POSTGRESQL - FUNCTIONS

PostgreSQL **functions**, also known as Stored Procedures, allow you to carry out operations that would normally take several queries and round trips in a single function within the database. Functions allow database reuse as other applications can interact directly with your stored procedures instead of a middle-tier or duplicating code.

Functions can be created in language of your choice like SQL, PL/pgSQL, C, Python, etc.

Syntax

The basic syntax to create a function is as follows:

```
CREATE [OR REPLACE] FUNCTION function_name (arguments)
RETURNS return_datatype AS $variable_name$

DECLARE
   declaration;
   [...]
BEGIN
   < function_body >
   [...]
   RETURN { variable_name | value }
END; LANGUAGE plpgsql;
```

Where,

- **function-name** specifies the name of the function.
- [OR REPLACE] option allows modifying an existing function.
- The function must contain a return statement.
- **RETURN** clause specifies that data type you are going to return from the function. The **return_datatype** can be a base, composite, or domain type, or can reference the type of a table column.
- function-body contains the executable part.
- The AS keyword is used for creating a standalone function.
- **plpgsql** is the name of the language that the function is implemented in. Here, we use this option for PostgreSQL, it Can be SQL, C, internal, or the name of a user-defined procedural language. For backward compatibility, the name can be enclosed by single guotes.

Example

The following example illustrates creating and calling a standalone function. This function returns the total number of records in the COMPANY table. We will use the COMPANY table, which has the following records:

Function totalRecords is as follows:

```
CREATE OR REPLACE FUNCTION totalRecords ()
RETURNS integer AS $total$
declare
total integer;
BEGIN
SELECT count(*) into total FROM COMPANY;
RETURN total;
END;
$total$ LANGUAGE plpgsql;
```

When the above query is executed, the result would be:

```
testdb# CREATE FUNCTION
```

Now, let's execute a call to this function and check the records in the COMPANY table

```
testdb=# select totalRecords();
```

When the above query is executed, the result would be:

```
totalrecords
------
7
(1_row)
Loading [MathJax]/jax/output/HTML-CSS/fonts/TeX/fontdata.js
```
