bound parameters.

Disabling Data-At-Execution

Is it possible to disable data-at-execution using a flag?

If you do not want to use data-at-execution, remove the corresponding calls. For example:

```
SQLLEN ylen = SQL_LEN_DATA_AT_EXEC(10);
SQLBindCol(hstmt,2,SQL_C_BINARY, buf, 10, &ylen);
```

Would become:

```
SQLBindCol(hstmt,2,SQL_C_BINARY, buf, 10, NULL);
```

Note that in the call to `SQLBindCol()`, &ylen has been replaced by NULL.

For further information, refer to the MSDN documentation for `SQLBindCol()`.

NULLABLE Attribute for AUTO_INCREMENT Columns

When you call `SQLColumns()` for a table column that is `AUTO_INCREMENT`, the `NULLABLE` column of the result set is always `SQL_NULLABLE (1)`.

This is because MySQL reports the `DEFAULT` value for such a column as `NULL`. It means, if you insert a `NULL` value into the column, you will get the next integer value for the table's `auto_increment` counter.

Connector/ODBC Support

There are many different places where you can get support for using Connector/ODBC. Always try the Connector/ODBC Mailing List or Connector/ODBC Forum. See Connector/ODBC Community Support, for help before reporting a specific bug or issue to MySQL.

Connector/ODBC Community Support

Oracle provides assistance to the user community by means of its mailing lists. For Connector/ODBC-related issues, you can get help from experienced users by using the `<myodbc@lists.mysql.com>` mailing list. Archives are available online at http://lists.mysql.com/myodbc.

For information about subscribing to MySQL mailing lists or to browse list archives, visit http://lists.mysql.com/. See MySQL Mailing Lists.

Community support from experienced users is also available through the ODBC Forum. You may also find help from other users in the other MySQL Forums, located at http://forums.mysql.com. See MySQL Community Support at the MySQL Forums.

How to Report Connector/ODBC Problems or Bugs

If you encounter difficulties or problems with Connector/ODBC, start by making a log file from the `ODBC Manager` (the log you get when requesting logs from `ODBC ADMIN`) and Connector/ODBC. The procedure for doing this is described in Getting an ODBC Trace File.

Check the Connector/ODBC trace file to find out what could be wrong. Determine what statements were issued by searching for the string `>mysql_real_query` in the `myodbc.log` file.

Also, try issuing the statements from the `mysql` client program or from `admndemo`. This helps you determine whether the error is in Connector/ODBC or MySQL.

If you find out something is wrong, please only send the relevant rows (maximum 40 rows) to the `myodbc` mailing list. See MySQL Mailing Lists. Please never send the whole Connector/ODBC or ODBC log file!

Ideally, include the following information with the email:

- Operating system and version
- Connector/ODBC version
- ODBC Driver Manager type and version
- MySQL server version
- ODBC trace from Driver Manager
- Connector/ODBC log file from Connector/ODBC driver
- Simple reproducible sample

Remember that the more information you can supply to us, the more likely it is that we can fix the problem!

Also, before posting the bug, check the MyODBC mailing list archive at http://lists.mysql.com/myodbc.

If you are unable to find out what is wrong, the last option is to create an archive in `tar` or `zip` format that contains a Connector/ODBC trace file, the ODBC log file, and a `README` file that explains the problem. You can send this to ftp://ftp.mysql.com/pub/mysql/upload/. Only MySQL engineers have access to the files you upload, and we are very discreet with the data.

If you can create a program that also demonstrates the problem, please include it in the archive as well.

If the program works with another SQL server, include an ODBC log file where you perform exactly the same SQL statements so that we can compare the results between the two systems.

Remember that the more information you can supply to us, the more likely it is that we can fix the problem.

How to Submit a Connector/ODBC Patch

You can send a patch or suggest a better solution for any existing code or problems by sending a mail message to `<myodbc@lists.mysql.com>`.

Connector/ODBC Change History

The Connector/ODBC Change History (Changelog) is located with the main Changelog for MySQL. See MySQL Connector/ODBC (MyODBC) Change History.

MySQL Connector/Net

Connector/Net lets you easily develop .NET applications that require secure, high-performance data connectivity with MySQL. It implements the required ADO.NET interfaces and integrates into ADO.NET-aware tools. Developers can build applications using their choice of .NET languages. Connector/Net is a fully managed ADO.NET driver written in 100% pure C#.

Connector/Net includes full support for:

- Features provided by MySQL Server up to and including MySQL Server version 5.5.
- Large-packet support for sending and receiving rows and BLOBs up to 2 gigabytes in size.
- Protocol compression, which enables compressing the data stream between the client and server.
- Connections using TCP/IP sockets, named pipes, or shared memory on Windows.
- Connections using TCP/IP sockets or Unix sockets on Unix.
- The Open Source Mono framework developed by Novell.
- Fully managed, does not utilize the MySQL client library.

This document is intended as a user's guide to Connector/Net and includes a full syntax reference. Syntax information is also included within the `Documentation.chm` file included with the Connector/Net distribution.

If you are using MySQL 5.0 or later, and Visual Studio as your development environment, you can also use the MySQL Visual Studio Plugin. The plugin acts as a DDEX (Data Designer Extensibility) provider: you can use the data design tools within Visual Studio to manipulate the schema and objects within a MySQL database. For more information, see Connector/Net Visual Studio Integration.

Note

Connector/Net 5.1.2 and later include the Visual Studio Plugin by default.

MySQL Connector/Net supports full versions of Visual Studio 2005, 2008, and 2010, although certain features are only available in Visual Studio 2010 when using MySQL Connector/Net version 6.3.2 and later. Note that MySQL Connector/Net does not currently support Express versions of Microsoft products, including Microsoft Visual Web Developer.

Key topics:

- For connection string properties when using the `MySqlConnection` class, see Connector/Net Connection String Options Reference.

Connector/Net Versions

There are several versions of Connector/Net available:

- Connector/Net 6.5 includes support for MySQL Server 5.6, 5.5, 5.1, and 5.0. Important new features include interceptor classes for exceptions and commands, support for the MySQL 5.6 fractional

seconds feature, better partial-trust support, and better IntelliSense, including auto-completion when editing stored procedures or `.mysql` files.

- Connector/Net 6.4 includes support for MySQL Server 5.5, 5.1, and 5.0. Important new features include support for Windows authentication (when connecting to MySQL Server 5.5+), table caching on the client side, simple connection fail-over support, and improved SQL generation from the Entity Framework provider.
- Connector/Net 6.3 includes support for MySQL Server 5.5, 5.1, and 5.0. Important new features include integration with Visual Studio 2010, such as availability of DDL T4 template for Entity Framework, and a custom MySQL SQL Editor. Other features include refactored transaction scope: Connector/Net now supports nested transactions in a scope where they use the same connection string.
- Connector/Net 6.2 includes support for MySQL Server 5.5, 5.1, 5.0, and 4.1. Important new features include a new logging system and client SSL certificates.
- Connector/Net 6.1 includes support for MySQL Server 5.5, 5.1, 5.0, and 4.1. Important new features include the MySQL Website Configuration Tool and a Session State Provider.
- Connector/Net 6.0 includes support for MySQL Server 5.5, 5.1, 5.0, and 4.1.

  This version of Connector/Net is no longer supported.
- Connector/Net 5.2 includes support for MySQL Server 5.5, 5.1, 5.0, and 4.1 features. Connector/Net 5.2 also includes support for a new membership/role provider, Compact Framework 2.0, a new stored procedure parser and improvements to `GetSchema`. Connector/Net 5.2 also includes the Visual Studio Plugin as a standard installable component.

  This version of Connector/Net is no longer supported.
- Connector/Net 5.1 includes support for MySQL Server 5.5, 5.1, 5.0, 4.1, and 4.0 features. Connector/Net 5.1 also includes support for a new membership/role provider, Compact Framework 2.0, a new stored procedure parser and improvements to `GetSchema`. Connector/Net 5.1 also includes the Visual Studio Plugin as a standard installable component.

  This version of Connector/Net is no longer supported.
- Connector/Net 5.0 includes support for MySQL Server 5.1, 5.0, 4.1 and 4.0 features. Connector/Net 5.0 also includes full support for the ADO.Net 2.0 interfaces and subclasses, includes support for the usage advisor and performance monitor (PerfMon) hooks.

  This version of Connector/Net is no longer supported.
- Connector/Net 1.0 includes support for MySQL Server 5.0, 4.1, and 4.0 features, and full compatibility with the ADO.NET driver interface.

  This version of Connector/Net is no longer supported.

The latest source code for Connector/Net can be downloaded from the MySQL public Subversion server. For further details, see Installing Connector/Net from the Source Code.

The following tables shows the .NET Framework version required, and the MySQL Server version supported by Connector/Net:

Table 21.5. Connector/Net Requirements for Related Products

Connector/Net version	ADO.NET version supported	.NET Framework version required	MySQL Server version supported	Currently supported
6.4	2.x+	2.x+, 4.x+ for VS 2010 support	5.5, 5.1, 5.0	Yes

Connector/Net version	ADO.NET version supported	.NET Framework version required	MySQL Server version supported	Currently supported
6.3	2.x+	2.x+, 4.x+ for VS 2010 support	5.5, 5.1, 5.0	Yes
6.2	2.x+	2.x+	5.5, 5.1, 5.0, 4.1	Yes
6.1	2.x+	2.x+	5.5, 5.1, 5.0, 4.1	Yes
6.0	2.x+	2.x+	5.5, 5.1, 5.0, 4.1	Critical issues only
5.2	2.x+	2.x+	5.5, 5.1, 5.0, 4.1	No
5.1	2.x+	2.x+	5.5, 5.1, 5.0, 4.1, 4.0	No
5.0	2.x+	2.x+	5.0, 4.1, 4.0	No
1.0	1.x	1.x	5.0, 4.1, 4.0	No

Note

Version numbers for MySQL products are formatted as X.Y.Z, where Z=0 indicates alpha, Z=1 indicates beta, and Z>=2 indicates GA. However, Windows tools (Control Panel, properties display) may show the version numbers as XX.YY.ZZ. For example, the official MySQL formatted version number 5.0.9 may be displayed by Windows tools as 5.00.09. The two versions are the same; only the number display format is different.

Installing Connector/Net

Connector/Net runs on any platform that supports the .NET framework. The .NET framework is primarily supported on recent versions of Microsoft Windows, and is supported on Linux through the Open Source Mono framework (see http://www.mono-project.com).

Connector/Net is available for download from http://dev.mysql.com/downloads/connector/net/.

Installing Connector/Net on Windows

On Windows, you can install either through a binary installation process or by downloading a zip file with the Connector/Net components.

Before installing, ensure that your system is up to date, including installing the latest version of the .NET Framework.

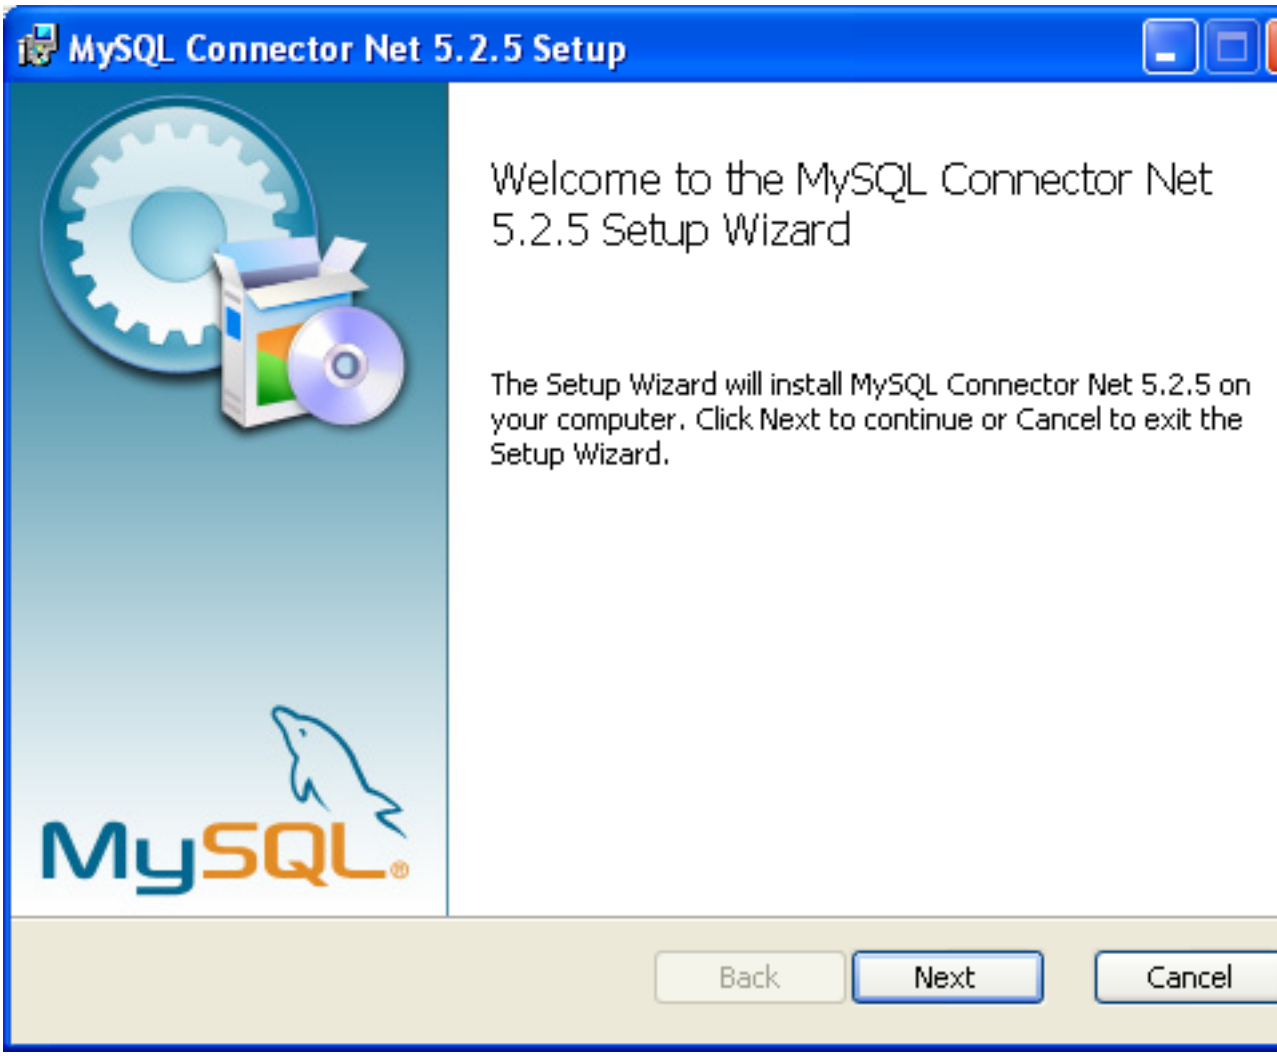
Installing Connector/Net using the Installer

Using the installer is the most straightforward method of installing Connector/Net on Windows and the installed components include the source code, test code and full reference documentation.

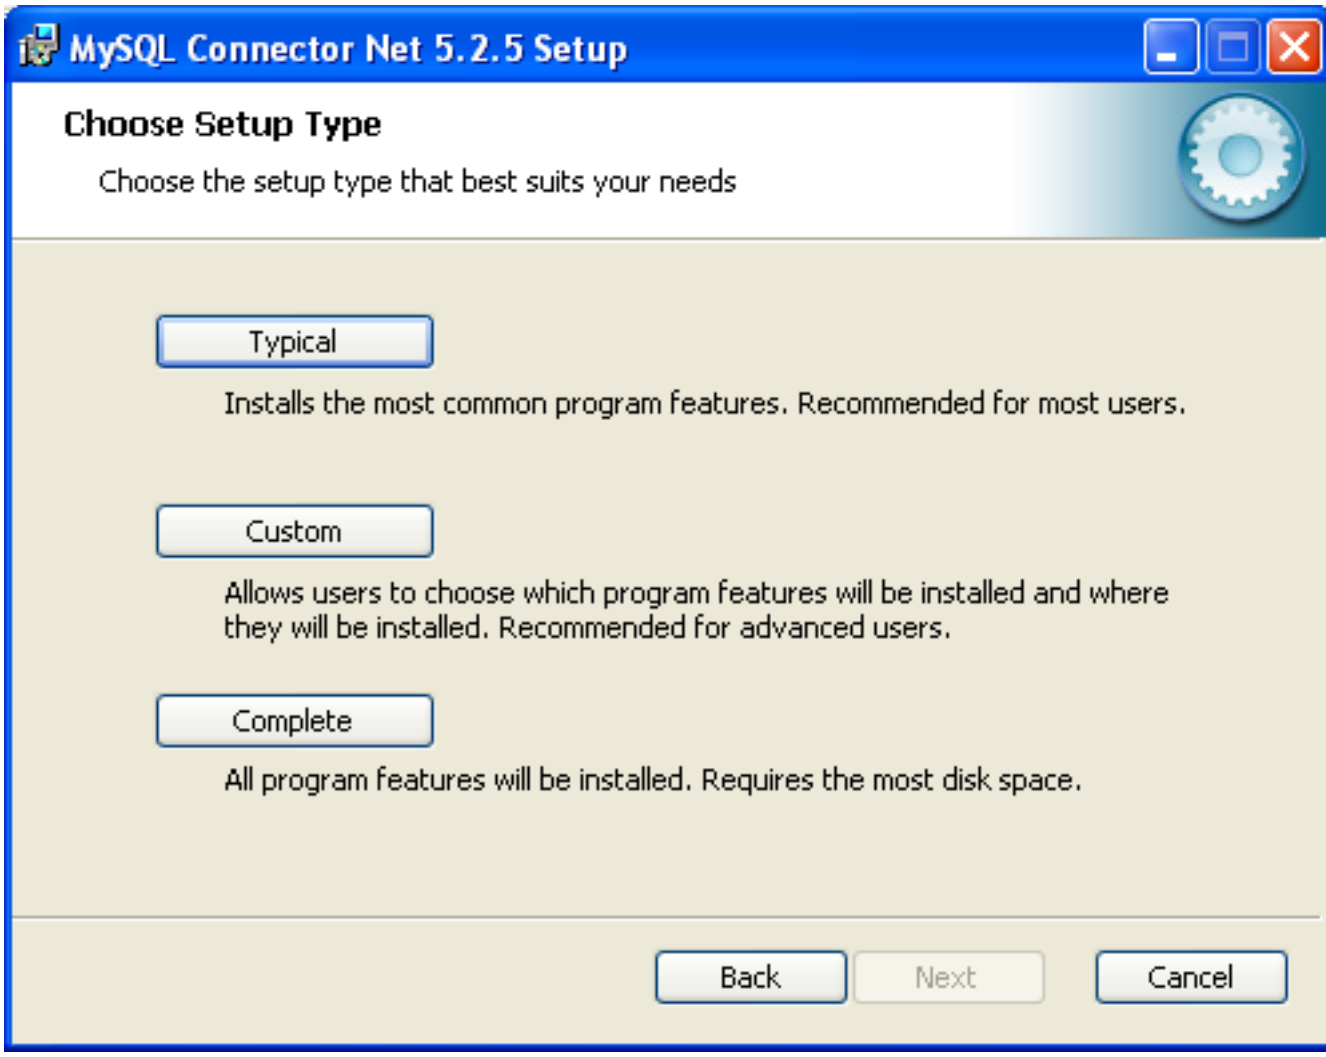
You install Connector/Net through a Windows Installer (`.msi`) installation package, which can install Connector/Net on all Windows operating systems. The MSI package is contained within a zip archive named `mysql-connector-net-`*`version`*`.zip`, where *`version`* indicates the Connector/Net version.

To install Connector/Net:

1. Double-click the MSI installer file extracted from the zip you downloaded. Click Next to start the installation.



2. You must choose the type of installation to perform.



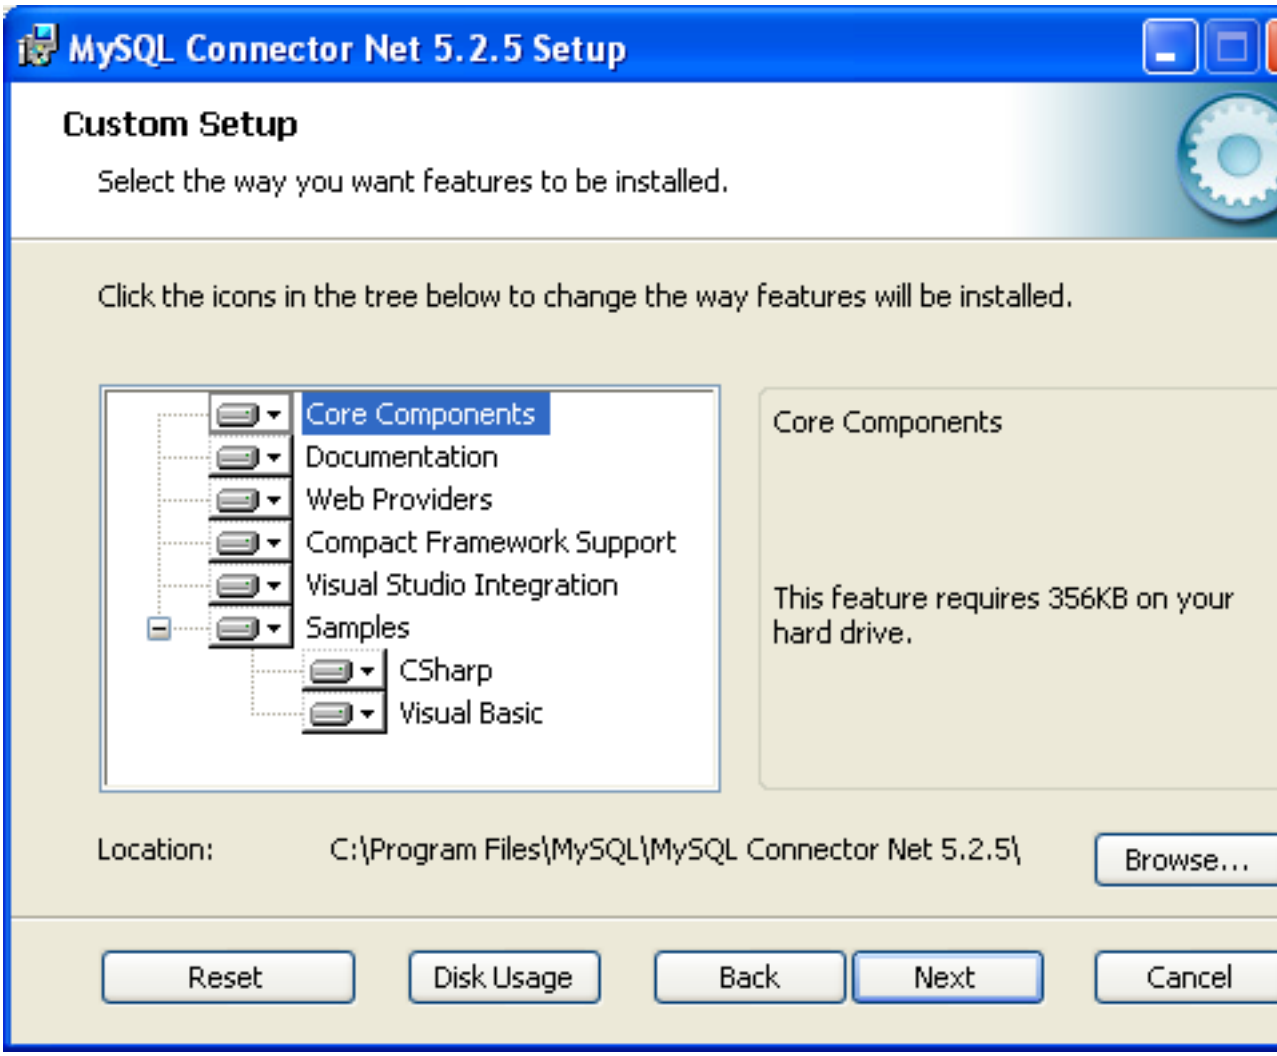
For most situations, the Typical installation is suitable. Click the Typical button and proceed to Step 5. A Complete installation installs all the available files. To conduct a Complete installation, click the Complete button and proceed to step 5. To customize your installation, including choosing the components to install and some installation options, click the Custom button and proceed to Step 3.

The Connector/Net installer will register the connector within the Global Assembly Cache (GAC) - this will make the Connector/Net component available to all applications, not just those where you explicitly reference the Connector/Net component. The installer will also create the necessary links in the Start menu to the documentation and release notes.

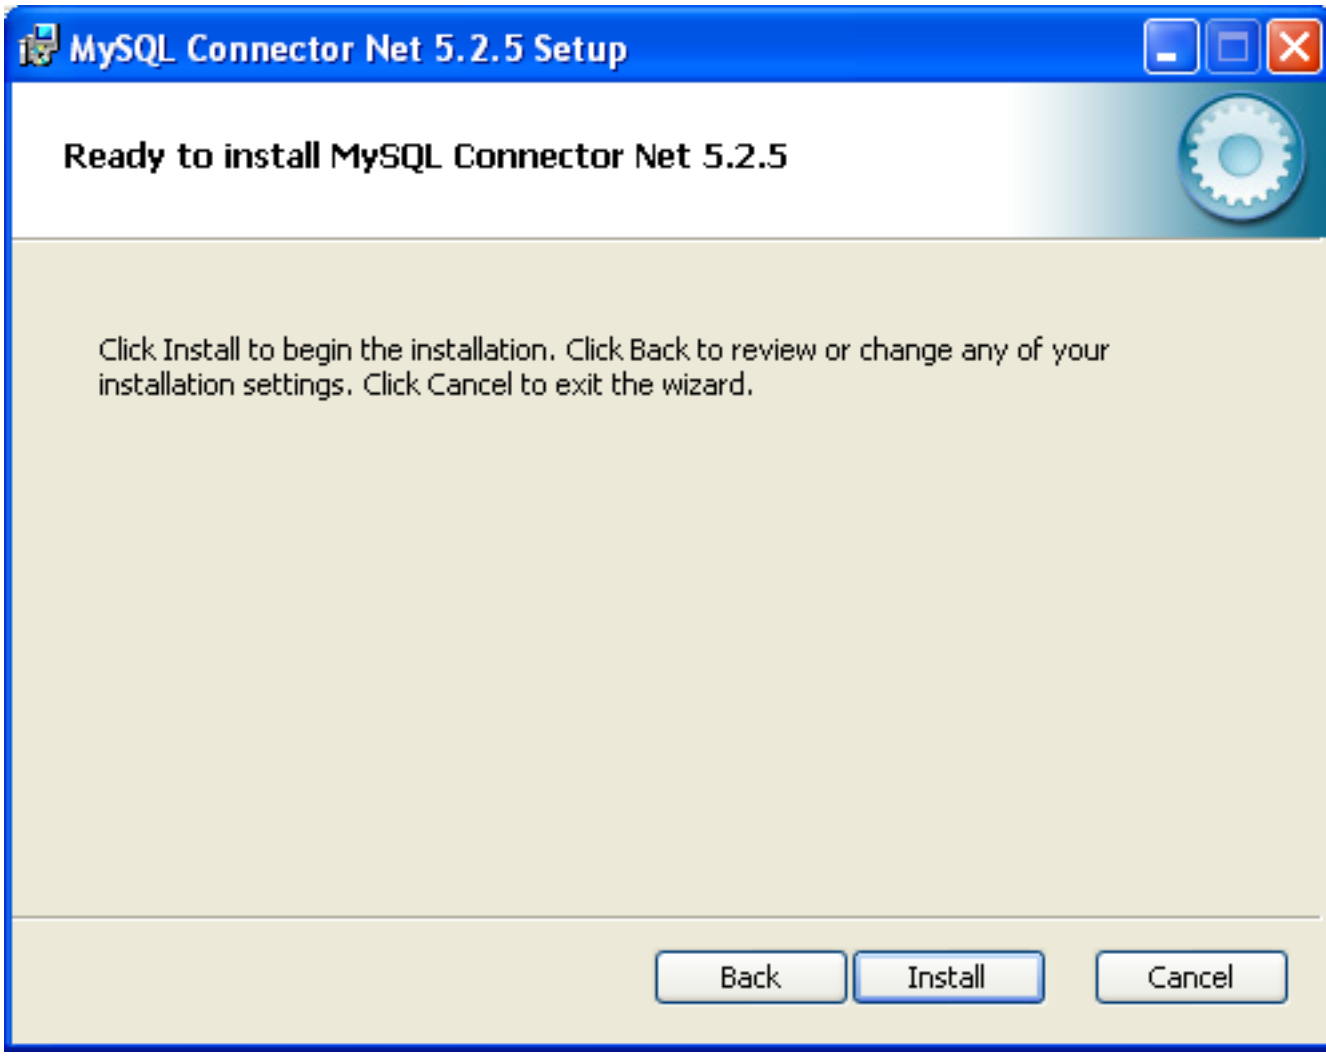
3. If you have chosen a custom installation, you can select the individual components to install, including the core interface component, supporting documentation (a CHM file) samples and examples, and the source code. Select the items, and their installation level, and then click Next to continue the installation.

Note

For Connector/Net 1.0.8 or lower and Connector 5.0.4 and lower the installer will attempt to install binaries for both 1.x and 2.x of the .NET Framework. If you only have one version of the framework installed, the connector installation may fail. If this happens, you can choose the framework version to be installed through the custom installation step.



4. You will be given a final opportunity to confirm the installation. Click Install to copy and install the files onto your machine.



5. Once the installation has been completed, click Finish to exit the installer.

Unless you choose otherwise, Connector/Net is installed in `C:\Program Files\MySQL\MySQL Connector Net X.X.X`, where *`X.X.X`* is replaced with the version of Connector/Net you are installing. New installations do not overwrite existing versions of Connector/Net.

Depending on your installation type, the installed components will include some or all of the following components:

- `bin`: Connector/Net MySQL libraries for different versions of the .NET environment.
- `docs`: Connector/Net documentation in CHM format.
- `samples`: Sample code and applications that use the Connector/Net component.
- `src`: The source code for the Connector/Net component.

You may also use the `/quiet` or `/q` command-line option with the `msiexec` tool to install the Connector/Net package automatically (using the default options) with no notification to the user. Using this method the user cannot select options. Additionally, no prompts, messages or dialog boxes will be displayed.

```
C:\> msiexec /package connector-net.msi /quiet
```

To provide a progress bar to the user during automatic installation, use the `/passive` option.

Installing Connector/Net Using the Zip Packages

If you have problems running the installer, you can download a zip file without an installer as an alternative. That file is called `mysql-connector-net-version-noinstall.zip`. After downloading the zip archive, extract the files to a location of your choice.

The file contains the following directories:

- `bin`: Connector/Net MySQL libraries for different versions of the .NET environment.
- `Docs`: Connector/Net documentation in CHM format.
- `Samples`: Sample code and applications that use the Connector/Net component.

Connector/Net 6.0.x has a different directory structure:

- `Assemblies`: A collection of DLLs that make up the connector functionality.
- `Documentation`: Connector/Net documentation in CHM format.
- `Samples`: sample code and applications that use the Connector/Net component.

Another zip file available for download contains the source code distribution. This file is named `mysql-connector-net-version-src.zip`.

The file contains the following directories:

- `Documentation`: Source files to build the documentation into the compiled HTML (CHM) format.
- `Installer`: Source files to build the Connector/Net installer program.
- `MySql.Data`: Source files for the core data provider.
- `MySql.VisualStudio`: Source files for the Microsoft Visual Studio extensions.
- `MySql.Web`: Source files for the web providers. This includes code for the membership provider, role provider and profile provider. These are used in ASP.NET web sites.
- `Samples`: Source files for several example applications.
- `Tests`: A spreadsheet listing test cases.
- `VisualStudio`: Resources used by the Visual Studio plugin.

Finally, ensure that `MySql.Data.dll` is accessible to your program at build time (and run time). If using Microsoft Visual Studio, add `MySql.Data` as a Reference to your project.

Note

If using MySQL Connector/Net 6.3.5 and above, the `MySql.Data.dll` file provided will work with both .NET Framework 2.x and 4.x.

Installing Connector/Net on Unix with Mono

There is no installer available for installing the Connector/Net component on your Unix installation. Before installing, ensure that you have a working Mono project installation. To test whether your system has Mono installed, enter:

```
shell> mono --version
```

The version of the Mono JIT compiler is displayed.

To compile C# source code, make sure a Mono C# compiler is installed. Note that there are two Mono C# compilers available, `mcs`, which accesses the 1.0-profile libraries, and `gmcs`, which accesses the 2.0-profile libraries.

To install Connector/Net on Unix/Mono:

1. Download the `mysql-connector-net-version-noinstall.zip` and extract the contents to a directory of your choice, for example: `~/connector-net/`.

2. In the directory where you unzipped the connector to, change into the `bin` subdirectory. Ensure the file `MySql.Data.dll` is present. This filename is case-sensitive.

3. You must register the Connector/Net component, `MySql.Data`, in the Global Assembly Cache (GAC). In the current directory enter the `gacutil` command:

   ```
   root-shell> gacutil /i MySql.Data.dll
   ```

   This will register `MySql.Data` into the GAC. You can check this by listing the contents of `/usr/lib/mono/gac`, where you will find `MySql.Data` if the registration has been successful.

You are now ready to compile your application. You must ensure that when you compile your application you include the Connector/Net component using the `-r:` command-line option. For example:

```
shell> gmcs -r:System.dll -r:System.Data.dll -r:MySql.Data.dll HelloWorld.cs
```

Note, the assemblies that are referenced depend on the requirements of the application, but applications using Connector/Net must provide `-r:MySql.Data` as a minimum.

You can further check your installation by running the compiled program, for example:

```
shell> mono HelloWorld.exe
```

Installing Connector/Net from the Source Code

Caution

Read this section only if you are interested in helping us test our new code. If you just want to get Connector/Net up and running on your system, use a standard release distribution.

Obtaining the Source Code

To obtain the most recent development source tree, first download and install Bazaar. You can obtain Bazaar from the Bazaar VCS Website. Bazaar is supported by any platform that supports Python, and is therefore compatible with any Linux, Unix, Windows or Mac OS X host. Instructions for downloading and installing Bazaar on the different platforms are available on the Bazaar Web site.

The most recent development source tree is available from our public Subversion trees at http://dev.mysql.com/tech-resources/sources.html.

To check out out the Connector/Net sources, change to the directory where you want the copy of the Connector/Net tree to be stored, then use the following command:

```
shell> bzr branch lp:connectornet/trunk
```

To download a specific version of Connector/Net, specify the version number instead of `trunk`. For example, to obtain a copy of the 6.0 version of the source tree:

```
shell> bzr branch lp:connectornet/6.0
```

Source packages are also available on the downloads page.

Building the Source Code on Windows

The following procedure can be used to build the connector on Microsoft Windows.

- Obtain the source code, either from the Subversion server, or through one of the prepared source code packages.
- Navigate to the root of the source code tree.
- A Microsoft Visual Studio 2005 solution file is available to build the connector, this is called `MySQL-VS2005.sln`. Click this file to load the solution into Visual Studio.
- Select Build, Build Solution from the main menu to build the solution.

Building the Source Code on Unix

Support for building Connector/Net on Mono/Unix is currently not available.

Connector/Net Visual Studio Integration

When MySQL Connector/Net is installed on Microsoft Windows, Visual Studio integration components are also installed and initialized. This enables the developer to work seamlessly with MySQL Connector/Net in the familiar Visual Studio environment, as described in the following sections of the manual.

MySQL Connector/Net supports Visual Studio versions 2005, 2008, and 2010. However, only MySQL Connector/Net version 6.3 and higher fully integrate with Visual Studio 2010, although applications using earlier versions of the connector can be built with the Visual Studio 2010 environment using .NET 2.x frameworks.

Visual Studio 2010 support was introduced with MySQL Connector/Net 6.3.2. From version 6.3.2 the connector ships with both .NET 2.x and .NET 4.x versions of the entity framework support files, `mysql.data.ef.dll` and `mysql.visualstudio.dll`. The .NET 4.x versions are required to enable new integration features supported in Visual Studio 2010, including:

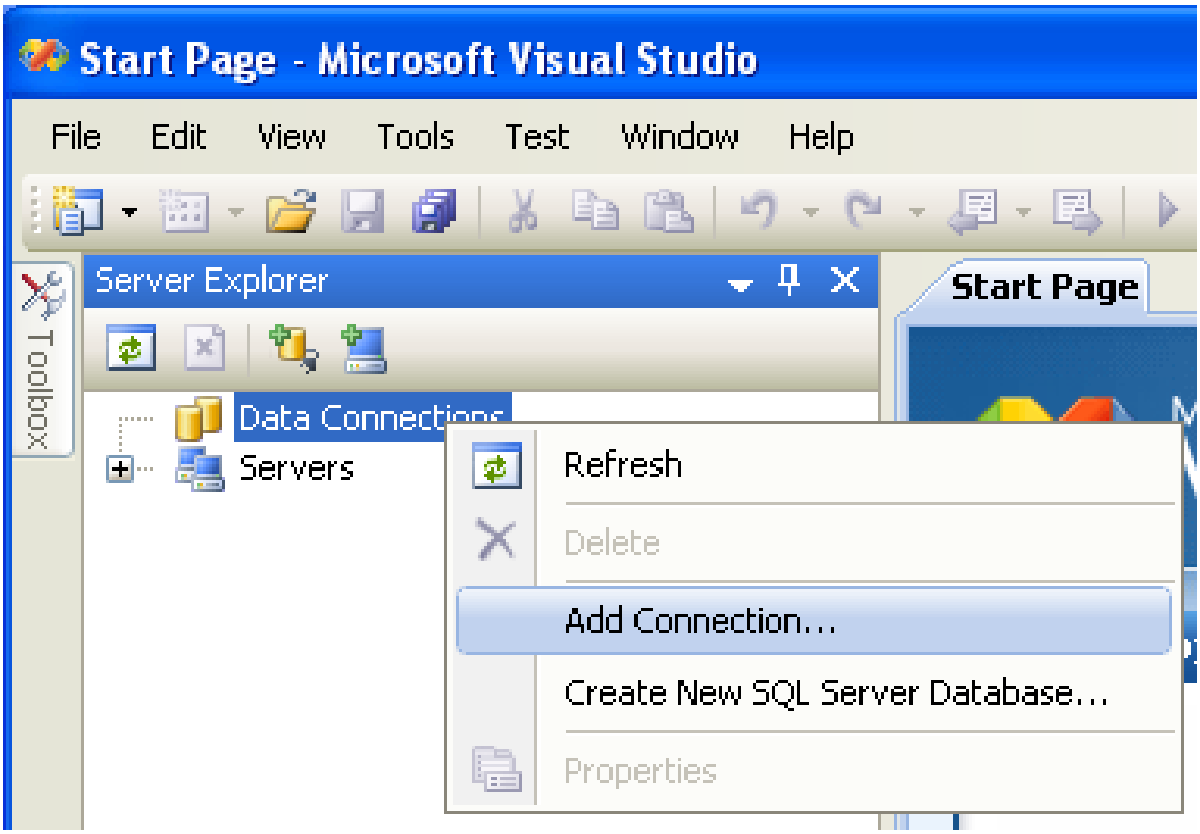
- New DDL T4 template for the Entity Framework (EF) - This enables developers to design an EF model from scratch and use the native Visual Studio 2010 facility to generate MySQL DDL from that model. This is done by creating the model, and with the model open, choosing the SSDLToMySQL template in the properties window. The correct DDL is then generated. The developer can then save this code as a `.mysql` file in their project and execute it against the MySQL server.
- New SQL Editor - A new SQL editor lets you connect to a MySQL server to execute SQL. This is activated by creating a new file with a `.mysql` extension. A new template lets you create files with this file type using the Visual Studio 2010 main menu item File, New. Note that the MySQL SQL Editor is also available in Visual Studio 2005 and 2008.

Making a Connection

Once the connector is installed, you can use it to create, modify, and delete connections to MySQL databases. To create a connection with a MySQL database, perform the following steps:

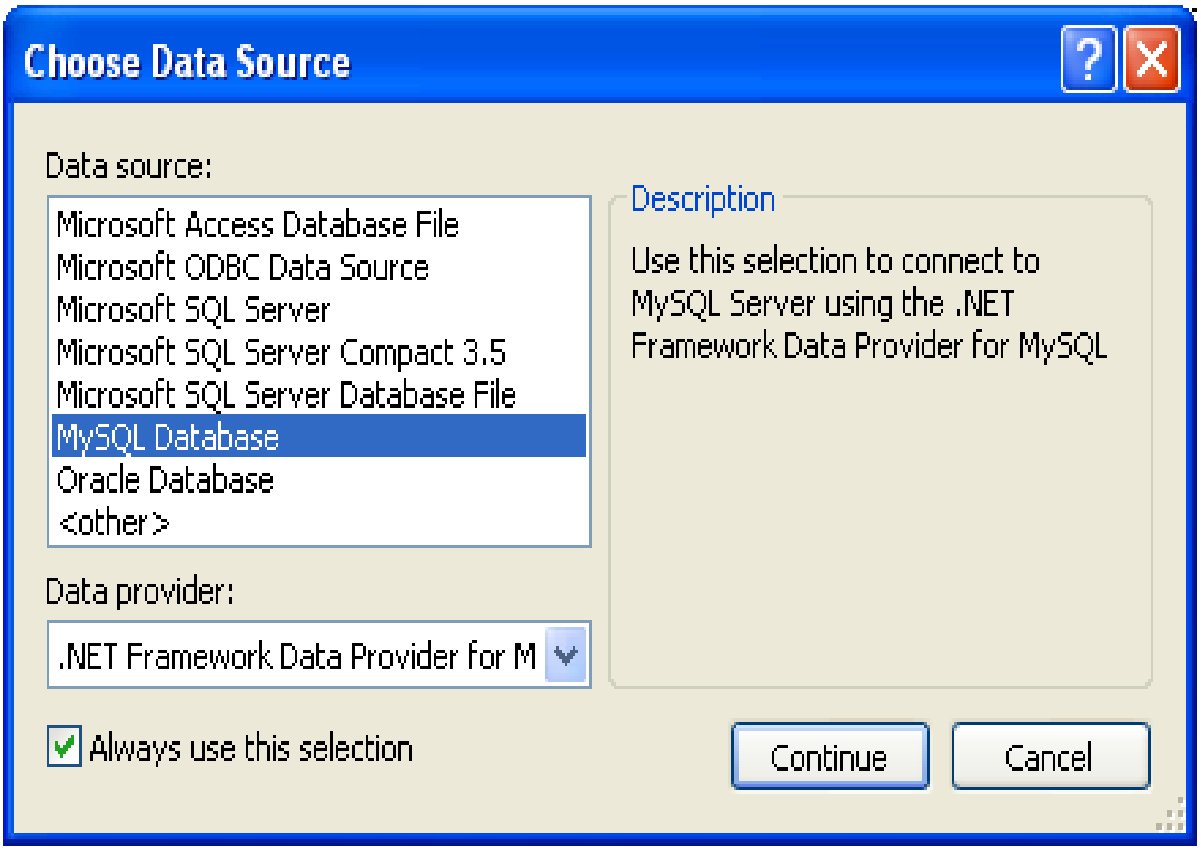
- Start Visual Studio, and open the Server Explorer window (View, Server Explorer option in the main Visual Studio menu, or **Control+W**, **L** keyboard shortcuts).
- Right-click the Data Connections node, and choose the Add Connection... menu item.
- Add Connection dialog opens. Press the Change button to choose MySQL Database as a data source.

Figure 21.1. Add Connection Context Menu



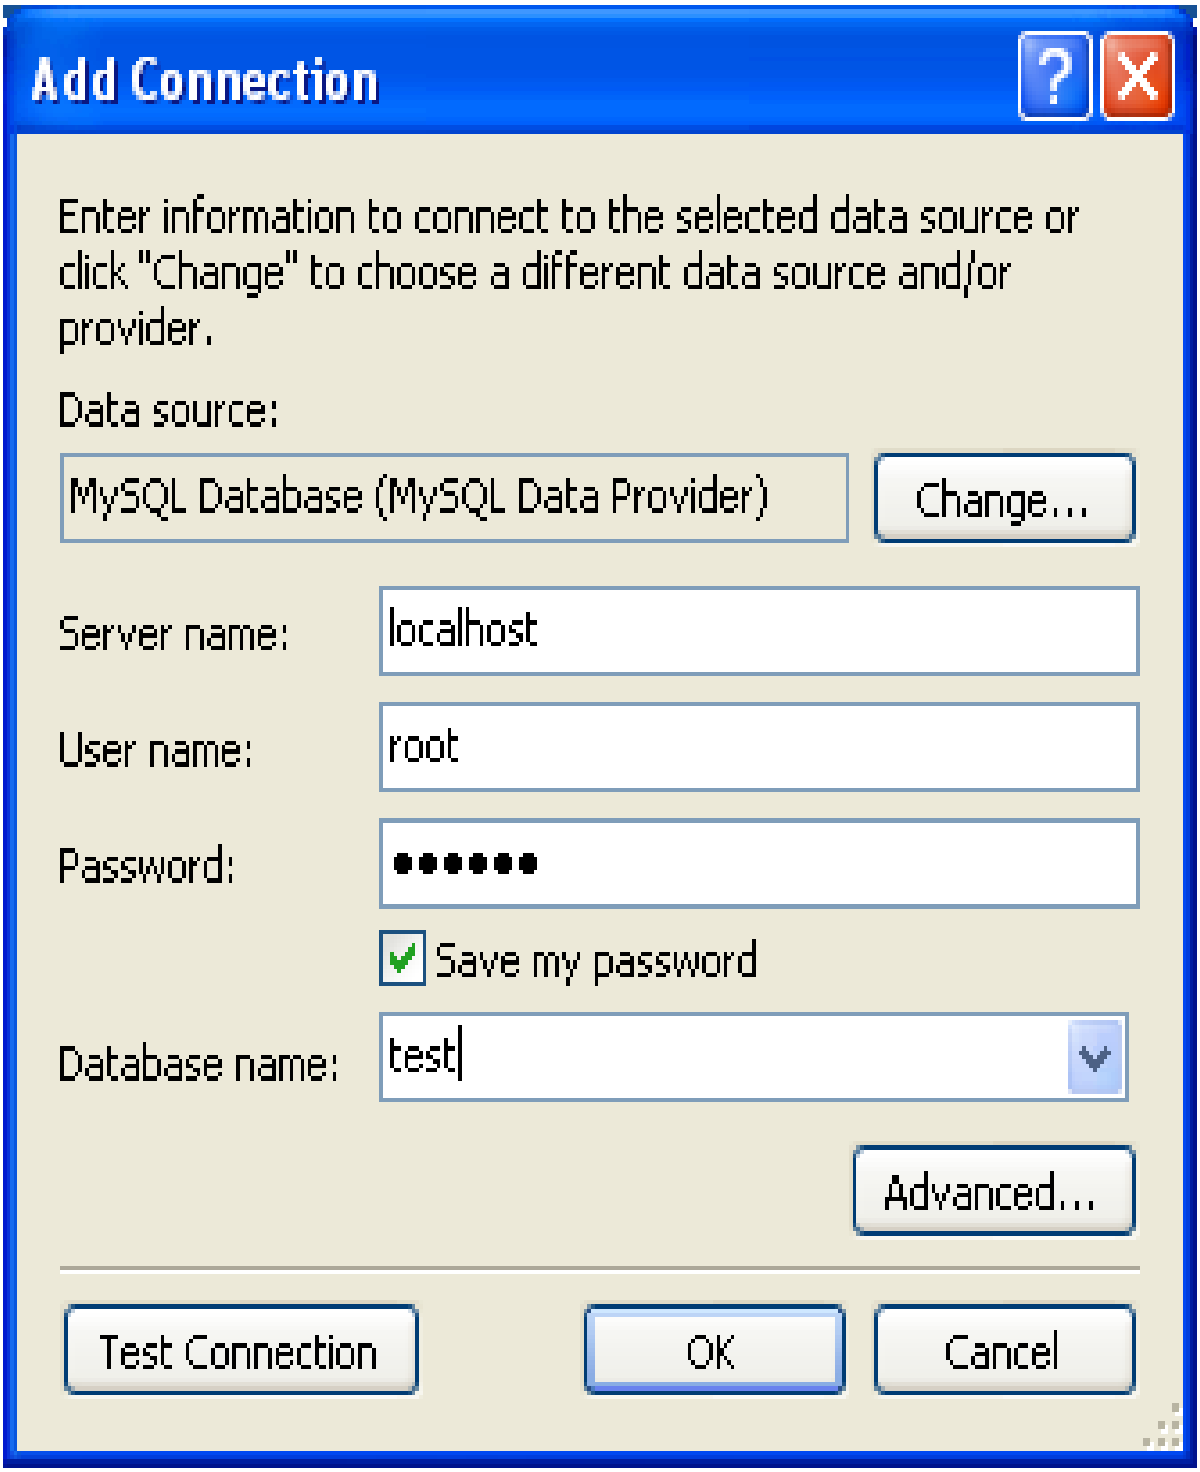
- **Change Data Source** dialog opens. Choose **MySQL Database** in the list of data sources (or the `<other>` option, if MySQL Database is absent), and then choose **.NET Framework Data Provider for MySQL** in the combo box of data providers.

Figure 21.2. Choose Data Source



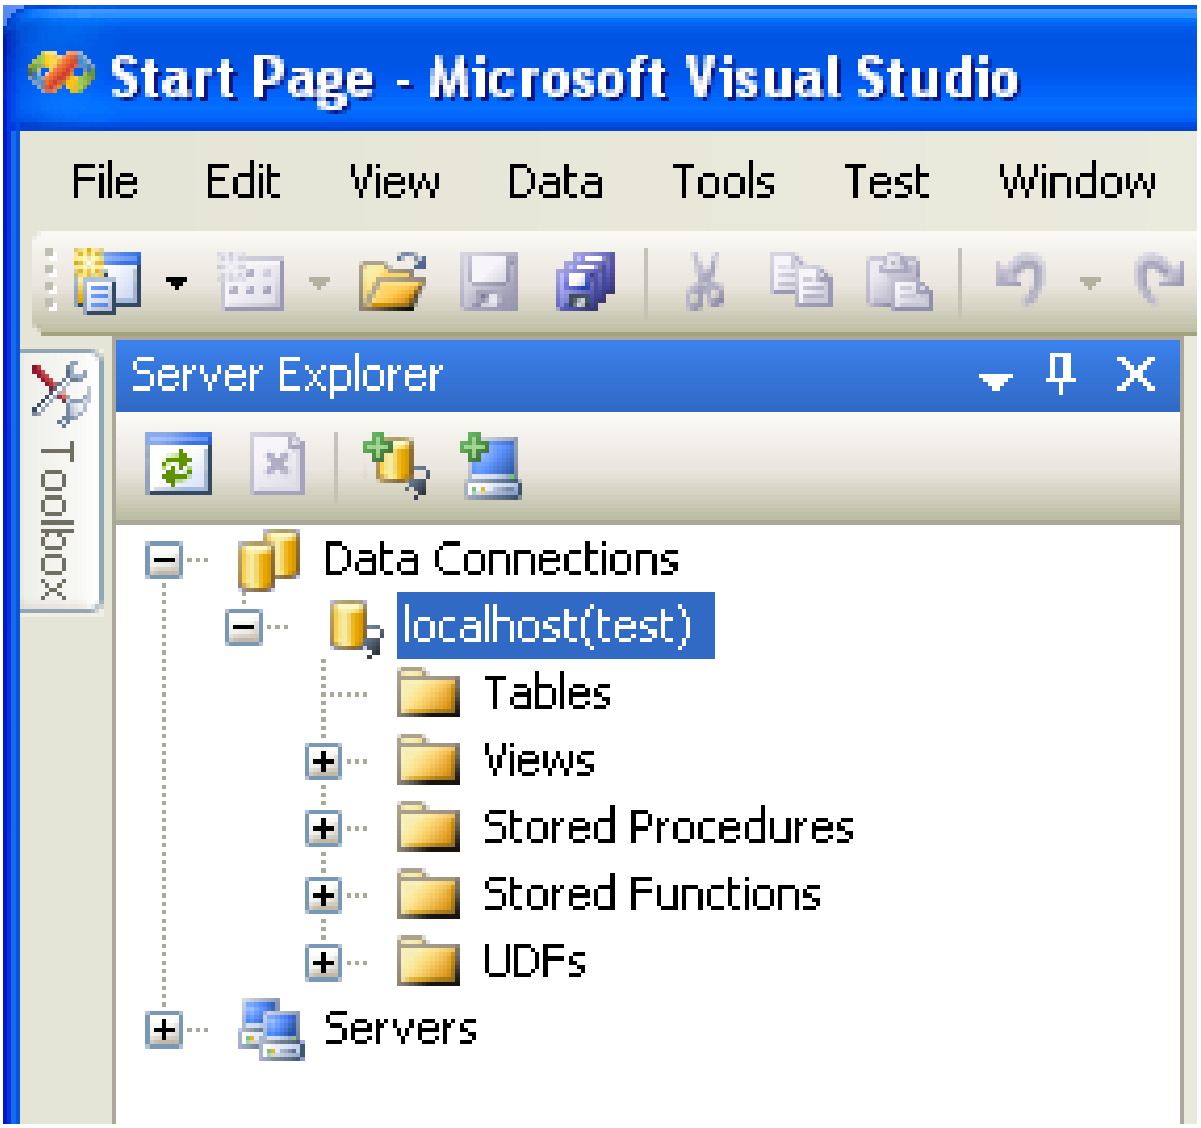
- Input the connection settings: the server host name (for example, localhost if the MySQL server is installed on the local machine), the user name, the password, and the default schema name. Note that you must specify the default schema name to open the connection.

Figure 21.3. Add Connection Dialog



- You can also set the port to connect with the MySQL server by pressing the Advanced button. To test connection with the MySQL server, set the server host name, the user name, and the password, and press the Test Connection button. If the test succeeds, the success confirmation dialog opens.
- After you set all settings and test the connection, press OK. The newly created connection is displayed in Server Explorer. Now you can work with the MySQL server through standard Server Explorer GUI.

Figure 21.4. New Data Connection



After the connection is successfully established, all settings are saved for future use. When you start Visual Studio for the next time, open the connection node in Server Explorer to establish a connection to the MySQL server again.

To modify and delete a connection, use the Server Explorer context menu for the corresponding node. You can modify any of the settings by overwriting the existing values with new ones. Note that the connection may be modified or deleted only if no active editor for its objects is opened: otherwise, you may lose your data.

Using IntelliSense in the SQL Editor

IntelliSense support is available starting in Connector/Net 6.5. Once you have established a connection, for example, using the Connect to MySql toolbar button, you can get autocompletion as you type, or by pressing **Control+J**. Depending on the context, the autocompletion dialog can show the list of available tables, table columns, or stored procedures (with the routine's signature as a tooltip). Typing some characters before pressing **Control+J** filters the choices to those items starting with that prefix.

Editing Tables

Connector/Net contains a table editor, which enables the visual creation and modification of tables.

The Table Designer can be accessed through a mouse action on table-type node of Server Explorer. To create a new table, right-click the **Tables** node (under the connection node) and choose the Create Table command from the context menu.

To modify an existing table, double-click the node of the table to modify, or right-click this node and choose the Design item from the context menu. Either of the commands opens the Table Designer.

The table editor is implemented in the manner of the well-known Query Browser Table Editor, but with minor differences.

Figure 21.5. Editing New Table

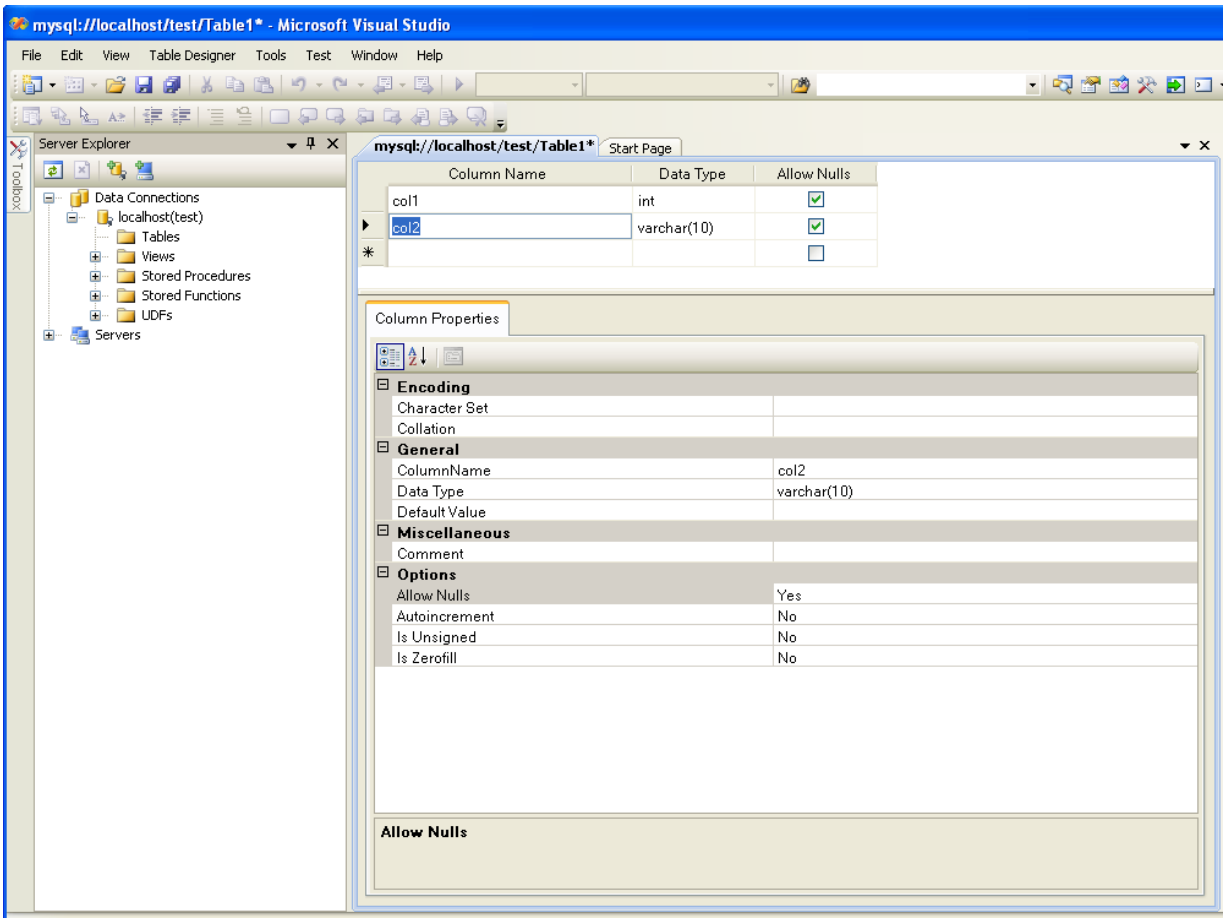


Table Designer consists of the following parts:

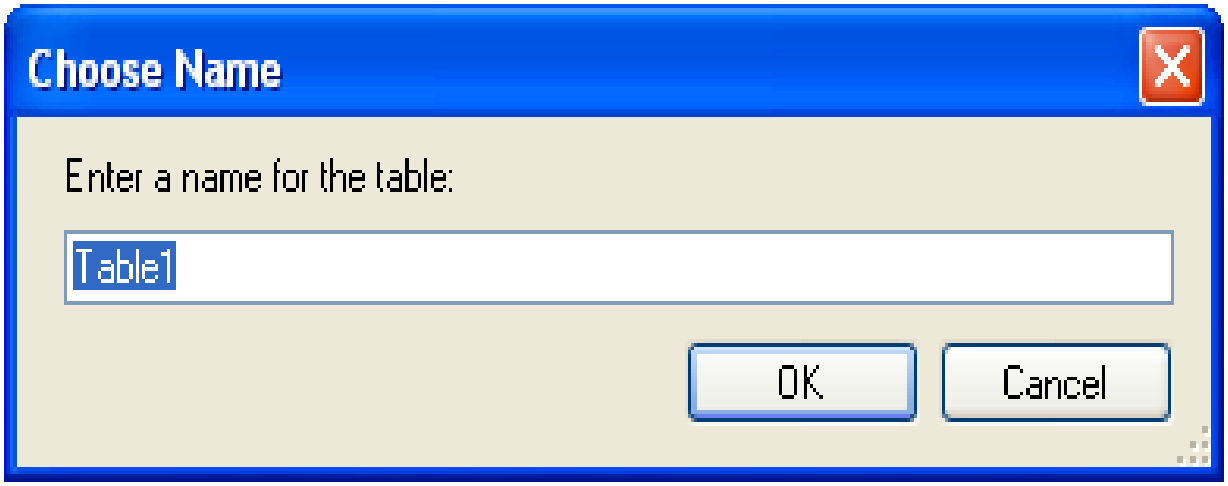
- Columns Editor - a data grid on top of the Table Designer. Use the Columns grid for column creation, modification, and deletion.
- Indexes tab - a tab on bottom of the Table Designer. Use the Indexes tab for indexes management.
- Foreign Keys tab - a tab on bottom of the Table Designer. Use the Foreign Keys tab for foreign keys management.
- Column Details tab - a tab on bottom of the Table Designer. Use the Column Details tab to set advanced column options.
- Properties window - a standard Visual Studio Properties window, where the properties of the edited table are displayed. Use the Properties window to set the table properties.

Each of these areas is discussed in more detail in subsequent sections.

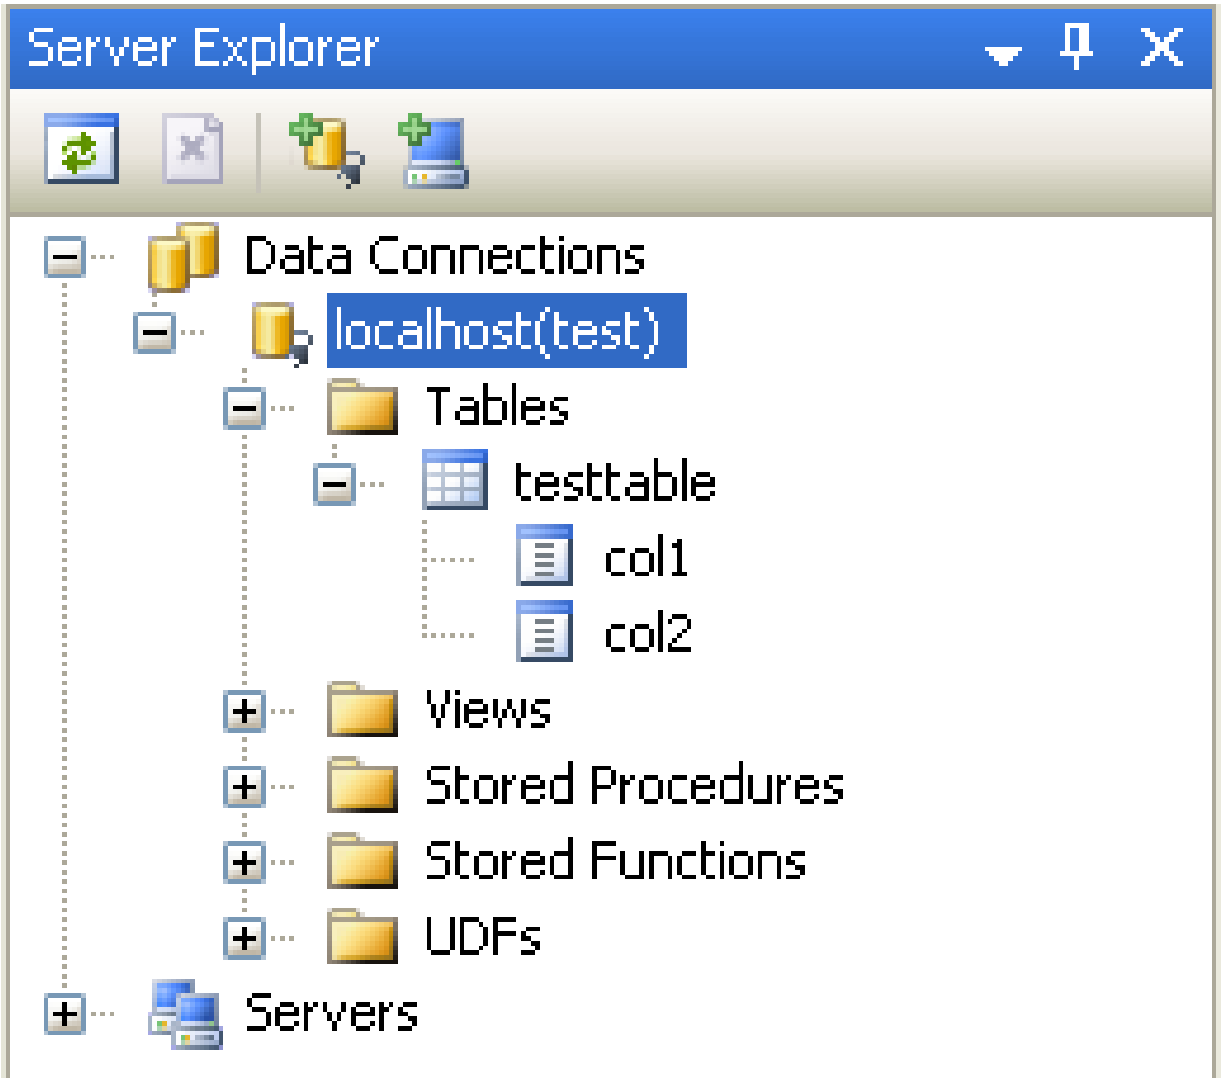
To save changes you have made in the Table Designer, use either Save or Save All button of the Visual Studio main toolbar, or press **Control+S**. If you have not already named the table, you will be prompted to do so.

Figure 21.6. Choose Table Name



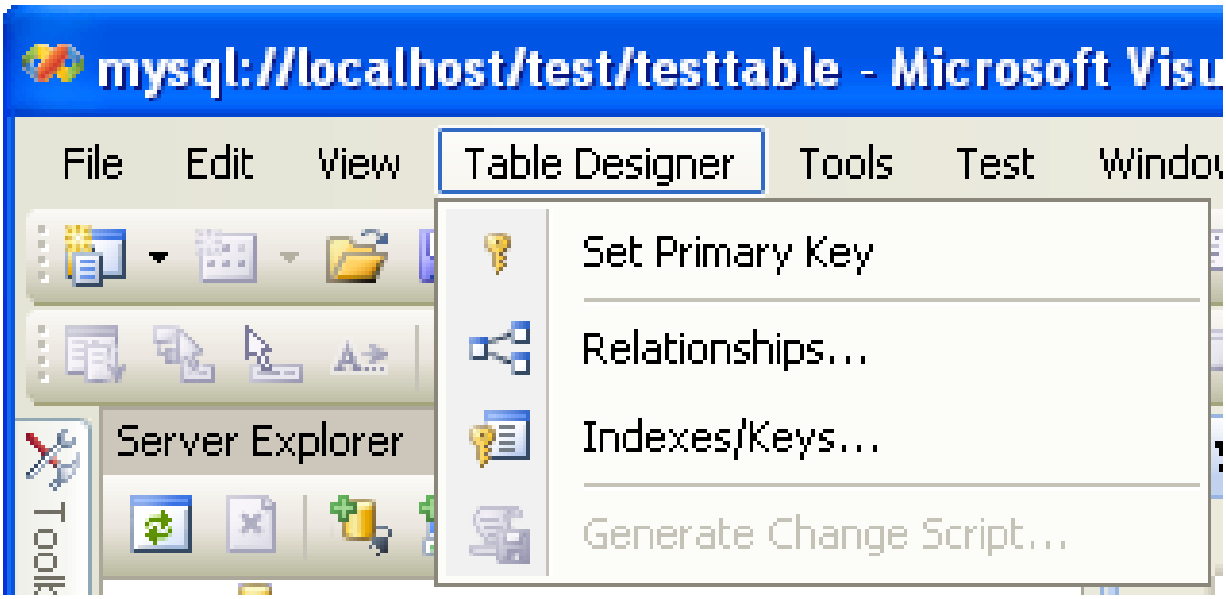
Once the table is created, you can view it in the Server Explorer.

Figure 21.7. Newly Created Table



The Table Designer main menu lets you set a primary key column, edit relationships such as foreign keys, and create indexes.

Figure 21.8. Table Designer Main Menu



Column Editor

You can use the Column Editor to set or change the name, data type, default value, and other properties of a table column. To set the focus to a needed cell of a grid, use the mouse click. Also you can move through the grid using **Tab** and **Shift**+**Tab** keys.

To set or change the name, data type, default value and comment of a column, activate the appropriate cell and type the desired value.

To set or unset flag-type column properties (`NOT NULL`, auto incremented, flags), check or uncheck the corresponding check boxes. Note that the set of column flags depends on its data type.

To reorder columns, index columns or foreign key columns in the Column Editor, select the whole column to reorder by clicking the selector column on the left of the column grid. Then move the column by using **Control+Up** (to move the column up) or **Control+Down** (to move the column down) keys.

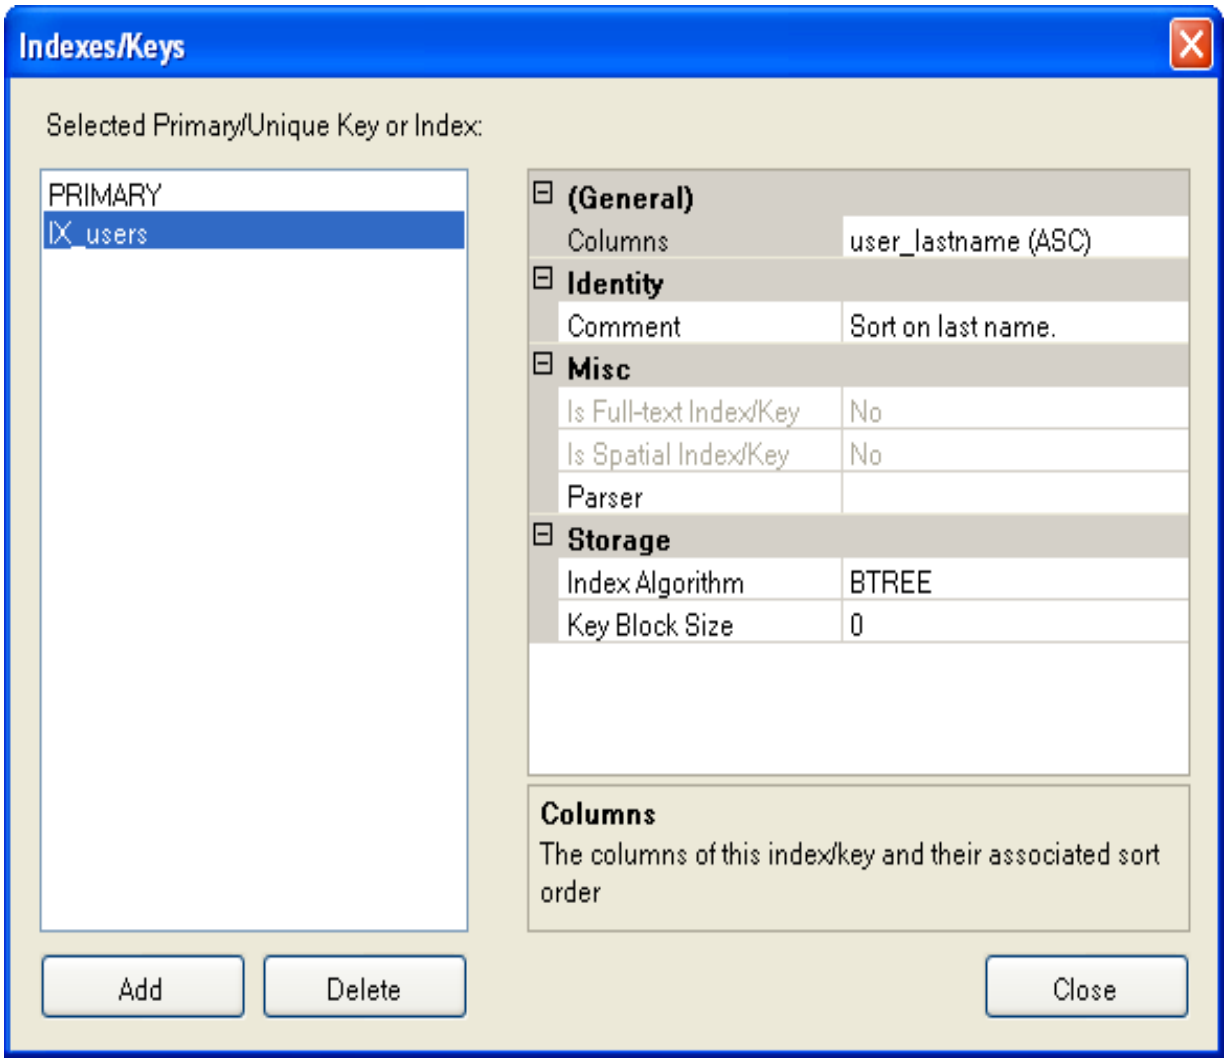
To delete a column, select it by clicking the selector column on the left of the column grid, then press the **Delete** button on a keyboard.

Editing Indexes

Indexes management is performed using the **Indexes/Keys** dialog.

To add an index, select Table Designer, Indexes/Keys... from the main menu, and click Add to add a new index. You can then set the index name, index kind, index type, and a set of index columns.

Figure 21.9. Indexes Dialog



To remove an index, select it in the list box on the left, and click the Delete button.

To change index settings, select the needed index in the list box on the left. The detailed information about the index is displayed in the panel on the right hand side. Change the desired values.

Editing Foreign Keys

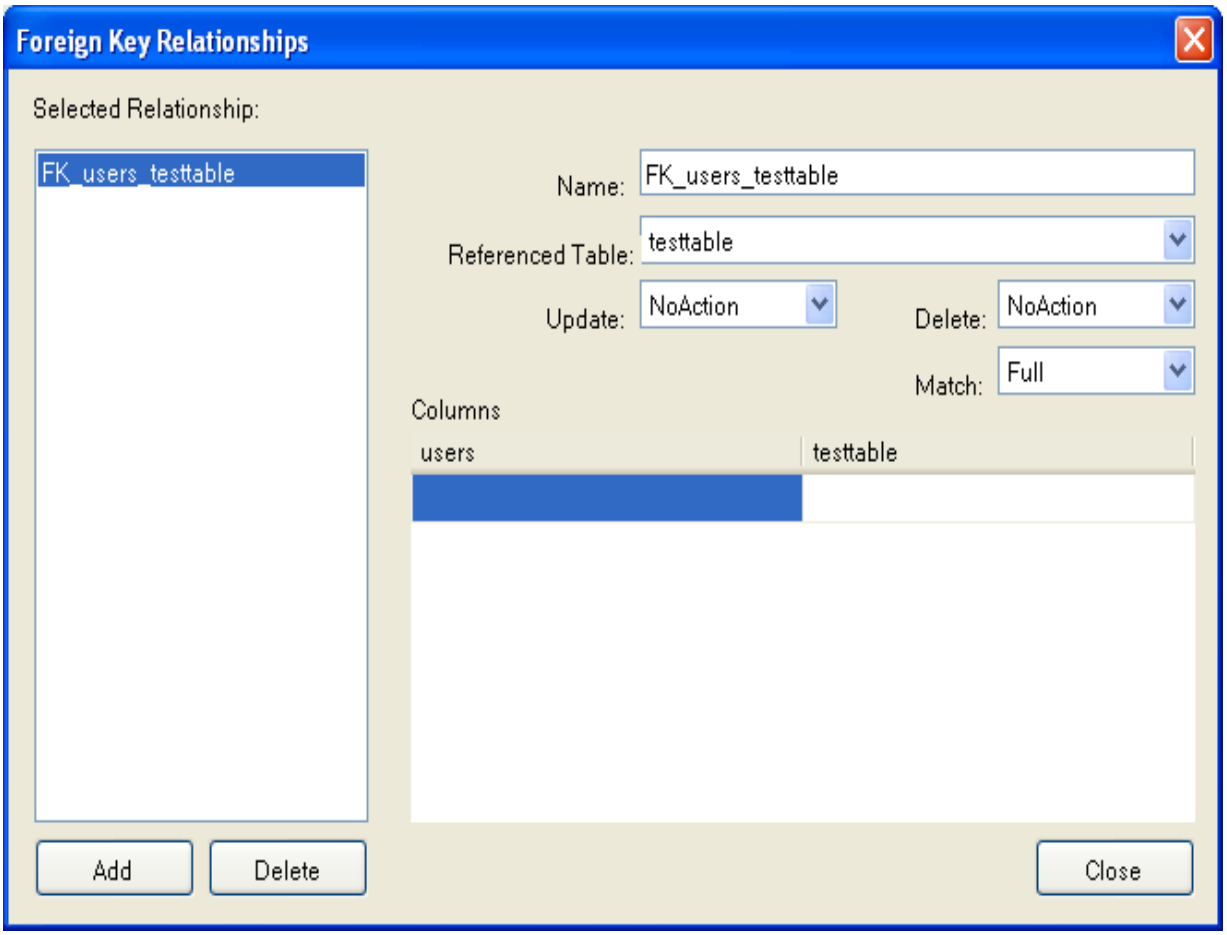
You manage foreign keys for `InnoDB` tables using the **Foreign Key Relationships** dialog.

To add a foreign key, select Table Designer, Relationships... from the main menu. This displays the **Foreign Key Relationship** dialog. Click Add. You can then set the foreign key name, referenced table name, foreign key columns, and actions upon update and delete.

To remove a foreign key, select it in the list box on the left, and click the Delete button.

To change foreign key settings, select the required foreign key in the list box on the left. The detailed information about the foreign key is displayed in the right hand panel. Change the desired values.

Figure 21.10. Foreign Key Relationships Dialog



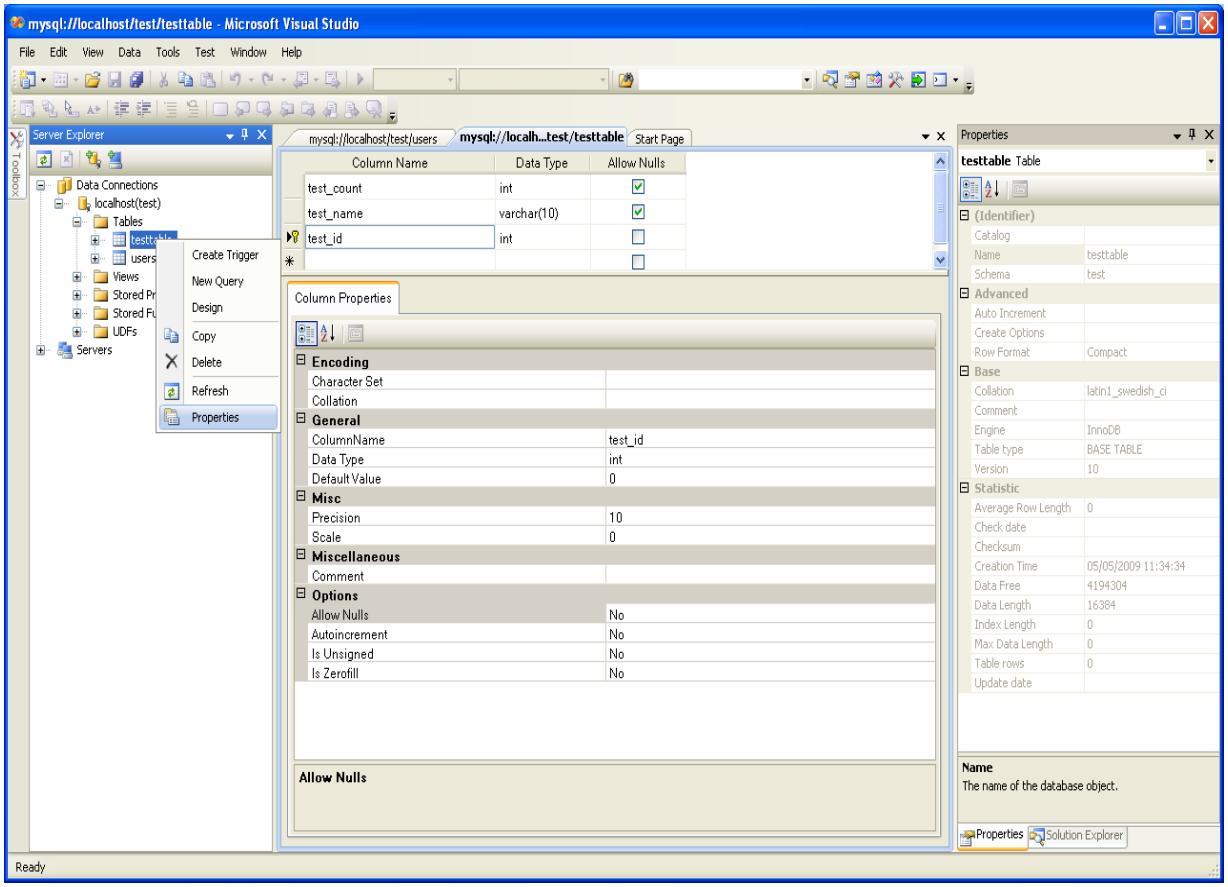
Column Properties

The **Column Properties** tab can be used to set column options. In addition to the general column properties presented in the Column Editor, in the **Column Properties** tab you can set additional properties such as Character Set, Collation and Precision.

Table Properties

To bring up Table Properties select the table and right-click to activate the context menu. Select Properties. The **Table Properties** dockable window will be displayed.

Figure 21.11. Table Properties Menu Item

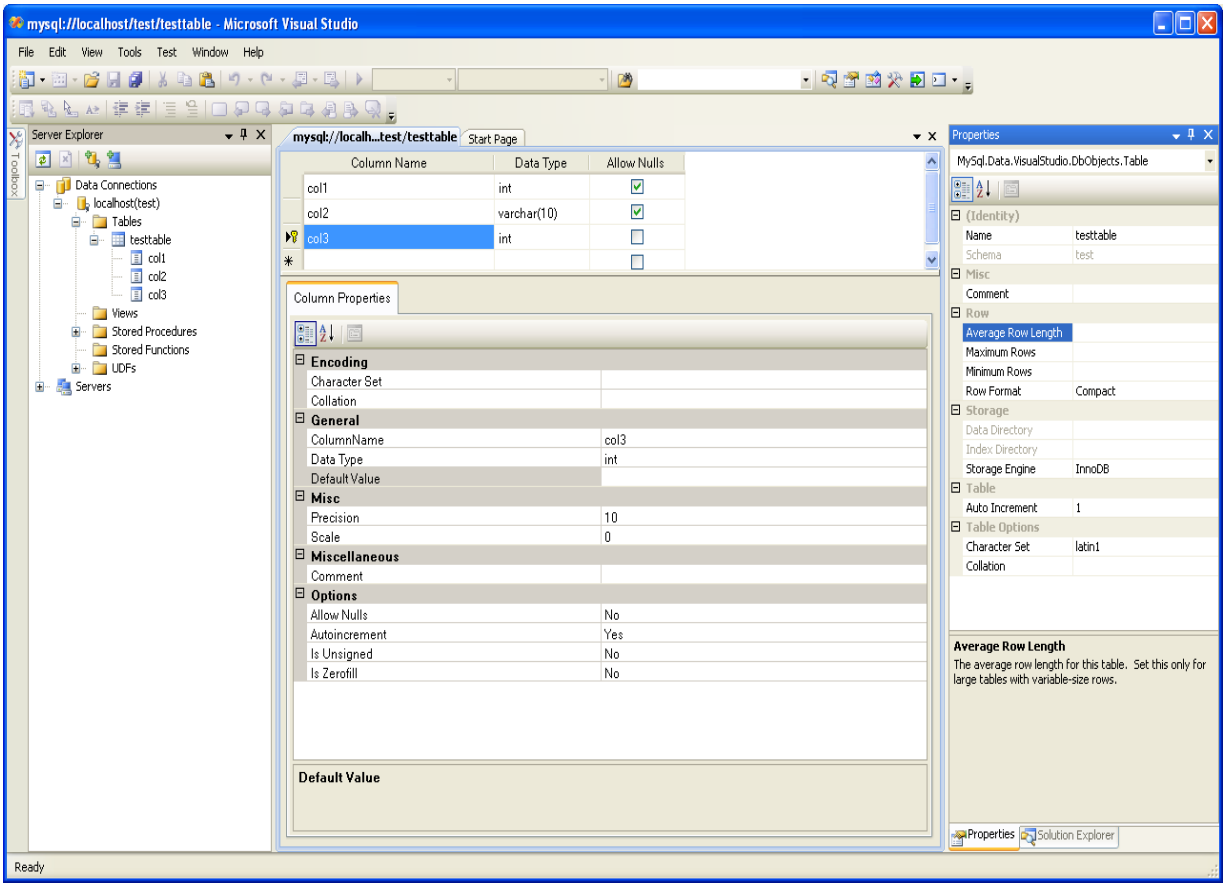


The following table properties can be set:

- Auto Increment.
- Average Row Length.
- Character Set.
- Collation.
- Comment.
- Data Directory.
- Index Directory.
- Maximum Rows.
- Minimum Rows.
- Name.
- Row Format.
- Schema.
- Storage Engine. Note that in MySQL 5.5 and higher, the default storage engine for new tables is `InnoDB`. See InnoDB as the Default MySQL Storage Engine for more information about the choice of storage engine, and considerations if you convert existing tables to `InnoDB`.

The property `Schema` is read-only.

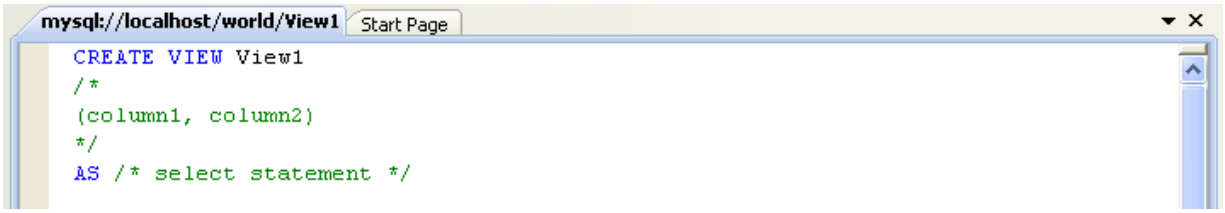
Figure 21.12. Table Properties



Editing Views

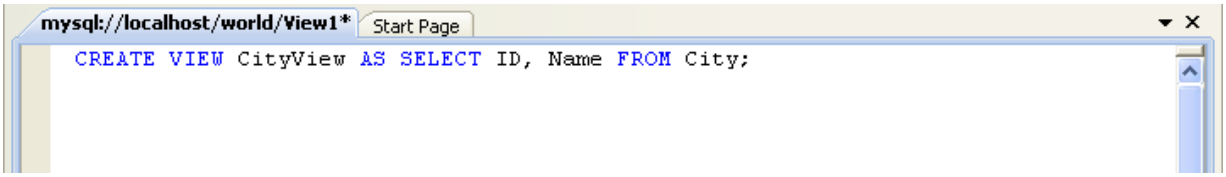
To create a new view, right-click the Views node under the connection node in Server Explorer. From the node's context menu, choose the Create View command. This command opens the SQL Editor.

Figure 21.13. Editing View SQL



You can then enter the SQL for your view.

Figure 21.14. View SQL Added



To modify an existing view, double-click a node of the view to modify, or right-click this node and choose the Alter View command from a context menu. Either of the commands opens the SQL Editor.

All other view properties can be set in the Properties window. These properties are:

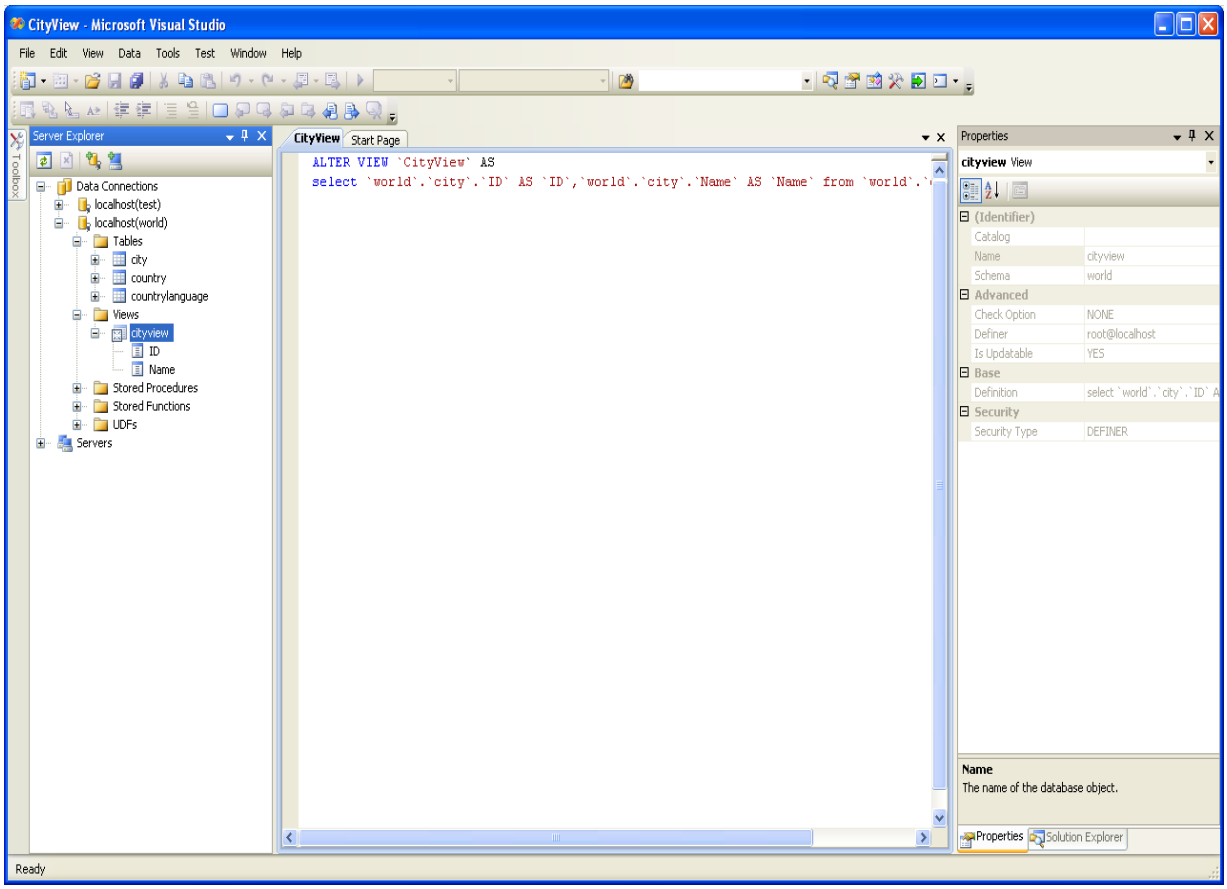
- Catalog
- Check Option
- Definer
- Definition
- Definer
- Is Updatable
- Name
- Schema
- Security Type

Some of these properties can have arbitrary text values, others accept values from a predefined set. In the latter case, set the desired value with an embedded combobox.

The properties `Is Updatable` and `Schema` are readonly.

To save changes you have made, use either Save or Save All buttons of the Visual Studio main toolbar, or press **Control+S**.

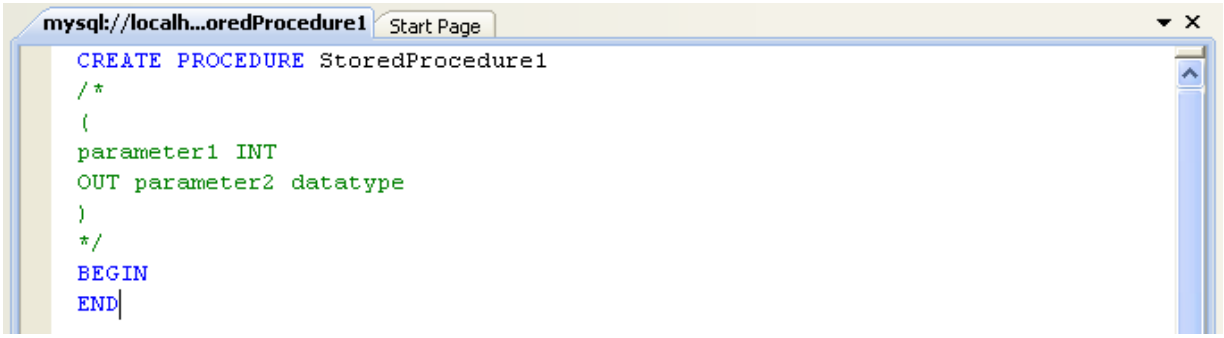
Figure 21.15. View SQL Saved



Editing Stored Procedures and Functions

To create a new stored procedure, right-click the **Stored Procedures** node under the connection node in Server Explorer. From the node's context menu, choose the **Create Routine** command. This command opens the SQL Editor.

Figure 21.16. Edit Stored Procedure SQL



To create a new stored function, right-click the **Functions** node under the connection node in Server Explorer. From the node's context menu, choose the **Create Routine** command.

To modify an existing stored routine (procedure or function), double-click the node of the routine to modify, or right-click this node and choose the **Alter Routine** command from the context menu. Either of the commands opens the SQL Editor.

To create or alter the routine definition using SQL Editor, type this definition in the SQL Editor using standard SQL. All other routine properties can be set in the Properties window. These properties are:

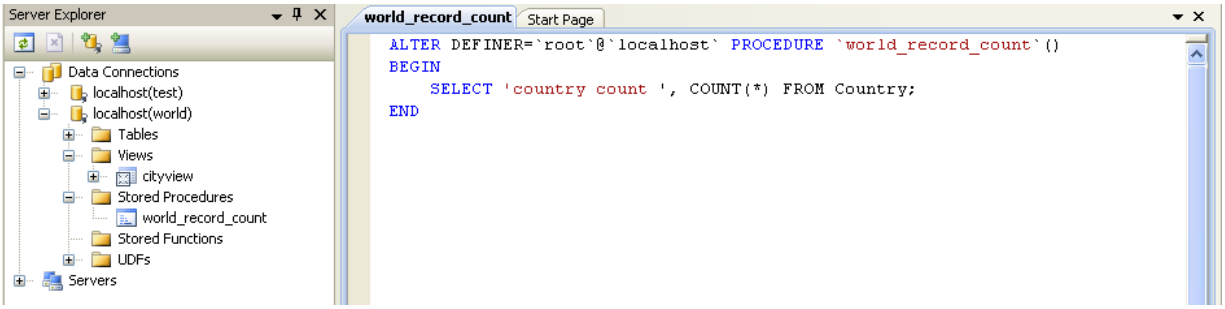
- Body
- Catalog
- Comment
- Creation Time
- Data Access
- Definer
- Definition
- External Name
- External Language
- Is Deterministic
- Last Modified
- Name
- Parameter Style
- Returns
- Schema
- Security Type
- Specific Name
- SQL Mode
- SQL Path
- Type

Some of these properties can have arbitrary text values, others accept values from a predefined set. In the latter case, set the desired value using the embedded combo box.

You can also set all the options directly in the SQL Editor, using the standard `CREATE PROCEDURE` or `CREATE FUNCTION` statement. However, it is recommended to use the Properties window instead.

To save changes you have made, use either **Save** or **Save All** buttons of the Visual Studio main toolbar, or press **Control+S**.

Figure 21.17. Stored Procedure SQL Saved



To observe the runtime behavior of a stored routine and debug any problems, use the Stored Procedure Debugger (available in Connector/Net 6.6 and higher). See Debugging Stored Procedures and Functions for details.

Editing Triggers

To create a new trigger, right-click the node of the table in which to add the trigger. From the node's context menu, choose the **Create Trigger** command. This command opens the SQL Editor.

To modify an existing trigger, double-click the node of the trigger to modify, or right-click this node and choose the **Alter Trigger** command from the context menu. Either of the commands opens the SQL Editor.

To create or alter the trigger definition using SQL Editor, type the trigger statement in the SQL Editor using standard SQL.

Note

Enter only the trigger statement, that is, the part of the `CREATE TRIGGER` query that is placed after the `FOR EACH ROW` clause.

All other trigger properties are set in the Properties window. These properties are:

- Definer
- Event Manipulation
- Name
- Timing

Some of these properties can have arbitrary text values, others accept values from a predefined set. In the latter case, set the desired value using the embedded combo box.

The properties `Event Table`, `Schema`, and `Server` in the Properties window are read-only.

To save changes you have made, use either Save or Save All buttons of the Visual Studio main toolbar, or press **Control+S**. Before changes are saved, you will be asked to confirm the execution of the corresponding SQL query in a confirmation dialog.

To observe the runtime behavior of a stored routine and debug any problems, use the Stored Procedure Debugger (available in Connector/Net 6.6 and higher). See Debugging Stored Procedures and Functions for details.

Editing User Defined Functions (UDF)

To create a new User Defined Function (UDF), right-click the **UDFs** node under the connection node in Server Explorer. From the node's context menu, choose the Create UDF command. This command opens the UDF Editor.

To modify an existing UDF, double-click the node of the UDF to modify, or right-click this node and choose the Alter UDF command from the context menu. Either of these commands opens the UDF Editor.

The UDF editor enables you to set the following properties:

- Name
- So-name (DLL name)
- Return type
- Is Aggregate

There are text fields for both names, a combo box for the return type, and a check box to indicate if the UDF is aggregate. All these options are also accessible using the Properties window.

The property `Server` in the Properties window is read-only.

To save changes you have made, use either Save or Save All buttons of the Visual Studio main toolbar, or press **Control+S**. Before changes are saved, you will be asked to confirm the execution of the corresponding SQL query in a confirmation dialog.

To observe the runtime behavior of a stored routine and debug any problems, use the Stored Procedure Debugger (available in Connector/Net 6.6 and higher). See Debugging Stored Procedures and Functions for details.

Debugging Stored Procedures and Functions

The stored procedure debugger, new in Connector/Net 6.6, provides facilities for setting breakpoints, stepping into individual statements (Step Into, Step Out, Step Over), evaluating and changing local variable values, evaluating breakpoints, and other typical debugging tasks.

Installing the Debugger

To enable the stored procedure debugger, install Connector/Net 6.6 or higher and choose the **Complete** option.

Privileges

The debugger recreates at the start of each debug session a `serversidedebugger` database in your server. This database helps to track the instrumented code and implement observability logic in the debugged routine. Your current connection needs to have privileges to create that database, and its associated stored routines, functions, and tables.

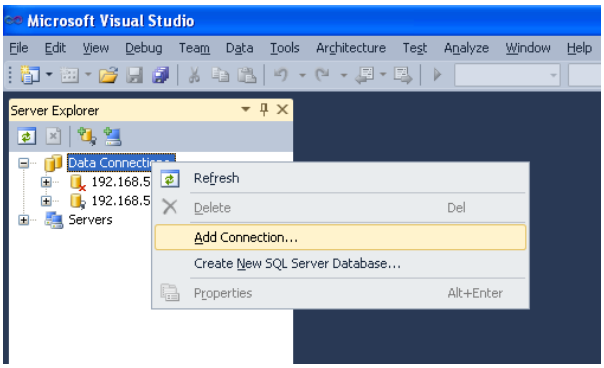
The debugger makes changes behind the scenes to temporarily add instrumentation code to the stored routines that you debug. You must have the `ALTER ROUTINE` privilege for each stored procedure, function, or trigger that you debug. (Including procedures and functions that are called, and triggers that are fired, by a procedure that you are debugging.)

Starting the Debugger

To start the debugger, follow these steps:

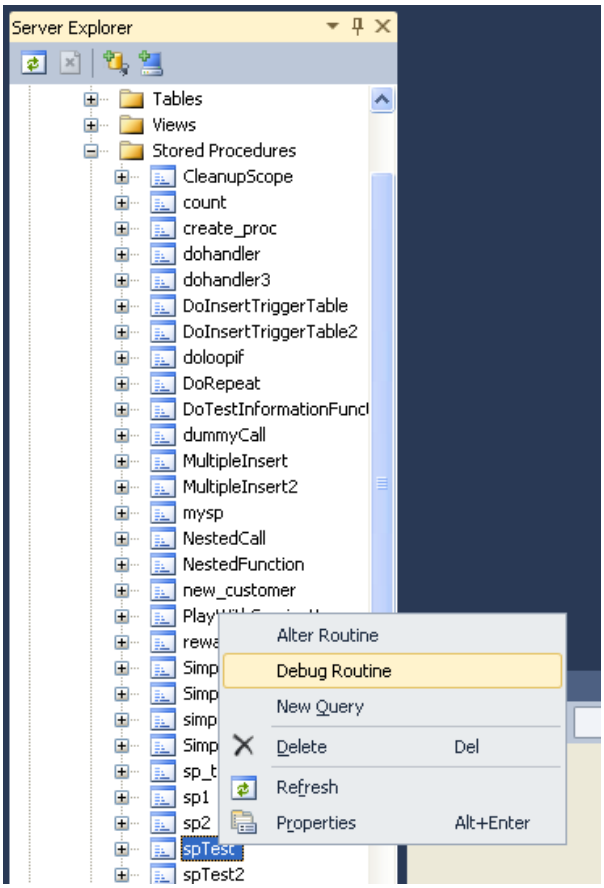
- Choose a connection in the Visual Studio Server Explorer.

Figure 21.18. Connection Dialog



- Expand the `Stored Procedures` folder. Only stored procedures can be debugged directly. To debug a user-defined function, create a stored procedure that calls the function.
- Click on a stored procedure node, then right-click and from the context menu choose **Debug Routine**.

Figure 21.19. Choose a Stored Routine to Debug



At this point, Visual Studio switches to debug mode, opening the source code of the routine being debugged in step mode, positioned on the first statement.

If the initial routine you debug has one or more arguments, a popup will show up with a grid (a row per each argument and three columns: one for the argument, one for the argument value (this is editable) and one for nullifying that argument value (a checkbox)). After setting up all the argument values, you can press **OK** to start the debug session, or **Cancel** to cancel the debug session.

Figure 21.20. Setting Arguments (1 of 2)

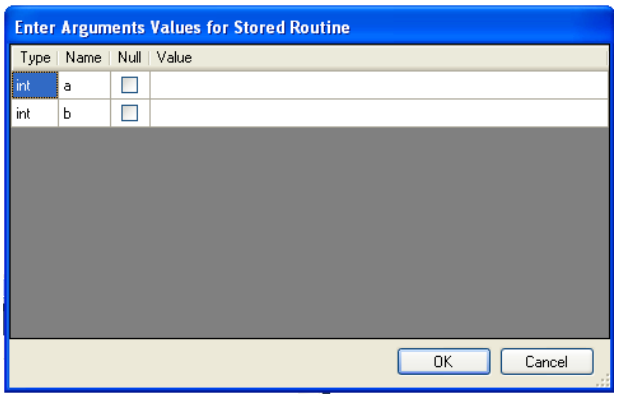


Figure 21.21. Setting Arguments (2 of 2)

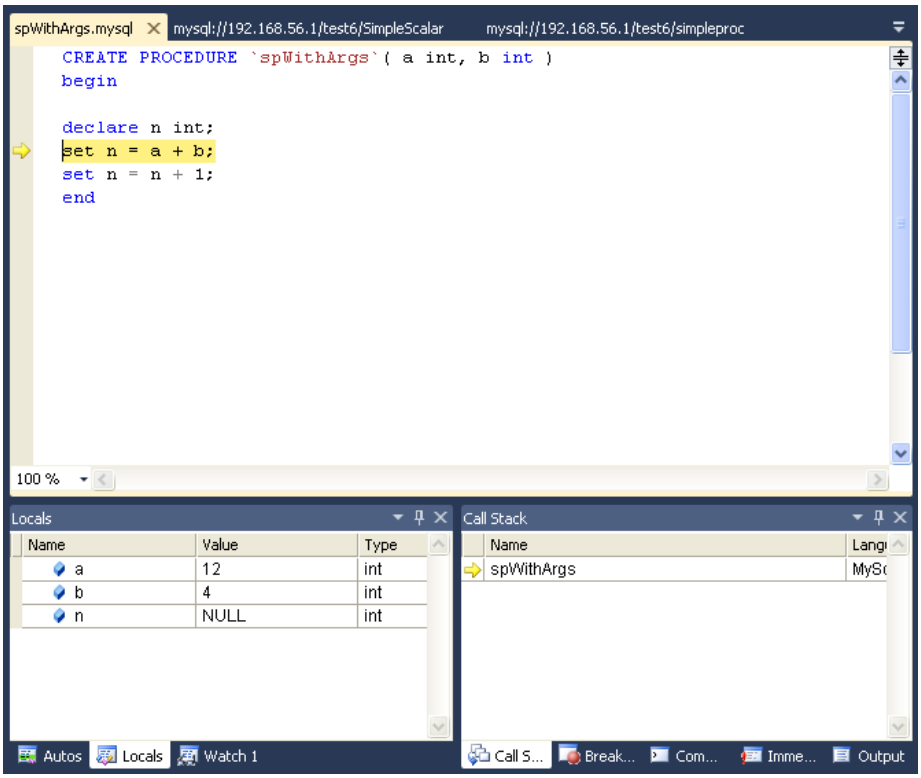


How the Debugger Works

To have visibility into the internal workings of a stored routine, the debugger prepares a special version of the procedure, function, or trigger being debugged, instrumented with extra code to keep track of the current line being stepped into and the values of all the local variables. Any other stored procedures, functions, or triggers called from the routine being debugged are instrumented the same way. The debug versions of the routines are prepared for you automatically, and when the debug session ends (by either pressing **F5** or **Shift+F5**), the original versions of the routines are automatically restored.

A copy of the original version of each instrumented routine (the version without instrumentation) is stored in the `AppData\Roaming\MySqlDebuggerCache` folder for the current Windows user (the path returned by calling `System.Environment.GetFolderPath(Environment.SpecialFolder.ApplicationData)` in .NET, plus appending `MySqlDebuggerCache`. There is one file for each instrumented routine, named *`routine_name`*`.mysql`. For example, in Windows 7, for a user named `fergs`, the path is `C:\Users\fergs\AppData\Roaming\MySqlDebuggerCache`.

Two threads are used, one for the debugger and one for the routine being debugged. The threads run in strict alternation, switching between the debugger and the routine as each statement is executed in the stored routine.

Basic Debugging Operations

The debugger has the same look and feel as the standard Visual Studio debuggers for C#, VB.NET or C++. In particular, the following are true:

Locals and Watches

- To show the Locals tab, choose the menu item **Debug -> Windows -> Locals**.

  The **Locals** tab lists all the variables available in the current scope: variables defined with `DECLARE` at any point in the routine, argument parameters, and session variables that are referenced.

- If the last step operation changes the value of a local, its value will be highlighted in red (until another statement is executed or stepped.

- You can change the value of any local.

- To show the **Watch** tab, choose the menu item **Debug -> Windows -> Watch**.

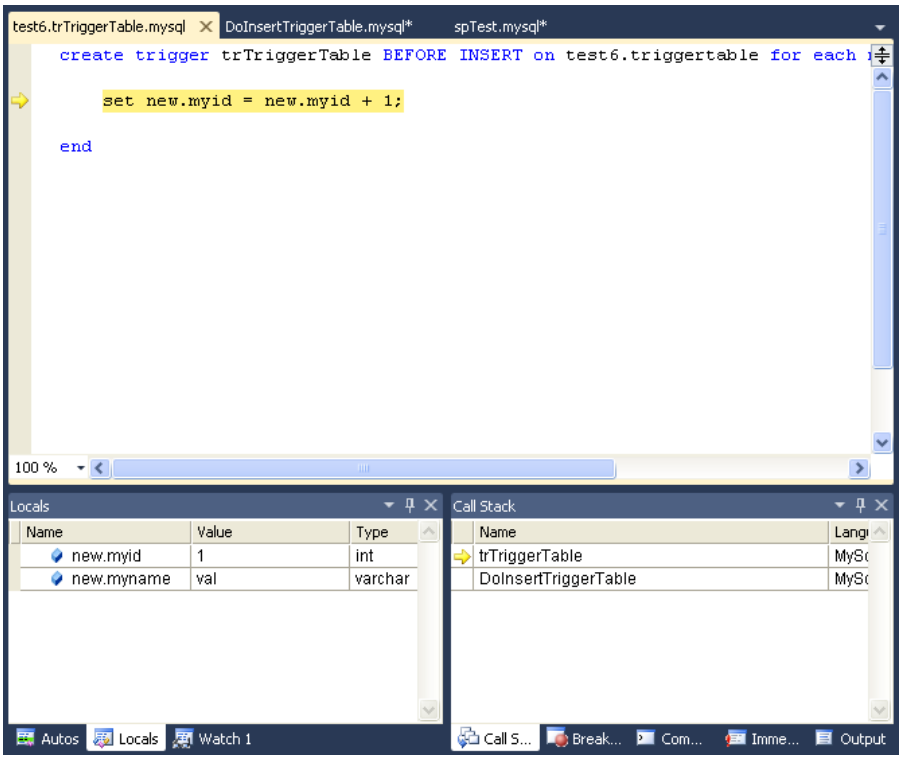
  To define a watch, type any valid MySQL expression, optionally including function calls. If the watch evaluation makes sense in the current context (current stack frame), it will show its value, otherwise it will show an error message in the same row the watch was defined.

- When debugging a trigger, in addition to any locals declared or session variables referenced, the new and old object (when aplicable) will be listed. For example in a trigger for `INSERT`, for a table defined like:

  ```
  create table t1( id int, myname varchar( 50 ));
  ```

  the locals will list the extra variables `new.id` and `new.myname`. For an `UPDATE` trigger, you will also get the extra variables `old.id` and `old.myname`. These variables from the new and old objects can be manipulated the same way as any ordinary local variable.

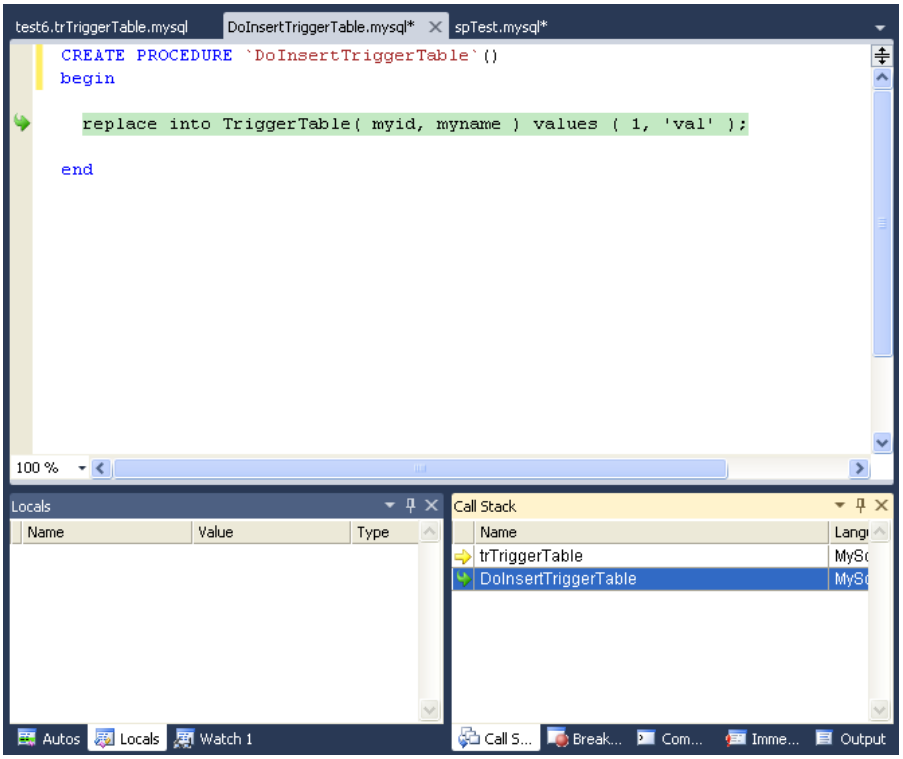
Figure 21.22. Debugging a Trigger



Call Stack

- To show the **Call Stack** tab, choose the menu item **Debug -> Windows -> Call Stack**.
- The stack trace (in the **Call Stack** tab) will list all the stack traces, one for each routine invocation. The one with a yellow mark is the current stepping point. Clicking in another will activate in the editor the tab for that routine source, highlighting in green the last statement stepped.

Figure 21.23. Call Stack



Stepping

- Stepping of a new routine starts in the first executable instruction (excluding declares, handlers, cursor declarations, and so on).

Figure 21.24. Debug Stepping

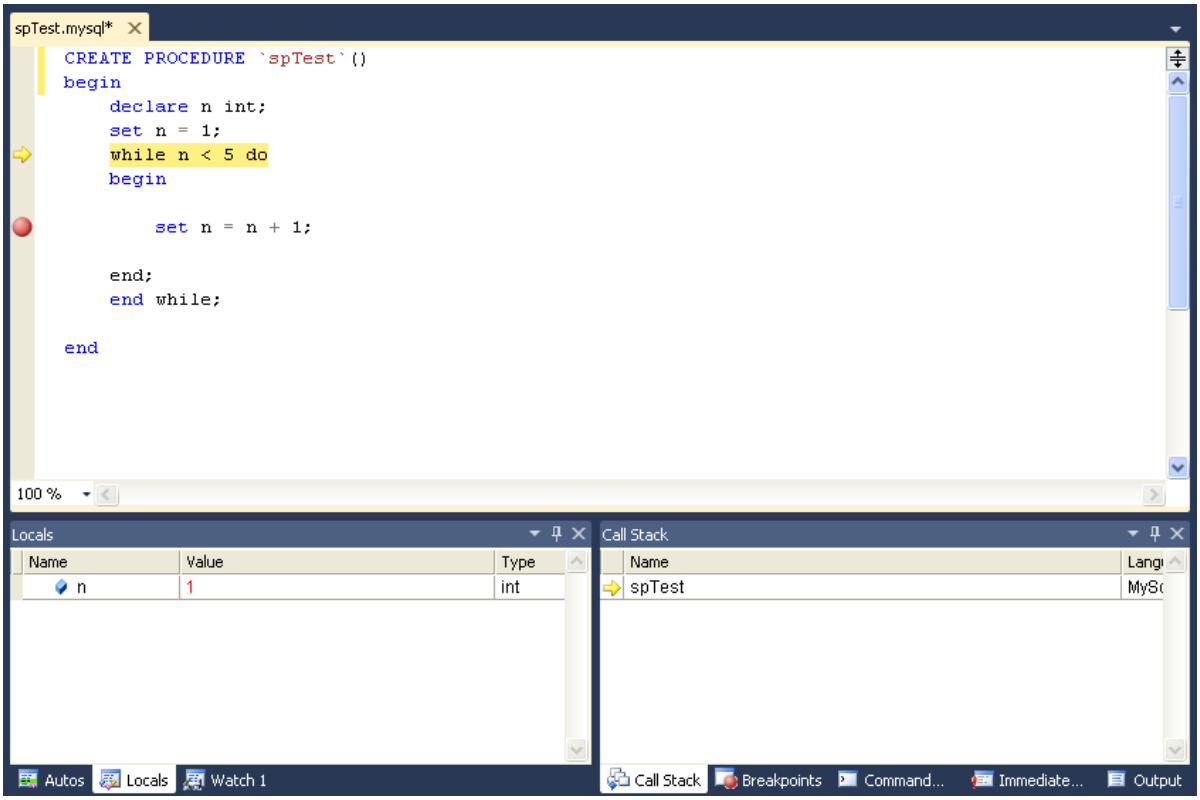


Figure 21.25. Function Stepping (1 of 2)

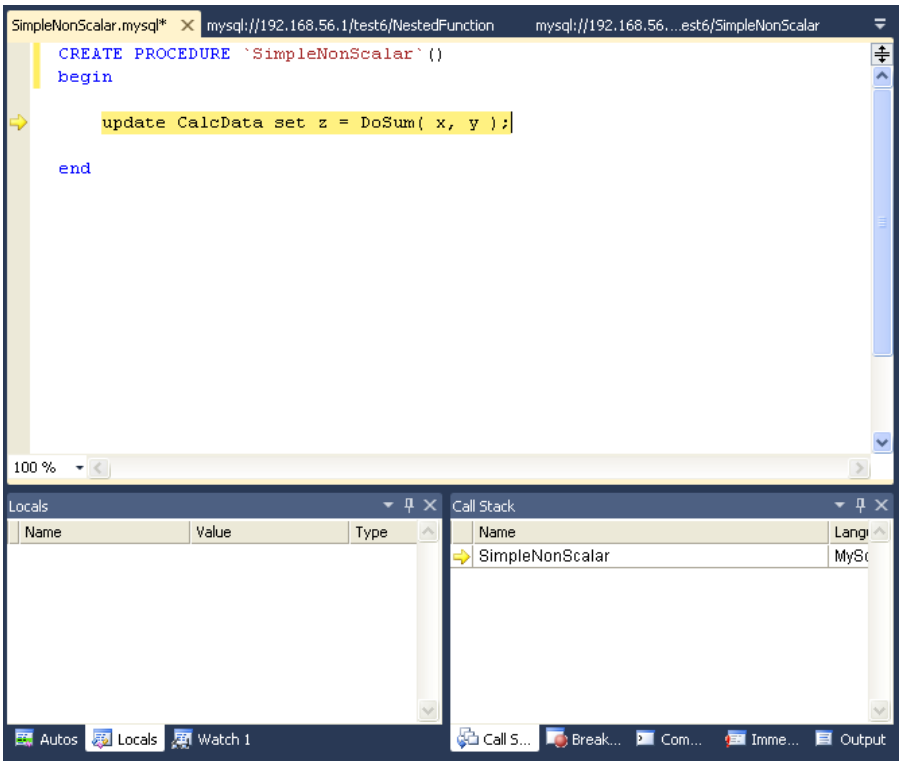

Figure 21.26. Function Stepping (2 of 2)

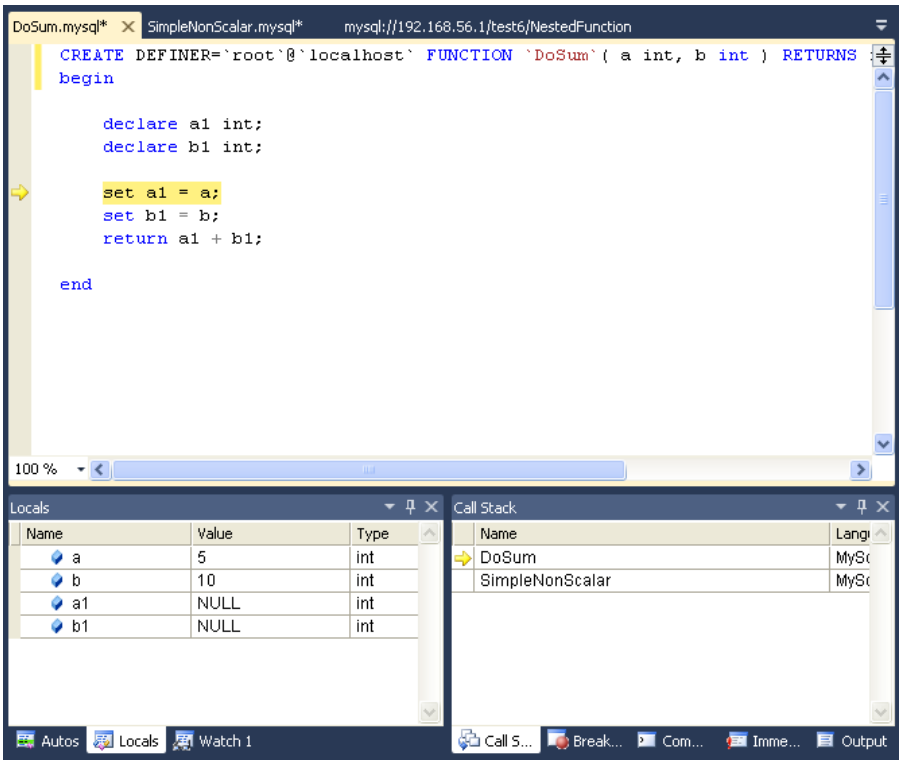

- To step into the code of a condition handler, the condition must be triggered in the rest of the MySQL routine.
- The next statement to be executed is highlighted in yellow.

- To continue stepping, you can choose between **Step Into** (by pressing **F11**), **Step Out** (by pressing **F10**) or **Step Over** (by presssing **Shift+F11**).
- You can step out of any of functions, triggers or stored procedures. If you step from the main routine, it will run that routine to completion and finish the debug session.
- You can step over stored procedure calls, stored functions, and triggers. (To step over a trigger, step over the statement that would cause the trigger to fire.)
- When stepping into a single statement, the debugger will step into each individual function invoked by that statement and each trigger fired by that statement. The order in which they are debugged is the same order in which the MySQL server executes them.
- You can step into triggers triggered from `INSERT`, `DELETE`, `UPDATE`, and `REPLACE` statements.
- Also, the number of times you enter into a stored function or trigger depends on how many rows are evaluated by the function or affected by the trigger. For example, if you press **F11** (**Step Into**) into an `UPDATE` statement that modifies three rows (calling a function for a column in the `SET` clause, thus invoking the function for each of the three rows), you will step into into that function three times in succession, once for each of the rows. You can accelerate this debug session by disabling any breakpoints defined in the given stored function and pressing **Shift+F11** to step out. In this example, the order in which the different instances of the stored function are debugged is server-specific: the same order used by the current MySQL server instance to evaluate the three function invocations.

Breakpoints

- To show the **Breakpoints** tab, choose the menu item **Debug -> Windows -> Breakpoints**.
- The **Breakpoints** tab will show all the breakpoints defined. From here, you can enable and disable breakpoints one by one or all at once (using the toolbar on top of the **Breakpoints** tab).
- You can define new breakpoints only in the middle of a debug session. Click in the left gray border of any MySQL editor, or click anywhere in a MySQL editor and press **F9**. In the familiar Visual Studio way, you press **F9** once to create a breakpoint in that line, and press it again to remove that breakpoint.
- Once a breakpoint is defined, it will appear enabled (as filled red circle left to the current row if that line is a valid statement to put a breakpoint) or disabled (as a non-filled red circle left to the current row if that row is not valid to put a breakpoint).
- To define conditional breakpoints, after creating the breakpoint, right click in the red dot and choose **Condition...**. There you can put any valid MySQL expression and state if the condition is **Is True** or **Has changed**. The former will trigger the breakpoint every time the condition is true, the latter every time the condition value has changed. (If you define a conditional breakpoint, it is not enough to step into the line with the breakpoint defined to trigger such a breakpoint.)

Figure 21.27. Conditional Breakpoints

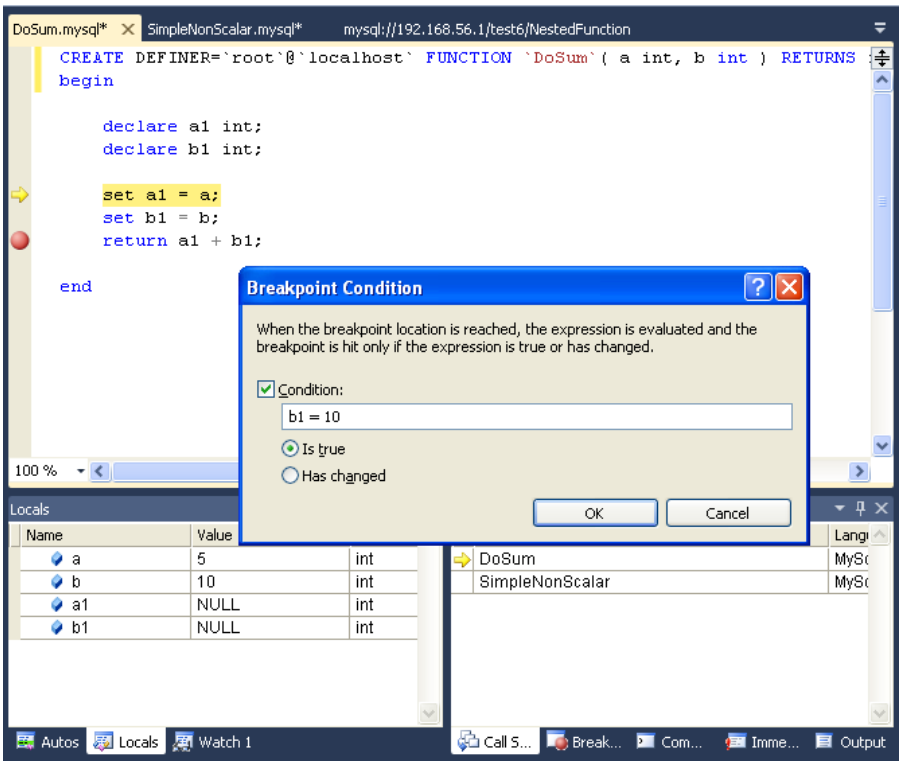

Figure 21.28. Expressions and Breakpoints

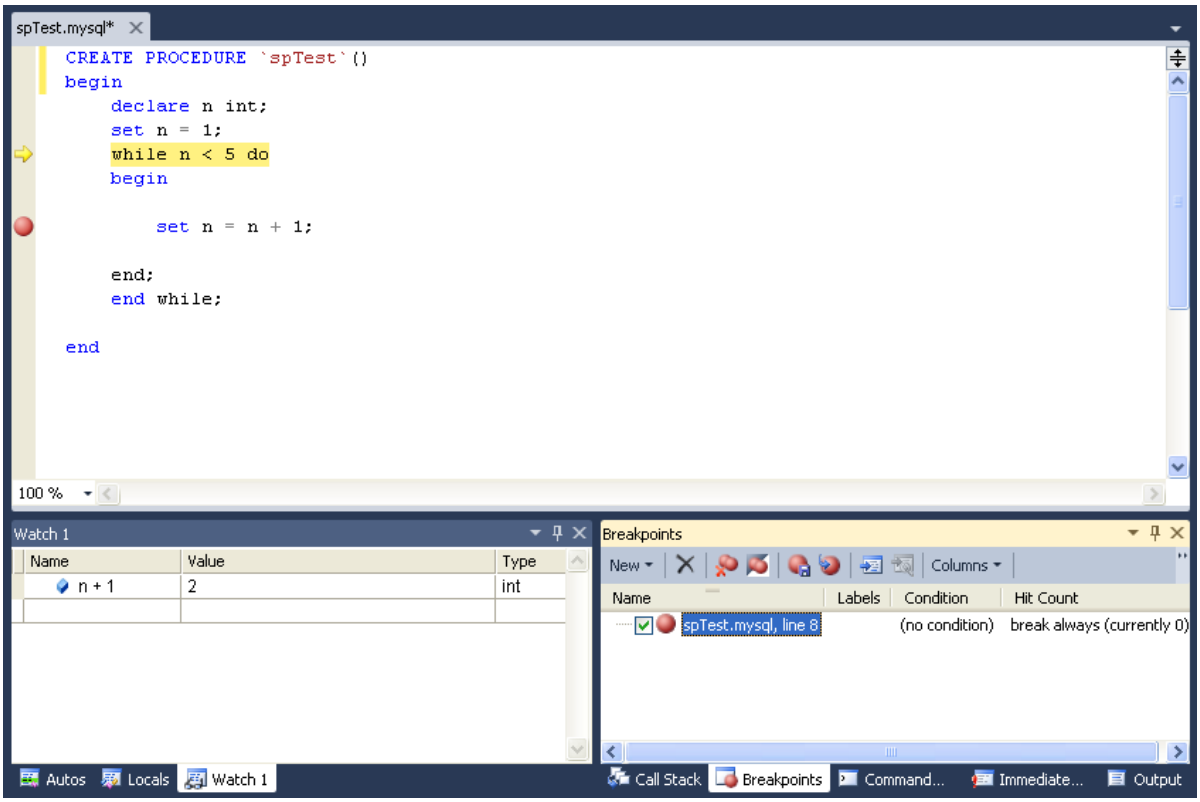


- To define pass count breakpoints, after creating the breakpoint, right click in the red dot and choose **Hit Count...**. In the popup dialog, define the specific condition to set. For example, **break when the hit count is equal to** and a value 3 will trigger the breakpoint the third time it is hit.

Other Features

- To abort the debug session (and the execution of the current call stack of routines), press Shift+F5.
- To run the routine to completion (or until next breakpoint hit), press F5.
- For all functionality you can use (in addition to the shortcuts documented), see the options in the **Debug** menu of Visual Studio.

Limitations

- Code being debugged must not use `get_lock` or `release_lock` MySQL functions, since they are used internally by the debugger infrastructure to synchronize the debugger and the debugged routine.
- Code being debugged must avoid using any transaction code (`START TRANSACTION`, `COMMIT`, `ROLLBACK`) due to the possibility of wiping out the contents of the debugger tables. (This limitation may be removed in the future).
- You cannot debug the routines in the `serversidedebugger` database.
- The MySQL server running the routine being debugged can be any version between 5.0 and 5.6, running on Windows, Linux, or any other supported platform.
- We recommend always running debug sessions on test and development servers, rather than against a MySQL production server, because debugging can cause temporary performance issues or even deadlocks. The instrumented versions of the routines being debugged use locks, that the rest of the production code may not be aware of.

Keyboard Shortcuts

The following list summarizes the keyboard shortcuts for debugging:

- **F9** Toggles breakpoints
- **F11**: Step into once
- **F10**: Step over once
- **Shift+F11**: Step out once
- **F5**: Run
- **Shift+F5**: Abort current debug session

Cloning Database Objects

Tables, views, stored procedures, and functions can be cloned using the appropriate Clone command from the context menu: Clone Table, Clone View, Clone Routine. The clone commands open the corresponding editor for a new object: the **Table Editor** for cloning a table, and the **SQL Editor** for cloning a view or a routine.

The editor is filled with values of the original object. You can modify these values in the usual manner.

To save the cloned object, use either **Save** or **Save All** buttons of the Visual Studio main toolbar, or press **Control+S**. Before changes are saved, you will be asked to confirm the execution of the corresponding SQL query in a confirmation dialog.

Dropping Database Objects

Tables, views, stored routines, triggers, and UDFs can be dropped with the appropriate Drop command selected from its context menu: Drop Table, Drop View, Drop Routine, Drop Trigger, Drop UDF.

You will be asked to confirm the execution of the corresponding drop query in a confirmation dialog.

You can only drop a single object at a time.

Using the ADO.NET Entity Framework

Connector/Net 6.0 introduced support for the ADO.NET Entity Framework. ADO.NET Entity Framework was included with .NET Framework 3.5 Service Pack 1, and Visual Studio 2008 Service Pack 1. ADO.NET Entity Framework was released on 11th August 2008.

ADO.NET Entity Framework provides an Object Relational Mapping (ORM) service, mapping the relational database schema to objects. The ADO.NET Entity Framework defines several layers, these can be summarized as:

- **Logical** - this layer defines the relational data and is defined by the Store Schema Definition Language (SSDL).
- **Conceptual** - this layer defines the .NET classes and is defined by the Conceptual Schema Definition Language (CSDL)
- **Mapping** - this layer defines the mapping from .NET classes to relational tables and associations, and is defined by Mapping Specification Language (MSL).

Connector/Net integrates with Visual Studio 2008 to provide a range of helpful tools to assist the developer.

A full treatment of ADO.NET Entity Framework is beyond the scope of this manual. If you are unfamiliar with ADO.NET, review the Microsoft ADO.NET Entity Framework documentation.

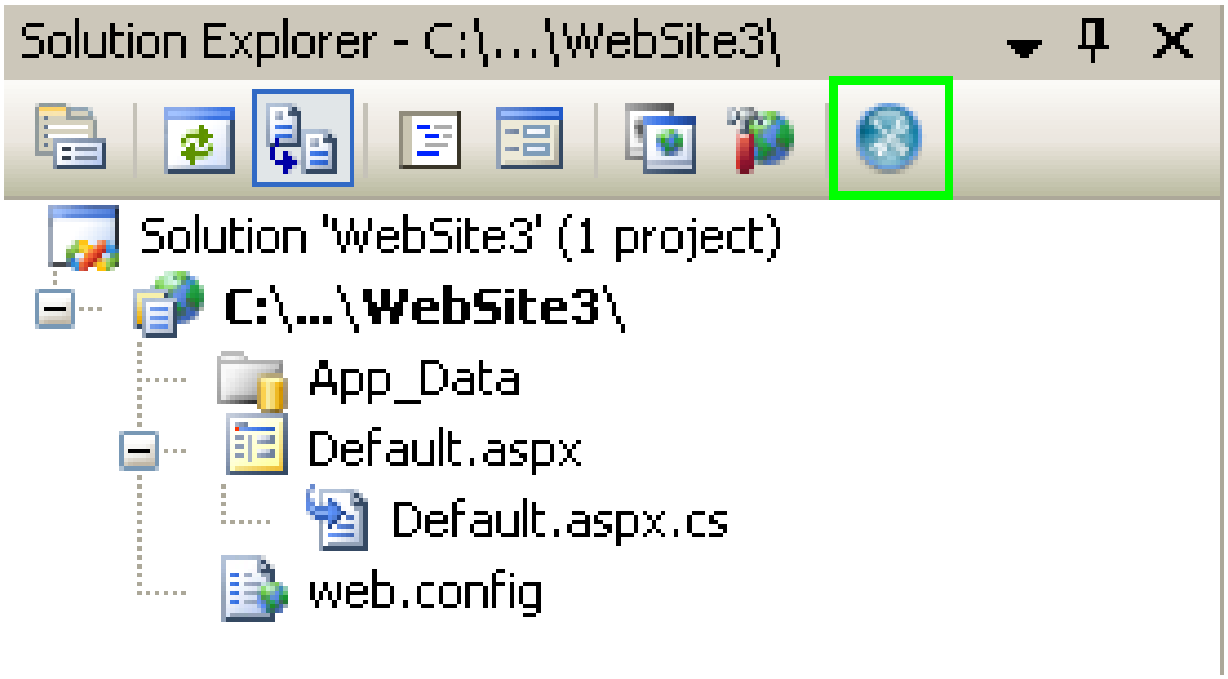
Tutorials on getting started with ADO.NET Entity Framework are available. See Tutorial: Using an Entity Framework Entity as a Windows Forms Data Source and Tutorial: Databinding in ASP.NET using LINQ on Entities.

MySQL Website Configuration Tool

MySQL Connector/Net 6.1 introduced the MySQL Website Configuration Tool. This is a facility available in Visual Studio that enables you to configure the Membership, Role, Session State and Profile Provider, without editing configuration files. You set your configuration options within the tool, and the tool modifies your `web.config` file accordingly.

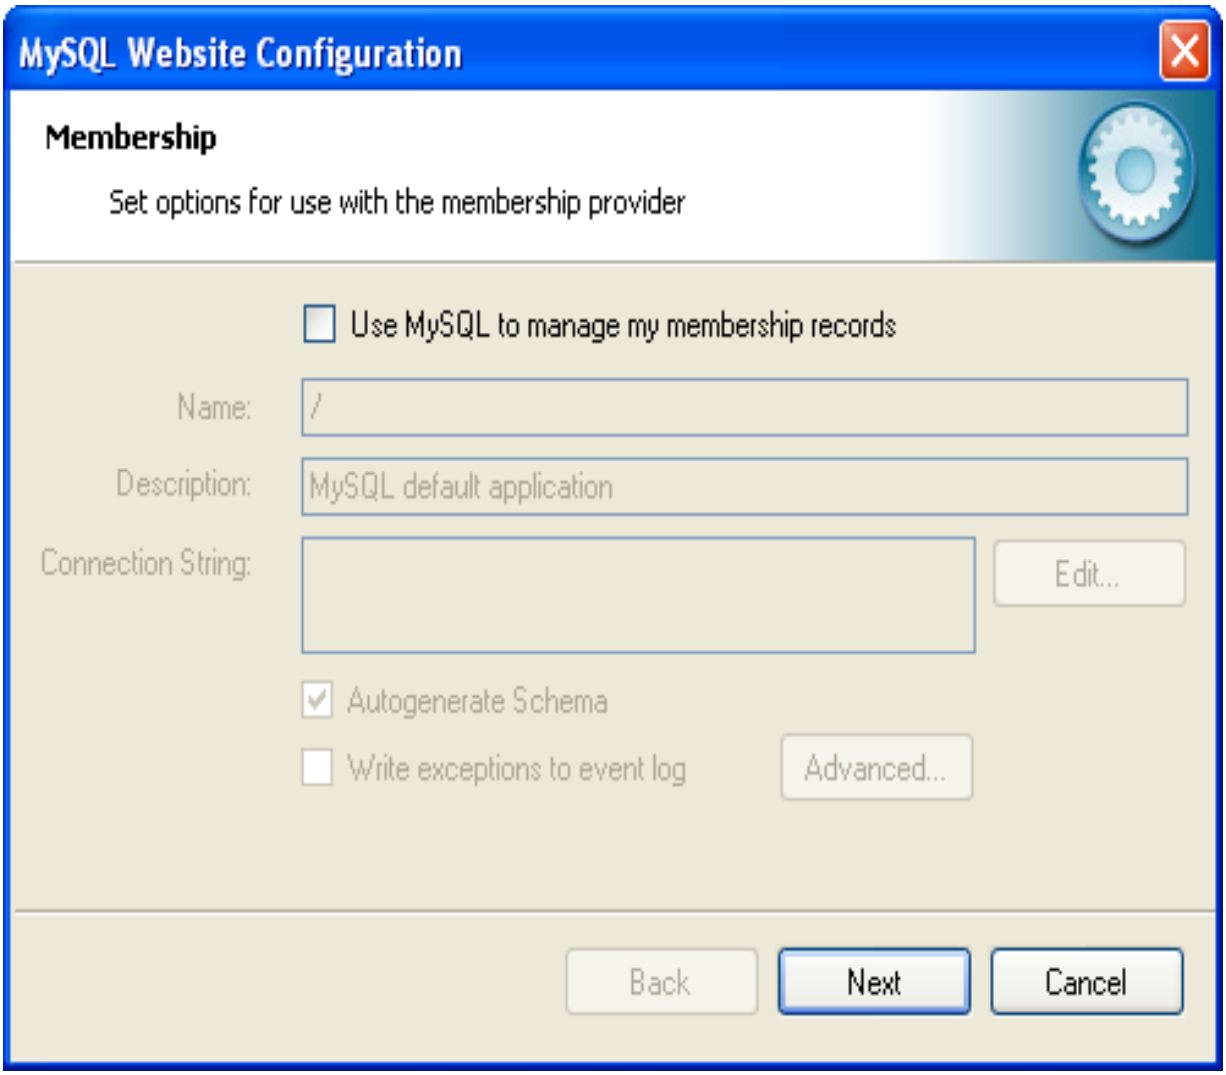
The MySQL Website Configuration Tool appears as a small icon on the Solution Explorer toolbar in Visual Studio, as show by the following screenshot:

Figure 21.29. MySQL Website Configuration Tool



Clicking the Website Configuration Tool icon launches the wizard and displays the first screen:

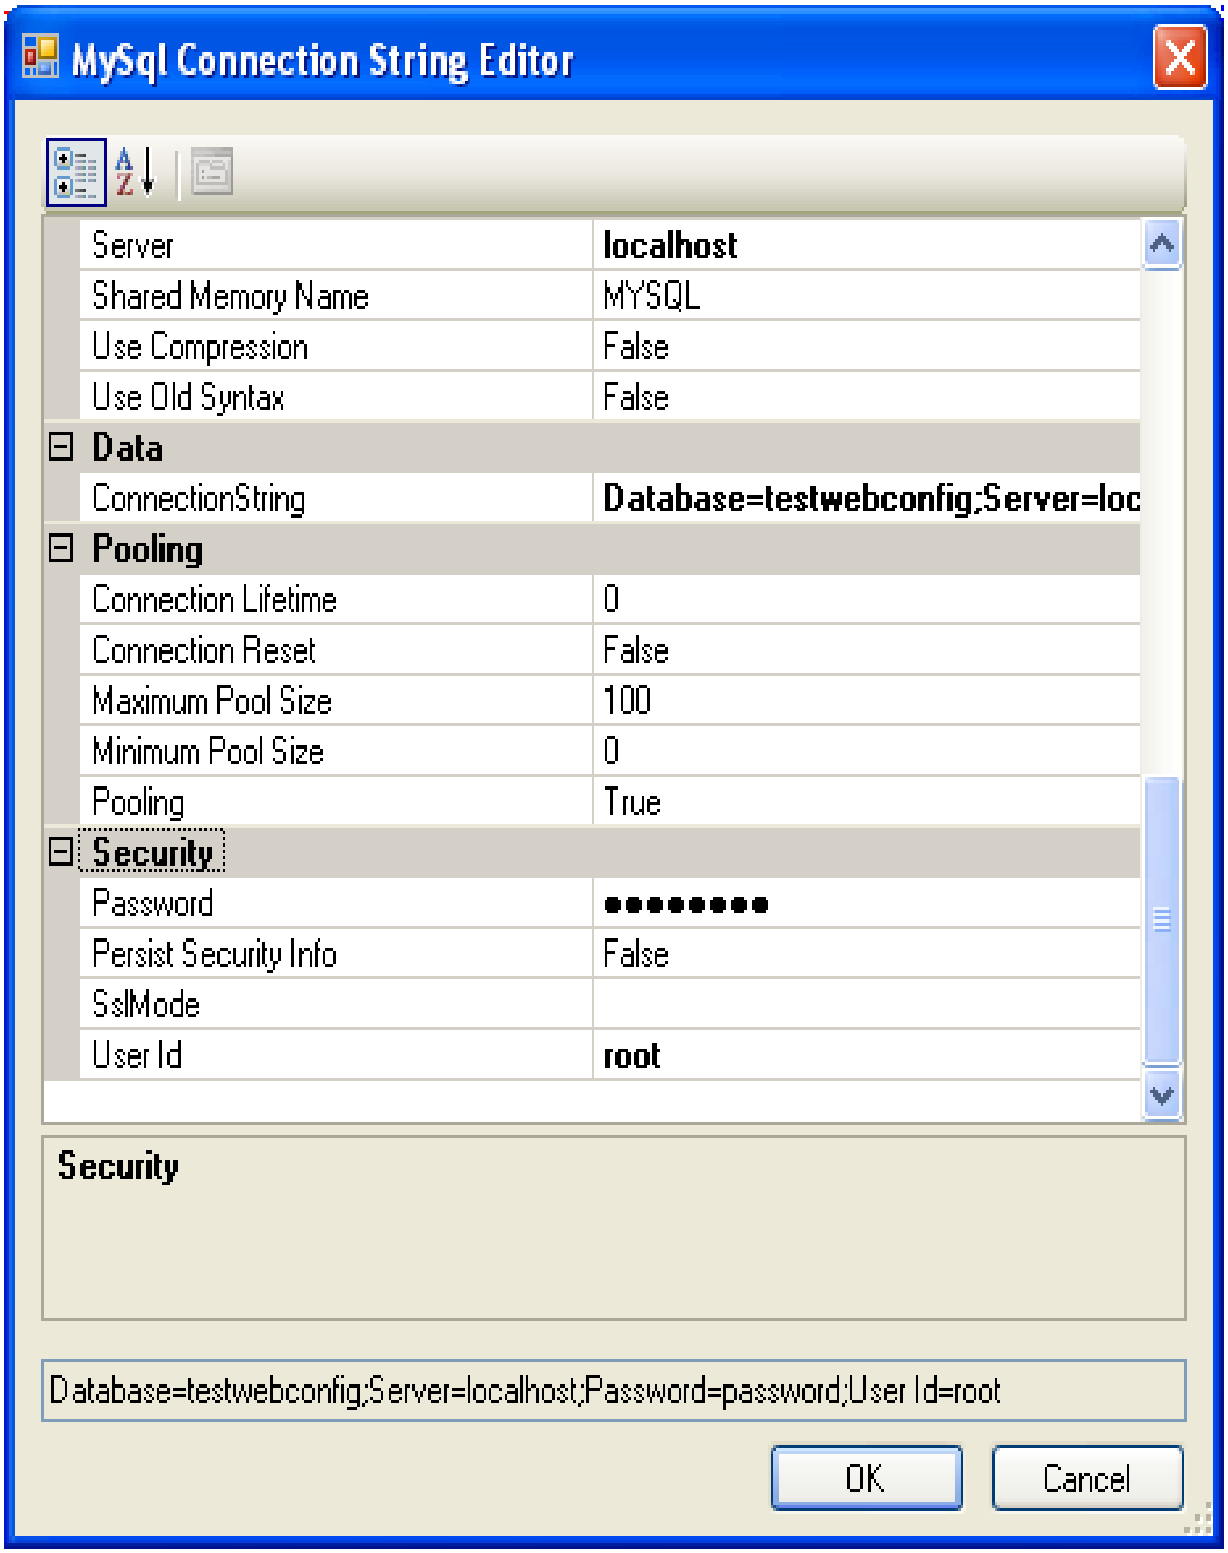
Figure 21.30. MySQL Website Configuration Tool - Membership



This allows you to enable use of the MySQL Membership Provider. Click the check box to enable this. You can now enter the name of the application that you are creating the configuration for. You can also enter a description for the application.

You can then click the Edit... button to launch the Connection String Editor:

Figure 21.31. MySQL Website Configuration Tool - Connection String Editor

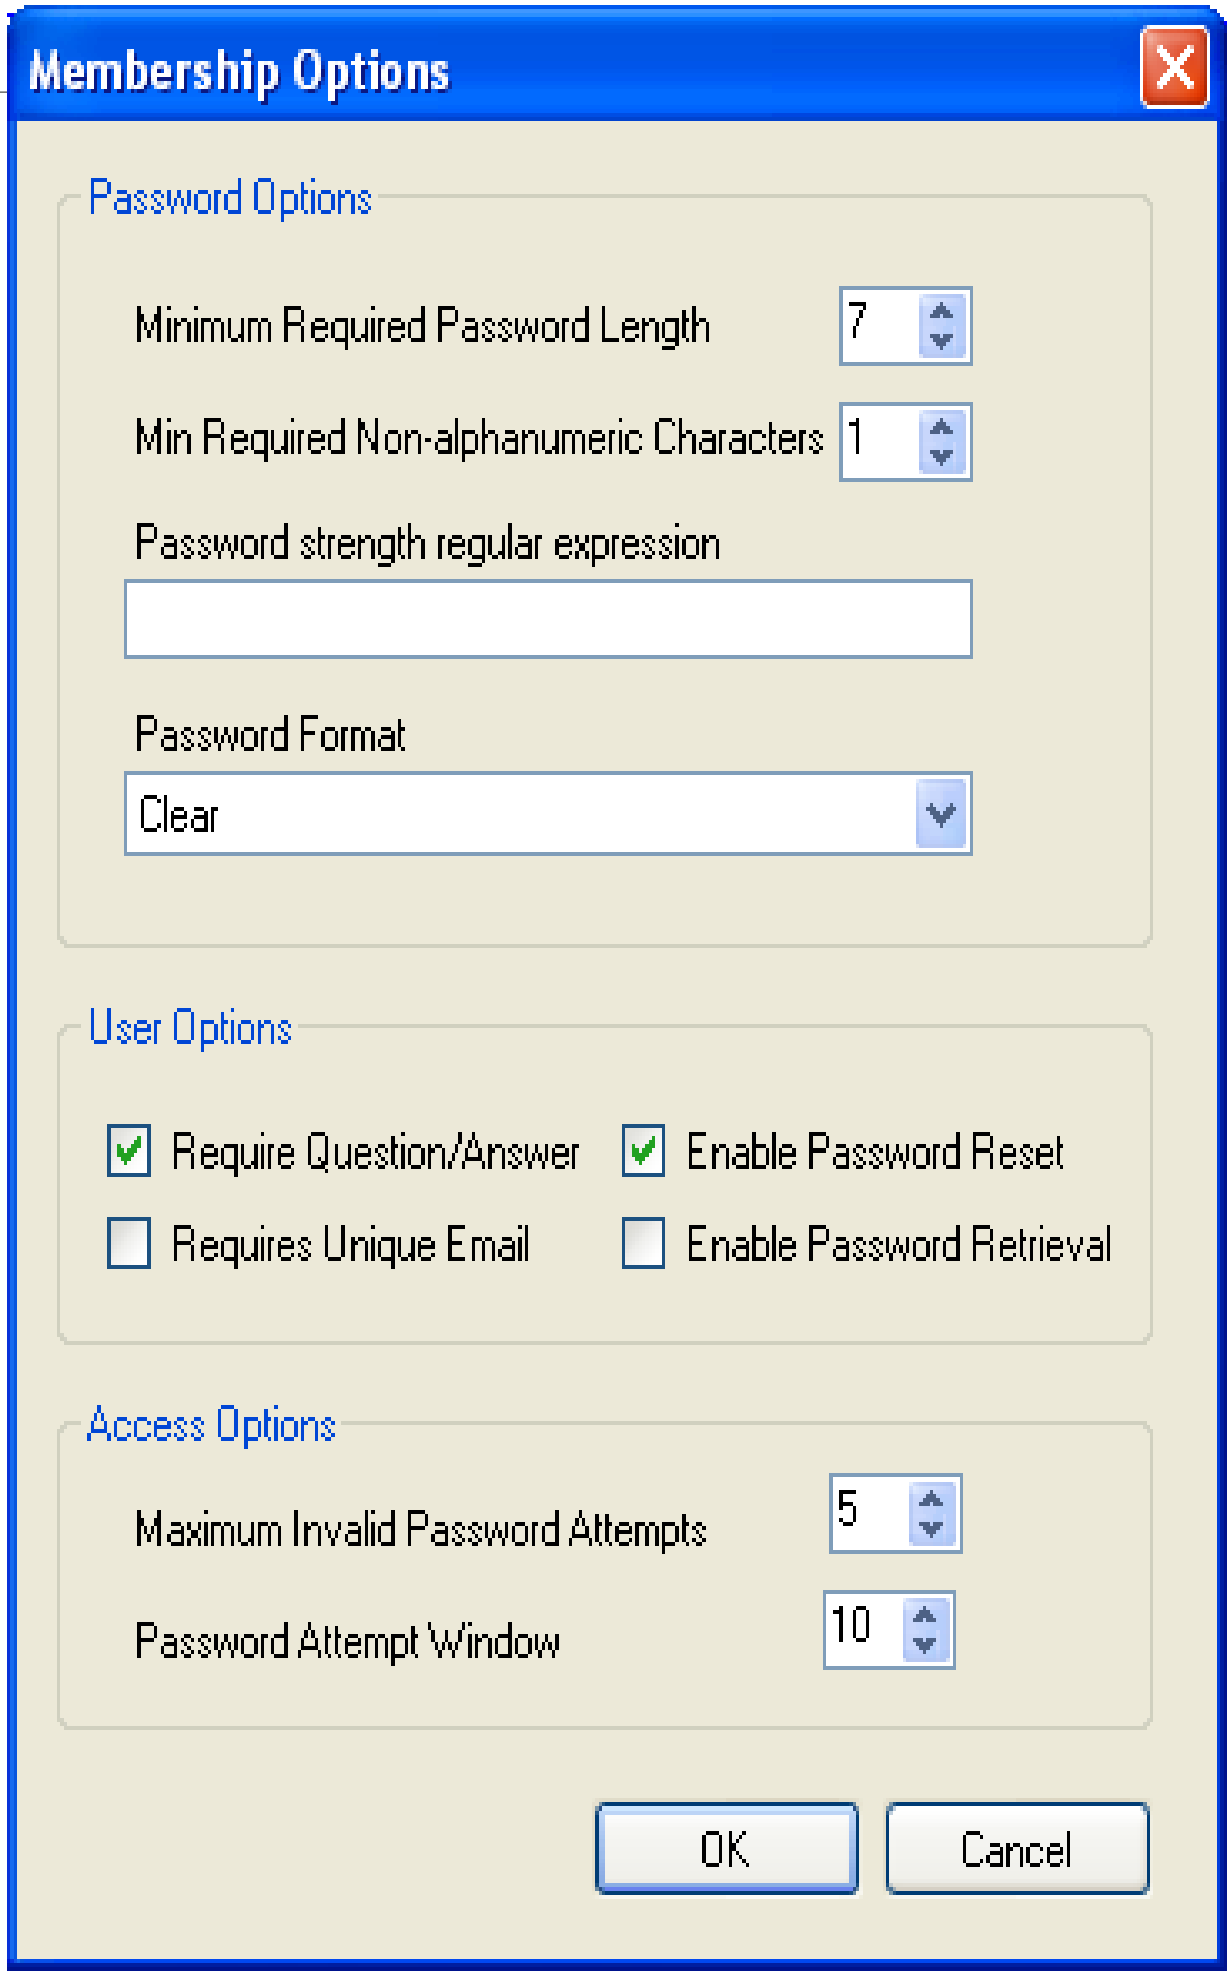


Note that if you have already defined a connection string for the providers manually in `web.config`, or previously using the tool, this will be automatically loaded and displayed, and can then be modified in this dialog.

You can also ensure that the necessary schemas are created automatically for you by selecting the Autogenerate Schema check box. These schemas are used to store membership information. The database used to storage is the one specified in the connection string.

You can also ensure that exceptions generated by the application will be written to the Windows event log by selecting the **Write exceptions to event log** check box.

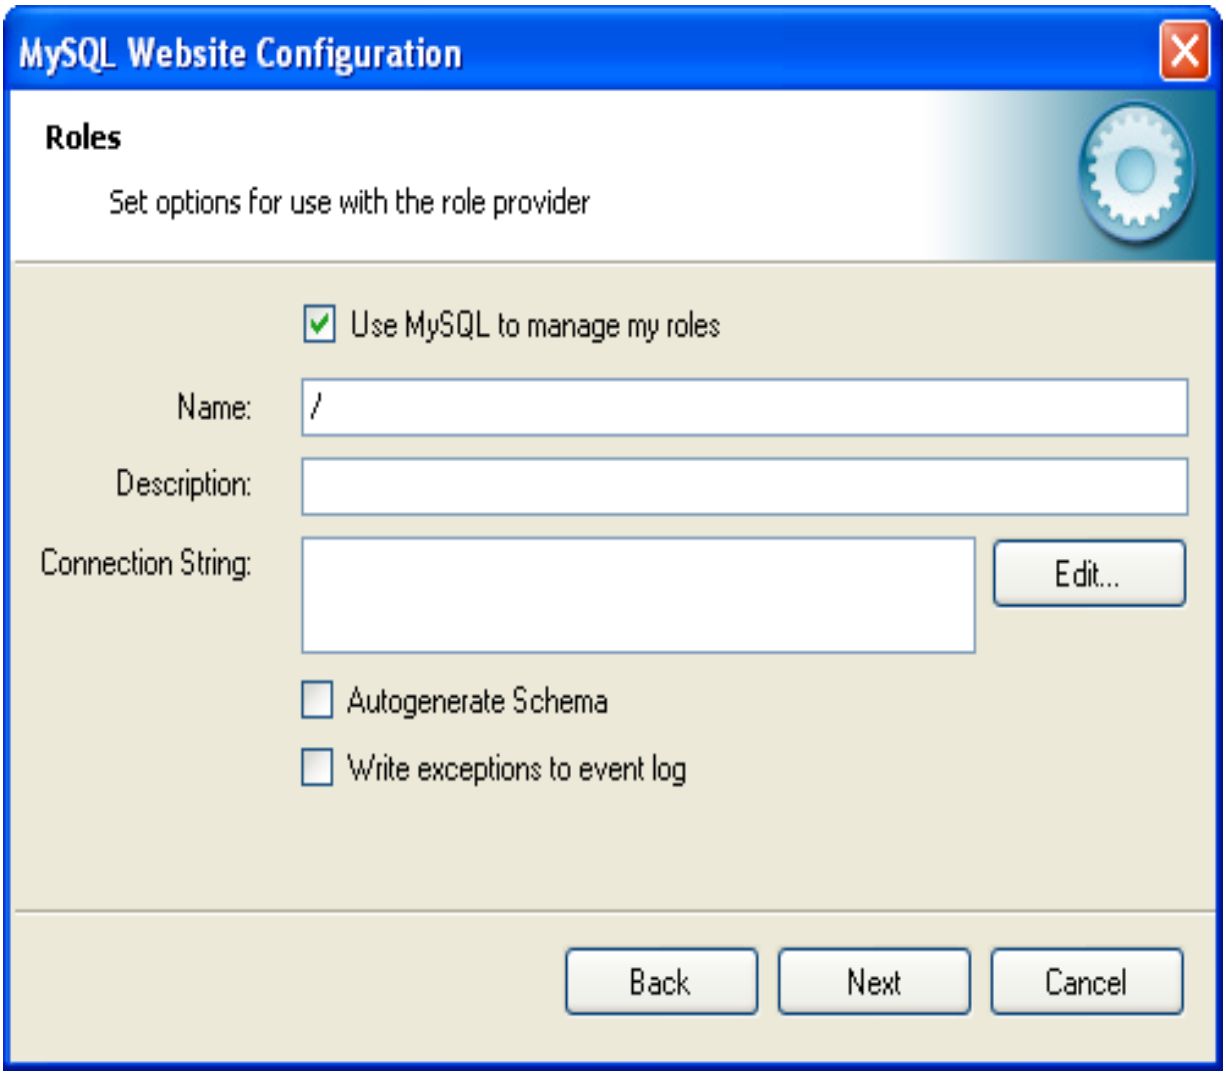
Clicking the Advanced... button launches a dialog that enables you to set Membership Options. These options dictate such variables as password length required when a user signs up, whether the password is encrypted and whether the user can reset their password or not.



Membership Options
Password Options
Minimum Required Password Length
7
Min Required Non-alphanumeric Characters
1
Password strength regular expression
Password Format
Clear
User Options
Require Question/Answer
Enable Password Reset
Requires Unique Email
Enable Password Retrieval
Access Options
Maximum Invalid Password Attempts
5
Password Attempt Window
10
OK
Cancel

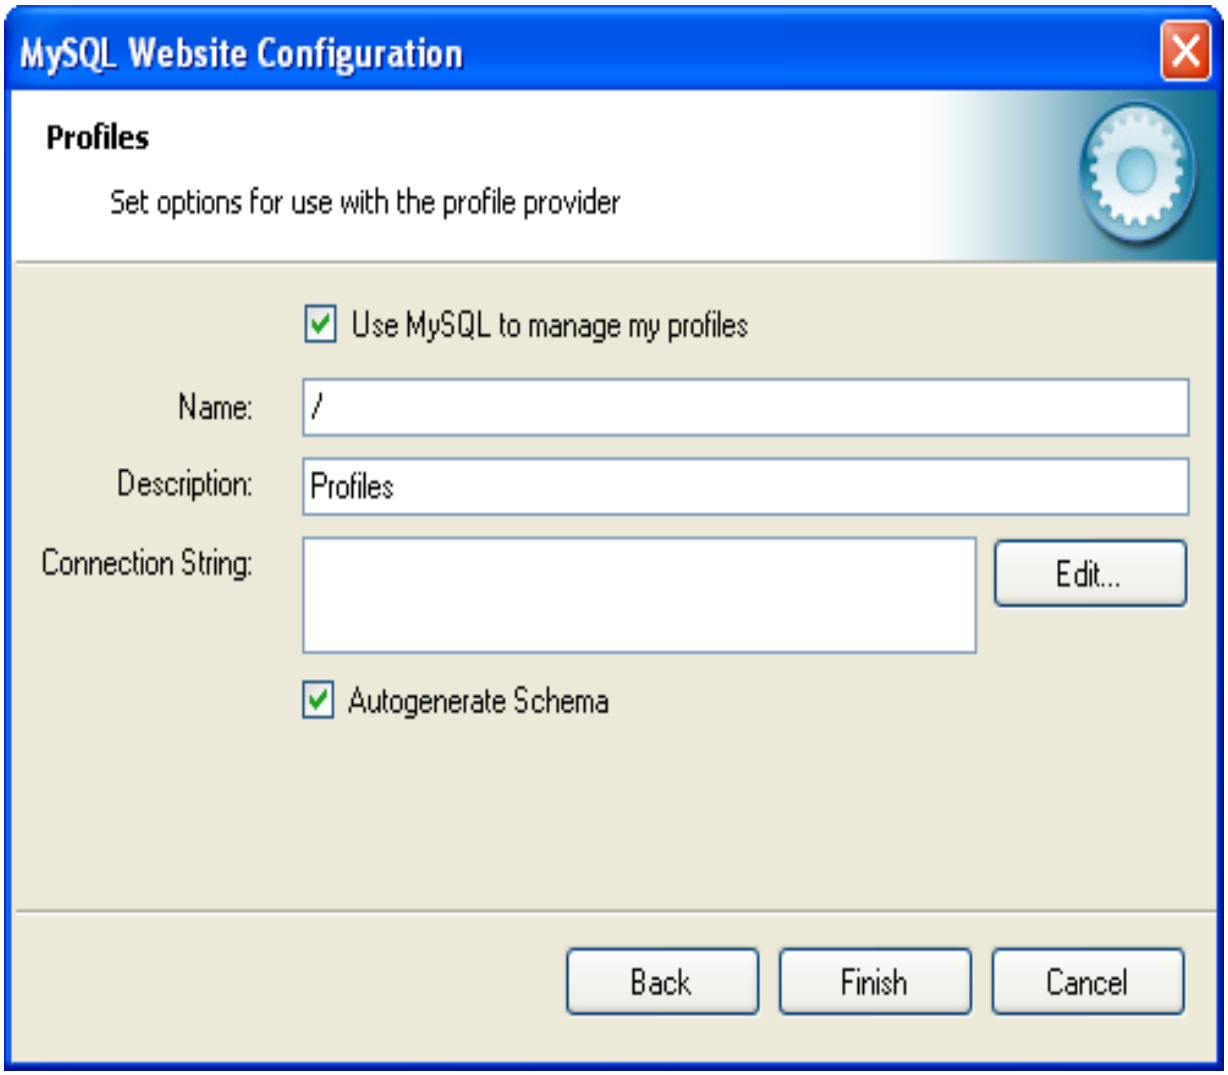
Once information has been set up as required for configuration of the Membership Provider, the Next button can be clicked to display the Roles Provider screen:

Figure 21.33. MySQL Website Configuration Tool - Roles



Again the connection string can be edited, a description added and Autogenerate Schema can be enabled before clicking Next to go to the Profiles Provider screen:

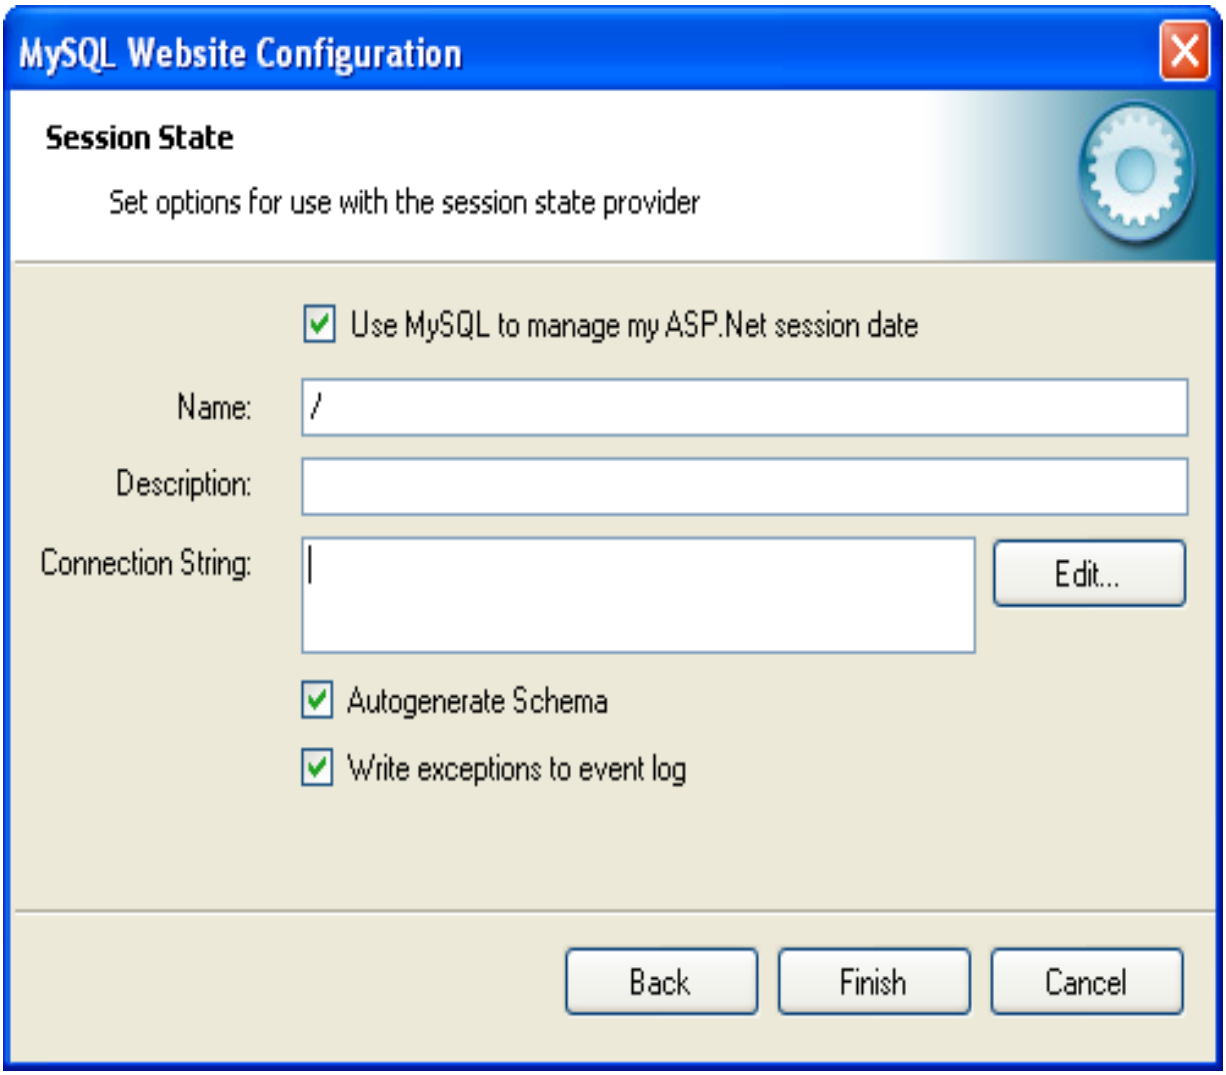
Figure 21.34. MySQL Website Configuration Tool - Profiles



This screen display similar options to the previous screens.

Click Next to proceed to the Session State configuration page:

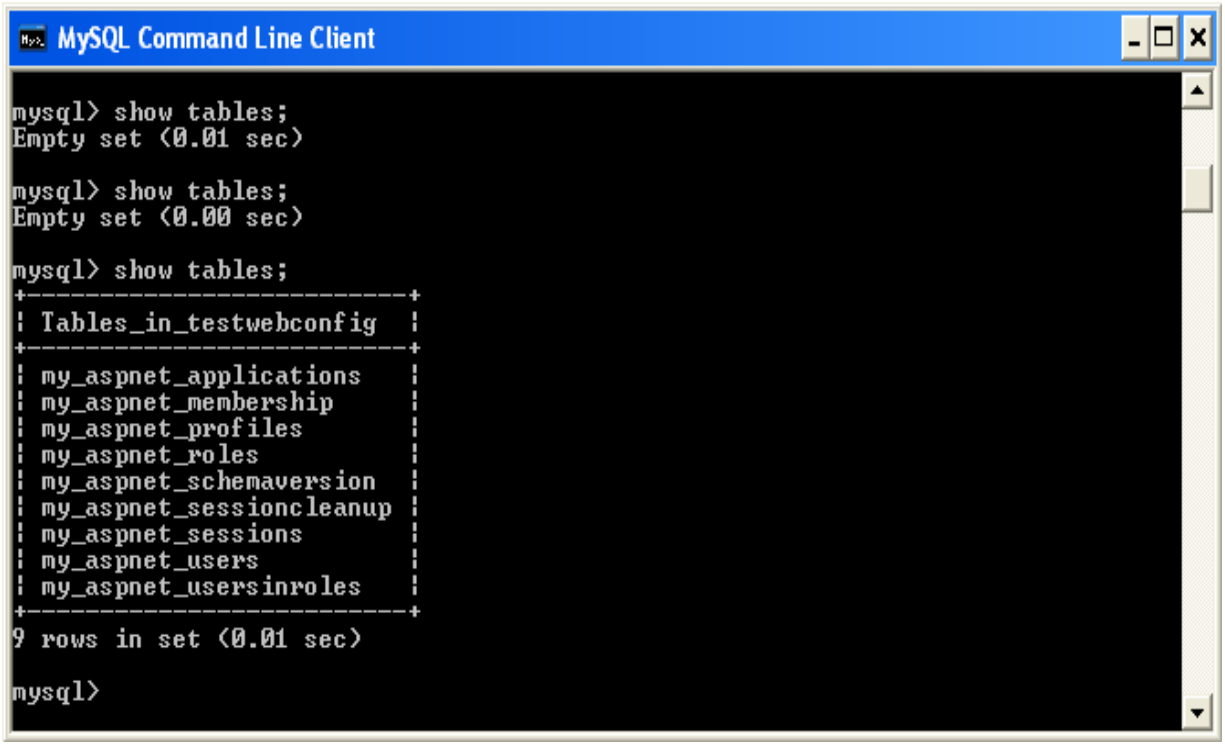
Figure 21.35. MySQL Website Configuration Tool - Session State



Once you have set up the Session State Provider as required, click Finish to exit the wizard.

At this point, select the **Authentication Type** to **From Internet**. Launch the ASP.NET Configuration Tool and select the Security tab. Click the **Select authentication type** link and ensure that the **From the internet** radio button is selected. You can now examine the database you created to store membership information. All the necessary tables will have been created for you:

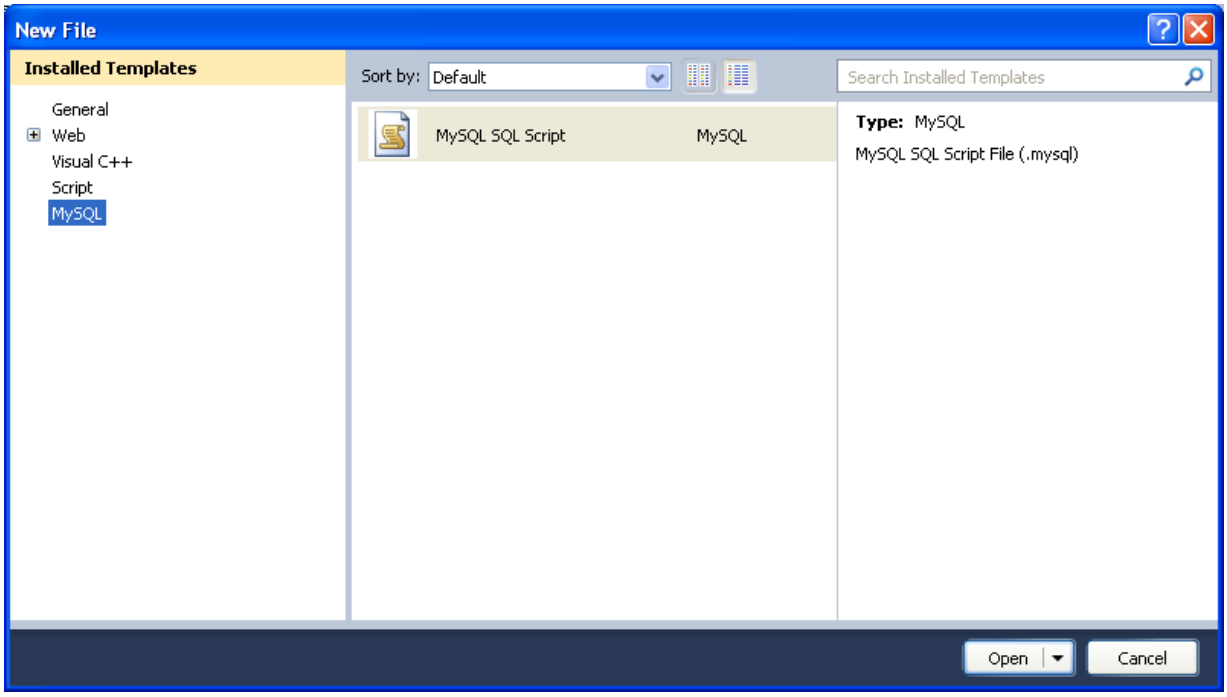
Figure 21.36. MySQL Website Configuration Tool - Tables



MySQL SQL Editor

MySQL Connector/Net 6.3.2 introduced a new MySQL SQL Editor. The easiest way to invoke the editor is by selecting the New, File menu item from the Visual Studio main menu. This displays the **New File** dialog:

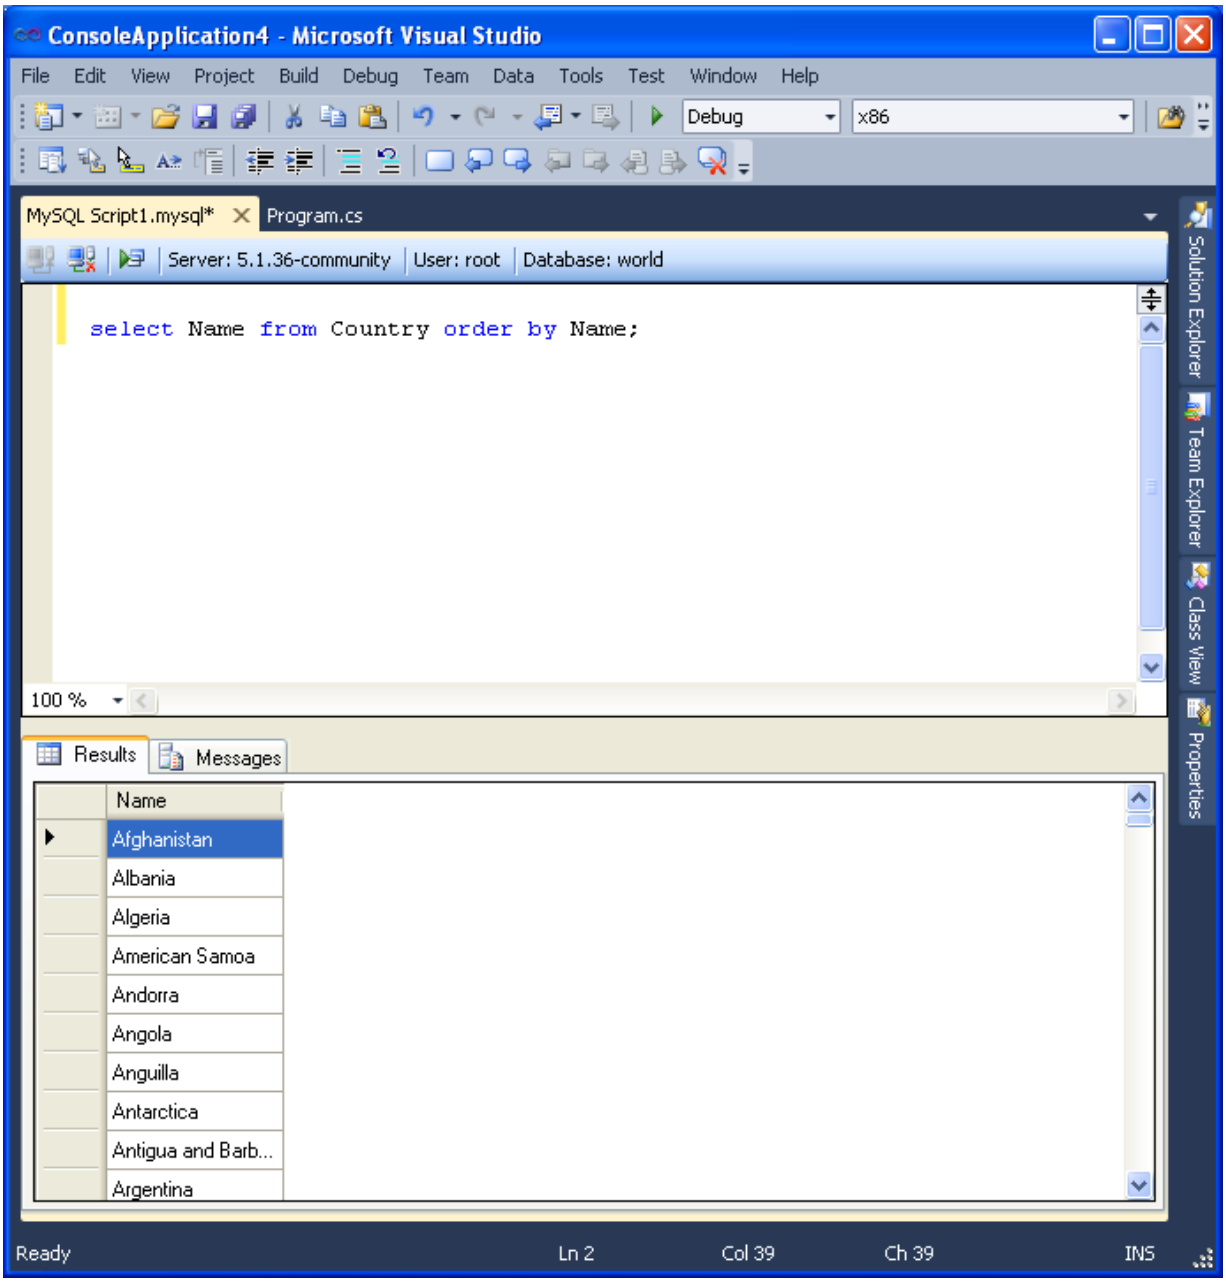
Figure 21.37. MySQL SQL Editor - New File



From the **New File** dialog, select the MySQL template, and then double-click the **MySQL SQL Script** document, or click the Open button.

The MySQL SQL Editor will be displayed. You can now enter SQL code as required, or connect to a MySQL server. Click the Connect to MySQL button in the MySQL SQL Editor toolbar. You can enter the connection details into the **Connect to MySQL** dialog that is displayed. You can enter the server name, user ID, password and database to connect to, or click the Advanced button to select other connection string options. Click the Connect button to connect to the MySQL server. To execute your SQL code against the server, click the Run SQL button on the toolbar.

Figure 21.38. MySQL SQL Editor - Query



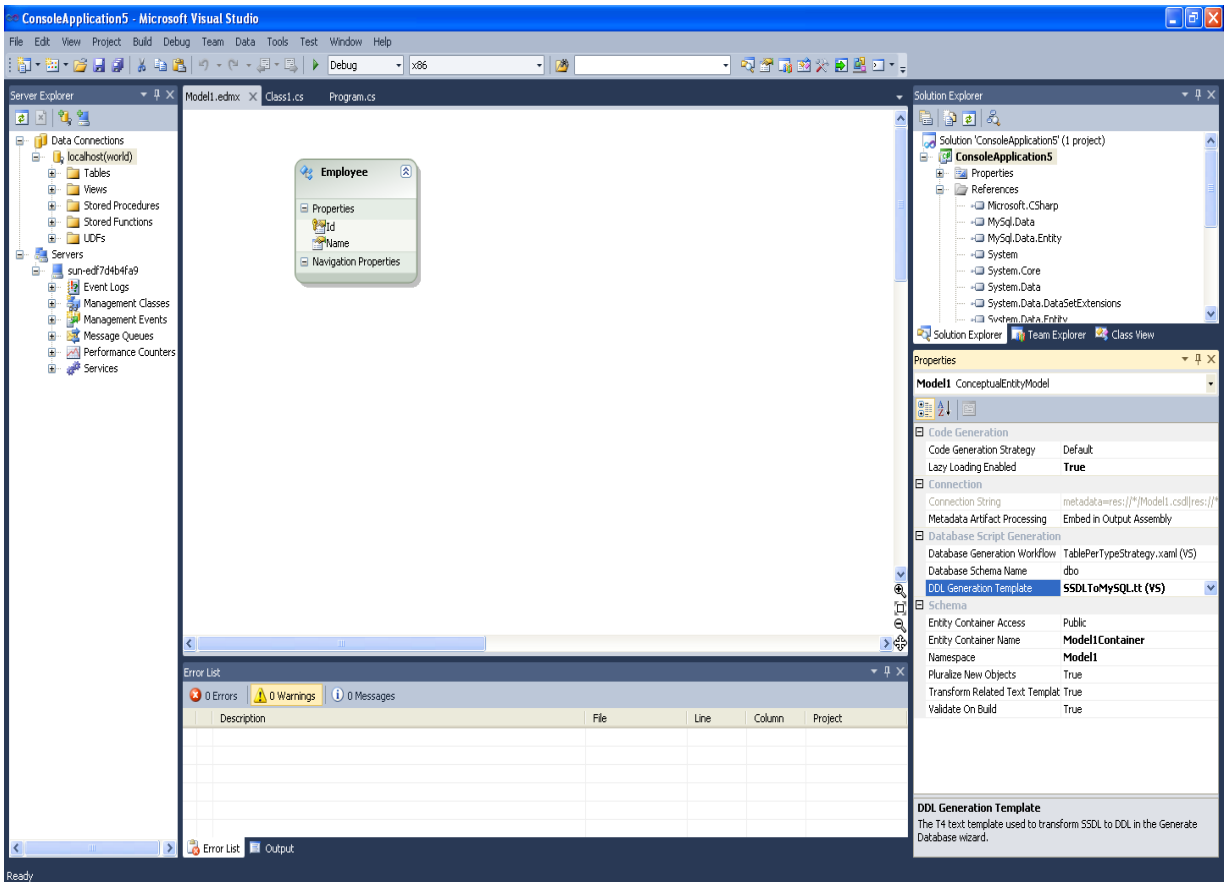
The results from any queries are displayed on the **Results** tab. Any errors are displayed on the **Messages** tab.

DDL T4 Template Macro

MySQL Connector/Net 6.3 introduced the ability to convert an Entity Framework model to MySQL DDL code. Starting with a blank model, you can develop an entity model in Visual Studio's designer. Once the model is created, you can select the model's properties, and in the Database Script Generation

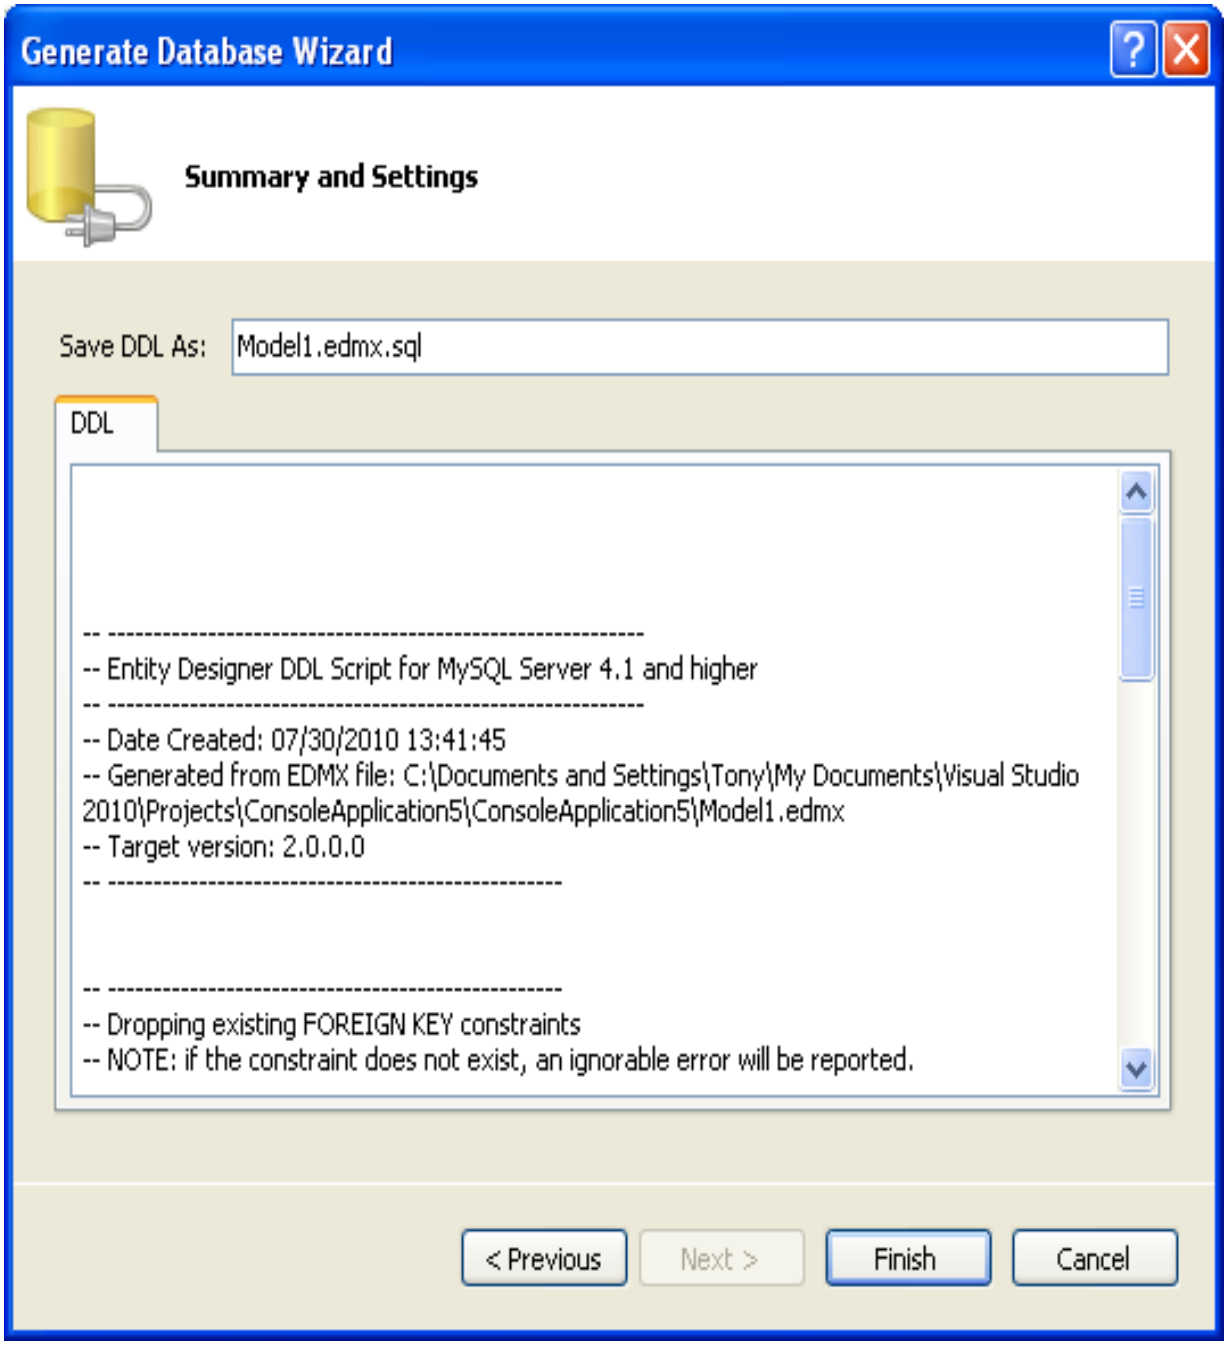
category of the model's properties, the property **DDL Generation** can be found. Select the value **SSDLToMySQL.tt(VS)** from the drop-down listbox.

Figure 21.39. DDL T4 Template Macro - Model Properties



Right-clicking the model design area displays a context-sensitive menu. Selecting **Generate Database from Model** from the menu displays the **Generate Database Wizard**. The wizard can then be used to generate MySQL DDL code.

Figure 21.40. DDL T4 Template Macro - Generate Database Wizard



Connector/Net Tutorials

The following tutorials illustrate how to develop MySQL programs using technologies such as Visual Studio, C#, ASP.NET, and the .NET and Mono frameworks. Work through the first tutorial to verify that you have the right software components installed and configured, then choose other tutorials to try depending on the features you intend to use in your applications.

Tutorial: An Introduction to Connector/Net Programming

This section provides a gentle introduction to programming with Connector/Net. The example code is written in C#, and is designed to work on both Microsoft .NET Framework and Mono.

This tutorial is designed to get you up and running with Connector/Net as quickly as possible, it does not go into detail on any particular topic. However, the following sections of this manual describe each

of the topics introduced in this tutorial in more detail. In this tutorial you are encouraged to type in and run the code, modifying it as required for your setup.

This tutorial assumes you have MySQL and Connector/Net already installed. It also assumes that you have installed the World example database, which can be downloaded from the MySQL Documentation page. You can also find details on how to install the database on the same page.

Note

Before compiling the example code, make sure that you have added References to your project as required. The References required are `System`, `System.Data` and `MySql.Data`.

The MySqlConnection Object

For your Connector/Net application to connect to a MySQL database, it must establish a connection by using a `MySqlConnection` object.

The `MySqlConnection` constructor takes a connection string as one of its parameters. The connection string provides necessary information to make the connection to the MySQL database. The connection string is discussed more fully in Connecting to MySQL Using Connector/Net. For a list of supported connection string options, see Connector/Net Connection String Options Reference.

The following code shows how to create a connection object:

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial1
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=******;";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();
            // Perform database operations
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }
        conn.Close();
        Console.WriteLine("Done.");
    }
}
```

When the `MySqlConnection` constructor is invoked, it returns a connection object, which is used for subsequent database operations. Open the connection before any other operations take place. Before the application exits, close the connection to the database by calling `Close` on the connection object.

Sometimes an attempt to perform an `Open` on a connection object can fail, generating an exception that can be handled using standard exception handling code.

In this section you have learned how to create a connection to a MySQL database, and open and close the corresponding connection object.

The MySqlCommand Object

Once a connection has been established with the MySQL database, the next step is do carry out the desired database operations. This can be achieved through the use of the `MySqlCommand` object.

You will see how to create a `MySqlCommand` object. Once it has been created, there are three main methods of interest that you can call:

- **ExecuteReader** - used to query the database. Results are usually returned in a `MySqlDataReader` object, created by `ExecuteReader`.
- **ExecuteNonQuery** - used to insert and delete data.
- **ExecuteScalar** - used to return a single value.

Once a `MySqlCommand` object has been created, you will call one of the above methods on it to carry out a database operation, such as perform a query. The results are usually returned into a `MySqlDataReader` object, and then processed, for example the results might be displayed. The following code demonstrates how this could be done.

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial2
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=******;";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();

            string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent='Oceania'";
            MySqlCommand cmd = new MySqlCommand(sql, conn);
            MySqlDataReader rdr = cmd.ExecuteReader();

            while (rdr.Read())
            {
                Console.WriteLine(rdr[0]+" -- "+rdr[1]);
            }
            rdr.Close();
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }

        conn.Close();
        Console.WriteLine("Done.");
    }
}
```

When a connection has been created and opened, the code then creates a `MySqlCommand` object. Note that the SQL query to be executed is passed to the `MySqlCommand` constructor. The `ExecuteReader` method is then used to generate a `MySqlReader` object. The `MySqlReader` object contains the results generated by the SQL executed on the command object. Once the results have been obtained in a `MySqlReader` object, the results can be processed. In this case, the information is printed out by a `while` loop. Finally, the `MySqlReader` object is disposed of by running its `Close` method on it.

In the next example, you will see how to use the `ExecuteNonQuery` method.

The procedure for performing an `ExecuteNonQuery` method call is simpler, as there is no need to create an object to store results. This is because `ExecuteNonQuery` is only used for inserting, updating and deleting data. The following example illustrates a simple update to the `Country` table:

```
using System;
```

```
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial3
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=******;";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();

            string sql = "INSERT INTO Country (Name, HeadOfState, Continent) VALUES ('Disneyland','Mickey M
            MySqlCommand cmd = new MySqlCommand(sql, conn);
            cmd.ExecuteNonQuery();
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }

        conn.Close();
        Console.WriteLine("Done.");
    }
}
```

The query is constructed, the command object created and the `ExecuteNonQuery` method called on the command object. You can access your MySQL database with the `mysql` command interpreter and verify that the update was carried out correctly.

Finally, you will see how the `ExecuteScalar` method can be used to return a single value. Again, this is straightforward, as a `MySqlDataReader` object is not required to store results, a simple variable will do. The following code illustrates how to use `ExecuteScalar`:

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial4
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=******;";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();

            string sql = "SELECT COUNT(*) FROM Country";
            MySqlCommand cmd = new MySqlCommand(sql, conn);
            object result = cmd.ExecuteScalar();
            if (result != null)
            {
                int r = Convert.ToInt32(result);
                Console.WriteLine("Number of countries in the World database is: " + r);
            }

        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }

        conn.Close();
```

```
        Console.WriteLine("Done.");
    }
}
```

This example uses a simple query to count the rows in the `Country` table. The result is obtained by calling `ExecuteScalar` on the command object.

Working with Decoupled Data

Previously, when using `MySqlDataReader`, the connection to the database was continually maintained, unless explicitly closed. It is also possible to work in a manner where a connection is only established when needed. For example, in this mode, a connection could be established to read a chunk of data, the data could then be modified by the application as required. A connection could then be reestablished only if and when the application writes data back to the database. This decouples the working data set from the database.

This decoupled mode of working with data is supported by Connector/Net. There are several parts involved in allowing this method to work:

- **Data Set** - The Data Set is the area in which data is loaded to read or modify it. A `DataSet` object is instantiated, which can store multiple tables of data.
- **Data Adapter** - The Data Adapter is the interface between the Data Set and the database itself. The Data Adapter is responsible for efficiently managing connections to the database, opening and closing them as required. The Data Adapter is created by instantiating an object of the `MySqlDataAdapter` class. The `MySqlDataAdapter` object has two main methods: `Fill` which reads data into the Data Set, and `Update`, which writes data from the Data Set to the database.
- **Command Builder** - The Command Builder is a support object. The Command Builder works in conjunction with the Data Adapter. When a `MySqlDataAdapter` object is created, it is typically given an initial SELECT statement. From this `SELECT` statement the Command Builder can work out the corresponding `INSERT`, `UPDATE` and `DELETE` statements that would be required to update the database. To create the Command Builder, an object of the class `MySqlCommandBuilder` is created.

Each of these classes will now be discussed in more detail.

Instantiating a DataSet object

A `DataSet` object can be created simply, as shown in the following example code snippet:

```
DataSet dsCountry;
...
dsCountry = new DataSet();
```

Although this creates the `DataSet` object, it has not yet filled it with data. For that, a Data Adapter is required.

Instantiating a MySqlDataAdapter object

The `MySqlDataAdapter` can be created as illustrated by the following example:

```
MySqlDataAdapter daCountry;
...
string sql = "SELECT Code, Name, HeadOfState FROM Country WHERE Continent='North America'";
daCountry = new MySqlDataAdapter (sql, conn);
```

Note, the `MySqlDataAdapter` is given the SQL specifying the data to work with.

Instantiating a MySqlCommandBuilder object

Once the `MySqlDataAdapter` has been created, it is necessary to generate the additional statements required for inserting, updating and deleting data. There are several ways to do this, but in this tutorial

you will see how this can most easily be done with `MySqlCommandBuilder`. The following code snippet illustrates how this is done:

```
MySqlCommandBuilder cb = new MySqlCommandBuilder(daCountry);
```

Note that the `MySqlDataAdapter` object is passed as a parameter to the command builder.

Filling the Data Set

To do anything useful with the data from your database, you need to load it into a Data Set. This is one of the jobs of the `MySqlDataAdapter` object, and is carried out with its `Fill` method. The following example code illustrates this:

```
DataSet dsCountry;
...
dsCountry = new DataSet();
...
daCountry.Fill(dsCountry, "Country");
```

Note the `Fill` method is a `MySqlDataAdapter` method, the Data Adapter knows how to establish a connec tion with the database and retrieve the required data, and then populates the Data Set when the `Fill` method is called. The second parameter “Country” is the table in the Data Set to update.

Updating the Data Set

The data in the Data Set can now be manipulated by the application as required. At some point, changes to data will need to be written back to the database. This is achieved through a `MySqlDataAdapter` method, the `Update` method.

```
daCountry.Update(dsCountry, "Country");
```

Again, the Data Set and the table within the Data Set to update are specified.

Working Example

The interactions between the `DataSet`, `MySqlDataAdapter` and `MySqlCommandBuilder` classes can be a little confusing, so their operation can perhaps be best illustrated by working code.

In this example, data from the World database is read into a Data Grid View control. Here, the data can be viewed and changed before clicking an update button. The update button then activates code to write changes back to the database. The code uses the principles explained above. The application was built using the Microsoft Visual Studio to place and create the user interface controls, but the main code that uses the key classes described above is shown below, and is portable.

```
using System;
using System.Collections.Generic;
using System.ComponentModel;
using System.Data;
using System.Drawing;
using System.Linq;
using System.Text;
using System.Windows.Forms;

using MySql.Data;
using MySql.Data.MySqlClient;

namespace WindowsFormsApplication5
{
    public partial class Form1 : Form
    {
        MySqlDataAdapter daCountry;
        DataSet dsCountry;

        public Form1()
```

```
        {
            InitializeComponent();
        }

        private void Form1_Load(object sender, EventArgs e)
        {

            string connStr = "server=localhost;user=root;database=world;port=3306;password=******;";
            MySqlConnection conn = new MySqlConnection(connStr);
            try
            {
                label2.Text = "Connecting to MySQL...";

                string sql = "SELECT Code, Name, HeadOfState FROM Country WHERE Continent='North Americ
                daCountry = new MySqlDataAdapter (sql, conn);
                MySqlCommandBuilder cb = new MySqlCommandBuilder(daCountry);

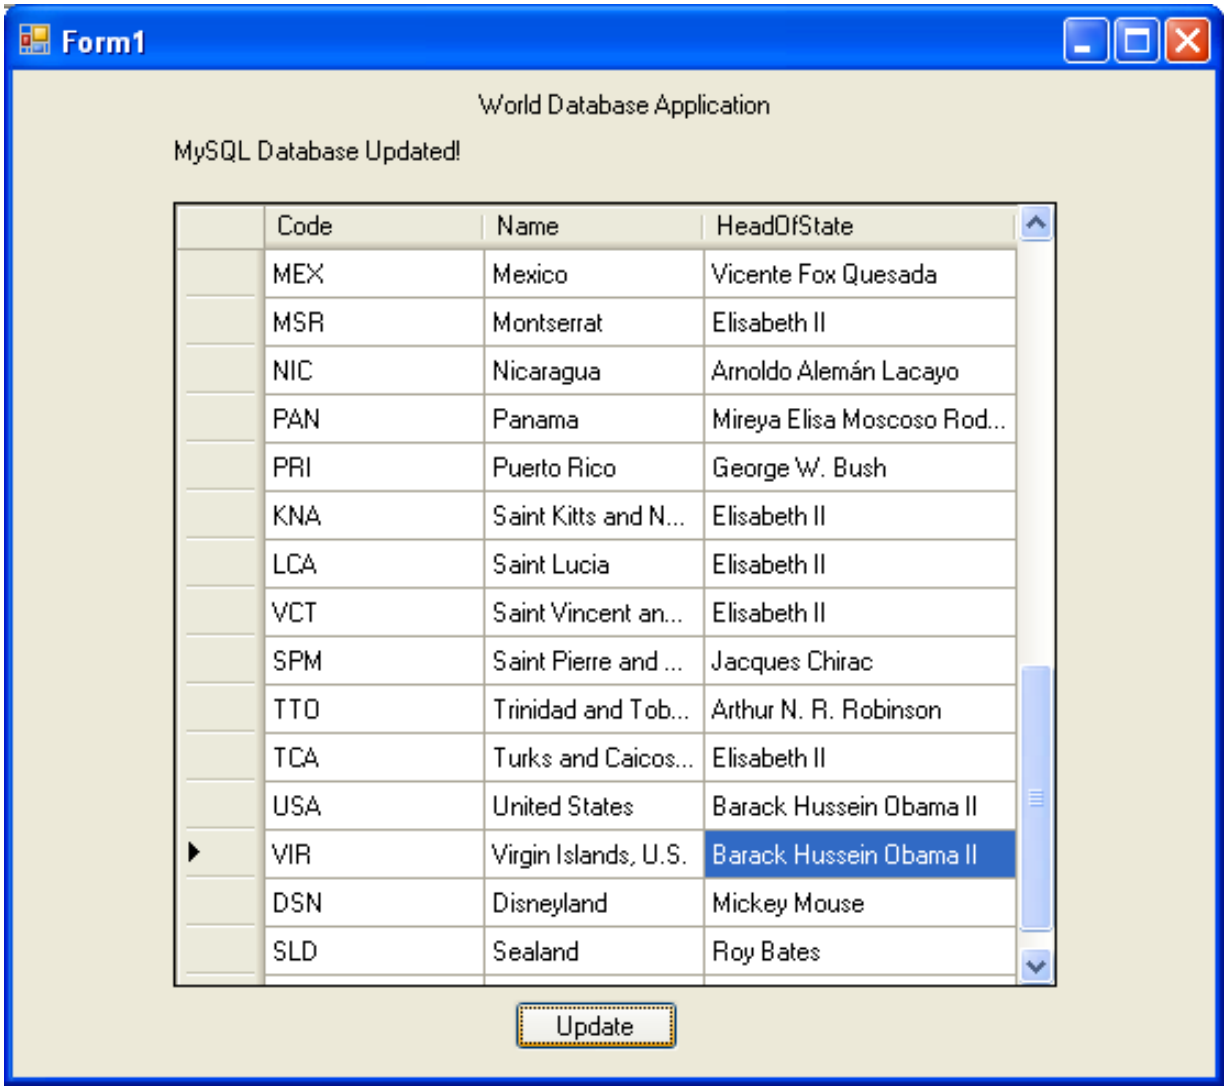
                dsCountry = new DataSet();
                daCountry.Fill(dsCountry, "Country");
                dataGridView1.DataSource = dsCountry;
                dataGridView1.DataMember = "Country";
            }
            catch (Exception ex)
            {
                label2.Text = ex.ToString();
            }
        }

        private void button1_Click(object sender, EventArgs e)
        {
            daCountry.Update(dsCountry, "Country");
            label2.Text = "MySQL Database Updated!";
        }

    }
}
```

The application running is shown below:

Figure 21.41. World Database Application



Working with Parameters

This part of the tutorial shows you how to use parameters in your Connector/Net application.

Although it is possible to build SQL query strings directly from user input, this is not advisable as it does not prevent erroneous or malicious information being entered. It is safer to use parameters as they will be processed as field data only. For example, imagine the following query was constructed from user input:

```
string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent = "+user_continent;
```

If the string `user_continent` came from a Text Box control, there would potentially be no control over the string entered by the user. The user could enter a string that generates a run time error, or in the worst case actually harms the system. When using parameters it is not possible to do this because a parameter is only ever treated as a field parameter, rather than an arbitrary piece of SQL code.

The same query written user a parameter for user input would be:

```
string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent = @Continent";
```

Note that the parameter is preceded by an '@' symbol to indicate it is to be treated as a parameter.

As well as marking the position of the parameter in the query string, it is necessary to add a parameter to the Command object. This is illustrated by the following code snippet:

```
cmd.Parameters.AddWithValue("@Continent", "North America");
```

In this example the string "North America" is supplied as the parameter value statically, but in a more practical example it would come from a user input control.

A further example illustrates the complete process:

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial5
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=******;";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();

            string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent=@Continent";
            MySqlCommand cmd = new MySqlCommand(sql, conn);

            Console.WriteLine("Enter a continent e.g. 'North America', 'Europe': ");
            string user_input = Console.ReadLine();

            cmd.Parameters.AddWithValue("@Continent", user_input);

            MySqlDataReader rdr = cmd.ExecuteReader();

            while (rdr.Read())
            {
                Console.WriteLine(rdr["Name"]+" --- "+rdr["HeadOfState"]);
            }
            rdr.Close();
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }

        conn.Close();
        Console.WriteLine("Done.");
    }
}
```

In this part of the tutorial you have see how to use parameters to make your code more secure.

Working with Stored Procedures

This section illustrates how to work with stored procedures. Putting database-intensive operations into stored procedures lets you define an API for your database application. You can reuse this API across multiple applications and multiple programming languages. This technique avoids duplicating database code, saving time and effort when you make updates due to schema changes, tune the performance of queries, or add new database operations for logging, security, and so on. Before working through this tutorial, familiarize yourself with the `CREATE PROCEDURE` and `CREATE FUNCTION` statements that create different kinds of stored routines.

For the purposes of this tutorial, you will create a simple stored procedure to see how it can be called from Connector/Net. In the MySQL Client program, connect to the World database and enter the following stored procedure:

```
DELIMITER //
CREATE PROCEDURE country_hos
(IN con CHAR(20))
```

```
BEGIN
  SELECT Name, HeadOfState FROM Country
  WHERE Continent = con;
END //
DELIMITER ;
```

Test that the stored procedure works as expected by typing the following into the `mysql` command interpreter:

```
CALL country_hos('Europe');
```

Note that The stored routine takes a single parameter, which is the continent to restrict your search to.

Having confirmed that the stored procedure is present and correct, you can see how to access it from Connector/Net.

Calling a stored procedure from your Connector/Net application is similar to techniques you have seen earlier in this tutorial. A `MySqlCommand` object is created, but rather than taking an SQL query as a parameter, it takes the name of the stored procedure to call. Set the `MySqlCommand` object to the type of stored procedure, as shown by the following code snippet:

```
string rtn = "country_hos";
MySqlCommand cmd = new MySqlCommand(rtn, conn);
cmd.CommandType = CommandType.StoredProcedure;
```

In this case, the stored procedure requires you to pass a parameter. This can be achieved using the techniques seen in the previous section on parameters, Working with Parameters, as shown in the following code snippet:

```
cmd.Parameters.AddWithValue("@con", "Europe");
```

The value of the parameter `@con` could more realistically have come from a user input control, but for simplicity it is set as a static string in this example.

At this point, everything is set up and you can call the routine using techniques also learned in earlier sections. In this case, the `ExecuteReader` method of the `MySqlCommand` object is used.

Complete working code for the stored procedure example is shown below:

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial6
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=******;";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();

            string rtn = "country_hos";
            MySqlCommand cmd = new MySqlCommand(rtn, conn);
            cmd.CommandType = CommandType.StoredProcedure;

            cmd.Parameters.AddWithValue("@con", "Europe");

            MySqlDataReader rdr = cmd.ExecuteReader();
            while (rdr.Read())
            {
                Console.WriteLine(rdr[0] + " --- " + rdr[1]);
            }
            rdr.Close();
        }
```

```
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }

        conn.Close();
        Console.WriteLine("Done.");
    }
}
```

In this section, you have seen how to call a stored procedure from Connector/Net. For the moment, this concludes our introductory tutorial on programming with Connector/Net.

Tutorial: MySQL Connector/Net ASP.NET Membership and Role Provider

Many web sites feature the facility for the user to create a user account. They can then log into the web site and enjoy a personalized experience. This requires that the developer creates database tables to store user information, along with code to gather and process this data. This represents a burden on the developer, and there is the possibility for security issues to creep into the developed code. However, ASP.NET 2.0 introduced the Membership system. This system is designed around the concept of Membership, Profile and Role Providers, which together provide all of the functionality to implement a user system, that previously would have to have been created by the developer from scratch.

Currently, MySQL Connector/Net provides Membership, Role, Profile and Session State Providers.

This tutorial shows you how to set up your ASP.NET web application to use the MySQL Connector/Net Membership and Role Providers. It assumes that you have MySQL Server installed, along with MySQL Connector/Net and Microsoft Visual Studio. This tutorial was tested with MySQL Connector/Net 6.0.4 and Microsoft Visual Studio 2008 Professional Edition. It is recommended you use 6.0.4 or above for this tutorial.

1. Create a new database in the MySQL Server using the MySQL Command Line Client program (`mysql`), or other suitable tool. It does not matter what name is used for the database, but record it. You specify it in the connection string constructed later in this tutorial. This database contains the tables, automatically created for you later, used to store data about users and roles.

2. Create a new ASP.NET Web Site in Visual Studio. If you are not sure how to do this, refer to Tutorial: Databinding in ASP.NET using LINQ on Entities, which demonstrates how to create a simple ASP.NET web site.

3. Add References to `MySql.Data` and `MySql.Web` to the web site project.

4. Locate the `machine.config` file on your system, which is the configuration file for the .NET Framework.

5. Search the `machine.config` file to find the membership provider `MySQLMembershipProvider`.

6. Add the attribute `autogenerateschema="true"`. The appropriate section should now resemble the following (note: for the sake of brevity some information has been excluded):

```
<membership>
 <providers>
   <add name="AspNetSqlMembershipProvider"
     type="System.Web.Security.SqlMembershipProvider"
     ...
     connectionStringName="LocalSqlServer"
     ... />
   <add name="MySQLMembershipProvider"
     autogenerateschema="true"
     type="MySql.Web.Security.MySQLMembershipProvider, MySql.Web, Version=6.0.4.0, Culture=neutral,
     connectionStringName="LocalMySqlServer"
     ... />
 </providers>
</membership>
```

Note that the name for the connection string to be used to connect to the server that contains the membership database is `LocalMySqlServer`.

The `autogenerateschema="true"` attribute will cause MySQL Connector/Net to silently create, or upgrade, the schema on the database server, to contain the required tables for storing membership information.

7. It is now necessary to create the connection string referenced in the previous step. Load the web site's `web.config` file into Visual Studio.

8. Locate the section marked `<connectionStrings>`. Add the following connection string information:

```
<connectionStrings>
  <remove name="LocalMySqlServer"/>
  <add name="LocalMySqlServer"
       connectionString="Datasource=localhost;Database=users;uid=root;pwd=password;"
       providerName="MySql.Data.MySqlClient"/>
</connectionStrings>
```

   The database specified is the one created in the first step. You could alternatively have used an existing database.

9. At this point build the solution to ensure no errors are present. This can be done by selecting Build, Build Solution from the main menu, or pressing **F6**.

10. ASP.NET supports the concept of locally and remotely authenticated users. With local authentication the user is validated using their Windows credentials when they attempt to access the web site. This can be useful in an Intranet environment. With remote authentication, a user is prompted for their login details when accessing the web site, and these credentials are checked against the membership information stored in a database server such as MySQL Server. You will now see how to choose this form of authentication.

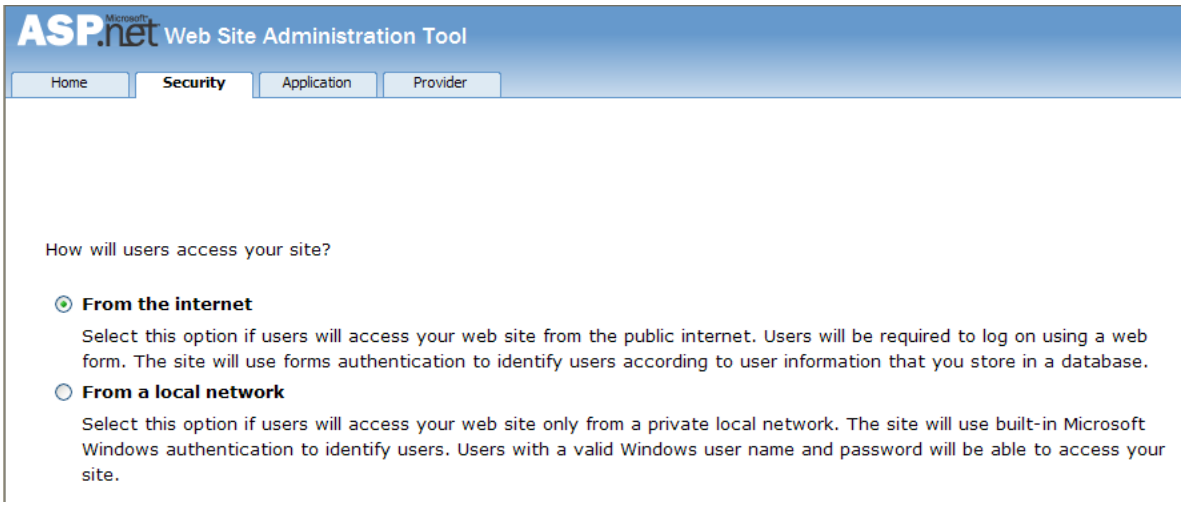
    Start the ASP.NET Web Site Administration Tool. This can be done quickly by clicking the small hammer/Earth icon in the Solution Explorer. You can also launch this tool by selecting Website, ASP.NET Configuration from the main menu.

11. In the ASP.NET Web Site Administration Tool click the **Security** tab.

12. Now click the **User Authentication Type** link.

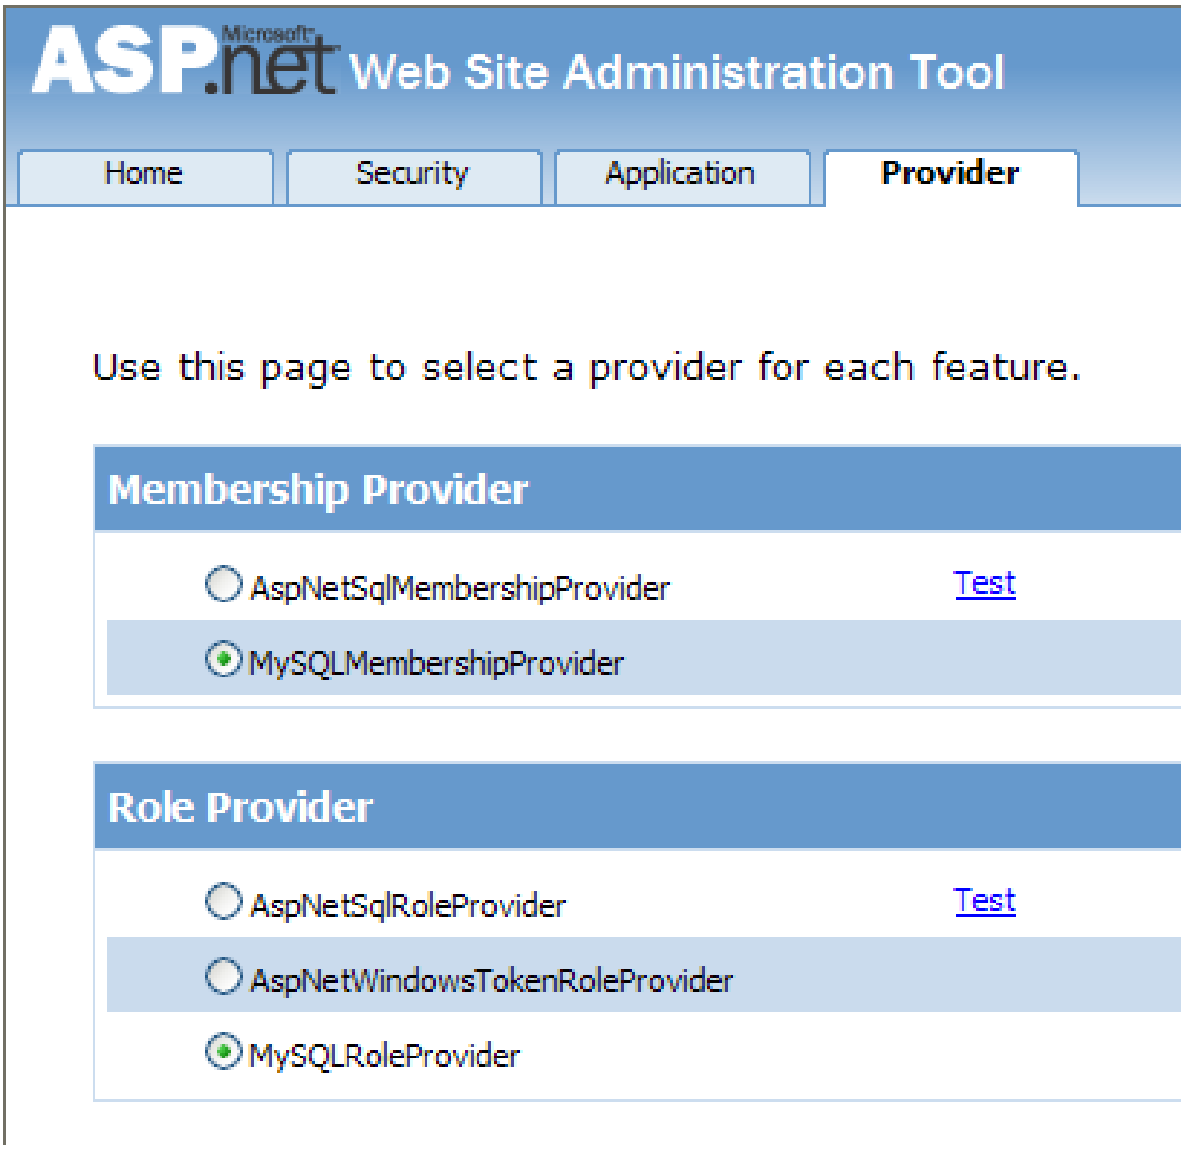
13. Select the **From the internet** radio button. The web site will now need to provide a form to allow the user to enter their login details. These will be checked against membership information stored in the MySQL database.

Figure 21.42. Authentication Type



14. You now need to specify the Role and Membership Provider to be used. Click the **Provider** tab.
15. Click the **Select a different provider for each feature (advanced)** link.
16. Now select the **MySQLMembershipProvider** and the **MySQLRoleProvider** radio buttons.

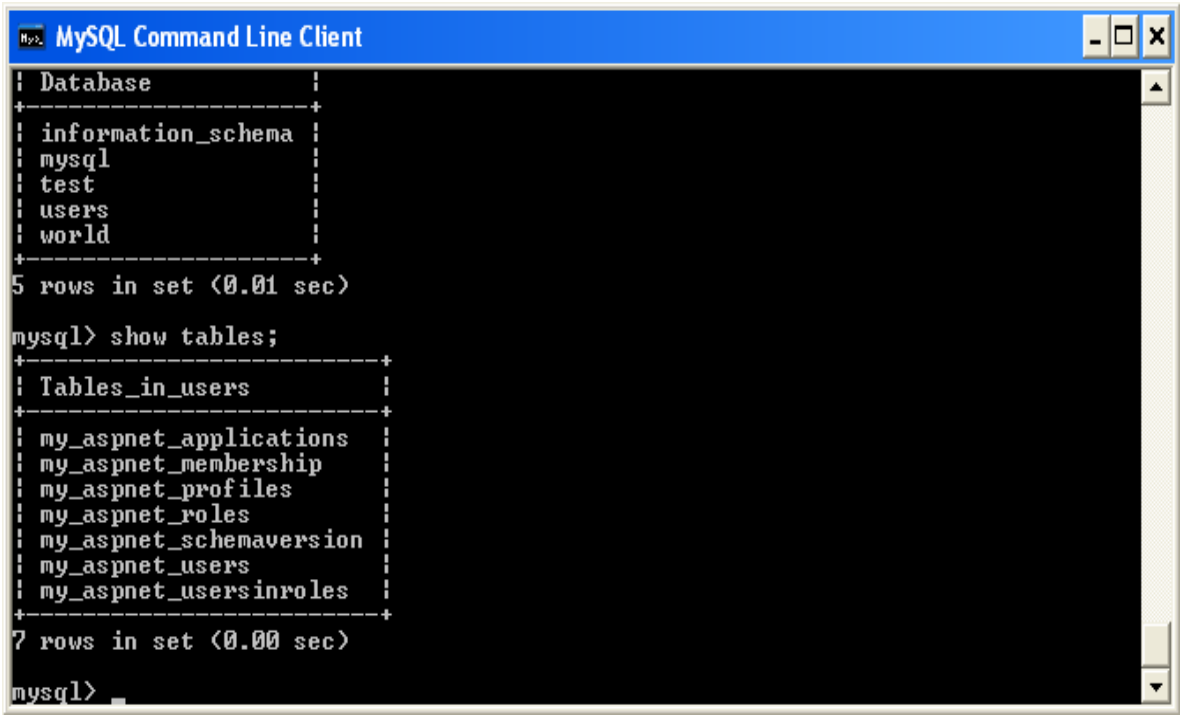
Figure 21.43. Select Membership and Role Provider



17. In Visual Studio, rebuild the solution by selecting Build, Rebuild Solution from the main menu.

18. Check that the necessary schema has been created. This can be achieved using the `mysql` command interpreter.

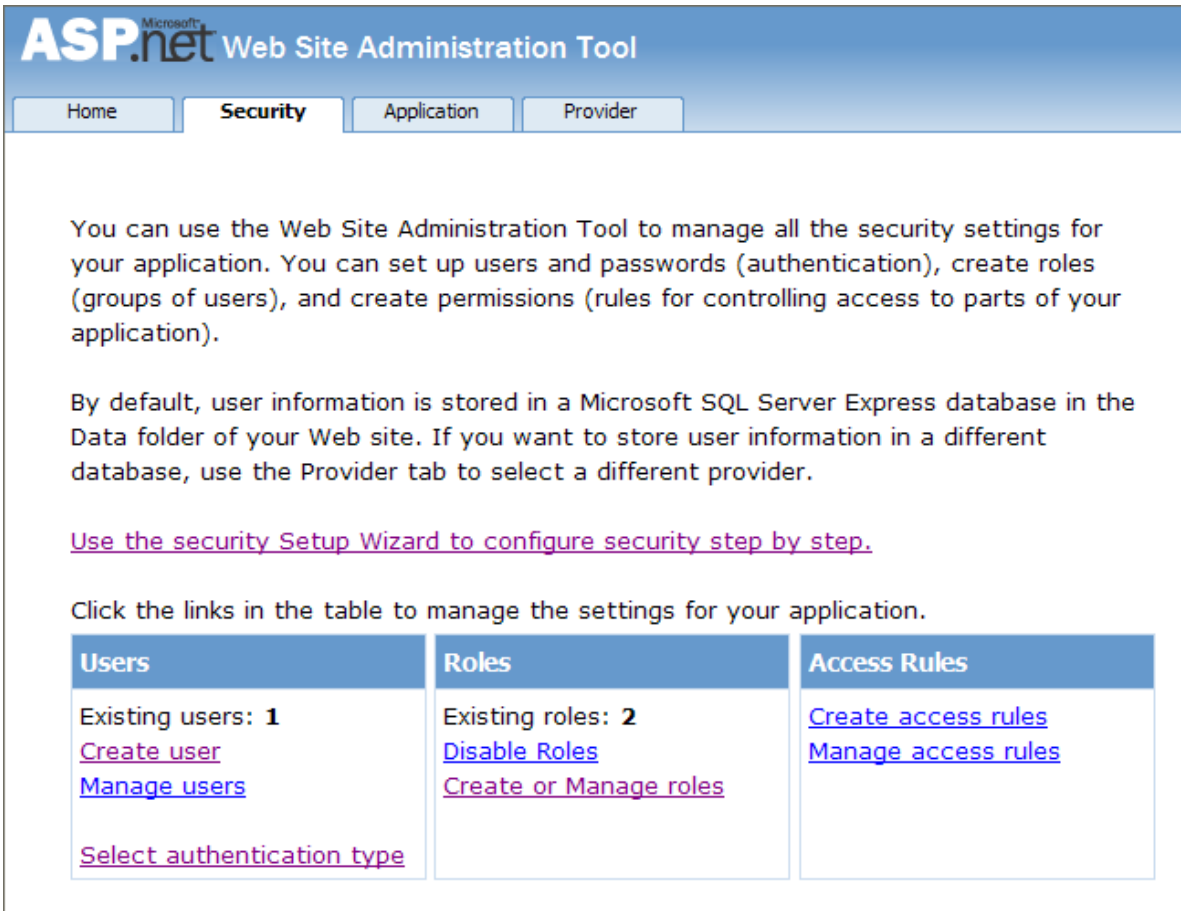
Figure 21.44. Membership and Role Provider Tables



19. Assuming all is present and correct, you can now create users and roles for your web application. The easiest way to do this is with the ASP.NET Web Site Administration Tool. However, many web applications contain their own modules for creating roles and users. For simplicity, the ASP.NET Web Site Administration Tool will be used in this tutorial.

20. In the ASP.NET Web Site Administration Tool, click the **Security** tab. Now that both the Membership and Role Provider are enabled, you will see links for creating roles and users. Click the **Create or Manage Roles** link.

Figure 21.45. Security Tab

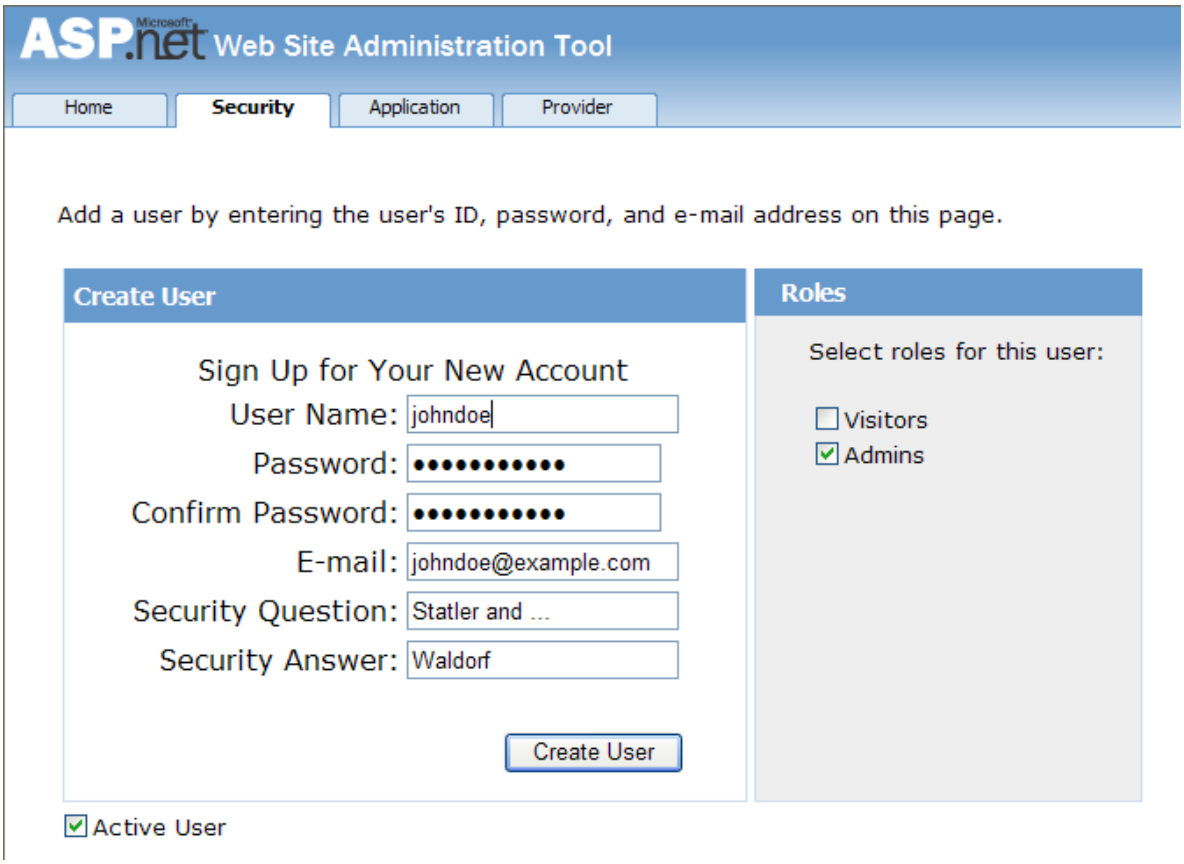


21. You can now enter the name of a new Role and click Add Role to create the new Role. Create new Roles as required.

22. Click the Back button.

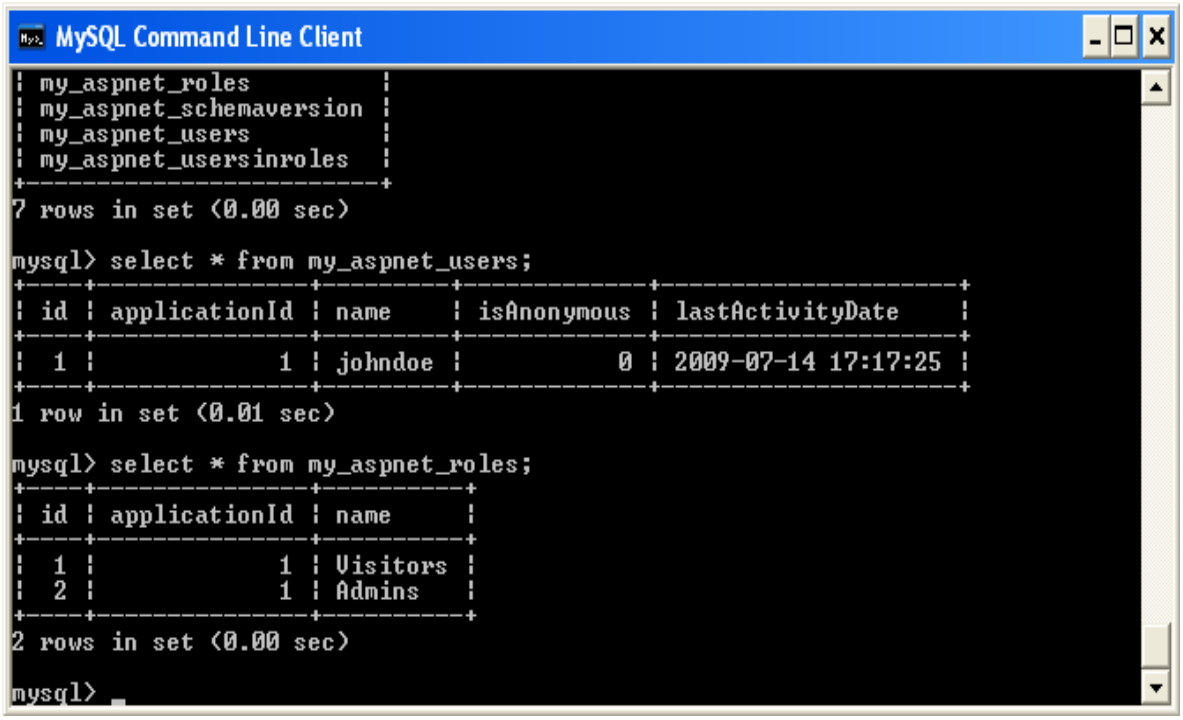
23. Click the **Create User** link. You can now fill in information about the user to be created, and also allocate that user to one or more Roles.

Figure 21.46. Create User



24. Using the `mysql` command interpreter, you can check that your database has been correctly populated with the Membership and Role data.

Figure 21.47. Membership and Roles Table Contents



In this tutorial, you have seen how to set up the MySQL Connector/Net Membership and Role Providers for use in your ASP.NET web application.

Tutorial: MySQL Connector/Net ASP.NET Session State Provider

MySQL Connector/Net from version 6.1 has included a MySQL Session State Provider. This provider enables you to store session state in a MySQL database. The following tutorial shows you how to prepare to use the MySQL Session State Provider, and then store session data into the MySQL database. This tutorial uses Microsoft Visual Studio 2008 Professional Edition, MySQL Connector/Net 6.1.1 and MySQL Server 5.1. This tutorial also assumes you have created an empty database, for example `test`, where you will store session data. You could do this using the `mysql` command interpreter.

1. In Visual Studio, create a new ASP.NET web site. If you are not sure how to do this, refer to the tutorial Tutorial: Databinding in ASP.NET using LINQ on Entities, which demonstrates how to do this.

2. Launch the MySQL MySQL Website Configuration tool. Due to a bug in 6.1.1, this may not appear unless you are connected to a server in the Server Explorer. If you are unfamiliar with the MySQL Website Configuration tool, consider first working through the tutorial in MySQL Website Configuration Tool.

3. Navigate through the wizard to the Session State page. Make sure the check box **Use MySQL to manage my ASP.NET session data** is selected.

4. On the same page, configure the connection string to the database that will contain your session data. If this database is empty, MySQL Connector/Net will create the schema required to store session data.

5. Ensure that the check box **Autogenerate Schema** is selected so that MySQL Connector/Net will create the schema in your database to store the session data correctly.

6. Enter the name of your application.

7. Click Finish. The MySQL Website Configuration tool will now update your application's `web.config` file with information about the connection string and default providers to be used. In this case, we have selected the MySQL Session State Provider.

At this point, you are ready to use the MySQL database to store session data. To test that the set up has worked, you can write a simple program that uses session variables.

1. Open `Default.aspx.cs`. In the `Page_Load` method, add the following code:

```
Session["SessionVariable1"] = "Test string";
```

2. Build your solution.

3. Run the solution (without debugging). When the application runs, the provider will autogenerate tables required in the database you chose when setting up the application.

4. Check that the schema was in fact created. Using the MySQL Command Line Client use the target database and then type `SHOW TABLES;`. You will see that MySQL Connector/Net has created the required schema automatically, as we selected this to happen in the MySQL Website Configuration tool.

5. Now view the contents of these tables by typing `SELECT * FROM my_aspnet_sessions;` in the `mysql` command interpreter. This will display the session data our application used. Note that this is stored in binary format so some data may not display as expected.

At this point, you have installed the Session State Provider and carried out a preliminary test of the installation. You will now work a bit more with the Session State Provider.

In this part of the tutorial, you will set and retrieve a session variable. You can work with your existing project.

1. Select the `Default.aspx` and switch to Design View. Add a text box and three buttons. Change the text property for the buttons to “Store Session Variable”, “Clear Textbox”, and “Show Session Variable”. These will be `Button1`, `Button2` and `Button3` respectively. Build your solution to ensure that no errors have been introduced.

2. Still in the Design View, double-click `Button1`. Now to the `Button1_Click` event handler add code some the handler resembles the following:

   ```
   protected void Button1_Click(object sender, EventArgs e)
   {
       Session["SessionString"] = TextBox1.Text;
   }
   ```

   You have created a new Session variable accessed using the key “SessionString”. This will be set to the text that was entered into the text box when `Button1` is clicked.

3. In Design View, double-click `Button2` to add its click event handler. This button needs to clear text from the text box. The code to do this is as follows:

   ```
   protected void Button2_Click(object sender, EventArgs e)
   {
       TextBox1.Text = "";
   }
   ```

   The code simply assigns an empty string to the `Text` property of the text box.

4. In the Design View double-click `Button3` and modify the click handler as follows:

   ```
   protected void Button3_Click(object sender, EventArgs e)
   {
       TextBox1.Text = (String)Session["SessionString"];
   }
   ```

   This will retrieve the session string and display it in the text box.

5. Now modify the `Page_Load` method as follows:

   ```
   protected void Page_Load(object sender, EventArgs e)
   {
       if (!IsPostBack)
       {
          TextBox1.Text = "Enter some text";
       }
   }
   ```

   This ensures that when the page loads the text box `Text` property is reset.

6. Ensure that the solution is saved and then rebuild the solution.

7. Run the solution without debugging.

8. The form will be displayed. Enter some text into the text box. Now click Store Session Variable. At this point you have stored the string in a session variable.

9. Now click Clear Text to clear the text box.

10. Now click Show Session Variable to retrieve and display the session variable.

11. Refresh the page to destroy the form and display a new form.

12. Click Show Session Variable the text box will display the stored session variable, demonstrating that the refreshing the page does not destroy the session variable.

This illustrates that the session state data is not destroyed when a page is reloaded.

Tutorial: MySQL Connector/Net ASP.NET Profile Provider

This tutorial shows you how to use the MySQL Profile Provider to store user profile information in a MySQL database. The tutorial uses MySQL Connector/Net 6.1.1, MySQL Server 5.1 and Microsoft Visual Studio 2008 Professional Edition.

Many modern web sites allow the user to create a personal profile. This requires a significant amount of code, but ASP.NET reduces this considerable by including the functionality in its Profile classes. The Profile Provider provides an abstraction between these classes and a data source. The MySQL Profile Provider enables profile data to be stored in a MySQL database. This enables the profile properties to be written to a persistent store, and be retrieved when required. The Profile Provider also enables profile data to be managed effectively, for example it enables profiles that have not been accessed since a specific date to be deleted.

The following steps show you how you can select the MySQL Profile Provider.

1. Create a new ASP.NET web project.
2. Select the MySQL Website Configuration tool. Due to a bug in 6.1.1 you may have to first connect to a server in Server Explorer before the tool's icon will display in the toolbar of the Solution Explorer.
3. In the MySQL Website Configuration tool navigate through the tool to the Profiles page.
4. Select the **Use MySQL to manage my profiles** check box.
5. Select the **Autogenerate Schema** check box.
6. Click the Edit... button and configure a connection string for the database that will be used to store user profile information.
7. Navigate to the last page of the tool and click Finish to save your changes and exit the tool.

At this point you are now ready to start using the MySQL Profile Provider. With the following steps you can carry out a preliminary test of your installation.

1. Open your `web.config` file.
2. Add a simple profile such as the following:

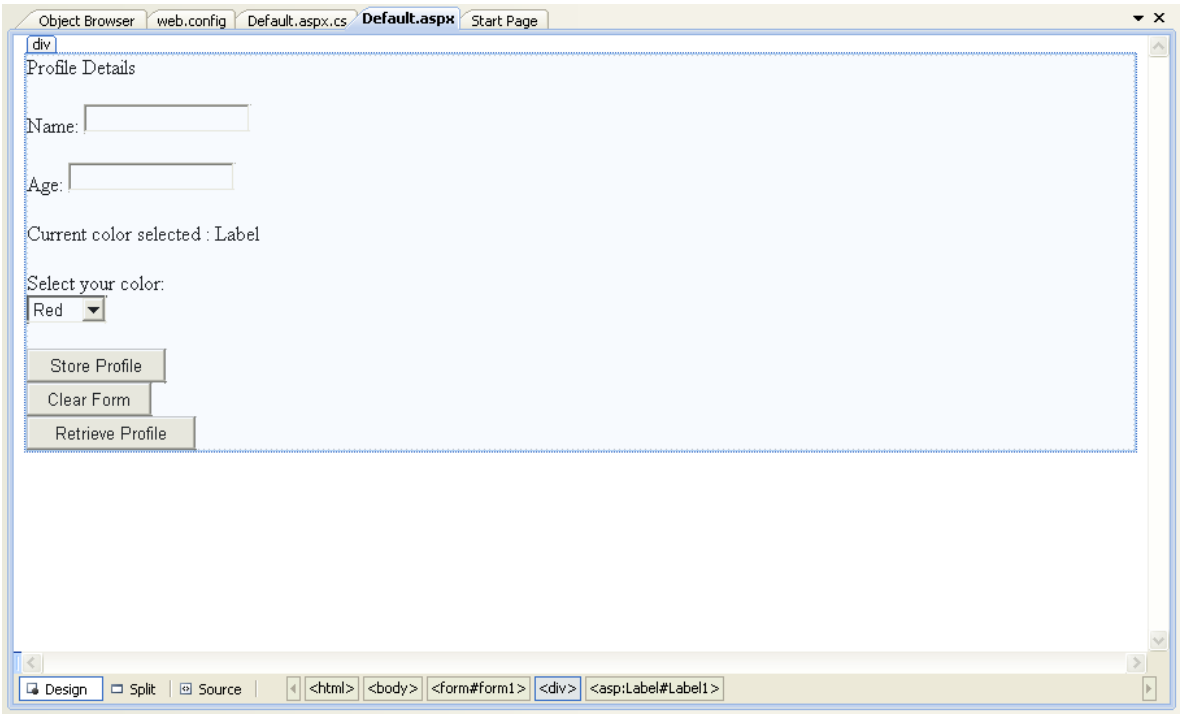
```
<system.web>
  <anonymousIdentification enabled="true"/>
  <profile defaultProvider="MySQLProfileProvider">
    ...
    <properties>
      <add name="Name" allowAnonymous="true"/>
      <add name="Age" allowAnonymous="true" type="System.UInt16"/>
      <group name="UI">
        <add name="Color" allowAnonymous="true" defaultValue="Blue"/>
        <add name="Style" allowAnonymous="true" defaultValue="Plain"/>
      </group>
    </properties>
  </profile>
  ...
```

   Note that `anonymousIdentification` has been set to true. This enables users who have not been authenticated to use profiles. They are identified by a GUID in a cookie rather than by user name.

Now that the simple profile has been defined in `web.config`, the next step is to write some code to test the profile.

1. In Design View design a simple page with the following controls:

Figure 21.48. Simple Profile Application



These will allow the user to enter some profile information. The user can also use the buttons to save their profile, clear the page, and restore their profile data.

2. In the Code View add code as follows:

```
...
protected void Page_Load(object sender, EventArgs e)
{
    if (!IsPostBack)
    {
        TextBox1.Text = Profile.Name;
        TextBox2.Text = Profile.Age.ToString();
        Label1.Text = Profile.UI.Color;
    }
}

// Store Profile
protected void Button1_Click(object sender, EventArgs e)
{
    Profile.Name = TextBox1.Text;
    Profile.Age = UInt16.Parse(TextBox2.Text);
}

// Clear Form
protected void Button2_Click(object sender, EventArgs e)
{
    TextBox1.Text = "";
    TextBox2.Text = "";
    Label1.Text = "";
}

// Retrieve Profile
protected void Button3_Click(object sender, EventArgs e)
{
    TextBox1.Text = Profile.Name;
    TextBox2.Text = Profile.Age.ToString();
    Label1.Text = Profile.UI.Color;
}

protected void DropDownList1_SelectedIndexChanged(object sender, EventArgs e)
```

```
{
    Profile.UI.Color = DropDownList1.SelectedValue;
}
...
```

3. Save all files and build the solution to check that no errors have been introduced.
4. Run the application.
5. Enter your name, age and select a color from the listbox. Now store this information in your profile by clicking Store Profile. Note that if you do not select a color from the listbox your profile will use the default color `Blue` that was specified in the `web.config` file.
6. Click Clear Form to clear text from the textboxes and the label that displays your chosen color.
7. Now click Retrieve Profile to restore your profile data from the MySQL database.
8. Now exit the browser to terminate the application.
9. Run the application again. Note that when the page loads your profile information is restored from the MySQL database.

In this tutorial you have seen how to using the MySQL Profile Provider with MySQL Connector/Net.

Tutorial: Using an Entity Framework Entity as a Windows Forms Data Source

In this tutorial you will learn how to create a Windows Forms Data Source from an Entity in an Entity Data Model. This tutorial assumes that you have installed the World example database, which can be downloaded from the MySQL Documentation page. You can also find details on how to install the database on the same page. It will also be convenient for you to create a connection to the World database after it is installed. For instructions on how to do this see Making a Connection.

Creating a new Windows Forms application

The first step is to create a new Windows Forms application.

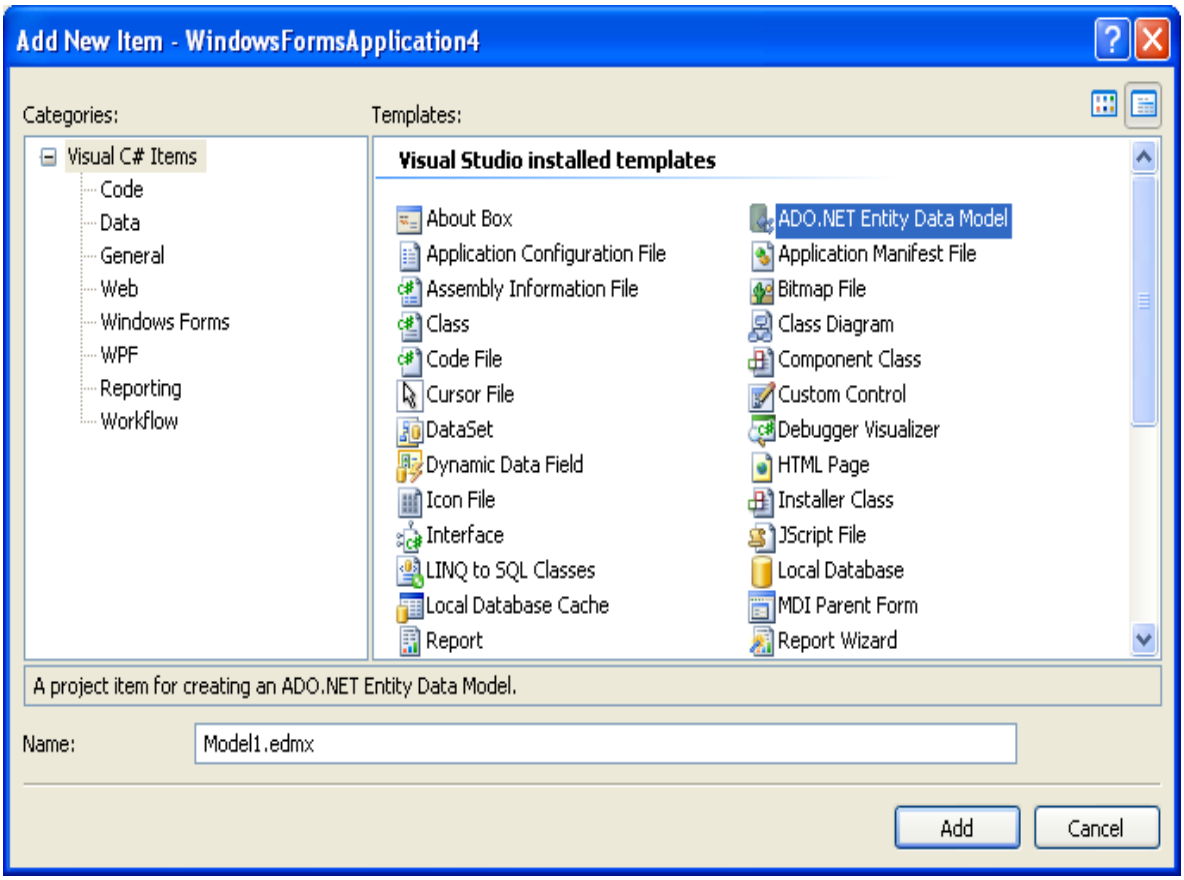
1. In Visual Studio, select File, New, Project from the main menu.
2. Choose the **Windows Forms Application** installed template. Click OK. The solution is created.

Adding an Entity Data Model

You will now add an Entity Data Model to your solution.

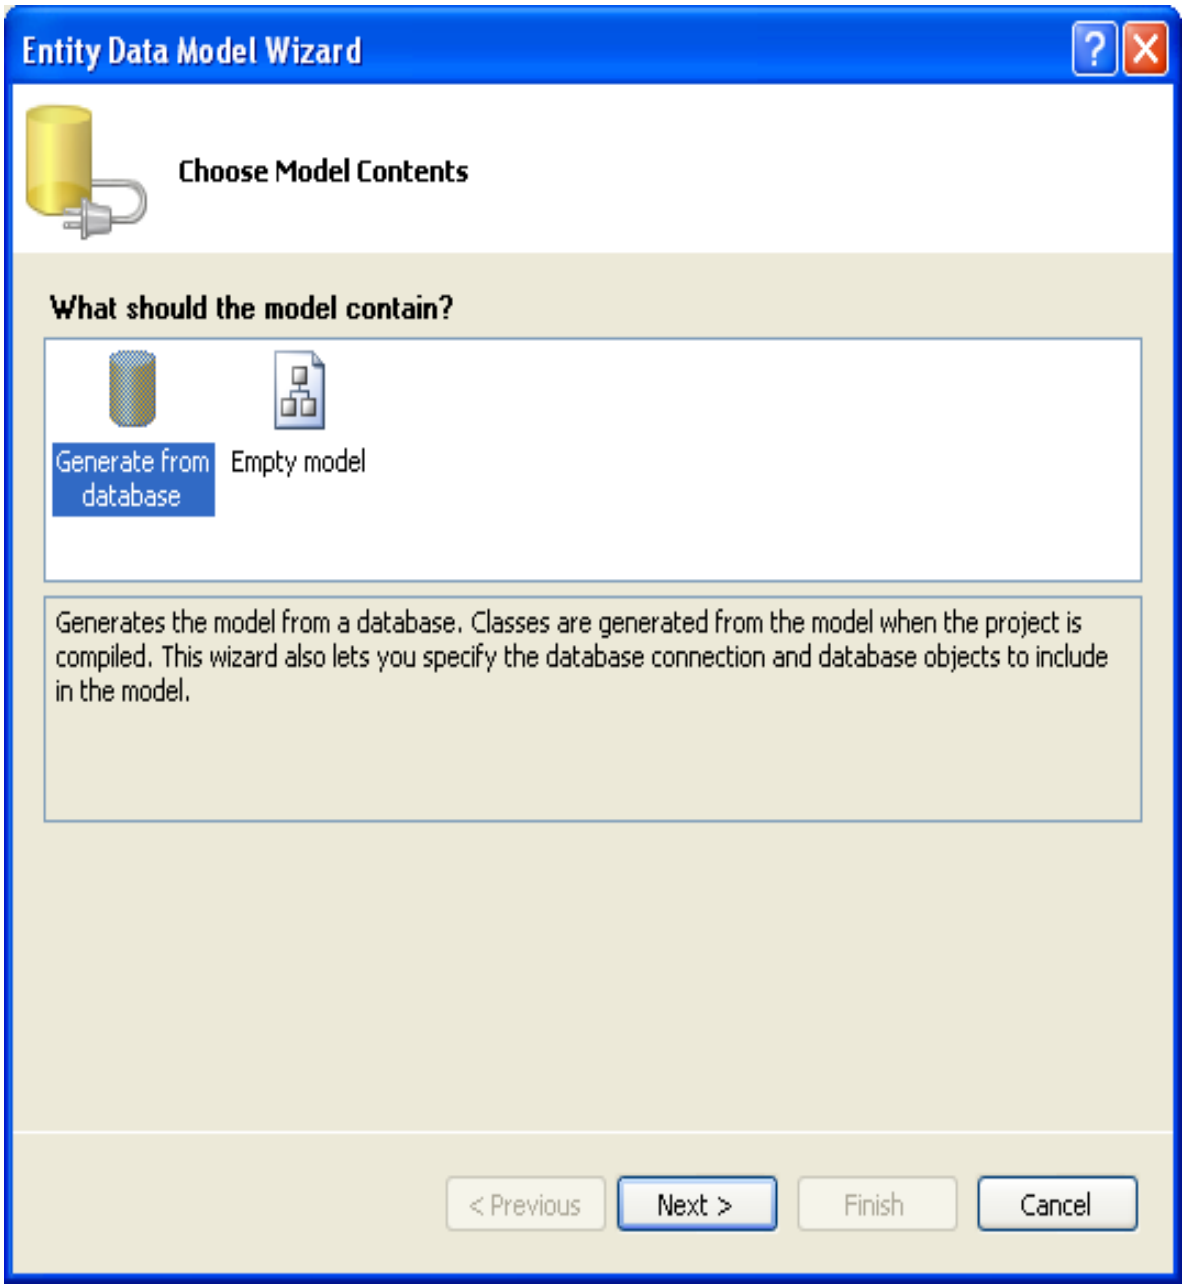
1. In the Solution Explorer, right-click your application and select Add, New Item.... From **Visual Studio installed templates** select **ADO.NET Entity Data Model**. Click Add.

Figure 21.49. Add Entity Data Model



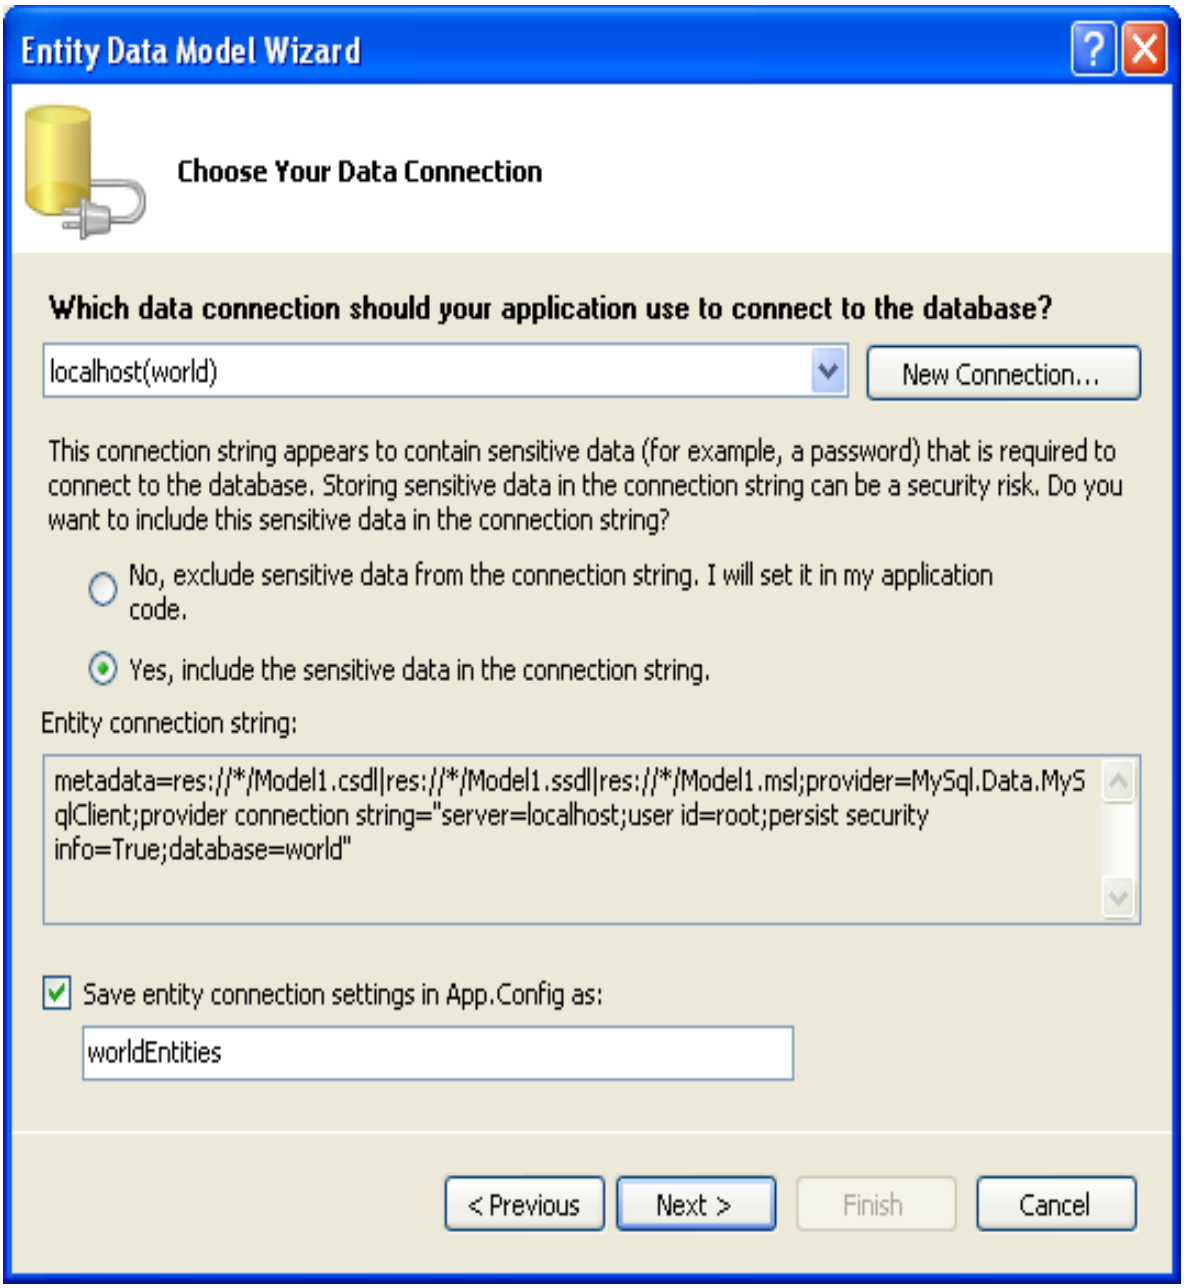
2. You will now see the Entity Data Model Wizard. You will use the wizard to generate the Entity Data Model from the world example database. Select the icon **Generate from database**. Click Next.

Figure 21.50. Entity Data Model Wizard Screen 1



3. You can now select the connection you made earlier to the World database. If you have not already done so, you can create the new connection at this time by clicking New Connection.... For further instructions on creating a connection to a database see Making a Connection.

Figure 21.51. Entity Data Model Wizard Screen 2

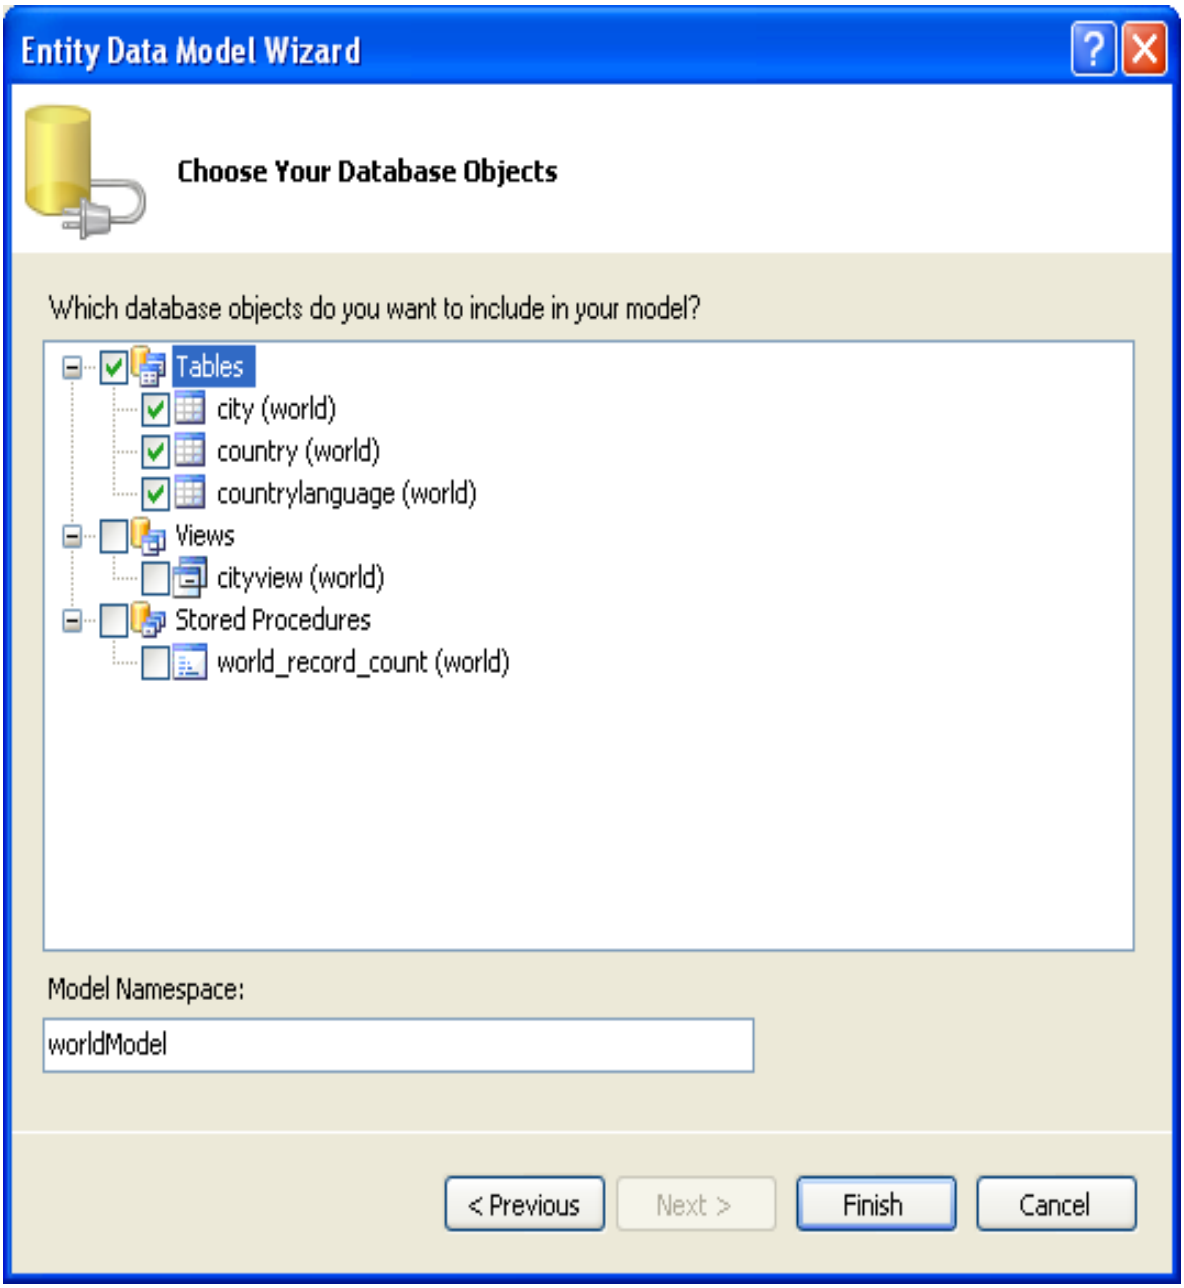


4. Make a note of the entity connection settings to be used in App.Config, as these will be used later to write the necessary control code.

5. Click Next.

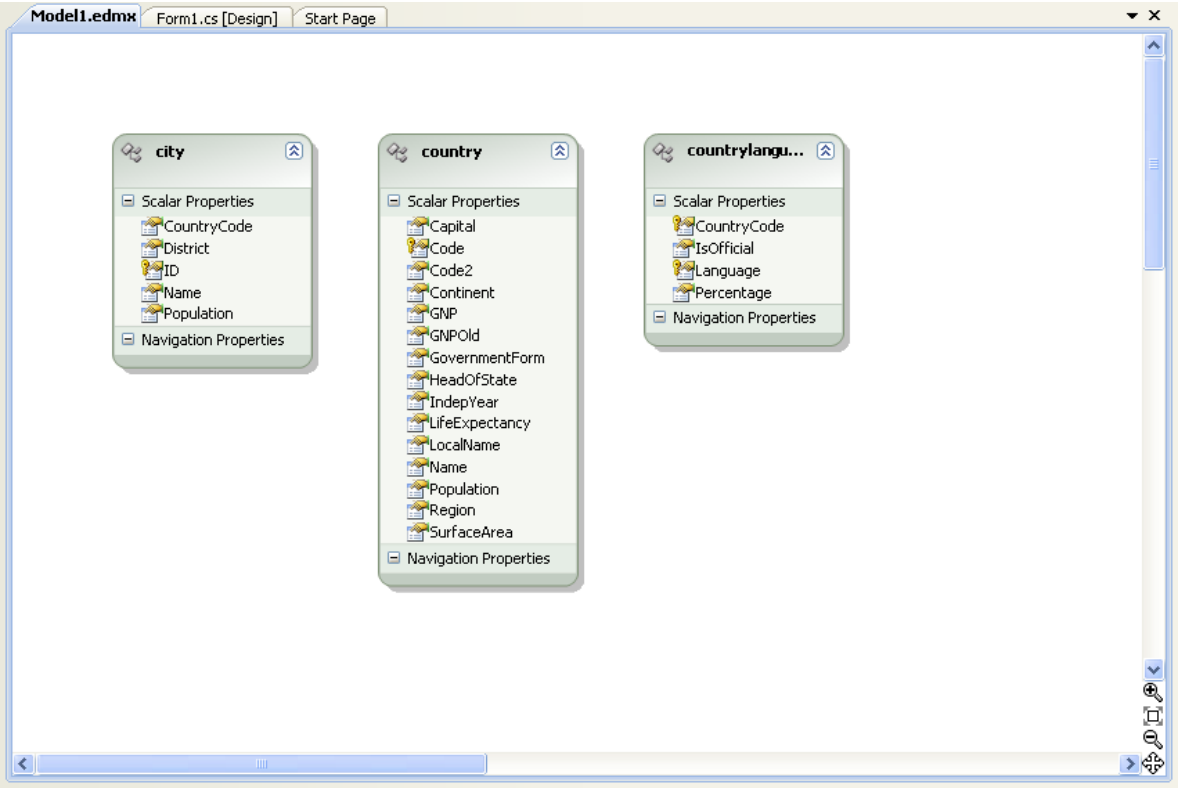
6. The Entity Data Model Wizard connects to the database. You are then presented with a tree structure of the database. From this you can select the object you would like to include in your model. If you had created Views and Stored Routines these will be displayed along with any tables. In this example you just need to select the tables. Click Finish to create the model and exit the wizard.

Figure 21.52. Entity Data Model Wizard Screen 3



7. Visual Studio will generate the model and then display it.

Figure 21.53. Entity Data Model Diagram



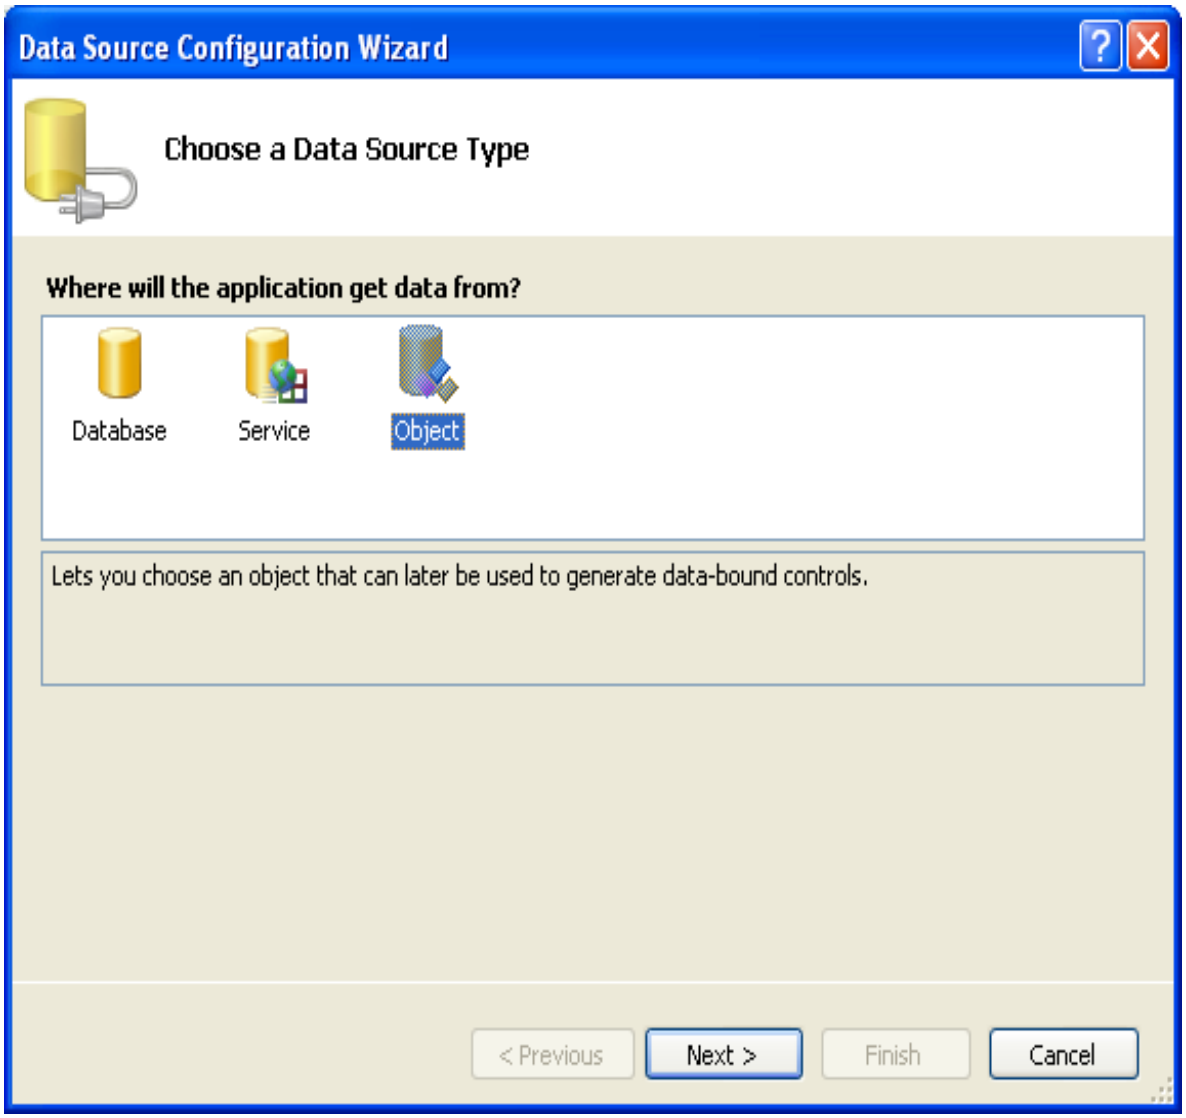
8. From the Visual Studio main menu select Build, Build Solution, to ensure that everything compiles correctly so far.

Adding a new Data Source

You will now add a new Data Source to your project and see how it can be used to read and write to the database.

1. From the Visual Studio main menu select Data, Add New Data Source.... You will be presented with the Data Source Configuration Wizard.

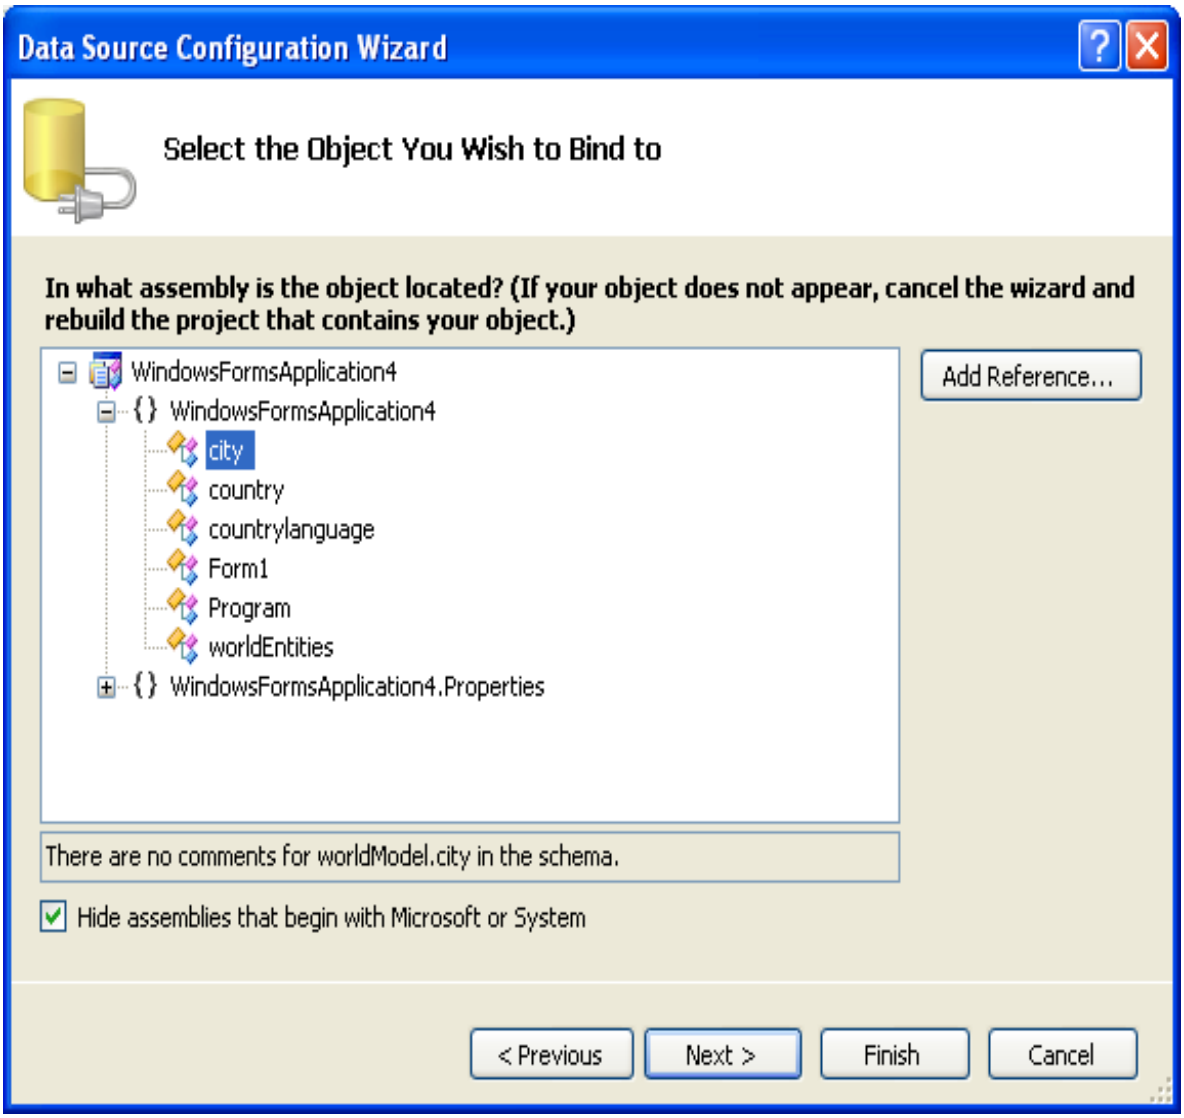
Figure 21.54. Entity Data Source Configuration Wizard Screen 1



2. Select the **Object** icon. Click Next.

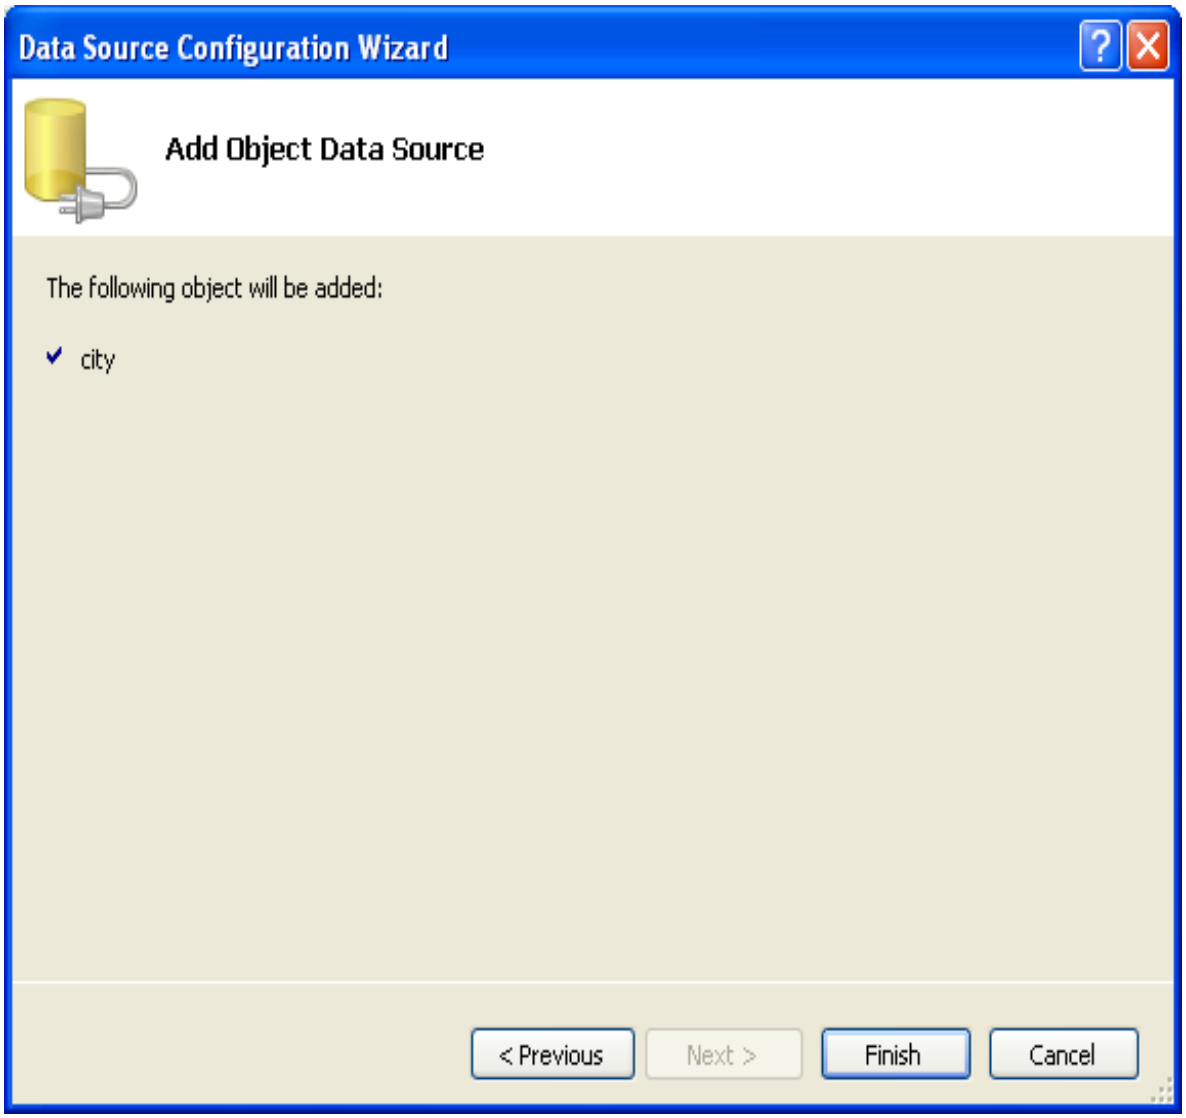
3. You will now select the Object to bind to. Expand the tree. In this tutorial, you will select the city table. Once the city table has been selected click Next.

Figure 21.55. Entity Data Source Configuration Wizard Screen 2



4. The wizard will confirm that the city object is to be added. Click Finish.

Figure 21.56. Entity Data Source Configuration Wizard Screen 3



5. The city object will be display in the Data Sources panel. If the Data Sources panel is not displayed, select Data, Show Data Sources from the Visual Studio main menu. The docked panel will then be displayed.

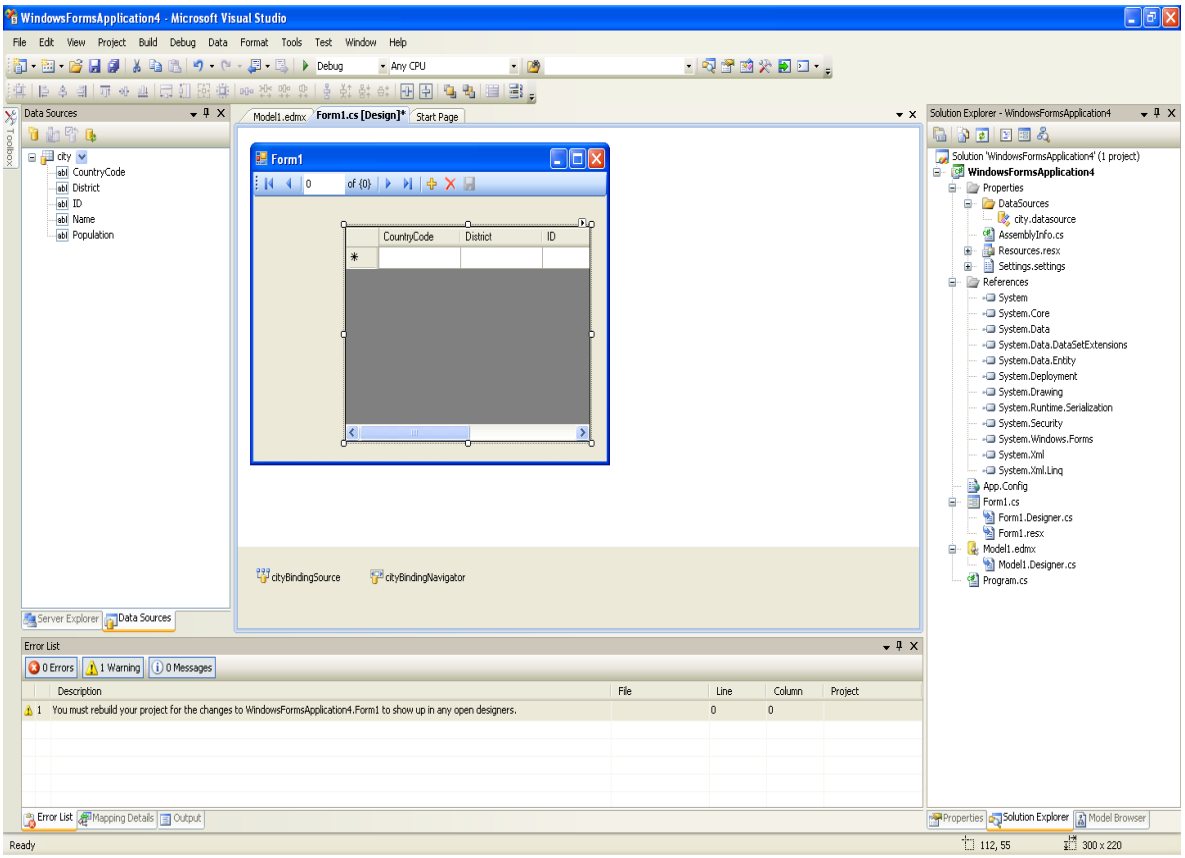
Figure 21.57. Data Sources

Using the Data Source in a Windows Form

You will now learn how to use the Data Source in a Windows Form.

1. In the Data Sources panel select the Data Source you just created and drag and drop it onto the Form Designer. By default the Data Source object will be added as a Data Grid View control. Note that the Data Grid View control is bound to the `cityBindingSource` and the Navigator control is bound to `cityBindingNavigator`.

Figure 21.58. Data Form Designer



2. Save and rebuild the solution before continuing.

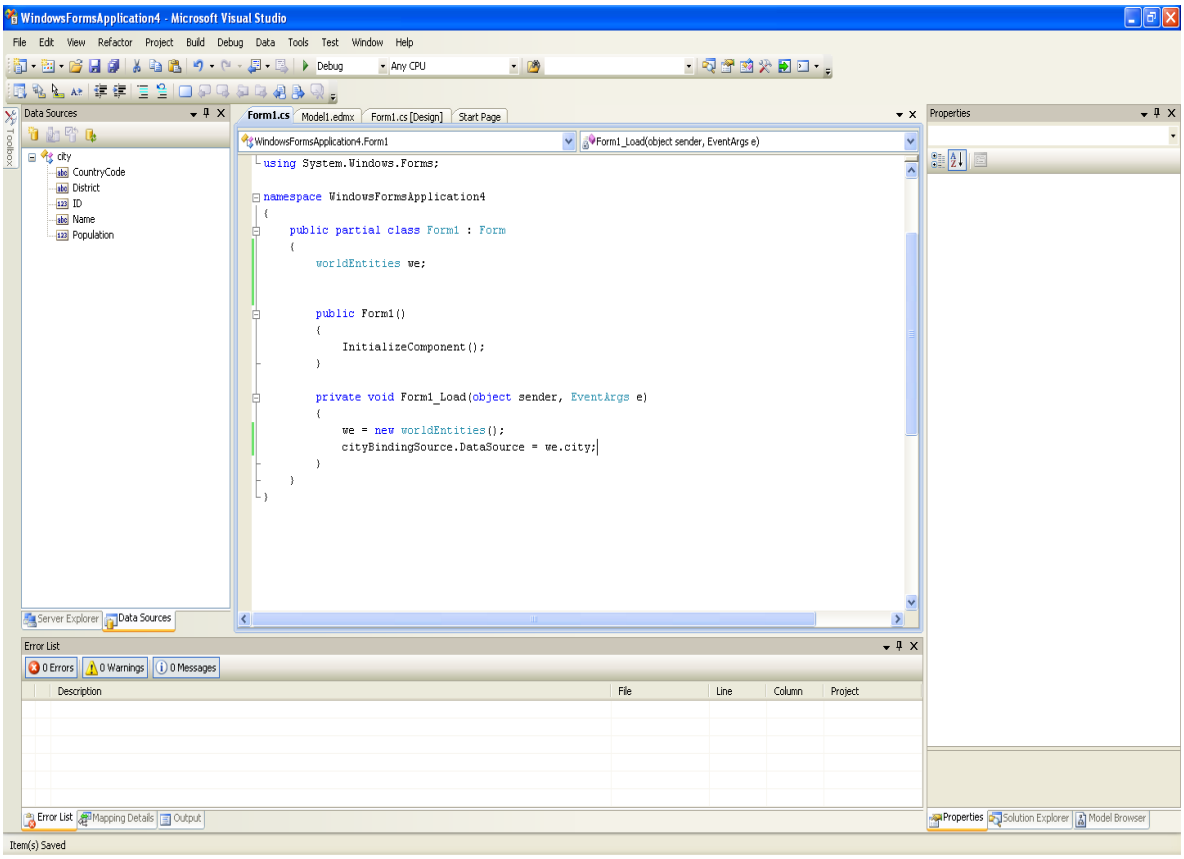
Adding Code to Populate the Data Grid View

You are now ready to add code to ensure that the Data Grid View control will be populated with data from the City database table.

1. Double-click the form to access its code.

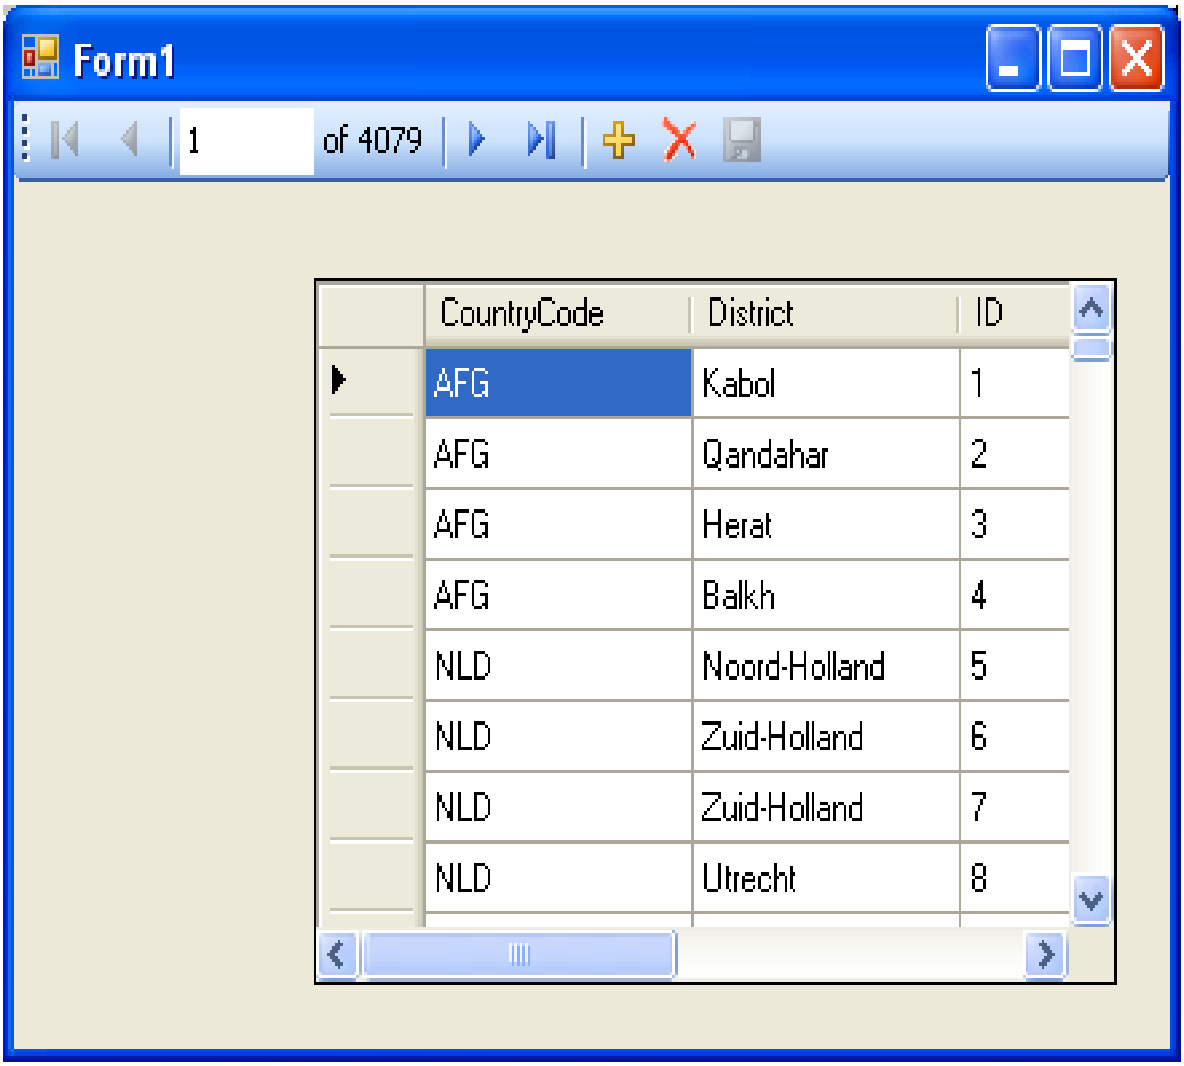
2. Add code to instantiate the Entity Data Model's EntityContainer object and retrieve data from the database to populate the control.

Figure 21.59. Adding Code to the Form



3. Save and rebuild the solution.
4. Run the solution. Ensure the grid is populated and you can navigate the database.

Figure 21.60. The Populated Grid Control



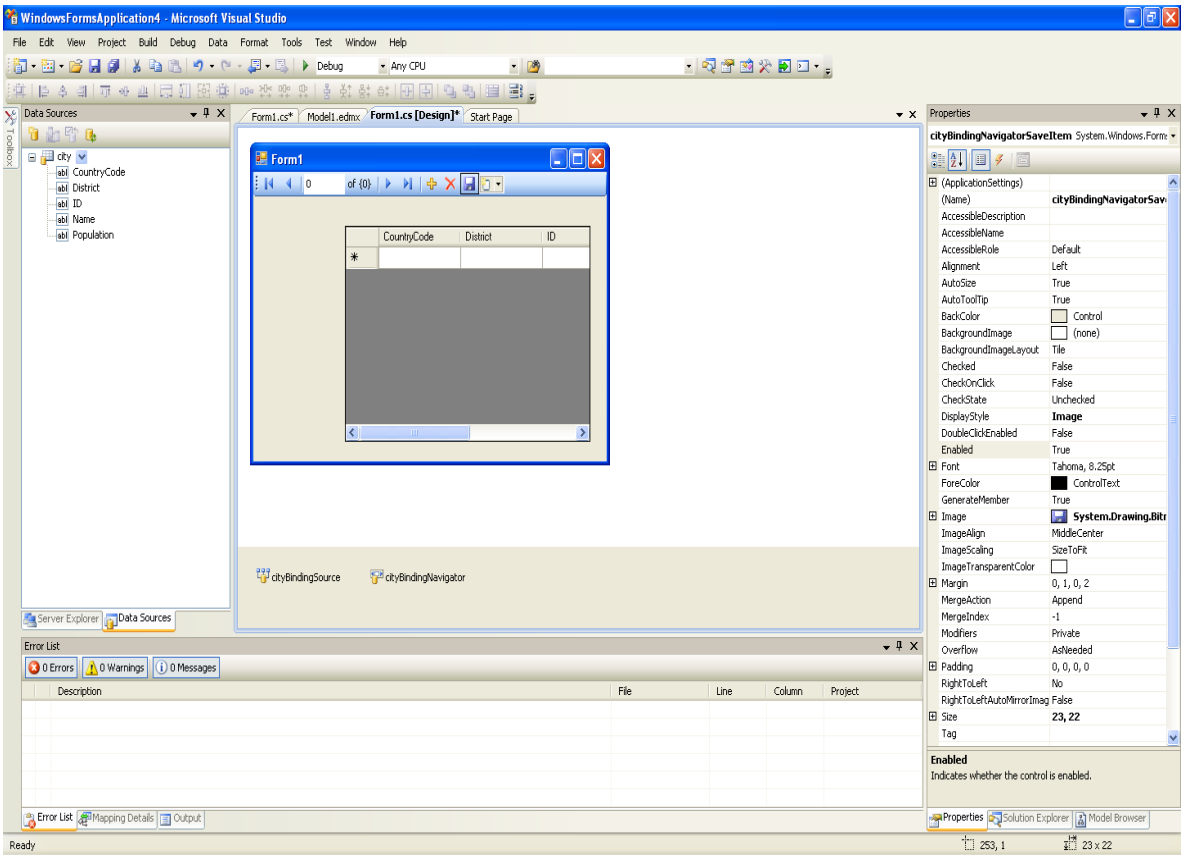
Adding Code to Save Changes to the Database

You will now add code to enable you to save changes to the database.

The Binding source component ensures that changes made in the Data Grid View control are also made to the Entity classes bound to it. However, that data needs to be saved back from the entities to the database itself. This can be achieved by the enabling of the Save button in the Navigator control, and the addition of some code.

1. In the Form Designer, click the Save icon in the Form toolbar and ensure that its Enabled property is set to True.

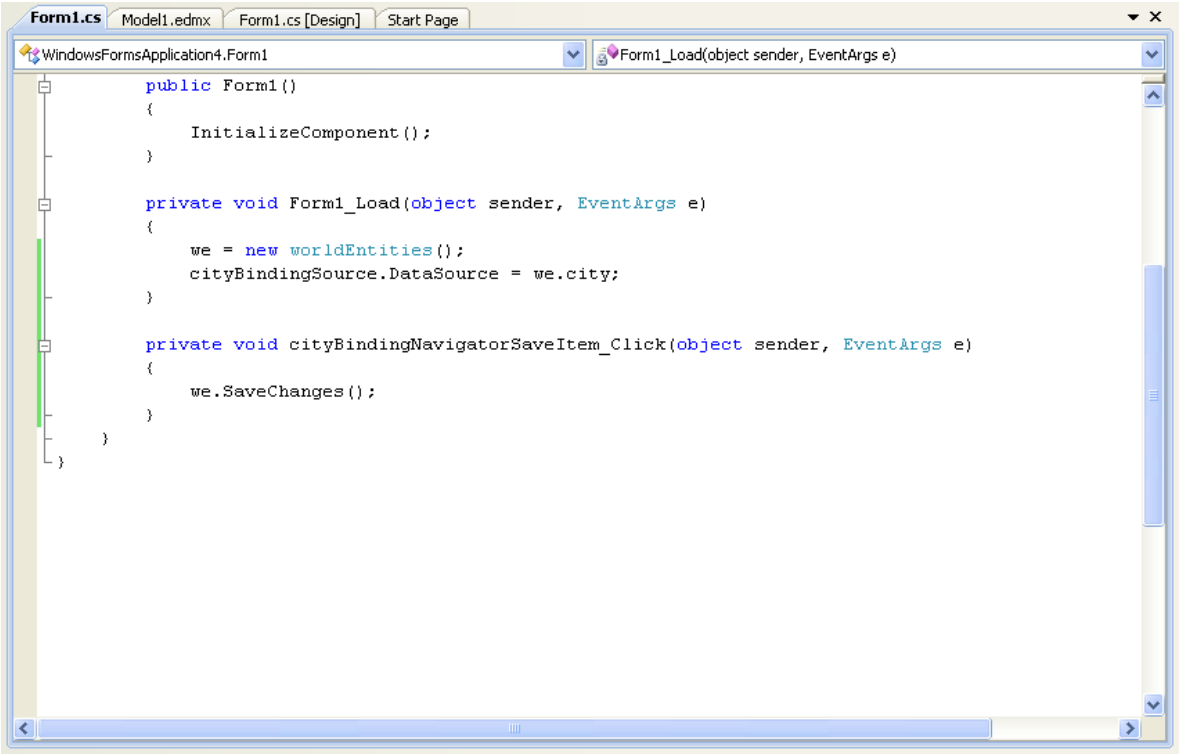
Figure 21.61. Save Button Enabled



2. Double-click the Save icon in the Form toolbar to display its code.

3. You now need to add code to ensure that data is saved to the database when the save button is clicked in the application.

Figure 21.62. Adding Save Code to the Form



4. Once the code has been added, save the solution and rebuild it. Run the application and verify that changes made in the grid are saved.

Tutorial: Databinding in ASP.NET using LINQ on Entities

In this tutorial you create an ASP.NET web page that binds LINQ queries to entities using the Entity Framework mapping.

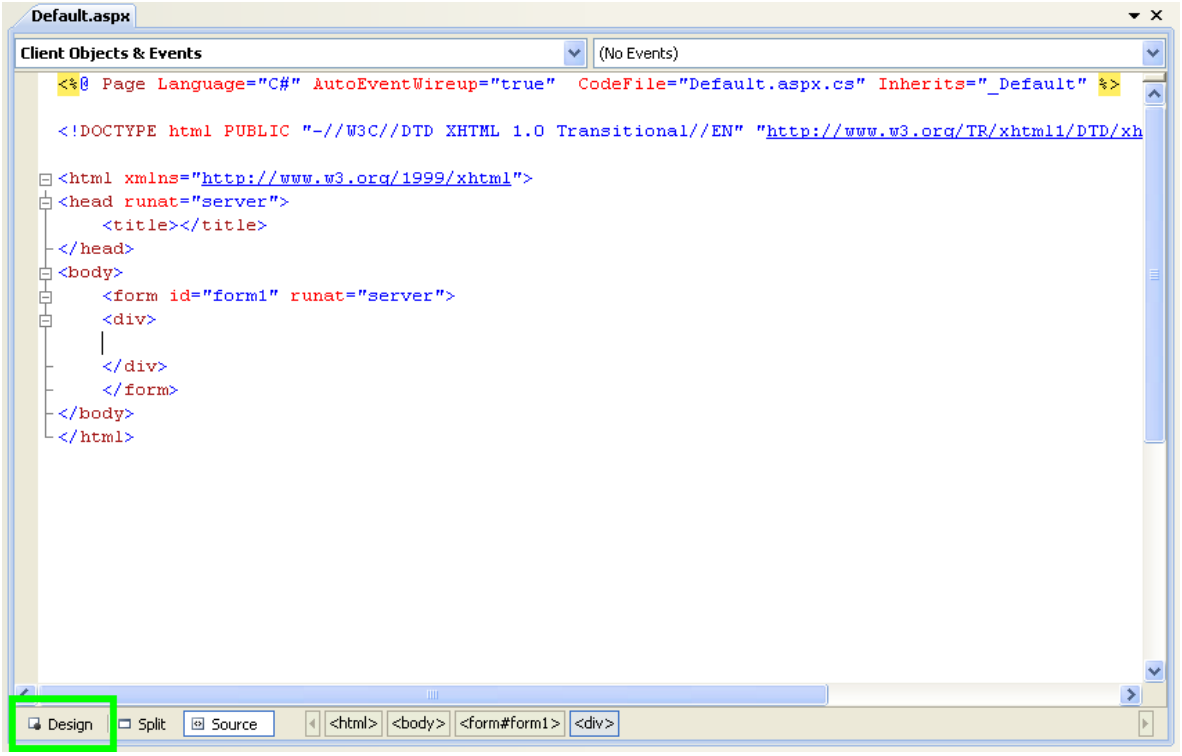
If you have not already done so, install the World example database prior to attempting this tutorial. See the tutorial Tutorial: Using an Entity Framework Entity as a Windows Forms Data Source for instructions on downloading and installing this database.

Creating an ASP.NET web site

In this part of the tutorial, you create an ASP.NET web site. The web site uses the World database. The main web page features a drop down list from which you can select a country. Data about that country's cities is then displayed in a grid view control.

1. From the Visual Studio main menu select File, New, Web Site....
2. From the Visual Studio installed templates select **ASP.NET Web Site**. Click OK. You will be presented with the Source view of your web page by default.
3. Click the Design view tab situated underneath the Source view panel.

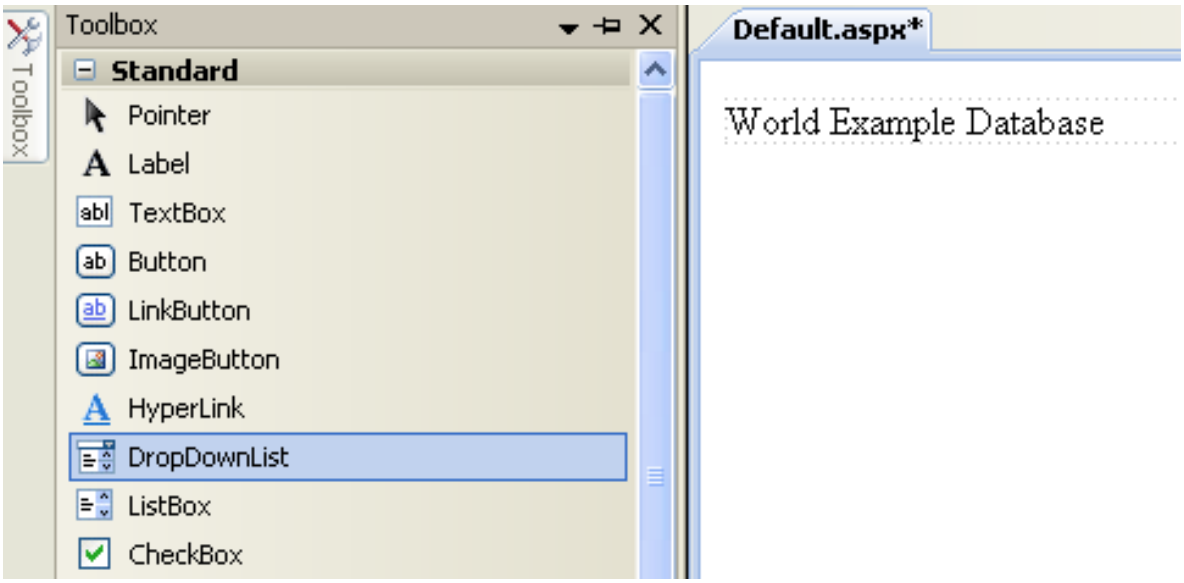
Figure 21.63. The Design Tab



4. In the Design view panel, enter some text to decorate the blank web page.

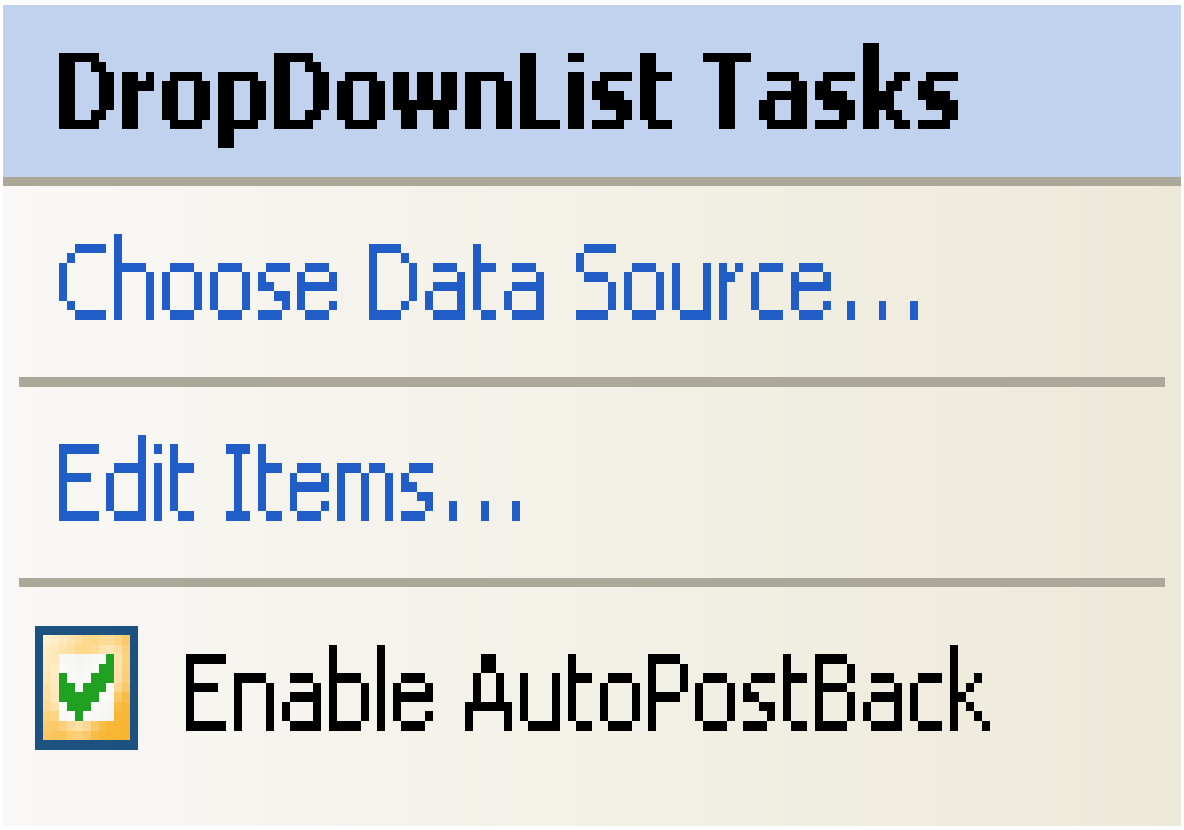
5. Click Toolbox. From the list of controls select **DropDownList**. Drag and drop the control to a location beneath the text on your web page.

Figure 21.64. Drop Down List



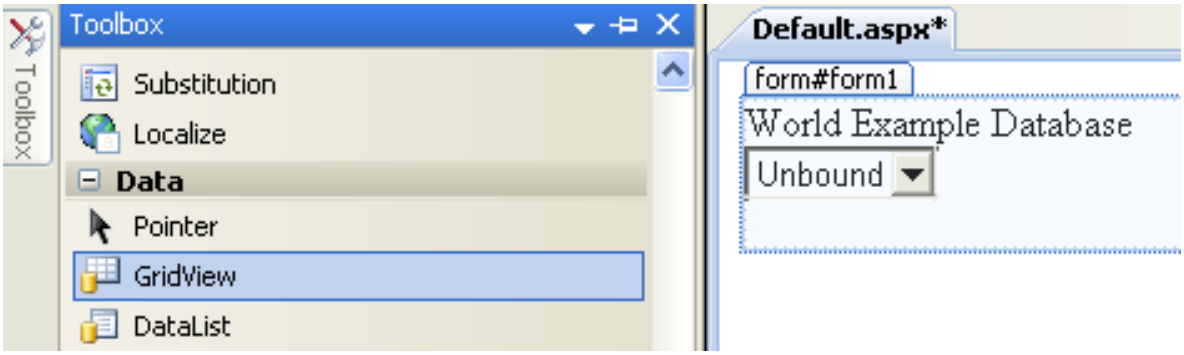
6. From the **DropDownList** control's context menu, ensure that the **Enable AutoPostBack** check box is enabled. This will ensure the control's event handler is called when an item is selected. The user's choice will in turn be used to populate the **GridView** control.

Figure 21.65. Enable AutoPostBack



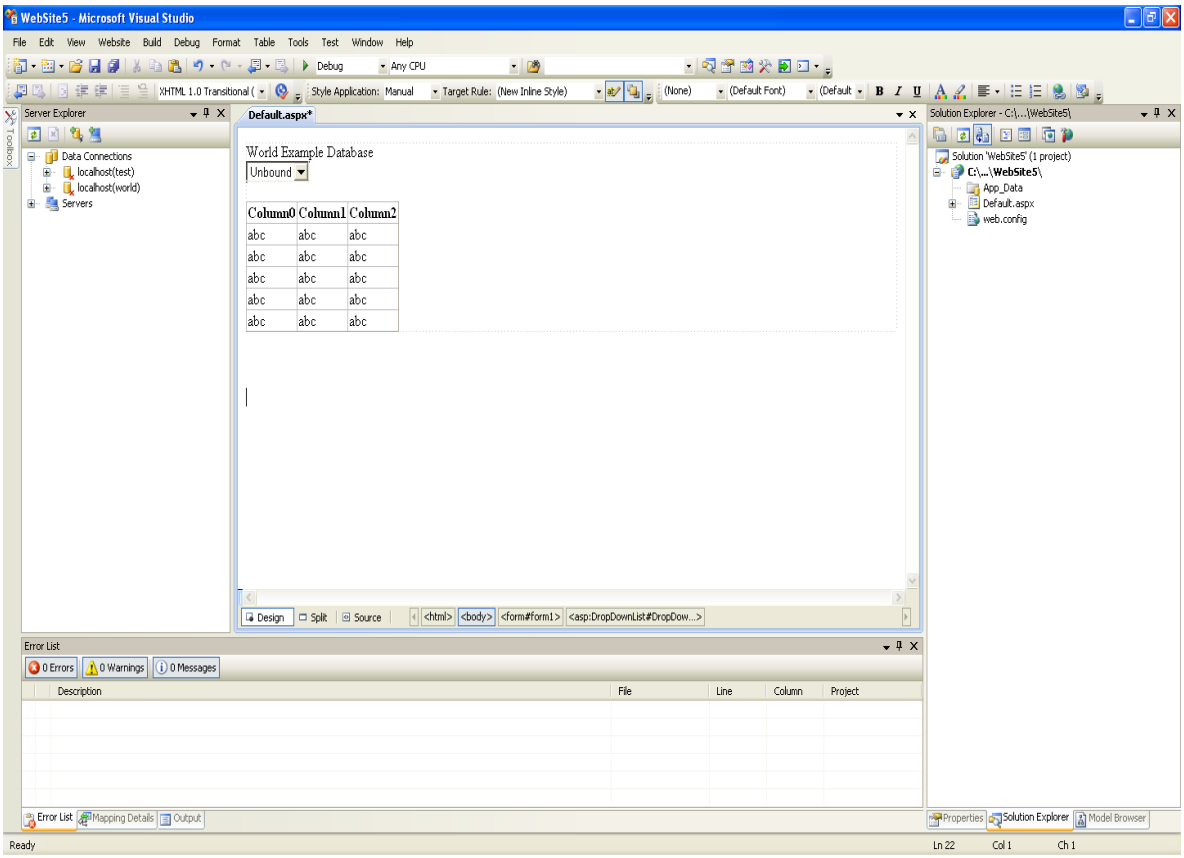
7. From the Toolbox select the **GridView** control.

Figure 21.66. Grid View Control



Drag and drop the Grid Vew control to a location just below the Drop Down List you already placed.

Figure 21.67. Placed Grid Vew Control



8. At this point it is recommended that you save your solution, and build the solution to ensure that there are no errors.

9. If you run the solution you will see that the text and drop down list are displayed, but the list is empty. Also, the grid view does not appear at all. Adding this functionality is described in the following sections.

At this stage you have a web site that will build, but further functionality is required. The next step will be to use the Entity Framework to create a mapping from the World database into entities that you can control programmatically.

Creating an ADO.NET Entity Data Model

In this stage of the tutorial you will add an ADO.NET Entity Data Model to your project, using the World database at the storage level. The procedure for doing this is described in the tutorial Tutorial: Using an Entity Framework Entity as a Windows Forms Data Source, and so will not be repeated here.

Populating a Drop Data List Box with using the results of a entity LINQ query

In this part of the tutorial you will write code to populate the DropDownList control. When the web page loads the data to populate the list will be achieved by using the results of a LINQ query on the model created previously.

1. In the Design view panel, double-click any blank area. This brings up the `Page_Load` method.

2. Modify the relevant section of code according to the following listing:

```
...
public partial class _Default : System.Web.UI.Page
{
```

```
    worldModel.worldEntities we;

    protected void Page_Load(object sender, EventArgs e)
    {
        we = new worldModel.worldEntities();

        if (!IsPostBack)
        {
            var countryQuery = from c in we.country
                               orderby c.Name
                               select new { c.Code, c.Name };
            DropDownList1.DataValueField = "Code";
            DropDownList1.DataTextField = "Name";
            DropDownList1.DataSource = countryQuery;
            DataBind();
        }
    }
...
```

Note that the list control only needs to be populated when the page first loads. The conditional code ensures that if the page is subsequently reloaded, the list control is not repopulated, which would cause the user selection to be lost.

3. Save the solution, build it and run it. You should see the list control has been populated. You can select an item, but as yet the grid view control does not appear.

At this point you have a working Drop Down List control, populated by a LINQ query on your entity data model.

Populating a Grid View control using an entity LINQ query

In the last part of this tutorial you will populate the Grid View Control using a LINQ query on your entity data model.

1. In the Design view, double-click the **DropDownList** control. This causes its `SelectedIndexChanged` code to be displayed. This method is called when a user selects an item in the list control and thus fires an AutoPostBack event.

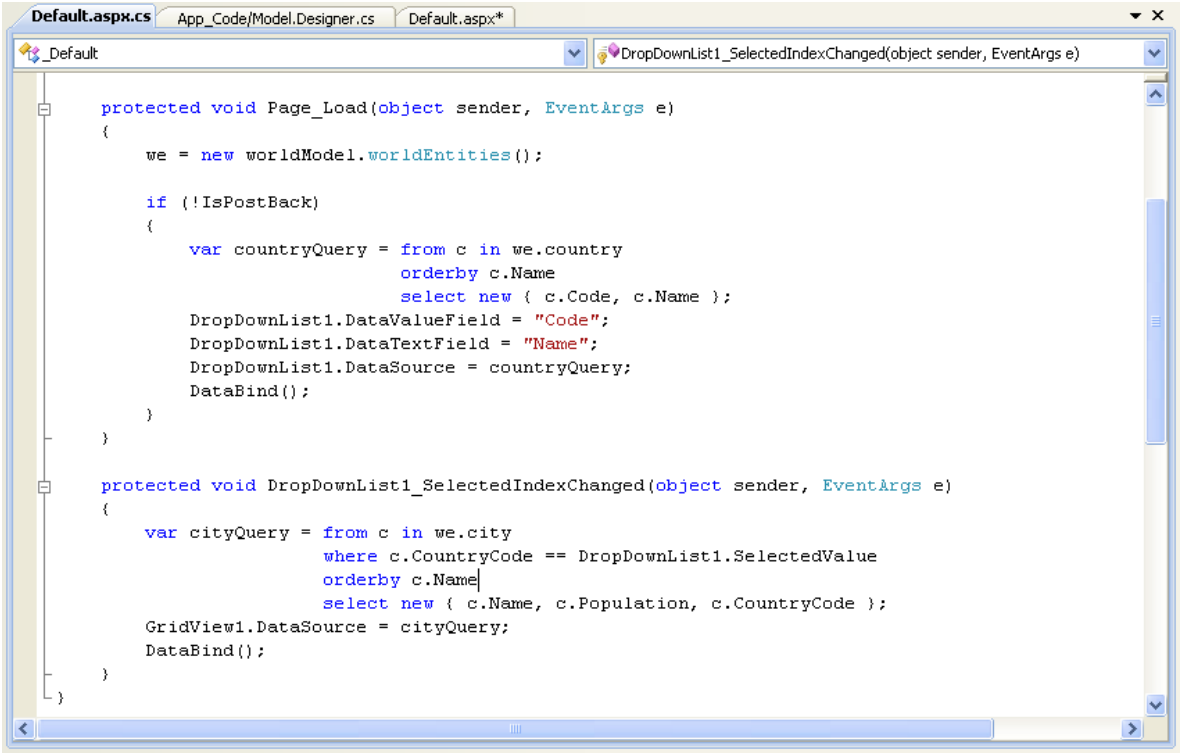
2. Modify the relevant section of code accordingly to the following listing:

```
...
    protected void DropDownList1_SelectedIndexChanged(object sender, EventArgs e)
    {
        var cityQuery = from c in we.city
                        where c.CountryCode == DropDownList1.SelectedValue
                        orderby c.Name
                        select new { c.Name, c.Population, c.CountryCode };
        GridView1.DataSource = cityQuery;
        DataBind();
    }
...
```

The grid view control is populated from the result of the LINQ query on the entity data model.

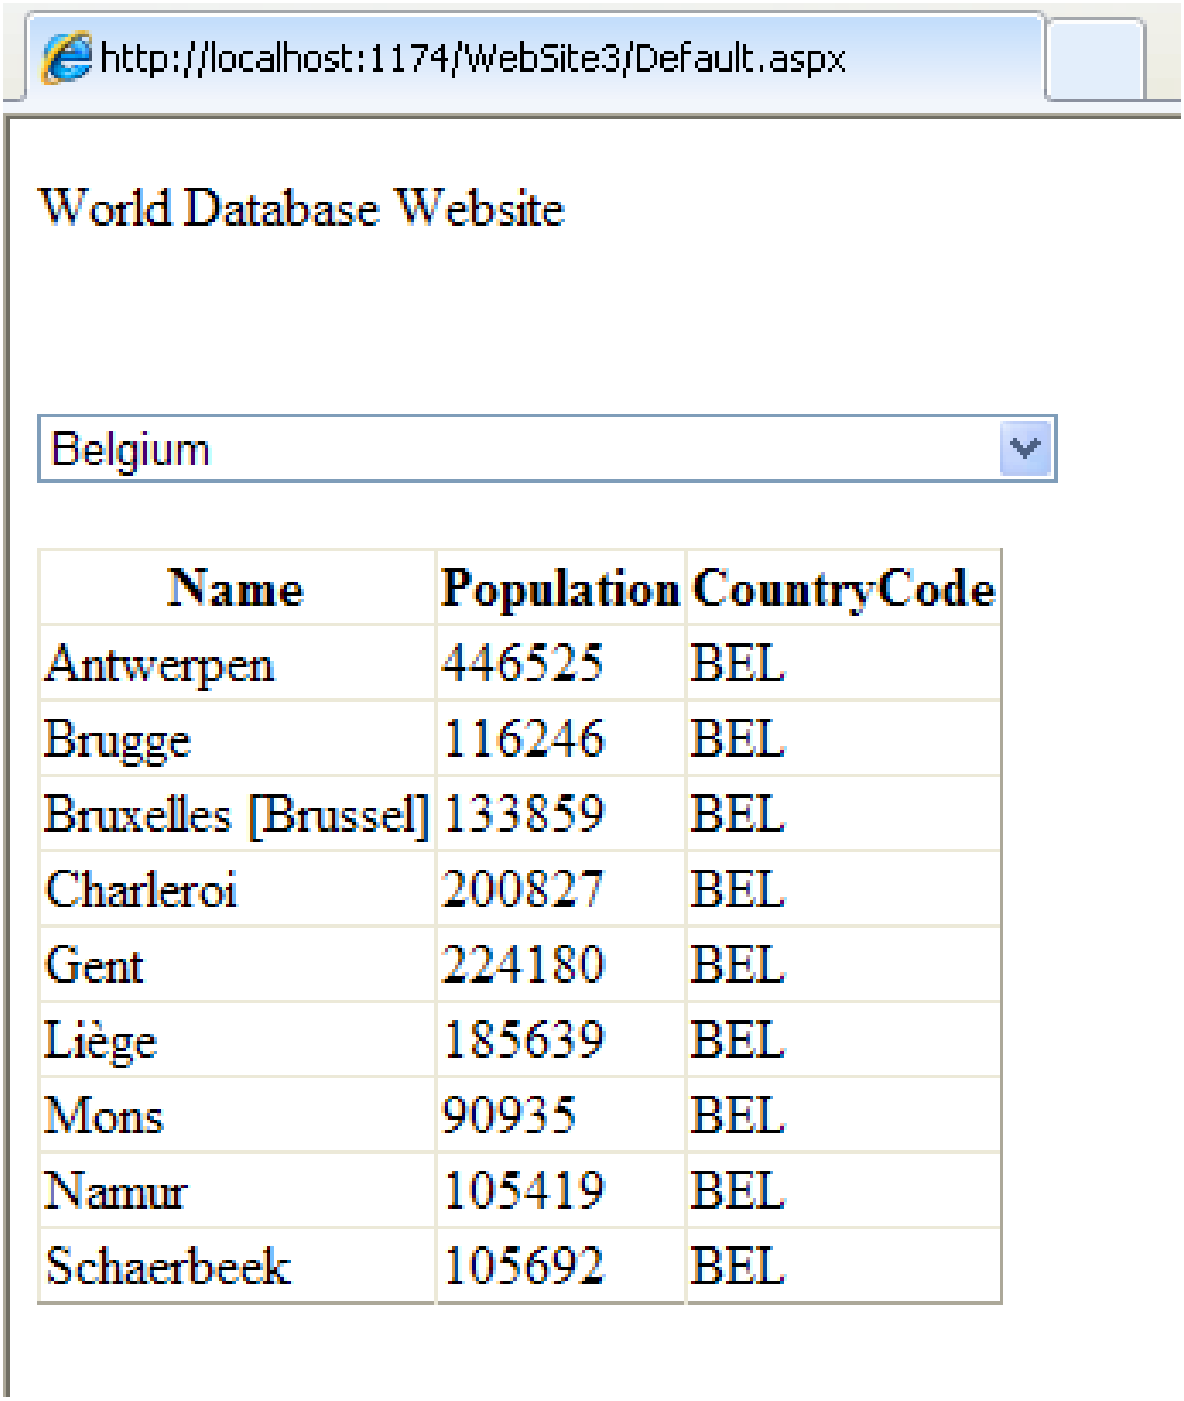
3. As a check compare your code to that shown in the following screenshot:

Figure 21.68. Source Code



4. Save, build and run the solution. As you select a country you will see its cities are displayed in the grid view control.

Figure 21.69. The Working Web Site



In this tutorial you have seen how to create an ASP.NET web site, you have also seen how you can access a MySQL database using LINQ queries on an entity data model.

Tutorial: Using SSL with MySQL Connector/Net

In this tutorial you will learn how you can use MySQL Connector/Net to connect to a MySQL server configured to use SSL. Support for SSL client certificates was added with MySQL Connector/Net 6.2.

MySQL Server uses the PEM format for certificates and private keys. This tutorial will use the test certificates from the server test suite by way of example. You can obtain the MySQL Server source code from MySQL Downloads. The certificates can be found in the directory `./mysql-test/std_data`.

To carry out the steps in this tutorial, you must have Open SSL installed. This can be downloaded for Microsoft Windows at no charge from Shining Light Productions.

Further details on the connection string options used in this tutorial can be found at Connector/Net Connection String Options Reference.

Configuring the MySQL Server to use SSL

1. In the MySQL Server configuration file, set the SSL parameters as follows:

```
ssl-ca=path/to/repo/mysql-test/std_data/cacert.pem
ssl-cert=path/to/repo/mysql-test/std_data/server-cert.pem
ssl-key=path/to/repo/mysql-test/std_data/server-key.pem
```

   Adjust the directories according to the location in which you installed the MySQL source code.

2. In this step you create a test user and set the user to require SSL.

   Using the MySQL Command Line Client, connect as root and create the user `sslclient`.

3. To set privileges and requirements, issue the following command:

```
GRANT ALL PRIVILEGES ON *.* TO sslclient@'%' REQUIRE SSL;
```

Creating a certificate file to use with the .NET client

1. The .NET client does not use the PEM file format, as .NET does not support this format natively. You will be using test client certificates from the same server repository, for the purposes of this example. Convert these to PFX format first. This format is also known as PKCS#12. An article describing this procedure can be found at the Citrix website. From the directory *`server-repository-root`*`/mysql-test/std_data`, issue the following command:

```
openssl pkcs12 -export -in client-cert.pem -inkey client-key.pem -certfile cacert.pem -out client.pf
```

2. When asked for an export password, enter the password “pass”. The file `client.pfx` will be generated. This file is used in the remainder of the tutorial.

Connecting to the server using a file-based certificate

1. You will use PFX file, `client.pfx` you created in the previous step to authenticate the client. The following example demonstrates how to connect using the `SSL Mode`, `CertificateFile` and `CertificatePassword` connection string options:

```
using (MySqlConnection connection = new MySqlConnection(
  "database=test;user=sslclient;" +
  "CertificateFile=H:\\bzr\\mysql-trunk\\mysql-test\\std_data\\client.pfx" +
  "CertificatePassword=pass;" +
  "SSL Mode=Required "))
{
    connection.Open();
}
```

   The path to the certificate file will need to be changed to reflect your individual installation.

Connecting to the server using a store-based certificate

1. The first step is to import the PFX file, `client.pfx`, into the Personal Store. Double-click the file in Windows explorer. This launches the Certificate Import Wizard.

2. Follow the steps dictated by the wizard, and when prompted for the password for the PFX file, enter “pass”.

3. Click Finish to close the wizard and import the certificate into the personal store.

Examine certificates in the Personal Store

1. Start the Microsoft Management Console by entering `mmc.exe` at a command prompt.
2. Select File, Add/Remove snap-in. Click Add. Select **Certificates** from the list of available snap-ins in the dialog.
3. Click Add button in the dialog, and select the **My user account** radio button. This is used for personal certificates.
4. Click the Finish button.
5. Click OK to close the Add/Remove Snap-in dialog.
6. You will now have **Certificates – Current User** displayed in the left panel of the Microsoft Management Console. Expand the Certificates - Current User tree item and select **Personal**, **Certificates**. The right-hand panel will display a certificate issued to MySQL. This is the certificate that was previously imported. Double-click the certificate to display its details.
7. After you have imported the certificate to the Personal Store, you can use a more succint connection string to connect to the database, as illustrated by the following code:

```
using (MySqlConnection connection = new MySqlConnection(
   "database=test;user=sslclient;" +
   "Certificate Store Location=CurrentUser;" +
   "SSL Mode=Required"))
{
   connection.Open();
}
```

Certificate Thumbprint Parameter

If you have a large number of certificates in your store, and many have the same Issuer, this can be a source of confusion and result in the wrong certificate being used. To alleviate this situation, there is an optional Certificate Thumbprint parameter that can additionally be specified as part of the connection string. As mentioned before, you can double-click a certificate in the Microsoft Management Console to display the certificate's details. When the Certificate dialog is displayed click the **Details** tab and scroll down to see the thumbprint. The thumbprint will typically be a number such as `#47 94 36 00 9a 40 f3 01 7a 14 5c f8 47 9e 76 94 d7 aa de f0`. This thumbprint can be used in the connection string, as the following code illustrates:

```
using (MySqlConnection connection = new MySqlConnection(
      "database=test;user=sslclient;" +
      "Certificate Store Location=CurrentUser;" +
      "Certificate Thumbprint=479436009a40f3017a145cf8479e7694d7aadef0;"+
      "SSL Mode=Required"))
{
    connection.Open();
}
```

Spaces in the thumbprint parameter are optional and the value is case-insensitive.

Tutorial: Using MySqlScript

This tutorial teaches you how to use the `MySqlScript` class. This class enables you to execute a series of statements. Depending on the circumstances, this can be more convenient than using the `MySqlCommand` approach.

Further details of the `MySqlScript` class can be found in the reference documentation supplied with MySQL Connector/Net.

To run the example programs in this tutorial, set up a simple test database and table using the `mysql` Command Line Client or MySQL Workbench. Commands for the `mysql` Command Line Client are given here:

```
CREATE DATABASE TestDB;
USE TestDB;
```

```
CREATE TABLE TestTable (id INT NOT NULL PRIMARY KEY
  AUTO_INCREMENT, name VARCHAR(100));
```

The main method of the `MySqlScript` class is the `Execute` method. This method causes the script (sequence of statements) assigned to the Query property of the MySqlScript object to be executed. Note the Query property can be set through the `MySqlScript` constructor or using the Query property. `Execute` returns the number of statements executed.

The `MySqlScript` object will execute the specified script on the connection set using the Connection property. Again, this property can be set directly or through the `MySqlScript` constructor. The following code snippets illustrate this:

```
string sql = "SELECT * FROM TestTable";
...
MySqlScript script = new MySqlScript(conn, sql);
...
MySqlScript script = new MySqlScript();
script.Query = sql;
script.Connection = conn;
...
script.Execute();
```

The MySqlScript class has several events associated with it. There are:

1. Error - generated if an error occurs.
2. ScriptCompleted - generated when the script successfully completes execution.
3. StatementExecuted - generated after each statement is executed.

It is possible to assign event handlers to each of these events. These user-provided routines are called back when the connected event occurs. The following code shows how the event handlers are set up.

```
script.Error += new MySqlScriptErrorEventHandler(script_Error);
script.ScriptCompleted += new EventHandler(script_ScriptCompleted);
script.StatementExecuted += new MySqlStatementExecutedEventHandler(script_StatementExecuted);
```

In VisualStudio, you can save typing by using tab completion to fill out stub routines. Start by typing, for example, “script.Error +=”. Then press **TAB**, and then press **TAB** again. The assignment is completed, and a stub event handler created. A complete working example is shown below:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;

namespace MySqlScriptTest
{
    class Program
    {
        static void Main(string[] args)
        {
            string connStr = "server=localhost;user=root;database=TestDB;port=3306;password=******;";
            MySqlConnection conn = new MySqlConnection(connStr);

            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();

                string sql = "INSERT INTO TestTable(name) VALUES ('Superman');" +
                             "INSERT INTO TestTable(name) VALUES ('Batman');" +
                             "INSERT INTO TestTable(name) VALUES ('Wolverine');" +
                             "INSERT INTO TestTable(name) VALUES ('Storm');";
```

```
                MySqlScript script = new MySqlScript(conn, sql);

                script.Error += new MySqlScriptErrorEventHandler(script_Error);
                script.ScriptCompleted += new EventHandler(script_ScriptCompleted);
                script.StatementExecuted += new MySqlStatementExecutedEventHandler(script_StatementExecuted

                int count = script.Execute();

                Console.WriteLine("Executed " + count + " statement(s).");
                Console.WriteLine("Delimiter: " + script.Delimiter);
            }
            catch (Exception ex)
            {
                Console.WriteLine(ex.ToString());
            }

            conn.Close();
            Console.WriteLine("Done.");
        }

        static void script_StatementExecuted(object sender, MySqlScriptEventArgs args)
        {
            Console.WriteLine("script_StatementExecuted");
        }

        static void script_ScriptCompleted(object sender, EventArgs e)
        {
            /// EventArgs e will be EventArgs.Empty for this method
            Console.WriteLine("script_ScriptCompleted!");
        }

        static void script_Error(Object sender, MySqlScriptErrorEventArgs args)
        {
            Console.WriteLine("script_Error: " + args.Exception.ToString());
        }
    }
}
```

Note that in the `script_ScriptCompleted` event handler, the `EventArgs` parameter `e` will be `EventArgs.Empty`. In the case of the `ScriptCompleted` event there is no additional data to be obtained, which is why the event object is `EventArgs.Empty`.

Using Delimiters with MySqlScript

Depending on the nature of the script, you may need control of the delimiter used to separate the statements that will make up a script. The most common example of this is where you have a multi-statement stored routine as part of your script. In this case if the default delimiter of ";" is used you will get an error when you attempt to execute the script. For example, consider the following stored routine:

```
CREATE PROCEDURE test_routine()
BEGIN
    SELECT name FROM TestTable ORDER BY name;
    SELECT COUNT(name) FROM TestTable;
END
```

This routine actually needs to be executed on the MySQL Server as a single statement. However, with the default delimiter of ";", the `MySqlScript` class would interpret the above as two statements, the first being:

```
CREATE PROCEDURE test_routine()
BEGIN
    SELECT name FROM TestTable ORDER BY name;
```

Executing this as a statement would generate an error. To solve this problem `MySqlScript` supports the ability to set a different delimiter. This is achieved through the Delimiter property. For example, you could set the delimiter to "??", in which case the above stored routine would no longer generate an error when executed. Multiple statements can be delimited in the script, so for example, you could have a three statement script such as:

```
string sql = "DROP PROCEDURE IF EXISTS test_routine??" +
             "CREATE PROCEDURE test_routine() " +
             "BEGIN " +
             "SELECT name FROM TestTable ORDER BY name;" +
             "SELECT COUNT(name) FROM TestTable;" +
             "END??" +
             "CALL test_routine()";
```

You can change the delimiter back at any point by setting the Delimiter property. The following code shows a complete working example:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

using MySql.Data;
using MySql.Data.MySqlClient;

namespace ConsoleApplication8
{
    class Program
    {
        static void Main(string[] args)
        {
            string connStr = "server=localhost;user=root;database=TestDB;port=3306;password=******;";
            MySqlConnection conn = new MySqlConnection(connStr);

            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();

                string sql =    "DROP PROCEDURE IF EXISTS test_routine??" +
                                "CREATE PROCEDURE test_routine() " +
                                "BEGIN " +
                                "SELECT name FROM TestTable ORDER BY name;" +
                                "SELECT COUNT(name) FROM TestTable;" +
                                "END??" +
                                "CALL test_routine()";

                MySqlScript script = new MySqlScript(conn);

                script.Query = sql;
                script.Delimiter = "??";
                int count = script.Execute();
                Console.WriteLine("Executed " + count + " statement(s)");
                script.Delimiter = ";";
                Console.WriteLine("Delimiter: " + script.Delimiter);
                Console.WriteLine("Query: " + script.Query);
            }
            catch (Exception ex)
            {
                Console.WriteLine(ex.ToString());
            }

            conn.Close();
            Console.WriteLine("Done.");
        }
    }
}
```

Tutorial: Generating MySQL DDL from an Entity Framework Model

In this tutorial, you will learn how to create MySQL DDL from an Entity Framework model. Use Visual Studio 2010 and MySQL Connector/Net 6.3 to carry out this tutorial.

1. Create a new console application in Visual Studio 2010.

2. Using the **Solution Explorer**, add a reference to `MySql.Data.Entity`.

3. From the **Solution Explorer** select Add, New Item. In the **Add New Item** dialog select **Online Templates**. Select **ADO.NET Entity Data Model** and click Add. The **Entity Data Model** dialog will be displayed.
4. In the **Entity Data Model** dialog select **Empty Model**. Click Finish. A blank model will be created.
5. Create a simple model. A single Entity will do for the purposes of this tutorial.
6. In the **Properties** panel select ConceptualEntityModel from the drop-down listbox.
7. In the **Properties** panel, locate the **DDL Generation Template** in the category **Database Script Generation**.
8. For the **DDL Generation** property select SSDLToMySQL.tt(VS) from the drop-down listbox.
9. Save the solution.
10. Right-click an empty space in the model design area. The context-sensitive menu will be displayed.
11. From the context-sensitive menu select Generate Database from Model. The **Generate Database Wizard** dialog will be displayed.
12. In the **Generate Database Wizard** dialog select an existing connection, or create a new connection to a server. Select an appropriate radio button to show or hide sensitive data. For the purposes of this tutorial you can select **Yes** (although you might skip this for commercial applications).
13. Click Next. MySQL compatible DDL code will be generated. Click Finish to exit the wizard.

You have seen how to create MySQL DDL code from an Entity Framework model.

Connector/Net Programming

Connector/Net comprises several classes that are used to connect to the database, execute queries and statements, and manage query results.

The following are the major classes of Connector/Net:

- `MySqlCommand`: Represents an SQL statement to execute against a MySQL database.
- `MySqlCommandBuilder`: Automatically generates single-table commands used to reconcile changes made to a DataSet with the associated MySQL database.
- `MySqlConnection`: Represents an open connection to a MySQL Server database.
- `MySqlDataAdapter`: Represents a set of data commands and a database connection that are used to fill a data set and update a MySQL database.
- `MySqlDataReader`: Provides a means of reading a forward-only stream of rows from a MySQL database.
- `MySqlException`: The exception that is thrown when MySQL returns an error.
- `MySqlHelper`: Helper class that makes it easier to work with the provider.
- `MySqlTransaction`: Represents an SQL transaction to be made in a MySQL database.

In the following sections, you will learn about some common use cases for Connector/Net, including BLOB handling, date handling, and using Connector/Net with common tools such as Crystal Reports.

Connecting to MySQL Using Connector/Net

All interaction between a .NET application and the MySQL server is routed through a `MySqlConnection` object. Before your application can interact with the server, a `MySqlConnection` object must be instantiated, configured, and opened.

Even when using the `MySqlHelper` class, a `MySqlConnection` object is created by the helper class.

In this section, we will describe how to connect to MySQL using the `MySqlConnection` object.

Creating a Connector/Net Connection String

The `MySqlConnection` object is configured using a connection string. A connection string contains several key/value pairs, separated by semicolons. Each key/value pair is joined with an equal sign.

The following is a sample connection string:

```
Server=127.0.0.1;Uid=root;Pwd=12345;Database=test;
```

In this example, the `MySqlConnection` object is configured to connect to a MySQL server at `127.0.0.1`, with a user name of `root` and a password of `12345`. The default database for all statements will be the `test` database. All other options may be found here: Connector/Net Connection String Options Reference.

Note

Using the '@' symbol for parameters is now the preferred approach although the old pattern of using '?' is still supported.

Please be aware however that using '@' can cause conflicts when user variables are also used. To help with this situation please see the documentation on the `Allow User Variables` connection string option, which can be found here: Connector/Net Connection String Options Reference. The `Old Syntax` connection string option has now been deprecated.

Opening a Connection

Once you have created a connection string it can be used to open a connection to the MySQL server.

The following code is used to create a `MySqlConnection` object, assign the connection string, and open the connection.

Connector/Net can also connect using the native Windows authentication plugin. See Using the Windows Native Authentication Plugin for details.

You can further extend the authentication mechanism by writing your own authentication plugin. See Writing a Custom Authentication Plugin for details.

Visual Basic Example

```
Dim conn As New MySql.Data.MySqlClient.MySqlConnection
Dim myConnectionString as String

myConnectionString = "server=127.0.0.1;" _
            & "uid=root;" _
            & "pwd=12345;" _
            & "database=test;"

Try
  conn.ConnectionString = myConnectionString
  conn.Open()

Catch ex As MySql.Data.MySqlClient.MySqlException
  MessageBox.Show(ex.Message)
End Try
```

C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";
```

```
try
{
    conn = new MySql.Data.MySqlClient.MySqlConnection();
    conn.ConnectionString = myConnectionString;
    conn.Open();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message);
}
```

You can also pass the connection string to the constructor of the `MySqlConnection` class:

Visual Basic Example

```
Dim myConnectionString as String

myConnectionString = "server=127.0.0.1;" _
             & "uid=root;" _
             & "pwd=12345;" _
             & "database=test;"

Try
    Dim conn As New MySql.Data.MySqlClient.MySqlConnection(myConnectionString)
    conn.Open()
Catch ex As MySql.Data.MySqlClient.MySqlException
   MessageBox.Show(ex.Message)
End Try
```

C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn = new MySql.Data.MySqlClient.MySqlConnection(myConnectionString);
    conn.Open();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message);
}
```

Once the connection is open it can be used by the other Connector/Net classes to communicate with the MySQL server.

Handling Connection Errors

Because connecting to an external server is unpredictable, it is important to add error handling to your .NET application. When there is an error connecting, the `MySqlConnection` class will return a `MySqlException` object. This object has two properties that are of interest when handling errors:

- `Message`: A message that describes the current exception.
- `Number`: The MySQL error number.

When handling errors, you can your application's response based on the error number. The two most common error numbers when connecting are as follows:

- `0`: Cannot connect to server.
- `1045`: Invalid user name and/or password.

The following code shows how to adapt the application's response based on the actual error:

Visual Basic Example

```
Dim myConnectionString as String

myConnectionString = "server=127.0.0.1;" _
          & "uid=root;" _
          & "pwd=12345;" _
          & "database=test;"

Try
    Dim conn As New MySql.Data.MySqlClient.MySqlConnection(myConnectionString)
    conn.Open()
Catch ex As MySql.Data.MySqlClient.MySqlException
    Select Case ex.Number
        Case 0
            MessageBox.Show("Cannot connect to server. Contact administrator")
        Case 1045
            MessageBox.Show("Invalid username/password, please try again")
    End Select
End Try
```

C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn = new MySql.Data.MySqlClient.MySqlConnection(myConnectionString);
    conn.Open();
}
    catch (MySql.Data.MySqlClient.MySqlException ex)
{
    switch (ex.Number)
    {
        case 0:
            MessageBox.Show("Cannot connect to server.  Contact administrator");
        case 1045:
            MessageBox.Show("Invalid username/password, please try again");
    }
}
```

Important

Note that if you are using multilanguage databases you must specify the character set in the connection string. If you do not specify the character set, the connection defaults to the `latin1` charset. You can specify the character set as part of the connection string, for example:

```
MySqlConnection myConnection = new MySqlConnection("server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;Charset=latin1;");
```

Using GetSchema on a Connection

The `GetSchema()` method of the connection object can be used to retrieve schema information about the database currently connected to. The schema information is returned in the form of a `DataTable`. The schema information is organized into a number of collections. Different forms of the `GetSchema()` method can be used depending on the information required. There are three forms of the `GetSchema()` method:

- `GetSchema()` - This call will return a list of available collections.
- `GetSchema(String)` - This call returns information about the collection named in the string parameter. If the string “MetaDataCollections” is used then a list of all available collections is returned. This is the same as calling `GetSchema()` without any parameters.

- `GetSchema(String, String[])` - In this call the first string parameter represents the collection name, and the second parameter represents a string array of restriction values. Restriction values limit the amount of data that will be returned. Restriction values are explained in more detail in the Microsoft .NET documentation.

Collections

The collections can be broadly grouped into two types: collections that are common to all data providers, and collections specific to a particular provider.

Common

The following collections are common to all data providers:

- MetaDataCollections
- DataSourceInformation
- DataTypes
- Restrictions
- ReservedWords

Provider-specific

The following are the collections currently provided by MySQL Connector/Net, in addition to the common collections above:

- Databases
- Tables
- Columns
- Users
- Foreign Keys
- IndexColumns
- Indexes
- Foreign Key Columns
- UDF
- Views
- ViewColumns
- Procedure Parameters
- Procedures
- Triggers

Example Code

A list of available collections can be obtained using the following code:

```
using System;
using System.Data;
using System.Text;
using MySql.Data;
```

```
using MySql.Data.MySqlClient;

namespace ConsoleApplication2
{
    class Program
    {

        private static void DisplayData(System.Data.DataTable table)
        {
            foreach (System.Data.DataRow row in table.Rows)
            {
                foreach (System.Data.DataColumn col in table.Columns)
                {
                    Console.WriteLine("{0} = {1}", col.ColumnName, row[col]);
                }
                Console.WriteLine("============================");
            }
        }

        static void Main(string[] args)
        {

            string connStr = "server=localhost;user=root;database=world;port=3306;password=******;";
            MySqlConnection conn = new MySqlConnection(connStr);

            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();

                DataTable table = conn.GetSchema("MetaDataCollections");
                //DataTable table = conn.GetSchema("UDF");
                DisplayData(table);

                conn.Close();
            }
            catch (Exception ex)
            {
                Console.WriteLine(ex.ToString());
            }
            Console.WriteLine("Done.");
        }
    }
}
```

Further information on the `GetSchema()` method and schema collections can be found in the Microsoft .NET documentation.

Using MySqlCommand

A `MySqlCommand` has the `CommandText` and `CommandType` properties associated with it. The `CommandText` will be handled differently depending on the setting of `CommandType`. `CommandType` can be one of:

1. Text - A SQL text command (default)
2. StoredProcedure - The name of a Stored Procedure
3. TableDirect - The name of a table (new in Connector/Net 6.2)

The default `CommandType`, `Text`, is used for executing queries and other SQL commands. Some example of this can be found in the following section The MySqlCommand Object.

If `CommandType` is set to `StoredProcedure`, set `CommandText` to the name of the Stored Procedure to access.

If `CommandType` is set to `TableDirect`, all rows and columns of the named table will be returned when you call one of the Execute methods. In effect, this command performs a `SELECT *` on the table

specified. The `CommandText` property is set to the name of the table to query. This is illustrated by the following code snippet:

```
...
MySqlCommand cmd = new MySqlCommand();
cmd.CommandText = "mytable";
cmd.Connection = someConnection;
cmd.CommandType = CommandType.TableDirect;
MySqlDataReader reader = cmd.ExecuteReader();
while (reader.Read())
{
   Console.WriteLn(reader[0], reader[1]...);
}
...
```

Examples of using the CommandType of StoredProcedure can be found in the section Accessing Stored Procedures with Connector/Net.

Commands can have a timeout associated with them. This is useful as you may not want a situation were a command takes up an excessive amount of time. A timeout can be set using the `CommandTimeout` property. The following code snippet sets a timeout of one minute:

```
MySqlCommand cmd = new MySqlCommand();
cmd.CommandTimeout = 60;
```

The default value is 30 seconds. Avoid a value of 0, which indicates an indefinite wait. To change the default command timeout, use the connection string option `Default Command Timeout`.

Prior to MySQL Connector/Net 6.2, `MySqlCommand.CommandTimeout` included user processing time, that is processing time not related to direct use of the connector. Timeout was implemented through a .NET Timer, that triggered after `CommandTimeout` seconds. This timer consumed a thread.

MySQL Connector/Net 6.2 introduced timeouts that are aligned with how Microsoft handles `SqlCommand.CommandTimeout`. This property is the cumulative timeout for all network reads and writes during command execution or processing of the results. A timeout can still occur in the `MySqlReader.Read` method after the first row is returned, and does not include user processing time, only IO operations. The 6.2 implementation uses the underlying stream timeout facility, so is more efficient in that it does not require the additional timer thread as was the case with the previous implementation.

Further details on this can be found in the relevant Microsoft documentation.

Using Connector/Net with Connection Pooling

The Connector/Net supports connection pooling for better performance and scalability with database-intensive applications. This is enabled by default. You can turn it off or adjust its performance characteristics using the connection string options `Pooling`, `Connection Reset`, `Connection Lifetime`, `Cache Server Properties`, `Max Pool Size` and `Min Pool Size`. See Creating a Connector/Net Connection String for further information.

Connection pooling works by keeping the native connection to the server live when the client disposes of a `MySqlConnection`. Subsequently, if a new `MySqlConnection` object is opened, it will be created from the connection pool, rather than creating a new native connection. This improves performance.

Guidelines

To work as designed, it is best to let the connection pooling system manage all connections. Do not create a globally accessible instance of `MySqlConnection` and then manually open and close it. This interferes with the way the pooling works and can lead to unpredictable results or even exceptions.

One approach that simplifies things is to avoid manually creating a `MySqlConnection` object. Instead use the overloaded methods that take a connection string as an argument. Using this approach,

Connector/Net will automatically create, open, close and destroy connections, using the connection pooling system for best performance.

Typed Datasets and the `MembershipProvider` and `RoleProvider` classes use this approach. Most classes that have methods that take a `MySqlConnection` as an argument, also have methods that take a connection string as an argument. This includes `MySqlDataAdapter`.

Instead of manually creating `MySqlCommand` objects, you can use the static methods of the `MySqlHelper` class. These take a connection string as an argument, and they fully support connection pooling.

Resource Usage

Starting with MySQL Connector/Net 6.2, there is a background job that runs every three minutes and removes connections from pool that have been idle (unused) for more than three minutes. The pool cleanup frees resources on both client and server side. This is because on the client side every connection uses a socket, and on the server side every connection uses a socket and a thread.

Prior to this change, connections were never removed from the pool, and the pool always contained the peak number of open connections. For example, a web application that peaked at 1000 concurrent database connections would consume 1000 threads and 1000 open sockets at the server, without ever freeing up those resources from the connection pool. Note, connections, no matter how old, will not be closed if the number of connections in the pool is less than or equal to the value set by the `Min Pool Size` connection string parameter.

Using the Windows Native Authentication Plugin

Connector/Net applications can authenticate to a MySQL server using the Windows Native Authentication Plugin as of Connector/Net 6.4.4 and MySQL 5.5.16. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password. For background and usage information about the authentication plugin, see, The Windows Native Authentication Plugin.

The interface matches the MySql.Data.MySqlClient object. To enable, pass in `Integrated Security` to the connection string with a value of `yes` or `sspi`.

Passing in a user ID is optional. When Windows authentication is set up, a MySQL user is created and configured to be used by Windows authentication. By default, this user ID is named `auth_windows`, but can be defined using a different name. If the default name is used, then passing the user ID to the connection string from Connector/Net is optional, because it will use the `auth_windows` user. Otherwise, the name must be passed to the connection string using the standard user ID element.

Writing a Custom Authentication Plugin

Advanced users with special security requirements can create their own authentication plugins for Connector/Net applications. You can extend the handshake protocol, adding custom logic. This capability requires Connector/Net 6.6.3 or higher, and MySQL 5.5.16 or higher. For background and usage information about MySQL authentication plugins, see, Authentication Plugins and Writing Authentication Plugins.

To write a custom authentication plugin, you will need a reference to the assembly `MySql.Data.dll`. The classes relevant for writing authentication plugins are available at the namespace `MySql.Data.MySqlClient.Authentication`.

How the Custom Authentication Plugin Works

At some point during handshake, the internal method

```
void Authenticate(bool reset)
```

of `MySqlAuthenticationPlugin` is called. This method in turns calls several overridable methods of the current plugin.

Creating the Authentication Plugin Class

You put the authentication plugin logic inside a new class derived from `MySql.Data.MySqlClient.Authentication.MySqlAuthenticationPlugin`. The following methods are available to be overridden:

```
protected virtual void CheckConstraints()
protected virtual void AuthenticationFailed(Exception ex)
protected virtual void AuthenticationSuccessful()
protected virtual byte[] MoreData(byte[] data)
protected virtual void AuthenticationChange()
public abstract string PluginName { get; }
public virtual string GetUsername()
public virtual object GetPassword()
protected byte[] AuthData;
```

The following is a brief explanation of each one:

```

/// <summary>
/// This method must check authentication method specific constraints in the
environment and throw an Exception
/// if the conditions are not met. The default implementation does nothing.
/// </summary>
protected virtual void CheckConstraints()

/// <summary>
/// This method, called when the authentication failed, provides a chance to
plugins to manage the error
/// the way they consider decide (either showing a message, logging it, etc.).
/// The default implementation wraps the original exception in a MySqlException
with an standard message and rethrows it.
/// </summary>
/// <param name="ex">The exception with extra information on the error.</param>
protected virtual void AuthenticationFailed(Exception ex)

/// <summary>
/// This method is invoked when the authentication phase was successful accepted
by the server.
/// Derived classes must override this if they want to be notified of such
condition.
/// </summary>
/// <remarks>The default implementation does nothing.</remarks>
protected virtual void AuthenticationSuccessful()

/// <summary>
/// This method provides a chance for the plugin to send more data when the
server requests so during the
/// authentication phase. This method will be called at least once, and more
than one depending upon whether the
/// server response packets have the 0x01 prefix.
/// </summary>
/// <param name="data">The response data from the server, during the
authentication phase the first time is called is null, in
subsequent calls contains the server response.</param>
/// <returns>The data generated by the plugin for server consumption.</returns>
/// <remarks>The default implementation always returns null.</remarks>
protected virtual byte[] MoreData(byte[] data)

/// <summary>
/// The plugin name.
/// </summary>
public abstract string PluginName { get; }

/// <summary>
/// Gets the user name to send to the server in the authentication phase.
/// </summary>
/// <returns>An string with the user name</returns>
/// <remarks>Default implementation returns the UserId passed from the
connection string.</remarks>
public virtual string GetUsername()
```

```
/// <summary>
/// Gets the password to send to the server in the authentication phase. This
can can be an string or a
/// </summary>
/// <returns>An object, can be byte[], string or null, with the password.
</returns>
/// <remarks>Default implementation returns null.</remarks>
public virtual object GetPassword()

/// <summary>
/// The authentication data passed when creating the plugin.
/// For example in mysql_native_password this is the seed to encrypt the
password.
/// </summary>
protected byte[] AuthData;
```

Sample Authentication Plugin

Here is an example showing how to create the authentication plugin, then enable it by means of a configuration file. Follow these steps:

1. Create a console app, adding a reference to `MySql.Data.dll`.
2. Design the main program as follows:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using MySql.Data.MySqlClient;

namespace AuthPluginTest
{
  class Program
  {
    static void Main(string[] args)
    {
      // Customize the connection string as necessary.
      MySqlConnection con = new MySqlConnection("server=localhost;
database=test; user id=myuser; password=mypass");
      con.Open();
      con.Close();
    }
  }
}
```

3. Create your plugin class. In this example, we add an “alternative” implementation of the Native password plugin by just using the same code from the original plugin. We name our class `MySqlNativePasswordPlugin2`:

```
using System.IO;
using System;
using System.Text;
using System.Security.Cryptography;
using MySql.Data.MySqlClient.Authentication;
using System.Diagnostics;

namespace AuthPluginTest
{
  public class MySqlNativePasswordPlugin2 : MySqlAuthenticationPlugin
  {
    public override string PluginName
    {
      get { return "mysql_native_password"; }
    }

    public override object GetPassword()
    {
```

```
      Debug.WriteLine("Calling MySqlNativePasswordPlugin2.GetPassword");
      return Get411Password(Settings.Password, AuthData);
    }

    /// <summary>
    /// Returns a byte array containing the proper encryption of the
    /// given password/seed according to the new 4.1.1 authentication scheme.
    /// </summary>
    /// <param name="password"></param>
    /// <param name="seed"></param>
    /// <returns></returns>
    private byte[] Get411Password(string password, byte[] seedBytes)
    {
      // if we have no password, then we just return 1 zero byte
      if (password.Length == 0) return new byte[1];

      SHA1 sha = new SHA1CryptoServiceProvider();

      byte[] firstHash = sha.ComputeHash(Encoding.Default.GetBytes(password));
      byte[] secondHash = sha.ComputeHash(firstHash);

      byte[] input = new byte[seedBytes.Length + secondHash.Length];
      Array.Copy(seedBytes, 0, input, 0, seedBytes.Length);
      Array.Copy(secondHash, 0, input, seedBytes.Length, secondHash.Length);
      byte[] thirdHash = sha.ComputeHash(input);

      byte[] finalHash = new byte[thirdHash.Length + 1];
      finalHash[0] = 0x14;
      Array.Copy(thirdHash, 0, finalHash, 1, thirdHash.Length);

      for (int i = 1; i < finalHash.Length; i++)
        finalHash[i] = (byte)(finalHash[i] ^ firstHash[i - 1]);
      return finalHash;
    }
  }
}
```

4. Notice that the plugin implementation just overrides `GetPassword`, and provides an implementaion to encrypt the password using the 4.1 protocol. We also put the following line in the `GetPassword` body:

   ```
   Debug.WriteLine("Calling MySqlNativePasswordPlugin2.GetPassword");
   ```

   to provide confirmation that the plugin was effectively used. (You could also put a breakpoint on that method.)

5. Enable the new plugin in the configuration file:

   ```
   <?xml version="1.0"?>
   <configuration>
     <configSections>
       <section name="MySQL" type="MySql.Data.MySqlClient.MySqlConfiguration,
   MySql.Data"/>
     </configSections>
     <MySQL>
       <AuthenticationPlugins>
         <add name="mysql_native_password"
   type="AuthPluginTest.MySqlNativePasswordPlugin2, AuthPluginTest"></add>
       </AuthenticationPlugins>
     </MySQL>
   <startup><supportedRuntime version="v4.0" sku=".NETFramework,Version=v4.0"/>
   </startup></configuration>
   ```

6. Run the application. In Visual Studio, you will see the message `Calling MySqlNativePasswordPlugin2.GetPassword` in the debug window.

7. Continue enhancing the authentication logic, overriding more methods if you required.

Using Connector/Net with Table Caching

This feature exists with Connector/Net versions 6.4 and above.

Table caching is a feature that can be used to cache slow-changing datasets on the client side. This is useful for applications that are designed to use readers, but still want to minimize trips to the server for slow-changing tables.

This feature is transparent to the application, and is disabled by default.

Configuration

- To enable table caching, add `'table cache = true'` to the connection string.
- Optionally, specify the `'Default Table Cache Age'` connection string option, which represents the number of seconds a table is cached before the cached data is discarded. The default value is `60`.
- You can turn caching on and off and set caching options at runtime, on a per-command basis.

Using the Connector/Net with Prepared Statements

As of MySQL 4.1, it is possible to use prepared statements with Connector/Net. Use of prepared statements can provide significant performance improvements on queries that are executed more than once.

Prepared execution is faster than direct execution for statements executed more than once, primarily because the query is parsed only once. In the case of direct execution, the query is parsed every time it is executed. Prepared execution also can provide a reduction of network traffic because for each execution of the prepared statement, it is necessary only to send the data for the parameters.

Another advantage of prepared statements is that it uses a binary protocol that makes data transfer between client and server more efficient.

Preparing Statements in Connector/Net

To prepare a statement, create a command object and set the `.CommandText` property to your query.

After entering your statement, call the `.Prepare` method of the `MySqlCommand` object. After the statement is prepared, add parameters for each of the dynamic elements in the query.

After you enter your query and enter parameters, execute the statement using the `.ExecuteNonQuery()`, `.ExecuteScalar()`, or `.ExecuteReader` methods.

For subsequent executions, you need only modify the values of the parameters and call the execute method again, there is no need to set the `.CommandText` property or redefine the parameters.

Visual Basic Example

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

conn.ConnectionString = strConnection

Try
   conn.Open()
   cmd.Connection = conn

   cmd.CommandText = "INSERT INTO myTable VALUES(NULL, @number, @text)"
   cmd.Prepare()

   cmd.Parameters.AddWithValue("@number", 1)
   cmd.Parameters.AddWithValue("@text", "One")

   For i = 1 To 1000
       cmd.Parameters("@number").Value = i
       cmd.Parameters("@text").Value = "A string value"

       cmd.ExecuteNonQuery()
```

```
     Next
Catch ex As MySqlException
    MessageBox.Show("Error " & ex.Number & " has occurred: " & ex.Message, "Error", MessageBoxButtons.OK, M
End Try
```

C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();

conn.ConnectionString = strConnection;

try
{
    conn.Open();
    cmd.Connection = conn;

    cmd.CommandText = "INSERT INTO myTable VALUES(NULL, @number, @text)";
    cmd.Prepare();

    cmd.Parameters.AddWithValue("@number", 1);
    cmd.Parameters.AddWithValue("@text", "One");

    for (int i=1; i <= 1000; i++)
    {
        cmd.Parameters["@number"].Value = i;
        cmd.Parameters["@text"].Value = "A string value";

        cmd.ExecuteNonQuery();
    }
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

Accessing Stored Procedures with Connector/Net

MySQL server version 5 and up supports stored procedures with the SQL 2003 stored procedure syntax.

A stored procedure is a set of SQL statements that is stored in the server. Clients make a single call to the stored procedure, passing parameters that can influence the procedure logic and query conditions, rather than issuing individual hardcoded SQL statements.

Stored procedures can be particularly useful in situations such as the following:

- Stored procedures can act as an API or abstraction layer, allowing multiple client applications to perform the same database operations. The applications can be written in different languages and run on different platforms. The applications do not need to hardcode table and column names, complicated queries, and so on. When you extend and optimize the queries in a stored procedure, all the applications that call the procedure automatically receive the benefits.
- When security is paramount, stored procedures keep applications from directly manipulating tables, or even knowing details such as table and column names. Banks, for example, use stored procedures for all common operations. This provides a consistent and secure environment, and procedures can ensure that each operation is properly logged. In such a setup, applications and users would not get any access to the database tables directly, but can only execute specific stored procedures.

Connector/Net supports the calling of stored procedures through the `MySqlCommand` object. Data can be passed in and out of a MySQL stored procedure through use of the `MySqlCommand.Parameters` collection.

Note

When you call a stored procedure, the command object makes an additional `SELECT` call to determine the parameters of the stored procedure. You must ensure that the user calling the procedure has the `SELECT` [627] privilege on the `mysql.proc` table to enable them to verify the parameters. Failure to do this will result in an error when calling the procedure.

This section will not provide in-depth information on creating Stored Procedures. For such information, please refer to http://dev.mysql.com/doc/mysql/en/stored-routines.html.

A sample application demonstrating how to use stored procedures with Connector/Net can be found in the `Samples` directory of your Connector/Net installation.

Using Stored Routines from Connector/Net

Stored procedures in MySQL can be created using a variety of tools. First, stored procedures can be created using the `mysql` command-line client. Second, stored procedures can be created using MySQL Workbench. Finally, stored procedures can be created using the `.ExecuteNonQuery` method of the `MySqlCommand` object.

Unlike the command-line and GUI clients, you are not required to specify a special delimiter when creating stored procedures in Connector/Net.

To call a stored procedure using Connector/Net, you create a `MySqlCommand` object and pass the stored procedure name as the `.CommandText` property. You then set the `.CommandType` property to `CommandType.StoredProcedure`.

After the stored procedure is named, you create one `MySqlCommand` parameter for every parameter in the stored procedure. `IN` parameters are defined with the parameter name and the object containing the value, `OUT` parameters are defined with the parameter name and the data type that is expected to be returned. All parameters need the parameter direction defined.

After defining the parameters, you call the stored procedure by using the `MySqlCommand.ExecuteNonQuery()` method.

Once the stored procedure is called, the values of the output parameters can be retrieved by using the `.Value` property of the `MySqlConnector.Parameters` collection.

Note

When a stored procedure is called using `MySqlCommand.ExecuteReader`, and the stored procedure has output parameters, the output parameters are only set after the `MySqlDataReader` returned by `ExecuteReader` is closed.

The following C# example code demonstrates the use of stored procedures. It assumes the database 'employees' has already been created:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;

namespace UsingStoredRoutines
{
    class Program
    {
        static void Main(string[] args)
        {
            MySqlConnection conn = new MySqlConnection();
            conn.ConnectionString = "server=localhost;user=root;database=employees;port=3306;password=*
```

```
            MySqlCommand cmd = new MySqlCommand();

            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();
                cmd.Connection = conn;
                cmd.CommandText = "DROP PROCEDURE IF EXISTS add_emp";
                cmd.ExecuteNonQuery();
                cmd.CommandText = "DROP TABLE IF EXISTS emp";
                cmd.ExecuteNonQuery();
                cmd.CommandText = "CREATE TABLE emp (empno INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY
                cmd.ExecuteNonQuery();

                cmd.CommandText = "CREATE PROCEDURE add_emp(" +
                                  "IN fname VARCHAR(20), IN lname VARCHAR(20), IN bday DATETIME, OUT empno
                                  "BEGIN INSERT INTO emp(first_name, last_name, birthdate) " +
                                  "VALUES(fname, lname, DATE(bday)); SET empno = LAST_INSERT_ID(); END";

                cmd.ExecuteNonQuery();
            }
            catch (MySqlException ex)
            {
                Console.WriteLine ("Error " + ex.Number + " has occurred: " + ex.Message);
            }
            conn.Close();
            Console.WriteLine("Connection closed.");
            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();
                cmd.Connection = conn;

                cmd.CommandText = "add_emp";
                cmd.CommandType = CommandType.StoredProcedure;

                cmd.Parameters.AddWithValue("@lname", "Jones");
                cmd.Parameters["@lname"].Direction = ParameterDirection.Input;

                cmd.Parameters.AddWithValue("@fname", "Tom");
                cmd.Parameters["@fname"].Direction = ParameterDirection.Input;

                cmd.Parameters.AddWithValue("@bday", "1940-06-07");
                cmd.Parameters["@bday"].Direction = ParameterDirection.Input;

                cmd.Parameters.AddWithValue("@empno", MySqlDbType.Int32);
                cmd.Parameters["@empno"].Direction = ParameterDirection.Output;

                cmd.ExecuteNonQuery();

                Console.WriteLine("Employee number: "+cmd.Parameters["@empno"].Value);
                Console.WriteLine("Birthday: " + cmd.Parameters["@bday"].Value);
            }
            catch (MySql.Data.MySqlClient.MySqlException ex)
            {
                Console.WriteLine("Error " + ex.Number + " has occurred: " + ex.Message);
            }
            conn.Close();
            Console.WriteLine("Done.");
        }
    }
}
```

The following code shows the same application in Visual Basic:

```
Imports System
Imports System.Collections.Generic
Imports System.Linq
Imports System.Text

Imports System.Data
```

```
Imports MySql.Data
Imports MySql.Data.MySqlClient

Module Module1

    Sub Main()
        Dim conn As New MySqlConnection()
        conn.ConnectionString = "server=localhost;user=root;database=world;port=3306;password=******;"
        Dim cmd As New MySqlCommand()

        Try
            Console.WriteLine("Connecting to MySQL...")
            conn.Open()
            cmd.Connection = conn
            cmd.CommandText = "DROP PROCEDURE IF EXISTS add_emp"
            cmd.ExecuteNonQuery()
            cmd.CommandText = "DROP TABLE IF EXISTS emp"
            cmd.ExecuteNonQuery()
            cmd.CommandText = "CREATE TABLE emp (empno INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY
            cmd.ExecuteNonQuery()

            cmd.CommandText = "CREATE PROCEDURE add_emp(" & "IN fname VARCHAR(20), IN lname VARCHAR(20)

            cmd.ExecuteNonQuery()
        Catch ex As MySqlException
            Console.WriteLine(("Error " & ex.Number & " has occurred: ") + ex.Message)
        End Try
        conn.Close()
        Console.WriteLine("Connection closed.")
        Try
            Console.WriteLine("Connecting to MySQL...")
            conn.Open()
            cmd.Connection = conn

            cmd.CommandText = "add_emp"
            cmd.CommandType = CommandType.StoredProcedure

            cmd.Parameters.AddWithValue("@lname", "Jones")
            cmd.Parameters("@lname").Direction = ParameterDirection.Input

            cmd.Parameters.AddWithValue("@fname", "Tom")
            cmd.Parameters("@fname").Direction = ParameterDirection.Input

            cmd.Parameters.AddWithValue("@bday", "1940-06-07")
            cmd.Parameters("@bday").Direction = ParameterDirection.Input

            cmd.Parameters.AddWithValue("@empno", MySqlDbType.Int32)
            cmd.Parameters("@empno").Direction = ParameterDirection.Output

            cmd.ExecuteNonQuery()

            Console.WriteLine("Employee number: " & cmd.Parameters("@empno").Value)
            Console.WriteLine("Birthday: " & cmd.Parameters("@bday").Value)
        Catch ex As MySql.Data.MySqlClient.MySqlException
            Console.WriteLine(("Error " & ex.Number & " has occurred: ") + ex.Message)
        End Try
        conn.Close()
        Console.WriteLine("Done.")

    End Sub

End Module
```

Handling BLOB Data With Connector/Net

One common use for MySQL is the storage of binary data in `BLOB` columns. MySQL supports four different BLOB data types: `TINYBLOB`, `BLOB`, `MEDIUMBLOB`, and `LONGBLOB`, all described in The `BLOB` and `TEXT` Types and Data Type Storage Requirements.

Data stored in a `BLOB` column can be accessed using Connector/Net and manipulated using client-side code. There are no special requirements for using Connector/Net with `BLOB` data.

Simple code examples will be presented within this section, and a full sample application can be found in the `Samples` directory of the Connector/Net installation.

Preparing the MySQL Server

The first step is using MySQL with `BLOB` data is to configure the server. Let's start by creating a table to be accessed. In my file tables, I usually have four columns: an `AUTO_INCREMENT` column of appropriate size (`UNSIGNED SMALLINT`) to serve as a primary key to identify the file, a `VARCHAR` column that stores the file name, an `UNSIGNED MEDIUMINT` column that stores the size of the file, and a `MEDIUMBLOB` column that stores the file itself. For this example, I will use the following table definition:

```
CREATE TABLE file(
file_id SMALLINT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
file_name VARCHAR(64) NOT NULL,
file_size MEDIUMINT UNSIGNED NOT NULL,
file MEDIUMBLOB NOT NULL);
```

After creating a table, you might need to modify the `max_allowed_packet` system variable. This variable determines how large of a packet (that is, a single row) can be sent to the MySQL server. By default, the server only accepts a maximum size of 1MB from the client application. If you intend to exceed 1MB in your file transfers, increase this number.

The `max_allowed_packet` option can be modified using MySQL Administrator's Startup Variables screen. Adjust the Maximum permitted option in the Memory section of the Networking tab to an appropriate setting. After adjusting the value, click the Apply Changes button and restart the server using the `Service Control` screen of MySQL Administrator. You can also adjust this value directly in the `my.cnf` file (add a line that reads `max_allowed_packet=xxM`), or use the `SET max_allowed_packet=xxM;` syntax from within MySQL.

Try to be conservative when setting `max_allowed_packet`, as transfers of BLOB data can take some time to complete. Try to set a value that will be adequate for your intended use and increase the value if necessary.

Writing a File to the Database

To write a file to a database, we need to convert the file to a byte array, then use the byte array as a parameter to an `INSERT` query.

The following code opens a file using a FileStream object, reads it into a byte array, and inserts it into the `file` table:

Visual Basic Example

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

Dim SQL As String

Dim FileSize As UInt32
Dim rawData() As Byte
Dim fs As FileStream

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test"

Try
    fs = New FileStream("c:\image.png", FileMode.Open, FileAccess.Read)
    FileSize = fs.Length

    rawData = New Byte(FileSize) {}
    fs.Read(rawData, 0, FileSize)
    fs.Close()
```

```
    conn.Open()

    SQL = "INSERT INTO file VALUES(NULL, @FileName, @FileSize, @File)"

    cmd.Connection = conn
    cmd.CommandText = SQL
    cmd.Parameters.AddWithValue("@FileName", strFileName)
    cmd.Parameters.AddWithValue("@FileSize", FileSize)
    cmd.Parameters.AddWithValue("@File", rawData)

    cmd.ExecuteNonQuery()

    MessageBox.Show("File Inserted into database successfully!", _
    "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk)

    conn.Close()
Catch ex As Exception
    MessageBox.Show("There was an error: " & ex.Message, "Error", _
        MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();

string SQL;
UInt32 FileSize;
byte[] rawData;
FileStream fs;

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    fs = new FileStream(@"c:\image.png", FileMode.Open, FileAccess.Read);
    FileSize = fs.Length;

    rawData = new byte[FileSize];
    fs.Read(rawData, 0, FileSize);
    fs.Close();

    conn.Open();

    SQL = "INSERT INTO file VALUES(NULL, @FileName, @FileSize, @File)";

    cmd.Connection = conn;
    cmd.CommandText = SQL;
    cmd.Parameters.AddWithValue("@FileName", strFileName);
    cmd.Parameters.AddWithValue("@FileSize", FileSize);
    cmd.Parameters.AddWithValue("@File", rawData);

    cmd.ExecuteNonQuery();

    MessageBox.Show("File Inserted into database successfully!",
        "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk);

    conn.Close();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

The `Read` method of the `FileStream` object is used to load the file into a byte array which is sized according to the `Length` property of the `FileStream` object.

After assigning the byte array as a parameter of the `MySqlCommand` object, the `ExecuteNonQuery` method is called and the `BLOB` is inserted into the `file` table.

Reading a BLOB from the Database to a File on Disk

Once a file is loaded into the `file` table, we can use the `MySqlDataReader` class to retrieve it.

The following code retrieves a row from the `file` table, then loads the data into a `FileStream` object to be written to disk:

Visual Basic Example

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myData As MySqlDataReader
Dim SQL As String
Dim rawData() As Byte
Dim FileSize As UInt32
Dim fs As FileStream

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test"

SQL = "SELECT file_name, file_size, file FROM file"

Try
    conn.Open()

    cmd.Connection = conn
    cmd.CommandText = SQL

    myData = cmd.ExecuteReader

    If Not myData.HasRows Then Throw New Exception("There are no BLOBs to save")

    myData.Read()

    FileSize = myData.GetUInt32(myData.GetOrdinal("file_size"))
    rawData = New Byte(FileSize) {}

    myData.GetBytes(myData.GetOrdinal("file"), 0, rawData, 0, FileSize)

    fs = New FileStream("C:\newfile.png", FileMode.OpenOrCreate, FileAccess.Write)
    fs.Write(rawData, 0, FileSize)
    fs.Close()

    MessageBox.Show("File successfully written to disk!", "Success!", MessageBoxButtons.OK, MessageBoxIcon.

    myData.Close()
    conn.Close()
Catch ex As Exception
    MessageBox.Show("There was an error: " & ex.Message, "Error", MessageBoxButtons.OK, MessageBoxIcon.Erro
End Try
```

C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataReader myData;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();

string SQL;
UInt32 FileSize;
byte[] rawData;
FileStream fs;
```

```
conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

SQL = "SELECT file_name, file_size, file FROM file";

try
{
    conn.Open();

    cmd.Connection = conn;
    cmd.CommandText = SQL;

    myData = cmd.ExecuteReader();

    if (! myData.HasRows)
        throw new Exception("There are no BLOBs to save");

    myData.Read();

    FileSize = myData.GetUInt32(myData.GetOrdinal("file_size"));
    rawData = new byte[FileSize];

    myData.GetBytes(myData.GetOrdinal("file"), 0, rawData, 0, (int)FileSize);

    fs = new FileStream(@"C:\newfile.png", FileMode.OpenOrCreate, FileAccess.Write);
    fs.Write(rawData, 0, (int)FileSize);
    fs.Close();

    MessageBox.Show("File successfully written to disk!",
        "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk);

    myData.Close();
    conn.Close();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

After connecting, the contents of the `file` table are loaded into a `MySqlDataReader` object. The `GetBytes` method of the `MySqlDataReader` is used to load the `BLOB` into a byte array, which is then written to disk using a `FileStream` object.

The `GetOrdinal` method of the MySqlDataReader can be used to determine the integer index of a named column. Use of the GetOrdinal method prevents errors if the column order of the `SELECT` query is changed.

Using the Connector/Net Interceptor Classes

An interceptor is a software design pattern that provides a transparent way to extend or modify some aspect of a program, similar to a user exit. No recompiling is required. With Connector/Net, the interceptors are enabled and disabled by updating the connection string to refer to different sets of interceptor classes that you instantiate.

Connector/Net includes the following interceptor classes:

- The `BaseCommandInterceptor` lets you perform additional operations when a program issues a SQL command. For example, you can examine the SQL statement for logging or debugging purposes, substitute your own result set to implement a caching mechanism, and so on. Depending on the use case, your code can supplement the SQL command or replace it entirely.

  The `BaseCommandInterceptor` class has these methods that you can override:

  ```
  public virtual bool ExecuteScalar(string sql, ref object returnValue);
  public virtual bool ExecuteNonQuery(string sql, ref int returnValue);
  public virtual bool ExecuteReader(string sql, CommandBehavior behavior, ref MySqlDataReader returnVal
  public virtual void Init(MySqlConnection connection);
  ```

If your interceptor overrides one of the `Execute...` methods, set the `returnValue` output parameter and return `true` if you handled the event, or `false` if you did not handle the event. The SQL command is processed normally only when all command interceptors return `false`.

The connection passed to the `Init` method is the connection that is attached to this interceptor.

- The `BaseExceptionInterceptor` lets you perform additional operations when a program encounters a SQL exception. The exception interception mechanism is modeled after the Connector/J model. You can code an interceptor class and connect it to an existing program without recompiling, and intercept exceptions when they are created. You can then change the exception type and optionally attach information to it. This capability lets you turn on and off logging and debugging code without hardcoding anything in the application. This technique applies to exceptions raised at the SQL level, not to lower-level system or I/O errors.

  You develop an exception interceptor first by creating a subclass of the `BaseExceptionInterceptor` class. You must override the `InterceptException()` method. You can also override the `Init()` method to do some one-time initialization.

  Each exception interceptor has 2 methods:

  ```
  public abstract Exception InterceptException(Exception exception,
   MySqlConnection connection);
  public virtual void Init(MySqlConnection connection);
  ```

  The connection passed to `Init()` is the connection that is attached to this interceptor.

  Each interceptor is required to override `InterceptException` and return an exception. It can return the exception it is given, or it can wrap it in a new exception. We currently do not offer the ability to suppress the exception.

Here are examples of using the FQN (fully qualified name) on the connection string:

```
MySqlConnection c1 = new MySqlConnection(@"server=localhost;pooling=false;
commandinterceptors=CommandApp.MyCommandInterceptor,CommandApp");

MySqlConnection c2 = new MySqlConnection(@"server=localhost;pooling=false;
exceptioninterceptors=ExceptionStackTraceTest.MyExceptionInterceptor,ExceptionStackTraceTest");
```

In this example, the command interceptor is called `CommandApp.MyCommandInterceptor` and exists in the `CommandApp` assembly. The exception interceptor is called `ExceptionStackTraceTest.MyExceptionInterceptor` and exists in the `ExceptionStackTraceTest` assembly.

To shorten the connection string, you can register your exception interceptors in your `app.config` or `web.config` file like this:

```
<configSections>
<section name="MySQL" type="MySql.Data.MySqlClient.MySqlConfiguration,
MySql.Data"/>
</configSections>
<MySQL>
<CommandInterceptors>
  <add name="myC" type="CommandApp.MyCommandInterceptor,CommandApp" />
</CommandInterceptors>
</MySQL>

<configSections>
<section name="MySQL" type="MySql.Data.MySqlClient.MySqlConfiguration,
MySql.Data"/>
</configSections>
<MySQL>
<ExceptionInterceptors>
  <add name="myE"
type="ExceptionStackTraceTest.MyExceptionInterceptor,ExceptionStackTraceTest" />
```

```
</ExceptionInterceptors>
</MySQL>
```

Once you have done that, your connection strings can look like these:

```
MySqlConnection c1 = new MySqlConnection(@"server=localhost;pooling=false;
commandinterceptors=myC");

MySqlConnection c2 = new MySqlConnection(@"server=localhost;pooling=false;
exceptioninterceptors=myE");
```

Handling Date and Time Information in Connector/Net

MySQL and the .NET languages handle date and time information differently, with MySQL allowing dates that cannot be represented by a .NET data type, such as '`0000-00-00 00:00:00`'. These differences can cause problems if not properly handled.

The following sections demonstrate how to properly handle date and time information when using Connector/Net.

Fractional Seconds

Connector/Net 6.5 and higher support the fractional seconds feature introduced in MySQL 5.6.4. Fractional seconds could always be specified in a date literal or passed back and forth as parameters and return values, but the fractional part was always stripped off when stored in a table column. In MySQL 5.6.4 and higher, the fractional part is now preserved in data stored and retrieved through SQL. For fractional second handling in MySQL 5.6.4 and higher, see Fractional Seconds in Time Values. For the behavior of fractional seconds prior to MySQL 5.6.4, see Fractional Seconds in Time Values.

To use the more precise date and time types, specify a value from 1 to 6 when creating the table column, for example `TIME(3)` or `DATETIME(6)`, representing the number of digits of precision after the decimal point. Specifying a precision of 0 leaves the fractional part out entirely. In your C# or Visual Basic code, refer to the `Millisecond` member to retrieve the fractional second value from the `MySqlDateTime` object returned by the `GetMySqlDateTime` function. The `DateTime` object returned by the `GetDateTime` function also contains the fractional value, but only the first 3 digits.

For related code examples, see the following blog post: https://blogs.oracle.com/MySqlOnWindows/entry/milliseconds_value_support_on_datetime

Problems when Using Invalid Dates

The differences in date handling can cause problems for developers who use invalid dates. Invalid MySQL dates cannot be loaded into native .NET `DateTime` objects, including `NULL` dates.

Because of this issue, .NET `DataSet` objects cannot be populated by the `Fill` method of the `MySqlDataAdapter` class as invalid dates will cause a `System.ArgumentOutOfRangeException` exception to occur.

Restricting Invalid Dates

The best solution to the date problem is to restrict users from entering invalid dates. This can be done on either the client or the server side.

Restricting invalid dates on the client side is as simple as always using the .NET `DateTime` class to handle dates. The `DateTime` class will only allow valid dates, ensuring that the values in your database are also valid. The disadvantage of this is that it is not useful in a mixed environment where .NET and non .NET code are used to manipulate the database, as each application must perform its own date validation.

Users of MySQL 5.0.2 and higher can use the new `traditional` SQL mode to restrict invalid date values. For information on using the `traditional` SQL mode, see Server SQL Modes.

Handling Invalid Dates

Although it is strongly recommended that you avoid the use of invalid dates within your .NET application, it is possible to use invalid dates by means of the `MySqlDateTime` data type.

The `MySqlDateTime` data type supports the same date values that are supported by the MySQL server. The default behavior of Connector/Net is to return a .NET DateTime object for valid date values, and return an error for invalid dates. This default can be modified to cause Connector/Net to return `MySqlDateTime` objects for invalid dates.

To instruct Connector/Net to return a `MySqlDateTime` object for invalid dates, add the following line to your connection string:

```
Allow Zero Datetime=True
```

Please note that the use of the `MySqlDateTime` class can still be problematic. The following are some known issues:

1. Data binding for invalid dates can still cause errors (zero dates like 0000-00-00 do not seem to have this problem).
2. The `ToString` method return a date formatted in the standard MySQL format (for example, `2005-02-23 08:50:25`). This differs from the `ToString` behavior of the .NET DateTime class.
3. The `MySqlDateTime` class supports NULL dates, while the .NET DateTime class does not. This can cause errors when trying to convert a MySQLDateTime to a DateTime if you do not check for NULL first.

Because of the known issues, the best recommendation is still to use only valid dates in your application.

Handling NULL Dates

The .NET `DateTime` data type cannot handle `NULL` values. As such, when assigning values from a query to a `DateTime` variable, you must first check whether the value is in fact `NULL`.

When using a `MySqlDataReader`, use the `.IsDBNull` method to check whether a value is `NULL` before making the assignment:

Visual Basic Example

```
If Not myReader.IsDBNull(myReader.GetOrdinal("mytime")) Then
    myTime = myReader.GetDateTime(myReader.GetOrdinal("mytime"))
Else
    myTime = DateTime.MinValue
End If
```

C# Example

```
if (! myReader.IsDBNull(myReader.GetOrdinal("mytime")))
    myTime = myReader.GetDateTime(myReader.GetOrdinal("mytime"));
else
    myTime = DateTime.MinValue;
```

`NULL` values will work in a data set and can be bound to form controls without special handling.

Using the `MySqlBulkLoader` Class

MySQL Connector/Net features a bulk loader class that wraps the MySQL statement `LOAD DATA INFILE`. This gives MySQL Connector/Net the ability to load a data file from a local or remote host to the server. The class concerned is `MySqlBulkLoader`. This class has various methods, the main one being `load` to cause the specified file to be loaded to the server. Various parameters can be set to control how the data file is processed. This is achieved through setting various properties of the class. For example, the field separator used, such as comma or tab, can be specified, along with the record terminator, such as newline.

The following code shows a simple example of using the `MySqlBulkLoader` class. First an empty table needs to be created, in this case in the `test` database:

```
CREATE TABLE Career (
       Name VARCHAR(100) NOT NULL,
       Age INTEGER,
       Profession VARCHAR(200)
);
```

A simple tab-delimited data file is also created (it could use any other field delimiter such as comma):

```
Table Career in Test Database
Name Age Profession

Tony 47 Technical Writer
Ana 43 Nurse
Fred 21 IT Specialist
Simon 45 Hairy Biker
```

Note that with this test file the first three lines will need to be ignored, as they do not contain table data. This can be achieved using the `NumberOfLinesToSkip` property. This file can then be loaded and used to populate the `Career` table in the `test` database:

```
using System;
using System.Text;
using MySql.Data;
using MySql.Data.MySqlClient;

namespace ConsoleApplication1
{
    class Program
    {
        static void Main(string[] args)
        {

            string connStr = "server=localhost;user=root;database=test;port=3306;password=******;";
            MySqlConnection conn = new MySqlConnection(connStr);

            MySqlBulkLoader bl = new MySqlBulkLoader(conn);
            bl.TableName = "Career";
            bl.FieldTerminator = "\t";
            bl.LineTerminator = "\n";
            bl.FileName = "c:/career_data.txt";
            bl.NumberOfLinesToSkip = 3;

            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();

                // Upload data from file
                int count = bl.Load();
                Console.WriteLine(count + " lines uploaded.");

                string sql = "SELECT Name, Age, Profession FROM Career";
                MySqlCommand cmd = new MySqlCommand(sql, conn);
                MySqlDataReader rdr = cmd.ExecuteReader();

                while (rdr.Read())
                {
                    Console.WriteLine(rdr[0] + " -- " + rdr[1] + " -- " + rdr[2]);
                }

                rdr.Close();

                conn.Close();
            }
            catch (Exception ex)
            {
                Console.WriteLine(ex.ToString());
            }
```

```
            Console.WriteLine("Done.");
        }
    }
}
```

Further information on `LOAD DATA INFILE` can be found in `LOAD DATA INFILE` Syntax. Further information on `MySqlBulkLoader` can be found in the reference documentation that was included with your connector.

Using the MySQL Connector/Net Trace Source Object

MySQL Connector/Net 6.2 introduced support for .NET 2.0 compatible tracing, using `TraceSource` objects.

The .NET 2.0 tracing architecture consists of four main parts:

- *Source* - This is the originator of the trace information. The source is used to send trace messages. The name of the source provided by MySQL Connector/Net is `mysql`.
- *Switch* - This defines the level of trace information to emit. Typically, this is specified in the `app.config` file, so that it is not necessary to recompile an application to change the trace level.
- *Listener* - Trace listeners define where the trace information will be written to. Supported listeners include, for example, the Visual Studio Output window, the Windows Event Log, and the console.
- *Filter* - Filters can be attached to listeners. Filters determine the level of trace information that will be written. While a switch defines the level of information that will be written to all listeners, a filter can be applied on a per-listener basis, giving finer grained control of trace information.

To use tracing a `TraceSource` object first needs to be created. To create a `TraceSource` object in MySQL Connector/Net you would use code similar to the following:

```
TraceSource ts = new TraceSource("mysql");
```

To enable trace messages, configure a trace switch. There are three main switch classes, `BooleanSwitch`, `SourceSwitch`, and `TraceSwitch`. Trace switches also have associated with them a trace level enumeration, these are `Off`, `Error`, `Warning`, `Info`, and `Verbose`. The following code snippet illustrates creating a switch:

```
ts.Switch = new SourceSwitch("MySwitch", "Verbose");
```

This creates a `SourceSwitch`, called `MySwitch`, and sets the trace level to `Verbose`, meaning that all trace messages will be written.

It is convenient to be able to change the trace level without having to recompile the code. This is achieved by specifying the trace level in application configuration file, `app.config`. You then simply need to specify the desired trace level in the configuration file and restart the application. The trace source is configured within the `system.diagnostics` section of the file. The following XML snippet illustrates this:

```
<configuration>
  ...
  <system.diagnostics>
    <sources>
      <source name="mysql" switchName="MySwitch"
              switchType="System.Diagnostics.SourceSwitch" />
      ...
    </sources>
    <switches>
      <add name="MySwitch" value="Verbose"/>
      ...
    </switches>
  </system.diagnostics>
  ...
</configuration>
```

By default, trace information is written to the Output window of Microsoft Visual Studio. There are a wide range of listeners that can be attached to the trace source, so that trace messages can be written out to various destinations. You can also create custom listeners to allow trace messages to be written to other destinations as mobile devices and web services. A commonly used example of a listener is `ConsoleTraceListener`, which writes trace messages to the console.

To add a listener at run time, use code such as the following:

```
ts.Listeners.Add(new ConsoleTraceListener());
```

Then, call methods on the trace source object to generate trace information. For example, the `TraceInformation()`, `TraceEvent()`, or `TraceData()` methods can be used.

The `TraceInformation()` method simply prints a string passed as a parameter. The `TraceEvent()` method, as well as the optional informational string, requires a `TraceEventType` value to be passed to indicate the trace message type, and also an application specific ID. The `TraceEventType` can have a value of `Verbose`, `Information`, `Warning`, `Error`, and `Critical`. Using the `TraceData()` method you can pass any object, for example an exception object, instead of a message.

To ensure than these generated trace messages gets flushed from the trace source buffers to listeners, invoke the `Flush()` method. When you are finished using a trace source, call the `Close()` method. The `Close()` method first calls `Flush()`, to ensure any remaining data is written out. It then frees up resources, and closes the listeners associated with the trace source.

```
ts.TraceInformation("Informational message");
ts.TraceEvent(TraceEventType.Error, 3, "Optional error message");
ts.TraceData(TraceEventType.Error, 3, ex); // pass exception object
ts.Flush();
...
ts.Close();
```

Viewing MySQL Trace Information

This section describes how to set up your application to view MySQL trace information.

The first thing you need to do is create a suitable `app.config` file for your application. An example is shown in the following code:

```
<?xml version="1.0" encoding="utf-8" ?>
<configuration>
  <system.diagnostics>
    <sources>
      <source name="mysql" switchName="SourceSwitch"
        switchType="System.Diagnostics.SourceSwitch" >
        <listeners>
          <add name="console" />
          <remove name ="Default" />
        </listeners>
      </source>
    </sources>
    <switches>
      <!-- You can set the level at which tracing is to occur -->
      <add name="SourceSwitch" value="Verbose" />
      <!-- You can turn tracing off -->
      <!--add name="SourceSwitch" value="Off" -->
    </switches>
    <sharedListeners>
      <add name="console"
        type="System.Diagnostics.ConsoleTraceListener"
        initializeData="false"/>
    </sharedListeners>
  </system.diagnostics>
</configuration>
```

This ensures a suitable trace source is created, along with a switch. The switch level in this case is set to `Verbose` to display the maximum amount of information.

In the application the only other step required is to add `logging=true` to the connection string. An example application could be:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Diagnostics;
using MySql.Data;
using MySql.Data.MySqlClient;
using MySql.Web;

namespace ConsoleApplication1
{
    class Program
    {
        static void Main(string[] args)
        {

            string connStr = "server=localhost;user=root;database=world;port=3306;password=******;logging=t
            MySqlConnection conn = new MySqlConnection(connStr);
            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();

                string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent='Oceania'";
                MySqlCommand cmd = new MySqlCommand(sql, conn);
                MySqlDataReader rdr = cmd.ExecuteReader();

                while (rdr.Read())
                {
                    Console.WriteLine(rdr[0] + " -- " + rdr[1]);
                }

                rdr.Close();

                conn.Close();
            }
            catch (Exception ex)
            {
                Console.WriteLine(ex.ToString());
            }
            Console.WriteLine("Done.");
        }
    }
}
```

This simple application will then generate the following output:

```
Connecting to MySQL...
mysql Information: 1 : 1: Connection Opened: connection string = 'server=localhost;User Id=root;database=wo
;password=******;logging=True'
mysql Information: 3 : 1: Query Opened: SHOW VARIABLES
mysql Information: 4 : 1: Resultset Opened: field(s) = 2, affected rows = -1, inserted id = -1
mysql Information: 5 : 1: Resultset Closed. Total rows=272, skipped rows=0, size (bytes)=7058
mysql Information: 6 : 1: Query Closed
mysql Information: 3 : 1: Query Opened: SHOW COLLATION
mysql Information: 4 : 1: Resultset Opened: field(s) = 6, affected rows = -1, inserted id = -1
mysql Information: 5 : 1: Resultset Closed. Total rows=127, skipped rows=0, size (bytes)=4102
mysql Information: 6 : 1: Query Closed
mysql Information: 3 : 1: Query Opened: SET character_set_results=NULL
mysql Information: 4 : 1: Resultset Opened: field(s) = 0, affected rows = 0, inserted id = 0
mysql Information: 5 : 1: Resultset Closed. Total rows=0, skipped rows=0, size (bytes)=0
mysql Information: 6 : 1: Query Closed
mysql Information: 10 : 1: Set Database: world
mysql Information: 3 : 1: Query Opened: SELECT Name, HeadOfState FROM Country WHERE Continent='Oceania'
mysql Information: 4 : 1: Resultset Opened: field(s) = 2, affected rows = -1, inserted id = -1
American Samoa -- George W. Bush
Australia -- Elisabeth II
...
```

```
Wallis and Futuna -- Jacques Chirac
Vanuatu -- John Bani
United States Minor Outlying Islands -- George W. Bush
mysql Information: 5 : 1: Resultset Closed. Total rows=28, skipped rows=0, size (bytes)=788
mysql Information: 6 : 1: Query Closed
Done.
mysql Information: 2 : 1: Connection Closed
```

The first number displayed in the trace message corresponds to the MySQL event type:

Event	Description
1	ConnectionOpened: connection string
2	ConnectionClosed:
3	QueryOpened: mysql server thread id, query text
4	ResultOpened: field count, affected rows (-1 if select), inserted id (-1 if select)
5	ResultClosed: total rows read, rows skipped, size of resultset in bytes
6	QueryClosed:
7	StatementPrepared: prepared sql, statement id
8	StatementExecuted: statement id, mysql server thread id
9	StatementClosed: statement id
10	NonQuery: [varies]
11	UsageAdvisorWarning: usage advisor flag. NoIndex = 1, BadIndex = 2, SkippedRows = 3, SkippedColumns = 4, FieldConversion = 5.
12	Warning: level, code, message
13	Error: error number, error message

The second number displayed in the trace message is the connection count.

Although this example uses the `ConsoleTraceListener`, any of the other standard listeners could have been used. Another possibility is to create a custom listener that uses the information passed using the `TraceEvent` method. For example, a custom trace listener could be created to perform active monitoring of the MySQL event messages, rather than simply writing these to an output device.

It is also possible to add listeners to the MySQL Trace Source at run time. This can be done with the following code:

```
MySqlTrace.Listeners.Add(new ConsoleTraceListener());
```

MySQL Connector/Net 6.3.2 introduced the ability to switch tracing on and off at run time. This can be achieved using the calls `MySqlTrace.EnableQueryAnalyzer(string host, int postInterval)` and `MySqlTrace.DisableQueryAnalyzer()`. The parameter `host` is the URL of the MySQL Enterprise Monitor server to monitor. The parameter `postInterval` is how often to post the data to MySQL Enterprise Monitor, in seconds.

Building Custom Listeners

To build custom listeners that work with the MySQL Connector/Net Trace Source, it is necessary to understand the key methods used, and the event data formats used.

The main method involved in passing trace messages is the `TraceSource.TraceEvent` method. This has the prototype:

```
public void TraceEvent(
    TraceEventType eventType,
    int id,
```

```
    string format,
    params Object[] args
)
```

This trace source method will process the list of attached listeners and call the listener's TraceListener.TraceEvent method. The prototype for the `TraceListener.TraceEvent` method is as follows:

```
public virtual void TraceEvent(
    TraceEventCache eventCache,
    string source,
    TraceEventType eventType,
    int id,
    string format,
    params Object[] args
)
```

The first three parameters are used in the standard as defined by Microsoft. The last three parameters contain MySQL-specific trace information. Each of these parameters is now discussed in more detail.

`int id`

This is a MySQL-specific identifier. It identifies the MySQL event type that has occurred, resulting in a trace message being generated. This value is defined by the `MySqlTraceEventType` public enum contained in the MySQL Connector/Net code:

```
public enum MySqlTraceEventType : int
{
    ConnectionOpened = 1,
    ConnectionClosed,
    QueryOpened,
    ResultOpened,
    ResultClosed,
    QueryClosed,
    StatementPrepared,
    StatementExecuted,
    StatementClosed,
    NonQuery,
    UsageAdvisorWarning,
    Warning,
    Error
}
```

The MySQL event type also determines the contents passed using the parameter `params Object[] args`. The nature of the `args` parameters are described in further detail in the following material.

`string format`

This is the format string that contains zero or more format items, which correspond to objects in the args array. This would be used by a listener such as `ConsoleTraceListener` to write a message to the output device.

`params Object[] args`

This is a list of objects that depends on the MySQL event type, `id`. However, the first parameter passed using this list is always the driver id. The driver id is a unique number that is incremented each time the connector is opened. This enables groups of queries on the same connection to be identified. The parameters that follow driver id depend of the MySQL event id, and are as follows:

MySQL-specific event type	Arguments (params Object[] args)
ConnectionOpened	Connection string
ConnectionClosed	No additional parameters
QueryOpened	mysql server thread id, query text
ResultOpened	field count, affected rows (-1 if select), inserted id (-1 if select)
ResultClosed	total rows read, rows skipped, size of resultset in bytes

MySQL-specific event type	Arguments (params Object[] args)
QueryClosed	No additional parameters
StatementPrepared	prepared sql, statement id
StatementExecuted	statement id, mysql server thread id
StatementClosed	statement id
NonQuery	Varies
UsageAdvisorWarning	usage advisor flag. NoIndex = 1, BadIndex = 2, SkippedRows = 3, SkippedColumns = 4, FieldConversion = 5.
Warning	level, code, message
Error	error number, error message

This information will allow you to create custom trace listeners that can actively monitor the MySQL-specific events.

Binary/Nonbinary Issues

There are certain situations where MySQL will return incorrect metadata about one or more columns. More specifically, the server will sometimes report that a column is binary when it is not and vice versa. In these situations, it becomes practically impossible for the connector to be able to correctly identify the correct metadata.

Some examples of situations that may return incorrect metadata are:

- Execution of `SHOW PROCESSLIST`. Some of the columns will be returned as binary even though they only hold string data.
- When a temporary table is used to process a resultset, some columns may be returned with incorrect binary flags.
- Some server functions such `DATE_FORMAT` will incorrectly return the column as binary.

With the availability of `BINARY` and `VARBINARY` data types, it is important that we respect the metadata returned by the server. However, we are aware that some existing applications may break with this change, so we are creating a connection string option to enable or disable it. By default, Connector/Net 5.1 respects the binary flags returned by the server. You might need to make small changes to your application to accommodate this change.

In the event that the changes required to your application would be too large, adding `'respect binary flags=false'` to your connection string causes the connector to use the prior behavior: any column that is marked as string, regardless of binary flags, will be returned as string. Only columns that are specifically marked as a `BLOB` will be returned as `BLOB`.

Character Set Considerations for Connector/Net

Treating Binary Blobs As UTF8

MySQL doesn't currently support 4-byte UTF8 sequences. This makes it difficult to represent some multi-byte languages such as Japanese. To try and alleviate this, Connector/Net now supports a mode where binary blobs can be treated as strings.

To do this, you set the `'Treat Blobs As UTF8'` connection string keyword to `yes`. This is all that needs to be done to enable conversion of all binary blobs to UTF8 strings. To convert only some of your BLOB columns, you can make use of the `'BlobAsUTF8IncludePattern'` and `'BlobAsUTF8ExcludePattern'` keywords. Set these to a regular expression pattern that matches the column names to include or exclude respectively.

When the regular expression patterns both match a single column, the include pattern is applied before the exclude pattern. The result, in this case, would be that the column would be excluded. Also, be

aware that this mode does not apply to columns of type `BINARY` or `VARBINARY` and also do not apply to nonbinary `BLOB` columns.

Currently, this mode only applies to reading strings out of MySQL. To insert 4-byte UTF8 strings into blob columns, use the .NET `Encoding.GetBytes` function to convert your string to a series of bytes. You can then set this byte array as a parameter for a `BLOB` column.

Using Connector/Net with Crystal Reports

Crystal Reports is a common tool used by Windows application developers to perform reporting and document generation. In this section we will show how to use Crystal Reports XI with MySQL and Connector/Net.

Creating a Data Source

When creating a report in Crystal Reports there are two options for accessing the MySQL data while designing your report.

The first option is to use Connector/ODBC as an ADO data source when designing your report. You will be able to browse your database and choose tables and fields using drag and drop to build your report. The disadvantage of this approach is that additional work must be performed within your application to produce a data set that matches the one expected by your report.

The second option is to create a data set in VB.NET and save it as XML. This XML file can then be used to design a report. This works quite well when displaying the report in your application, but is less versatile at design time because you must choose all relevant columns when creating the data set. If you forget a column you must re-create the data set before the column can be added to the report.

The following code can be used to create a data set from a query and write it to disk:

Visual Basic Example

```
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=world"

Try
    conn.Open()
    cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " _
        & "country.name, country.population, country.continent " _
        & "FROM country, city ORDER BY country.continent, country.name"
    cmd.Connection = conn

    myAdapter.SelectCommand = cmd
    myAdapter.Fill(myData)

    myData.WriteXml("C:\dataset.xml", XmlWriteMode.WriteSchema)
Catch ex As Exception
    MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

C# Example

```
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();
```

```
conn.ConnectionString = "server=127.0.0.1;uid=root;" +
  "pwd=12345;database=test;";

try
{
  cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " +
  "country.name, country.population, country.continent " +
  "FROM country, city ORDER BY country.continent, country.name";
  cmd.Connection = conn;

  myAdapter.SelectCommand = cmd;
  myAdapter.Fill(myData);

  myData.WriteXml(@"C:\dataset.xml", XmlWriteMode.WriteSchema);
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
  MessageBox.Show(ex.Message, "Report could not be created",
  MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

The resulting XML file can be used as an ADO.NET XML datasource when designing your report.

If you choose to design your reports using Connector/ODBC, it can be downloaded from dev.mysql.com.

Creating the Report

For most purposes, the Standard Report wizard helps with the initial creation of a report. To start the wizard, open Crystal Reports and choose the **New > Standard Report** option from the File menu.

The wizard first prompts you for a data source. If you use Connector/ODBC as your data source, use the OLEDB provider for ODBC option from the OLE DB (ADO) tree instead of the ODBC (RDO) tree when choosing a data source. If using a saved data set, choose the ADO.NET (XML) option and browse to your saved data set.

The remainder of the report creation process is done automatically by the wizard.

After the report is created, choose the Report Options... entry of the File menu. Un-check the Save Data With Report option. This prevents saved data from interfering with the loading of data within our application.

Displaying the Report

To display a report we first populate a data set with the data needed for the report, then load the report and bind it to the data set. Finally we pass the report to the crViewer control for display to the user.

The following references are needed in a project that displays a report:

- CrystalDecisions.CrystalReports.Engine
- CrystalDecisions.ReportSource
- CrystalDecisions.Shared
- CrystalDecisions.Windows.Forms

The following code assumes that you created your report using a data set saved using the code shown in Creating a Data Source, and have a crViewer control on your form named `myViewer`.

Visual Basic Example

```
Imports CrystalDecisions.CrystalReports.Engine
Imports System.Data
Imports MySql.Data.MySqlClient

Dim myReport As New ReportDocument
```

```
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = _
    "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test"

Try
    conn.Open()

    cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " _
        & "country.name, country.population, country.continent " _
        & "FROM country, city ORDER BY country.continent, country.name"
    cmd.Connection = conn

    myAdapter.SelectCommand = cmd
    myAdapter.Fill(myData)

    myReport.Load(".\world_report.rpt")
    myReport.SetDataSource(myData)
    myViewer.ReportSource = myReport
Catch ex As Exception
    MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

C# Example

```
using CrystalDecisions.CrystalReports.Engine;
using System.Data;
using MySql.Data.MySqlClient;

ReportDocument myReport = new ReportDocument();
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " +
        "country.name, country.population, country.continent " +
        "FROM country, city ORDER BY country.continent, country.name";
    cmd.Connection = conn;

    myAdapter.SelectCommand = cmd;
    myAdapter.Fill(myData);

    myReport.Load(@".\world_report.rpt");
    myReport.SetDataSource(myData);
    myViewer.ReportSource = myReport;
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message, "Report could not be created",
        MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

A new data set it generated using the same query used to generate the previously saved data set. Once the data set is filled, a ReportDocument is used to load the report file and bind it to the data set. The ReportDocument is the passed as the ReportSource of the crViewer.

This same approach is taken when a report is created from a single table using Connector/ODBC. The data set replaces the table used in the report and the report is displayed properly.

When a report is created from multiple tables using Connector/ODBC, a data set with multiple tables must be created in our application. This enables each table in the report data source to be replaced with a report in the data set.

We populate a data set with multiple tables by providing multiple `SELECT` statements in our MySqlCommand object. These `SELECT` statements are based on the SQL query shown in Crystal Reports in the Database menu's Show SQL Query option. Assume the following query:

```
SELECT `country`.`Name`, `country`.`Continent`, `country`.`Population`, `city`.`Name`, `city`.`Populati
FROM `world`.`country` `country` LEFT OUTER JOIN `world`.`city` `city` ON `country`.`Code`=`city`.`Coun
ORDER BY `country`.`Continent`, `country`.`Name`, `city`.`Name`
```

This query is converted to two `SELECT` queries and displayed with the following code:

Visual Basic Example

```
Imports CrystalDecisions.CrystalReports.Engine
Imports System.Data
Imports MySql.Data.MySqlClient

Dim myReport As New ReportDocument
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=world"

Try
    conn.Open()
    cmd.CommandText = "SELECT name, population, countrycode FROM city ORDER BY countrycode, name; " _
        & "SELECT name, population, code, continent FROM country ORDER BY continent, name"
    cmd.Connection = conn

    myAdapter.SelectCommand = cmd
    myAdapter.Fill(myData)

    myReport.Load(".\world_report.rpt")
    myReport.Database.Tables(0).SetDataSource(myData.Tables(0))
    myReport.Database.Tables(1).SetDataSource(myData.Tables(1))
    myViewer.ReportSource = myReport
Catch ex As Exception
    MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons.OK, MessageBoxIcon.Err
End Try
```

C# Example

```
using CrystalDecisions.CrystalReports.Engine;
using System.Data;
using MySql.Data.MySqlClient;

ReportDocument myReport = new ReportDocument();
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";
```

```
try
{
    cmd.CommandText = "SELECT name, population, countrycode FROM city ORDER " +
        "BY countrycode, name; SELECT name, population, code, continent FROM " +
        "country ORDER BY continent, name";
    cmd.Connection = conn;

    myAdapter.SelectCommand = cmd;
    myAdapter.Fill(myData);

    myReport.Load(@".\world_report.rpt");
    myReport.Database.Tables(0).SetDataSource(myData.Tables(0));
    myReport.Database.Tables(1).SetDataSource(myData.Tables(1));
    myViewer.ReportSource = myReport;
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message, "Report could not be created",
        MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

It is important to order the `SELECT` queries in alphabetic order, as this is the order the report will expect its source tables to be in. One SetDataSource statement is needed for each table in the report.

This approach can cause performance problems because Crystal Reports must bind the tables together on the client-side, which will be slower than using a pre-saved data set.

ASP.NET Provider Model

MySQL Connector/Net provides support for the ASP.NET 2.0 provider model. This model enables application developers to focus on the business logic of their application instead of having to recreate such boilerplate items as membership and roles support.

MySQL Connector/Net supplies the following providers:

- Membership Provider
- Role Provider
- Profile Provider
- Session State Provider (MySQL Connector/Net 6.1 and later)

The following tables show the supported providers, their default provider and the corresponding MySQL provider.

Membership Provider

Default Provider	MySQL Provider
System.Web.Security.SqlMembershipProvider	MySql.Web.Security.MySQLMembershipProvider

Role Provider

Default Provider	MySQL Provider
System.Web.Security.SqlRoleProvider	MySql.Web.Security.MySQLRoleProvider

Profile Provider

Default Provider	MySQL Provider
System.Web.Profile.SqlProfileProvider	MySql.Web.Profile.MySQLProfileProvider

SessionState Provider

Default Provider	MySQL Provider
System.Web.SessionState.InProcSessionStateStore	MySql.Web.SessionState.MySqlSessionStateStore

Note

The MySQL Session State provider uses slightly different capitalization on the class name compared to the other MySQL providers.

Installing The Providers

The installation of Connector/Net 5.1 or later will install the providers and register them in your machine's .NET configuration file, `machine.config`. The additional entries created will result in the `system.web` section appearing similar to the following code:

```
<system.web>
  <processModel autoConfig="true" />
  <httpHandlers />
  <membership>
    <providers>
      <add name="AspNetSqlMembershipProvider" type="System.Web.Security.SqlMembershipProvider, System.w
      <add name="MySQLMembershipProvider" type="MySql.Web.Security.MySQLMembershipProvider, MySql.Web,
    </providers>
  </membership>
  <profile>
    <providers>
      <add name="AspNetSqlProfileProvider" connectionStringName="LocalSqlServer" applicationName="/" ty
      <add name="MySQLProfileProvider" type="MySql.Web.Profile.MySQLProfileProvider, MySql.Web, Version
    </providers>
  </profile>
  <roleManager>
    <providers>
      <add name="AspNetSqlRoleProvider" connectionStringName="LocalSqlServer" applicationName="/" type=
      <add name="AspNetWindowsTokenRoleProvider" applicationName="/" type="System.Web.Security.WindowsT
      <add name="MySQLRoleProvider" type="MySql.Web.Security.MySQLRoleProvider, MySql.Web, Version=6.1.
    </providers>
  </roleManager>
</system.web>
```

Each provider type can have multiple provider implementations. The default provider can also be set here using the `defaultProvider` attribute, but usually this is set in the `web.config` file either manually or by using the ASP.NET configuration tool.

At time of writing, the `MySqlSessionStateStore` is not added to `machine.config` at install time, and so add the following:

```
<sessionState>
  <providers>
    <add name="MySqlSessionStateStore" type="MySql.Web.SessionState.MySqlSessionStateStore, MySql.Web,
  </providers>
</sessionState>
```

The SessionState Provider uses the `customProvider` attribute, rather than `defaultProvider`, to set the provider as the default. A typical `web.config` file might contain:

```
   <system.web>
        <membership defaultProvider="MySQLMembershipProvider" />
        <roleManager defaultProvider="MySQLRoleProvider" />
        <profile defaultProvider="MySQLProfileProvider" />
        <sessionState customProvider="MySqlSessionStateStore" />
        <compilation debug="false">
          ...
```

This sets the MySQL Providers as the defaults to be used in this web application.

The providers are implemented in the file `mysql.web.dll` and this file can be found in your MySQL Connector/Net installation folder. There is no need to run any type of SQL script to set up the database schema, as the providers create and maintain the proper schema automatically.

Using The Providers

The easiest way to start using the providers is to use the ASP.NET configuration tool that is available on the Solution Explorer toolbar when you have a website project loaded.

In the web pages that open, you can select the MySQL membership and roles providers by picking a custom provider for each area.

When the provider is installed, it creates a dummy connection string named `LocalMySqlServer`. Although this has to be done so that the provider will work in the ASP.NET configuration tool, you override this connection string in your `web.config` file. You do this by first removing the dummy connection string and then adding in the proper one, as shown in the following example:

```
<connectionStrings>
  <remove name="LocalMySqlServer"/>
  <add name="LocalMySqlServer" connectionString="server=xxx;uid=xxx;pwd=xxx;database=xxx;"/>
</connectionStrings>
```

Note the database to connect to must be specified.

Rather than manually editing configuration files, consider using the MySQL Website Configuration tool to configure your desired provider setup. From MySQL Connector/Net 6.1.1 onwards, all providers can be selected and configured from this wizard. The tool modifies your `website.config` file to the desired configuration. A tutorial on doing this is available in the following section MySQL Website Configuration Tool.

A tutorial demonstrating how to use the Membership and Role Providers can be found in the following section Tutorial: MySQL Connector/Net ASP.NET Membership and Role Provider.

Deployment

To use the providers on a production server, distribute the `MySql.Data` and the `MySql.Web` assemblies, and either register them in the remote systems Global Assembly Cache or keep them in your application's `bin/` directory.

Working with Partial Trust

.NET applications operate under a given trust level. Normal desktop applications operate under full trust, while web applications that are hosted in shared environments are normally run under the partial trust level (also known as “medium trust”). Some hosting providers host shared applications in their own app pools and allow the application to run under full trust, but this configuration is relatively rare. The Connector/Net support for partial trust has improved over time to simplify the configuration and deployment process for hosting providers.

6.5.1 and Above: Full Support for Partial Trust

Connector/Net 6.5 fully enables our provider to run in a partial trust environment when the library is installed in the Global Assembly Cache (GAC). The new `MySqlClientPermission` class, derived from the .NET `DBDataPermission` class, helps to simplify the permission setup.

Starting from 6.5 you can use the Connector/Net library inside any medium-trust level environment without any issue.

The following list shows steps and code fragments needed to run a Connector/Net application in a partial trust environment. For illustration purposes, we use the Pipe Connections protocol in this example.

1. Configure the MySQL server to accept pipe connections, by adding the `--enable-named-pipe` option on the command line. If you need more information about this, see Installing MySQL on Microsoft Windows.

2. Confirm that the hosting provider has installed the Connector/Net library (`MySql.Data.dll`) in the GAC.

3. Optionally, the hosting provider can avoid granting permissions globally by using the new `MySqlClientPermission` class in the trust policies. (The alternative is to globally enable the permissions `System.Net.SocketPermission`,

`System.Security.Permissions.ReflectionPermission`, `System.Net.DnsPermission`, and `System.Security.Permissions.SecurityPermission`.)

4. Create a simple web application using Visual Studio 2010.
5. Add the reference in your application for the `MySql.Data.MySqlClient` library.
6. Edit your `web.config` file so that your application runs using a Medium trust level:

```
<system.web>
    <trust level="Medium"/>
 </system.web>
```

7. Add the `MySql.Data.MySqlClient` namespace to your server-code page.
8. Define the connection string:

```
MySqlConnectionStringBuilder myconnString = new MySqlConnectionStringBuilder("server=localhost;User
          myconnString.PipeName = "MySQL55";
          myconnString.ConnectionProtocol = MySqlConnectionProtocol.Pipe;
```

9. Define the `MySqlConnection` to use:

```
MySqlConnection myconn = new MySqlConnection(myconnString.ConnectionString);
myconn.Open();
```

10. Retrieve some data from your tables:

```
MySqlCommand cmd = new MySqlCommand("Select * from products", myconn);
MySqlDataAdapter da = new MySqlDataAdapter(cmd);
DataSet1 tds = new DataSet1();
da.Fill(tds, tds.Tables[0].TableName);
GridView1.DataSource = tds;
GridView1.DataBind();
myconn.Close()
```

11. Run the program. It should execute successfully, without requiring any special code or encountering any security problems.

5.0.8 / 5.1.3 and Above: Partial Trust Requires Socket Permissions

Starting with these versions, Connector/Net can be used under partial trust hosting that has been modified to allow the use of sockets for communication. By default, partial trust does not include `SocketPermission`. Connector/Net uses sockets to talk with the MySQL server so the hosting provider must create a new trust level that is an exact clone of partial trust but that has the following permissions added:

- `System.Net.SocketPermission`
- `System.Security.Permissions.ReflectionPermission`
- `System.Net.DnsPermission`
- `System.Security.Permissions.SecurityPermission`

Prior to 5.0.8 / 5.1.3: Partial Trust Not Supported

Connector/Net versions prior to 5.0.8 and 5.1.3 were not compatible with partial trust hosting.

Connector/Net Connection String Options Reference

For usage information about connection strings, see Creating a Connector/Net Connection String. The first table list options that apply generally to all server configurations. The options related to systems using a connection pool are split into a separate table.

General Options

Table 21.6. Connector/Net Connection String Options - General

Name	Default	Description
`Allow Batch`, `AllowBatch`	true	When true, multiple SQL statements can be sent with one command execution. Note: starting with MySQL 4.1.1, batch statements should be separated by the server-defined separator character. Commands sent to earlier versions of MySQL should be separated with ';'.
`Allow User Variables`, `AllowUserVariables`	false	Setting this to `true` indicates that the provider expects user variables in the SQL. This option was added in Connector/Net version 5.2.2.
`Allow Zero Datetime`, `AllowZeroDateTime`	false	If set to `True`, `MySqlDataReader.GetValue()` returns a `MySqlDateTime` object for date or datetime columns that have disallowed values, such as zero datetime values, and a `System.DateTime` object for valid values. If set to `False` (the default setting) it causes a `System.DateTime` object to be returned for all valid values and an exception to be thrown for disallowed values, such as zero datetime values.
`Auto Enlist`, `AutoEnlist`	true	If `AutoEnlist` is set to `true`, which is the default, a connection opened using `TransactionScope` participates in this scope, it commits when the scope commits and rolls back if `TransactionScope` does not commit. However, this feature is considered security sensitive and therefore cannot be used in a medium trust environment.
`BlobAsUTF8ExcludePattern`	null	A POSIX-style regular expression that matches the names of BLOB columns that do not contain UTF-8 character data. See Character Set Considerations for Connector/Net for usage details.
`BlobAsUTF8IncludePattern`	null	A POSIX-style regular expression that matches the names of BLOB columns containing UTF-8 character data. See Character Set Considerations for Connector/Net for usage details.
`Certificate File`, `CertificateFile`	null	This option specifies the path to a certificate file in PKCS #12 format (`.pfx`). For an example of usage, see Tutorial: Using SSL with MySQL Connector/Net. Was introduced with 6.2.1.
`Certificate Password`, `CertificatePassword`	null	Specifies a password that is used in conjunction with a certificate specified using the option `CertificateFile`. For an example of usage, see Tutorial: Using SSL with MySQL Connector/Net. Was introduced with 6.2.1.
`Certificate Store Location`, `CertificateStoreLocation`	null	Enables you to access a certificate held in a personal store, rather than use a certificate file and password combination. For an example of usage, see Tutorial: Using SSL with MySQL Connector/Net. Was introduced with 6.2.1.
`Certificate Thumbprint`, `CertificateThumbprint`	null	Specifies a certificate thumbprint to ensure correct identification of a certificate contained within a personal store. For an example of usage, see Tutorial: Using SSL with MySQL Connector/Net. Was introduced with 6.2.1.

Name	Default	Description
CharSet, Character Set, CharacterSet		Specifies the character set that should be used to encode all queries sent to the server. Resultsets are still returned in the character set of the result data.
Check Parameters, CheckParameters	true	Indicates if stored routine parameters should be checked against the server.
Command Interceptors, CommandInterceptors		The list of interceptors that can intercept SQL command operations.
Connect Timeout, Connection Timeout, ConnectionTimeout	15	The length of time (in seconds) to wait for a connection to the server before terminating the attempt and generating an error.
Convert Zero Datetime, ConvertZeroDateTime	false	True to have MySqlDataReader.GetValue() and MySqlDataReader.GetDateTime() return DateTime.MinValue for date or datetime columns that have disallowed values.
Default Command Timeout, DefaultCommandTimeout	30	Sets the default value of the command timeout to be used. This does not supercede the individual command timeout property on an individual command object. If you set the command timeout property, that will be used. This option was added in Connector/Net 5.1.4
Default Table Cache Age, DefaultTableCacheAge	60	Specifies how long a TableDirect result should be cached, in seconds. For usage information about table caching, see Using Connector/Net with Table Caching. This option was added in Connector/Net 6.4.
enableSessionExpireCallback	false	When set to true, causes the session-expiry scanner to raise the session_end event before deleting the session data stored in the my_aspnet_sessions table, when a session times out. Enable this option to write additional application-specific cleanup code to handle the session_end event of the global.asax class, before the stored data of the session gets deleted. Within the session_end method, any other required cleanup can be done. This option was added in Connector/Net 6.4.5; it is not yet available in Connector/Net 6.5.x releases.
Encrypt, UseSSL	false	For Connector/Net 5.0.3 and later, when true, SSL encryption is used for all data sent between the client and server if the server has a certificate installed. Recognized values are true, false, yes, and no. In versions before 5.0.3, this option had no effect. From version 6.2.1, this option is deprecated and is replaced by SSL Mode. The option still works if used. If this option is set to true, it is equivalent to SSL Mode = Preferred.
Exception Interceptors, ExceptionInterceptors		The list of interceptors that can triage thrown MySqlException exceptions.
Functions Return String, FunctionsReturnString	false	Causes the connector to return binary/varbinary values as strings, if they do not have a tablename in the metadata.
Host, Server, Data Source, DataSource, Address, Addr, Network Address	localhost	The name or network address of the instance of MySQL to which to connect. Multiple hosts can be specified separated by commas. This can be useful where multiple MySQL servers are configured for

Name	Default	Description
		replication and you are not concerned about the precise server you are connecting to. No attempt is made by the provider to synchronize writes to the database, so take care when using this option. In Unix environment with Mono, this can be a fully qualified path to a MySQL socket file. With this configuration, the Unix socket is used instead of the TCP/IP socket. Currently, only a single socket name can be given, so accessing MySQL in a replicated environment using Unix sockets is not currently supported.
`Ignore Prepare`, `IgnorePrepare`	true	When true, instructs the provider to ignore any calls to `MySqlCommand.Prepare()`. This option is provided to prevent issues with corruption of the statements when used with server-side prepared statements. If you use server-side prepare statements, set this option to false. This option was added in Connector/Net 5.0.3 and Connector/Net 1.0.9.
`Initial Catalog`, `Database`	mysql	The case-sensitive name of the database to use initially.
`Interactive`, `Interactive Session`, `InteractiveSession`	false	If set to true, the client is interactive. An interactive client is one where the server variable `CLIENT_INTERACTIVE` is set. If an interactive client is set, the `wait_timeout` variable is set to the value of `interactive_timeout`. The client will then time out after this period of inactivity. For more details, see Server System Variables in the MySQL Reference Manual.
`Integrated Security`, `IntegratedSecurity`	no	Use Windows authentication when connecting to server. By default, it is turned off. To enable, specify a value of `yes`. (You can also use the value `sspi` as an alternative to `yes`.) For details, see Using the Windows Native Authentication Plugin. This option was introduced in Connector/Net 6.4.4.
`Keep Alive`, `Keepalive`	0	For TCP connections, idle connection time measured in seconds, before the first keepalive packet is sent. A value of 0 indicates that keepalive is not used.
`Logging`	false	When true, various pieces of information is output to any configured TraceListeners. See Using the MySQL Connector/Net Trace Source Object for further details.
`Old Guids`, `OldGuids`	false	This option was introduced in Connector/Net 6.1.1. The backend representation of a GUID type was changed from `BINARY(16)` to `CHAR(36)`. This was done to allow developers to use the server function `UUID()` [1042] to populate a GUID table - `UUID()` generates a 36-character string. Developers of older applications can add `'Old Guids=true'` to the connection string to use a GUID of data type `BINARY(16)`.
`Old Syntax`, `OldSyntax`, `Use Old Syntax`, `UseOldSyntax`	false	This option was deprecated in Connector/Net 5.2.2. All code should now be written using the '@' symbol as the parameter marker.
`Password`, `pwd`		The password for the MySQL account being used.

Name	Default	Description
`Persist Security Info`, `PersistSecurityInfo`	false	When set to `false` or `no` (strongly recommended), security-sensitive information, such as the password, is not returned as part of the connection if the connection is open or has ever been in an open state. Resetting the connection string resets all connection string values, including the password. Recognized values are `true`, `false`, `yes`, and `no`.
`Pipe Name`, `Pipe`, `PipeName`	mysql	When set to the name of a named pipe, the `MySqlConnection` attempts to connect to MySQL on that named pipe. This setting only applies to the Windows platform.
`Port`	3306	The port MySQL is using to listen for connections. This value is ignored if Unix socket is used.
`Procedure Cache Size`, `ProcedureCacheSize`, `procedure cache`, `procedurecache`	25	Sets the size of the stored procedure cache. By default, Connector/Net stores the metadata (input/output data types) about the last 25 stored procedures used. To disable the stored procedure cache, set the value to zero (0). This option was added in Connector/Net 5.0.2 and Connector/Net 1.0.9.
`Protocol`, `Connection Protocol`, `ConnectionProtocol`	socket	Specifies the type of connection to make to the server. Values can be: `socket` or `tcp` for a socket connection, `pipe` for a named pipe connection, `unix` for a Unix socket connection, `memory` to use MySQL shared memory.
`Replication`	false	Indicates if this connection is to use replicated servers.
`Respect Binary Flags`, `RespectBinaryFlags`	true	Setting this option to `false` means that Connector/Net ignores a column's binary flags as set by the server. This option was added in Connector/Net version 5.1.3.
`Shared Memory Name`, `SharedMemoryName`	MYSQL	The name of the shared memory object to use for communication if the connection protocol is set to `memory`.
`Sql Server Mode`, `sqlservermode`	false	Allow SQL Server syntax. When set to `true`, enables Connector/Net to support square brackets around symbols instead of backticks. This enables Visual Studio wizards that bracket symbols with [] to work with Connector/Net. This option incurs a performance hit, so should only be used if necessary. This option was added in version 6.3.1.
`SSL Mode`, `SslMode`	None	This option has the following values: • **None** - do not use SSL. • **Preferred** - use SSL if the server supports it, but allow connection in all cases. • **Required** - Always use SSL. Deny connection if server does not support SSL. • **VerifyCA** - Always use SSL. Validate the CA but tolerate name mismatch. • **VerifyFull** - Always use SSL. Fail if the host name is not correct.

Name	Default	Description
		This option was introduced in MySQL Connector/Net 6.2.1.
`Table Cache`, `tablecache`, `tablecaching`	false	Enables or disables caching of `TableDirect` commands. A value of `true` enables the cache while `false` disables it. For usage information about table caching, see Using Connector/Net with Table Caching. This option was added in Connector/Net 6.4.
`Treat BLOBs as UTF8`, `TreatBlobsAsUTF8`	false	
`Treat Tiny As Boolean`, `TreatTinyAsBoolean`	true	Setting this value to `false` causes `TINYINT(1)` to be treated as an `INT`. See Numeric Type Overview for a further explanation of the `TINYINT` and `BOOL` data types.
`Use Affected Rows`, `UseAffectedRows`	false	When `true`, the connection reports changed rows instead of found rows. This option was added in Connector/Net version 5.2.6.
`Use Procedure Bodies`, `UseProcedureBodies`, `procedure bodies`	true	When set to `true`, the default value, MySQL Connector/Net expects the body of the procedure to be viewable. This enables it to determine the parameter types and order. Set the option to `false` when the user connecting to the database does not have the `SELECT` [627] privileges for the `mysql.proc` (stored procedures) table, or cannot view `INFORMATION_SCHEMA.ROUTINES`. In this case, MySQL Connector/Net cannot determine the types and order of the parameters, and must be alerted to this fact by setting this option to `false`. When set to `false`, MySQL Connector/Net does not rely on this information being available when the procedure is called. Because MySQL Connector/Net will not be able to determine this information, explicitly set the types of all the parameters before the call and add the parameters to the command in the same order as they appear in the procedure definition. This option was added in MySQL Connector/Net 5.0.4 and MySQL Connector/Net 1.0.10.
`User Id`, `UserID`, `Username`, `Uid`, `User name`, `User`		The MySQL login account being used.
`Compress`, `Use Compression`, `UseCompression`	false	Setting this option to `true` enables compression of packets exchanged between the client and the server. This exchange is defined by the MySQL client/server protocol. Compression is used if both client and server support ZLIB compression, and the client has requested compression using this option. A compressed packet header is: packet length (3 bytes), packet number (1 byte), and Uncompressed Packet Length (3 bytes). The Uncompressed Packet Length is the number of bytes in the original, uncompressed packet. If this is zero, the data in this packet has not been compressed. When the compression protocol is in use, either the client or the server may compress packets. However, compression

Name	Default	Description
		will not occur if the compressed length is greater than the original length. Thus, some packets will contain compressed data while other packets will not.
`Use Usage Advisor`, `Usage Advisor`, `UseUsageAdvisor`	false	Logs inefficient database operations.
`Use Performance Monitor`, `UsePerformanceMonitor`, `userperfmon`, `perfmon`	false	Indicates that performance counters should be updated during execution.

Connection Pooling Options

The following table lists the valid names for options related to connection pooling within the `ConnectionString`. For more information about connection pooling, see Using Connector/Net with Connection Pooling.

Table 21.7. Connector/Net Connection String Options - Connection Pooling

Name	Default	Description
`Cache Server Properties`, `CacheServerProperties`	false	Specifies whether server variable settings are updated by a `SHOW VARIABLES` command each time a pooled connection is returned. Enabling this setting speeds up connections in a connection pool environment. Your application is not informed of any changes to configuration variables made by other connections. This option was added in Connector/Net 6.3.
`Connection Lifetime`, `ConnectionLifeTime`	0	When a connection is returned to the pool, its creation time is compared with the current time, and the connection is destroyed if that time span (in seconds) exceeds the value specified by `Connection Lifetime`. This is useful in clustered configurations to force load balancing between a running server and a server just brought online. A value of zero (0) causes pooled connections to have the maximum connection timeout.
`Connection Reset`, `ConnectionReset`	false	If true, the connection state is reset when it is retrieved from the pool. The default value of false avoids making an additional server round trip when obtaining a connection, but the connection state is not reset.
`Maximum Pool Size`, `Max Pool Size`, `maximumpoolsize`	100	The maximum number of connections allowed in the pool.
`Minimum Pool Size`, `Min Pool Size`, `MinimumPoolSize`	0	The minimum number of connections allowed in the pool.
`Pooling`	true	When `true`, the `MySqlConnection` object is drawn from the appropriate pool, or if necessary, is created and added to the appropriate pool. Recognized values are `true`, `false`, `yes`, and `no`.

Connector/Net API Reference

This section of the manual contains a complete reference to the Connector/Net ADO.NET component, automatically generated from the embedded documentation.

`MySql.Data.MySqlClient`

Namespace hierarchy

Classes

Class	Description
BaseCommandInterceptor	Provides a means of enhancing or replacing SQL commands through the connection string rather than recompiling.
BaseExceptionInterceptor	Provides a means of enabling and disabling exception handling through the connection string rather than recompiling.
MySqlClientPermission	Derived from the .NET DBDataPermission class. For usage information, see Working with Partial Trust.
MySqlCommand	
MySqlCommandBuilder	
MySqlConnection	
MySqlDataAdapter	
MySqlDataReader	Provides a means of reading a forward-only stream of rows from a MySQL database. This class cannot be inherited.
MySqlError	Collection of error codes that can be returned by the server
MySqlException	The exception that is thrown when MySQL returns an error. This class cannot be inherited.
MySqlHelper	Helper class that makes it easier to work with the provider.
MySqlInfoMessageEventArgs	Provides data for the InfoMessage event. This class cannot be inherited.
MySqlParameter	Represents a parameter to a MySqlCommand, and optionally, its mapping to DataSetcolumns. This class cannot be inherited.
MySqlParameterCollection	Represents a collection of parameters relevant to a MySqlCommand as well as their respective mappings to columns in a DataSet. This class cannot be inherited.
MySqlRowUpdatedEventArgs	Provides data for the RowUpdated event. This class cannot be inherited.
MySqlRowUpdatingEventArgs	Provides data for the RowUpdating event. This class cannot be inherited.
MySqlTransaction	

Delegates

Delegate	Description
MySqlInfoMessageEventHandler	Represents the method that will handle the InfoMessage event of a MySqlConnection.
MySqlRowUpdatedEventHandler	Represents the method that will handle the RowUpdatedevent of a MySqlDataAdapter.
MySqlRowUpdatingEventHandler	Represents the method that will handle the RowUpdatingevent of a MySqlDataAdapter.

Enumerations

Enumeration	Description
MySqlDbType	Specifies MySQL-specific data type of a field, property, for use in a MySqlParameter.
MySqlErrorCode

MySql.Data.MySqlClient Namespace

BaseCommandInterceptor

The `BaseCommandInterceptor` class has these methods that you can override:

```
public virtual bool ExecuteScalar(string sql, ref object returnValue);
public virtual bool ExecuteNonQuery(string sql, ref int returnValue);
public virtual bool ExecuteReader(string sql, CommandBehavior behavior, ref MySqlDataReader returnValue
public virtual void Init(MySqlConnection connection);
```

If your interceptor overrides one of the `Execute...` methods, set the `returnValue` output parameter and return `true` if you handled the event, or `false` if you did not handle the event. The SQL command is processed normally only when all command interceptors return `false`.

The connection passed to the `Init` method is the connection that is attached to this interceptor.

For full usage and examples, see Using the Connector/Net Interceptor Classes.

BaseExceptionInterceptor

You develop an exception interceptor first by creating a subclass of the `BaseExceptionInterceptor` class. You must override the `InterceptException()` method. You can also override the `Init()` method to do some one-time initialization.

Each exception interceptor has 2 methods:

```
public abstract Exception InterceptException(Exception exception,
  MySqlConnection connection);
public virtual void Init(MySqlConnection connection);
```

The connection passed to `Init()` is the connection that is attached to this interceptor.

Each interceptor is required to override `InterceptException` and return an exception. It can return the exception it is given, or it can wrap it in a new exception. We currently do not offer the ability to suppress the exception.

For full usage and examples, see Using the Connector/Net Interceptor Classes.

MySqlCommand Class

For a list of all members of this type, see MySqlCommand Members.

Syntax: Visual Basic

```
NotInheritable Public Class MySqlCommand_
  Inherits Component_
  Implements IDbCommand, ICloneable
```

Syntax: C#

```
public sealed class MySqlCommand : Component, IDbCommand, ICloneable
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: MySql.Data.MySqlClient

Assembly: MySql.Data (in MySql.Data.dll)

`MySqlCommand` Members

MySqlCommand overview

Public Instance Constructors

MySqlCommand	Overloaded. Initializes a new instance of the MySqlCommand class.

Public Instance Properties

CommandText	
CommandTimeout	
CommandType	
Connection	
Container (inherited from Component)	Gets the IContainer that contains the Component.
IsPrepared	
Parameters	
Site (inherited from Component)	Gets or sets the ISite of the Component.
Transaction	
UpdatedRowSource	

Public Instance Methods

Cancel	Attempts to cancel the execution of a MySqlCommand. This operation is not supported.
CreateObjRef (inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
CreateParameter	Creates a new instance of a MySqlParameter object.
Dispose (inherited from Component)	Releases all resources used by the Component.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
ExecuteNonQuery	
ExecuteReader	Overloaded.

ExecuteScalar	
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetLifetimeService (inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
InitializeLifetimeService (inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
Prepare	
ToString (inherited from Component)	Returns a String containing the name of the Component, if any. This method should not be overridden.

Public Instance Events

Disposed (inherited from Component)	Adds an event handler to listen to the Disposed event on the component.

MySqlTransaction Class, MySql.Data.MySqlClient Namespace

Connection Property

Gets the MySqlConnection object associated with the transaction, or a null reference (Nothing in Visual Basic) if the transaction is no longer valid.

Syntax: Visual Basic

```
Public ReadOnly Property Connection As MySqlConnection
```

Syntax: C#

```
public MySqlConnection Connection {get;}
```

Property Value

The MySqlConnection object associated with this transaction.

Remarks

A single application may have multiple database connections, each with zero or more transactions. This property enables you to determine the connection object associated with a particular transaction created by BeginTransaction.

See Also

MySqlTransaction Class, MySql.Data.MySqlClient Namespace

IsolationLevel Property

Specifies the IsolationLevel for this transaction.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property IsolationLevel As IsolationLevel _
_
  Implements IDbTransaction.IsolationLevel
```

Syntax: C#

```
public System.Data.IsolationLevel IsolationLevel {get;}
```

Property Value

The IsolationLevel for this transaction. The default is ReadCommitted.

Implements

IDbTransaction.IsolationLevel

Remarks

Parallel transactions are not supported. Therefore, the IsolationLevel applies to the entire transaction.

Public Event InfoMessage As MySqlInfoMessageEventHandler
```

Syntax: C#

```
public event MySqlInfoMessageEventHandler InfoMessage;
```

See Also

MySqlConnection Class, MySql.Data.MySqlClient Namespace

`MySqlInfoMessageEventHandler` Delegate

Represents the method that will handle the InfoMessage event of a MySqlConnection.

Syntax: Visual Basic

```
Public Delegate Sub MySqlInfoMessageEventHandler( _
   ByVal sender As Object, _
   ByVal args As MySqlInfoMessageEventArgs _
)
```

Syntax: C#

```
public delegate void MySqlInfoMessageEventHandler(
objectsender,
MySqlInfoMessageEventArgsargs
);
```

Requirements

Namespace: MySql.Data.MySqlClient

Assembly: MySql.Data (in MySql.Data.dll)

See Also

MySql.Data.MySqlClient Namespace

`MySqlInfoMessageEventArgs` Class

Provides data for the InfoMessage event. This class cannot be inherited.

For a list of all members of this type, see MySqlInfoMessageEventArgs Members .

Syntax: Visual Basic

```
Public Class MySqlInfoMessageEventArgs_
  Inherits EventArgs
```

Syntax: C#

```
public class MySqlInfoMessageEventArgs : EventArgs
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: MySql.Data.MySqlClient

Assembly: MySql.Data (in MySql.Data.dll)

MySqlInfoMessageEventArgs overview

Public Instance Constructors

MySqlInfoMessageEventArgs Constructor	Initializes a new instance of the MySqlInfoMessageEventArgs class.

Public Instance Fields

errors	

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

MySqlParameterCollection overview

Public Instance Constructors

MySqlParameterCollection Constructor	Initializes a new instance of the MySqlParameterCollection class.

Public Instance Properties

Count	Gets the number of MySqlParameter objects in the collection.
Item	Overloaded. Gets the MySqlParameter with a specified attribute. In C#, this property is the indexer for the MySqlParameterCollection class.

Public Instance Methods

Add	Overloaded. Adds the specified MySqlParameter object to the MySqlParameterCollection.
Clear	Removes all items from the collection.
Contains	Overloaded. Gets a value indicating whether a MySqlParameter exists in the collection.
CopyTo	Copies MySqlParameter objects from the MySqlParameterCollection to the specified array.
CreateObjRef (inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetLifetimeService (inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IndexOf	Overloaded. Gets the location of a MySqlParameter in the collection.
InitializeLifetimeService (inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
Insert	Inserts a MySqlParameter into the collection at the specified index.
Remove	Removes the specified MySqlParameter from the collection.
RemoveAt	Overloaded. Removes the specified MySqlParameter from the collection.
ToString (inherited from Object)	Returns a String that represents the current Object.

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace

`MySqlParameterCollection` Constructor

Initializes a new instance of the MySqlParameterCollection class.

Syntax: Visual Basic

```
Public Sub New()
```

Syntax: C#

```
public MySqlParameterCollection();
```

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace

Count Property

Gets the number of MySqlParameter objects in the collection.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property Count As Integer _
_
  Implements ICollection.Count
```

Syntax: C#

```
public int Count {get;}
```

Implements

ICollection.Count

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace

Item Property

Gets the MySqlParameter with a specified attribute. In C#, this property is the indexer for the MySqlParameterCollection class.

Overload List

Gets the MySqlParameter at the specified index.

- public MySqlParameter this[int] {get; set;}

Gets the MySqlParameter with the specified name.

- public MySqlParameter this[string] {get; set;}

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace

`MySqlParameter` Class

Represents a parameter to a MySqlCommand, and optionally, its mapping to DataSetcolumns. This class cannot be inherited.

For a list of all members of this type, see MySqlParameter Members .

Syntax: Visual Basic

```
NotInheritable Public Class MySqlParameter_
  Inherits MarshalByRefObject_
  Implements IDataParameter, IDbDataParameter, ICloneable
```

Syntax: C#

```
public sealed class MySqlParameter : MarshalByRefObject, IDataParameter, IDbDataParameter, ICloneable
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: MySql.Data.MySqlClient

Assembly: MySql.Data (in MySql.Data.dll)

See Also

MySqlParameter Members, MySql.Data.MySqlClient Namespace

`MySqlParameter` Members

MySqlParameter overview

Public Instance Constructors

MySqlParameter	Overloaded. Initializes a new instance of the MySqlParameter class.

Public Instance Properties

DbType	Gets or sets the DbType of the parameter.
Direction	Gets or sets a value indicating whether the parameter is input-only, output-only, bidirectional, or a stored procedure return value parameter. As of MySQL version 4.1 and earlier, input-only is the only valid choice.
IsNullable	Gets or sets a value indicating whether the parameter accepts null values.
IsUnsigned	
MySqlDbType	Gets or sets the MySqlDbType of the parameter.
ParameterName	Gets or sets the name of the MySqlParameter.
Precision	Gets or sets the maximum number of digits used to represent the Value property.
Scale	Gets or sets the number of decimal places to which Value is resolved.
Size	Gets or sets the maximum size, in bytes, of the data within the column.
SourceColumn	Gets or sets the name of the source column that is mapped to the DataSetand used for loading or returning the Value.
SourceVersion	Gets or sets the DataRowVersion to use when loading Value.

Value	Gets or sets the value of the parameter.

Public Instance Methods

CreateObjRef (inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetLifetimeService (inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
InitializeLifetimeService (inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
ToString	Overridden. Gets a string containing the ParameterName.

MySqlParameter Class, MySql.Data.MySqlClient Namespace

`MySqlParameter` Constructor

Initializes a new instance of the MySqlParameter class.

Overload List

Initializes a new instance of the MySqlParameter class.

- public MySqlParameter();

Initializes a new instance of the MySqlParameter class with the parameter name and the data type.

- public MySqlParameter(string,MySqlDbType);

Initializes a new instance of the MySqlParameter class with the parameter name, the MySqlDbType, and the size.

- public MySqlParameter(string,MySqlDbType,int);

Initializes a new instance of the MySqlParameter class with the parameter name, the type of the parameter, the size of the parameter, a ParameterDirection, the precision of the parameter, the scale of the parameter, the source column, a DataRowVersion to use, and the value of the parameter.

- public MySqlParameter(string,MySqlDbType,int,ParameterDirection,bool,byte,byte,string,DataRowVersion,object);

Initializes a new instance of the MySqlParameter class with the parameter name, the MySqlDbType, the size, and the source column name.

- public MySqlParameter(string,MySqlDbType,int,string);

Initializes a new instance of the MySqlParameter class with the parameter name and a value of the new MySqlParameter.

- public MySqlParameter(string,object);

See Also

MySqlParameter Class, MySql.Data.MySqlClient Namespace

`MySqlParameter` Constructor ()

Initializes a new instance of the MySqlParameter class.

Syntax: Visual Basic

```
Overloads Public Sub New()
```

Syntax: C#

```
public MySqlParameter();
```

See Also

MySqlParameter Class, MySql.Data.MySqlClient Namespace, MySqlParameter Constructor Overload List

`MySqlParameter` Constructor

Initializes a new instance of the MySqlParameter class with the parameter name and the data type.

Syntax: Visual Basic

```
Overloads Public Sub New( _
   ByVal parameterName As String, _
   ByVal dbType As MySqlDbType _
)
```

Syntax: C#

```
public MySqlParameter(
stringparameterName,
MySqlDbTypedbType
);
```

Parameters

- `parameterName`: The name of the parameter to map.
- `dbType`: One of the MySqlDbType values.

See Also

MySqlParameter Class, MySql.Data.MySqlClient Namespace, MySqlParameter Constructor Overload List

`MySqlDbType` Enumeration

Specifies MySQL-specific data type of a field, property, for use in a MySqlParameter.

Syntax: Visual Basic

```
Public Enum MySqlDbType
```

Syntax: C#

```
public enum MySqlDbType
```

Members

Member Name	Description
Newdate	Obsolete. Use Datetime or Date type.
Timestamp	A timestamp. The range is '1970-01-01 00:00:01.000000' to '2038-01-19 03:14:07.999999'. (Fractional seconds can only be stored with a MySQL 5.6.4 or higher database server.)
Time	The range is '-838:59:59.000000' to '838:59:59.000000'. (Fractional seconds can only be stored with a MySQL 5.6.4 or higher database server.)
Date	The supported range is '1000-01-01' to '9999-12-31'.
Datetime	The supported range is '1000-01-01 00:00:00.000000' to '9999-12-31 23:59:59.999999'. (Fractional seconds can only be stored with a MySQL 5.6.4 or higher database server.)
Year	A year in 2- or 4-digit format (default is 4-digit). The allowable values are 1901 to 2155, 0000 in the 4-digit year format, and 1970-2069 if you use the 2-digit format (70-69).
TinyBlob	A BLOB column with a maximum length of 255 (2^8 - 1) characters.
Blob	A BLOB column with a maximum length of 65535 (2^16 - 1) characters.
MediumBlob	A BLOB column with a maximum length of 16777215 (2^24 - 1) characters.
LongBlob	A BLOB column with a maximum length of 4294967295 or 4G (2^32 - 1) characters.
Int16	A 16-bit signed integer. The signed range is -32768 to 32767. The unsigned range is 0 to 65535.
Int24	Specifies a 24 (3 byte) signed or unsigned value.
Int32	A 32-bit signed integer.
Int64	A 64-bit signed integer.
Byte	The signed range is -128 to 127. The unsigned range is 0 to 255.
Float	A small (single-precision) floating-point number. Allowable values are -3.402823466E+38 to -1.175494351E-38, 0, and 1.175494351E-38 to 3.402823466E+38.
Double	A normal-size (double-precision) floating-point number. Allowable values are -1.7976931348623157E +308 to -2.2250738585072014E-308, 0, and 2.2250738585072014E-308 to 1.7976931348623157E+308.
UByte	An 8-bit unsigned value.

UInt16	A 16-bit unsigned value.
UInt24	A 24-bit unsigned value.
UInt32	A 32-bit unsigned value.
UInt64	A 64-bit unsigned value.
Decimal	A fixed precision and scale numeric value between -10^38-1 and 10^38-1.
NewDecimal	New Decimal
Set	A set. A string object that can have zero or more values, each of which must be chosen from the list of values 'value1', 'value2', ... A SET can have a maximum of 64 members.
String	Obsolete. Use VarChar type.
VarChar	A variable-length string containing 0 to 255 characters.
VarString	A variable-length string containing 0 to 65535 characters.
Enum	An enumeration. A string object that can have only one value, chosen from the list of values 'value1', 'value2', ..., NULL or the special "" error value. An ENUM can have a maximum of 65535 distinct values.
Geometry	
Bit	Bit-field data type.
TinyText	A nonbinary string column supporting a maximum length of 255 (2^8 - 1) characters.
Text	A nonbinary string column supporting a maximum length of 65535 (2^16 - 1) characters.
MediumText	A nonbinary string column supporting a maximum length of 16777215 (2^24 - 1) characters.
LongText	A nonbinary string column supporting a maximum length of 4294967295 (2^32 - 1) characters.

Requirements

Namespace: MySql.Data.MySqlClient

Assembly: MySql.Data (in MySql.Data.dll)

MySql.Data.MySqlClient Namespace

`MySqlParameter` Constructor (String, MySqlDbType, Int32)

Initializes a new instance of the MySqlParameter class with the parameter name, the MySqlDbType, and the size.

Syntax: Visual Basic

```
Overloads Public Sub New( _
   ByVal parameterName As String, _
   ByVal dbType As MySqlDbType, _
   ByVal size As Integer _
)
```

Syntax: C#

```
public MySqlParameter(
stringparameterName,
MySqlDbTypedbType,
intsize
);
```

Parameters

- `parameterName`: The name of the parameter to map.
- `dbType`: One of the MySqlDbType values.
- `size`: The length of the parameter.

See Also

MySqlParameter Class, MySql.Data.MySqlClient Namespace, MySqlParameter Constructor Overload List

`MySqlParameter` Constructor

Initializes a new instance of the MySqlParameter class with the parameter name, the type of the parameter, the size of the parameter, a ParameterDirection, the precision of the parameter, the scale of the parameter, the source column, a DataRowVersion to use, and the value of the parameter.

Syntax: Visual Basic

```
Overloads Public Sub New( _
   ByVal parameterName As String, _
   ByVal dbType As MySqlDbType, _
   ByVal size As Integer, _
   ByVal direction As ParameterDirection, _
   ByVal isNullable As Boolean, _
   ByVal precision As Byte, _
   ByVal scale As Byte, _
   ByVal sourceColumn As String, _
   ByVal sourceVersion As DataRowVersion, _
   ByVal value As Object _
)
```

Syntax: C#

```
public MySqlParameter(
stringparameterName,
MySqlDbTypedbType,
intsize,
ParameterDirectiondirection,
boolisNullable,
byteprecision,
bytescale,
stringsourceColumn,
DataRowVersionsourceVersion,
objectvalue
);
```

Parameters

- `parameterName`: The name of the parameter to map.
- `dbType`: One of the MySqlDbType values.
- `size`: The length of the parameter.
- `direction`: One of the ParameterDirectionvalues.
- `isNullable`: true if the value of the field can be null, otherwise false.

- `precision`: The total number of digits to the left and right of the decimal point to which Value is resolved.
- `scale`: The total number of decimal places to which Value is resolved.
- `sourceColumn`: The name of the source column.
- `sourceVersion`: One of the DataRowVersionvalues.
- `value`: An Object that is the value of the MySqlParameter.

`MySqlParameter` Constructor

Initializes a new instance of the MySqlParameter class with the parameter name and a value of the new MySqlParameter.

Syntax: Visual Basic

```
Overloads Public Sub New( _
   ByVal parameterName As String, _
   ByVal value As Object _
)
```

Syntax: C#

```
public MySqlParameter(
stringparameterName,
objectvalue
);
```

Parameters

- `parameterName`: The name of the parameter to map.
- `value`: An Object that is the value of the MySqlParameter.

See Also

MySqlParameter Class, MySql.Data.MySqlClient Namespace, MySqlParameter Constructor Overload List

DbType Property

Gets or sets the DbType of the parameter.

Syntax: Visual Basic

```
NotOverridable Public Property DbType As DbType _
_
  Implements IDataParameter.DbType
```

Syntax: C#

```
public System.Data.DbType DbType {get; set;}
```

Implements

IDataParameter.DbType

See Also

MySqlParameter Class, MySql.Data.MySqlClient Namespace

Direction Property

Gets or sets a value indicating whether the parameter is input-only, output-only, bidirectional, or a stored procedure return value parameter. As of MySQL version 4.1 and earlier, input-only is the only valid choice.

Syntax: Visual Basic

```
NotOverridable Public Property Direction As ParameterDirection _
_
  Implements IDataParameter.Direction
```

Syntax: C#

```
public System.Data.ParameterDirection Direction {get; set;}
```

Implements

IDataParameter.Direction

See Also

MySqlParameter Class, MySql.Data.MySqlClient Namespace

IsNullable Property

Gets or sets a value indicating whether the parameter accepts null values.

Syntax: Visual Basic

```
NotOverridable Public Property IsNullable As Boolean _
_
  Implements IDataParameter.IsNullable
```

Syntax: C#

```
public bool IsNullable {get; set;}
```

Implements

IDataParameter.IsNullable

See Also

MySqlParameter Class, MySql.Data.MySqlClient Namespace

IsUnsigned Property

Syntax: Visual Basic

```
Public Property IsUnsigned As Boolean
```

Syntax: C#

```
public bool IsUnsigned {get; set;}
```

See Also

MySqlParameter Class, MySql.Data.MySqlClient Namespace

`MySqlDbType` Property

Gets or sets the MySqlDbType of the parameter.

Syntax: Visual Basic

```
Public Property MySqlDbType As MySqlDbType
```

Syntax: C#

```
public MySqlDbType MySqlDbType {get; set;}
```

See Also

MySqlParameter Class, MySql.Data.MySqlClient Namespace

ParameterName Property

Gets or sets the name of the MySqlParameter.

Syntax: Visual Basic

```
NotOverridable Public Property ParameterName As String _
_
  Implements IDataParameter.ParameterName
```

Syntax: C#

```
public string ParameterName {get; set;}
```

Implements

IDataParameter.ParameterName

See Also

MySqlParameter Class, MySql.Data.MySqlClient Namespace

Precision Property

Gets or sets the maximum number of digits used to represent the Value property.

Syntax: Visual Basic

```
NotOverridable Public Property Precision As Byte _
_
  Implements IDbDataParameter.Precision
```

Syntax: C#

```
public byte Precision {get; set;}
```

Implements

IDbDataParameter.Precision

See Also

MySqlParameter Class, MySql.Data.MySqlClient Namespace

Scale Property

Gets or sets the number of decimal places to which Value is resolved.

Syntax: Visual Basic

```
NotOverridable Public Property Scale As Byte _
_
  Implements IDbDataParameter.Scale
```

Syntax: C#

```
public byte Scale {get; set;}
```

Implements

IDbDataParameter.Scale

See Also

MySqlParameter Class, MySql.Data.MySqlClient Namespace

Size Property

Gets or sets the maximum size, in bytes, of the data within the column.

Syntax: Visual Basic

```
NotOverridable Public Property Size As Integer _
_
  Implements IDbDataParameter.Size
```

Syntax: C#

```
public int Size {get; set;}
```

Implements

IDbDataParameter.Size

See Also

MySqlParameter Class, MySql.Data.MySqlClient Namespace

SourceColumn Property

Gets or sets the name of the source column that is mapped to the DataSetand used for loading or returning the Value.

Syntax: Visual Basic

```
NotOverridable Public Property SourceColumn As String _
_
  Implements IDataParameter.SourceColumn
```

Syntax: C#

```
public string SourceColumn {get; set;}
```

Implements

IDataParameter.SourceColumn

See Also

MySqlParameter Class, MySql.Data.MySqlClient Namespace

SourceVersion Property

Gets or sets the DataRowVersion to use when loading Value.

Syntax: Visual Basic

```
NotOverridable Public Property SourceVersion As DataRowVersion _
_
  Implements IDataParameter.SourceVersion
```

Syntax: C#

```
public System.Data.DataRowVersion SourceVersion {get; set;}
```

Implements

IDataParameter.SourceVersion

See Also

MySqlParameter Class, MySql.Data.MySqlClient Namespace

`MySqlParameter.ToString` Method

Overridden. Gets a string containing the ParameterName.

Syntax: Visual Basic

```
Overrides Public Function ToString() As String
```

Syntax: C#

```
public override string ToString();
```

Return Value

See Also

MySqlParameter Class, MySql.Data.MySqlClient Namespace

Item Property (Int32)

Gets the MySqlParameter at the specified index.

Syntax: Visual Basic

```
Overloads Public Default Property Item( _
   ByVal index As Integer _
) As MySqlParameter
```

Syntax: C#

```
public MySqlParameter this[
intindex
] {get; set;}
```

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace,
MySqlParameterCollection.Item Overload List

Item Property (String)

Gets the MySqlParameter with the specified name.

Syntax: Visual Basic

```
Overloads Public Default Property Item( _
   ByVal name As String _
) As MySqlParameter
```

Syntax: C#

```
public MySqlParameter this[
stringname
] {get; set;}
```

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace, MySqlParameterCollection.Item Overload List

Add Method

Adds the specified MySqlParameter object to the MySqlParameterCollection.

Overload List

Adds the specified MySqlParameter object to the MySqlParameterCollection.

- public MySqlParameter Add(MySqlParameter);

Adds the specified MySqlParameter object to the MySqlParameterCollection.

- public int Add(object);

Adds a MySqlParameter to the MySqlParameterCollection given the parameter name and the data type.

- public MySqlParameter Add(string,MySqlDbType);

Adds a MySqlParameter to the MySqlParameterCollection with the parameter name, the data type, and the column length.

- public MySqlParameter Add(string,MySqlDbType,int);

Adds a MySqlParameter to the MySqlParameterCollection with the parameter name, the data type, the column length, and the source column name.

- public MySqlParameter Add(string,MySqlDbType,int,string);

Adds a MySqlParameter to the MySqlParameterCollection given the specified parameter name and value.

- public MySqlParameter Add(string,object);

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace

`MySqlParameterCollection.Add` Method

Adds the specified MySqlParameter object to the MySqlParameterCollection.

Syntax: Visual Basic

```
Overloads Public Function Add( _
   ByVal value As MySqlParameter _
) As MySqlParameter
```

Syntax: C#

```
public MySqlParameter Add(
MySqlParametervalue
);
```

Parameters

- `value`: The MySqlParameter to add to the collection.

Return Value

The newly added MySqlParameter object.

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace, MySqlParameterCollection.Add Overload List

`MySqlParameterCollection.Add` Method

Adds the specified MySqlParameter object to the MySqlParameterCollection.

Syntax: Visual Basic

```
NotOverridable Overloads Public Function Add( _
   ByVal value As Object _
) As Integer _
_
  Implements IList.Add
```

Syntax: C#

```
public int Add(
objectvalue
);
```

Parameters

- `value`: The MySqlParameter to add to the collection.

Return Value

The index of the new MySqlParameter object.

Implements

IList.Add

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace, MySqlParameterCollection.Add Overload List

`MySqlParameterCollection.Add` Method

Adds a MySqlParameter to the MySqlParameterCollection given the parameter name and the data type.

Syntax: Visual Basic

```
Overloads Public Function Add( _
   ByVal parameterName As String, _
   ByVal dbType As MySqlDbType _
) As MySqlParameter
```

Syntax: C#

```
public MySqlParameter Add(
stringparameterName,
MySqlDbTypedbType
);
```

Parameters

- `parameterName`: The name of the parameter.
- `dbType`: One of the MySqlDbType values.

Return Value

The newly added MySqlParameter object.

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace, MySqlParameterCollection.Add Overload List

`MySqlParameterCollection.Add` Method

Adds a MySqlParameter to the MySqlParameterCollection with the parameter name, the data type, and the column length.

Syntax: Visual Basic

```
Overloads Public Function Add( _
   ByVal parameterName As String, _
   ByVal dbType As MySqlDbType, _
   ByVal size As Integer _
) As MySqlParameter
```

Syntax: C#

```
public MySqlParameter Add(
stringparameterName,
MySqlDbTypedbType,
intsize
);
```

Parameters

- `parameterName`: The name of the parameter.
- `dbType`: One of the MySqlDbType values.
- `size`: The length of the column.

Return Value

The newly added MySqlParameter object.

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace, MySqlParameterCollection.Add Overload List

`MySqlParameterCollection.Add` Method

Adds a MySqlParameter to the MySqlParameterCollection with the parameter name, the data type, the column length, and the source column name.

Syntax: Visual Basic

```
Overloads Public Function Add( _
   ByVal parameterName As String, _
   ByVal dbType As MySqlDbType, _
   ByVal size As Integer, _
   ByVal sourceColumn As String _
) As MySqlParameter
```

Syntax: C#

```
public MySqlParameter Add(
stringparameterName,
MySqlDbTypedbType,
```

```
intsize,
stringsourceColumn
);
```

Parameters

- `parameterName`: The name of the parameter.
- `dbType`: One of the MySqlDbType values.
- `size`: The length of the column.
- `sourceColumn`: The name of the source column.

Return Value

The newly added MySqlParameter object.

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace, MySqlParameterCollection.Add Overload List

`MySqlParameterCollection.Add` Method

Adds a MySqlParameter to the MySqlParameterCollection given the specified parameter name and value.

Syntax: Visual Basic

```
Overloads Public Function Add( _
   ByVal parameterName As String, _
   ByVal value As Object _
) As MySqlParameter
```

Syntax: C#

```
public MySqlParameter Add(
stringparameterName,
objectvalue
);
```

Parameters

- `parameterName`: The name of the parameter.
- `value`: The Value of the MySqlParameter to add to the collection.

Return Value

The newly added MySqlParameter object.

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace, MySqlParameterCollection.Add Overload List

`MySqlParameterCollection.Clear` Method

Removes all items from the collection.

Syntax: Visual Basic

```
NotOverridable Public Sub Clear() _
_
  Implements IList.Clear
```

Syntax: C#

```
public void Clear();
```

Implements

IList.Clear

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace

Contains Method

Gets a value indicating whether a MySqlParameter exists in the collection.

Overload List

Gets a value indicating whether a MySqlParameter exists in the collection.

- public bool Contains(object);

Gets a value indicating whether a MySqlParameter with the specified parameter name exists in the collection.

- public bool Contains(string);

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace

`MySqlParameterCollection.Contains` Method

Gets a value indicating whether a MySqlParameter exists in the collection.

Syntax: Visual Basic

```
NotOverridable Overloads Public Function Contains( _
   ByVal value As Object _
) As Boolean _
_
  Implements IList.Contains
```

Syntax: C#

```
public bool Contains(
objectvalue
);
```

Parameters

- `value`: The value of the MySqlParameter object to find.

Return Value

true if the collection contains the MySqlParameter object; otherwise, false.

Implements

IList.Contains

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace, MySqlParameterCollection.Contains Overload List

`MySqlParameterCollection.Contains` Method

Gets a value indicating whether a MySqlParameter with the specified parameter name exists in the collection.

Syntax: Visual Basic

```
NotOverridable Overloads Public Function Contains( _
   ByVal name As String _
) As Boolean _
_
  Implements IDataParameterCollection.Contains
```

Syntax: C#

```
public bool Contains(
stringname
);
```

Parameters

- `name`: The name of the MySqlParameter object to find.

Return Value

true if the collection contains the parameter; otherwise, false.

Implements

IDataParameterCollection.Contains

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace, MySqlParameterCollection.Contains Overload List

`MySqlParameterCollection.CopyTo` Method

Copies MySqlParameter objects from the MySqlParameterCollection to the specified array.

Syntax: Visual Basic

```
NotOverridable Public Sub CopyTo( _
   ByVal array As Array, _
   ByVal index As Integer _
) _
_
  Implements ICollection.CopyTo
```

Syntax: C#

```
public void CopyTo(
Arrayarray,
intindex
);
```

Parameters

- `array`:
- `index` [698]:

Implements

ICollection.CopyTo

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace

IndexOf Method

Gets the location of a MySqlParameter in the collection.

Overload List

Gets the location of a MySqlParameter in the collection.

- public int IndexOf(object);

Gets the location of the MySqlParameter in the collection with a specific parameter name.

- public int IndexOf(string);

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace

`MySqlParameterCollection.IndexOf` Method

Gets the location of a MySqlParameter in the collection.

Syntax: Visual Basic

```
NotOverridable Overloads Public Function IndexOf( _
   ByVal value As Object _
) As Integer _
_
  Implements IList.IndexOf
```

Syntax: C#

```
public int IndexOf(
objectvalue
);
```

Parameters

- `value`: The MySqlParameter object to locate.

Return Value

The zero-based location of the MySqlParameter in the collection.

Implements

IList.IndexOf

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace,
MySqlParameterCollection.IndexOf Overload List

`MySqlParameterCollection.IndexOf` Method

Gets the location of the MySqlParameter in the collection with a specific parameter name.

Syntax: Visual Basic

```
NotOverridable Overloads Public Function IndexOf( _
   ByVal parameterName As String _
) As Integer _
_
```

```
  Implements IDataParameterCollection.IndexOf
```

Syntax: C#

```
public int IndexOf(
stringparameterName
);
```

Parameters

- `parameterName`: The name of the MySqlParameter object to retrieve.

Return Value

The zero-based location of the MySqlParameter in the collection.

Implements

IDataParameterCollection.IndexOf

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace, MySqlParameterCollection.IndexOf Overload List

`MySqlParameterCollection.Insert` Method

Inserts a MySqlParameter into the collection at the specified index.

Syntax: Visual Basic

```
NotOverridable Public Sub Insert( _
   ByVal index As Integer, _
   ByVal value As Object _
) _
_
  Implements IList.Insert
```

Syntax: C#

```
public void Insert(
intindex,
objectvalue
);
```

Parameters

- `index` [698]:
- `value`:

Implements

IList.Insert

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace

`MySqlParameterCollection.Remove` Method

Removes the specified MySqlParameter from the collection.

Syntax: Visual Basic

```
NotOverridable Public Sub Remove( _
```

```
   ByVal value As Object _
) _
_
  Implements IList.Remove
```

Syntax: C#

```
public void Remove(
objectvalue
);
```

Parameters

- `value`:

Implements

IList.Remove

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace

RemoveAt Method

Removes the specified MySqlParameter from the collection.

Overload List

Removes the specified MySqlParameter from the collection using a specific index.

- public void RemoveAt(int);

Removes the specified MySqlParameter from the collection using the parameter name.

- public void RemoveAt(string);

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace

`MySqlParameterCollection.RemoveAt` Method

Removes the specified MySqlParameter from the collection using a specific index.

Syntax: Visual Basic

```
NotOverridable Overloads Public Sub RemoveAt( _
   ByVal index As Integer _
) _
_
  Implements IList.RemoveAt
```

Syntax: C#

```
public void RemoveAt(
intindex
);
```

Parameters

- `index` [698]: The zero-based index of the parameter.

Implements

IList.RemoveAt

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace, MySqlParameterCollection.RemoveAt Overload List

`MySqlParameterCollection.RemoveAt` Method

Removes the specified MySqlParameter from the collection using the parameter name.

Syntax: Visual Basic

```
NotOverridable Overloads Public Sub RemoveAt( _
   ByVal name As String _
) _
_
  Implements IDataParameterCollection.RemoveAt
```

Syntax: C#

```
public void RemoveAt(
stringname
);
```

Parameters

- `name`: The name of the MySqlParameter object to retrieve.

Implements

IDataParameterCollection.RemoveAt

See Also

MySqlParameterCollection Class, MySql.Data.MySqlClient Namespace, MySqlParameterCollection.RemoveAt Overload List

Transaction Property

Syntax: Visual Basic

```
Public Property Transaction As MySqlTransaction
```

Syntax: C#

```
public MySqlTransaction Transaction {get; set;}
```

See Also

MySqlCommand Class, MySql.Data.MySqlClient Namespace

UpdatedRowSource Property

Syntax: Visual Basic

```
NotOverridable Public Property UpdatedRowSource As UpdateRowSource _
_
  Implements IDbCommand.UpdatedRowSource
```

Syntax: C#

```
public System.Data.UpdateRowSource UpdatedRowSource {get; set;}
```

Implements

IDbCommand.UpdatedRowSource

See Also

MySqlCommand Class, MySql.Data.MySqlClient Namespace

`MySqlCommand.Cancel` Method

Attempts to cancel the execution of a MySqlCommand. This operation is not supported.

Syntax: Visual Basic

```
NotOverridable Public Sub Cancel() _
_
  Implements IDbCommand.Cancel
```

Syntax: C#

```
public void Cancel();
```

Implements

IDbCommand.Cancel

Remarks

Cancelling an executing command is currently not supported on any version of MySQL.

Exceptions

Exception Type	Condition
NotSupportedException	This operation is not supported.

See Also

MySqlCommand Class, MySql.Data.MySqlClient Namespace

`MySqlCommand.CreateParameter` Method

Creates a new instance of a MySqlParameter object.

Syntax: Visual Basic

```
Public Function CreateParameter() As MySqlParameter
```

Syntax: C#

```
public MySqlParameter CreateParameter();
```

Return Value

A MySqlParameter object.

Remarks

This method is a strongly-typed version of CreateParameter.

See Also

MySqlCommand Class, MySql.Data.MySqlClient Namespace

`MySqlCommand.ExecuteNonQuery` Method

Syntax: Visual Basic

```
NotOverridable Public Function ExecuteNonQuery() As Integer _
```

```
_
  Implements IDbCommand.ExecuteNonQuery
```

Syntax: C#

```
public int ExecuteNonQuery();
```

Implements

IDbCommand.ExecuteNonQuery

See Also

MySqlCommand Class, MySql.Data.MySqlClient Namespace

ExecuteReader Method

Overload List

- public MySqlDataReader ExecuteReader();
- public MySqlDataReader ExecuteReader(CommandBehavior);

See Also

MySqlCommand Class, MySql.Data.MySqlClient Namespace

`MySqlCommand.ExecuteReader` Method

Syntax: Visual Basic

```
Overloads Public Function ExecuteReader() As MySqlDataReader
```

Syntax: C#

```
public MySqlDataReader ExecuteReader();
```

See Also

MySqlCommand Class, MySql.Data.MySqlClient Namespace, MySqlCommand.ExecuteReader Overload List

`MySqlDataReader` Class

Provides a means of reading a forward-only stream of rows from a MySQL database. This class cannot be inherited.

For a list of all members of this type, see MySqlDataReader Members .

Syntax: Visual Basic

```
NotInheritable Public Class MySqlDataReader_
  Inherits MarshalByRefObject_
  Implements IEnumerable, IDataReader, IDisposable, IDataRecord
```

Syntax: C#

```
public sealed class MySqlDataReader : MarshalByRefObject, IEnumerable, IDataReader, IDisposable, IDataRecor
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: MySql.Data.MySqlClient

Assembly: MySql.Data (in MySql.Data.dll)

See Also

MySqlDataReader Members, MySql.Data.MySqlClient Namespace

`MySqlDataReader` Members

MySqlDataReader overview

Public Instance Properties

Depth	Gets a value indicating the depth of nesting for the current row. This method is not supported currently and always returns 0.
FieldCount	Gets the number of columns in the current row.
HasRows	Gets a value indicating whether the MySqlDataReader contains one or more rows.
IsClosed	Gets a value indicating whether the data reader is closed.
Item	Overloaded. Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the MySqlDataReader class.
RecordsAffected	Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.

Public Instance Methods

Close	Closes the MySqlDataReader object.
CreateObjRef (inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBoolean	Gets the value of the specified column as a Boolean.
GetByte	Gets the value of the specified column as a byte.
GetBytes	Reads a stream of bytes from the specified column offset into the buffer an array starting at the given buffer offset.
GetChar	Gets the value of the specified column as a single character.
GetChars	Reads a stream of characters from the specified column offset into the buffer as an array starting at the given buffer offset.
GetDataTypeName	Gets the name of the source data type.
GetDateTime	
GetDecimal	
GetDouble	
GetFieldType	Gets the Type that is the data type of the object.

GetFloat	
GetGuid	
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetInt16	
GetInt32	
GetInt64	
GetLifetimeService (inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetMySqlDateTime	
GetName	Gets the name of the specified column.
GetOrdinal	Gets the column ordinal, given the name of the column.
GetSchemaTable	Returns a DataTable that describes the column metadata of the MySqlDataReader.
GetString	
GetTimeSpan	
GetType (inherited from Object)	Gets the Type of the current instance.
GetUInt16	
GetUInt32	
GetUInt64	
GetValue	Gets the value of the specified column in its native format.
GetValues	Gets all attribute columns in the collection for the current row.
InitializeLifetimeService (inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
IsDBNull	Gets a value indicating whether the column contains non-existent or missing values.
NextResult	Advances the data reader to the next result, when reading the results of batch SQL statements.
Read	Advances the MySqlDataReader to the next record.
ToString (inherited from Object)	Returns a String that represents the current Object.

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

Depth Property

Gets a value indicating the depth of nesting for the current row. This method is not supported currently and always returns 0.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property Depth As Integer _
_
  Implements IDataReader.Depth
```

Syntax: C#

```
public int Depth {get;}
```

Implements

IDataReader.Depth

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

FieldCount Property

Gets the number of columns in the current row.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property FieldCount As Integer _
_
  Implements IDataRecord.FieldCount
```

Syntax: C#

```
public int FieldCount {get;}
```

Implements

IDataRecord.FieldCount

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

HasRows Property

Gets a value indicating whether the MySqlDataReader contains one or more rows.

Syntax: Visual Basic

```
Public ReadOnly Property HasRows As Boolean
```

Syntax: C#

```
public bool HasRows {get;}
```

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

IsClosed Property

Gets a value indicating whether the data reader is closed.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property IsClosed As Boolean _
_
  Implements IDataReader.IsClosed
```

Syntax: C#

```
public bool IsClosed {get;}
```

Implements

IDataReader.IsClosed

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

Item Property

Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the MySqlDataReader class.

Overload List

Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the MySqlDataReader class.

- public object this[int] {get;}

Gets the value of a column in its native format. In C#, this property is the indexer for the MySqlDataReader class.

- public object this[string] {get;}

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

Item Property (Int32)

Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the MySqlDataReader class.

Syntax: Visual Basic

```
NotOverridable Overloads Public Default ReadOnly Property Item( _
   ByVal i As Integer _
) _
_
  Implements IDataRecord.Item As Object _
_
  Implements IDataRecord.Item
```

Syntax: C#

```
public object this[
inti
] {get;}
```

Implements

IDataRecord.Item

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace, MySqlDataReader.Item Overload List

Item Property (String)

Gets the value of a column in its native format. In C#, this property is the indexer for the MySqlDataReader class.

Syntax: Visual Basic

```
NotOverridable Overloads Public Default ReadOnly Property Item( _
   ByVal name As String _
```

```
) _
_
  Implements IDataRecord.Item As Object _
_
  Implements IDataRecord.Item
```

Syntax: C#

```
public object this[
stringname
] {get;}
```

Implements

IDataRecord.Item

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace, MySqlDataReader.Item Overload List

RecordsAffected Property

Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property RecordsAffected As Integer _
_
  Implements IDataReader.RecordsAffected
```

Syntax: C#

```
public int RecordsAffected {get;}
```

Implements

IDataReader.RecordsAffected

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.Close` Method

Closes the MySqlDataReader object.

Syntax: Visual Basic

```
NotOverridable Public Sub Close() _
_
  Implements IDataReader.Close
```

Syntax: C#

```
public void Close();
```

Implements

IDataReader.Close

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.GetBoolean` Method

Gets the value of the specified column as a Boolean.

Syntax: Visual Basic

```
NotOverridable Public Function GetBoolean( _
   ByVal i As Integer _
) As Boolean _
_
  Implements IDataRecord.GetBoolean
```

Syntax: C#

```
public bool GetBoolean(
inti
);
```

Parameters

- `i`:

Return Value

Implements

IDataRecord.GetBoolean

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.GetByte` Method

Gets the value of the specified column as a byte.

Syntax: Visual Basic

```
NotOverridable Public Function GetByte( _
   ByVal i As Integer _
) As Byte _
_
  Implements IDataRecord.GetByte
```

Syntax: C#

```
public byte GetByte(
inti
);
```

Parameters

- `i`:

Return Value

Implements

IDataRecord.GetByte

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.GetBytes` Method

Reads a stream of bytes from the specified column offset into the buffer an array starting at the given buffer offset.

Syntax: Visual Basic

```
NotOverridable Public Function GetBytes( _
   ByVal i As Integer, _
   ByVal dataIndex As Long, _
   ByVal buffer As Byte(), _
   ByVal bufferIndex As Integer, _
   ByVal length As Integer _
) As Long _
_
  Implements IDataRecord.GetBytes
```

Syntax: C#

```
public long GetBytes(
inti,
longdataIndex,
byte[]buffer,
intbufferIndex,
intlength
);
```

Parameters

- `i`: The zero-based column ordinal.
- `dataIndex`: The index within the field from which to begin the read operation.
- `buffer`: The buffer into which to read the stream of bytes.
- `bufferIndex`: The index for buffer to begin the read operation.
- `length`: The maximum length to copy into the buffer.

Return Value

The actual number of bytes read.

Implements

IDataRecord.GetBytes

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.GetChar` Method

Gets the value of the specified column as a single character.

Syntax: Visual Basic

```
NotOverridable Public Function GetChar( _
   ByVal i As Integer _
) As Char _
_
  Implements IDataRecord.GetChar
```

Syntax: C#

```
public char GetChar(
inti
);
```

Parameters

- `i`:

Return Value

Implements

IDataRecord.GetChar

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.GetChars` Method

Reads a stream of characters from the specified column offset into the buffer as an array starting at the given buffer offset.

Syntax: Visual Basic

```
NotOverridable Public Function GetChars( _
   ByVal i As Integer, _
   ByVal fieldOffset As Long, _
   ByVal buffer As Char(), _
   ByVal bufferoffset As Integer, _
   ByVal length As Integer _
) As Long _
_
  Implements IDataRecord.GetChars
```

Syntax: C#

```
public long GetChars(
inti,
longfieldOffset,
char[]buffer,
intbufferoffset,
intlength
);
```

Parameters

- `i`:
- `fieldOffset`:
- `buffer`:
- `bufferoffset`:
- `length`:

Return Value

Implements

IDataRecord.GetChars

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.GetDataTypeName` Method

Gets the name of the source data type.

Syntax: Visual Basic

```
NotOverridable Public Function GetDataTypeName( _
   ByVal i As Integer _
) As String _
_
```

```
  Implements IDataRecord.GetDataTypeName
```

Syntax: C#

```
public string GetDataTypeName(
inti
);
```

Parameters

- `i`:

Return Value

Implements

IDataRecord.GetDataTypeName

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.GetDateTime` Method

Syntax: Visual Basic

```
NotOverridable Public Function GetDateTime( _
   ByVal index As Integer _
) As Date _
_
  Implements IDataRecord.GetDateTime
```

Syntax: C#

```
public DateTime GetDateTime(
intindex
);
```

Implements

IDataRecord.GetDateTime

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.GetDecimal` Method

Syntax: Visual Basic

```
NotOverridable Public Function GetDecimal( _
   ByVal index As Integer _
) As Decimal _
_
  Implements IDataRecord.GetDecimal
```

Syntax: C#

```
public decimal GetDecimal(
intindex
);
```

Implements

IDataRecord.GetDecimal

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.GetDouble` Method

Syntax: Visual Basic

```
NotOverridable Public Function GetDouble( _
   ByVal index As Integer _
) As Double _
_
  Implements IDataRecord.GetDouble
```

Syntax: C#

```
public double GetDouble(
intindex
);
```

Implements

IDataRecord.GetDouble

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.GetFieldType` Method

Gets the Type that is the data type of the object.

Syntax: Visual Basic

```
NotOverridable Public Function GetFieldType( _
   ByVal i As Integer _
) As Type _
_
  Implements IDataRecord.GetFieldType
```

Syntax: C#

```
public Type GetFieldType(
inti
);
```

Parameters

- `i`:

Return Value

Implements

IDataRecord.GetFieldType

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.GetFloat` Method

Syntax: Visual Basic

```
NotOverridable Public Function GetFloat( _
   ByVal index As Integer _
) As Single _
_
  Implements IDataRecord.GetFloat
```

Syntax: C#

```
public float GetFloat(
intindex
);
```

Implements

IDataRecord.GetFloat

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.GetGuid` Method

Syntax: Visual Basic

```
NotOverridable Public Function GetGuid( _
   ByVal index As Integer _
) As Guid _
_
  Implements IDataRecord.GetGuid
```

Syntax: C#

```
public Guid GetGuid(
intindex
);
```

Implements

IDataRecord.GetGuid

See Also

`MySqlDataReader.GetInt64` Method

Syntax: Visual Basic

```
NotOverridable Public Function GetInt64( _
   ByVal index As Integer _
) As Long _
_
  Implements IDataRecord.GetInt64
```

Syntax: C#

```
public long GetInt64(
intindex
);
```

Implements

IDataRecord.GetInt64

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.GetMySqlDateTime` Method

Syntax: Visual Basic

```
Public Function GetMySqlDateTime( _
   ByVal index As Integer _
) As MySqlDateTime
```

Syntax: C#

```
public MySqlDateTime GetMySqlDateTime(
intindex
);
```

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.GetName` Method

Gets the name of the specified column.

Syntax: Visual Basic

```
NotOverridable Public Function GetName( _
   ByVal i As Integer _
) As String _
_
  Implements IDataRecord.GetName
```

Syntax: C#

```
public string GetName(
inti
);
```

Parameters

- `i`:

Return Value

Implements

IDataRecord.GetName

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.GetOrdinal` Method

Gets the column ordinal, given the name of the column.

Syntax: Visual Basic

```
NotOverridable Public Function GetOrdinal( _
   ByVal name As String _
) As Integer _
_
  Implements IDataRecord.GetOrdinal
```

Syntax: C#

```
public int GetOrdinal(
stringname
);
```

Parameters

- `name`:

Return Value

Implements

IDataRecord.GetOrdinal

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.GetSchemaTable` Method

Returns a DataTable that describes the column metadata of the MySqlDataReader.

Syntax: Visual Basic

```
NotOverridable Public Function GetSchemaTable() As DataTable _
_
```

```
  Implements IDataReader.GetSchemaTable
```

Syntax: C#

```
public DataTable GetSchemaTable();
```

Return Value

Implements

IDataReader.GetSchemaTable

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.GetString` Method

Syntax: Visual Basic

```
NotOverridable Public Function GetString( _
   ByVal index As Integer _
) As String _
_
  Implements IDataRecord.GetString
```

Syntax: C#

```
public string GetString(
intindex
);
```

Implements

IDataRecord.GetString

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.GetTimeSpan` Method

Syntax: Visual Basic

```
Public Function GetTimeSpan( _
   ByVal index As Integer _
) As TimeSpan
```

Syntax: C#

```
public TimeSpan GetTimeSpan(
intindex
);
```

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.GetUInt16` Method

Syntax: Visual Basic

```
Public Function GetUInt16( _
   ByVal index As Integer _
) As UInt16
```

Syntax: C#

```
public ushort GetUInt16(
intindex
);
```

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.GetUInt32` Method

Syntax: Visual Basic

```
Public Function GetUInt32( _
   ByVal index As Integer _
) As UInt32
```

Syntax: C#

```
public uint GetUInt32(
intindex
);
```

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.GetUInt64` Method

Syntax: Visual Basic

```
Public Function GetUInt64( _
   ByVal index As Integer _
) As UInt64
```

Syntax: C#

```
public ulong GetUInt64(
intindex
);
```

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.GetValue` Method

Gets the value of the specified column in its native format.

Syntax: Visual Basic

```
NotOverridable Public Function GetValue( _
   ByVal i As Integer _
) As Object _
_
  Implements IDataRecord.GetValue
```

Syntax: C#

```
public object GetValue(
inti
);
```

Parameters

- `i`:

Return Value

Implements

IDataRecord.GetValue

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.GetValues` Method

Gets all attribute columns in the collection for the current row.

Syntax: Visual Basic

```
NotOverridable Public Function GetValues( _
   ByVal values As Object() _
) As Integer _
_
  Implements IDataRecord.GetValues
```

Syntax: C#

```
public int GetValues(
object[]values
);
```

Parameters

- `values`:

Return Value

Implements

IDataRecord.GetValues

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.IsDBNull` Method

Gets a value indicating whether the column contains non-existent or missing values.

Syntax: Visual Basic

```
NotOverridable Public Function IsDBNull( _
   ByVal i As Integer _
) As Boolean _
_
  Implements IDataRecord.IsDBNull
```

Syntax: C#

```
public bool IsDBNull(
inti
);
```

Parameters

- `i`:

Return Value

Implements

IDataRecord.IsDBNull

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.NextResult` Method

Advances the data reader to the next result, when reading the results of batch SQL statements.

Syntax: Visual Basic

```
NotOverridable Public Function NextResult() As Boolean _
_
  Implements IDataReader.NextResult
```

Syntax: C#

```
public bool NextResult();
```

Return Value

Implements

IDataReader.NextResult

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlDataReader.Read` Method

Advances the MySqlDataReader to the next record.

Syntax: Visual Basic

```
NotOverridable Public Function Read() As Boolean _
_
  Implements IDataReader.Read
```

Syntax: C#

```
public bool Read();
```

Return Value

Implements

IDataReader.Read

See Also

MySqlDataReader Class, MySql.Data.MySqlClient Namespace

`MySqlCommand.ExecuteReader` Method

Syntax: Visual Basic

```
Overloads Public Function ExecuteReader( _
   ByVal behavior As CommandBehavior _
) As MySqlDataReader
```

Syntax: C#

```
public MySqlDataReader ExecuteReader(
CommandBehaviorbehavior
```

```
);
```

```

Syntax: C#

```
public sealed class MySqlCommandBuilder : Component
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: MySql.Data.MySqlClient

Assembly: MySql.Data (in MySql.Data.dll)

See Also

MySqlCommandBuilder Members, MySql.Data.MySqlClient Namespace

`MySqlCommandBuilder` Members

MySqlCommandBuilder overview

Public Static (Shared) Methods

DeriveParameters	Overloaded. Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySql.

Public Instance Constructors

MySqlCommandBuilder	Overloaded. Initializes a new instance of the MySqlCommandBuilder class.

Public Instance Properties

Container (inherited from Component)	Gets the IContainer that contains the Component.
DataAdapter	
QuotePrefix	
QuoteSuffix	
Site (inherited from Component)	Gets or sets the ISite of the Component.

Public Instance Methods

CreateObjRef (inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
Dispose (inherited from Component)	Releases all resources used by the Component.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetDeleteCommand	
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetInsertCommand	
GetLifetimeService (inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
GetUpdateCommand	
InitializeLifetimeService (inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.

RefreshSchema	
ToString (inherited from Component)	Returns a String containing the name of the Component, if any. This method should not be overridden.

Public Instance Events

Disposed (inherited from Component)	Adds an event handler to listen to the Disposed event on the component.

See Also

MySqlCommandBuilder Class, MySql.Data.MySqlClient Namespace

DeriveParameters Method

Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySql.

Overload List

Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySql.

- public static void DeriveParameters(MySqlCommand);
- public static void DeriveParameters(MySqlCommand,bool);

See Also

MySqlCommandBuilder Class, MySql.Data.MySqlClient Namespace

`MySqlCommandBuilder.DeriveParameters` Method

Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySql.

Syntax: Visual Basic

```
Overloads Public Shared Sub DeriveParameters( _
   ByVal command As MySqlCommand _
)
```

Syntax: C#

```
public static void DeriveParameters(
MySqlCommandcommand
);
```

Parameters

- `command`: The MySqlCommand referencing the stored procedure from which the parameter information is to be derived. The derived parameters are added to the Parameters collection of the MySqlCommand.

Exceptions

Exception Type	Condition

InvalidOperationException	The command text is not a valid stored procedure name.

`MySqlDataAdapter` Class

For a list of all members of this type, see MySqlDataAdapter Members .

Syntax: Visual Basic

```
NotInheritable Public Class MySqlDataAdapter_
  Inherits DbDataAdapter
```

Syntax: C#

```
public sealed class MySqlDataAdapter : DbDataAdapter
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: MySql.Data.MySqlClient

Assembly: MySql.Data (in MySql.Data.dll)

See Also

MySqlDataAdapter Members, MySql.Data.MySqlClient Namespace

`MySqlDataAdapter` Members

MySqlDataAdapter overview

Public Instance Constructors

MySqlDataAdapter	Overloaded. Initializes a new instance of the MySqlDataAdapter class.

Public Instance Properties

AcceptChangesDuringFill (inherited from DataAdapter)	Gets or sets a value indicating whether AcceptChangesis called on a DataRowafter it is added to the DataTableduring any of the Fill operations.

AcceptChangesDuringUpdate (inherited from DataAdapter)	Gets or sets whether AcceptChangesis called during a Update.
Container (inherited from Component)	Gets the IContainer that contains the Component.
ContinueUpdateOnError (inherited from DataAdapter)	Gets or sets a value that specifies whether to generate an exception when an error is encountered during a row update.
DeleteCommand	Overloaded.
FillLoadOption (inherited from DataAdapter)	Gets or sets the LoadOption that determines how the adapter fills the DataTablefrom the DbDataReader.
InsertCommand	Overloaded.
MissingMappingAction (inherited from DataAdapter)	Determines the action to take when incoming data does not have a matching table or column.
MissingSchemaAction (inherited from DataAdapter)	Determines the action to take when existing DataSetschema does not match incoming data.
ReturnProviderSpecificTypes (inherited from DataAdapter)	Gets or sets whether the Fillmethod should return provider-specific values or common CLS-compliant values.
SelectCommand	Overloaded.
Site (inherited from Component)	Gets or sets the ISite of the Component.
TableMappings (inherited from DataAdapter)	Gets a collection that provides the master mapping between a source table and a DataTable.
UpdateBatchSize (inherited from DbDataAdapter)	Gets or sets a value that enables or disables batch processing support, and specifies the number of commands that can be executed in a batch.
UpdateCommand	Overloaded.

Public Instance Methods

CreateObjRef (inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
Dispose (inherited from Component)	Releases all resources used by the Component.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
Fill (inherited from DbDataAdapter)	Overloaded. Adds or refreshes rows in the DataSetto match those in the data source using the DataSetname, and creates a DataTablenamed "Table."
FillSchema (inherited from DbDataAdapter)	Overloaded. Configures the schema of the specified DataTablebased on the specified SchemaType.
GetFillParameters (inherited from DbDataAdapter)	Gets the parameters set by the user when executing an SQL `SELECT` statement.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetLifetimeService (inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.

GetType (inherited from Object)	Gets the Type of the current instance.
InitializeLifetimeService (inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
ResetFillLoadOption (inherited from DataAdapter)	Resets FillLoadOptionto its default state and causes Fillto honor AcceptChangesDuringFill.
ShouldSerializeAcceptChangesDuringFill (inherited from DataAdapter)	Determines whether the AcceptChangesDuringFillproperty should be persisted.
ShouldSerializeFillLoadOption (inherited from DataAdapter)	Determines whether the FillLoadOptionproperty should be persisted.
ToString (inherited from Component)	Returns a String containing the name of the Component, if any. This method should not be overridden.
Update (inherited from DbDataAdapter)	Overloaded. Calls the respective INSERT, UPDATE, or DELETE statements for each inserted, updated, or deleted row in the specified DataSet.

Public Instance Events

Disposed (inherited from Component)	Adds an event handler to listen to the Disposed event on the component.
FillError (inherited from DataAdapter)	Returned when an error occurs during a fill operation.
RowUpdated	Occurs during Update after a command is executed against the data source. The attempt to update is made, so the event fires.
RowUpdating	Occurs during Update before a command is executed against the data source. The attempt to update is made, so the event fires.

Protected Internal Instance Properties

FillCommandBehavior (inherited from DbDataAdapter)	Gets or sets the behavior of the command used to fill the data adapter.

`MySqlDataAdapter.RowUpdated` Event

Occurs during Update after a command is executed against the data source. The attempt to update is made, so the event fires.

Syntax: Visual Basic

```
Public Event RowUpdated As MySqlRowUpdatedEventHandler
```

Syntax: C#

```
public event MySqlRowUpdatedEventHandler RowUpdated;
```

Event Data

The event handler receives an argument of type MySqlRowUpdatedEventArgs containing data related to this event. The following MySqlRowUpdatedEventArgsproperties provide information specific to this event.

Property	Description
Command	Gets or sets the MySqlCommand executed when Update is called.
Errors	Gets any errors generated by the .NET Framework data provider when the Commandwas executed.
RecordsAffected	Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.
Row	Gets the DataRowsent through an Update.
RowCount	Gets the number of rows processed in a batch of updated records.
StatementType	Gets the type of SQL statement executed.
Status	Gets the UpdateStatus of the Commandproperty.
TableMapping	Gets the DataTableMappingsent through an Update.

`MySqlRowUpdatedEventArgs` Members

MySqlRowUpdatedEventArgs overview

Public Instance Constructors

MySqlRowUpdatedEventArgs Constructor	Initializes a new instance of the MySqlRowUpdatedEventArgs class.

Public Instance Properties

Command	Overloaded. Gets or sets the MySqlCommand executed when Update is called.
Errors (inherited from RowUpdatedEventArgs)	Gets any errors generated by the .NET Framework data provider when the Commandwas executed.
RecordsAffected (inherited from RowUpdatedEventArgs)	Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.
Row (inherited from RowUpdatedEventArgs)	Gets the DataRowsent through an Update.

RowCount (inherited from RowUpdatedEventArgs)	Gets the number of rows processed in a batch of updated records.
StatementType (inherited from RowUpdatedEventArgs)	Gets the type of SQL statement executed.
Status (inherited from RowUpdatedEventArgs)	Gets the UpdateStatus of the Commandproperty.
TableMapping (inherited from RowUpdatedEventArgs)	Gets the DataTableMappingsent through an Update.

Public Instance Methods

CopyToRows (inherited from RowUpdatedEventArgs)	Overloaded. Copies references to the modified rows into the provided array.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

See Also

MySqlRowUpdatedEventArgs Class, MySql.Data.MySqlClient Namespace

`MySqlRowUpdatedEventArgs` Constructor

Initializes a new instance of the MySqlRowUpdatedEventArgs class.

Syntax: Visual Basic

```
Public Sub New( _
   ByVal row As DataRow, _
   ByVal command As IDbCommand, _
   ByVal statementType As StatementType, _
   ByVal tableMapping As DataTableMapping _
)
```

Syntax: C#

```
public MySqlRowUpdatedEventArgs(
DataRowrow,
IDbCommandcommand,
StatementTypestatementType,
DataTableMappingtableMapping
);
```

Parameters

- `row`: The DataRowsent through an Update.
- `command`: The IDbCommand executed when Update is called.
- `statementType`: One of the StatementTypevalues that specifies the type of query executed.
- `tableMapping`: The DataTableMapping sent through an Update.

See Also

MySqlRowUpdatedEventArgs Class, MySql.Data.MySqlClient Namespace

Command Property

Gets or sets the MySqlCommand executed when Update is called.

Syntax: Visual Basic

```
Overloads Public ReadOnly Property Command As MySqlCommand
```

Syntax: C#

```
new public MySqlCommand Command {get;}
```

See Also

MySqlRowUpdatedEventArgs Class, MySql.Data.MySqlClient Namespace

`MySqlDataAdapter.RowUpdating` Event

Occurs during Update before a command is executed against the data source. The attempt to update is made, so the event fires.

Syntax: Visual Basic

```
Public Event RowUpdating As MySqlRowUpdatingEventHandler
```

Syntax: C#

```
public event MySqlRowUpdatingEventHandler RowUpdating;
```

Event Data

The event handler receives an argument of type MySqlRowUpdatingEventArgs containing data related to this event. The following MySqlRowUpdatingEventArgsproperties provide information specific to this event.

Property	Description
Command	Gets or sets the MySqlCommand to execute when performing the Update.
Errors	Gets any errors generated by the .NET Framework data provider when the Command executes.
Row	Gets the DataRow that will be sent to the server as part of an insert, update, or delete operation.
StatementType	Gets the type of SQL statement to execute.
Status	Gets or sets the UpdateStatus of the Commandproperty.
TableMapping	Gets the DataTableMapping to send through the Update.

MySqlDataAdapter Class, MySql.Data.MySqlClient Namespace

`MySqlRowUpdatingEventHandler` Delegate

Represents the method that will handle the RowUpdatingevent of a MySqlDataAdapter.

Syntax: Visual Basic

```
Public Delegate Sub MySqlRowUpdatingEventHandler( _
```

```
   ByVal sender As Object, _
   ByVal e As MySqlRowUpdatingEventArgs _
)
```

Syntax: C#

```
public delegate void MySqlRowUpdatingEventHandler(
objectsender,
MySqlRowUpdatingEventArgs
);
```

Requirements

Namespace: MySql.Data.MySqlClient

Assembly: MySql.Data (in MySql.Data.dll)

See Also

MySql.Data.MySqlClient Namespace

`MySqlRowUpdatingEventArgs` Class

Provides data for the RowUpdating event. This class cannot be inherited.

For a list of all members of this type, see MySqlRowUpdatingEventArgs Members .

Syntax: Visual Basic

```
NotInheritable Public Class MySqlRowUpdatingEventArgs_
  Inherits RowUpdatingEventArgs
```

Syntax: C#

```
public sealed class MySqlRowUpdatingEventArgs : RowUpdatingEventArgs
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: MySql.Data.MySqlClient

Assembly: MySql.Data (in MySql.Data.dll)

See Also

MySqlRowUpdatingEventArgs Members, MySql.Data.MySqlClient Namespace

`MySqlRowUpdatingEventArgs` Members

MySqlRowUpdatingEventArgs overview

Public Instance Constructors

MySqlRowUpdatingEventArgs Constructor	Initializes a new instance of the MySqlRowUpdatingEventArgs class.

Public Instance Properties

Command	Overloaded. Gets or sets the MySqlCommand to execute when performing the Update.

Errors (inherited from RowUpdatingEventArgs)	Gets any errors generated by the .NET Framework data provider when the Command executes.
Row (inherited from RowUpdatingEventArgs)	Gets the DataRow that will be sent to the server as part of an insert, update, or delete operation.
StatementType (inherited from RowUpdatingEventArgs)	Gets the type of SQL statement to execute.
Status (inherited from RowUpdatingEventArgs)	Gets or sets the UpdateStatus of the Commandproperty.
TableMapping (inherited from RowUpdatingEventArgs)	Gets the DataTableMapping to send through the Update.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

MySqlRowUpdatingEventArgs Class, MySql.Data.MySqlClient Namespace

`MySqlRowUpdatingEventArgs` Constructor

Initializes a new instance of the MySqlRowUpdatingEventArgs class.

Syntax: Visual Basic

```
Public Sub New( _
   ByVal row As DataRow, _
   ByVal command As IDbCommand, _
   ByVal statementType As StatementType, _
   ByVal tableMapping As DataTableMapping _
)
```

Syntax: C#

```
public MySqlRowUpdatingEventArgs(
DataRowrow,
IDbCommandcommand,
StatementTypestatementType,
DataTableMappingtableMapping
);
```

Parameters

- `row`: The DataRowto Update.
- `command`: The IDbCommandto execute during Update.
- `statementType`: One of the StatementTypevalues that specifies the type of query executed.
- `tableMapping`: The DataTableMappingsent through an Update.

Command Property

Gets or sets the MySqlCommand to execute when performing the Update.

Syntax: Visual Basic

```
Overloads Public Property Command As MySqlCommand
```

Syntax: C#

```
new public MySqlCommand Command {get; set;}
```

`MySqlException` Class

The exception that is thrown when MySQL returns an error. This class cannot be inherited.

For a list of all members of this type, see MySqlException Members .

Syntax: Visual Basic

```
NotInheritable Public Class MySqlException_
  Inherits SystemException
```

Syntax: C#

```
public sealed class MySqlException : SystemException
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: MySql.Data.MySqlClient

Assembly: MySql.Data (in MySql.Data.dll)

See Also

MySqlException Members, MySql.Data.MySqlClient Namespace

`MySqlException` Members

MySqlException overview

Public Instance Properties

Data (inherited from Exception)	Gets a collection of key/value pairs that provide additional, user-defined information about the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.

InnerException (inherited from Exception)	Gets the `Exception`instance that caused the current exception.
Message (inherited from Exception)	Gets a message that describes the current exception.
Number	Gets a number that identifies the type of error. This number corresponds to the error numbers given in Server Error Codes and Messages.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Exception)	Gets the runtime type of the current instance.
ToString (inherited from Exception)	Creates and returns a string representation of the current exception.

MySqlException Class, MySql.Data.MySqlClient Namespace

Number Property

Gets a number that identifies the type of error.

Syntax: Visual Basic

```
Public ReadOnly Property Number As Integer
```

Syntax: C#

```
public int Number {get;}
```

See Also

MySqlException Class, MySql.Data.MySqlClient Namespace

`MySqlHelper` Class

Helper class that makes it easier to work with the provider.

For a list of all members of this type, see MySqlHelper Members .

Syntax: Visual Basic

```
NotInheritable Public Class MySqlHelper
```

Syntax: C#

```
public sealed class MySqlHelper
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: MySql.Data.MySqlClient

Assembly: MySql.Data (in MySql.Data.dll)

See Also

MySqlHelper Members, MySql.Data.MySqlClient Namespace

`MySqlHelper` Members

MySqlHelper overview

Public Static (Shared) Methods

ExecuteDataRow	Executes a single SQL statement and returns the first row of the resultset. A new MySqlConnection object is created, opened, and closed during this method.
ExecuteDataset	Overloaded. Executes a single SQL statement and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.
ExecuteNonQuery	Overloaded. Executes a single command against a MySQL database. The MySqlConnection is assumed to be open when the method is called and remains open after the method completes.
ExecuteReader	Overloaded. Executes a single command against a MySQL database.
ExecuteScalar	Overloaded. Execute a single command against a MySQL database.
UpdateDataSet	Updates the given table with data from the given DataSet

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

See Also

MySqlHelper Class, MySql.Data.MySqlClient Namespace

`MySqlHelper.ExecuteDataRow` Method

Executes a single SQL statement and returns the first row of the resultset. A new MySqlConnection object is created, opened, and closed during this method.

Syntax: Visual Basic

```
Public Shared Function ExecuteDataRow( _
   ByVal connectionString As String, _
   ByVal commandText As String, _
   ParamArray parms As MySqlParameter() _
) As DataRow
```

Syntax: C#

```
public static DataRow ExecuteDataRow(
stringconnectionString,
stringcommandText,
   params MySqlParameter[]parms
);
```

Parameters

- `connectionString`: Settings to be used for the connection
- `commandText`: Command to execute
- `parms`: Parameters to use for the command

Return Value

DataRow containing the first row of the resultset

See Also

MySqlHelper Class, MySql.Data.MySqlClient Namespace

ExecuteDataset Method

Executes a single SQL statement and returns the resultset in a DataSet. The state of the MySqlConnection object remains unchanged after execution of this method.

Overload List

Executes a single SQL statement and returns the resultset in a DataSet. The state of the MySqlConnection object remains unchanged after execution of this method.

- public static DataSet ExecuteDataset(MySqlConnection,string);

Executes a single SQL statement and returns the resultset in a DataSet. The state of the MySqlConnection object remains unchanged after execution of this method.

- public static DataSet ExecuteDataset(MySqlConnection,string,params MySqlParameter[]);

Executes a single SQL statement and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.

- public static DataSet ExecuteDataset(string,string);

Executes a single SQL statement and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.

- public static DataSet ExecuteDataset(string,string,params MySqlParameter[]);

See Also

MySqlHelper Class, MySql.Data.MySqlClient Namespace

`MySqlHelper.ExecuteDataset` Method

Executes a single SQL statement and returns the resultset in a DataSet. The state of the MySqlConnection object remains unchanged after execution of this method.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteDataset( _
   ByVal connection As MySqlConnection, _
   ByVal commandText As String _
) As DataSet
```

Syntax: C#

```
public static DataSet ExecuteDataset(
MySqlConnectionconnection,
stringcommandText
);
```

Parameters

- `connection`: MySqlConnection object to use
- `commandText`: Command to execute

Return Value

DataSetcontaining the resultset

See Also

MySqlHelper Class, MySql.Data.MySqlClient Namespace, MySqlHelper.ExecuteDataset Overload List

`MySqlHelper.ExecuteDataset` Method

Executes a single SQL statement and returns the resultset in a DataSet. The state of the MySqlConnection object remains unchanged after execution of this method.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteDataset( _
   ByVal connection As MySqlConnection, _
   ByVal commandText As String, _
   ParamArray commandParameters As MySqlParameter() _
) As DataSet
```

Syntax: C#

```
public static DataSet ExecuteDataset(
MySqlConnectionconnection,
stringcommandText,
   params MySqlParameter[]commandParameters
);
```

Parameters

- `connection`: MySqlConnection object to use
- `commandText`: Command to execute

- `commandParameters`: Parameters to use for the command

Return Value

DataSetcontaining the resultset

See Also

MySqlHelper Class, MySql.Data.MySqlClient Namespace, MySqlHelper.ExecuteDataset Overload List

`MySqlHelper.ExecuteDataset` Method

Executes a single SQL statement and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteDataset( _
   ByVal connectionString As String, _
   ByVal commandText As String _
) As DataSet
```

Syntax: C#

```
public static DataSet ExecuteDataset(
stringconnectionString,
stringcommandText
);
```

Parameters

- `connectionString`: Settings to be used for the connection
- `commandText`: Command to execute

Return Value

DataSetcontaining the resultset

See Also

MySqlHelper Class, MySql.Data.MySqlClient Namespace, MySqlHelper.ExecuteDataset Overload List

`MySqlHelper.ExecuteDataset` Method

Executes a single SQL statement and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteDataset( _
   ByVal connectionString As String, _
   ByVal commandText As String, _
   ParamArray commandParameters As MySqlParameter() _
) As DataSet
```

Syntax: C#

```
public static DataSet ExecuteDataset(
stringconnectionString,
stringcommandText,
   params MySqlParameter[]commandParameters
);
```

Parameters

- `connectionString`: Settings to be used for the connection
- `commandText`: Command to execute
- `commandParameters`: Parameters to use for the command

Return Value

DataSetcontaining the resultset

See Also

MySqlHelper Class, MySql.Data.MySqlClient Namespace, MySqlHelper.ExecuteDataset Overload List

ExecuteNonQuery Method

Executes a single command against a MySQL database. The MySqlConnection is assumed to be open when the method is called and remains open after the method completes.

Overload List

Executes a single command against a MySQL database. The MySqlConnection is assumed to be open when the method is called and remains open after the method completes.

- public static int ExecuteNonQuery(MySqlConnection,string,params MySqlParameter[]);

Executes a single command against a MySQL database. A new MySqlConnection is created using the ConnectionString given.

- public static int ExecuteNonQuery(string,string,params MySqlParameter[]);

See Also

MySqlHelper Class, MySql.Data.MySqlClient Namespace

`MySqlHelper.ExecuteNonQuery` Method

Executes a single command against a MySQL database. The MySqlConnection is assumed to be open when the method is called and remains open after the method completes.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteNonQuery( _
   ByVal connection As MySqlConnection, _
   ByVal commandText As String, _
   ParamArray commandParameters As MySqlParameter() _
) As Integer
```

Syntax: C#

```
public static int ExecuteNonQuery(
MySqlConnectionconnection,
stringcommandText,
   params MySqlParameter[]commandParameters
);
```

Parameters

- `connection`: MySqlConnection object to use
- `commandText`: SQL statement to be executed
- `commandParameters`: Array of MySqlParameter objects to use with the command.

Return Value

See Also

MySqlHelper Class, MySql.Data.MySqlClient Namespace, MySqlHelper.ExecuteNonQuery Overload List

`MySqlHelper.ExecuteNonQuery` Method

Executes a single command against a MySQL database. A new MySqlConnection is created using the ConnectionString given.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteNonQuery( _
   ByVal connectionString As String, _
   ByVal commandText As String, _
   ParamArray parms As MySqlParameter() _
) As Integer
```

Syntax: C#

```
public static int ExecuteNonQuery(
stringconnectionString,
stringcommandText,
   params MySqlParameter[]parms
);
```

Parameters

- `connectionString`: ConnectionString to use
- `commandText`: SQL statement to be executed
- `parms`: Array of MySqlParameter objects to use with the command.

Return Value

See Also

MySqlHelper Class, MySql.Data.MySqlClient Namespace, MySqlHelper.ExecuteNonQuery Overload List

ExecuteReader Method

Executes a single command against a MySQL database.

Overload List

Executes a single command against a MySQL database.

- public static MySqlDataReader ExecuteReader(string,string);

Executes a single command against a MySQL database.

- public static MySqlDataReader ExecuteReader(string,string,params MySqlParameter[]);

See Also

MySqlHelper Class, MySql.Data.MySqlClient Namespace

`MySqlHelper.ExecuteReader` Method

Executes a single command against a MySQL database.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteReader( _
   ByVal connectionString As String, _
   ByVal commandText As String _
) As MySqlDataReader
```

Syntax: C#

```
public static MySqlDataReader ExecuteReader(
stringconnectionString,
stringcommandText
);
```

Parameters

- `connectionString`: Settings to use for this command
- `commandText`: Command text to use

Return Value

MySqlDataReader object ready to read the results of the command

See Also

MySqlHelper Class, MySql.Data.MySqlClient Namespace, MySqlHelper.ExecuteReader Overload List

`MySqlHelper.ExecuteReader` Method

Executes a single command against a MySQL database.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteReader( _
   ByVal connectionString As String, _
   ByVal commandText As String, _
   ParamArray commandParameters As MySqlParameter() _
) As MySqlDataReader
```

Syntax: C#

```
public static MySqlDataReader ExecuteReader(
stringconnectionString,
stringcommandText,
   params MySqlParameter[]commandParameters
);
```

Parameters

- `connectionString`: Settings to use for this command
- `commandText`: Command text to use
- `commandParameters`: Array of MySqlParameter objects to use with the command

Return Value

MySqlDataReader object ready to read the results of the command

See Also

MySqlHelper Class, MySql.Data.MySqlClient Namespace, MySqlHelper.ExecuteReader Overload List

ExecuteScalar Method

Execute a single command against a MySQL database.

Overload List

Execute a single command against a MySQL database.

- public static object ExecuteScalar(MySqlConnection,string);

Execute a single command against a MySQL database.

- public static object ExecuteScalar(MySqlConnection,string,params MySqlParameter[]);

Execute a single command against a MySQL database.

- public static object ExecuteScalar(string,string);

Execute a single command against a MySQL database.

- public static object ExecuteScalar(string,string,params MySqlParameter[]);

See Also

MySqlHelper Class, MySql.Data.MySqlClient Namespace

`MySqlHelper.ExecuteScalar` Method

Execute a single command against a MySQL database.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteScalar( _
   ByVal connection As MySqlConnection, _
   ByVal commandText As String _
) As Object
```

Syntax: C#

```
public static object ExecuteScalar(
MySqlConnectionconnection,
stringcommandText
);
```

Parameters

- `connection`: MySqlConnection object to use
- `commandText`: Command text to use for the command

Return Value

The first column of the first row in the result set, or a null reference if the result set is empty.

See Also

MySqlHelper Class, MySql.Data.MySqlClient Namespace, MySqlHelper.ExecuteScalar Overload List

`MySqlHelper.ExecuteScalar` Method

Execute a single command against a MySQL database.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteScalar( _
   ByVal connection As MySqlConnection, _
   ByVal commandText As String, _
   ParamArray commandParameters As MySqlParameter() _
) As Object
```

Syntax: C#

```
public static object ExecuteScalar(
MySqlConnectionconnection,
stringcommandText,
   params MySqlParameter[]commandParameters
);
```

Parameters

- `connection`: MySqlConnection object to use
- `commandText`: Command text to use for the command
- `commandParameters`: Parameters to use for the command

Return Value

The first column of the first row in the result set, or a null reference if the result set is empty.

See Also

MySqlHelper Class, MySql.Data.MySqlClient Namespace, MySqlHelper.ExecuteScalar Overload List

`MySqlHelper.ExecuteScalar` Method

Execute a single command against a MySQL database.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteScalar( _
   ByVal connectionString As String, _
   ByVal commandText As String _
) As Object
```

Syntax: C#

```
public static object ExecuteScalar(
stringconnectionString,
stringcommandText
);
```

Parameters

- `connectionString`: Settings to use for the update
- `commandText`: Command text to use for the update

Return Value

The first column of the first row in the result set, or a null reference if the result set is empty.

See Also

MySqlHelper Class, MySql.Data.MySqlClient Namespace, MySqlHelper.ExecuteScalar Overload List

`MySqlHelper.ExecuteScalar` Method

Execute a single command against a MySQL database.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteScalar( _
   ByVal connectionString As String, _
   ByVal commandText As String, _
```

```
   ParamArray commandParameters As MySqlParameter() _
) As Object
```

Syntax: C#

```
public static object ExecuteScalar(
stringconnectionString,
stringcommandText,
   params MySqlParameter[]commandParameters
);
```

Parameters

- `connectionString`: Settings to use for the command
- `commandText`: Command text to use for the command
- `commandParameters`: Parameters to use for the command

Return Value

The first column of the first row in the result set, or a null reference if the result set is empty.

See Also

MySqlHelper Class, MySql.Data.MySqlClient Namespace, MySqlHelper.ExecuteScalar Overload List

`MySqlHelper.UpdateDataSet` Method

Updates the given table with data from the given DataSet

Syntax: Visual Basic

```
Public Shared Sub UpdateDataSet( _
   ByVal connectionString As String, _
   ByVal commandText As String, _
   ByVal ds As DataSet, _
   ByVal tablename As String _
)
```

Syntax: C#

```
public static void UpdateDataSet(
stringconnectionString,
stringcommandText,
DataSetds,
stringtablename
);
```

Parameters

- `connectionString`: Settings to use for the update
- `commandText`: Command text to use for the update
- `ds`: DataSetcontaining the new data to use in the update
- `tablename`: Tablename in the data set to update

MySqlConversionException overview

Public Instance Constructors

MySqlConversionException Constructor	Ctor

Public Instance Properties

Data (inherited from Exception)	Gets a collection of key/value pairs that provide additional, user-defined information about the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the `Exceptioninstance` that caused the current exception.
Message (inherited from Exception)	Gets a message that describes the current exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.

GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Exception)	Gets the runtime type of the current instance.
ToString (inherited from Exception)	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets `HRESULT`, a coded numeric value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

`MySqlDateTime` Members

MySqlDateTime overview

Public Static (Shared) Type Conversions

Explicit MySqlDateTime to DateTime Conversion	

Public Instance Properties

Day	Returns the day portion of this datetime
Hour	Returns the hour portion of this datetime
IsNull (inherited from MySqlValue)	
IsValidDateTime	Indicates if this object contains a value that can be represented as a DateTime
Minute	Returns the minute portion of this datetime
Month	Returns the month portion of this datetime
Second	Returns the second portion of this datetime
Millisecond	Returns the millisecond portion of this datetime
ValueAsObject (inherited from MySqlValue)	Returns the value of this field as an object
Year	Returns the year portion of this datetime

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetDateTime	Returns this value as a DateTime
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Returns a MySQL-specific string representation of this value

Protected Instance Fields

classType (inherited from MySqlValue)	The system type represented by this value
dbType (inherited from MySqlValue)	The generic dbtype of this value
isNull (inherited from MySqlValue)	Is this value null
mySqlDbType (inherited from MySqlValue)	The specific MySQL db type
mySqlTypeName (inherited from MySqlValue)	The MySQL-specific typename of this value

objectValue (inherited from MySqlValue)	

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

numberFormat	

Public Instance Constructors

MySqlValue Constructor	Initializes a new instance of the MySqlValue class.

Public Instance Properties

IsNull	
ValueAsObject	Returns the value of this field as an object

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Returns a string representation of this value

Protected Instance Fields

classType	The system type represented by this value
dbType	The generic dbtype of this value
isNull	Is this value null
mySqlDbType	The specific MySQL db type
mySqlTypeName	The MySQL-specific typename of this value
objectValue	

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

Connector/Net Support

The developers of Connector/Net greatly value the input of our users in the software development process. If you find Connector/Net lacking some feature important to you, or if you discover a bug and need to file a bug report, please use the instructions in How to Report Bugs or Problems.

Connector/Net Community Support

- Community support for Connector/Net can be found through the forums at http://forums.mysql.com.
- Community support for Connector/Net can also be found through the mailing lists at http://lists.mysql.com.
- Paid support is available from Oracle. Additional information is available at http://dev.mysql.com/support/.

How to Report Connector/Net Problems or Bugs

If you encounter difficulties or problems with Connector/Net, contact the Connector/Net community, as explained in Connector/Net Community Support.

First try to execute the same SQL statements and commands from the `mysql` client program or from `admndemo`. This helps you determine whether the error is in Connector/Net or MySQL.

If reporting a problem, ideally include the following information with the email:

- Operating system and version.
- Connector/Net version.
- MySQL server version.
- Copies of error messages or other unexpected output.
- Simple reproducible sample.

Remember that the more information you can supply to us, the more likely it is that we can fix the problem.

If you believe the problem to be a bug, then you must report the bug through http://bugs.mysql.com/.

Connector/Net Change History

The Connector/Net Change History (Changelog) is located with the main Changelog for MySQL. See MySQL Connector/Net Change History.

Connector/Net FAQ

Questions

- 22.2.9.1: [2980] How do I obtain the value of an auto-incremented column?

Questions and Answers

22.2.9.1: How do I obtain the value of an auto-incremented column?

When using `CommandBuilder`, setting `ReturnGeneratedIdentifiers` property to `true` no longer works, as `CommandBuilder` does not add `last_insert_id()` by default.

CommandBuilder hooks up to the `DataAdapter.RowUpdating` event handler, which means it will get called for every row. It examines the command object and, if it is the same referenced object, it essentially rebuilds the object, thereby destroying your command text changes.

One approach to solving this problem is to clone the command object so you have a different actual reference:

```
dataAdapter.InsertCommand = cb.GetInsertCommand().Clone()
```

This will work, but since the CommandBuilder is still connected to the DataAdapter, the RowUpdating event will still fire and performance will be hit. To stop that, once all your commands have been added you need to disconnect the CommandBuilder from the DataAdapter:

```
cb.DataAdapter = null;
```

The last requirement is to make sure the `id` that is returned by `last_insert_id()` has the correct name. For example:

```
SELECT last_insert_id() AS id
```

A complete working example is shown here:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
```

```
using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;

namespace GetAutoIncId
{
    class Program
    {
        static void Main(string[] args)
        {
            string connStr = "server=localhost;user=root;database=TestDB;port=3306;password=******;";
            MySqlConnection conn = new MySqlConnection(connStr);

            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();

                string sql = "SELECT * FROM TestTable";

                MySqlDataAdapter da = new MySqlDataAdapter(sql, conn);
                MySqlCommandBuilder cb = new MySqlCommandBuilder(da);

                MySqlCommand cmd = new MySqlCommand();
                cmd.Connection = conn;
                cmd.CommandText = sql;
                // use Cloned object to avoid .NET rebuilding the object, and
                // thereby throwing away our command text additions.
                MySqlCommand insertCmd = cb.GetInsertCommand().Clone();
                insertCmd.CommandText = insertCmd.CommandText + ";SELECT last_insert_id() AS id";
                insertCmd.UpdatedRowSource = UpdateRowSource.FirstReturnedRecord;
                da.InsertCommand = insertCmd;
                cb.DataAdapter = null; // Unhook RowUpdating event handler

                DataTable dt = new DataTable();
                da.Fill(dt);

                DataRow row = dt.NewRow();
                row["name"] = "Joe Smith";

                dt.Rows.Add(row);
                da.Update(dt);

                System.Console.WriteLine("ID after update: " + row["id"]);
            }
            catch (Exception ex)
            {
                Console.WriteLine(ex.ToString());
            }

            conn.Close();
            Console.WriteLine("Done.");
        }
    }
}
```

MySQL Connector/J

This section explains how to configure and develop Java applications with MySQL Connector/J, the JDBC driver that is integrated with MySQL.

Overview of MySQL Connector/J

MySQL provides connectivity for client applications developed in the Java programming language through a JDBC driver, which is called MySQL Connector/J.

MySQL Connector/J is a JDBC Type 4 driver. Different versions are available that are compatible with the JDBC 3.0 and JDBC 4.0 specifications. The Type 4 designation means that the driver is pure-Java implementation of the MySQL protocol and does not rely on the MySQL client libraries.

For large-scale programs that use common design patterns of data access, consider using one of the popular persistence frameworks such as Hibernate, Spring's JDBC templates or Ibatis SQL Maps to reduce the amount of JDBC code for you to debug, tune, secure, and maintain.

This section is not designed to be a complete JDBC tutorial. If you need more information about using JDBC you might be interested in the following online tutorials that are more in-depth than the information presented here:

- JDBC Basics: A tutorial from Sun covering beginner topics in JDBC
- JDBC Short Course: A more in-depth tutorial from Sun and JGuru

Key Topics

- For help with connection strings, connection options, and setting up your connection through JDBC, see Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J.

Connector/J Versions

There are currently four versions of MySQL Connector/J available:

- Connector/J 5.1 is the Type 4 pure Java JDBC driver, which conforms to the JDBC 3.0 and JDBC 4.0 specifications. It provides compatibility with all the functionality of MySQL, including 4.1, 5.0, 5.1, 5.4 and 5.5. Connector/J 5.1 provides ease of development features, including auto-registration with the Driver Manager, standardized validity checks, categorized SQLExceptions, support for the JDBC-4.0 XML processing, per connection client information, `NCHAR`, `NVARCHAR` and `NCLOB` types. This release also includes all bug fixes up to and including Connector/J 5.0.6.
- Connector/J 5.0 provides support for all the functionality offered by Connector/J 3.1 and includes distributed transaction (XA) support.
- Connector/J 3.1 was designed for connectivity to MySQL 4.1 and MySQL 5.0 servers and provides support for all the functionality in MySQL 5.0 except distributed transaction (XA) support.
- Connector/J 3.0 provides core functionality and was designed for connectivity to MySQL 3.x or MySQL 4.1 servers, although it provides basic compatibility with later versions of MySQL. Connector/J 3.0 does not support server-side prepared statements, and does not support any of the features in versions of MySQL later than 4.1.

The following table summarizes the Connector/J versions available:

Connector/J version	Driver Type	JDBC version	MySQL Server version	Status
5.1	4	3.0, 4.0	4.1, 5.0, 5.1, 5.4, 5.5	Recommended version
5.0	4	3.0	4.1, 5.0	Released version
3.1	4	3.0	4.1, 5.0	Obsolete
3.0	4	3.0	3.x, 4.1	Obsolete

The current recommended version for Connector/J is 5.1. This guide covers all four connector versions, with specific notes given where a setting applies to a specific option.

Java Versions Supported

The following table summarizes Connector/J Java dependencies:

Connector/J version	Java RTE required	JDK required (to build source code)
5.1	1.5.x, 1.6.x	1.6.x and 1.5.x

Connector/J version	Java RTE required	JDK required (to build source code)
5.0	1.3.x, 1.4.x, 1.5.x, 1.6.x	1.4.2, 1.5.x, 1.6.x
3.1	1.2.x, 1.3.x, 1.4.x, 1.5.x, 1.6.x	1.4.2, 1.5.x, 1.6.x
3.0	1.2.x, 1.3.x, 1.4.x, 1.5.x, 1.6.x	1.4.2, 1.5.x, 1.6.x

If you are building Connector/J from source code using the source distribution (see Installing from the Development Source Tree), you must use JDK 1.4.2 or newer to compile the Connector package. For Connector/J 5.1, you must have both JDK-1.6.x and JDK-1.5.x installed to be able to build the source code.

Because of the implementation of `java.sql.Savepoint`, Connector/J 3.1.0 and newer will not run on a Java runtime older than 1.4 unless the class verifier is turned off (by setting the `-Xverify:none` option to the Java runtime). This is because the class verifier will try to load the class definition for `java.sql.Savepoint` even though it is not accessed by the driver unless you actually use savepoint functionality.

Caching functionality provided by Connector/J 3.1.0 or newer is also not available on JVMs older than 1.4.x, as it relies on `java.util.LinkedHashMap` which was first available in JDK-1.4.0.

MySQL Connector/J does not support JDK-1.1.x or JDK-1.0.x.

Connector/J Installation

You can install the Connector/J package using either the binary or source distribution. The binary distribution provides the easiest method for installation; the source distribution lets you customize your installation further. With either solution, you manually add the Connector/J location to your Java `CLASSPATH`.

If you are upgrading from a previous version, read the upgrade information in Upgrading from an Older Version before continuing.

Connector/J is also available as part of the Maven project. For more information, and to download the Connector/J JAR files, see the Maven repository.

Installing Connector/J from a Binary Distribution

For the easiest method of installation, use the binary distribution of the Connector/J package. The binary distribution is available either as a tar/gzip or zip file. Extract it to a suitable location, then optionally make the information about the package available by changing your `CLASSPATH` (see Installing the Driver and Configuring the `CLASSPATH`).

MySQL Connector/J is distributed as a `.zip` or `.tar.gz` archive containing the sources, the class files, and the JAR archive named `mysql-connector-java-`*`version`*`-bin.jar`.

Starting with Connector/J 3.1.9, the `.class` files that constitute the JAR files are only included as part of the driver JAR file.

Starting with Connector/J 3.1.8, the archive also includes a debug build of the driver in a file named `mysql-connector-java-`*`version`*`-bin-g.jar`. Do not use the debug build of the driver unless instructed to do so when reporting a problem or a bug, as it is not designed to be run in production environments, and will have adverse performance impact when used. The debug binary also depends on the Aspect/J runtime library, which is located in the `src/lib/aspectjrt.jar` file that comes with the Connector/J distribution.

Use the appropriate graphical or command-line utility to extract the distribution (for example, WinZip for the .zip archive, and `tar` for the .tar.gz archive). Because there are potentially long file names in the distribution, we use the GNU tar archive format. Use GNU tar (or an application that understands the GNU tar archive format) to unpack the .tar.gz variant of the distribution.

Installing the Driver and Configuring the CLASSPATH

Once you have extracted the distribution archive, you can install the driver by placing `mysql-connector-java-version-bin.jar` in your classpath, either by adding the full path to it to your `CLASSPATH` environment variable, or by directly specifying it with the command line switch `-cp` when starting the JVM.

To use the driver with the JDBC `DriverManager`, use `com.mysql.jdbc.Driver` as the class that implements `java.sql.Driver`.

You can set the `CLASSPATH` environment variable under UNIX, Linux or Mac OS X either locally for a user within their `.profile`, `.login` or other login file. You can also set it globally by editing the global `/etc/profile` file.

For example, add the Connector/J driver to your `CLASSPATH` using one of the following forms, depending on your command shell:

```
# Bourne-compatible shell (sh, ksh, bash, zsh):
shell> export CLASSPATH=/path/mysql-connector-java-ver-bin.jar:$CLASSPATH

# C shell (csh, tcsh):
shell> setenv CLASSPATH /path/mysql-connector-java-ver-bin.jar:$CLASSPATH
```

Within Windows 2000, Windows XP, Windows Server 2003 and Windows Vista, you set the environment variable through the System Control Panel.

To use MySQL Connector/J with an application server such as GlassFish, Tomcat or JBoss, read your vendor's documentation for more information on how to configure third-party class libraries, as most application servers ignore the `CLASSPATH` environment variable. For configuration examples for some J2EE application servers, see Connection Pooling with Connector/J Load Balancing with Connector/J, and Failover with Connector/J. However, the authoritative source for JDBC connection pool configuration information for your particular application server is the documentation for that application server.

If you are developing servlets or JSPs, and your application server is J2EE-compliant, you can put the driver's `.jar` file in the `WEB-INF/lib` subdirectory of your webapp, as this is a standard location for third party class libraries in J2EE web applications.

You can also use the `MysqlDataSource` or `MysqlConnectionPoolDataSource` classes in the `com.mysql.jdbc.jdbc2.optional` package, if your J2EE application server supports or requires them. Starting with Connector/J 5.0.0, the `javax.sql.XADataSource` interface is implemented using the `com.mysql.jdbc.jdbc2.optional.MysqlXADataSource` class, which supports XA distributed transactions when used in combination with MySQL server version 5.0.

The various `MysqlDataSource` classes support the following parameters (through standard set mutators):

- `user`
- `password`
- `serverName` (see the previous section about fail-over hosts)
- `databaseName`
- `port`

Upgrading from an Older Version

This section has information for users who are upgrading from one version of Connector/J to another, or to a new version of the MySQL server that supports a more recent level of JDBC. A newer version of

Connector/J might include changes to support new features, improve existing functionality, or comply with new standards.

Upgrading to MySQL Connector/J 5.1.x

- In Connector/J 5.0.x and earlier, the alias for a table in a `SELECT` statement is returned when accessing the result set metadata using `ResultSetMetaData.getColumnName()`. This behavior however is not JDBC compliant, and in Connector/J 5.1 this behavior was changed so that the original table name, rather than the alias, is returned.

  The JDBC-compliant behavior is designed to let API users reconstruct the DML statement based on the metadata within `ResultSet` and `ResultSetMetaData`.

  You can get the alias for a column in a result set by calling `ResultSetMetaData.getColumnLabel()`. To use the old noncompliant behavior with `ResultSetMetaData.getColumnName()`, use the `useOldAliasMetadataBehavior` option and set the value to `true`.

  In Connector/J 5.0.x, the default value of `useOldAliasMetadataBehavior` was `true`, but in Connector/J 5.1 this was changed to a default value of `false`.

JDBC-Specific Issues When Upgrading to MySQL Server 4.1 or Newer

- *Using the UTF-8 Character Encoding* - Prior to MySQL server version 4.1, the UTF-8 character encoding was not supported by the server, however the JDBC driver could use it, allowing storage of multiple character sets in `latin1` tables on the server.

  Starting with MySQL-4.1, this functionality is deprecated. If you have applications that rely on this functionality, and can not upgrade them to use the official Unicode character support in MySQL server version 4.1 or newer, add the following property to your connection URL:

  ```
  useOldUTF8Behavior=true
  ```

- *Server-side Prepared Statements* - Connector/J 3.1 will automatically detect and use server-side prepared statements when they are available (MySQL server version 4.1.0 and newer). If your application encounters issues with server-side prepared statements, you can revert to the older client-side emulated prepared statement code that is still presently used for MySQL servers older than 4.1.0 with the following connection property:

  ```
  useServerPrepStmts=false
  ```

Upgrading from MySQL Connector/J 3.0 to 3.1

Connector/J 3.1 is designed to be backward-compatible with Connector/J 3.0 as much as possible. Major changes are isolated to new functionality exposed in MySQL-4.1 and newer, which includes Unicode character sets, server-side prepared statements, `SQLState` codes returned in error messages by the server and various performance enhancements that can be enabled or disabled using configuration properties.

- **Unicode Character Sets**: See the next section, as well as Character Set Support, for information on this MySQL feature. If you have something misconfigured, it will usually show up as an error with a message similar to `Illegal mix of collations`.

- **Server-side Prepared Statements**: Connector/J 3.1 will automatically detect and use server-side prepared statements when they are available (MySQL server version 4.1.0 and newer).

  Starting with version 3.1.7, the driver scans SQL you are preparing using all variants of `Connection.prepareStatement()` to determine if it is a supported type of statement to prepare on the server side, and if it is not supported by the server, it instead prepares it as a client-side emulated prepared statement. You can disable this feature by passing `emulateUnsupportedPstmts=false` in your JDBC URL.

If your application encounters issues with server-side prepared statements, you can revert to the older client-side emulated prepared statement code that is still presently used for MySQL servers older than 4.1.0 with the connection property `useServerPrepStmts=false`.

- **Datetimes** with all-zero components (`0000-00-00 ...`): These values cannot be represented reliably in Java. Connector/J 3.0.x always converted them to `NULL` when being read from a ResultSet.

  Connector/J 3.1 throws an exception by default when these values are encountered, as this is the most correct behavior according to the JDBC and SQL standards. This behavior can be modified using the `zeroDateTimeBehavior` configuration property. The permissible values are:

  - `exception` (the default), which throws an SQLException with an SQLState of `S1009`.
  - `convertToNull`, which returns `NULL` instead of the date.
  - `round`, which rounds the date to the nearest closest value which is `0001-01-01`.

  Starting with Connector/J 3.1.7, `ResultSet.getString()` can be decoupled from this behavior using `noDatetimeStringSync=true` (the default value is `false`) so that you can retrieve the unaltered all-zero value as a String. Note that this also precludes using any time zone conversions, therefore the driver will not allow you to enable `noDatetimeStringSync` and `useTimezone` at the same time.

- **New SQLState Codes**: Connector/J 3.1 uses SQL:1999 SQLState codes returned by the MySQL server (if supported), which are different from the legacy X/Open state codes that Connector/J 3.0 uses. If connected to a MySQL server older than MySQL-4.1.0 (the oldest version to return SQLStates as part of the error code), the driver will use a built-in mapping. You can revert to the old mapping by using the configuration property `useSqlStateCodes=false`.

- **`ResultSet.getString()`**: Calling `ResultSet.getString()` on a `BLOB` column will now return the address of the `byte[]` array that represents it, instead of a `String` representation of the `BLOB`. `BLOB` values have no character set, so they cannot be converted to `java.lang.String`s without data loss or corruption.

  To store strings in MySQL with LOB behavior, use one of the `TEXT` types, which the driver will treat as a `java.sql.Clob`.

- **Debug builds**: Starting with Connector/J 3.1.8 a debug build of the driver in a file named `mysql-connector-java-`*`version`*`-bin-g.jar` is shipped alongside the normal binary jar file that is named `mysql-connector-java-`*`version`*`-bin.jar`.

  Starting with Connector/J 3.1.9, we do not ship the `.class` files unbundled, they are only available in the JAR archives that ship with the driver.

  Do not use the debug build of the driver unless instructed to do so when reporting a problem or bug, as it is not designed to be run in production environments, and will have adverse performance impact when used. The debug binary also depends on the Aspect/J runtime library, which is located in the `src/lib/aspectjrt.jar` file that comes with the Connector/J distribution.

Installing from the Development Source Tree

Caution

Read this section only if you are interested in helping us test our new code. To just get MySQL Connector/J up and running on your system, use a standard binary release distribution.

To install MySQL Connector/J from the development source tree, make sure that you have the following prerequisites:

- A Bazaar client, to check out the sources from our Launchpad repository (available from http://bazaar-vcs.org/).
- Apache Ant version 1.7 or newer (available from http://ant.apache.org/).
- JDK 1.4.2 or later. Although MySQL Connector/J can be be used with older JDKs, compiling it from source requires at least JDK 1.4.2. To build Connector/J 5.1 requires JDK 1.6.x *and* an older JDK such as JDK 1.5.x; point your `JAVA_HOME` environment variable at the older installation.

To check out and compile a specific branch of MySQL Connector/J, follow these steps:

1. Check out the latest code from the branch that you want with one of the following commands.

   The source code repository for MySQL Connector/J is located on Launchpad at https://code.launchpad.net/connectorj. To check out the latest development branch, use:

   ```
   shell> bzr branch lp:connectorji
   ```

   This creates a `connectorj` subdirectory in the current directory that contains the latest sources for the requested branch.

   To check out the latest 5.1 code, use:

   ```
   shell> bzr branch lp:connectorj/5.1
   ```

   This creates a `5.1` subdirectory in the current directory containing the latest 5.1 code.

2. To build Connector/J 5.1, make sure that you have both JDK 1.6.x installed and an older JDK such as JDK 1.5.x. This is because Connector/J supports both JDBC 3.0 (which was prior to JDK 1.6.x) and JDBC 4.0. Set your `JAVA_HOME` environment variable to the path of the older JDK installation.
3. Change your current working directory to either the `connectorj` or `5.1` directory, depending on which branch you intend to build.
4. To build Connector/J 5.1, edit the `build.xml` to reflect the location of your JDK 1.6.x installation. The lines to change are:

   ```
   <property name="com.mysql.jdbc.java6.javac" value="C:\jvms\jdk1.6.0\bin\javac.exe" />
   <property name="com.mysql.jdbc.java6.rtjar" value="C:\jvms\jdk1.6.0\jre\lib\rt.jar" />
   ```

   Alternatively, you can set the value of these property names through the Ant `-D` option.

5. Issue the following command to compile the driver and create a `.jar` file suitable for installation:

   ```
   shell> ant dist
   ```

   This creates a `build` directory in the current directory, where all build output will go. A directory is created in the `build` directory that includes the version number of the sources you are building from. This directory contains the sources, compiled `.class` files, and a `.jar` file suitable for deployment. For other possible targets, including ones that will create a fully packaged distribution, issue the following command:

   ```
   shell> ant -projecthelp
   ```

6. A newly created `.jar` file containing the JDBC driver will be placed in the directory `build/mysql-connector-java-version`.

   Install the newly created JDBC driver as you would a binary `.jar` file that you download from MySQL, by following the instructions in Installing the Driver and Configuring the `CLASSPATH`.

A package containing both the binary and source code for Connector/J 5.1 can also be found at the following location: Connector/J 5.1 Download

Connector/J Examples

Examples of using Connector/J are located throughout this document. This section provides a summary and links to these examples.

- Example 21.1, “Connector/J: Obtaining a connection from the `DriverManager`”
- Example 21.2, “Connector/J: Using java.sql.Statement to execute a `SELECT` query”
- Example 21.3, “Connector/J: Calling Stored Procedures”
- Example 21.4, “Connector/J: Using `Connection.prepareCall()`”
- Example 21.5, “Connector/J: Registering output parameters”
- Example 21.6, “Connector/J: Setting `CallableStatement` input parameters”
- Example 21.7, “Connector/J: Retrieving results and output parameter values”
- Example 21.8, “Connector/J: Retrieving `AUTO_INCREMENT` column values using `Statement.getGeneratedKeys()`”
- Example 21.9, “Connector/J: Retrieving `AUTO_INCREMENT` column values using `SELECT LAST_INSERT_ID()`”
- Example 21.10, “Connector/J: Retrieving `AUTO_INCREMENT` column values in `Updatable ResultSets`”
- Example 21.11, “Connector/J: Using a connection pool with a J2EE application server”
- Example 21.12, “Connector/J: Example of transaction with retry logic”

Connector/J (JDBC) Reference

This section of the manual contains reference material for MySQL Connector/J.

Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J

The name of the class that implements `java.sql.Driver` in MySQL Connector/J is `com.mysql.jdbc.Driver`. The `org.gjt.mm.mysql.Driver` class name is also usable for backward compatibility with MM.MySQL, the predecessor of Connector/J. Use this class name when registering the driver, or when otherwise configuring software to use MySQL Connector/J.

JDBC URL Format

The JDBC URL format for MySQL Connector/J is as follows, with items in square brackets ([,]) being optional:

```
jdbc:mysql://[host][,failoverhost...][:port]/[database] »
[?propertyName1][=propertyValue1][&propertyName2][=propertyValue2]...
```

If the host name is not specified, it defaults to `127.0.0.1`. If the port is not specified, it defaults to `3306`, the default port number for MySQL servers.

```
jdbc:mysql://[host:port],[host:port].../[database] »
[?propertyName1][=propertyValue1][&propertyName2][=propertyValue2]...
```

Here is a sample connection URL:

```
jdbc:mysql://localhost:3306/sakila?profileSQL=true
```

IPv6 Connections

For IPv6 connections, use this alternative syntax to specify hosts in the URL, `address=(key=value)`. Supported keys are:

- `(protocol=tcp)`, or `(protocol=pipe)` for named pipes on Windows.

- `(path=path_to_pipe)` for named pipes.
- `(host=hostname)` for TCP connections.
- `(port=port_number)` for TCP connections.

For example:

```
jdbc:mysql://address=(protocol=tcp)(host=localhost)(port=3306)(user=test)/db
```

Any other parameters are treated as host-specific properties that follow the conventions of the JDBC URL properties. This now allows per-host overrides of any configuration property for multi-host connections (that is, when using failover, load balancing, or replication). Limit the overrides to user, password, network timeouts and statement and metadata cache sizes; the results of other per-host overrides are not defined.

Initial Database for Connection

If the database is not specified, the connection is made with no default database. In this case, either call the `setCatalog()` method on the Connection instance, or fully specify table names using the database name (that is, `SELECT dbname.tablename.colname FROM dbname.tablename...`) in your SQL. Opening a connection without specifying the database to use is generally only useful when building tools that work with multiple databases, such as GUI database managers.

Note

Always use the `Connection.setCatalog()` method to specify the desired database in JDBC applications, rather than the `USE database` statement.

Failover Support

MySQL Connector/J has failover support. This enables the driver to fail over to any number of slave hosts and still perform read-only queries. Failover only happens when the connection is in an `autoCommit(true)` state, because failover cannot happen reliably when a transaction is in progress. Most application servers and connection pools set `autoCommit` to `true` at the end of every transaction/connection use.

The failover functionality has the following behavior:

- If the URL property `autoReconnect` is `false`: Failover only happens at connection initialization, and failback occurs when the driver determines that the first host has become available again.
- If the URL property `autoReconnect` is `true`: Failover happens when the driver determines that the connection has failed (checked before *every* query), and falls back to the first host when it determines that the host has become available again (after `queriesBeforeRetryMaster` queries have been issued).

In either case, whenever you are connected to a “failed-over” server, the connection is set to read-only state, so queries that attempt to modify data will throw exceptions (the query will **never** be processed by the MySQL server).

Setting Configuration Properties

Configuration properties define how Connector/J will make a connection to a MySQL server. Unless otherwise noted, properties can be set for a `DataSource` object or for a `Connection` object.

Configuration properties can be set in one of the following ways:

- Using the `set*()` methods on MySQL implementations of `java.sql.DataSource` (which is the preferred method when using implementations of `java.sql.DataSource`):
  - `com.mysql.jdbc.jdbc2.optional.MysqlDataSource`
  - `com.mysql.jdbc.jdbc2.optional.MysqlConnectionPoolDataSource`

- As a key/value pair in the `java.util.Properties` instance passed to `DriverManager.getConnection()` or `Driver.connect()`
- As a JDBC URL parameter in the URL given to `java.sql.DriverManager.getConnection()`, `java.sql.Driver.connect()` or the MySQL implementations of the `javax.sql.DataSource setURL()` method.

Note

If the mechanism you use to configure a JDBC URL is XML-based, use the XML character literal & to separate configuration parameters, as the ampersand is a reserved character for XML.

The properties are listed in the following tables.

Connection/Authentication.

Property Name	Definition	Default Value	Since Version
`user`	The user to connect as		all versions
`password`	The password to use when connecting		all versions
`socketFactory`	The name of the class that the driver should use for creating socket connections to the server. This class must implement the interface 'com.mysql.jdbc.SocketFactory' and have public no-args constructor.	`com.mysql.jdbc.StandardS`	3.0.3
`connectTimeout`	Timeout for socket connect (in milliseconds), with 0 being no timeout. Only works on JDK-1.4 or newer. Defaults to '0'.	`0`	3.0.1
`socketTimeout`	Timeout on network socket operations (0, the default means no timeout).	`0`	3.0.1
`connectionLifecycleInterceptors`	A comma-delimited list of classes that implement "com.mysql.jdbc.ConnectionLifecycleInterceptor" that should notified of connection lifecycle events (creation, destruction, commit, rollback, setCatalog and setAutoCommit) and potentially alter the execution of these commands. ConnectionLifecycleInterceptors are "stackable", more than one interceptor may be specified via the configuration property as a comma-delimited list, with the interceptors executed in order from left to right.		5.1.4
`useConfigs`	Load the comma-delimited list of configuration properties before parsing the URL or applying user-specified properties. These configurations are explained in the 'Configurations' of the documentation.		3.1.5
`authenticationPlugins`	Comma-delimited list of classes that implement com.mysql.jdbc.AuthenticationPlugin and which will be used for authentication unless disabled by "disabledAuthenticationPlugins" property.		5.1.19
`defaultAuthenticationPlugin`	Name of a class implementing com.mysql.jdbc.AuthenticationPlugin which will be used as the default authentication plugin	`com.mysql.jdbc.authentic`	5.1.19

	(see below). It is an error to use a class which is not listed in "authenticationPlugins" nor it is one of the built-in plugins. It is an error to set as default a plugin which was disabled with "disabledAuthenticationPlugins" property. It is an error to set this value to null or the empty string (i.e. there must be at least a valid default authentication plugin specified for the connection, meeting all constraints listed above).		
`disabledAuthenticationPlugins`	Comma-delimited list of classes implementing com.mysql.jdbc.AuthenticationPlugin or mechanisms, i.e. "mysql_native_password". The authentication plugins or mechanisms listed will not be used for authentication which will fail if it requires one of them. It is an error to disable the default authentication plugin (either the one named by "defaultAuthenticationPlugin" property or the hard-coded one if "defaultAuthenticationPlugin" propery is not set).		5.1.19
`interactiveClient`	Set the CLIENT_INTERACTIVE flag, which tells MySQL to timeout connections based on INTERACTIVE_TIMEOUT instead of WAIT_TIMEOUT	`false`	3.1.0
`localSocketAddress`	Hostname or IP address given to explicitly configure the interface that the driver will bind the client side of the TCP/IP connection to when connecting.		5.0.5
`propertiesTransform`	An implementation of com.mysql.jdbc.ConnectionPropertiesTransform that the driver will use to modify URL properties passed to the driver before attempting a connection		3.1.4
`useCompression`	Use zlib compression when communicating with the server (true/false)? Defaults to 'false'.	`false`	3.0.17

Networking.

Property Name	Definition	Default Value	Since Version
`maxAllowedPacket`	Maximum allowed packet size to send to server. If not set, the value of system variable 'max_allowed_packet' will be used to initialize this upon connecting. This value will not take effect if set larger than the value of 'max_allowed_packet'.	`-1`	5.1.8
`tcpKeepAlive`	If connecting using TCP/IP, should the driver set SO_KEEPALIVE?	`true`	5.0.7
`tcpNoDelay`	If connecting using TCP/IP, should the driver set SO_TCP_NODELAY (disabling the Nagle Algorithm)?	`true`	5.0.7
`tcpRcvBuf`	If connecting using TCP/IP, should the driver set SO_RCV_BUF to the given value? The default value of '0', means use the platform default value for this property)	`0`	5.0.7

tcpSndBuf	If connecting using TCP/IP, should the driver set SO_SND_BUF to the given value? The default value of '0', means use the platform default value for this property)	0	5.0.7
tcpTrafficClass	If connecting using TCP/IP, should the driver set traffic class or type-of-service fields ?See the documentation for java.net.Socket.setTrafficClass() for more information.	0	5.0.7

High Availability and Clustering.

Property Name	Definition	Default Value	Since Version
autoReconnect	Should the driver try to re-establish stale and/or dead connections? If enabled the driver will throw an exception for a queries issued on a stale or dead connection, which belong to the current transaction, but will attempt reconnect before the next query issued on the connection in a new transaction. The use of this feature is not recommended, because it has side effects related to session state and data consistency when applications don't handle SQLExceptions properly, and is only designed to be used when you are unable to configure your application to handle SQLExceptions resulting from dead and stale connections properly. Alternatively, as a last option, investigate setting the MySQL server variable "wait_timeout" to a high value, rather than the default of 8 hours.	false	1.1
autoReconnectForPools	Use a reconnection strategy appropriate for connection pools (defaults to 'false')	false	3.1.3
failOverReadOnly	When failing over in autoReconnect mode, should the connection be set to 'read-only'?	true	3.0.12
maxReconnects	Maximum number of reconnects to attempt if autoReconnect is true, default is '3'.	3	1.1
reconnectAtTxEnd	If autoReconnect is set to true, should the driver attempt reconnections at the end of every transaction?	false	3.0.10
retriesAllDown	When using loadbalancing, the number of times the driver should cycle through available hosts, attempting to connect. Between cycles, the driver will pause for 250ms if no servers are available.	120	5.1.6
initialTimeout	If autoReconnect is enabled, the initial time to wait between re-connect attempts (in seconds, defaults to '2').	2	1.1
roundRobinLoadBalance	When autoReconnect is enabled, and failoverReadonly is false, should we pick hosts to connect to on a round-robin basis?	false	3.1.2
queriesBeforeRetryMaster	Number of queries to issue before falling back to master when failed over (when using multi-host failover). Whichever condition is met first, 'queriesBeforeRetryMaster' or	50	3.0.2

	'secondsBeforeRetryMaster' will cause an attempt to be made to reconnect to the master. Defaults to 50.		
secondsBeforeRetryMaster	How long should the driver wait, when failed over, before attempting	30	3.0.2
selfDestructOnPingMaxOperations	If set to a non-zero value, the driver will report close the connection and report failure when Connection.ping() or Connection.isValid(int) is called if the connnection's count of commands sent to the server exceeds this value.	0	5.1.6
selfDestructOnPingSecondsLifetime	If set to a non-zero value, the driver will report close the connection and report failure when Connection.ping() or Connection.isValid(int) is called if the connnection's lifetime exceeds this value.	0	5.1.6
resourceId	A globally unique name that identifies the resource that this datasource or connection is connected to, used for XAResource.isSameRM() when the driver can't determine this value based on hostnames used in the URL		5.0.1

Security.

Property Name	Definition	Default Value	Since Version
allowMultiQueries	Allow the use of ';' to delimit multiple queries during one statement (true/false), defaults to 'false', and does not affect the addBatch() and executeBatch() methods, which instead rely on rewriteBatchStatements.	false	3.1.1
useSSL	Use SSL when communicating with the server (true/false), defaults to 'false'	false	3.0.2
requireSSL	Require SSL connection if useSSL=true? (defaults to 'false').	false	3.1.0
verifyServerCertificate	If "useSSL" is set to "true", should the driver verify the server's certificate? When using this feature, the keystore parameters should be specified by the "clientCertificateKeyStore*" properties, rather than system properties.	true	5.1.6
clientCertificateKeyStoreUrl	URL to the client certificate KeyStore (if not specified, use defaults)		5.1.0
clientCertificateKeyStoreType	KeyStore type for client certificates (NULL or empty means use the default, which is "JKS". Standard keystore types supported by the JVM are "JKS" and "PKCS12", your environment may have more available depending on what security products are installed and available to the JVM.	JKS	5.1.0
clientCertificateKeyStorePassword	Password for the client certificates KeyStore		5.1.0
trustCertificateKeyStoreUrl	URL to the trusted root certificate KeyStore (if not specified, use defaults)		5.1.0
trustCertificateKeyStoreType	KeyStore type for trusted root certificates (NULL or empty means use the default, which is "JKS". Standard keystore types supported by the JVM	JKS	5.1.0

	are "JKS" and "PKCS12", your environment may have more available depending on what security products are installed and available to the JVM.		
trustCertificateKeyStorePassword	Password for the trusted root certificates KeyStore		5.1.0
allowLoadLocalInfile	Should the driver allow use of 'LOAD DATA LOCAL INFILE...' (defaults to 'true').	true	3.0.3
allowUrlInLocalInfile	Should the driver allow URLs in 'LOAD DATA LOCAL INFILE' statements?	false	3.1.4
paranoid	Take measures to prevent exposure sensitive information in error messages and clear data structures holding sensitive data when possible? (defaults to 'false')	false	3.0.1
passwordCharacterEncoding	What character encoding is used for passwords? Leaving this set to the default value (null), uses the platform character set, which works for ISO8859_1 (i.e. "latin1") passwords. For passwords in other character encodings, the encoding will have to be specified with this property, as it's not possible for the driver to auto-detect this.		5.1.7

Performance Extensions.

Property Name	Definition	Default Value	Since Version
callableStmtCacheSize	If 'cacheCallableStmts' is enabled, how many callable statements should be cached?	100	3.1.2
metadataCacheSize	The number of queries to cache ResultSetMetadata for if cacheResultSetMetaData is set to 'true' (default 50)	50	3.1.1
useLocalSessionState	Should the driver refer to the internal values of autocommit and transaction isolation that are set by Connection.setAutoCommit() and Connection.setTransactionIsolation() and transaction state as maintained by the protocol, rather than querying the database or blindly sending commands to the database for commit() or rollback() method calls?	false	3.1.7
useLocalTransactionState	Should the driver use the in-transaction state provided by the MySQL protocol to determine if a commit() or rollback() should actually be sent to the database?	false	5.1.7
prepStmtCacheSize	If prepared statement caching is enabled, how many prepared statements should be cached?	25	3.0.10
prepStmtCacheSqlLimit	If prepared statement caching is enabled, what's the largest SQL the driver will cache the parsing for?	256	3.0.10
parseInfoCacheFactory	Name of a class implementing com.mysql.jdbc.CacheAdapterFactory, which will be used to create caches for the parsed representation of client-side prepared statements.	com.mysql.jdbc.PerConnec	5.1.1
alwaysSendSetIsolation	Should the driver always communicate with the database when	true	3.1.7

	Connection.setTransactionIsolation() is called? If set to false, the driver will only communicate with the database when the requested transaction isolation is different than the whichever is newer, the last value that was set via Connection.setTransactionIsolation(), or the value that was read from the server when the connection was established. Note that useLocalSessionState=true will force the same behavior as alwaysSendSetIsolation=false, regardless of how alwaysSendSetIsolation is set.		
maintainTimeStats	Should the driver maintain various internal timers to enable idle time calculations as well as more verbose error messages when the connection to the server fails? Setting this property to false removes at least two calls to System.getCurrentTimeMillis() per query.	true	3.1.9
useCursorFetch	If connected to MySQL > 5.0.2, and setFetchSize() > 0 on a statement, should that statement use cursor-based fetching to retrieve rows?	false	5.0.0
blobSendChunkSize	Chunk to use when sending BLOB/CLOBs via ServerPreparedStatements	1048576	3.1.9
cacheCallableStmts	Should the driver cache the parsing stage of CallableStatements	false	3.1.2
cachePrepStmts	Should the driver cache the parsing stage of PreparedStatements of client-side prepared statements, the "check" for suitability of server-side prepared and server-side prepared statements themselves?	false	3.0.10
cacheResultSetMetadata	Should the driver cache ResultSetMetaData for Statements and PreparedStatements? (Req. JDK-1.4+, true/false, default 'false')	false	3.1.1
cacheServerConfiguration	Should the driver cache the results of 'SHOW VARIABLES' and 'SHOW COLLATION' on a per-URL basis?	false	3.1.5
defaultFetchSize	The driver will call setFetchSize(n) with this value on all newly-created Statements	0	3.1.9
dontTrackOpenResources	The JDBC specification requires the driver to automatically track and close resources, however if your application doesn't do a good job of explicitly calling close() on statements or result sets, this can cause memory leakage. Setting this property to true relaxes this constraint, and can be more memory efficient for some applications.	false	3.1.7
dynamicCalendars	Should the driver retrieve the default calendar when required, or cache it per connection/ session?	false	3.1.5
elideSetAutoCommits	If using MySQL-4.1 or newer, should the driver only issue 'set autocommit=n' queries when the server's state doesn't match the requested state by Connection.setAutoCommit(boolean)?	false	3.1.3

enableQueryTimeouts	When enabled, query timeouts set via Statement.setQueryTimeout() use a shared java.util.Timer instance for scheduling. Even if the timeout doesn't expire before the query is processed, there will be memory used by the TimerTask for the given timeout which won't be reclaimed until the time the timeout would have expired if it hadn't been cancelled by the driver. High-load environments might want to consider disabling this functionality.	true	5.0.6
holdResultsOpenOverStatementClose	Should the driver close result sets on Statement.close() as required by the JDBC specification?	false	3.1.7
largeRowSizeThreshold	What size result set row should the JDBC driver consider "large", and thus use a more memory-efficient way of representing the row internally?	2048	5.1.1
loadBalanceStrategy	If using a load-balanced connection to connect to SQL nodes in a MySQL Cluster/NDB configuration (by using the URL prefix "jdbc:mysql:loadbalance://"), which load balancing algorithm should the driver use: (1) "random" - the driver will pick a random host for each request. This tends to work better than round-robin, as the randomness will somewhat account for spreading loads where requests vary in response time, while round-robin can sometimes lead to overloaded nodes if there are variations in response times across the workload. (2) "bestResponseTime" - the driver will route the request to the host that had the best response time for the previous transaction.	random	5.0.6
locatorFetchBufferSize	If 'emulateLocators' is configured to 'true', what size buffer should be used when fetching BLOB data for getBinaryInputStream?	1048576	3.2.1
rewriteBatchedStatements	Should the driver use multiqueries (irregardless of the setting of "allowMultiQueries") as well as rewriting of prepared statements for INSERT into multi-value inserts when executeBatch() is called? Notice that this has the potential for SQL injection if using plain java.sql.Statements and your code doesn't sanitize input correctly. Notice that for prepared statements, server-side prepared statements can not currently take advantage of this rewrite option, and that if you don't specify stream lengths when using PreparedStatement.set*Stream(), the driver won't be able to determine the optimum number of parameters per batch and you might receive an error from the driver that the resultant packet is too large. Statement.getGeneratedKeys() for these rewritten statements only works when the entire batch includes INSERT statements.	false	3.1.13
useDirectRowUnpack	Use newer result set row unpacking code that skips a copy from network buffers to a MySQL	true	5.1.1

	packet instance and instead reads directly into the result set row data buffers.		
useDynamicCharsetInfo	Should the driver use a per-connection cache of character set information queried from the server when necessary, or use a built-in static mapping that is more efficient, but isn't aware of custom character sets or character sets implemented after the release of the JDBC driver?	true	5.0.6
useFastDateParsing	Use internal String->Date/Time/Timestamp conversion routines to avoid excessive object creation?	true	5.0.5
useFastIntParsing	Use internal String->Integer conversion routines to avoid excessive object creation?	true	3.1.4
useJvmCharsetConverters	Always use the character encoding routines built into the JVM, rather than using lookup tables for single-byte character sets?	false	5.0.1
useReadAheadInput	Use newer, optimized non-blocking, buffered input stream when reading from the server?	true	3.1.5

Debugging/Profiling.

Property Name	Definition	Default Value	Since Version
logger	The name of a class that implements "com.mysql.jdbc.log.Log" that will be used to log messages to. (default is "com.mysql.jdbc.log.StandardLogger", which logs to STDERR)	com.mysql.jdbc.log.St	3.1.1
gatherPerfMetrics	Should the driver gather performance metrics, and report them via the configured logger every 'reportMetricsIntervalMillis' milliseconds?	false	3.1.2
profileSQL	Trace queries and their execution/fetch times to the configured logger (true/false) defaults to 'false'	false	3.1.0
profileSql	Deprecated, use 'profileSQL' instead. Trace queries and their execution/fetch times on STDERR (true/false) defaults to 'false'		2.0.14
reportMetricsIntervalMillis	If 'gatherPerfMetrics' is enabled, how often should they be logged (in ms)?	30000	3.1.2
maxQuerySizeToLog	Controls the maximum length/size of a query that will get logged when profiling or tracing	2048	3.1.3
packetDebugBufferSize	The maximum number of packets to retain when 'enablePacketDebug' is true	20	3.1.3
slowQueryThresholdMillis	If 'logSlowQueries' is enabled, how long should a query (in ms) before it is logged as 'slow'?	2000	3.1.2
slowQueryThresholdNanos	If 'useNanosForElapsedTime' is set to true, and this property is set to a non-zero value, the driver will use this threshold (in nanosecond units) to determine if a query was slow.	0	5.0.7
useUsageAdvisor	Should the driver issue 'usage' warnings advising proper and efficient usage of JDBC and MySQL Connector/J to the log (true/false, defaults to 'false')?	false	3.1.1

autoGenerateTestcaseScript	Should the driver dump the SQL it is executing, including server-side prepared statements to STDERR?	false	3.1.9
autoSlowLog	Instead of using slowQueryThreshold* to determine if a query is slow enough to be logged, maintain statistics that allow the driver to determine queries that are outside the 99th percentile?	true	5.1.4
clientInfoProvider	The name of a class that implements the com.mysql.jdbc.JDBC4ClientInfoProvider interface in order to support JDBC-4.0's Connection.get/setClientInfo() methods	com.mysql.jdbc.JDBC4Comm	5.1.0
dumpMetadataOnColumnNotFound	Should the driver dump the field-level metadata of a result set into the exception message when ResultSet.findColumn() fails?	false	3.1.13
dumpQueriesOnException	Should the driver dump the contents of the query sent to the server in the message for SQLExceptions?	false	3.1.3
enablePacketDebug	When enabled, a ring-buffer of 'packetDebugBufferSize' packets will be kept, and dumped when exceptions are thrown in key areas in the driver's code	false	3.1.3
explainSlowQueries	If 'logSlowQueries' is enabled, should the driver automatically issue an 'EXPLAIN' on the server and send the results to the configured log at a WARN level?	false	3.1.2
includeInnodbStatusInDeadlockExceptions	Include the output of "SHOW ENGINE INNODB STATUS" in exception messages when deadlock exceptions are detected?	false	5.0.7
includeThreadDumpInDeadlockExceptions	Include a current Java thread dump in exception messages when deadlock exceptions are detected?	false	5.1.15
includeThreadNamesAsStatementComment	Include the name of the current thread as a comment visible in "SHOW PROCESSLIST", or in Innodb deadlock dumps, useful in correlation with "includeInnodbStatusInDeadlockExceptions=true" and "includeThreadDumpInDeadlockExceptions=true".	false	5.1.15
logSlowQueries	Should queries that take longer than 'slowQueryThresholdMillis' be logged?	false	3.1.2
logXaCommands	Should the driver log XA commands sent by MysqlXaConnection to the server, at the DEBUG level of logging?	false	5.0.5
profilerEventHandler	Name of a class that implements the interface com.mysql.jdbc.profiler.ProfilerEventHandler that will be used to handle profiling/tracing events.	com.mysql.jdbc.profiler.	5.1.6
resultSetSizeThreshold	If the usage advisor is enabled, how many rows should a result set contain before the driver warns that it is suspiciously large?	100	5.0.5
traceProtocol	Should trace-level network protocol be logged?	false	3.1.2

useNanosForElapsedTime	For profiling/debugging functionality that measures elapsed time, should the driver try to use nanoseconds resolution if available (JDK >= 1.5)?	false	5.0.7

Miscellaneous.

Property Name	Definition	Default Value	Since Version
useUnicode	Should the driver use Unicode character encodings when handling strings? Should only be used when the driver can't determine the character set mapping, or you are trying to 'force' the driver to use a character set that MySQL either doesn't natively support (such as UTF-8), true/false, defaults to 'true'	true	1.1g
characterEncoding	If 'useUnicode' is set to true, what character encoding should the driver use when dealing with strings? (defaults is to 'autodetect')		1.1g
characterSetResults	Character set to tell the server to return results as.		3.0.13
connectionCollation	If set, tells the server to use this collation via 'set collation_connection'		3.0.13
useBlobToStoreUTF8OutsideBMP	Tells the driver to treat [MEDIUM/LONG]BLOB columns as [LONG]VARCHAR columns holding text encoded in UTF-8 that has characters outside the BMP (4-byte encodings), which MySQL server can't handle natively.	false	5.1.3
utf8OutsideBmpExcludedColumnNamePattern	When "useBlobToStoreUTF8OutsideBMP" is set to "true", column names matching the given regex will still be treated as BLOBs unless they match the regex specified for "utf8OutsideBmpIncludedColumnNamePattern". The regex must follow the patterns used for the java.util.regex package.		5.1.3
utf8OutsideBmpIncludedColumnNamePattern	Used to specify exclusion rules to "utf8OutsideBmpExcludedColumnNamePattern". The regex must follow the patterns used for the java.util.regex package.		5.1.3
loadBalanceEnableJMX	Enables JMX-based management of load-balanced connection groups, including live addition/removal of hosts from load-balancing pool.	false	5.1.13
sessionVariables	A comma-separated list of name/value pairs to be sent as SET SESSION ... to the server when the driver connects.		3.1.8
useColumnNamesInFindColumn	Prior to JDBC-4.0, the JDBC specification had a bug related to what could be given as a "column name" to ResultSet methods like findColumn(), or getters that took a String property. JDBC-4.0 clarified "column name" to mean the label, as given in an "AS" clause and returned by ResultSetMetaData.getColumnLabel(), and if no AS clause, the column name. Setting this property to "true" will give behavior that is congruent to JDBC-3.0 and earlier	false	5.1.7

	versions of the JDBC specification, but which because of the specification bug could give unexpected results. This property is preferred over "useOldAliasMetadataBehavior" unless you need the specific behavior that it provides with respect to ResultSetMetadata.		
allowNanAndInf	Should the driver allow NaN or +/- INF values in PreparedStatement.setDouble()?	false	3.1.5
autoClosePStmtStreams	Should the driver automatically call .close() on streams/readers passed as arguments via set*() methods?	false	3.1.12
autoDeserialize	Should the driver automatically detect and de-serialize objects stored in BLOB fields?	false	3.1.5
blobsAreStrings	Should the driver always treat BLOBs as Strings - specifically to work around dubious metadata returned by the server for GROUP BY clauses?	false	5.0.8
capitalizeTypeNames	Capitalize type names in DatabaseMetaData? (usually only useful when using WebObjects, true/false, defaults to 'false')	true	2.0.7
clobCharacterEncoding	The character encoding to use for sending and retrieving TEXT, MEDIUMTEXT and LONGTEXT values instead of the configured connection characterEncoding		5.0.0
clobberStreamingResults	This will cause a 'streaming' ResultSet to be automatically closed, and any outstanding data still streaming from the server to be discarded if another query is executed before all the data has been read from the server.	false	3.0.9
compensateOnDuplicateKeyUpdateCounts	Should the driver compensate for the update counts of "ON DUPLICATE KEY" INSERT statements (2 = 1, 0 = 1) when using prepared statements?	false	5.1.7
continueBatchOnError	Should the driver continue processing batch commands if one statement fails. The JDBC spec allows either way (defaults to 'true').	true	3.0.3
createDatabaseIfNotExist	Creates the database given in the URL if it doesn't yet exist. Assumes the configured user has permissions to create databases.	false	3.1.9
emptyStringsConvertToZero	Should the driver allow conversions from empty string fields to numeric values of '0'?	true	3.1.8
emulateLocators	Should the driver emulate java.sql.Blobs with locators? With this feature enabled, the driver will delay loading the actual Blob data until the one of the retrieval methods (getInputStream(), getBytes(), and so forth) on the blob data stream has been accessed. For this to work, you must use a column alias with the value of the column to the actual name of the Blob. The feature also has the following restrictions: The SELECT that created the result set must reference only one table, the table must have a primary key; the SELECT must alias the original blob column name, specified as a string, to an alternate name;	false	3.1.0

	the SELECT must cover all columns that make up the primary key.		
emulateUnsupportedPstmts	Should the driver detect prepared statements that are not supported by the server, and replace them with client-side emulated versions?	true	3.1.7
exceptionInterceptors	Comma-delimited list of classes that implement com.mysql.jdbc.ExceptionInterceptor. These classes will be instantiated one per Connection instance, and all SQLExceptions thrown by the driver will be allowed to be intercepted by these interceptors, in a chained fashion, with the first class listed as the head of the chain.		5.1.8
functionsNeverReturnBlobs	Should the driver always treat data from functions returning BLOBs as Strings - specifically to work around dubious metadata returned by the server for GROUP BY clauses?	false	5.0.8
generateSimpleParameterMetadata	Should the driver generate simplified parameter metadata for PreparedStatements when no metadata is available either because the server couldn't support preparing the statement, or server-side prepared statements are disabled?	false	5.0.5
ignoreNonTxTables	Ignore non-transactional table warning for rollback? (defaults to 'false').	false	3.0.9
jdbcCompliantTruncation	Should the driver throw java.sql.DataTruncation exceptions when data is truncated as is required by the JDBC specification when connected to a server that supports warnings (MySQL 4.1.0 and newer)? This property has no effect if the server sql-mode includes STRICT_TRANS_TABLES.	true	3.1.2
loadBalanceAutoCommitStatementRegex	When load-balancing is enabled for auto-commit statements (via loadBalanceAutoCommitStatementThreshold), the statement counter will only increment when the SQL matches the regular expression. By default, every statement issued matches.		5.1.15
loadBalanceAutoCommitStatementThreshold	When auto-commit is enabled, the number of statements which should be executed before triggering load-balancing to rebalance. Default value of 0 causes load-balanced connections to only rebalance when exceptions are encountered, or auto-commit is disabled and transactions are explicitly committed or rolled back.	0	5.1.15
loadBalanceBlacklistTimeout	Time in milliseconds between checks of servers which are unavailable, by controlling how long a server lives in the global blacklist.	0	5.1.0
loadBalanceConnectionGroup	Logical group of load-balanced connections within a classloader, used to manage different groups independently. If not specified, live management of load-balanced connections is disabled.		5.1.13
loadBalanceExceptionChecker	Fully-qualified class name of custom exception checker. The class must implement com.mysql.jdbc.LoadBalanceExceptionChecker interface, and is used to inspect SQLExceptions and determine whether they should trigger	com.mysql.jdbc.Standa	5.1.13

	fail-over to another host in a load-balanced deployment.		
loadBalancePingTimeout	Time in milliseconds to wait for ping response from each of load-balanced physical connections when using load-balanced Connection.	0	5.1.13
loadBalanceSQLExceptionSubclassFailover	Comma-delimited list of classes/interfaces used by default load-balanced exception checker to determine whether a given SQLException should trigger failover. The comparison is done using Class.isInstance(SQLException) using the thrown SQLException.		5.1.13
loadBalanceSQLStateFailover	Comma-delimited list of SQLState codes used by default load-balanced exception checker to determine whether a given SQLException should trigger failover. The SQLState of a given SQLException is evaluated to determine whether it begins with any value in the comma-delimited list.		5.1.13
loadBalanceValidateConnectionOnSwapServer	Should the load-balanced Connection explicitly check whether the connection is live when swapping to a new physical connection at commit/rollback?	false	5.1.13
maxRows	The maximum number of rows to return (0, the default means return all rows).	-1	all versions
netTimeoutForStreamingResults	What value should the driver automatically set the server setting 'net_write_timeout' to when the streaming result sets feature is in use? (value has unit of seconds, the value '0' means the driver will not try and adjust this value)	600	5.1.0
noAccessToProcedureBodies	When determining procedure parameter types for CallableStatements, and the connected user can't access procedure bodies through "SHOW CREATE PROCEDURE" or select on mysql.proc should the driver instead create basic metadata (all parameters reported as IN VARCHARs, but allowing registerOutParameter() to be called on them anyway) instead of throwing an exception?	false	5.0.3
noDatetimeStringSync	Don't ensure that ResultSet.getDatetimeType().toString().equals(ResultSet.getString())	false	3.1.7
noTimezoneConversionForTimeType	Don't convert TIME values using the server timezone if 'useTimezone'='true'	false	5.0.0
nullCatalogMeansCurrent	When DatabaseMetadataMethods ask for a 'catalog' parameter, does the value null mean use the current catalog? (this is not JDBC-compliant, but follows legacy behavior from earlier versions of the driver)	true	3.1.8
nullNamePatternMatchesAll	Should DatabaseMetaData methods that accept *pattern parameters treat null the same as '%' (this is not JDBC-compliant, however older versions of the driver accepted this departure from the specification)	true	3.1.8
overrideSupportsIntegrityEnhancementFacility	Should the driver return "true" for DatabaseMetaData.supportsIntegrityEnhancementFacility()	false	3.1.12

	even if the database doesn't support it to workaround applications that require this method to return "true" to signal support of foreign keys, even though the SQL specification states that this facility contains much more than just foreign key support (one such application being OpenOffice)?		
padCharsWithSpace	If a result set column has the CHAR type and the value does not fill the amount of characters specified in the DDL for the column, should the driver pad the remaining characters with space (for ANSI compliance)?	false	5.0.6
pedantic	Follow the JDBC spec to the letter.	false	3.0.0
pinGlobalTxToPhysicalConnection	When using XAConnections, should the driver ensure that operations on a given XID are always routed to the same physical connection? This allows the XAConnection to support "XA START ... JOIN" after "XA END" has been called	false	5.0.1
populateInsertRowWithDefaultValues	When using ResultSets that are CONCUR_UPDATABLE, should the driver pre-populate the "insert" row with default values from the DDL for the table used in the query so those values are immediately available for ResultSet accessors? This functionality requires a call to the database for metadata each time a result set of this type is created. If disabled (the default), the default values will be populated by the an internal call to refreshRow() which pulls back default values and/or values changed by triggers.	false	5.0.5
processEscapeCodesForPrepStmts	Should the driver process escape codes in queries that are prepared?	true	3.1.12
queryTimeoutKillsConnection	If the timeout given in Statement.setQueryTimeout() expires, should the driver forcibly abort the Connection instead of attempting to abort the query?	false	5.1.9
relaxAutoCommit	If the version of MySQL the driver connects to does not support transactions, still allow calls to commit(), rollback() and setAutoCommit() (true/false, defaults to 'false')?	false	2.0.13
retainStatementAfterResultSetClose	Should the driver retain the Statement reference in a ResultSet after ResultSet.close() has been called. This is not JDBC-compliant after JDBC-4.0.	false	3.1.11
rollbackOnPooledClose	Should the driver issue a rollback() when the logical connection in a pool is closed?	true	3.0.15
runningCTS13	Enables workarounds for bugs in Sun's JDBC compliance testsuite version 1.3	false	3.1.7
serverTimezone	Override detection/mapping of timezone. Used when timezone from server doesn't map to Java timezone		3.0.2
statementInterceptors	A comma-delimited list of classes that implement "com.mysql.jdbc.StatementInterceptor" that should be placed "in between" query execution to influence the results. StatementInterceptors are "chainable", the results returned by the "current"		5.1.1

	interceptor will be passed on to the next in in the chain, from left-to-right order, as specified in this property.		
strictFloatingPoint	Used only in older versions of compliance test	false	3.0.0
strictUpdates	Should the driver do strict checking (all primary keys selected) of updatable result sets (true, false, defaults to 'true')?	true	3.0.4
tinyInt1isBit	Should the driver treat the datatype TINYINT(1) as the BIT type (because the server silently converts BIT -> TINYINT(1) when creating tables)?	true	3.0.16
transformedBitIsBoolean	If the driver converts TINYINT(1) to a different type, should it use BOOLEAN instead of BIT for future compatibility with MySQL-5.0, as MySQL-5.0 has a BIT type?	false	3.1.9
treatUtilDateAsTimestamp	Should the driver treat java.util.Date as a TIMESTAMP for the purposes of PreparedStatement.setObject()?	true	5.0.5
ultraDevHack	Create PreparedStatements for prepareCall() when required, because UltraDev is broken and issues a prepareCall() for _all_ statements? (true/false, defaults to 'false')	false	2.0.3
useAffectedRows	Don't set the CLIENT_FOUND_ROWS flag when connecting to the server (not JDBC-compliant, will break most applications that rely on "found" rows vs. "affected rows" for DML statements), but does cause "correct" update counts from "INSERT ... ON DUPLICATE KEY UPDATE" statements to be returned by the server.	false	5.1.7
useGmtMillisForDatetimes	Convert between session timezone and GMT before creating Date and Timestamp instances (value of "false" is legacy behavior, "true" leads to more JDBC-compliant behavior.	false	3.1.12
useHostsInPrivileges	Add '@hostname' to users in DatabaseMetaData.getColumn/TablePrivileges() (true/false), defaults to 'true'.	true	3.0.2
useInformationSchema	When connected to MySQL-5.0.7 or newer, should the driver use the INFORMATION_SCHEMA to derive information used by DatabaseMetaData?	false	5.0.0
useJDBCCompliantTimezoneShift	Should the driver use JDBC-compliant rules when converting TIME/TIMESTAMP/DATETIME values' timezone information for those JDBC arguments which take a java.util.Calendar argument? (Notice that this option is exclusive of the "useTimezone=true" configuration option.)	false	5.0.0
useLegacyDatetimeCode	Use code for DATE/TIME/DATETIME/ TIMESTAMP handling in result sets and statements that consistently handles timezone conversions from client to server and back again, or use the legacy code for these datatypes that has been in the driver for backwards-compatibility?	true	5.1.6

useOldAliasMetadataBehavior	Should the driver use the legacy behavior for "AS" clauses on columns and tables, and only return aliases (if any) for ResultSetMetaData.getColumnName() or ResultSetMetaData.getTableName() rather than the original column/table name? In 5.0.x, the default value was true.	false	5.0.4
useOldUTF8Behavior	Use the UTF-8 behavior the driver did when communicating with 4.0 and older servers	false	3.1.6
useOnlyServerErrorMessages	Don't prepend 'standard' SQLState error messages to error messages returned by the server.	true	3.0.15
useSSPSCompatibleTimezoneShift	If migrating from an environment that was using server-side prepared statements, and the configuration property "useJDBCCompliantTimeZoneShift" set to "true", use compatible behavior when not using server-side prepared statements when sending TIMESTAMP values to the MySQL server.	false	5.0.5
useServerPrepStmts	Use server-side prepared statements if the server supports them?	false	3.1.0
useSqlStateCodes	Use SQL Standard state codes instead of 'legacy' X/Open/SQL state codes (true/false), default is 'true'	true	3.1.3
useStreamLengthsInPrepStmts	Honor stream length parameter in PreparedStatement/ResultSet.setXXXStream() method calls (true/false, defaults to 'true')?	true	3.0.2
useTimezone	Convert time/date types between client and server timezones (true/false, defaults to 'false')?	false	3.0.2
useUnbufferedInput	Don't use BufferedInputStream for reading data from the server	true	3.0.11
yearIsDateType	Should the JDBC driver treat the MySQL type "YEAR" as a java.sql.Date, or as a SHORT?	true	3.1.9
zeroDateTimeBehavior	What should happen when the driver encounters DATETIME values that are composed entirely of zeros (used by MySQL to represent invalid dates)? Valid values are "exception", "round" and "convertToNull".	exception	3.1.4

Connector/J also supports access to MySQL using named pipes on Windows NT, Windows 2000, or Windows XP using the `NamedPipeSocketFactory` as a plugin-socket factory using the `socketFactory` property. If you do not use a `namedPipePath` property, the default of `'\\.\pipe\MySQL'` is used. If you use the `NamedPipeSocketFactory`, the host name and port number values in the JDBC url are ignored. To enable this feature, use:

```
socketFactory=com.mysql.jdbc.NamedPipeSocketFactory
```

Named pipes only work when connecting to a MySQL server on the same physical machine where the JDBC driver is running. In simple performance tests, named pipe access is between 30%-50% faster than the standard TCP/IP access. However, this varies per system, and named pipes are slower than TCP/IP in many Windows configurations.

To create your own socket factories, follow the example code in `com.mysql.jdbc.NamedPipeSocketFactory`, or `com.mysql.jdbc.StandardSocketFactory`.

Properties Files for the `useConfigs` Option

The `useConfigs` connection option is a convenient shorthand for specifying combinations of options for particular scenarios. The argument values you can use with this option correspond to the names of `.properties` files within the Connector/J `mysql-connector-java-`*`version`*`-bin.jar` JAR file. For example, the Connector/J 5.1.9 driver includes the following configuration properties files:

```
$ unzip mysql-connector-java-5.1.19-bin.jar '*/configs/*'
Archive:  mysql-connector-java-5.1.19-bin.jar
   creating: com/mysql/jdbc/configs/
  inflating: com/mysql/jdbc/configs/3-0-Compat.properties
  inflating: com/mysql/jdbc/configs/5-0-Compat.properties
  inflating: com/mysql/jdbc/configs/clusterBase.properties
  inflating: com/mysql/jdbc/configs/coldFusion.properties
  inflating: com/mysql/jdbc/configs/fullDebug.properties
  inflating: com/mysql/jdbc/configs/maxPerformance.properties
  inflating: com/mysql/jdbc/configs/solarisMaxPerformance.properties
```

To specify one of these combinations of options, specify `useConfigs=3-0-Compat`, `useConfigs=maxPerformance`, and so on. The following sections show the options that are part of each `useConfigs` setting. For the details of why each one is included, see the comments in the `.properties` files.

3-0-Compat

```
emptyStringsConvertToZero=true
jdbcCompliantTruncation=false
noDatetimeStringSync=true
nullCatalogMeansCurrent=true
nullNamePatternMatchesAll=true
transformedBitIsBoolean=false
dontTrackOpenResources=true
zeroDateTimeBehavior=convertToNull
useServerPrepStmts=false
autoClosePStmtStreams=true
processEscapeCodesForPrepStmts=false
useFastDateParsing=false
populateInsertRowWithDefaultValues=false
useDirectRowUnpack=false
```

5-0-Compat

```
useDirectRowUnpack=false
```

clusterBase

```
autoReconnect=true
failOverReadOnly=false
roundRobinLoadBalance=true
```

coldFusion

```
useDynamicCharsetInfo=false
alwaysSendSetIsolation=false
useLocalSessionState=true
autoReconnect=true
```

fullDebug

```
profileSQL=true
gatherPerMetrics=true
useUsageAdvisor=true
logSlowQueries=true
explainSlowQueries=true
```

maxPerformance

```
cachePrepStmts=true
cacheCallableStmts=true
cacheServerConfiguration=true
```

```
useLocalSessionState=true
elideSetAutoCommits=true
alwaysSendSetIsolation=false
enableQueryTimeouts=false
```

solarisMaxPerformance

```
useUnbufferedInput=false
useReadAheadInput=false
maintainTimeStats=false
```

JDBC API Implementation Notes

MySQL Connector/J passes all of the tests in the publicly available version of Sun's JDBC compliance test suite. This section gives details on a interface-by-interface level about implementation decisions that might affect how you code applications with MySQL Connector/J. The JDBC specification is vague about how certain functionality should be implemented, or the specification enables leeway in implementation.

- **BLOB**

  Starting with Connector/J version 3.1.0, you can emulate BLOBs with locators by adding the property `emulateLocators=true` to your JDBC URL. Using this method, the driver will delay loading the actual BLOB data until you retrieve the other data and then use retrieval methods (`getInputStream()`, `getBytes()`, and so forth) on the BLOB data stream.

  You must use a column alias with the value of the column to the actual name of the BLOB, for example:

  ```
  SELECT id, 'data' as blob_data from blobtable
  ```

  You must also follow these rules:

  - The `SELECT` must reference only one table. The table must have a primary key.
  - The `SELECT` must alias the original BLOB column name, specified as a string, to an alternate name.
  - The `SELECT` must cover all columns that make up the primary key.

  The BLOB implementation does not allow in-place modification (they are copies, as reported by the `DatabaseMetaData.locatorsUpdateCopies()` method). Because of this, use the corresponding `PreparedStatement.setBlob()` or `ResultSet.updateBlob()` (in the case of updatable result sets) methods to save changes back to the database.

- **CallableStatement**

  Starting with Connector/J 3.1.1, stored procedures are supported when connecting to MySQL version 5.0 or newer using the `CallableStatement` interface. Currently, the `getParameterMetaData()` method of `CallableStatement` is not supported.

- **CLOB**

  The CLOB implementation does not allow in-place modification (they are copies, as reported by the `DatabaseMetaData.locatorsUpdateCopies()` method). Because of this, use the `PreparedStatement.setClob()` method to save changes back to the database. The JDBC API does not have a `ResultSet.updateClob()` method.

- **Connection**

  Unlike the pre-Connector/J JDBC driver (`MM.MySQL`), the `isClosed()` method does not ping the server to determine if it is available. In accordance with the JDBC specification, it only returns true if `closed()` has been called on the connection. If you need to determine if the connection is still valid,

issue a simple query, such as `SELECT 1`. The driver will throw an exception if the connection is no longer valid.

- **DatabaseMetaData**

  Foreign key information (`getImportedKeys()`/`getExportedKeys()` and `getCrossReference()`) is only available from `InnoDB` tables. The driver uses `SHOW CREATE TABLE` to retrieve this information, so if any other storage engines add support for foreign keys, the driver would transparently support them as well.

- **PreparedStatement**

  PreparedStatements are implemented by the driver, as MySQL does not have a prepared statement feature. Because of this, the driver does not implement `getParameterMetaData()` or `getMetaData()` as it would require the driver to have a complete SQL parser in the client.

  Starting with version 3.1.0 MySQL Connector/J, server-side prepared statements and binary-encoded result sets are used when the server supports them.

  Take care when using a server-side prepared statement with **large** parameters that are set using `setBinaryStream()`, `setAsciiStream()`, `setUnicodeStream()`, `setBlob()`, or `setClob()`. To re-execute the statement with any large parameter changed to a nonlarge parameter, call `clearParameters()` and set all parameters again. The reason for this is as follows:

  - During both server-side prepared statements and client-side emulation, large data is exchanged only when `PreparedStatement.execute()` is called.
  - Once that has been done, the stream used to read the data on the client side is closed (as per the JDBC spec), and cannot be read from again.
  - If a parameter changes from large to nonlarge, the driver must reset the server-side state of the prepared statement to allow the parameter that is being changed to take the place of the prior large value. This removes all of the large data that has already been sent to the server, thus requiring the data to be re-sent, using the `setBinaryStream()`, `setAsciiStream()`, `setUnicodeStream()`, `setBlob()` or `setClob()` method.

  Consequently, to change the type of a parameter to a nonlarge one, you must call `clearParameters()` and set all parameters of the prepared statement again before it can be re-executed.

- **ResultSet**

  By default, ResultSets are completely retrieved and stored in memory. In most cases this is the most efficient way to operate, and due to the design of the MySQL network protocol is easier to implement. If you are working with ResultSets that have a large number of rows or large values, and cannot allocate heap space in your JVM for the memory required, you can tell the driver to stream the results back one row at a time.

  To enable this functionality, create a `Statement` instance in the following manner:

```
stmt = conn.createStatement(java.sql.ResultSet.TYPE_FORWARD_ONLY,
              java.sql.ResultSet.CONCUR_READ_ONLY);
stmt.setFetchSize(Integer.MIN_VALUE);
```

  The combination of a forward-only, read-only result set, with a fetch size of `Integer.MIN_VALUE` serves as a signal to the driver to stream result sets row-by-row. After this, any result sets created with the statement will be retrieved row-by-row.

  There are some caveats with this approach. You must read all of the rows in the result set (or close it) before you can issue any other queries on the connection, or an exception will be thrown.

The earliest the locks these statements hold can be released (whether they be `MyISAM` table-level locks or row-level locks in some other storage engine such as `InnoDB`) is when the statement completes.

If the statement is within scope of a transaction, then locks are released when the transaction completes (which implies that the statement needs to complete first). As with most other databases, statements are not complete until all the results pending on the statement are read or the active result set for the statement is closed.

Therefore, if using streaming results, process them as quickly as possible if you want to maintain concurrent access to the tables referenced by the statement producing the result set.

- **ResultSetMetaData**

  The `isAutoIncrement()` method only works when using MySQL servers 4.0 and newer.

- **Statement**

  When using versions of the JDBC driver earlier than 3.2.1, and connected to server versions earlier than 5.0.3, the `setFetchSize()` method has no effect, other than to toggle result set streaming as described above.

  Connector/J 5.0.0 and later include support for both `Statement.cancel()` and `Statement.setQueryTimeout()`. Both require MySQL 5.0.0 or newer server, and require a separate connection to issue the `KILL QUERY` statement. In the case of `setQueryTimeout()`, the implementation creates an additional thread to handle the timeout functionality.

  Note

  Failures to cancel the statement for `setQueryTimeout()` may manifest themselves as `RuntimeException` rather than failing silently, as there is currently no way to unblock the thread that is executing the query being cancelled due to timeout expiration and have it throw the exception instead.

  Note

  The MySQL statement `KILL QUERY` (which is what the driver uses to implement `Statement.cancel()`) is non-deterministic; thus, avoid the use of `Statement.cancel()` if possible. If no query is in process, the next query issued will be killed by the server. This race condition is guarded against as of Connector/J 5.1.18.

  MySQL does not support SQL cursors, and the JDBC driver doesn't emulate them, so `setCursorName()` has no effect.

  Connector/J 5.1.3 and later include two additional methods:

  - `setLocalInfileInputStream()` sets an `InputStream` instance that will be used to send data to the MySQL server for a `LOAD DATA LOCAL INFILE` statement rather than a `FileInputStream` or `URLInputStream` that represents the path given as an argument to the statement.

    This stream will be read to completion upon execution of a `LOAD DATA LOCAL INFILE` statement, and will automatically be closed by the driver, so it needs to be reset before each call to `execute*()` that would cause the MySQL server to request data to fulfill the request for `LOAD DATA LOCAL INFILE`.

    If this value is set to `NULL`, the driver will revert to using a `FileInputStream` or `URLInputStream` as required.

- `getLocalInfileInputStream()` returns the `InputStream` instance that will be used to send data in response to a `LOAD DATA LOCAL INFILE` statement.

  This method returns `NULL` if no such stream has been set using `setLocalInfileInputStream()`.

Java, JDBC and MySQL Types

MySQL Connector/J is flexible in the way it handles conversions between MySQL data types and Java data types.

In general, any MySQL data type can be converted to a `java.lang.String`, and any numeric type can be converted to any of the Java numeric types, although round-off, overflow, or loss of precision may occur.

Note

All `TEXT` types return `Types.LONGVARCHAR` with different `getPrecision()` values (65535, 255, 16777215, and 2147483647 respectively) with `getColumnType()` returning `-1`. This behavior is intentional even though `TINYTEXT` does not fall, regarding to its size, within the `LONGVARCHAR` category. This is to avoid different handling inside the same base type. And `getColumnType()` returns `-1` because the internal server handling is of type `TEXT`, which is similar to `BLOB`.

Also note that `getColumnTypeName()` will return `VARCHAR` even though `getColumnType()` returns `Types.LONGVARCHAR`, because `VARCHAR` is the designated column database-specific name for this type.

Starting with Connector/J 3.1.0, the JDBC driver issues warnings or throws `DataTruncation` exceptions as is required by the JDBC specification unless the connection was configured not to do so by using the property `jdbcCompliantTruncation` and setting it to `false`.

The conversions that are always guaranteed to work are listed in the following table:

Connection Properties - Miscellaneous.

These MySQL Data Types	Can always be converted to these Java types
`CHAR, VARCHAR, BLOB, TEXT, ENUM, and SET`	`java.lang.String, java.io.InputStream, java.io.Reader, java.sql.Blob, java.sql.Clob`
`FLOAT, REAL, DOUBLE PRECISION, NUMERIC, DECIMAL, TINYINT, SMALLINT, MEDIUMINT, INTEGER, BIGINT`	`java.lang.String, java.lang.Short, java.lang.Integer, java.lang.Long, java.lang.Double, java.math.BigDecimal`
`DATE, TIME, DATETIME, TIMESTAMP`	`java.lang.String, java.sql.Date, java.sql.Timestamp`

Note

Round-off, overflow or loss of precision may occur if you choose a Java numeric data type that has less precision or capacity than the MySQL data type you are converting to/from.

The `ResultSet.getObject()` method uses the type conversions between MySQL and Java types, following the JDBC specification where appropriate. The value returned by `ResultSetMetaData.GetColumnClassName()` is also shown below. For more information on the `java.sql.Types` classes see Java 2 Platform Types.

MySQL Types to Java Types for ResultSet.getObject().

MySQL Type Name	Return value of `GetColumnClassName`	Returned as Java Class
`BIT(1)` (new in MySQL-5.0)	`BIT`	`java.lang.Boolean`
`BIT( > 1)` (new in MySQL-5.0)	`BIT`	`byte[]`
`TINYINT`	`TINYINT`	`java.lang.Boolean` if the configuration property `tinyInt1isBit` is set to `true` (the default) and the storage size is 1, or `java.lang.Integer` if not.
`BOOL`, `BOOLEAN`	`TINYINT`	See `TINYINT`, above as these are aliases for `TINYINT(1)`, currently.
`SMALLINT[(M)] [UNSIGNED]`	`SMALLINT [UNSIGNED]`	`java.lang.Integer` (regardless if `UNSIGNED` or not)
`MEDIUMINT[(M)] [UNSIGNED]`	`MEDIUMINT [UNSIGNED]`	`java.lang.Integer,` if `UNSIGNED` `java.lang.Long` (C/J 3.1 and earlier), or `java.lang.Integer` for C/J 5.0 and later
`INT,INTEGER[(M)] [UNSIGNED]`	`INTEGER [UNSIGNED]`	`java.lang.Integer`, if `UNSIGNED` `java.lang.Long`
`BIGINT[(M)] [UNSIGNED]`	`BIGINT [UNSIGNED]`	`java.lang.Long`, if UNSIGNED `java.math.BigInteger`
`FLOAT[(M,D)]`	`FLOAT`	`java.lang.Float`
`DOUBLE[(M,B)]`	`DOUBLE`	`java.lang.Double`
`DECIMAL[(M[,D])]`	`DECIMAL`	`java.math.BigDecimal`
`DATE`	`DATE`	`java.sql.Date`
`DATETIME`	`DATETIME`	`java.sql.Timestamp`
`TIMESTAMP[(M)]`	`TIMESTAMP`	`java.sql.Timestamp`
`TIME`	`TIME`	`java.sql.Time`
`YEAR[(2|4)]`	`YEAR`	If `yearIsDateType` configuration property is set to `false`, then the returned object type is `java.sql.Short`. If set to `true` (the default), then the returned object is of type `java.sql.Date` with the date set to January 1st, at midnight.
`CHAR(M)`	`CHAR`	`java.lang.String` (unless the character set for the column is `BINARY`, then `byte[]` is returned.
`VARCHAR(M) [BINARY]`	`VARCHAR`	`java.lang.String` (unless the character set for the column is `BINARY`, then `byte[]` is returned.
`BINARY(M)`	`BINARY`	`byte[]`
`VARBINARY(M)`	`VARBINARY`	`byte[]`
`TINYBLOB`	`TINYBLOB`	`byte[]`
`TINYTEXT`	`VARCHAR`	`java.lang.String`
`BLOB`	`BLOB`	`byte[]`
`TEXT`	`VARCHAR`	`java.lang.String`
`MEDIUMBLOB`	`MEDIUMBLOB`	`byte[]`
`MEDIUMTEXT`	`VARCHAR`	`java.lang.String`

MySQL Type Name	Return value of GetColumnClassName	Returned as Java Class
LONGBLOB	LONGBLOB	byte[]
LONGTEXT	VARCHAR	java.lang.String
ENUM('value1','value2',...)	CHAR	java.lang.String
SET('value1','value2',..)	CHAR	java.lang.String

Using Character Sets and Unicode

All strings sent from the JDBC driver to the server are converted automatically from native Java Unicode form to the client character encoding, including all queries sent using `Statement.execute()`, `Statement.executeUpdate()`, `Statement.executeQuery()` as well as all `PreparedStatement` and `CallableStatement` parameters with the exclusion of parameters set using `setBytes()`, `setBinaryStream()`, `setAsciiStream()`, `setUnicodeStream()` and `setBlob()`.

Number of Encodings Per Connection

In MySQL Server 4.1 and higher, Connector/J supports a single character encoding between client and server, and any number of character encodings for data returned by the server to the client in `ResultSets`.

Prior to MySQL Server 4.1, Connector/J supported a single character encoding per connection, which could either be automatically detected from the server configuration, or could be configured by the user through the *`useUnicode`* and *`characterEncoding`* properties.

Setting the Character Encoding

The character encoding between client and server is automatically detected upon connection. You specify the encoding on the server using the `character_set_server` [465] for server versions 4.1.0 and newer, and `character_set` system variable for server versions older than 4.1.0. The driver automatically uses the encoding specified by the server. For more information, see Server Character Set and Collation.

For example, to use 4-byte UTF-8 character sets with Connector/J, configure the MySQL server with `character_set_server=utf8mb4` [465], and leave `characterEncoding` out of the Connector/J connection string. Connector/J will then autodetect the UTF-8 setting.

To override the automatically detected encoding on the client side, use the *`characterEncoding`* property in the URL used to connect to the server.

To allow multiple character sets to be sent from the client, use the UTF-8 encoding, either by configuring `utf8` as the default server character set, or by configuring the JDBC driver to use UTF-8 through the `characterEncoding` property.

When specifying character encodings on the client side, use Java-style names. The following table lists Java-style names for MySQL character sets:

MySQL to Java Encoding Name Translations.

MySQL Character Set Name	Java-Style Character Encoding Name
ascii	US-ASCII
big5	Big5
gbk	GBK
sjis	SJIS (or Cp932 or MS932 for MySQL Server < 4.1.11)
cp932	Cp932 or MS932 (MySQL Server > 4.1.11)

MySQL Character Set Name	Java-Style Character Encoding Name
gb2312	EUC_CN
ujis	EUC_JP
euckr	EUC_KR
latin1	Cp1252
latin2	ISO8859_2
greek	ISO8859_7
hebrew	ISO8859_8
cp866	Cp866
tis620	TIS620
cp1250	Cp1250
cp1251	Cp1251
cp1257	Cp1257
macroman	MacRoman
macce	MacCentralEurope
utf8	UTF-8
ucs2	UnicodeBig

Warning

Do not issue the query `set names` with Connector/J, as the driver will not detect that the character set has changed, and will continue to use the character set detected during the initial connection setup.

Connecting Securely Using SSL

SSL in MySQL Connector/J encrypts all data (other than the initial handshake) between the JDBC driver and the server. The performance penalty for enabling SSL is an increase in query processing time between 35% and 50%, depending on the size of the query, and the amount of data it returns.

For SSL support to work, you must have the following:

- A JDK that includes JSSE (Java Secure Sockets Extension), like JDK-1.4.1 or newer. SSL does not currently work with a JDK that you can add JSSE to, like JDK-1.2.x or JDK-1.3.x due to the following JSSE bug: http://developer.java.sun.com/developer/bugParade/bugs/4273544.html
- A MySQL server that supports SSL and has been compiled and configured to do so, which is MySQL 4.0.4 or later. For more information, see Configuring MySQL for SSL.
- A client certificate (covered later in this section)

The system works through two Java truststore files, one file contains the certificate information for the server (`truststore` in the examples below). The other file contains the certificate for the client (`keystore` in the examples below). All Java truststore files are password protected by supplying a suitable password to the `keytool` when you create the files. You need the file names and associated passwords to create an SSL connection.

You will first need to import the MySQL server CA Certificate into a Java truststore. A sample MySQL server CA Certificate is located in the `SSL` subdirectory of the MySQL source distribution. This is what SSL will use to determine if you are communicating with a secure MySQL server. Alternatively, use the CA Certificate that you have generated or been provided with by your SSL provider.

To use Java's `keytool` to create a truststore in the current directory , and import the server's CA certificate (`cacert.pem`), you can do the following (assuming that `keytool` is in your path. The `keytool` is typically located in the `bin` subdirectory of your JDK or JRE):

```
shell> keytool -import -alias mysqlServerCACert \
      -file cacert.pem -keystore truststore
```

Enter the password when prompted for the keystore file. Interaction with `keytool` looks like this:

```
Enter keystore password:  *********
Owner: EMAILADDRESS=walrus@example.com, CN=Walrus,
       O=MySQL AB, L=Orenburg, ST=Some-State, C=RU
Issuer: EMAILADDRESS=walrus@example.com, CN=Walrus,
       O=MySQL AB, L=Orenburg, ST=Some-State, C=RU
Serial number: 0
Valid from:
   Fri Aug 02 16:55:53 CDT 2002 until: Sat Aug 02 16:55:53 CDT 2003
Certificate fingerprints:
    MD5:  61:91:A0:F2:03:07:61:7A:81:38:66:DA:19:C4:8D:AB
    SHA1: 25:77:41:05:D5:AD:99:8C:14:8C:CA:68:9C:2F:B8:89:C3:34:4D:6C
Trust this certificate? [no]:  yes
Certificate was added to keystore
```

You then have two options: either import the client certificate that matches the CA certificate you just imported, or create a new client certificate.

Importing an existing certificate requires the certificate to be in DER format. You can use `openssl` to convert an existing certificate into the new format. For example:

```
shell> openssl x509 -outform DER -in client-cert.pem -out client.cert
```

Now import the converted certificate into your keystore using `keytool`:

```
shell> keytool -import -file client.cert -keystore keystore -alias mysqlClientCertificate
```

To generate your own client certificate, use `keytool` to create a suitable certificate and add it to the `keystore` file:

```
shell> keytool -genkey -keyalg rsa \
     -alias mysqlClientCertificate -keystore keystore
```

Keytool will prompt you for the following information, and create a keystore named `keystore` in the current directory.

Respond with information that is appropriate for your situation:

```
Enter keystore password:  *********
What is your first and last name?
  [Unknown]:  Matthews
What is the name of your organizational unit?
  [Unknown]:  Software Development
What is the name of your organization?
  [Unknown]:  MySQL AB
What is the name of your City or Locality?
  [Unknown]:  Flossmoor
What is the name of your State or Province?
  [Unknown]:  IL
What is the two-letter country code for this unit?
  [Unknown]:  US
Is <CN=Matthews, OU=Software Development, O=MySQL AB,
 L=Flossmoor, ST=IL, C=US> correct?
  [no]:  y

Enter key password for <mysqlClientCertificate>
        (RETURN if same as keystore password):
```

Finally, to get JSSE to use the keystore and truststore that you have generated, you need to set the following system properties when you start your JVM, replacing *`path_to_keystore_file`* with the full path to the keystore file you created, *`path_to_truststore_file`* with the path to the truststore file you created, and using the appropriate password values for each property. You can do this either on the command line:

```
-Djavax.net.ssl.keyStore=path_to_keystore_file
-Djavax.net.ssl.keyStorePassword=password
```

```
-Djavax.net.ssl.trustStore=path_to_truststore_file
-Djavax.net.ssl.trustStorePassword=password
```

Or you can set the values directly within the application:

```
System.setProperty("javax.net.ssl.keyStore","path_to_keystore_file");
System.setProperty("javax.net.ssl.keyStorePassword","password");
System.setProperty("javax.net.ssl.trustStore","path_to_truststore_file");
System.setProperty("javax.net.ssl.trustStorePassword","password");
```

You will also need to set `useSSL` to `true` in your connection parameters for MySQL Connector/J, either by adding `useSSL=true` to your URL, or by setting the property `useSSL` to `true` in the `java.util.Properties` instance you pass to `DriverManager.getConnection()`.

You can test that SSL is working by turning on JSSE debugging (as detailed below), and look for the following key events:

```

JSSE provides debugging (to `stdout`) when you set the following system property: `-Djavax.net.debug=all` This will tell you what keystores and truststores are being used, as well as what is going on during the SSL handshake and certificate exchange. It will be helpful when trying to determine what is not working when trying to get an SSL connection to happen.

Connecting Using PAM Authentication

Java applications using Connector/J 5.1.21 and higher can can connect to MySQL servers that use the pluggable authentication module (PAM) authentication scheme.

For PAM authentication to work, you must have the following:

- A MySQL server that supports PAM authentication: a commercial distribution of MySQL 5.5.16 or higher. See The PAM Authentication Plugin for more information. Connector/J implements the same cleartext authentication method as in The Cleartext Client-Side Authentication Plugin.

- SSL capability, as explained in Connecting Securely Using SSL. Because the PAM authentication scheme sends the original password to the server, the connection to the server must be encrypted.

PAM authentication support is enabled by default in Connector/J 5.1.21 and up, so no extra configuration is needed.

To disable the PAM authentication feature, specify `mysql_clear_password` (the method) or `com.mysql.jdbc.authentication.MysqlClearPasswordPlugin` (the class name) in the comma-separated list of arguments for the `disabledAuthenticationPlugins` connection option. See Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J for details about that connection option.

Using Master/Slave Replication with ReplicationConnection

Connector/J 3.1.7 and higher includes a variant of the driver that will automatically send queries to a read/write master, or a failover or round-robin loadbalanced set of slaves based on the state of `Connection.getReadOnly()`.

An application signals that it wants a transaction to be read-only by calling `Connection.setReadOnly(true)`, this replication-aware connection will use one of the slave connections, which are load-balanced per-vm using a round-robin scheme (a given connection is sticky to a slave unless that slave is removed from service). If you have a write transaction, or if you have a read that is time-sensitive (remember, replication in MySQL is asynchronous), set the connection to be not read-only, by calling `Connection.setReadOnly(false)` and the driver will ensure that further calls are sent to the master MySQL server. The driver takes care of propagating the current state of autocommit, isolation level, and catalog between all of the connections that it uses to accomplish this load balancing functionality.

To enable this functionality, use the `com.mysql.jdbc.ReplicationDriver` class when configuring your application server's connection pool or when creating an instance of a JDBC driver for your standalone application. Because it accepts the same URL format as the standard MySQL JDBC driver, `ReplicationDriver` does not currently work with `java.sql.DriverManager`-based connection creation unless it is the only MySQL JDBC driver registered with the `DriverManager` .

Here is a short example of how `ReplicationDriver` might be used in a standalone application:

```
import java.sql.Connection;
import java.sql.ResultSet;
import java.util.Properties;

import com.mysql.jdbc.ReplicationDriver;

public class ReplicationDriverDemo {

  public static void main(String[] args) throws Exception {
    ReplicationDriver driver = new ReplicationDriver();

    Properties props = new Properties();

    // We want this for failover on the slaves
    props.put("autoReconnect", "true");

    // We want to load balance between the slaves
    props.put("roundRobinLoadBalance", "true");

    props.put("user", "foo");
    props.put("password", "bar");

    //
    // Looks like a normal MySQL JDBC url, with a
    // comma-separated list of hosts, the first
    // being the 'master', the rest being any number
    // of slaves that the driver will load balance against
    //

    Connection conn =
```

```
        driver.connect("jdbc:mysql:replication://master,slave1,slave2,slave3/test",
            props);

    //
    // Perform read/write work on the master
    // by setting the read-only flag to "false"
    //

    conn.setReadOnly(false);
    conn.setAutoCommit(false);
    conn.createStatement().executeUpdate("UPDATE some_table ....");
    conn.commit();

    //
    // Now, do a query from a slave, the driver automatically picks one
    // from the list
    //

    conn.setReadOnly(true);

    ResultSet rs =
      conn.createStatement().executeQuery("SELECT a,b FROM alt_table");

     .......
  }
}
```

Consider investigating the Load Balancing JDBC Pool (`lbpool`) tool, which provides a wrapper around the standard JDBC driver and enables you to use DB connection pools that includes checks for system failures and uneven load distribution. For more information, see Load Balancing JDBC Pool (lbpool).

Mapping MySQL Error Numbers to JDBC SQLState Codes

The table below provides a mapping of the MySQL error numbers to JDBC `SQLState` values.

Table 21.8. Mapping of MySQL Error Numbers to SQLStates

MySQL Error Number	MySQL Error Name	Legacy (X/Open) SQLState	SQL Standard SQLState

JDBC Concepts

This section provides some general JDBC background.

Connecting to MySQL Using the JDBC `DriverManager` Interface

When you are using JDBC outside of an application server, the `DriverManager` class manages the establishment of Connections.

Specify to the `DriverManager` which JDBC drivers to try to make Connections with. The easiest way to do this is to use `Class.forName()` on the class that implements the `java.sql.Driver` interface. With MySQL Connector/J, the name of this class is `com.mysql.jdbc.Driver`. With this method, you could use an external configuration file to supply the driver class name and driver parameters to use when connecting to a database.

The following section of Java code shows how you might register MySQL Connector/J from the `main()` method of your application. If testing this code, first read the installation section at Connector/J Installation, to make sure you have connector installed correctly and the `CLASSPATH` set up. Also, ensure that MySQL is configured to accept external TCP/IP connections.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;

// Notice, do not import com.mysql.jdbc.*
// or you will have problems!

public class LoadDriver {
    public static void main(String[] args) {
        try {
            // The newInstance() call is a work around for some
            // broken Java implementations

            Class.forName("com.mysql.jdbc.Driver").newInstance();
        } catch (Exception ex) {
            // handle the error
        }
    }
}
```

After the driver has been registered with the `DriverManager`, you can obtain a `Connection` instance that is connected to a particular database by calling `DriverManager.getConnection()`:

Example 21.1. Connector/J: Obtaining a connection from the `DriverManager`

If you have not already done so, please review the section Connecting to MySQL Using the JDBC `DriverManager` Interface before working with these examples.

This example shows how you can obtain a `Connection` instance from the `DriverManager`. There are a few different signatures for the `getConnection()` method. Consult the API documentation that comes with your JDK for more specific information on how to use them.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;

Connection conn = null;
...
try {
    conn =
       DriverManager.getConnection("jdbc:mysql://localhost/test?" +
                                   "user=monty&password=greatsqldb");

    // Do something with the Connection

   ...
} catch (SQLException ex) {
    // handle any errors
    System.out.println("SQLException: " + ex.getMessage());
    System.out.println("SQLState: " + ex.getSQLState());
    System.out.println("VendorError: " + ex.getErrorCode());
}
```

Once a `Connection` is established, it can be used to create `Statement` and `PreparedStatement` objects, as well as retrieve metadata about the database. This is explained in the following sections.

Using JDBC `Statement` Objects to Execute SQL

`Statement` objects allow you to execute basic SQL queries and retrieve the results through the `ResultSet` class, which is described later.

To create a `Statement` instance, you call the `createStatement()` method on the `Connection` object you have retrieved using one of the `DriverManager.getConnection()` or `DataSource.getConnection()` methods described earlier.

Once you have a `Statement` instance, you can execute a `SELECT` query by calling the `executeQuery(String)` method with the SQL you want to use.

To update data in the database, use the `executeUpdate(String SQL)` method. This method returns the number of rows matched by the update statement, not the number of rows that were modified.

If you do not know ahead of time whether the SQL statement will be a `SELECT` or an `UPDATE`/`INSERT`, then you can use the `execute(String SQL)` method. This method will return true if the SQL query was a `SELECT`, or false if it was an `UPDATE`, `INSERT`, or `DELETE` statement. If the statement was a `SELECT` query, you can retrieve the results by calling the `getResultSet()` method. If the statement was an `UPDATE`, `INSERT`, or `DELETE` statement, you can retrieve the affected rows count by calling `getUpdateCount()` on the `Statement` instance.

Example 21.2. Connector/J: Using java.sql.Statement to execute a `SELECT` query

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.sql.Statement;
import java.sql.ResultSet;

// assume that conn is an already created JDBC connection (see previous examples)

Statement stmt = null;
ResultSet rs = null;

try {
    stmt = conn.createStatement();
    rs = stmt.executeQuery("SELECT foo FROM bar");

    // or alternatively, if you don't know ahead of time that
    // the query will be a SELECT...

    if (stmt.execute("SELECT foo FROM bar")) {
        rs = stmt.getResultSet();
    }

    // Now do something with the ResultSet ....
}
catch (SQLException ex){
    // handle any errors
    System.out.println("SQLException: " + ex.getMessage());
    System.out.println("SQLState: " + ex.getSQLState());
    System.out.println("VendorError: " + ex.getErrorCode());
}
finally {
    // it is a good idea to release
    // resources in a finally{} block
    // in reverse-order of their creation
    // if they are no-longer needed

    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException sqlEx) { } // ignore
```

```
            rs = null;
        }

        if (stmt != null) {
            try {
                stmt.close();
            } catch (SQLException sqlEx) { } // ignore

            stmt = null;
        }
    }
```

Using JDBC `CallableStatements` to Execute Stored Procedures

Starting with MySQL server version 5.0 when used with Connector/J 3.1.1 or newer, the `java.sql.CallableStatement` interface is fully implemented with the exception of the `getParameterMetaData()` method.

For more information on MySQL stored procedures, please refer to http://dev.mysql.com/doc/mysql/en/stored-routines.html.

Connector/J exposes stored procedure functionality through JDBC's `CallableStatement` interface.

Note

Current versions of MySQL server do not return enough information for the JDBC driver to provide result set metadata for callable statements. This means that when using `CallableStatement`, `ResultSetMetaData` may return `NULL`.

The following example shows a stored procedure that returns the value of `inOutParam` incremented by 1, and the string passed in using `inputParam` as a `ResultSet`:

Example 21.3. Connector/J: Calling Stored Procedures

```
CREATE PROCEDURE demoSp(IN inputParam VARCHAR(255), \
                        INOUT inOutParam INT)
BEGIN
    DECLARE z INT;
    SET z = inOutParam + 1;
    SET inOutParam = z;

    SELECT inputParam;

    SELECT CONCAT('zyxw', inputParam);
END
```

To use the `demoSp` procedure with Connector/J, follow these steps:

1. Prepare the callable statement by using `Connection.prepareCall()`.

   Notice that you have to use JDBC escape syntax, and that the parentheses surrounding the parameter placeholders are not optional:

   Example 21.4. Connector/J: Using `Connection.prepareCall()`

   ```
   import java.sql.CallableStatement;

   ...

       //
       // Prepare a call to the stored procedure 'demoSp'
       // with two parameters
       //
       // Notice the use of JDBC-escape syntax ({call ...})
       //

       CallableStatement cStmt = conn.prepareCall("{call demoSp(?, ?)}");
   ```

```
    cStmt.setString(1, "abcdefg");
```

Note

`Connection.prepareCall()` is an expensive method, due to the metadata retrieval that the driver performs to support output parameters. For performance reasons, minimize unnecessary calls to `Connection.prepareCall()` by reusing `CallableStatement` instances in your code.

2. Register the output parameters (if any exist)

   To retrieve the values of output parameters (parameters specified as `OUT` or `INOUT` when you created the stored procedure), JDBC requires that they be specified before statement execution using the various `registerOutputParameter()` methods in the `CallableStatement` interface:

   Example 21.5. Connector/J: Registering output parameters

```
import java.sql.Types;
...
//
// Connector/J supports both named and indexed
// output parameters. You can register output
// parameters using either method, as well
// as retrieve output parameters using either
// method, regardless of what method was
// used to register them.
//
// The following examples show how to use
// the various methods of registering
// output parameters (you should of course
// use only one registration per parameter).
//

//
// Registers the second parameter as output, and
// uses the type 'INTEGER' for values returned from
// getObject()
//

cStmt.registerOutParameter(2, Types.INTEGER);

//
// Registers the named parameter 'inOutParam', and
// uses the type 'INTEGER' for values returned from
// getObject()
//

cStmt.registerOutParameter("inOutParam", Types.INTEGER);
...
```

3. Set the input parameters (if any exist)

   Input and in/out parameters are set as for `PreparedStatement` objects. However, `CallableStatement` also supports setting parameters by name:

   Example 21.6. Connector/J: Setting `CallableStatement` input parameters

```
...

    //
    // Set a parameter by index
    //

    cStmt.setString(1, "abcdefg");
```

```
    //
    // Alternatively, set a parameter using
    // the parameter name
    //

    cStmt.setString("inputParameter", "abcdefg");

    //
    // Set the 'in/out' parameter using an index
    //

    cStmt.setInt(2, 1);

    //
    // Alternatively, set the 'in/out' parameter
    // by name
    //

    cStmt.setInt("inOutParam", 1);

...
```

4. Execute the `CallableStatement`, and retrieve any result sets or output parameters.

   Although `CallableStatement` supports calling any of the `Statement` execute methods (`executeUpdate()`, `executeQuery()` or `execute()`), the most flexible method to call is `execute()`, as you do not need to know ahead of time if the stored procedure returns result sets:

   Example 21.7. Connector/J: Retrieving results and output parameter values

```
...

    boolean hadResults = cStmt.execute();

    //
    // Process all returned result sets
    //

    while (hadResults) {
        ResultSet rs = cStmt.getResultSet();

        // process result set
        ...

        hadResults = cStmt.getMoreResults();
    }

    //
    // Retrieve output parameters
    //
    // Connector/J supports both index-based and
    // name-based retrieval
    //

    int outputValue = cStmt.getInt(2); // index-based

    outputValue = cStmt.getInt("inOutParam"); // name-based

...
```

Retrieving `AUTO_INCREMENT` Column Values through JDBC

Before version 3.0 of the JDBC API, there was no standard way of retrieving key values from databases that supported auto increment or identity columns. With older JDBC drivers for MySQL, you could always use a MySQL-specific method on the `Statement` interface, or issue the query `SELECT LAST_INSERT_ID()` after issuing an `INSERT` to a table that had an `AUTO_INCREMENT` key. Using the MySQL-specific method call isn't portable, and issuing a `SELECT` to get the `AUTO_INCREMENT` key's value requires another round-trip to the database, which isn't as efficient as possible. The

following code snippets demonstrate the three different ways to retrieve `AUTO_INCREMENT` values. First, we demonstrate the use of the new JDBC 3.0 method `getGeneratedKeys()` which is now the preferred method to use if you need to retrieve `AUTO_INCREMENT` keys and have access to JDBC 3.0. The second example shows how you can retrieve the same value using a standard `SELECT LAST_INSERT_ID()` query. The final example shows how updatable result sets can retrieve the `AUTO_INCREMENT` value when using the `insertRow()` method.

Example 21.8. Connector/J: Retrieving `AUTO_INCREMENT` column values using `Statement.getGeneratedKeys()`

```
   Statement stmt = null;
   ResultSet rs = null;

   try {

    //
    // Create a Statement instance that we can use for
    // 'normal' result sets assuming you have a
    // Connection 'conn' to a MySQL database already
    // available

    stmt = conn.createStatement(java.sql.ResultSet.TYPE_FORWARD_ONLY,
                                java.sql.ResultSet.CONCUR_UPDATABLE);

    //
    // Issue the DDL queries for the table for this example
    //

    stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
    stmt.executeUpdate(
            "CREATE TABLE autoIncTutorial ("
            + "priKey INT NOT NULL AUTO_INCREMENT, "
            + "dataField VARCHAR(64), PRIMARY KEY (priKey))");

    //
    // Insert one row that will generate an AUTO INCREMENT
    // key in the 'priKey' field
    //

    stmt.executeUpdate(
            "INSERT INTO autoIncTutorial (dataField) "
            + "values ('Can I Get the Auto Increment Field?')",
            Statement.RETURN_GENERATED_KEYS);

    //
    // Example of using Statement.getGeneratedKeys()
    // to retrieve the value of an auto-increment
    // value
    //

    int autoIncKeyFromApi = -1;

    rs = stmt.getGeneratedKeys();

    if (rs.next()) {
        autoIncKeyFromApi = rs.getInt(1);
    } else {

        // throw an exception from here
    }

    rs.close();

    rs = null;

    System.out.println("Key returned from getGeneratedKeys():"
        + autoIncKeyFromApi);
} finally {

    if (rs != null) {
        try {
```

```
            rs.close();
        } catch (SQLException ex) {
            // ignore
        }
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException ex) {
            // ignore
        }
    }
}
```

Example 21.9. Connector/J: Retrieving `AUTO_INCREMENT` column values using `SELECT LAST_INSERT_ID()`

```
   Statement stmt = null;
   ResultSet rs = null;

   try {

    //
    // Create a Statement instance that we can use for
    // 'normal' result sets.

    stmt = conn.createStatement();

    //
    // Issue the DDL queries for the table for this example
    //

    stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
    stmt.executeUpdate(
            "CREATE TABLE autoIncTutorial ("
            + "priKey INT NOT NULL AUTO_INCREMENT, "
            + "dataField VARCHAR(64), PRIMARY KEY (priKey))");

    //
    // Insert one row that will generate an AUTO INCREMENT
    // key in the 'priKey' field
    //

    stmt.executeUpdate(
            "INSERT INTO autoIncTutorial (dataField) "
            + "values ('Can I Get the Auto Increment Field?')");

    //
    // Use the MySQL LAST_INSERT_ID()
    // function to do the same thing as getGeneratedKeys()
    //

    int autoIncKeyFromFunc = -1;
    rs = stmt.executeQuery("SELECT LAST_INSERT_ID()");

    if (rs.next()) {
        autoIncKeyFromFunc = rs.getInt(1);
    } else {
        // throw an exception from here
    }

    rs.close();

    System.out.println("Key returned from " +
                       "'SELECT LAST_INSERT_ID()': " +
                       autoIncKeyFromFunc);

} finally {

    if (rs != null) {
        try {
```

```
            rs.close();
        } catch (SQLException ex) {
            // ignore
        }
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException ex) {
            // ignore
        }
    }
}
```

Example 21.10. Connector/J: Retrieving `AUTO_INCREMENT` column values in `Updatable ResultSets`

```
   Statement stmt = null;
   ResultSet rs = null;

   try {

    //
    // Create a Statement instance that we can use for
    // 'normal' result sets as well as an 'updatable'
    // one, assuming you have a Connection 'conn' to
    // a MySQL database already available
    //

    stmt = conn.createStatement(java.sql.ResultSet.TYPE_FORWARD_ONLY,
                                java.sql.ResultSet.CONCUR_UPDATABLE);

    //
    // Issue the DDL queries for the table for this example
    //

    stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
    stmt.executeUpdate(
            "CREATE TABLE autoIncTutorial ("
            + "priKey INT NOT NULL AUTO_INCREMENT, "
            + "dataField VARCHAR(64), PRIMARY KEY (priKey))");

    //
    // Example of retrieving an AUTO INCREMENT key
    // from an updatable result set
    //

    rs = stmt.executeQuery("SELECT priKey, dataField "
       + "FROM autoIncTutorial");

    rs.moveToInsertRow();

    rs.updateString("dataField", "AUTO INCREMENT here?");
    rs.insertRow();

    //
    // the driver adds rows at the end
    //

    rs.last();

    //
    // We should now be on the row we just inserted
    //

    int autoIncKeyFromRS = rs.getInt("priKey");

    rs.close();

    rs = null;
```

```
    System.out.println("Key returned for inserted row: "
        + autoIncKeyFromRS);

} finally {

    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException ex) {
            // ignore
        }
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException ex) {
            // ignore
        }
    }
}
```

Running the preceding example code should produce the following output:

```
Key returned from getGeneratedKeys(): 1
Key returned from SELECT LAST_INSERT_ID(): 1
Key returned for inserted row: 2
```

At times, it can be tricky to use the `SELECT LAST_INSERT_ID()` query, as that function's value is scoped to a connection. So, if some other query happens on the same connection, the value is overwritten. On the other hand, the `getGeneratedKeys()` method is scoped by the `Statement` instance, so it can be used even if other queries happen on the same connection, but not on the same `Statement` instance.

Connection Pooling with Connector/J

Connection pooling is a technique of creating and managing a pool of connections that are ready for use by any thread that needs them. Connection pooling can greatly increase the performance of your Java application, while reducing overall resource usage.

How Connection Pooling Works

Most applications only need a thread to have access to a JDBC connection when they are actively processing a transaction, which often takes only milliseconds to complete. When not processing a transaction, the connection sits idle. Connection pooling enables the idle connection to be used by some other thread to do useful work.

In practice, when a thread needs to do work against a MySQL or other database with JDBC, it requests a connection from the pool. When the thread is finished using the connection, it returns it to the pool, so that it can be used by any other threads.

When the connection is loaned out from the pool, it is used exclusively by the thread that requested it. From a programming point of view, it is the same as if your thread called `DriverManager.getConnection()` every time it needed a JDBC connection. With connection pooling, your thread may end up using either a new connection or an already-existing connection.

Benefits of Connection Pooling

The main benefits to connection pooling are:

- Reduced connection creation time.

  Although this is not usually an issue with the quick connection setup that MySQL offers compared to other databases, creating new JDBC connections still incurs networking and JDBC driver overhead that will be avoided if connections are recycled.

- Simplified programming model.

  When using connection pooling, each individual thread can act as though it has created its own JDBC connection, allowing you to use straightforward JDBC programming techniques.

- Controlled resource usage.

  If you create a new connection every time a thread needs one, rather than using connection pooling, your application's resource usage can be wasteful and lead to unpredictable behavior under load.

Using Connection Pooling with Connector/J

Sun has standardized the concept of connection pooling in JDBC through the JDBC 2.0 Optional interfaces, and all major application servers have implementations of these APIs that work with MySQL Connector/J.

Generally, you configure a connection pool in your application server configuration files, and access it through the Java Naming and Directory Interface (JNDI). The following code shows how you might use a connection pool from an application deployed in a J2EE application server:

Example 21.11. Connector/J: Using a connection pool with a J2EE application server

```
import java.sql.Connection;
import java.sql.SQLException;
import java.sql.Statement;

import javax.naming.InitialContext;
import javax.sql.DataSource;

public class MyServletJspOrEjb {

    public void doSomething() throws Exception {
        /*
         * Create a JNDI Initial context to be able to
         *  lookup  the DataSource
         *
         * In production-level code, this should be cached as
         * an instance or static variable, as it can
         * be quite expensive to create a JNDI context.
         *
         * Note: This code only works when you are using servlets
         * or EJBs in a J2EE application server. If you are
         * using connection pooling in standalone Java code, you
         * will have to create/configure datasources using whatever
         * mechanisms your particular connection pooling library
         * provides.
         */

        InitialContext ctx = new InitialContext();

         /*
          * Lookup the DataSource, which will be backed by a pool
          * that the application server provides. DataSource instances
          * are also a good candidate for caching as an instance
          * variable, as JNDI lookups can be expensive as well.
          */

        DataSource ds =
          (DataSource)ctx.lookup("java:comp/env/jdbc/MySQLDB");

        /*
         * The following code is what would actually be in your
         * Servlet, JSP or EJB 'service' method...where you need
         * to work with a JDBC connection.
         */

        Connection conn = null;
        Statement stmt = null;
```

```
        try {
            conn = ds.getConnection();

            /*
             * Now, use normal JDBC programming to work with
             * MySQL, making sure to close each resource when you're
             * finished with it, which permits the connection pool
             * resources to be recovered as quickly as possible
             */

            stmt = conn.createStatement();
            stmt.execute("SOME SQL QUERY");

            stmt.close();
            stmt = null;

            conn.close();
            conn = null;
        } finally {
            /*
             * close any jdbc instances here that weren't
             * explicitly closed during normal code path, so
             * that we don't 'leak' resources...
             */

            if (stmt != null) {
                try {
                    stmt.close();
                } catch (sqlexception sqlex) {
                    // ignore, as we can't do anything about it here
                }

                stmt = null;
            }

            if (conn != null) {
                try {
                    conn.close();
                } catch (sqlexception sqlex) {
                    // ignore, as we can't do anything about it here
                }

                conn = null;
            }
        }
    }
}
```

As shown in the example above, after obtaining the JNDI `InitialContext`, and looking up the `DataSource`, the rest of the code follows familiar JDBC conventions.

When using connection pooling, always make sure that connections, and anything created by them (such as statements or result sets) are closed. This rule applies no matter what happens in your code (exceptions, flow-of-control, and so forth). When these objects are closed, they can be re-used; otherwise, they will be stranded, which means that the MySQL server resources they represent (such as buffers, locks, or sockets) are tied up for some time, or in the worst case can be tied up forever.

Sizing the Connection Pool
