Lists conversions between character-set encodings. If *pattern* is specified, only conversions whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects. If + is appended to the command name, each object is listed with its associated description.

`\dc[+] [ pattern ]`

Lists type casts. If *pattern* is specified, only casts whose source or target types match the pattern are listed. If + is appended to the command name, each object is listed with its associated description.

`\dd[S] [ pattern ]`

Shows the descriptions of objects of type `constraint`, `operator class`, `operator family`, `rule`, and `trigger`. All other comments may be viewed by the respective backslash commands for those object types.

`\dd` displays descriptions for objects matching the *pattern*, or of visible objects of the appropriate type if no argument is given. But in either case, only objects that have a description are listed. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects.

Descriptions for objects can be created with the `COMMENT` SQL command.

`\ddp [ pattern ]`

Lists default access privilege settings. An entry is shown for each role (and schema, if applicable) for which the default privilege settings have been changed from the built-in defaults. If *pattern* is specified, only entries whose role name or schema name matches the pattern are listed.

The `ALTER DEFAULT PRIVILEGES` command is used to set default access privileges. The meaning of the privilege display is explained under `GRANT`.

`\dD[S+] [ pattern ]`

Lists domains. If *pattern* is specified, only domains whose names match the pattern are shown. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects. If + is appended to the command name, each object is listed with its associated permissions and description.

`\dE[S+] [ pattern ]`

`\di[S+] [ pattern ]`

`\dm[S+] [ pattern ]`

`\ds[S+] [ pattern ]`

`\dt[S+] [ pattern ]`

`\dv[S+] [ pattern ]`

In this group of commands, the letters *E*, *i*, *m*, *s*, *t*, and *v* stand for foreign table, index, materialized view, sequence, table, and view, respectively. You can specify any or all of these letters, in any order, to obtain a listing of objects of these types. For example, `\dit` lists indexes and tables. If + is appended to

the command name, each object is listed with its physical size on disk and its associated description, if any. If *pattern* is specified, only objects whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects.

`\des[+] [ pattern ]`

Lists foreign servers (mnemonic: “external servers”). If *pattern* is specified, only those servers whose name matches the pattern are listed. If the form `\des+` is used, a full description of each server is shown, including the server's ACL, type, version, options, and description.

`\det[+] [ pattern ]`

Lists foreign tables (mnemonic: “external tables”). If *pattern* is specified, only entries whose table name or schema name matches the pattern are listed. If the form `\det+` is used, generic options and the foreign table description are also displayed.

`\deu[+] [ pattern ]`

Lists user mappings (mnemonic: “external users”). If *pattern* is specified, only those mappings whose user names match the pattern are listed. If the form `\deu+` is used, additional information about each mapping is shown.

Caution

`\deu+` might also display the user name and password of the remote user, so care should be taken not to disclose them.

`\dew[+] [ pattern ]`

Lists foreign-data wrappers (mnemonic: “external wrappers”). If *pattern* is specified, only those foreign-data wrappers whose name matches the pattern are listed. If the form `\dew+` is used, the ACL, options, and description of the foreign-data wrapper are also shown.

`\df[antwS+] [ pattern ]`

Lists functions, together with their result data types, argument data types, and function types, which are classified as “agg” (aggregate), “normal”, “trigger”, or “window”. To display only functions of specific type(s), add the corresponding letters *a*, *n*, *t*, or *w* to the command. If *pattern* is specified, only functions whose names match the pattern are shown. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects. If the form `\df+` is used, additional information about each function is shown, including volatility, parallel safety, owner, security classification, access privileges, language, source code and description.

Tip

To look up functions taking arguments or returning values of a specific data type, use your pager's search capability to scroll through the `\df` output.

`\dF[+] [ pattern ]`

Lists text search configurations. If *pattern* is specified, only configurations whose names match the pattern are shown. If the form `\dF+` is used, a full description of each configuration is shown, including the underlying text search parser and the dictionary list for each parser token type.

`\dFd[+] [ pattern ]`

Lists text search dictionaries. If *pattern* is specified, only dictionaries whose names match the pattern are shown. If the form `\dFd+` is used, additional information is shown about each selected dictionary, including the underlying text search template and the option values.

`\dFp[+] [ pattern ]`

Lists text search parsers. If *pattern* is specified, only parsers whose names match the pattern are shown. If the form `\dFp+` is used, a full description of each parser is shown, including the underlying functions and the list of recognized token types.

`\dFt[+] [ pattern ]`

Lists text search templates. If *pattern* is specified, only templates whose names match the pattern are shown. If the form `\dFt+` is used, additional information is shown about each template, including the underlying function names.

`\dg[S+] [ pattern ]`

Lists database roles. (Since the concepts of “users” and “groups” have been unified into “roles”, this command is now equivalent to `\du`.) By default, only user-created roles are shown; supply the *s* modifier to include system roles. If *pattern* is specified, only those roles whose names match the pattern are listed. If the form `\dg+` is used, additional information is shown about each role; currently this adds the comment for each role.

`\dl`

This is an alias for `\lo_list`, which shows a list of large objects.

`\dL[S+] [ pattern ]`

Lists procedural languages. If *pattern* is specified, only languages whose names match the pattern are listed. By default, only user-created languages are shown; supply the *s* modifier to include system objects. If *+* is appended to the command name, each language is listed with its call handler, validator, access privileges, and whether it is a system object.

`\dn[S+] [ pattern ]`

Lists schemas (namespaces). If *pattern* is specified, only schemas whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects. If *+* is appended to the command name, each object is listed with its associated permissions and description, if any.

`\do[S+] [ pattern ]`

Lists operators with their operand and result types. If *pattern* is specified, only operators whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects. If *+* is appended to the command name, additional information about each operator is shown, currently just the name of the underlying function.

`\dO[S+] [ pattern ]`

Lists collations. If *pattern* is specified, only collations whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects. If *+* is appended to the command name, each collation is listed with its associated description, if any. Note that only collations usable with the current database's encoding are shown, so the results may vary in different databases of the same installation.

`\dp [ pattern ]`

Lists tables, views and sequences with their associated access privileges. If *pattern* is specified, only tables, views and sequences whose names match the pattern are listed.

The [GRANT](#) and [REVOKE](#) commands are used to set access privileges. The meaning of the privilege display is explained under [GRANT](#).

`\drds [ role-pattern [ database-pattern ] ]`

Lists defined configuration settings. These settings can be role-specific, database-specific, or both. *role-pattern* and *database-pattern* are used to select specific roles and databases to list,

respectively. If omitted, or if `*` is specified, all settings are listed, including those not role-specific or database-specific, respectively.

The [ALTER ROLE](#) and [ALTER DATABASE](#) commands are used to define per-role and per-database configuration settings.

`\dT[S+] [ pattern ]`

Lists data types. If *pattern* is specified, only types whose names match the pattern are listed. If `+` is appended to the command name, each type is listed with its internal name and size, its allowed values if it is an `enum` type, and its associated permissions. By default, only user-created objects are shown; supply a pattern or the `S` modifier to include system objects.

`\du[S+] [ pattern ]`

Lists database roles. (Since the concepts of “users” and “groups” have been unified into “roles”, this command is now equivalent to `\dg`.) By default, only user-created roles are shown; supply the `S` modifier to include system roles. If *pattern* is specified, only those roles whose names match the pattern are listed. If the form `\du+` is used, additional information is shown about each role; currently this adds the comment for each role.

`\dx[+] [ pattern ]`

Lists installed extensions. If *pattern* is specified, only those extensions whose names match the pattern are listed. If the form `\dx+` is used, all the objects belonging to each matching extension are listed.

`\dy[+] [ pattern ]`

Lists event triggers. If *pattern* is specified, only those event triggers whose names match the pattern are listed. If `+` is appended to the command name, each object is listed with its associated description.

`\e or \edit [ filename ] [ line_number ]`

If *filename* is specified, the file is edited; after the editor exits, its content is copied back to the query buffer. If no *filename* is given, the current query buffer is copied to a temporary file which is then edited in the same fashion.

The new query buffer is then re-parsed according to the normal rules of psql, where the whole buffer is treated as a single line. (Thus you cannot make scripts this way. Use `\i` for that.) This means that if the query ends with (or contains) a semicolon, it is immediately executed. Otherwise it will merely wait in the query buffer; type semicolon or `\g` to send it, or `\r` to cancel.

If a line number is specified, psql will position the cursor on the specified line of the file or query buffer. Note that if a single all-digits argument is given, psql assumes it is a line number, not a file name.

Tip

See under [the section called “Environment”](#) for how to configure and customize your editor.

`\echo text [ ... ]`

Prints the arguments to the standard output, separated by one space and followed by a newline. This can be useful to intersperse information in the output of scripts. For example:

```
=> \echo `date`  
Tue Oct 26 21:40:57 CEST 1999
```

If the first argument is an unquoted `-n` the trailing newline is not written.

Tip

If you use the `\o` command to redirect your query output you might wish to use `\qecho` instead of this command.

```
\ef [ function_description [ line_number ] ]
```

This command fetches and edits the definition of the named function, in the form of a `CREATE OR REPLACE FUNCTION` command. Editing is done in the same way as for `\edit`. After the editor exits, the updated command waits in the query buffer; type semicolon or `\g` to send it, or `\r` to cancel.

The target function can be specified by name alone, or by name and arguments, for example `foo(integer, text)`. The argument types must be given if there is more than one function of the same name.

If no function is specified, a blank `CREATE FUNCTION` template is presented for editing.

If a line number is specified, `psql` will position the cursor on the specified line of the function body. (Note that the function body typically does not begin on the first line of the file.)

Tip

See under [the section called “Environment”](#) for how to configure and customize your editor.

```
\encoding [ encoding ]
```

Sets the client character set encoding. Without an argument, this command shows the current encoding.

```
\errverbose
```

Repeats the most recent server error message at maximum verbosity, as though `VERBOSITY` were set to `verbose` and `SHOW_CONTEXT` were set to `always`.

```
\ev [ view_name [ line_number ] ]
```

This command fetches and edits the definition of the named view, in the form of a `CREATE OR REPLACE VIEW` command. Editing is done in the same way as for `\edit`. After the editor exits, the updated command waits in the query buffer; type semicolon or `\g` to send it, or `\r` to cancel.

If no view is specified, a blank `CREATE VIEW` template is presented for editing.

If a line number is specified, `psql` will position the cursor on the specified line of the view definition.

```
\f [ string ]
```

Sets the field separator for unaligned query output. The default is the vertical bar (`|`). See also `\pset` for a generic way of setting output options.

```
\g [ filename ]
```

```
\g [ |command ]
```

Sends the current query input buffer to the server, and optionally stores the query's output in *filename* or pipes the output to the shell command *command*. The file or command is written to only if the query successfully returns zero or more tuples, not if the query fails or is a non-data-returning SQL command.

A bare `\g` is essentially equivalent to a semicolon. A `\g` with argument is a “one-shot” alternative to the `\o` command.

\gexec

Sends the current query input buffer to the server, then treats each column of each row of the query's output (if any) as a SQL statement to be executed. For example, to create an index on each column of `my_table`:

```
=> SELECT format('create index on my_table(%I)', attname)
-> FROM pg_attribute
-> WHERE attrelid = 'my_table'::regclass AND attnum > 0
-> ORDER BY attnum
-> \gexec
CREATE INDEX
CREATE INDEX
CREATE INDEX
CREATE INDEX
```

The generated queries are executed in the order in which the rows are returned, and left-to-right within each row if there is more than one column. NULL fields are ignored. The generated queries are sent literally to the server for processing, so they cannot be psql meta-commands nor contain psql variable references. If any individual query fails, execution of the remaining queries continues unless `ON_ERROR_STOP` is set. Execution of each query is subject to `ECHO` processing. (Setting `ECHO` to `all` or `queries` is often advisable when using `\gexec`.) Query logging, single-step mode, timing, and other query execution features apply to each generated query as well.

\gset [*prefix*]

Sends the current query input buffer to the server and stores the query's output into psql variables (see [the section called “Variables”](#)). The query to be executed must return exactly one row. Each column of the row is stored into a separate variable, named the same as the column. For example:

```
=> SELECT 'hello' AS var1, 10 AS var2
-> \gset
=> \echo :var1 :var2
hello 10
```

If you specify a *prefix*, that string is prepended to the query's column names to create the variable names to use:

```
=> SELECT 'hello' AS var1, 10 AS var2
-> \gset result_
=> \echo :result_var1 :result_var2
hello 10
```

If a column result is NULL, the corresponding variable is unset rather than being set.

If the query fails or does not return one row, no variables are changed.

\h or **\help** [*command*]

Gives syntax help on the specified SQL command. If *command* is not specified, then psql will list all the commands for which syntax help is available. If *command* is an asterisk (*), then syntax help on all SQL commands is shown.

Note

To simplify typing, commands that consists of several words do not have to be quoted. Thus it is fine to type `\help alter table`.

\H or **\html**

Turns on HTML query output format. If the HTML format is already on, it is switched back to the default aligned text format. This command is for compatibility and convenience, but see `\pset` about setting other output options.

`\i` or `\include filename`

Reads input from the file *filename* and executes it as though it had been typed on the keyboard.

If *filename* is - (hyphen), then standard input is read until an EOF indication or `\q` meta-command. This can be used to intersperse interactive input with input from files. Note that Readline behavior will be used only if it is active at the outermost level.

Note

If you want to see the lines on the screen as they are read you must set the variable `ECHO` to `all`.

`\ir` or `\include_relative filename`

The `\ir` command is similar to `\i`, but resolves relative file names differently. When executing in interactive mode, the two commands behave identically. However, when invoked from a script, `\ir` interprets file names relative to the directory in which the script is located, rather than the current working directory.

`\l[+]` or `\list[+]` [*pattern*]

List the databases in the server and show their names, owners, character set encodings, and access privileges. If *pattern* is specified, only databases whose names match the pattern are listed. If + is appended to the command name, database sizes, default tablespaces, and descriptions are also displayed. (Size information is only available for databases that the current user can connect to.)

`\lo_export loid filename`

Reads the large object with OID *loid* from the database and writes it to *filename*. Note that this is subtly different from the server function `lo_export`, which acts with the permissions of the user that the database server runs as and on the server's file system.

Tip

Use `\lo_list` to find out the large object's OID.

`\lo_import filename [ comment ]`

Stores the file into a Postgres Pro large object. Optionally, it associates the given comment with the object. Example:

```
foo=> \lo_import '/home/peter/pictures/photo.xcf' 'a picture of me'
lo_import 152801
```

The response indicates that the large object received object ID 152801, which can be used to access the newly-created large object in the future. For the sake of readability, it is recommended to always associate a human-readable comment with every object. Both OIDs and comments can be viewed with the `\lo_list` command.

Note that this command is subtly different from the server-side `lo_import` because it acts as the local user on the local file system, rather than the server's user and file system.

`\lo_list`

Shows a list of all Postgres Pro large objects currently stored in the database, along with any comments provided for them.

`\lo_unlink loid`

Deletes the large object with OID *loid* from the database.

Tip

Use `\lo_list` to find out the large object's OID.

`\o` or `\out` [*filename*]

`\o` or `\out` [| *command*]

Arranges to save future query results to the file *filename* or pipe future results to the shell command *command*. If no argument is specified, the query output is reset to the standard output.

“Query results” includes all tables, command responses, and notices obtained from the database server, as well as output of various backslash commands that query the database (such as `\d`), but not error messages.

Tip

To intersperse text output in between query results, use `\qecho`.

`\p` or `\print`

Print the current query buffer to the standard output.

`\password` [*username*]

Changes the password of the specified user (by default, the current user). This command prompts for the new password, encrypts it, and sends it to the server as an `ALTER ROLE` command. This makes sure that the new password does not appear in cleartext in the command history, the server log, or elsewhere.

`\prompt` [*text*] *name*

Prompts the user to supply text, which is assigned to the variable *name*. An optional prompt string, *text*, can be specified. (For multiword prompts, surround the text with single quotes.)

By default, `\prompt` uses the terminal for input and output. However, if the `-f` command line switch was used, `\prompt` uses standard input and standard output.

`\pset` [*option* [*value*]]

This command sets options affecting the output of query result tables. *option* indicates which option is to be set. The semantics of *value* vary depending on the selected option. For some options, omitting *value* causes the option to be toggled or unset, as described under the particular option. If no such behavior is mentioned, then omitting *value* just results in the current setting being displayed.

`\pset` without any arguments displays the current status of all printing options.

Adjustable printing options are:

`border`

The *value* must be a number. In general, the higher the number the more borders and lines the tables will have, but details depend on the particular format. In HTML format, this will translate directly into the `border=...` attribute. In most other formats only values 0 (no border), 1 (internal dividing lines), and 2 (table frame) make sense, and values above 2 will be treated the same as `border = 2`. The `latex` and `latex-longtable` formats additionally allow a value of 3 to add dividing lines between data rows.

`columns`

Sets the target width for the `wrapped` format, and also the width limit for determining whether output is wide enough to require the pager or switch to the vertical display in expanded auto

mode. Zero (the default) causes the target width to be controlled by the environment variable `COLUMNS`, or the detected screen width if `COLUMNS` is not set. In addition, if `columns` is zero then the wrapped format only affects screen output. If `columns` is nonzero then file and pipe output is wrapped to that width as well.

expanded (or x)

If *value* is specified it must be either `on` or `off`, which will enable or disable expanded mode, or `auto`. If *value* is omitted the command toggles between the on and off settings. When expanded mode is enabled, query results are displayed in two columns, with the column name on the left and the data on the right. This mode is useful if the data wouldn't fit on the screen in the normal "horizontal" mode. In the auto setting, the expanded mode is used whenever the query output has more than one column and is wider than the screen; otherwise, the regular mode is used. The auto setting is only effective in the aligned and wrapped formats. In other formats, it always behaves as if the expanded mode is off.

fieldsep

Specifies the field separator to be used in unaligned output format. That way one can create, for example, tab- or comma-separated output, which other programs might prefer. To set a tab as field separator, type `\pset fieldsep '\t'`. The default field separator is `'|'` (a vertical bar).

fieldsep_zero

Sets the field separator to use in unaligned output format to a zero byte.

footer

If *value* is specified it must be either `on` or `off` which will enable or disable display of the table footer (the `(n rows)` count). If *value* is omitted the command toggles footer display on or off.

format

Sets the output format to one of `unaligned`, `aligned`, `wrapped`, `html`, `asciidoc`, `latex` (uses `tabular`), `latex-longtable`, or `troff-ms`. Unique abbreviations are allowed.

`unaligned` format writes all columns of a row on one line, separated by the currently active field separator. This is useful for creating output that might be intended to be read in by other programs (for example, tab-separated or comma-separated format).

`aligned` format is the standard, human-readable, nicely formatted text output; this is the default.

`wrapped` format is like `aligned` but wraps wide data values across lines to make the output fit in the target column width. The target width is determined as described under the `columns` option. Note that `psql` will not attempt to wrap column header titles; therefore, `wrapped` format behaves the same as `aligned` if the total width needed for column headers exceeds the target.

The `html`, `asciidoc`, `latex`, `latex-longtable`, and `troff-ms` formats put out tables that are intended to be included in documents using the respective mark-up language. They are not complete documents! This might not be necessary in HTML, but in LaTeX you must have a complete document wrapper. `latex-longtable` also requires the LaTeX `longtable` and `booktabs` packages.

linestyle

Sets the border line drawing style to one of `ascii`, `old-ascii`, or `unicode`. Unique abbreviations are allowed. (That would mean one letter is enough.) The default setting is `ascii`. This option only affects the `aligned` and `wrapped` output formats.

`ascii` style uses plain ASCII characters. Newlines in data are shown using a `+` symbol in the right-hand margin. When the `wrapped` format wraps data from one line to the next without a newline

character, a dot (.) is shown in the right-hand margin of the first line, and again in the left-hand margin of the following line.

`old-ascii` style uses plain ASCII characters, using the formatting style used in PostgreSQL 8.4 and earlier. Newlines in data are shown using a `:` symbol in place of the left-hand column separator. When the data is wrapped from one line to the next without a newline character, a `;` symbol is used in place of the left-hand column separator.

`unicode` style uses Unicode box-drawing characters. Newlines in data are shown using a carriage return symbol in the right-hand margin. When the data is wrapped from one line to the next without a newline character, an ellipsis symbol is shown in the right-hand margin of the first line, and again in the left-hand margin of the following line.

When the `border` setting is greater than zero, the `linestyle` option also determines the characters with which the border lines are drawn. Plain ASCII characters work everywhere, but Unicode characters look nicer on displays that recognize them.

`null`

Sets the string to be printed in place of a null value. The default is to print nothing, which can easily be mistaken for an empty string. For example, one might prefer `\pset null '(null)'`.

`numericlocale`

If *value* is specified it must be either `on` or `off` which will enable or disable display of a locale-specific character to separate groups of digits to the left of the decimal marker. If *value* is omitted the command toggles between regular and locale-specific numeric output.

`pager`

Controls use of a pager program for query and `psql help` output. If the environment variable `PAGER` is set, the output is piped to the specified program. Otherwise a platform-dependent default (such as `more`) is used.

When the `pager` option is `off`, the pager program is not used. When the `pager` option is `on`, the pager is used when appropriate, i.e., when the output is to a terminal and will not fit on the screen. The `pager` option can also be set to `always`, which causes the pager to be used for all terminal output regardless of whether it fits on the screen. `\pset pager` without a *value* toggles pager use on and off.

`pager_min_lines`

If `pager_min_lines` is set to a number greater than the page height, the pager program will not be called unless there are at least this many lines of output to show. The default setting is 0.

`recordsep`

Specifies the record (line) separator to use in unaligned output format. The default is a newline character.

`recordsep_zero`

Sets the record separator to use in unaligned output format to a zero byte.

`tableattr` (or `T`)

In HTML format, this specifies attributes to be placed inside the `table` tag. This could for example be `cellpadding` or `bgcolor`. Note that you probably don't want to specify `border` here, as that is already taken care of by `\pset border`. If no *value* is given, the table attributes are unset.

In `latex-longtable` format, this controls the proportional width of each column containing a left-aligned data type. It is specified as a whitespace-separated list of values, e.g., `'0.2 0.2 0.6'`. Unspecified output columns use the last specified value.

`title (or C)`

Sets the table title for any subsequently printed tables. This can be used to give your output descriptive tags. If no *value* is given, the title is unset.

`tuples_only (or t)`

If *value* is specified it must be either `on` or `off` which will enable or disable tuples-only mode. If *value* is omitted the command toggles between regular and tuples-only output. Regular output includes extra information such as column headers, titles, and various footers. In tuples-only mode, only actual table data is shown.

`unicode_border_linestyle`

Sets the border drawing style for the `unicode` line style to one of `single` or `double`.

`unicode_column_linestyle`

Sets the column drawing style for the `unicode` line style to one of `single` or `double`.

`unicode_header_linestyle`

Sets the header drawing style for the `unicode` line style to one of `single` or `double`.

Illustrations of how these different formats look can be seen in the [the section called “Examples”](#) section.

Tip

There are various shortcut commands for `\pset`. See `\a`, `\C`, `\f`, `\H`, `\t`, `\T`, and `\x`.

`\q` or `\quit`

Quits the `psql` program. In a script file, only execution of that script is terminated.

`\qecho text [ ... ]`

This command is identical to `\echo` except that the output will be written to the query output channel, as set by `\o`.

`\r` or `\reset`

Resets (clears) the query buffer.

`\s [ filename ]`

Print `psql`'s command line history to *filename*. If *filename* is omitted, the history is written to the standard output (using the pager if appropriate). This command is not available if `psql` was built without Readline support.

`\set [ name [ value [ ... ] ] ]`

Sets the `psql` variable *name* to *value*, or if more than one value is given, to the concatenation of all of them. If only one argument is given, the variable is set with an empty value. To unset a variable, use the `\unset` command.

`\set` without any arguments displays the names and values of all currently-set `psql` variables.

Valid variable names can contain letters, digits, and underscores. See the section [the section called “Variables”](#) below for details. Variable names are case-sensitive.

Although you are welcome to set any variable to anything you want, `psql` treats several variables as special. They are documented in the section about variables.

Note

This command is unrelated to the SQL command [SET](#).

`\setenv name [ value ]`

Sets the environment variable *name* to *value*, or if the *value* is not supplied, unsets the environment variable. Example:

```
testdb=> \setenv PAGER less
testdb=> \setenv LESS -imx4F
```

`\sf[+] function_description`

This command fetches and shows the definition of the named function, in the form of a `CREATE OR REPLACE FUNCTION` command. The definition is printed to the current query output channel, as set by `\o`.

The target function can be specified by name alone, or by name and arguments, for example `foo(integer, text)`. The argument types must be given if there is more than one function of the same name.

If `+` is appended to the command name, then the output lines are numbered, with the first line of the function body being line 1.

`\sv[+] view_name`

This command fetches and shows the definition of the named view, in the form of a `CREATE OR REPLACE VIEW` command. The definition is printed to the current query output channel, as set by `\o`.

If `+` is appended to the command name, then the output lines are numbered from 1.

`\t`

Toggles the display of output column name headings and row count footer. This command is equivalent to `\pset tuples_only` and is provided for convenience.

`\T table_options`

Specifies attributes to be placed within the `table` tag in HTML output format. This command is equivalent to `\pset tableattr table_options`.

`\timing [ on | off ]`

Without parameter, toggles a display of how long each SQL statement takes, in milliseconds. With parameter, sets same.

`\unset name`

Unsets (deletes) the psql variable *name*.

`\w or \write filename`

`\w or \write |command`

Outputs the current query buffer to the file *filename* or pipes it to the shell command *command*.

`\watch [ seconds ]`

Repeatedly execute the current query buffer (as `\g` does) until interrupted or the query fails. Wait the specified number of seconds (default 2) between executions. Each query result is displayed with a header that includes the `\pset title` string (if any), the time as of query start, and the delay interval.

`\x [ on | off | auto ]`

Sets or toggles expanded table formatting mode. As such it is equivalent to `\pset expanded`.

`\z [ pattern ]`

Lists tables, views and sequences with their associated access privileges. If a *pattern* is specified, only tables, views and sequences whose names match the pattern are listed.

This is an alias for `\dp` (“display privileges”).

`\! [ command ]`

Escapes to a separate shell or executes the shell command *command*. The arguments are not further interpreted; the shell will see them as-is. In particular, the variable substitution rules and backslash escapes do not apply.

`\? [ topic ]`

Shows help information. The optional *topic* parameter (defaulting to `commands`) selects which part of psql is explained: `commands` describes psql's backslash commands; `options` describes the command-line options that can be passed to psql; and `variables` shows help about psql configuration variables.

Patterns

The various `\d` commands accept a *pattern* parameter to specify the object name(s) to be displayed. In the simplest case, a pattern is just the exact name of the object. The characters within a pattern are normally folded to lower case, just as in SQL names; for example, `\dt FOO` will display the table named `foo`. As in SQL names, placing double quotes around a pattern stops folding to lower case. Should you need to include an actual double quote character in a pattern, write it as a pair of double quotes within a double-quote sequence; again this is in accord with the rules for SQL quoted identifiers. For example, `\dt "FOO"BAR` will display the table named `FOO"BAR` (not `foo"bar`). Unlike the normal rules for SQL names, you can put double quotes around just part of a pattern, for instance `\dt FOO"FOO"BAR` will display the table named `fooFOObar`.

Whenever the *pattern* parameter is omitted completely, the `\d` commands display all objects that are visible in the current schema search path — this is equivalent to using `*` as the pattern. (An object is said to be *visible* if its containing schema is in the search path and no object of the same kind and name appears earlier in the search path. This is equivalent to the statement that the object can be referenced by name without explicit schema qualification.) To see all objects in the database regardless of visibility, use `*.*` as the pattern.

Within a pattern, `*` matches any sequence of characters (including no characters) and `?` matches any single character. (This notation is comparable to Unix shell file name patterns.) For example, `\dt int*` displays tables whose names begin with `int`. But within double quotes, `*` and `?` lose these special meanings and are just matched literally.

A pattern that contains a dot (`.`) is interpreted as a schema name pattern followed by an object name pattern. For example, `\dt foo*.*bar*` displays all tables whose table name includes `bar` that are in schemas whose schema name starts with `foo`. When no dot appears, then the pattern matches only objects that are visible in the current schema search path. Again, a dot within double quotes loses its special meaning and is matched literally.

Advanced users can use regular-expression notations such as character classes, for example `[0-9]` to match any digit. All regular expression special characters work as specified in [Section 9.7.3](#), except for `.` which is taken as a separator as mentioned above, `*` which is translated to the regular-expression notation `.*`, `?` which is translated to `.`, and `$` which is matched literally. You can emulate these pattern characters at need by writing `? for .`, `(R+|)` for `R*`, or `(R|)` for `R?`. `$` is not needed as a regular-expression character since the pattern must match the whole name, unlike the usual interpretation of regular expressions (in other words, `$` is automatically appended to your pattern). Write `*` at the beginning and/or end if you don't wish the pattern to be anchored. Note that within double quotes, all regular expression

special characters lose their special meanings and are matched literally. Also, the regular expression special characters are matched literally in operator name patterns (i.e., the argument of `\do`).

Advanced Features

Variables

psql provides variable substitution features similar to common Unix command shells. Variables are simply name/value pairs, where the value can be any string of any length. The name must consist of letters (including non-Latin letters), digits, and underscores.

To set a variable, use the psql meta-command `\set`. For example,

```
testdb=> \set foo bar
```

sets the variable `foo` to the value `bar`. To retrieve the content of the variable, precede the name with a colon, for example:

```
testdb=> \echo :foo
bar
```

This works in both regular SQL commands and meta-commands; there is more detail in [the section called “SQL Interpolation”](#), below.

If you call `\set` without a second argument, the variable is set, with an empty string as value. To unset (i.e., delete) a variable, use the command `\unset`. To show the values of all variables, call `\set` without any argument.

Note

The arguments of `\set` are subject to the same substitution rules as with other commands. Thus you can construct interesting references such as `\set :foo 'something'` and get “soft links” or “variable variables” of Perl or PHP fame, respectively. Unfortunately (or fortunately?), there is no way to do anything useful with these constructs. On the other hand, `\set bar :foo` is a perfectly valid way to copy a variable.

A number of these variables are treated specially by psql. They represent certain option settings that can be changed at run time by altering the value of the variable, or in some cases represent changeable state of psql. Although you can use these variables for other purposes, this is not recommended, as the program behavior might grow really strange really quickly. By convention, all specially treated variables' names consist of all upper-case ASCII letters (and possibly digits and underscores). To ensure maximum compatibility in the future, avoid using such variable names for your own purposes. A list of all specially treated variables follows.

AUTOCOMMIT

When `on` (the default), each SQL command is automatically committed upon successful completion. To postpone commit in this mode, you must enter a `BEGIN` or `START TRANSACTION SQL` command. When `off` or `unset`, SQL commands are not committed until you explicitly issue `COMMIT` or `END`. The autocommit-off mode works by issuing an implicit `BEGIN` for you, just before any command that is not already in a transaction block and is not itself a `BEGIN` or other transaction-control command, nor a command that cannot be executed inside a transaction block (such as `VACUUM`).

Note

In autocommit-off mode, you must explicitly abandon any failed transaction by entering `ABORT` or `ROLLBACK`. Also keep in mind that if you exit the session without committing, your work will be lost.

Note

The autocommit-on mode is Postgres Pro's traditional behavior, but autocommit-off is closer to the SQL spec. If you prefer autocommit-off, you might wish to set it in the system-wide `psqlrc` file or your `~/.psqlrc` file.

COMP_KEYWORD_CASE

Determines which letter case to use when completing an SQL key word. If set to `lower` or `upper`, the completed word will be in lower or upper case, respectively. If set to `preserve-lower` or `preserve-upper` (the default), the completed word will be in the case of the word already entered, but words being completed without anything entered will be in lower or upper case, respectively.

DBNAME

The name of the database you are currently connected to. This is set every time you connect to a database (including program start-up), but can be unset.

ECHO

If set to `all`, all nonempty input lines are printed to standard output as they are read. (This does not apply to lines read interactively.) To select this behavior on program start-up, use the switch `-a`. If set to `queries`, `psql` prints each query to standard output as it is sent to the server. The switch for this is `-e`. If set to `errors`, then only failed queries are displayed on standard error output. The switch for this is `-b`. If unset, or if set to `none` (or any other value than those above) then no queries are displayed.

ECHO_HIDDEN

When this variable is set to `on` and a backslash command queries the database, the query is first shown. This feature helps you to study Postgres Pro internals and provide similar functionality in your own programs. (To select this behavior on program start-up, use the switch `-E`.) If you set the variable to the value `noexec`, the queries are just shown but are not actually sent to the server and executed.

ENCODING

The current client character set encoding.

FETCH_COUNT

If this variable is set to an integer value > 0 , the results of `SELECT` queries are fetched and displayed in groups of that many rows, rather than the default behavior of collecting the entire result set before display. Therefore only a limited amount of memory is used, regardless of the size of the result set. Settings of 100 to 1000 are commonly used when enabling this feature. Keep in mind that when using this feature, a query might fail after having already displayed some rows.

Tip

Although you can use any output format with this feature, the default `aligned` format tends to look bad because each group of `FETCH_COUNT` rows will be formatted separately, leading to varying column widths across the row groups. The other output formats work better.

HISTCONTROL

If this variable is set to `ignore-space`, lines which begin with a space are not entered into the history list. If set to a value of `ignore-dups`, lines matching the previous history line are not entered. A value of `ignore-both` combines the two options. If unset, or if set to `none` (or any other value than those above), all lines read in interactive mode are saved on the history list.

Note

This feature was shamelessly plagiarized from Bash.

HISTFILE

The file name that will be used to store the history list. The default value is `~/.psql_history`. For example, putting:

```
\set HISTFILE ~/.psql_history- :DBNAME
```

in `~/.psqlrc` will cause `psql` to maintain a separate history for each database.

Note

This feature was shamelessly plagiarized from Bash.

HISTSIZE

The number of commands to store in the command history. The default value is 500.

Note

This feature was shamelessly plagiarized from Bash.

HOST

The database server host you are currently connected to. This is set every time you connect to a database (including program start-up), but can be unset.

IGNOREEOF

If unset, sending an EOF character (usually **Control+D**) to an interactive session of `psql` will terminate the application. If set to a numeric value, that many EOF characters are ignored before the application terminates. If the variable is set but has no numeric value, the default is 10.

Note

This feature was shamelessly plagiarized from Bash.

LASTOID

The value of the last affected OID, as returned from an `INSERT` or `\lo_import` command. This variable is only guaranteed to be valid until after the result of the next SQL command has been displayed.

ON_ERROR_ROLLBACK

When set to `on`, if a statement in a transaction block generates an error, the error is ignored and the transaction continues. When set to `interactive`, such errors are only ignored in interactive sessions, and not when reading script files. When unset or set to `off`, a statement in a transaction block that generates an error aborts the entire transaction. The error rollback mode works by issuing an implicit `SAVEPOINT` for you, just before each command that is in a transaction block, and then rolling back to the savepoint if the command fails.

ON_ERROR_STOP

By default, command processing continues after an error. When this variable is set to `on`, processing will instead stop immediately. In interactive mode, `psql` will return to the command prompt;

otherwise, psql will exit, returning error code 3 to distinguish this case from fatal error conditions, which are reported using error code 1. In either case, any currently running scripts (the top-level script, if any, and any other scripts which it may have invoked) will be terminated immediately. If the top-level command string contained multiple SQL commands, processing will stop with the current command.

PORT

The database server port to which you are currently connected. This is set every time you connect to a database (including program start-up), but can be unset.

PROMPT1

PROMPT2

PROMPT3

These specify what the prompts psql issues should look like. See [the section called “Prompting”](#) below.

QUIET

Setting this variable to `on` is equivalent to the command line option `-q`. It is probably not too useful in interactive mode.

SHOW_CONTEXT

This variable can be set to the values `never`, `errors`, or `always` to control whether `CONTEXT` fields are displayed in messages from the server. The default is `errors` (meaning that context will be shown in error messages, but not in notice or warning messages). This setting has no effect when `VERBOSITY` is set to `terse`. (See also `\errverbose`, for use when you want a verbose version of the error you just got.)

SINGLELINE

Setting this variable to `on` is equivalent to the command line option `-s`.

SINGLESTEP

Setting this variable to `on` is equivalent to the command line option `-s`.

USER

The database user you are currently connected as. This is set every time you connect to a database (including program start-up), but can be unset.

VERBOSITY

This variable can be set to the values `default`, `verbose`, or `terse` to control the verbosity of error reports. (See also `\errverbose`, for use when you want a verbose version of the error you just got.)

SQL Interpolation

A key feature of psql variables is that you can substitute (“interpolate”) them into regular SQL statements, as well as the arguments of meta-commands. Furthermore, psql provides facilities for ensuring that variable values used as SQL literals and identifiers are properly quoted. The syntax for interpolating a value without any quoting is to prepend the variable name with a colon (`:`). For example,

```
testdb=> \set foo 'my_table'
testdb=> SELECT * FROM :foo;
```

would query the table `my_table`. Note that this may be unsafe: the value of the variable is copied literally, so it can contain unbalanced quotes, or even backslash commands. You must make sure that it makes sense where you put it.

When a value is to be used as an SQL literal or identifier, it is safest to arrange for it to be quoted. To quote the value of a variable as an SQL literal, write a colon followed by the variable name in single

quotes. To quote the value as an SQL identifier, write a colon followed by the variable name in double quotes. These constructs deal correctly with quotes and other special characters embedded within the variable value. The previous example would be more safely written this way:

```
testdb=> \set foo 'my_table'
testdb=> SELECT * FROM : "foo";
```

Variable interpolation will not be performed within quoted SQL literals and identifiers. Therefore, a construction such as `':foo'` doesn't work to produce a quoted literal from a variable's value (and it would be unsafe if it did work, since it wouldn't correctly handle quotes embedded in the value).

One example use of this mechanism is to copy the contents of a file into a table column. First load the file into a variable and then interpolate the variable's value as a quoted string:

```
testdb=> \set content `cat my_file.txt`
testdb=> INSERT INTO my_table VALUES (: 'content');
```

(Note that this still won't work if `my_file.txt` contains NUL bytes. psql does not support embedded NUL bytes in variable values.)

Since colons can legally appear in SQL commands, an apparent attempt at interpolation (that is, `:name`, `:'name'`, or `: "name"`) is not replaced unless the named variable is currently set. In any case, you can escape a colon with a backslash to protect it from substitution.

The colon syntax for variables is standard SQL for embedded query languages, such as ECPG. The colon syntaxes for array slices and type casts are Postgres Pro extensions, which can sometimes conflict with the standard usage. The colon-quote syntax for escaping a variable's value as an SQL literal or identifier is a psql extension.

Prompting

The prompts psql issues can be customized to your preference. The three variables `PROMPT1`, `PROMPT2`, and `PROMPT3` contain strings and special escape sequences that describe the appearance of the prompt. Prompt 1 is the normal prompt that is issued when psql requests a new command. Prompt 2 is issued when more input is expected during command entry, for example because the command was not terminated with a semicolon or a quote was not closed. Prompt 3 is issued when you are running an SQL `COPY FROM STDIN` command and you need to type in a row value on the terminal.

The value of the selected prompt variable is printed literally, except where a percent sign (%) is encountered. Depending on the next character, certain other text is substituted instead. Defined substitutions are:

- %M
The full host name (with domain name) of the database server, or `[local]` if the connection is over a Unix domain socket, or `[local:/dir/name]`, if the Unix domain socket is not at the compiled in default location.
- %m
The host name of the database server, truncated at the first dot, or `[local]` if the connection is over a Unix domain socket.
- %>
The port number at which the database server is listening.
- %n
The database session user name. (The expansion of this value might change during a database session as the result of the command `SET SESSION AUTHORIZATION`.)
- %/
The name of the current database.

`%~`

Like `%/`, but the output is `~` (tilde) if the database is your default database.

`%#`

If the session user is a database superuser, then a `#`, otherwise a `>`. (The expansion of this value might change during a database session as the result of the command `SET SESSION AUTHORIZATION`.)

`%P`

The process ID of the backend currently connected to.

`%R`

In prompt 1 normally `=`, but `^` if in single-line mode, or `!` if the session is disconnected from the database (which can happen if `\connect` fails). In prompt 2 `%R` is replaced by a character that depends on why psql expects more input: `-` if the command simply wasn't terminated yet, but `*` if there is an unfinished `/ * . . . */` comment, a single quote if there is an unfinished quoted string, a double quote if there is an unfinished quoted identifier, a dollar sign if there is an unfinished dollar-quoted string, or `(` if there is an unmatched left parenthesis. In prompt 3 `%R` doesn't produce anything.

`%x`

Transaction status: an empty string when not in a transaction block, or `*` when in a transaction block, or `!` when in a failed transaction block, or `?` when the transaction state is indeterminate (for example, because there is no connection).

`%l`

The line number inside the current statement, starting from 1.

`%digits`

The character with the indicated octal code is substituted.

`%:name:`

The value of the psql variable *name*. See the section [the section called “Variables”](#) for details.

`%`command``

The output of *command*, similar to ordinary “back-tick” substitution.

`%[ ... %]`

Prompts can contain terminal control characters which, for example, change the color, background, or style of the prompt text, or change the title of the terminal window. In order for the line editing features of Readline to work properly, these non-printing control characters must be designated as invisible by surrounding them with `%[` and `%)`. Multiple pairs of these can occur within the prompt. For example:

```
testdb=> \set PROMPT1 '%[%033[1;33;40m%]%n@%/%R%[%033[0m%]%# '
```

results in a boldfaced (1;) yellow-on-black (33;40) prompt on VT100-compatible, color-capable terminals.

To insert a percent sign into your prompt, write `%%`. The default prompts are `'%/%R%# '` for prompts 1 and 2, and `'>> '` for prompt 3.

Note

This feature was shamelessly plagiarized from tcsh.

Command-Line Editing

psql supports the Readline library for convenient line editing and retrieval. The command history is automatically saved when psql exits and is reloaded when psql starts up. Tab-completion is also supported, although the completion logic makes no claim to be an SQL parser. The queries generated by tab-completion can also interfere with other SQL commands, e.g., `SET TRANSACTION ISOLATION LEVEL`. If for some reason you do not like the tab completion, you can turn it off by putting this in a file named `.inputrc` in your home directory:

```
$if psql
set disable-completion on
$endif
```

(This is not a psql but a Readline feature. Read its documentation for further details.)

Environment

COLUMNS

If `\pset columns` is zero, controls the width for the wrapped format and width for determining if wide output requires the pager or should be switched to the vertical format in expanded auto mode.

PAGER

If the query results do not fit on the screen, they are piped through this command. Typical values are `more` or `less`. The default is platform-dependent. Use of the pager can be disabled by setting `PAGER` to empty, or by using pager-related options of the `\pset` command.

PGDATABASE

PGHOST

PGPORT

PGUSER

Default connection parameters (see [Section 32.14](#)).

PSQL_EDITOR

EDITOR

VISUAL

Editor used by the `\e`, `\ef`, and `\ev` commands. These variables are examined in the order listed; the first that is set is used.

The built-in default editors are `vi` on Unix systems and `notepad.exe` on Windows systems.

PSQL_EDITOR_LINENUMBER_ARG

When `\e`, `\ef`, or `\ev` is used with a line number argument, this variable specifies the command-line argument used to pass the starting line number to the user's editor. For editors such as Emacs or `vi`, this is a plus sign. Include a trailing space in the value of the variable if there needs to be space between the option name and the line number. Examples:

```
PSQL_EDITOR_LINENUMBER_ARG='+'
PSQL_EDITOR_LINENUMBER_ARG='--line '
```

The default is `+` on Unix systems (corresponding to the default editor `vi`, and useful for many other common editors); but there is no default on Windows systems.

PSQL_HISTORY

Alternative location for the command history file. Tilde (`~`) expansion is performed.

PSQLRC

Alternative location of the user's `.psqlrc` file. Tilde (`~`) expansion is performed.

SHELL

Command executed by the `\!` command.

TMPDIR

Directory for storing temporary files. The default is `/tmp`.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 32.14](#)).

Files

psqlrc and `~/.psqlrc`

Unless it is passed an `-x` option, psql attempts to read and execute commands from the system-wide startup file (`psqlrc`) and then the user's personal startup file (`~/.psqlrc`), after connecting to the database but before accepting normal commands. These files can be used to set up the client and/or the server to taste, typically with `\set` and `SET` commands.

The system-wide startup file is named `psqlrc` and is sought in the installation's "system configuration" directory, which is most reliably identified by running `pg_config --sysconfdir`. By default this directory will be `../etc/` relative to the directory containing the Postgres Pro executables. The name of this directory can be set explicitly via the `PGSYSCONFDIR` environment variable.

The user's personal startup file is named `.psqlrc` and is sought in the invoking user's home directory. On Windows, which lacks such a concept, the personal startup file is named `%APPDATA%\postgresql\psqlrc.conf`. The location of the user's startup file can be set explicitly via the `PSQLRC` environment variable.

Both the system-wide startup file and the user's personal startup file can be made psql-version-specific by appending a dash and the Postgres Pro major or minor release number to the file name, for example `~/.psqlrc-9.2` or `~/.psqlrc-9.2.5`. The most specific version-matching file will be read in preference to a non-version-specific file.

.psql_history

The command-line history is stored in the file `~/.psql_history`, or `%APPDATA%\postgresql\psql_history` on Windows.

The location of the history file can be set explicitly via the `PSQL_HISTORY` environment variable.

Notes

- psql works best with servers of the same or an older major version. Backslash commands are particularly likely to fail if the server is of a newer version than psql itself. However, backslash commands of the `\d` family should work with servers of versions back to 7.4, though not necessarily with servers newer than psql itself. The general functionality of running SQL commands and displaying query results should also work with servers of a newer major version, but this cannot be guaranteed in all cases.

If you want to use psql to connect to several servers of different major versions, it is recommended that you use the newest version of psql. Alternatively, you can keep around a copy of psql from each major version and be sure to use the version that matches the respective server. But in practice, this additional complication should not be necessary.

- Before Postgres Pro 9.6, the `-c` option implied `-x` (`--no-psqlrc`); this is no longer the case.
- Before PostgreSQL 8.4, psql allowed the first argument of a single-letter backslash command to start directly after the command, without intervening whitespace. Now, some whitespace is required.

Notes for Windows Users

psql is built as a “console application”. Since the Windows console windows use a different encoding than the rest of the system, you must take special care when using 8-bit characters within psql. If psql detects a problematic console code page, it will warn you at startup. To change the console code page, two things are necessary:

- Set the code page by entering `cmd.exe /c chcp 1252`. (1252 is a code page that is appropriate for German; replace it with your value.) If you are using Cygwin, you can put this command in `/etc/profile`.
- Set the console font to `Lucida Console`, because the raster font does not work with the ANSI code page.

Examples

The first example shows how to spread a command over several lines of input. Notice the changing prompt:

```
testdb=> CREATE TABLE my_table (  
testdb(>   first integer not null default 0,  
testdb(>   second text)  
testdb-> ;  
CREATE TABLE
```

Now look at the table definition again:

```
testdb=> \d my_table  
              Table "my_table"  
Attribute |   Type   |      Modifier  
-----+-----+-----  
first      | integer  | not null default 0  
second     | text     |
```

Now we change the prompt to something more interesting:

```
testdb=> \set PROMPT1 '%n@%m %~%R%# '  
peter@localhost testdb=>
```

Let's assume you have filled the table with data and want to take a look at it:

```
peter@localhost testdb=> SELECT * FROM my_table;  
 first | second  
-----+-----  
    1  | one  
    2  | two  
    3  | three  
    4  | four  
(4 rows)
```

You can display tables in different ways by using the `\pset` command:

```
peter@localhost testdb=> \pset border 2  
Border style is 2.  
peter@localhost testdb=> SELECT * FROM my_table;  
+-----+-----+  
| first | second |  
+-----+-----+  
|    1  | one    |  
|    2  | two    |  
|    3  | three  |  
|    4  | four   |
```

```
+-----+-----+
(4 rows)
```

```
peter@localhost testdb=> \pset border 0
Border style is 0.
peter@localhost testdb=> SELECT * FROM my_table;
first second
-----
1 one
2 two
3 three
4 four
(4 rows)
```

```
peter@localhost testdb=> \pset border 1
Border style is 1.
peter@localhost testdb=> \pset format unaligned
Output format is unaligned.
peter@localhost testdb=> \pset fieldsep ","
Field separator is ",".
peter@localhost testdb=> \pset tuples_only
Showing only tuples.
peter@localhost testdb=> SELECT second, first FROM my_table;
one,1
two,2
three,3
four,4
```

Alternatively, use the short commands:

```
peter@localhost testdb=> \a \t \x
Output format is aligned.
Tuples only is off.
Expanded display is on.
peter@localhost testdb=> SELECT * FROM my_table;
-[ RECORD 1 ]-
first  | 1
second | one
-[ RECORD 2 ]-
first  | 2
second | two
-[ RECORD 3 ]-
first  | 3
second | three
-[ RECORD 4 ]-
first  | 4
second | four
```

When suitable, query results can be shown in a crosstab representation with the `\crosstabview` command:

```
testdb=> SELECT first, second, first > 2 AS gt2 FROM my_table;
first | second | gt2
-----+-----+-----
1 | one | f
2 | two | f
3 | three | t
4 | four | t
(4 rows)
```

```
testdb=> \crosstabview first second
first | one | two | three | four
-----+-----+-----+-----+-----
    1 | f   |     |       | 
    2 |     | f   |       | 
    3 |     |     | t     | 
    4 |     |     |       | t
(4 rows)
```

This second example shows a multiplication table with rows sorted in reverse numerical order and columns with an independent, ascending numerical order.

```
testdb=> SELECT t1.first as "A", t2.first+100 AS "B", t1.first*(t2.first+100) as "AxB",
testdb(> row_number() over(order by t2.first) AS ord
testdb(> FROM my_table t1 CROSS JOIN my_table t2 ORDER BY 1 DESC

reindexdb

reindexdb — reindex a Postgres Pro database

Synopsis

```
reindexdb [connection-option...] [option...] [ -S | --schema schema ] ... [ -t | --table table ] ... [ -i | --index index ] ... [dbname]
```

```
reindexdb [connection-option...] [option...] -a | --all
```

```
reindexdb [connection-option...] [option...] -s | --system [dbname]
```

Description

reindexdb is a utility for rebuilding indexes in a Postgres Pro database.

reindexdb is a wrapper around the SQL command [REINDEX](#). There is no effective difference between reindexing databases via this utility and via other methods for accessing the server.

Options

reindexdb accepts the following command-line arguments:

```
-a  
--all
```

Reindex all databases.

```
[-d] dbname  
[--dbname=] dbname
```

Specifies the name of the database to be reindexed, when `-a/--all` is not used. If this is not specified, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used. The *dbname* can be a [connection string](#). If so, connection string parameters will override any conflicting command line options.

```
-e  
--echo
```

Echo the commands that reindexdb generates and sends to the server.

```
-i index  
--index=index
```

Recreate *index* only. Multiple indexes can be recreated by writing multiple `-i` switches.

```
-q  
--quiet
```

Do not display progress messages.

```
-s  
--system
```

Reindex database's system catalogs.

```
-S schema  
--schema=schema
```

Reindex *schema* only. Multiple schemas can be reindexed by writing multiple `-S` switches.

`-t table`
`--table=table`

Reindex *table* only. Multiple tables can be reindexed by writing multiple `-t` switches.

`-v`
`--verbose`

Print detailed information during processing.

`-V`
`--version`

Print the reindexdb version and exit.

`-?`
`--help`

Show help about reindexdb command line arguments, and exit.

reindexdb also accepts the following command-line arguments for connection parameters:

`-h host`
`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`
`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

`-U username`
`--username=username`

User name to connect as.

`-w`
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`
`--password`

Force reindexdb to prompt for a password before connecting to a database.

This option is never essential, since reindexdb will automatically prompt for a password if the server demands password authentication. However, reindexdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

`--maintenance-db=dbname`

Specifies the name of the database to connect to to discover which databases should be reindexed, when `-a/--all` is used. If not specified, the `postgres` database will be used, or if that does not exist, `template1` will be used. This can be a [connection string](#). If so, connection string parameters will override any conflicting command line options. Also, connection string parameters other than the database name itself will be re-used when connecting to other databases.

Environment

PGDATABASE
PGHOST
PGPORT
PGUSER

Default connection parameters

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 32.14](#)).

Diagnostics

In case of difficulty, see [REINDEX](#) and [psql](#) for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

Notes

reindexdb might need to connect several times to the Postgres Pro server, asking for a password each time. It is convenient to have a `~/.pgpass` file in such cases. See [Section 32.15](#) for more information.

Examples

To reindex the database `test`:

```
$ reindexdb test
```

To reindex the table `foo` and the index `bar` in a database named `abcd`:

```
$ reindexdb --table foo --index bar abcd
```

[REINDEX](#)

vacuumdb

vacuumdb — garbage-collect and analyze a Postgres Pro database

Synopsis

```
vacuumdb [connection-option...] [option...] [-t | --table table [( column [...])]] ... [dbname]
```

```
vacuumdb [connection-option...] [option...] -a | --all
```

Description

vacuumdb is a utility for cleaning a Postgres Pro database. vacuumdb will also generate internal statistics used by the Postgres Pro query optimizer.

vacuumdb is a wrapper around the SQL command [VACUUM](#). There is no effective difference between vacuuming and analyzing databases via this utility and via other methods for accessing the server.

Options

vacuumdb accepts the following command-line arguments:

-a
--all

Vacuum all databases.

[-d] *dbname*
[--dbname=] *dbname*

Specifies the name of the database to be cleaned or analyzed, when -a/--all is not used. If this is not specified, the database name is read from the environment variable PGDATABASE. If that is not set, the user name specified for the connection is used. The *dbname* can be a [connection string](#). If so, connection string parameters will override any conflicting command line options.

-e
--echo

Echo the commands that vacuumdb generates and sends to the server.

-f
--full

Perform “full” vacuuming.

-F
--freeze

Aggressively “freeze” tuples.

-j *njobs*
--jobs=*njobs*

Execute the vacuum or analyze commands in parallel by running *njobs* commands simultaneously. This option reduces the time of the processing but it also increases the load on the database server.

vacuumdb will open *njobs* connections to the database, so make sure your [max_connections](#) setting is high enough to accommodate all connections.

Note that using this mode together with the -f (FULL) option might cause deadlock failures if certain system catalogs are processed in parallel.

-q
--quiet

Do not display progress messages.

-t *table* [(*column* [, ...])]
--table=*table* [(*column* [, ...])]

Clean or analyze *table* only. Column names can be specified only in conjunction with the `--analyze` or `--analyze-only` options. Multiple tables can be vacuumed by writing multiple `-t` switches.

Tip

If you specify columns, you probably have to escape the parentheses from the shell. (See examples below.)

-v
--verbose

Print detailed information during processing.

-V
--version

Print the vacuumdb version and exit.

-z
--analyze

Also calculate statistics for use by the optimizer.

-Z
--analyze-only

Only calculate statistics for use by the optimizer (no vacuum).

--analyze-in-stages

Only calculate statistics for use by the optimizer (no vacuum), like `--analyze-only`. Run several (currently three) stages of analyze with different configuration settings, to produce usable statistics faster.

This option is useful to analyze a database that was newly populated from a restored dump or by `pg_upgrade`. This option will try to create some statistics as fast as possible, to make the database usable, and then produce full statistics in the subsequent stages.

-?
--help

Show help about vacuumdb command line arguments, and exit.

vacuumdb also accepts the following command-line arguments for connection parameters:

-h *host*
--host=*host*

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

-p *port*
--port=*port*

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

```
-U username
--username=username
```

User name to connect as.

```
-w
--no-password
```

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

```
-W
--password
```

Force vacuumdb to prompt for a password before connecting to a database.

This option is never essential, since vacuumdb will automatically prompt for a password if the server demands password authentication. However, vacuumdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

```
--maintenance-db=dbname
```

Specifies the name of the database to connect to to discover which databases should be vacuumed, when `-a/--all` is used. If not specified, the `postgres` database will be used, or if that does not exist, `template1` will be used. This can be a [connection string](#). If so, connection string parameters will override any conflicting command line options. Also, connection string parameters other than the database name itself will be re-used when connecting to other databases.

Environment

```
PGDATABASE
PGHOST
PGPORT
PGUSER
```

Default connection parameters

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 32.14](#)).

Diagnostics

In case of difficulty, see [VACUUM](#) and [psql](#) for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

Notes

vacuumdb might need to connect several times to the Postgres Pro server, asking for a password each time. It is convenient to have a `~/ .pgpass` file in such cases. See [Section 32.15](#) for more information.

Examples

To clean the database `test`:

```
$ vacuumdb test
```

To clean and analyze for the optimizer a database named `bigdb`:

```
$ vacuumdb --analyze bigdb
```

To clean a single table `foo` in a database named `xyzzzy`, and analyze a single column `bar` of the table for the optimizer:

```
$ vacuumdb --analyze --verbose --table 'foo(bar)' xyzzzy
```

Postgres Pro Server Applications

This part contains reference information for Postgres Pro server applications and support utilities. These commands can only be run usefully on the host where the database server resides. Other utility programs are listed in [Postgres Pro Client Applications](#).

initdb

initdb — create a new Postgres Pro database cluster

Synopsis

```
initdb [option...] [ --pgdata | -D ] directory
```

Description

`initdb` creates a new Postgres Pro database cluster. A database cluster is a collection of databases that are managed by a single server instance.

Creating a database cluster consists of creating the directories in which the database data will live, generating the shared catalog tables (tables that belong to the whole cluster rather than to any particular database), and creating the `template1` and `postgres` databases. When you later create a new database, everything in the `template1` database is copied. (Therefore, anything installed in `template1` is automatically copied into each database created later.) The `postgres` database is a default database meant for use by users, utilities and third party applications.

Although `initdb` will attempt to create the specified data directory, it might not have permission if the parent directory of the desired data directory is root-owned. To initialize in such a setup, create an empty data directory as root, then use `chown` to assign ownership of that directory to the database user account, then `su` to become the database user to run `initdb`.

`initdb` must be run as the user that will own the server process, because the server needs to have access to the files and directories that `initdb` creates. Since the server cannot be run as root, you must not run `initdb` as root either. (It will in fact refuse to do so.)

`initdb` initializes the database cluster's default locale and character set encoding. The character set encoding, collation order (`LC_COLLATE`) and character set classes (`LC_CTYPE`, e.g., upper, lower, digit) can be set separately for a database when it is created. `initdb` determines those settings for the `template1` database, which will serve as the default for all other databases.

To alter the default collation order or character set classes, use the `--lc-collate` and `--lc-ctype` options. Collation orders other than `C` or `POSIX` also have a performance penalty. For these reasons it is important to choose the right locale when running `initdb`.

The remaining locale categories can be changed later when the server is started. You can also use `--locale` to set the default for all locale categories, including collation order and character set classes. All server locale values (`lc_*`) can be displayed via `SHOW ALL`. More details can be found in [Section 23.1](#).

To alter the default encoding, use the `--encoding`. More details can be found in [Section 23.3](#).

Options

```
-A authmethod
--auth=authmethod
```

This option specifies the authentication method for local users used in `pg_hba.conf` (host and local lines). Do not use `trust` unless you trust all local users on your system. `trust` is the default for ease of installation.

```
--auth-host=authmethod
```

This option specifies the authentication method for local users via TCP/IP connections used in `pg_hba.conf` (host lines).

`--auth-local=authmethod`

This option specifies the authentication method for local users via Unix-domain socket connections used in `pg_hba.conf` (local lines).

`-D directory`

`--pgdata=directory`

This option specifies the directory where the database cluster should be stored. This is the only information required by `initdb`, but you can avoid writing it by setting the `PGDATA` environment variable, which can be convenient since the database server (`postgres`) can find the database directory later by the same variable.

`-E encoding`

`--encoding=encoding`

Selects the encoding of the template database. This will also be the default encoding of any database you create later, unless you override it there. The default is derived from the locale, or `SQL_ASCII` if that does not work. The character sets supported by the Postgres Pro server are described in [Section 23.3.1](#).

`-k`

`--data-checksums`

Use checksums on data pages to help detect corruption by the I/O system that would otherwise be silent. Enabling checksums may incur a noticeable performance penalty. This option can only be set during initialization, and cannot be changed later. If set, checksums are calculated for all objects, in all databases.

By default, Postgres Pro clusters are initialized with checksums enabled. To change this behavior, provide the `--no-data-checksums` option.

`--no-data-checksums`

Disable checksums on data pages.

By default, Postgres Pro clusters are initialized with checksums enabled.

`--locale=locale`

Sets the default locale for the database cluster. If this option is not specified, the locale is inherited from the environment that `initdb` runs in. Locale support is described in [Section 23.1](#).

`--lc-collate=locale`

`--lc-ctype=locale`

`--lc-messages=locale`

`--lc-monetary=locale`

`--lc-numeric=locale`

`--lc-time=locale`

Like `--locale`, but only sets the locale in the specified category.

`--no-locale`

Equivalent to `--locale=C`.

`-N`

`--nosync`

By default, `initdb` will wait for all files to be written safely to disk. This option causes `initdb` to return without waiting, which is faster, but means that a subsequent operating system crash can leave the data directory corrupt. Generally, this option is useful for testing, but should not be used when creating a production installation.

`--pwfile=filename`

Makes `initdb` read the database superuser's password from a file. The first line of the file is taken as the password.

`-S`

`--sync-only`

Safely write all database files to disk and exit. This does not perform any of the normal `initdb` operations.

`-T CFG`

`--text-search-config=CFG`

Sets the default text search configuration. See [default_text_search_config](#) for further information.

`-U username`

`--username=username`

Selects the user name of the database superuser. This defaults to the name of the effective user running `initdb`. It is really not important what the superuser's name is, but one might choose to keep the customary name `postgres`, even if the operating system user's name is different.

`-W`

`--pwprompt`

Makes `initdb` prompt for a password to give the database superuser. If you don't plan on using password authentication, this is not important. Otherwise you won't be able to use password authentication until you have a password set up.

`-X directory`

`--xlogdir=directory`

This option specifies the directory where the transaction log should be stored.

Other, less commonly used, options are also available:

`-d`

`--debug`

Print debugging output from the bootstrap backend and a few other messages of lesser interest for the general public. The bootstrap backend is the program `initdb` uses to create the catalog tables. This option generates a tremendous amount of extremely boring output.

`-L directory`

Specifies where `initdb` should find its input files to initialize the database cluster. This is normally not necessary. You will be told if you need to specify their location explicitly.

`-n`

`--noclean`

By default, when `initdb` determines that an error prevented it from completely creating the database cluster, it removes any files it might have created before discovering that it cannot finish the job. This option inhibits tidying-up and is thus useful for debugging.

Other options for testing 64-bit XID:

`-m START_MX_ID`

`--multixact-id=START_MX_ID`

Specifies a start multixact id value in the decimal format for new db instance to test 64-bit xids, default value is 0.

```
-o START_MX_OFFSET  
--multixact-offset=START_MX_OFFSET
```

Specifies a start multixact offset value in the decimal format for new db instance to test 64-bit xids, default value is 0.

```
-x START_XID  
--xid=START_XID
```

Specifies a start xid value in the decimal format for new db instance to test 64-bit xids, default value is 0.

Other options:

```
-V  
--version
```

Print the initdb version and exit.

```
-?  
--help
```

Show help about initdb command line arguments, and exit.

Environment

PGDATA

Specifies the directory where the database cluster is to be stored; can be overridden using the `-D` option.

TZ

Specifies the default time zone of the created database cluster. The value should be a full time zone name (see [Section 8.5.3](#)).

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 32.14](#)).

Notes

initdb can also be invoked via `pg_ctl initdb`.

See Also

[pg_ctl](#), [postgres](#)

pg_archivecleanup

pg_archivecleanup — clean up Postgres Pro WAL archive files

Synopsis

```
pg_archivecleanup [option...] archivelocation oldestkeptwalfile
```

Description

pg_archivecleanup is designed to be used as an `archive_cleanup_command` to clean up WAL file archives when running as a standby server (see [Section 26.2](#)). pg_archivecleanup can also be used as a standalone program to clean WAL file archives.

To configure a standby server to use pg_archivecleanup, put this into its `recovery.conf` configuration file:

```
archive_cleanup_command = 'pg_archivecleanup archivelocation %r'
```

where *archivelocation* is the directory from which WAL segment files should be removed.

When used within [archive_cleanup_command](#), all WAL files logically preceding the value of the `%r` argument will be removed from *archivelocation*. This minimizes the number of files that need to be retained, while preserving crash-restart capability. Use of this parameter is appropriate if the *archivelocation* is a transient staging area for this particular standby server, but *not* when the *archivelocation* is intended as a long-term WAL archive area, or when multiple standby servers are recovering from the same archive location.

When used as a standalone program all WAL files logically preceding the *oldestkeptwalfile* will be removed from *archivelocation*. In this mode, if you specify a `.partial` or `.backup` file name, then only the file prefix will be used as the *oldestkeptwalfile*. This treatment of `.backup` file name allows you to remove all WAL files archived prior to a specific base backup without error. For example, the following example will remove all files older than WAL file name `00000001000000037000000010`:

```
pg_archivecleanup -d archive 00000001000000037000000010.00000020.backup
```

```
pg_archivecleanup: keep WAL file "archive/00000001000000037000000010" and later
pg_archivecleanup: removing file "archive/0000000100000003700000000F"
pg_archivecleanup: removing file "archive/0000000100000003700000000E"
```

pg_archivecleanup assumes that *archivelocation* is a directory readable and writable by the server-owning user.

Options

pg_archivecleanup accepts the following command-line arguments:

`-d`

Print lots of debug logging output on `stderr`.

`-n`

Print the names of the files that would have been removed on `stdout` (performs a dry run).

`-V`

`--version`

Print the pg_archivecleanup version and exit.

`-x extension`

Provide an extension that will be stripped from all file names before deciding if they should be deleted. This is typically useful for cleaning up archives that have been compressed during storage, and therefore have had an extension added by the compression program. For example: `-x .gz`.

`-?`

`--help`

Show help about `pg_archivecleanup` command line arguments, and exit.

Notes

`pg_archivecleanup` is designed to work with PostgreSQL 8.0 and later when used as a standalone utility, or with PostgreSQL 9.0 and later when used as an archive cleanup command.

`pg_archivecleanup` is written in C and has an easy-to-modify source code, with specifically designated sections to modify for your own needs

Examples

On Linux or Unix systems, you might use:

```
archive_cleanup_command = 'pg_archivecleanup -d /mnt/standby/archive %r 2>>cleanup.log'
```

where the archive directory is physically located on the standby server, so that the `archive_command` is accessing it across NFS, but the files are local to the standby. This will:

- produce debugging output in `cleanup.log`
- remove no-longer-needed files from the archive directory

[pg_standby](#)

pg_controldata

pg_controldata — display control information of a Postgres Pro database cluster

Synopsis

```
pg_controldata [option] [[-D] datadir]
```

Description

pg_controldata prints information initialized during `initdb`, such as the catalog version. It also shows information about write-ahead logging and checkpoint processing. This information is cluster-wide, and not specific to any one database.

This utility can only be run by the user who initialized the cluster because it requires read access to the data directory. You can specify the data directory on the command line, or use the environment variable `PGDATA`. This utility supports the options `-v` and `--version`, which print the pg_controldata version and exit. It also supports options `-?` and `--help`, which output the supported arguments.

Environment

PGDATA

Default data directory location

See Also

[pgpro_controldata](#)

pg_ctl

pg_ctl — initialize, start, stop, or control a Postgres Pro server

Synopsis

```
pg_ctl init[db] [-s] [-D datadir] [-o initdb-options]

pg_ctl start [-w] [-t seconds] [-s] [-D datadir] [-l filename] [-o options] [-p path] [-c]

pg_ctl stop [-W] [-t seconds] [-s] [-D datadir] [-m s[mart] | f[ast] | i[mmediate] ]

pg_ctl restart [-w] [-t seconds] [-s] [-D datadir] [-c] [-m s[mart] | f[ast] | i[mmediate] ] [-o options]

pg_ctl reload [-s] [-D datadir]

pg_ctl status [-D datadir]

pg_ctl promote [-s] [-D datadir]

pg_ctl kill signal_name process_id

pg_ctl register [-N servicename] [-U username] [-P password] [-D datadir] [-S a[uto] | d[emand] ] [-w] [-t seconds] [-s] [-o options]

pg_ctl unregister [-N servicename]
```

Description

pg_ctl is a utility for initializing a Postgres Pro database cluster, starting, stopping, or restarting the Postgres Pro database server ([postgres](#)), or displaying the status of a running server. Although the server can be started manually, pg_ctl encapsulates tasks such as redirecting log output and properly detaching from the terminal and process group. It also provides convenient options for controlled shutdown.

The `init` or `initdb` mode creates a new Postgres Pro database cluster. A database cluster is a collection of databases that are managed by a single server instance. This mode invokes the `initdb` command. See [initdb](#) for details.

In `start` mode, a new server is launched. The server is started in the background, and its standard input is attached to `/dev/null` (or `nul` on Windows). On Unix-like systems, by default, the server's standard output and standard error are sent to pg_ctl's standard output (not standard error). The standard output of pg_ctl should then be redirected to a file or piped to another process such as a log rotating program like `rotatelogs`; otherwise `postgres` will write its output to the controlling terminal (from the background) and will not leave the shell's process group. On Windows, by default the server's standard output and standard error are sent to the terminal. These default behaviors can be changed by using `-l` to append the server's output to a log file. Use of either `-l` or output redirection is recommended.

In `stop` mode, the server that is running in the specified data directory is shut down. Three different shutdown methods can be selected with the `-m` option. “Smart” mode disallows new connections, then waits for all existing clients to disconnect and any online backup to finish. If the server is in hot standby, recovery and streaming replication will be terminated once all clients have disconnected. “Fast” mode (the default) does not wait for clients to disconnect and will terminate an online backup in progress. All active transactions are rolled back and clients are forcibly disconnected, then the server is shut down. “Immediate” mode will abort all server processes immediately, without a clean shutdown. This will lead to a crash-recovery run on the next restart.

`restart` mode effectively executes a stop followed by a start. This allows changing the `postgres` command-line options. `restart` might fail if relative paths specified were specified on the command-line during server start.

`reload mode` simply sends the `postgres` process a `SIGHUP` signal, causing it to reread its configuration files (`postgresql.conf`, `pg_hba.conf`, etc.). This allows changing of configuration-file options that do not require a complete restart to take effect.

`status mode` checks whether a server is running in the specified data directory. If it is, the PID and the command line options that were used to invoke it are displayed. If the server is not running, the process returns an exit status of 3. If an accessible data directory is not specified, the process returns an exit status of 4.

In `promote mode`, the standby server that is running in the specified data directory is commanded to exit recovery and begin read-write operations.

`kill mode` allows you to send a signal to a specified process. This is particularly valuable for Microsoft Windows which does not have a `kill` command. Use `--help` to see a list of supported signal names.

`register mode` allows you to register a system service on Microsoft Windows. The `-s` option allows selection of service start type, either “auto” (start service automatically on system startup) or “demand” (start service on demand).

`unregister mode` allows you to unregister a system service on Microsoft Windows. This undoes the effects of the `register` command.

Options

`-c`
`--core-file`

Attempt to allow server crashes to produce core files, on platforms where this is possible, by lifting any soft resource limit placed on core files. This is useful in debugging or diagnosing problems by allowing a stack trace to be obtained from a failed server process.

`-D datadir`
`--pgdata datadir`

Specifies the file system location of the database configuration files. If this is omitted, the environment variable `PGDATA` is used.

`-l filename`
`--log filename`

Append the server log output to *filename*. If the file does not exist, it is created. The umask is set to 077, so access to the log file is disallowed to other users by default.

`-m mode`
`--mode mode`

Specifies the shutdown mode. *mode* can be `smart`, `fast`, or `immediate`, or the first letter of one of these three. If this is omitted, `fast` is used.

`-o options`

Specifies options to be passed directly to the `postgres` command; multiple option invocations are appended.

The options should usually be surrounded by single or double quotes to ensure that they are passed through as a group.

`-o initdb-options`

Specifies options to be passed directly to the `initdb` command.

The options should usually be surrounded by single or double quotes to ensure that they are passed through as a group.

`-p path`

Specifies the location of the `postgres` executable. By default the `postgres` executable is taken from the same directory as `pg_ctl`, or failing that, the hard-wired installation directory. It is not necessary to use this option unless you are doing something unusual and get errors that the `postgres` executable was not found.

In `init` mode, this option analogously specifies the location of the `initdb` executable.

`-s`

`--silent`

Print only errors, no informational messages.

`-t`

`--timeout`

The maximum number of seconds to wait when waiting for startup or shutdown to complete. Defaults to the value of the `PGCTLTIMEOUT` environment variable or, if not set, to 60 seconds.

`-V`

`--version`

Print the `pg_ctl` version and exit.

`-w`

Wait for the startup or shutdown to complete. Waiting is the default option for shutdowns, but not startups. When waiting for startup, `pg_ctl` repeatedly attempts to connect to the server. When waiting for shutdown, `pg_ctl` waits for the server to remove its PID file. This option allows the entry of an SSL passphrase on startup. `pg_ctl` returns an exit code based on the success of the startup or shutdown.

`-W`

Do not wait for startup or shutdown to complete. This is the default for start and restart modes.

`-?`

`--help`

Show help about `pg_ctl` command line arguments, and exit.

Options for Windows

`-e source`

Name of the event source for `pg_ctl` to use for logging to the event log when running as a Windows service. The default is `Postgres Pro`. Note that this only controls the logging from `pg_ctl` itself; once started, the server will use the event source specified by [event source](#). Should the server fail during early startup, it might also log using the default event source `Postgres Pro`.

`-N servicename`

Name of the system service to register. The name will be used as both the service name and the display name.

`-P password`

Password for the user to start the service.

`-S start-type`

Start type of the system service to register. `start-type` can be `auto`, or `demand`, or the first letter of one of these two. If this is omitted, `auto` is used.

`-U username`

User name for the user to start the service. For domain users, use the format `DOMAIN\username`.

Environment

`PGCTLTIMEOUT`

Default limit on the number of seconds to wait when waiting for startup or shutdown to complete. If not set, the default is 60 seconds.

`PGDATA`

Default data directory location.

`pg_ctl`, like most other Postgres Pro utilities, also uses the environment variables supported by `libpq` (see [Section 32.14](#)). For additional server variables, see [postgres](#).

Files

`postmaster.pid`

The existence of this file in the data directory is used to help `pg_ctl` determine if the server is currently running.

`postmaster.opts`

If this file exists in the data directory, `pg_ctl` (in `restart` mode) will pass the contents of the file as options to `postgres`, unless overridden by the `-o` option. The contents of this file are also displayed in `status` mode.

Examples

Starting the Server

To start the server:

```
$ pg_ctl start
```

To start the server, waiting until the server is accepting connections:

```
$ pg_ctl -w start
```

To start the server using port 5433, and running without `fsync`, use:

```
$ pg_ctl -o "-F -p 5433" start
```

Stopping the Server

To stop the server, use:

```
$ pg_ctl stop
```

The `-m` option allows control over *how* the server shuts down:

```
$ pg_ctl stop -m fast
```

Restarting the Server

Restarting the server is almost equivalent to stopping the server and starting it again, except that `pg_ctl` saves and reuses the command line options that were passed to the previously running instance. To restart the server in the simplest form, use:

```
$ pg_ctl restart
```

To restart the server, waiting for it to shut down and restart:

```
$ pg_ctl -w restart
```

To restart using port 5433, disabling `fsync` upon restart:

```
$ pg_ctl -o "-F -p 5433" restart
```

Showing the Server Status

Here is sample status output from `pg_ctl`:

```
$ pg_ctl status
```

```
pg_ctl: server is running (PID: 13718)
/usr/local/pgsql/bin/postgres "-D" "/usr/local/pgsql/data" "-p" "5433" "-B" "128"
```

This is the command line that would be invoked in restart mode.

pg_resetxlog

`pg_resetxlog` — reset the write-ahead log and other control information of a Postgres Pro database cluster

Synopsis

```
pg_resetxlog [-f] [-n] [option...] {[-D] datadir}
```

Description

`pg_resetxlog` clears the write-ahead log (WAL) and optionally resets some other control information stored in the `pg_control` file. This function is sometimes needed if these files have become corrupted. It should be used only as a last resort, when the server will not start due to such corruption.

After running this command, it should be possible to start the server, but bear in mind that the database might contain inconsistent data due to partially-committed transactions. You should immediately dump your data, run `initdb`, and reload. After reload, check for inconsistencies and repair as needed.

This utility can only be run by the user who installed the server, because it requires read/write access to the data directory. For safety reasons, you must specify the data directory on the command line. `pg_resetxlog` does not use the environment variable `PGDATA`.

If `pg_resetxlog` complains that it cannot determine valid data for `pg_control`, you can force it to proceed anyway by specifying the `-f` (force) option. In this case plausible values will be substituted for the missing data. Most of the fields can be expected to match, but manual assistance might be needed for the next OID, next transaction ID, next multitransaction ID and offset, and WAL starting address fields. These fields can be set using the options discussed below. If you are not able to determine correct values for all these fields, `-f` can still be used, but the recovered database must be treated with even more suspicion than usual: an immediate dump and reload is imperative. *Do not* execute any data-modifying operations in the database before you dump, as any such action is likely to make the corruption worse.

Options

- `-f`
Force `pg_resetxlog` to proceed even if it cannot determine valid data for `pg_control`, as explained above.
- `-n`
The `-n` (no operation) option instructs `pg_resetxlog` to print the values reconstructed from `pg_control` and values about to be changed, and then exit without modifying anything. This is mainly a debugging tool, but can be useful as a sanity check before allowing `pg_resetxlog` to proceed for real.
- `-V`
`--version`
Display version information, then exit.
- `-?`
`--help`
Show help, then exit.

The following options are only needed when `pg_resetxlog` is unable to determine appropriate values by reading `pg_control`. Safe values can be determined as described below. For values that take numeric arguments, hexadecimal values can be specified by using the prefix `0x`.

`-c xid,xid`

Manually set the oldest and newest transaction IDs for which the commit time can be retrieved.

A safe value for the oldest transaction ID for which the commit time can be retrieved (first part) can be determined by looking for the numerically smallest file name in the directory `pg_commit_ts` under the data directory. Conversely, a safe value for the newest transaction ID for which the commit time can be retrieved (second part) can be determined by looking for the numerically greatest file name in the same directory. The file names are in hexadecimal.

`-l xlogfile`

Manually set the WAL starting address.

The WAL starting address should be larger than any WAL segment file name currently existing in the directory `pg_xlog` under the data directory. These names are also in hexadecimal and have three parts. The first part is the “timeline ID” and should usually be kept the same. For example, if `00000001000000320000004A` is the largest entry in `pg_xlog`, use `-l 00000001000000320000004B` or higher.

Note

`pg_resetxlog` itself looks at the files in `pg_xlog` and chooses a default `-l` setting beyond the last existing file name. Therefore, manual adjustment of `-l` should only be needed if you are aware of WAL segment files that are not currently present in `pg_xlog`, such as entries in an offline archive; or if the contents of `pg_xlog` have been lost entirely.

`-m mxid,mxid`

Manually set the next and oldest multitransaction ID.

A safe value for the next multitransaction ID (first part) can be determined by looking for the numerically largest file name in the directory `pg_multixact/offsets` under the data directory, adding one, and then multiplying by 65536 (0x10000). Conversely, a safe value for the oldest multitransaction ID (second part of `-m`) can be determined by looking for the numerically smallest file name in the same directory and multiplying by 65536. The file names are in hexadecimal, so the easiest way to do this is to specify the option value in hexadecimal and append four zeroes.

`-o oid`

Manually set the next OID.

There is no comparably easy way to determine a next OID that's beyond the largest one in the database, but fortunately it is not critical to get the next-OID setting right.

`-O mxoff`

Manually set the next multitransaction offset.

A safe value can be determined by looking for the numerically largest file name in the directory `pg_multixact/members` under the data directory, adding one, and then multiplying by 52352 (0xCC80). The file names are in hexadecimal. There is no simple recipe such as the ones for other options of appending zeroes.

`-x xid`

Manually set the next transaction ID.

A safe value can be determined by looking for the numerically largest file name in the directory `pg_clog` under the data directory, adding one, and then multiplying by 1048576 (0x100000). Note that the file names are in hexadecimal. It is usually easiest to specify the option value in hexadecimal

too. For example, if 0011 is the largest entry in `pg_clog`, `-x 0x1200000` will work (five trailing zeroes provide the proper multiplier).

Notes

This command must not be used when the server is running. `pg_resetxlog` will refuse to start up if it finds a server lock file in the data directory. If the server crashed then a lock file might have been left behind; in that case you can remove the lock file to allow `pg_resetxlog` to run. But before you do so, make doubly certain that there is no server process still alive.

`pg_resetxlog` works only with servers of the same major version.

pg_rewind

`pg_rewind` — synchronize a Postgres Pro data directory with another data directory that was forked from it

Synopsis

```
pg_rewind[option...] { -D | --target-pgdata } directory { --source-pgdata=directory | --source-server=connstr }
```

Description

`pg_rewind` is a tool for synchronizing a Postgres Pro cluster with another copy of the same cluster, after the clusters' timelines have diverged. A typical scenario is to bring an old master server back online after failover as a standby that follows the new master.

The result is equivalent to replacing the target data directory with the source one. Only changed blocks from relation files are copied; all other files are copied in full, including configuration files. The advantage of `pg_rewind` over taking a new base backup, or tools like `rsync`, is that `pg_rewind` does not require reading through unchanged blocks in the cluster. This makes it a lot faster when the database is large and only a small fraction of blocks differ between the clusters.

`pg_rewind` examines the timeline histories of the source and target clusters to determine the point where they diverged, and expects to find WAL in the target cluster's `pg_xlog` directory reaching all the way back to the point of divergence. The point of divergence can be found either on the target timeline, the source timeline, or their common ancestor. In the typical failover scenario where the target cluster was shut down soon after the divergence, this is not a problem, but if the target cluster ran for a long time after the divergence, the old WAL files might no longer be present. In that case, they can be manually copied from the WAL archive to the `pg_xlog` directory. The use of `pg_rewind` is not limited to failover, e.g., a standby server can be promoted, run some write transactions, and then rewound to become a standby again.

When the target server is started for the first time after running `pg_rewind`, it will go into recovery mode and replay all WAL generated in the source server after the point of divergence. If some of the WAL was no longer available in the source server when `pg_rewind` was run, and therefore could not be copied by the `pg_rewind` session, it must be made available when the target server is started. This can be done by creating a `recovery.conf` file in the target data directory with a suitable `restore_command`.

`pg_rewind` requires that the target server either has the [wal_log_hints](#) option enabled in `postgresql.conf` or data checksums enabled when the cluster was initialized with `initdb`. Neither of these are currently on by default. [full_page_writes](#) must also be set to `on`, but is enabled by default.

Warning

If `pg_rewind` fails while processing, then the data folder of the target is likely not in a state that can be recovered. In such a case, taking a new fresh backup is recommended.

`pg_rewind` will fail immediately if it finds files it cannot write directly to. This can happen for example when the source and the target server use the same file mapping for read-only SSL keys and certificates. If such files are present on the target server it is recommended to remove them before running `pg_rewind`. After doing the rewind, some of those files may have been copied from the source, in which case it may be necessary to remove the data copied and restore back the set of links used before the rewind.

Options

`pg_rewind` accepts the following command-line arguments:

`-D directory`

`--target-pgdata=directory`

This option specifies the target data directory that is synchronized with the source. The target server must be shut down cleanly before running `pg_rewind`

`--source-pgdata=directory`

Specifies the file system path to the data directory of the source server to synchronize the target with. This option requires the source server to be cleanly shut down.

`--source-server=connstr`

Specifies a libpq connection string to connect to the source Postgres Pro server to synchronize the target with. The connection must be a normal (non-replication) connection with superuser access. This option requires the source server to be running and not in recovery mode.

`-n`

`--dry-run`

Do everything except actually modifying the target directory.

`-P`

`--progress`

Enables progress reporting. Turning this on will deliver an approximate progress report while copying data from the source cluster.

`--debug`

Print verbose debugging output that is mostly useful for developers debugging `pg_rewind`.

`-V`

`--version`

Display version information, then exit.

`-?`

`--help`

Show help, then exit.

Environment

When `--source-server` option is used, `pg_rewind` also uses the environment variables supported by libpq (see [Section 32.14](#)).

Notes

When executing `pg_rewind` using an online cluster as source which has been recently promoted, it is necessary to execute a `CHECKPOINT` after promotion so as its control file reflects up-to-date timeline information, which is used by `pg_rewind` to check if the target cluster can be rewound using the designated source cluster.

How it works

The basic idea is to copy all file system-level changes from the source cluster to the target cluster:

1. Scan the WAL log of the target cluster, starting from the last checkpoint before the point where the source cluster's timeline history forked off from the target cluster. For each WAL record, record each data block that was touched. This yields a list of all the data blocks that were changed in the target cluster, after the source cluster forked off.
2. Copy all those changed blocks from the source cluster to the target cluster, either using direct file system access (`--source-pgdata`) or SQL (`--source-server`).

3. Copy all other files such as `pg_clog` and configuration files from the source cluster to the target cluster (everything except the relation files).
4. Apply the WAL from the source cluster, starting from the checkpoint created at failover. (Strictly speaking, `pg_rewind` doesn't apply the WAL, it just creates a backup label file that makes Postgres Pro start by replaying all WAL from that checkpoint forward.)

pg-setup

pg-setup — set up a new Postgres Pro database cluster

Synopsis

```
pg-setup initdb
```

Description

pg-setup is a shell script provided in the Postgres Pro distribution to automate database cluster setup on Linux systems. This script is provided as part of the server package. pg-setup must be run as root, but performs database administration operations as user `postgres`. You can only run this script with the `initdb` option, without passing any additional arguments.

Options

pg-setup accepts the following command-line options:

```
initdb
```

Initialize the database cluster on behalf of the `postgres` user.

pg-setup creates the database cluster with checksums enabled, `auth-local` parameter set to `peer`, and `auth-host` parameter set to `md5`. Localization settings are inherited from the `LANG` environment variable for the current session. All the `LC_*` environment variables are ignored.

Important

You cannot provide any `initdb` options to customize the installation. If this is not what you expect, do not use pg-setup for cluster initialization and run `initdb` directly instead.

Notes

For details on binary installation specifics on Linux, see [Section 17.1](#).

pg_test_fsync

pg_test_fsync — determine fastest wal_sync_method for Postgres Pro

Synopsis

```
pg_test_fsync [option...]
```

Description

pg_test_fsync is intended to give you a reasonable idea of what the fastest [wal_sync_method](#) is on your specific system, as well as supplying diagnostic information in the event of an identified I/O problem. However, differences shown by pg_test_fsync might not make any significant difference in real database throughput, especially since many database servers are not speed-limited by their transaction logs. pg_test_fsync reports average file sync operation time in microseconds for each wal_sync_method, which can also be used to inform efforts to optimize the value of [commit_delay](#).

Options

pg_test_fsync accepts the following command-line options:

- f
--filename
Specifies the file name to write test data in. This file should be in the same file system that the pg_xlog directory is or will be placed in. (pg_xlog contains the WAL files.) The default is pg_test_fsync.out in the current directory.
- s
--secs-per-test
Specifies the number of seconds for each test. The more time per test, the greater the test's accuracy, but the longer it takes to run. The default is 5 seconds, which allows the program to complete in under 2 minutes.
- V
--version
Print the pg_test_fsync version and exit.
- ?
--help
Show help about pg_test_fsync command line arguments, and exit.

See Also

[postgres](#)

pg_test_timing

pg_test_timing — measure timing overhead

Synopsis

pg_test_timing [*option...*]

Description

pg_test_timing is a tool to measure the timing overhead on your system and confirm that the system time never moves backwards. Systems that are slow to collect timing data can give less accurate EXPLAIN ANALYZE results.

Options

pg_test_timing accepts the following command-line options:

-d *duration*

--duration=*duration*

Specifies the test duration, in seconds. Longer durations give slightly better accuracy, and are more likely to discover problems with the system clock moving backwards. The default test duration is 3 seconds.

-V

--version

Print the pg_test_timing version and exit.

-?

--help

Show help about pg_test_timing command line arguments, and exit.

Usage

Interpreting results

Good results will show most (>90%) individual timing calls take less than one microsecond. Average per loop overhead will be even lower, below 100 nanoseconds. This example from an Intel i7-860 system using a TSC clock source shows excellent performance:

```
Testing timing overhead for 3 seconds.
Per loop time including overhead: 35.96 nsec
Histogram of timing durations:
< usec    % of total    count
    1      96.40465    80435604
    2       3.59518     2999652
    4       0.00015        126
    8       0.00002         13
   16       0.00000          2
```

Note that different units are used for the per loop time than the histogram. The loop can have resolution within a few nanoseconds (nsec), while the individual timing calls can only resolve down to one microsecond (usec).

Measuring executor timing overhead

When the query executor is running a statement using EXPLAIN ANALYZE, individual operations are timed as well as showing a summary. The overhead of your system can be checked by counting rows with the psql program:

```
CREATE TABLE t AS SELECT * FROM generate_series(1,100000);
\timing
SELECT COUNT(*) FROM t;
EXPLAIN ANALYZE SELECT COUNT(*) FROM t;
```

The i7-860 system measured runs the count query in 9.8 ms while the `EXPLAIN ANALYZE` version takes 16.6 ms, each processing just over 100,000 rows. That 6.8 ms difference means the timing overhead per row is 68 ns, about twice what `pg_test_timing` estimated it would be. Even that relatively small amount of overhead is making the fully timed count statement take almost 70% longer. On more substantial queries, the timing overhead would be less problematic.

Changing time sources

On some newer Linux systems, it's possible to change the clock source used to collect timing data at any time. A second example shows the slowdown possible from switching to the slower `acpi_pm` time source, on the same system used for the fast results above:

```
# cat /sys/devices/system/clocksource/clocksource0/available_clocksource
tsc hpet acpi_pm
# echo acpi_pm > /sys/devices/system/clocksource/clocksource0/current_clocksource
# pg_test_timing
Per loop time including overhead: 722.92 nsec
Histogram of timing durations:
< usec    % of total    count
    1      27.84870    1155682
    2      72.05956    2990371
    4       0.07810     3241
    8       0.01357     563
   16       0.00007       3
```

In this configuration, the sample `EXPLAIN ANALYZE` above takes 115.9 ms. That's 1061 nsec of timing overhead, again a small multiple of what's measured directly by this utility. That much timing overhead means the actual query itself is only taking a tiny fraction of the accounted for time, most of it is being consumed in overhead instead. In this configuration, any `EXPLAIN ANALYZE` totals involving many timed operations would be inflated significantly by timing overhead.

FreeBSD also allows changing the time source on the fly, and it logs information about the timer selected during boot:

```
# dmesg | grep "Timecounter"
Timecounter "ACPI-fast" frequency 3579545 Hz quality 900
Timecounter "i8254" frequency 1193182 Hz quality 0
Timecounters tick every 10.000 msec
Timecounter "TSC" frequency 2531787134 Hz quality 800
# sysctl kern.timecounter.hardware=TSC
kern.timecounter.hardware: ACPI-fast -> TSC
```

Other systems may only allow setting the time source on boot. On older Linux systems the "clock" kernel setting is the only way to make this sort of change. And even on some more recent ones, the only option you'll see for a clock source is "jiffies". Jiffies are the older Linux software clock implementation, which can have good resolution when it's backed by fast enough timing hardware, as in this example:

```
$ cat /sys/devices/system/clocksource/clocksource0/available_clocksource
jiffies
$ dmesg | grep time.c
time.c: Using 3.579545 MHz WALL PM GTOD PIT/TSC timer.
time.c: Detected 2400.153 MHz processor.
$ pg_test_timing
Testing timing overhead for 3 seconds.
Per timing duration including loop overhead: 97.75 ns
Histogram of timing durations:
```

< usec	% of total	count
1	90.23734	27694571
2	9.75277	2993204
4	0.00981	3010
8	0.00007	22
16	0.00000	1
32	0.00000	1

Clock hardware and timing accuracy

Collecting accurate timing information is normally done on computers using hardware clocks with various levels of accuracy. With some hardware the operating systems can pass the system clock time almost directly to programs. A system clock can also be derived from a chip that simply provides timing interrupts, periodic ticks at some known time interval. In either case, operating system kernels provide a clock source that hides these details. But the accuracy of that clock source and how quickly it can return results varies based on the underlying hardware.

Inaccurate time keeping can result in system instability. Test any change to the clock source very carefully. Operating system defaults are sometimes made to favor reliability over best accuracy. And if you are using a virtual machine, look into the recommended time sources compatible with it. Virtual hardware faces additional difficulties when emulating timers, and there are often per operating system settings suggested by vendors.

The Time Stamp Counter (TSC) clock source is the most accurate one available on current generation CPUs. It's the preferred way to track the system time when it's supported by the operating system and the TSC clock is reliable. There are several ways that TSC can fail to provide an accurate timing source, making it unreliable. Older systems can have a TSC clock that varies based on the CPU temperature, making it unusable for timing. Trying to use TSC on some older multicore CPUs can give a reported time that's inconsistent among multiple cores. This can result in the time going backwards, a problem this program checks for. And even the newest systems can fail to provide accurate TSC timing with very aggressive power saving configurations.

Newer operating systems may check for the known TSC problems and switch to a slower, more stable clock source when they are seen. If your system supports TSC time but doesn't default to that, it may be disabled for a good reason. And some operating systems may not detect all the possible problems correctly, or will allow using TSC even in situations where it's known to be inaccurate.

The High Precision Event Timer (HPET) is the preferred timer on systems where it's available and TSC is not accurate. The timer chip itself is programmable to allow up to 100 nanosecond resolution, but you may not see that much accuracy in your system clock.

Advanced Configuration and Power Interface (ACPI) provides a Power Management (PM) Timer, which Linux refers to as the `acpi_pm`. The clock derived from `acpi_pm` will at best provide 300 nanosecond resolution.

Timers used on older PC hardware include the 8254 Programmable Interval Timer (PIT), the real-time clock (RTC), the Advanced Programmable Interrupt Controller (APIC) timer, and the Cyclone timer. These timers aim for millisecond resolution.

[EXPLAIN](#)

pg_upgrade

pg_upgrade — upgrade a Postgres Pro server instance

Synopsis

```
pg_upgrade -b oldbindir -B newbindir -d olddatadir -D newdatadir [option...]
```

Description

pg_upgrade (formerly called pg_migrator) allows data stored in PostgreSQL or Postgres Pro data files to be upgraded to a later Postgres Pro major version without the data dump/reload typically required for major version upgrades, e.g., from 8.4.7 to the current major release of Postgres Pro. It is not required for minor version upgrades, e.g., from 9.0.1 to 9.0.4.

Major Postgres Pro releases regularly add new features that often change the layout of the system tables, but the internal data storage format rarely changes. pg_upgrade uses this fact to perform rapid upgrades by creating new system tables and simply reusing the old user data files. If a future major release ever changes the data storage format in a way that makes the old data format unreadable, pg_upgrade will not be usable for such upgrades. (The community will attempt to avoid such situations.)

pg_upgrade does its best to make sure the old and new clusters are binary-compatible, e.g., by checking for compatible compile-time settings, including 32/64-bit binaries. It is important that any external modules are also binary compatible, though this cannot be checked by pg_upgrade.

pg_upgrade supports upgrades from 8.4.X and later to the current major release of Postgres Pro, including snapshot and alpha releases.

Options

pg_upgrade accepts the following command-line arguments:

`-b bindir`

`--old-bindir=bindir`

the old Postgres Pro executable directory; environment variable `PGBINOLD`

`-B bindir`

`--new-bindir=bindir`

the new Postgres Pro executable directory; environment variable `PGBINNEW`

`-c`

`--check`

check clusters only, don't change any data

`-d datadir`

`--old-datadir=datadir`

the old cluster data directory; environment variable `PGDATAOLD`

`-D datadir`

`--new-datadir=datadir`

the new cluster data directory; environment variable `PGDATANEW`

`-j njobs`

`--jobs=njobs`

number of simultaneous processes or threads to use

`-k`

`--link`

use hard links instead of copying files to the new cluster

`-o options`
`--old-options options`
options to be passed directly to the old `postgres` command; multiple option invocations are appended

`-O options`
`--new-options options`
options to be passed directly to the new `postgres` command; multiple option invocations are appended

`-p port`
`--old-port=port`
the old cluster port number; environment variable `PGPORTOLD`

`-P port`
`--new-port=port`
the new cluster port number; environment variable `PGPORTNEW`

`-r`
`--retain`
retain SQL and log files even after successful completion

`-U username`
`--username=username`
cluster's install user name; environment variable `PGUSER`

`-v`
`--verbose`
enable verbose internal logging

`-V`
`--version`
display version information, then exit

`-?`
`--help`
show help, then exit

Usage

These are the steps to perform an upgrade with `pg_upgrade`:

1. Optionally move the old cluster

If you are using a version-specific installation directory, e.g., `/opt/PostgreSQL/9.1`, you do not need to move the old cluster. The graphical installers all use version-specific installation directories.

If your installation directory is not version-specific, e.g., `/usr/local/pgsql`, it is necessary to move the current Postgres Pro install directory so it does not interfere with the new Postgres Pro installation. Once the current Postgres Pro server is shut down, it is safe to rename the Postgres Pro installation directory; assuming the old directory is `/usr/local/pgsql`, you can do:

```
mv /usr/local/pgsql /usr/local/pgsql.old
```

to rename the directory.

2. Install the new Postgres Pro binaries

Install the new server's binaries and support files. `pg_upgrade` is included in a default installation.

3. Initialize the new Postgres Pro cluster

Initialize the new cluster using `initdb`. Use compatible `initdb` flags that match the old cluster. Many prebuilt installers do this step automatically. There is no need to start the new cluster.

4. Install custom shared object files

Install any custom shared object files (or DLLs) used by the old cluster into the new cluster, e.g., `pgcrypto.so`, whether they are from `contrib` or some other source. Do not install the schema definitions, e.g., `CREATE EXTENSION pgcrypto`, because these will be upgraded from the old cluster. Also, any custom full text search files (dictionary, synonym, thesaurus, stop words) must also be copied to the new cluster.

5. Adjust authentication

`pg_upgrade` will connect to the old and new servers several times, so you might want to set authentication to `peer` in `pg_hba.conf` or use a `~/.pgpass` file (see [Section 32.15](#)).

6. Stop both servers

Make sure both database servers are stopped using, on Unix, e.g.:

```
pg_ctl -D /opt/PostgreSQL/8.4 stop
pg_ctl -D /opt/PostgreSQL/9.0 stop
```

or on Windows, using the proper service names:

```
NET STOP postgresql-8.4
NET STOP postgresql-9.0
```

Streaming replication and log-shipping standby servers can remain running until a later step.

7. Prepare for standby server upgrades

If you are upgrading standby servers using methods outlined in [section Step 9](#), verify that the old standby servers are caught up by running `pg_controldata` against the old primary and standby clusters. Verify that the “Latest checkpoint location” values match in all clusters. (There will be a mismatch if old standby servers were shut down before the old primary or if the old standby servers are still running.) Also, make sure `wal_level` is not set to `minimal` in the `postgresql.conf` file on the new primary cluster.

8. Run pg_upgrade

Always run the `pg_upgrade` binary of the new server, not the old one. `pg_upgrade` requires the specification of the old and new cluster's data and executable (`bin`) directories. You can also specify user and port values, and whether you want the data linked instead of copied (the default).

If you use link mode, the upgrade will be much faster (no file copying) and use less disk space, but you will not be able to access your old cluster once you start the new cluster after the upgrade. Link mode also requires that the old and new cluster data directories be in the same file system. (Tablespaces and `pg_xlog` can be on different file systems.) See `pg_upgrade --help` for a full list of options.

The `--jobs` option allows multiple CPU cores to be used for copying/linking of files and to dump and reload database schemas in parallel; a good place to start is the maximum of the number of CPU cores and tablespaces. This option can dramatically reduce the time to upgrade a multi-database server running on a multiprocessor machine.

For Windows users, you must be logged into an administrative account, and then start a shell as the `postgres` user and set the proper path:

```
RUNAS /USER:postgres "CMD.EXE"
SET PATH=%PATH%;C:\Program Files\PostgreSQL\9.0\bin;
```

and then run `pg_upgrade` with quoted directories, e.g.:

```
pg_upgrade.exe
```

```
--old-datadir "C:/Program Files/PostgreSQL/8.4/data"  
--new-datadir "C:/Program Files/PostgreSQL/9.0/data"  
--old-bindir "C:/Program Files/PostgreSQL/8.4/bin"  
--new-bindir "C:/Program Files/PostgreSQL/9.0/bin"
```

Once started, `pg_upgrade` will verify the two clusters are compatible and then do the upgrade. You can use `pg_upgrade --check` to perform only the checks, even if the old server is still running. `pg_upgrade --check` will also outline any manual adjustments you will need to make after the upgrade. If you are going to be using link mode, you should use the `--link` option with `--check` to enable link-mode-specific checks. `pg_upgrade` requires write permission in the current directory.

Obviously, no one should be accessing the clusters during the upgrade. `pg_upgrade` defaults to running servers on port 50432 to avoid unintended client connections. You can use the same port number for both clusters when doing an upgrade because the old and new clusters will not be running at the same time. However, when checking an old running server, the old and new port numbers must be different.

If an error occurs while restoring the database schema, `pg_upgrade` will exit and you will have to revert to the old cluster as outlined in [Step 15](#) below. To try `pg_upgrade` again, you will need to modify the old cluster so the `pg_upgrade` schema restore succeeds. If the problem is a `contrib` module, you might need to uninstall the `contrib` module from the old cluster and install it in the new cluster after the upgrade, assuming the module is not being used to store user data.

9. Upgrade Streaming Replication and Log-Shipping standby servers

If you used link mode and have Streaming Replication (see [Section 26.2.5](#)) or Log-Shipping (see [Section 26.2](#)) standby servers, you can follow these steps to quickly upgrade them. You will not be running `pg_upgrade` on the standby servers, but rather `rsync` on the primary. Do not start any servers yet.

If you did *not* use link mode, do not have or do not want to use `rsync`, or want an easier solution, skip the instructions in this section and simply recreate the standby servers once `pg_upgrade` completes and the new primary is running.

a. Install the new Postgres Pro binaries on standby servers

Make sure the new binaries and support files are installed on all standby servers.

b. Make sure the new standby data directories do *not* exist

Make sure the new standby data directories do *not* exist or are empty. If `initdb` was run, delete the standby servers' new data directories.

c. Install custom shared object files

Install the same custom shared object files on the new standbys that you installed in the new primary cluster.

d. Stop standby servers

If the standby servers are still running, stop them now using the above instructions.

e. Save configuration files

Save any configuration files from the old standbys' configuration directories you need to keep, e.g., `postgresql.conf` (and any files included by it), `postgresql.auto.conf`, `recovery.conf`, `pg_hba.conf`, because these will be overwritten or removed in the next step.

f. Run `rsync`

When using link mode, standby servers can be quickly upgraded using `rsync`. To accomplish this, from a directory on the primary server that is above the old and new database cluster directories, run this on the *primary* for each standby server:

```
rsync --archive --delete --hard-links --size-only --no-inc-recursive old_cluster  
new_cluster remote_dir
```

where `old_cluster` and `new_cluster` are relative to the current directory on the primary, and `remote_dir` is *above* the old and new cluster directories on the standby. The directory structure under the specified directories on the primary and standbys must match. Consult the `rsync` manual page for details on specifying the remote directory, e.g.,

```
rsync --archive --delete --hard-links --size-only --no-inc-recursive /opt/
PostgreSQL/9.5 \
/opt/PostgreSQL/9.6 standby.example.com:/opt/PostgreSQL
```

You can verify what the command will do using `rsync`'s `--dry-run` option. While `rsync` must be run on the primary for at least one standby, it is possible to run `rsync` on an upgraded standby to upgrade other standbys, as long as the upgraded standby has not been started.

What this does is to record the links created by `pg_upgrade`'s link mode that connect files in the old and new clusters on the primary server. It then finds matching files in the standby's old cluster and creates links for them in the standby's new cluster. Files that were not linked on the primary are copied from the primary to the standby. (They are usually small.) This provides rapid standby upgrades. Unfortunately, `rsync` needlessly copies files associated with temporary and unlogged tables because these files don't normally exist on standby servers.

If you have tablespaces, you will need to run a similar `rsync` command for each tablespace directory, e.g.:

```
rsync --archive --delete --hard-links --size-only --no-inc-recursive /vol1/
pg_tblsp/PG_9.5_201510051 \
/vol1/pg_tblsp/PG_9.6_201608131 standby.example.com:/vol1/pg_tblsp
```

If you have relocated `pg_xlog` outside the data directories, `rsync` must be run on those directories too.

g. **Configure streaming replication and log-shipping standby servers**

Configure the servers for log shipping. (You do not need to run `pg_start_backup()` and `pg_stop_backup()` or take a file system backup as the standbys are still synchronized with the primary.)

10. **Restore `pg_hba.conf`**

If you modified `pg_hba.conf`, restore its original settings. It might also be necessary to adjust other configuration files in the new cluster to match the old cluster, e.g., `postgresql.conf` (and any files included by it), `postgresql.auto.conf`.

11. **Start the new server**

The new server can now be safely started, and then any `rsync`'ed standby servers.

12. **Post-Upgrade processing**

If any post-upgrade processing is required, `pg_upgrade` will issue warnings as it completes. It will also generate script files that must be run by the administrator. The script files will connect to each database that needs post-upgrade processing. Each script should be run using:

```
psql --username postgres --file script.sql postgres
```

The scripts can be run in any order and can be deleted once they have been run.

Caution

In general it is unsafe to access tables referenced in rebuild scripts until the rebuild scripts have run to completion; doing so could yield incorrect results or poor performance. Tables not referenced in rebuild scripts can be accessed immediately.

13. Statistics

Because optimizer statistics are not transferred by `pg_upgrade`, you will be instructed to run a command to regenerate that information at the end of the upgrade. You might need to set connection parameters to match your new cluster.

14. Delete old cluster

Once you are satisfied with the upgrade, you can delete the old cluster's data directories by running the script mentioned when `pg_upgrade` completes. (Automatic deletion is not possible if you have user-defined tablespaces inside the old data directory.) You can also delete the old installation directories (e.g., `bin`, `share`).

15. Reverting to old cluster

If, after running `pg_upgrade`, you wish to revert to the old cluster, there are several options:

- If the `--check` option was used, the old cluster was unmodified; it can be restarted.
- If the `--link` option was *not* used, the old cluster was unmodified; it can be restarted.
- If the `--link` option was used, the data files might be shared between the old and new cluster:
 - If `pg_upgrade` aborted before linking started, the old cluster was unmodified; it can be restarted.
 - If you did *not* start the new cluster, the old cluster was unmodified except that, when linking started, a `.old` suffix was appended to `$PGDATA/global/pg_control`. To reuse the old cluster, remove the `.old` suffix from `$PGDATA/global/pg_control`; you can then restart the old cluster.
 - If you did start the new cluster, it has written to shared files and it is unsafe to use the old cluster. The old cluster will need to be restored from backup in this case.

Notes

`pg_upgrade` does not support upgrading of databases containing these `reg*` OID-referencing system data types: `regproc`, `regprocedure`, `regoper`, `regoperator`, `regconfig`, and `regdictionary`. (`regtype` can be upgraded.)

All failure, rebuild, and reindex cases will be reported by `pg_upgrade` if they affect your installation; post-upgrade scripts to rebuild tables and indexes will be generated automatically. If you are trying to automate the upgrade of many clusters, you should find that clusters with identical database schemas require the same post-upgrade steps for all cluster upgrades; this is because the post-upgrade steps are based on the database schemas, and not user data.

For deployment testing, create a schema-only copy of the old cluster, insert dummy data, and upgrade that.

If you are upgrading a pre-PostgreSQL 9.2 cluster that uses a configuration-file-only directory, you must pass the real data directory location to `pg_upgrade`, and pass the configuration directory location to the server, e.g., `-d /real-data-directory -o '-D /configuration-directory'`.

If using a pre-9.1 old server that is using a non-default Unix-domain socket directory or a default that differs from the default of the new cluster, set `PGHOST` to point to the old server's socket location. (This is not relevant on Windows.)

If you want to use link mode and you do not want your old cluster to be modified when the new cluster is started, make a copy of the old cluster and upgrade that in link mode. To make a valid copy of the old cluster, use `rsync` to create a dirty copy of the old cluster while the server is running, then shut down the old server and run `rsync --checksum` again to update the copy with any changes to make it consistent. (`--checksum` is necessary because `rsync` only has file modification-time granularity of one second.) You might want to exclude some files, e.g., `postmaster.pid`, as documented in [Section 25.3.3](#). If your file system supports file system snapshots or copy-on-write file copies, you can use that to make a backup

of the old cluster and tablespaces, though the snapshot and copies must be created simultaneously or while the database server is down.

pgpro_upgrade

pgpro_upgrade — upgrade a Postgres Pro database cluster to a minor update version

Synopsis

```
pgpro_upgrade [{ -D | --pgdata } directory] [ --check ]
```

```
pgpro_upgrade [ --help ]
```

Description

pgpro_upgrade is a shell script provided in the Postgres Pro distribution to facilitate Postgres Pro upgrades to minor update versions based on the same PostgreSQL major version. This script checks whether the new version introduces any system catalog changes and adds the corresponding features into the catalog of the existing database cluster. When run without any options, pgpro_upgrade upgrades the cluster specified in the PGDATA environment variable.

Options

pgpro_upgrade accepts the following command-line arguments:

`-D directory`

`--pgdata directory`

Specify the data directory of the database cluster to be upgraded. By default, pgpro_upgrade upgrades the cluster specified in the PGDATA environment variable.

`--check`

Check whether the specified database cluster needs to be upgraded, without changing any data. Return values are:

- 0 if no changes are required.
- 1 if the cluster needs to be upgraded.

`-h`

`--help`

Show help, then exit.

Usage

For Postgres Pro minor updates that introduce any system catalog changes as compared to the previous version, pgpro_upgrade must be run to update system catalogs after installing such updates. If you are upgrading your Postgres Pro installation from a binary package, the pgpro_upgrade script is run automatically, unless you are prompted to run it manually. If you have compiled Postgres Pro from source code or created your database in a non-default location, you must run the pgpro_upgrade script manually.

By default, pgpro_upgrade is located in *install-dir/bin*, where *install-dir* is the Postgres Pro installation directory. To manually run pgpro_upgrade, follow this procedure:

1. Stop the postgres service.
2. Install the new Postgres Pro version into your current installation directory.
3. On behalf of the system user owning the database, run the pgpro_upgrade script with the `-D` option specifying the database cluster to upgrade:

```
install-dir/bin/pgpro_upgrade -D directory
```

The script checks whether any changes are needed and updates the system catalogs accordingly, if required.

Note

On Windows systems, you can also run `pgpro_upgrade` using `install-dir/scripts/pgpro_upgrade.cmd` wrapper provided for convenience. This wrapper launches the `pgpro_upgrade` script for the default database cluster, without taking any arguments.

[pg_upgrade](#)

pg_xlogdump

`pg_xlogdump` — display a human-readable rendering of the write-ahead log of a Postgres Pro database cluster

Synopsis

```
pg_xlogdump [option...] [timestamp-option...] [startseg [endseg] ]
```

Description

`pg_xlogdump` displays the write-ahead log (WAL) and prints timestamps for WAL records. This utility is mainly useful for debugging or educational purposes.

This utility can only be run by the user who installed the server, because it requires read-only access to the data directory.

Options

The following command-line options control the location and format of the output:

`startseg`

Start reading at the specified log segment file. This implicitly determines the path in which files will be searched for, and the timeline to use.

`endseg`

Stop after reading the specified log segment file.

`-b`

`--bkp-details`

Output detailed information about backup blocks.

`-e end`

`--end=end`

Stop reading at the specified log position, instead of reading to the end of the log stream.

`-f`

`--follow`

After reaching the end of valid WAL, keep polling once per second for new WAL to appear.

`-n limit`

`--limit=limit`

Display the specified number of records, then stop.

`-p path`

`--path=path`

Specify a directory to search for log segment files or a directory with a `pg_xlog` subdirectory that contains such files. The default is to search in the current directory, the `pg_xlog` subdirectory of the current directory, and the `pg_xlog` subdirectory of PGDATA.

`-r rmgr`

`--rmgr=rmgr`

Only display records generated by the specified `rmgr` resource manager. If you pass `list` as an argument, `pg_xlogdump` prints a list of valid resource manager names and exits.

`-s start`
`--start=start`

Log position at which to start reading. The default is to start reading the first valid log record found in the earliest file found.

`-t timeline`
`--timeline=timeline`

Timeline from which to read log records. The default is to use the value in *startseg*, if that is specified; otherwise, the default is 1.

`-V`
`--version`

Print the `pg_xlogdump` version and exit.

`-x xid`
`--xid=xid`

Only display records marked with the given transaction ID.

`-z`
`--stats[=record]`

Display summary statistics (number and size of records and full-page images) instead of individual records. Optionally generate statistics per-record instead of per-rmgr.

`-?`
`--help`

Show help about `pg_xlogdump` command line arguments, and exit.

The following command-line options enable printing timestamps for various types of WAL records. You can use these options together with *startseg*, *endseg*, *-s*, and *-e* options.

`-E`
Print the timestamp of the last WAL record of the specified type found in the log segment file. When using this option, you must also specify the *-s* option.

By default, `pg_xlogdump` prints timestamps only for COMMIT records. You can specify other record types using the *-F* option.

`-F [argument1,argument2,...]`
Specify WAL record types for which to print timestamps. When using this option, you must also specify the *-s* option.

The *-F* option can take the following arguments, in the comma-separated format:

- `XLOG_RESTORE_POINT` — named restore points created with the `pg_create_restore_point()` function.
- `XLOG_XACT_COMMIT` — commit records for transactions. These records are caused by the `COMMIT` command.
- `XLOG_XACT_COMMIT_PREPARED` — commit records for transactions that were earlier prepared for a two-phase commit. These records are caused by the `COMMIT PREPARED` command.
- `XLOG_XACT_ABORT` — abort records for transactions. These records are caused by the `ROLLBACK` command.
- `XLOG_XACT_ABORT_PREPARED` — abort records for transactions that were earlier prepared for a two-phase commit. These records are caused by the `ROLLBACK PREPARED` command.

By default, `pg_xlogdump` prints timestamps only for COMMIT records.

`-S`

Print the timestamp of the first WAL record of the specified type found in the log segment file. This option is required if you are going to use `-E` or `-F` options.

By default, `pg_xlogdump` prints timestamps only for COMMIT records. You can specify other record types using the `-F` option.

Notes

`pg_xlogdump` can give wrong results when the server is running.

Only the specified timeline is displayed (or the default, if none is specified). Records in other timelines are ignored.

`pg_xlogdump` cannot read WAL files with suffix `.partial`. If such files need to be read, `.partial` remove the suffix from the filename.

[Section 30.5](#)

postgres

postgres — Postgres Pro database server

Synopsis

```
postgres [option...]
```

Description

`postgres` is the Postgres Pro database server. In order for a client application to access a database it connects (over a network or locally) to a running `postgres` instance. The `postgres` instance then starts a separate server process to handle the connection.

One `postgres` instance always manages the data of exactly one database cluster. A database cluster is a collection of databases that is stored at a common file system location (the “data area”). More than one `postgres` instance can run on a system at one time, so long as they use different data areas and different communication ports (see below). When `postgres` starts it needs to know the location of the data area. The location must be specified by the `-D` option or the `PGDATA` environment variable; there is no default. Typically, `-D` or `PGDATA` points directly to the data area directory created by `initdb`. Other possible file layouts are discussed in [Section 19.2](#).

By default `postgres` starts in the foreground and prints log messages to the standard error stream. In practical applications `postgres` should be started as a background process, perhaps at boot time.

The `postgres` command can also be called in single-user mode. The primary use for this mode is during bootstrapping by `initdb`. Sometimes it is used for debugging or disaster recovery; note that running a single-user server is not truly suitable for debugging the server, since no realistic interprocess communication and locking will happen. When invoked in single-user mode from the shell, the user can enter queries and the results will be printed to the screen, but in a form that is more useful for developers than end users. In the single-user mode, the session user will be set to the user with ID 1, and implicit superuser powers are granted to this user. This user does not actually have to exist, so the single-user mode can be used to manually recover from certain kinds of accidental damage to the system catalogs.

Options

`postgres` accepts the following command-line arguments. For a detailed discussion of the options consult [Chapter 19](#). You can save typing most of these options by setting up a configuration file. Some (safe) options can also be set from the connecting client in an application-dependent way to apply only for that session. For example, if the environment variable `PGOPTIONS` is set, then libpq-based clients will pass that string to the server, which will interpret it as `postgres` command-line options.

General Purpose

`-B nbuffers`

Sets the number of shared buffers for use by the server processes. The default value of this parameter is chosen automatically by `initdb`. Specifying this option is equivalent to setting the [shared_buffers](#) configuration parameter.

`-c name=value`

Sets a named run-time parameter. The configuration parameters supported by Postgres Pro are described in [Chapter 19](#). Most of the other command line options are in fact short forms of such a parameter assignment. `-c` can appear multiple times to set multiple parameters.

`-C name`

Prints the value of the named run-time parameter, and exits. (See the `-c` option above for details.) This can be used on a running server, and returns values from `postgresql.conf`, modified by any

parameters supplied in this invocation. It does not reflect parameters supplied when the cluster was started.

This option is meant for other programs that interact with a server instance, such as [pg_ctl](#), to query configuration parameter values. User-facing applications should instead use [SHOW](#) or the `pg_settings` view.

`-d debug-level`

Sets the debug level. The higher this value is set, the more debugging output is written to the server log. Values are from 1 to 5. It is also possible to pass `-d 0` for a specific session, which will prevent the server log level of the parent `postgres` process from being propagated to this session.

`-D datadir`

Specifies the file system location of the database configuration files. See [Section 19.2](#) for details.

`-e`

Sets the default date style to “European”, that is `DMY` ordering of input date fields. This also causes the day to be printed before the month in certain date output formats. See [Section 8.5](#) for more information.

`-F`

Disables `fsync` calls for improved performance, at the risk of data corruption in the event of a system crash. Specifying this option is equivalent to disabling the `fsync` configuration parameter. Read the detailed documentation before using this!

`-h hostname`

Specifies the IP host name or address on which `postgres` is to listen for TCP/IP connections from client applications. The value can also be a comma-separated list of addresses, or `*` to specify listening on all available interfaces. An empty value specifies not listening on any IP addresses, in which case only Unix-domain sockets can be used to connect to the server. Defaults to listening only on localhost. Specifying this option is equivalent to setting the `listen_addresses` configuration parameter.

`-i`

Allows remote clients to connect via TCP/IP (Internet domain) connections. Without this option, only local connections are accepted. This option is equivalent to setting `listen_addresses` to `*` in `postgresql.conf` or via `-h`.

This option is deprecated since it does not allow access to the full functionality of `listen_addresses`. It's usually better to set `listen_addresses` directly.

`-k directory`

Specifies the directory of the Unix-domain socket on which `postgres` is to listen for connections from client applications. The value can also be a comma-separated list of directories. An empty value specifies not listening on any Unix-domain sockets, in which case only TCP/IP sockets can be used to connect to the server. The default value is normally `/tmp`, but that can be changed at build time. Specifying this option is equivalent to setting the `unix_socket_directories` configuration parameter.

`-l`

Enables secure connections using SSL. Postgres Pro must have been compiled with support for SSL for this option to be available. For more information on using SSL, refer to [Section 18.9](#).

`-N max-connections`

Sets the maximum number of client connections that this server will accept. The default value of this parameter is chosen automatically by `initdb`. Specifying this option is equivalent to setting the `max_connections` configuration parameter.

`-o extra-options`

The command-line-style arguments specified in *extra-options* are passed to all server processes started by this `postgres` process.

Spaces within *extra-options* are considered to separate arguments, unless escaped with a backslash (`\`); write `\\` to represent a literal backslash. Multiple arguments can also be specified via multiple uses of `-o`.

The use of this option is obsolete; all command-line options for server processes can be specified directly on the `postgres` command line.

`-p port`

Specifies the TCP/IP port or local Unix domain socket file extension on which `postgres` is to listen for connections from client applications. Defaults to the value of the `PGPORT` environment variable, or if `PGPORT` is not set, then defaults to the value established during compilation (normally 5432). If you specify a port other than the default port, then all client applications must specify the same port using either command-line options or `PGPORT`.

`-s`

Print time information and other statistics at the end of each command. This is useful for benchmarking or for use in tuning the number of buffers.

`-S work-mem`

Specifies the amount of memory to be used by internal sorts and hashes before resorting to temporary disk files. See the description of the `work_mem` configuration parameter in [Section 19.4.1](#).

`-V`

`--version`

Print the postgres version and exit.

`--name=value`

Sets a named run-time parameter; a shorter form of `-c`.

`--describe-config`

This option dumps out the server's internal configuration variables, descriptions, and defaults in tab-delimited `COPY` format. It is designed primarily for use by administration tools.

`-?`

`--help`

Show help about postgres command line arguments, and exit.

Semi-internal Options

The options described here are used mainly for debugging purposes, and in some cases to assist with recovery of severely damaged databases. There should be no reason to use them in a production database setup. They are listed here only for use by Postgres Pro system developers. Furthermore, these options might change or be removed in a future release without notice.

`-f { s | i | o | b | t | n | m | h }`

Forbids the use of particular scan and join methods: *s* and *i* disable sequential and index scans respectively, *o*, *b* and *t* disable index-only scans, bitmap index scans, and TID scans respectively, while *n*, *m*, and *h* disable nested-loop, merge and hash joins respectively.

Neither sequential scans nor nested-loop joins can be disabled completely; the `-fs` and `-fn` options simply discourage the optimizer from using those plan types if it has any other alternative.

- n
This option is for debugging problems that cause a server process to die abnormally. The ordinary strategy in this situation is to notify all other server processes that they must terminate and then reinitialize the shared memory and semaphores. This is because an errant server process could have corrupted some shared state before terminating. This option specifies that `postgres` will not reinitialize shared data structures. A knowledgeable system programmer can then use a debugger to examine shared memory and semaphore state.
- O
Allows the structure of system tables to be modified. This is used by `initdb`.
- P
Ignore system indexes when reading system tables, but still update the indexes when modifying the tables. This is useful when recovering from damaged system indexes.
- t pa[rser] | pl[anner] | e[xecutor]
Print timing statistics for each query relating to each of the major system modules. This option cannot be used together with the `-s` option.
- T
This option is for debugging problems that cause a server process to die abnormally. The ordinary strategy in this situation is to notify all other server processes that they must terminate and then reinitialize the shared memory and semaphores. This is because an errant server process could have corrupted some shared state before terminating. This option specifies that `postgres` will stop all other server processes by sending the signal `SIGSTOP`, but will not cause them to terminate. This permits system programmers to collect core dumps from all server processes by hand.
- v *protocol*
Specifies the version number of the frontend/backend protocol to be used for a particular session. This option is for internal use only.
- W *seconds*
A delay of this many seconds occurs when a new server process is started, after it conducts the authentication procedure. This is intended to give an opportunity to attach to the server process with a debugger.

Options for Single-User Mode

The following options only apply to the single-user mode (see [the section called “Single-User Mode”](#)).

- single
Selects the single-user mode. This must be the first argument on the command line.
- database*
Specifies the name of the database to be accessed. This must be the last argument on the command line. If it is omitted it defaults to the user name.
- E
Echo all commands to standard output before executing them.
- j
Use semicolon followed by two newlines, rather than just newline, as the command entry terminator.
- r *filename*
Send all server log output to *filename*. This option is only honored when supplied as a command-line option.

Environment

PGCLIENTENCODING

Default character encoding used by clients. (The clients can override this individually.) This value can also be set in the configuration file.

PGDATA

Default data directory location

PGDATESTYLE

Default value of the [DateStyle](#) run-time parameter. (The use of this environment variable is deprecated.)

PGPORT

Default port number (preferably set in the configuration file)

Diagnostics

A failure message mentioning `semget` or `shmget` probably indicates you need to configure your kernel to provide adequate shared memory and semaphores. For more discussion see [Section 18.4](#). You might be able to postpone reconfiguring your kernel by decreasing [shared_buffers](#) to reduce the shared memory consumption of Postgres Pro, and/or by reducing [max_connections](#) to reduce the semaphore consumption.

A failure message suggesting that another server is already running should be checked carefully, for example by using the command

```
$ ps ax | grep postgres
```

or

```
$ ps -ef | grep postgres
```

depending on your system. If you are certain that no conflicting server is running, you can remove the lock file mentioned in the message and try again.

A failure message indicating inability to bind to a port might indicate that that port is already in use by some non-Postgres Pro process. You might also get this error if you terminate `postgres` and immediately restart it using the same port; in this case, you must simply wait a few seconds until the operating system closes the port before trying again. Finally, you might get this error if you specify a port number that your operating system considers to be reserved. For example, many versions of Unix consider port numbers under 1024 to be “trusted” and only permit the Unix superuser to access them.

Notes

The utility command [pg_ctl](#) can be used to start and shut down the `postgres` server safely and comfortably.

If at all possible, *do not* use `SIGKILL` to kill the main `postgres` server. Doing so will prevent `postgres` from freeing the system resources (e.g., shared memory and semaphores) that it holds before terminating. This might cause problems for starting a fresh `postgres` run.

To terminate the `postgres` server normally, the signals `SIGTERM`, `SIGINT`, or `SIGQUIT` can be used. The first will wait for all clients to terminate before quitting, the second will forcefully disconnect all clients, and the third will quit immediately without proper shutdown, resulting in a recovery run during restart.

The `SIGHUP` signal will reload the server configuration files. It is also possible to send `SIGHUP` to an individual server process, but that is usually not sensible.

To cancel a running query, send the `SIGINT` signal to the process running that command. To terminate a backend process cleanly, send `SIGTERM` to that process. See also `pg_cancel_backend` and `pg_terminate_backend` in [Section 9.26.2](#) for the SQL-callable equivalents of these two actions.

The `postgres` server uses `SIGQUIT` to tell subordinate server processes to terminate without normal cleanup. This signal *should not* be used by users. It is also unwise to send `SIGKILL` to a server process — the main `postgres` process will interpret this as a crash and will force all the sibling processes to quit as part of its standard crash-recovery procedure.

Bugs

The `--` options will not work on FreeBSD or OpenBSD. Use `-c` instead. This is a bug in the affected operating systems; a future release of Postgres Pro will provide a workaround if this is not fixed.

Single-User Mode

To start a single-user mode server, use a command like

```
postgres --single -D /usr/local/pgsql/data other-options my_database
```

Provide the correct path to the database directory with `-D`, or make sure that the environment variable `PGDATA` is set. Also specify the name of the particular database you want to work in.

Normally, the single-user mode server treats newline as the command entry terminator; there is no intelligence about semicolons, as there is in `psql`. To continue a command across multiple lines, you must type backslash just before each newline except the last one. The backslash and adjacent newline are both dropped from the input command. Note that this will happen even when within a string literal or comment.

But if you use the `-j` command line switch, a single newline does not terminate command entry; instead, the sequence semicolon-newline-newline does. That is, type a semicolon immediately followed by a completely empty line. Backslash-newline is not treated specially in this mode. Again, there is no intelligence about such a sequence appearing within a string literal or comment.

In either input mode, if you type a semicolon that is not just before or part of a command entry terminator, it is considered a command separator. When you do type a command entry terminator, the multiple statements you've entered will be executed as a single transaction.

To quit the session, type EOF (**Control+D**, usually). If you've entered any text since the last command entry terminator, then EOF will be taken as a command entry terminator, and another EOF will be needed to exit.

Note that the single-user mode server does not provide sophisticated line-editing features (no command history, for example). Single-user mode also does not do any background processing, such as automatic checkpoints or replication.

Examples

To start `postgres` in the background using default values, type:

```
$ nohup postgres >logfile 2>&1 </dev/null &
```

To start `postgres` with a specific port, e.g., 1234:

```
$ postgres -p 1234
```

To connect to this server using `psql`, specify this port with the `-p` option:

```
$ psql -p 1234
```

or set the environment variable `PGPORT`:

```
$ export PGPORT=1234
$ psql
```

Named run-time parameters can be set in either of these styles:

```
$ postgres -c work_mem=1234  
$ postgres --work-mem=1234
```

Either form overrides whatever setting might exist for `work_mem` in `postgresql.conf`. Notice that underscores in parameter names can be written as either underscore or dash on the command line. Except for short-term experiments, it's probably better practice to edit the setting in `postgresql.conf` than to rely on a command-line switch to set a parameter.

Part VII. Internals

This part contains assorted information that might be of use to Postgres Pro developers.

Chapter 49. Overview of Postgres Pro Internals

Author

This chapter originated as part of [sim98](#), Stefan Simkovics' Master's Thesis prepared at Vienna University of Technology under the direction of O.Univ.Prof.Dr. Georg Gottlob and Univ.Ass. Mag. Katrin Seyr.

This chapter gives an overview of the internal structure of the backend of Postgres Pro. After having read the following sections you should have an idea of how a query is processed. This chapter does not aim to provide a detailed description of the internal operation of Postgres Pro, as such a document would be very extensive. Rather, this chapter is intended to help the reader understand the general sequence of operations that occur within the backend from the point at which a query is received, to the point at which the results are returned to the client.

49.1. The Path of a Query

Here we give a short overview of the stages a query has to pass in order to obtain a result.

1. A connection from an application program to the Postgres Pro server has to be established. The application program transmits a query to the server and waits to receive the results sent back by the server.
2. The *parser stage* checks the query transmitted by the application program for correct syntax and creates a *query tree*.
3. The *rewrite system* takes the query tree created by the parser stage and looks for any *rules* (stored in the *system catalogs*) to apply to the query tree. It performs the transformations given in the *rule bodies*.

One application of the rewrite system is in the realization of *views*. Whenever a query against a view (i.e., a *virtual table*) is made, the rewrite system rewrites the user's query to a query that accesses the *base tables* given in the *view definition* instead.

4. The *planner/optimizer* takes the (rewritten) query tree and creates a *query plan* that will be the input to the *executor*.

It does so by first creating all possible *paths* leading to the same result. For example if there is an index on a relation to be scanned, there are two paths for the scan. One possibility is a simple sequential scan and the other possibility is to use the index. Next the cost for the execution of each path is estimated and the cheapest path is chosen. The cheapest path is expanded into a complete plan that the executor can use.

5. The executor recursively steps through the *plan tree* and retrieves rows in the way represented by the plan. The executor makes use of the *storage system* while scanning relations, performs *sorts* and *joins*, evaluates *qualifications* and finally hands back the rows derived.

In the following sections we will cover each of the above listed items in more detail to give a better understanding of Postgres Pro's internal control and data structures.

49.2. How Connections are Established

Postgres Pro is implemented using a simple “process per user” client/server model. In this model there is one *client process* connected to exactly one *server process*. As we do not know ahead of time how many connections will be made, we have to use a *master process* that spawns a new server process every time a connection is requested. This master process is called `postgres` and listens at a specified

TCP/IP port for incoming connections. Whenever a request for a connection is detected the `postgres` process spawns a new server process. The server tasks communicate with each other using *semaphores* and *shared memory* to ensure data integrity throughout concurrent data access.

The client process can be any program that understands the Postgres Pro protocol described in [Chapter 51](#). Many clients are based on the C-language library `libpq`, but several independent implementations of the protocol exist, such as the Java JDBC driver.

Once a connection is established the client process can send a query to the *backend* (server). The query is transmitted using plain text, i.e., there is no parsing done in the *frontend* (client). The server parses the query, creates an *execution plan*, executes the plan and returns the retrieved rows to the client by transmitting them over the established connection.

49.3. The Parser Stage

The *parser stage* consists of two parts:

- The *parser* defined in `gram.y` and `scan.l` is built using the Unix tools `bison` and `flex`.
- The *transformation process* does modifications and augmentations to the data structures returned by the parser.

49.3.1. Parser

The parser has to check the query string (which arrives as plain text) for valid syntax. If the syntax is correct a *parse tree* is built up and handed back; otherwise an error is returned. The parser and lexer are implemented using the well-known Unix tools `bison` and `flex`.

The *lexer* is defined in the file `scan.l` and is responsible for recognizing *identifiers*, the *SQL key words* etc. For every key word or identifier that is found, a *token* is generated and handed to the parser.

The parser is defined in the file `gram.y` and consists of a set of *grammar rules* and *actions* that are executed whenever a rule is fired. The code of the actions (which is actually C code) is used to build up the parse tree.

The file `scan.l` is transformed to the C source file `scan.c` using the program `flex` and `gram.y` is transformed to `gram.c` using `bison`. After these transformations have taken place a normal C compiler can be used to create the parser. Never make any changes to the generated C files as they will be overwritten the next time `flex` or `bison` is called.

Note

The mentioned transformations and compilations are normally done automatically using the *makefiles* shipped with the Postgres Pro source distribution.

A detailed description of `bison` or the grammar rules given in `gram.y` would be beyond the scope of this paper. There are many books and documents dealing with `flex` and `bison`. You should be familiar with `bison` before you start to study the grammar given in `gram.y` otherwise you won't understand what happens there.

49.3.2. Transformation Process

The parser stage creates a parse tree using only fixed rules about the syntactic structure of SQL. It does not make any lookups in the system catalogs, so there is no possibility to understand the detailed semantics of the requested operations. After the parser completes, the *transformation process* takes the tree handed back by the parser as input and does the semantic interpretation needed to understand which tables, functions, and operators are referenced by the query. The data structure that is built to represent this information is called the *query tree*.

The reason for separating raw parsing from semantic analysis is that system catalog lookups can only be done within a transaction, and we do not wish to start a transaction immediately upon receiving a query string. The raw parsing stage is sufficient to identify the transaction control commands (`BEGIN`, `ROLLBACK`, etc), and these can then be correctly executed without any further analysis. Once we know that we are dealing with an actual query (such as `SELECT` or `UPDATE`), it is okay to start a transaction if we're not already in one. Only then can the transformation process be invoked.

The query tree created by the transformation process is structurally similar to the raw parse tree in most places, but it has many differences in detail. For example, a `FuncCall` node in the parse tree represents something that looks syntactically like a function call. This might be transformed to either a `FuncExpr` or `Aggref` node depending on whether the referenced name turns out to be an ordinary function or an aggregate function. Also, information about the actual data types of columns and expression results is added to the query tree.

49.4. The Postgres Pro Rule System

Postgres Pro supports a powerful *rule system* for the specification of *views* and ambiguous *view updates*. Originally the Postgres Pro rule system consisted of two implementations:

- The first one worked using *row level* processing and was implemented deep in the *executor*. The rule system was called whenever an individual row had been accessed. This implementation was removed in 1995 when the last official release of the Berkeley Postgres project was transformed into Postgres95.
- The second implementation of the rule system is a technique called *query rewriting*. The *rewrite system* is a module that exists between the *parser stage* and the *planner/optimizer*. This technique is still implemented.

The query rewriter is discussed in some detail in [Chapter 39](#), so there is no need to cover it here. We will only point out that both the input and the output of the rewriter are query trees, that is, there is no change in the representation or level of semantic detail in the trees. Rewriting can be thought of as a form of macro expansion.

49.5. Planner/Optimizer

The task of the *planner/optimizer* is to create an optimal execution plan. A given SQL query (and hence, a query tree) can be actually executed in a wide variety of different ways, each of which will produce the same set of results. If it is computationally feasible, the query optimizer will examine each of these possible execution plans, ultimately selecting the execution plan that is expected to run the fastest.

Note

In some situations, examining each possible way in which a query can be executed would take an excessive amount of time and memory space. In particular, this occurs when executing queries involving large numbers of join operations. In order to determine a reasonable (not necessarily optimal) query plan in a reasonable amount of time, Postgres Pro uses a *Genetic Query Optimizer* (see [Chapter 56](#)) when the number of joins exceeds a threshold (see [geqo_threshold](#)).

The planner's search procedure actually works with data structures called *paths*, which are simply cut-down representations of plans containing only as much information as the planner needs to make its decisions. After the cheapest path is determined, a full-fledged *plan tree* is built to pass to the executor. This represents the desired execution plan in sufficient detail for the executor to run it. In the rest of this section we'll ignore the distinction between paths and plans.

49.5.1. Generating Possible Plans

The planner/optimizer starts by generating plans for scanning each individual relation (table) used in the query. The possible plans are determined by the available indexes on each relation. There is always

the possibility of performing a sequential scan on a relation, so a sequential scan plan is always created. Assume an index is defined on a relation (for example a B-tree index) and a query contains the restriction `relation.attribute OPR constant`. If `relation.attribute` happens to match the key of the B-tree index and `OPR` is one of the operators listed in the index's *operator class*, another plan is created using the B-tree index to scan the relation. If there are further indexes present and the restrictions in the query happen to match a key of an index, further plans will be considered. Index scan plans are also generated for indexes that have a sort ordering that can match the query's `ORDER BY` clause (if any), or a sort ordering that might be useful for merge joining (see below).

If the query requires joining two or more relations, plans for joining relations are considered after all feasible plans have been found for scanning single relations. The three available join strategies are:

- *nested loop join*: The right relation is scanned once for every row found in the left relation. This strategy is easy to implement but can be very time consuming. (However, if the right relation can be scanned with an index scan, this can be a good strategy. It is possible to use values from the current row of the left relation as keys for the index scan of the right.)
- *merge join*: Each relation is sorted on the join attributes before the join starts. Then the two relations are scanned in parallel, and matching rows are combined to form join rows. This kind of join is more attractive because each relation has to be scanned only once. The required sorting might be achieved either by an explicit sort step, or by scanning the relation in the proper order using an index on the join key.
- *hash join*: the right relation is first scanned and loaded into a hash table, using its join attributes as hash keys. Next the left relation is scanned and the appropriate values of every row found are used as hash keys to locate the matching rows in the table.

When the query involves more than two relations, the final result must be built up by a tree of join steps, each with two inputs. The planner examines different possible join sequences to find the cheapest one.

If the query uses fewer than `geqo_threshold` relations, a near-exhaustive search is conducted to find the best join sequence. The planner preferentially considers joins between any two relations for which there exist a corresponding join clause in the `WHERE` qualification (i.e., for which a restriction like `where rel1.attr1=rel2.attr2` exists). Join pairs with no join clause are considered only when there is no other choice, that is, a particular relation has no available join clauses to any other relation. All possible plans are generated for every join pair considered by the planner, and the one that is (estimated to be) the cheapest is chosen.

When `geqo_threshold` is exceeded, the join sequences considered are determined by heuristics, as described in [Chapter 56](#). Otherwise the process is the same.

The finished plan tree consists of sequential or index scans of the base relations, plus nested-loop, merge, or hash join nodes as needed, plus any auxiliary steps needed, such as sort nodes or aggregate-function calculation nodes. Most of these plan node types have the additional ability to do *selection* (discarding rows that do not meet a specified Boolean condition) and *projection* (computation of a derived column set based on given column values, that is, evaluation of scalar expressions where needed). One of the responsibilities of the planner is to attach selection conditions from the `WHERE` clause and computation of required output expressions to the most appropriate nodes of the plan tree.

49.6. Executor

The *executor* takes the plan created by the planner/optimizer and recursively processes it to extract the required set of rows. This is essentially a demand-pull pipeline mechanism. Each time a plan node is called, it must deliver one more row, or report that it is done delivering rows.

To provide a concrete example, assume that the top node is a `MergeJoin` node. Before any merge can be done two rows have to be fetched (one from each subplan). So the executor recursively calls itself to process the subplans (it starts with the subplan attached to `lefttree`). The new top node (the top node of the left subplan) is, let's say, a `Sort` node and again recursion is needed to obtain an input row. The child node of the `Sort` might be a `SeqScan` node, representing actual reading of a table. Execution of this

node causes the executor to fetch a row from the table and return it up to the calling node. The `Sort` node will repeatedly call its child to obtain all the rows to be sorted. When the input is exhausted (as indicated by the child node returning a `NULL` instead of a row), the `Sort` code performs the sort, and finally is able to return its first output row, namely the first one in sorted order. It keeps the remaining rows stored so that it can deliver them in sorted order in response to later demands.

The `MergeJoin` node similarly demands the first row from its right subplan. Then it compares the two rows to see if they can be joined; if so, it returns a join row to its caller. On the next call, or immediately if it cannot join the current pair of inputs, it advances to the next row of one table or the other (depending on how the comparison came out), and again checks for a match. Eventually, one subplan or the other is exhausted, and the `MergeJoin` node returns `NULL` to indicate that no more join rows can be formed.

Complex queries can involve many levels of plan nodes, but the general approach is the same: each node computes and returns its next output row each time it is called. Each node is also responsible for applying any selection or projection expressions that were assigned to it by the planner.

The executor mechanism is used to evaluate all four basic SQL query types: `SELECT`, `INSERT`, `UPDATE`, and `DELETE`. For `SELECT`, the top-level executor code only needs to send each row returned by the query plan tree off to the client. `INSERT ... SELECT`, `UPDATE`, and `DELETE` are effectively `SELECT`s under a special top-level plan node called `ModifyTable`.

`INSERT ... SELECT` feeds the rows up to `ModifyTable` for insertion. For `UPDATE`, the planner arranges that each computed row includes all the updated column values, plus the *TID* (tuple ID, or row ID) of the original target row; this data is fed up to the `ModifyTable` node, which uses the information to create a new updated row and mark the old row deleted. For `DELETE`, the only column that is actually returned by the plan is the TID, and the `ModifyTable` node simply uses the TID to visit each target row and mark it deleted.

A simple `INSERT ... VALUES` command creates a trivial plan tree consisting of a single `Result` node, which computes just one result row, feeding that up to `ModifyTable` to perform the insertion.

Chapter 50. System Catalogs

The system catalogs are the place where a relational database management system stores schema metadata, such as information about tables and columns, and internal bookkeeping information. Postgres Pro's system catalogs are regular tables. You can drop and recreate the tables, add columns, insert and update values, and severely mess up your system that way. Normally, one should not change the system catalogs by hand, there are normally SQL commands to do that. (For example, `CREATE DATABASE` inserts a row into the `pg_database` catalog — and actually creates the database on disk.) There are some exceptions for particularly esoteric operations, but many of those have been made available as SQL commands over time, and so the need for direct manipulation of the system catalogs is ever decreasing.

50.1. Overview

Table 50.1 lists the system catalogs. More detailed documentation of each catalog follows below.

Most system catalogs are copied from the template database during database creation and are thereafter database-specific. A few catalogs are physically shared across all databases in a cluster; these are noted in the descriptions of the individual catalogs.

Table 50.1. System Catalogs

Catalog Name	Purpose
<code>pg_aggregate</code>	aggregate functions
<code>pg_am</code>	index access methods
<code>pg_amop</code>	access method operators
<code>pg_amproc</code>	access method support procedures
<code>pg_attrdef</code>	column default values
<code>pg_attribute</code>	table columns (“attributes”)
<code>pg_authid</code>	authorization identifiers (roles)
<code>pg_auth_members</code>	authorization identifier membership relationships
<code>pg_cast</code>	casts (data type conversions)
<code>pg_class</code>	tables, indexes, sequences, views (“relations”)
<code>pg_collation</code>	collations (locale information)
<code>pg_constraint</code>	check constraints, unique constraints, primary key constraints, foreign key constraints
<code>pg_conversion</code>	encoding conversion information
<code>pg_database</code>	databases within this database cluster
<code>pg_db_role_setting</code>	per-role and per-database settings
<code>pg_default_acl</code>	default privileges for object types
<code>pg_depend</code>	dependencies between database objects
<code>pg_description</code>	descriptions or comments on database objects
<code>pg_enum</code>	enum label and value definitions
<code>pg_event_trigger</code>	event triggers
<code>pg_extension</code>	installed extensions
<code>pg_foreign_data_wrapper</code>	foreign-data wrapper definitions
<code>pg_foreign_server</code>	foreign server definitions
<code>pg_foreign_table</code>	additional foreign table information
<code>pg_index</code>	additional index information

Catalog Name	Purpose
<code>pg_inherits</code>	table inheritance hierarchy
<code>pg_init_privs</code>	object initial privileges
<code>pg_language</code>	languages for writing functions
<code>pg_largeobject</code>	data pages for large objects
<code>pg_largeobject_metadata</code>	metadata for large objects
<code>pg_namespace</code>	schemas
<code>pg_opclass</code>	access method operator classes
<code>pg_operator</code>	operators
<code>pg_opfamily</code>	access method operator families
<code>pg_pltemplate</code>	template data for procedural languages
<code>pg_policy</code>	row-security policies
<code>pg_proc</code>	functions and procedures
<code>pg_range</code>	information about range types
<code>pg_replication_origin</code>	registered replication origins
<code>pg_rewrite</code>	query rewrite rules
<code>pg_seclabel</code>	security labels on database objects
<code>pg_shdepend</code>	dependencies on shared objects
<code>pg_shdescription</code>	comments on shared objects
<code>pg_shseclabel</code>	security labels on shared database objects
<code>pg_statistic</code>	planner statistics
<code>pg_tablespace</code>	tablespaces within this database cluster
<code>pg_transform</code>	transforms (data type to procedural language conversions)
<code>pg_trigger</code>	triggers
<code>pg_ts_config</code>	text search configurations
<code>pg_ts_config_map</code>	text search configurations' token mappings
<code>pg_ts_dict</code>	text search dictionaries
<code>pg_ts_parser</code>	text search parsers
<code>pg_ts_template</code>	text search templates
<code>pg_type</code>	data types
<code>pg_user_mapping</code>	mappings of users to foreign servers

50.2. pg_aggregate

The catalog `pg_aggregate` stores information about aggregate functions. An aggregate function is a function that operates on a set of values (typically one column from each row that matches a query condition) and returns a single value computed from all these values. Typical aggregate functions are `sum`, `count`, and `max`. Each entry in `pg_aggregate` is an extension of an entry in `pg_proc`. The `pg_proc` entry carries the aggregate's name, input and output data types, and other information that is similar to ordinary functions.

Table 50.2. pg_aggregate Columns

Name	Type	References	Description
aggfnoid	regproc	pg_proc .oid	pg_proc OID of the aggregate function
aggkind	char		Aggregate kind: n for “normal” aggregates, o for “ordered-set” aggregates, or h for “hypothetical-set” aggregates
aggnumdirectargs	int2		Number of direct (non-aggregated) arguments of an ordered-set or hypothetical-set aggregate, counting a variadic array as one argument. If equal to <code>pronargs</code> , the aggregate must be variadic and the variadic array describes the aggregated arguments as well as the final direct arguments. Always zero for normal aggregates.
aggtransfn	regproc	pg_proc .oid	Transition function
aggfinalfn	regproc	pg_proc .oid	Final function (zero if none)
aggcombinefn	regproc	pg_proc .oid	Combine function (zero if none)
aggserialfn	regproc	pg_proc .oid	Serialization function (zero if none)
aggdeserialfn	regproc	pg_proc .oid	Deserialization function (zero if none)
aggmtransfn	regproc	pg_proc .oid	Forward transition function for moving-aggregate mode (zero if none)
aggminvtransfn	regproc	pg_proc .oid	Inverse transition function for moving-aggregate mode (zero if none)
aggmfinalfn	regproc	pg_proc .oid	Final function for moving-aggregate mode (zero if none)
aggfinalextra	bool		True to pass extra dummy arguments to <code>aggfinalfn</code>
aggmfinalextra	bool		True to pass extra dummy arguments to <code>aggmfinalfn</code>

Name	Type	References	Description
aggsortop	oid	pg_operator .oid	Associated sort operator (zero if none)
aggtranstype	oid	pg_type .oid	Data type of the aggregate function's internal transition (state) data
aggtransspace	int4		Approximate average size (in bytes) of the transition state data, or zero to use a default estimate
aggmtranstype	oid	pg_type .oid	Data type of the aggregate function's internal transition (state) data for moving-aggregate mode (zero if none)
aggmtransspace	int4		Approximate average size (in bytes) of the transition state data for moving-aggregate mode, or zero to use a default estimate
agginitval	text		The initial value of the transition state. This is a text field containing the initial value in its external string representation. If this field is null, the transition state value starts out null.
aggminitval	text		The initial value of the transition state for moving-aggregate mode. This is a text field containing the initial value in its external string representation. If this field is null, the transition state value starts out null.

New aggregate functions are registered with the [CREATE AGGREGATE](#) command. See [Section 36.10](#) for more information about writing aggregate functions and the meaning of the transition functions, etc.

50.3. pg_am

The catalog `pg_am` stores information about relation access methods. There is one row for each access method supported by the system. Currently, only indexes have access methods. The requirements for index access methods are discussed in detail in [Chapter 57](#).

Table 50.3. pg_am Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
amname	name		Name of the access method
amhandler	regproc	pg_proc .oid	OID of a handler function that is responsible for supplying information about the access method
amtype	char		Currently always i to indicate an index access method; other values may be allowed in future

Note

Before Postgres Pro 9.6, `pg_am` contained many additional columns representing properties of index access methods. That data is now only directly visible at the C code level. However, `pg_index_column_has_property()` and related functions have been added to allow SQL queries to inspect index access method properties; see [Table 9.62](#).

50.4. pg_amop

The catalog `pg_amop` stores information about operators associated with access method operator families. There is one row for each operator that is a member of an operator family. A family member can be either a *search* operator or an *ordering* operator. An operator can appear in more than one family, but cannot appear in more than one search position nor more than one ordering position within a family. (It is allowed, though unlikely, for an operator to be used for both search and ordering purposes.)

Table 50.4. pg_amop Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
amopfamily	oid	pg_opfamily .oid	The operator family this entry is for
amoplefttype	oid	pg_type .oid	Left-hand input data type of operator
amoprightrighttype	oid	pg_type .oid	Right-hand input data type of operator
amopstrategy	int2		Operator strategy number
amoppurpose	char		Operator purpose, either s for search or o for ordering
amopopr	oid	pg_operator .oid	OID of the operator
amopmethod	oid	pg_am .oid	Index access method operator family is for

Name	Type	References	Description
amopsortfamily	oid	pg_opfamily .oid	The B-tree operator family this entry sorts according to, if an ordering operator; zero if a search operator

A “search” operator entry indicates that an index of this operator family can be searched to find all rows satisfying `WHERE indexed_column operator constant`. Obviously, such an operator must return boolean, and its left-hand input type must match the index's column data type.

An “ordering” operator entry indicates that an index of this operator family can be scanned to return rows in the order represented by `ORDER BY indexed_column operator constant`. Such an operator could return any sortable data type, though again its left-hand input type must match the index's column data type. The exact semantics of the `ORDER BY` are specified by the `amopsortfamily` column, which must reference a B-tree operator family for the operator's result type.

Note

At present, it's assumed that the sort order for an ordering operator is the default for the referenced operator family, i.e., `ASC NULLS LAST`. This might someday be relaxed by adding additional columns to specify sort options explicitly.

An entry's `amopmethod` must match the `opfmethod` of its containing operator family (including `amopmethod` here is an intentional denormalization of the catalog structure for performance reasons). Also, `amoplefttype` and `amoprighttype` must match the `oprleft` and `oprright` fields of the referenced `pg_operator` entry.

50.5. pg_amproc

The catalog `pg_amproc` stores information about support procedures associated with access method operator families. There is one row for each support procedure belonging to an operator family.

Table 50.5. pg_amproc Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
amprocfamily	oid	pg_opfamily .oid	The operator family this entry is for
amproclefttype	oid	pg_type .oid	Left-hand input data type of associated operator
amprocrighttype	oid	pg_type .oid	Right-hand input data type of associated operator
amprocnum	int2		Support procedure number
amproc	regproc	pg_proc .oid	OID of the procedure

The usual interpretation of the `amproclefttype` and `amprocrighttype` fields is that they identify the left and right input types of the operator(s) that a particular support procedure supports. For some access methods these match the input data type(s) of the support procedure itself, for others not. There is a notion of “default” support procedures for an index, which are those with `amproclefttype` and `amprocrighttype` both equal to the index operator class's `opcintype`.

50.6. pg_attrdef

The catalog `pg_attrdef` stores column default values. The main information about columns is stored in `pg_attribute` (see below). Only columns that explicitly specify a default value (when the table is created or the column is added) will have an entry here.

Table 50.6. pg_attrdef Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
adrelid	oid	pg_class .oid	The table this column belongs to
adnum	int2	pg_attribute .attnum	The number of the column
adbin	pg_node_tree		The internal representation of the column default value
adsrc	text		A human-readable representation of the default value

The `adsrc` field is historical, and is best not used, because it does not track outside changes that might affect the representation of the default value. Reverse-compiling the `adbin` field (with `pg_get_expr` for example) is a better way to display the default value.

50.7. pg_attribute

The catalog `pg_attribute` stores information about table columns. There will be exactly one `pg_attribute` row for every column in every table in the database. (There will also be attribute entries for indexes, and indeed all objects that have `pg_class` entries.)

The term attribute is equivalent to column and is used for historical reasons.

Table 50.7. pg_attribute Columns

Name	Type	References	Description
attrelid	oid	pg_class .oid	The table this column belongs to
attname	name		The column name
atttypid	oid	pg_type .oid	The data type of this column
attstattarget	int4		<code>attstattarget</code> controls the level of detail of statistics accumulated for this column by ANALYZE . A zero value indicates that no statistics should be collected. A negative value says to use the system default statistics target. The exact meaning of positive values is data type-dependent. For

Name	Type	References	Description
			scalar data types, <code>attstattarget</code> is both the target number of “most common values” to collect, and the target number of histogram bins to create.
<code>attlen</code>	<code>int2</code>		A copy of <code>pg_type.typelen</code> of this column's type
<code>attnum</code>	<code>int2</code>		The number of the column. Ordinary columns are numbered from 1 up. System columns, such as <code>oid</code> , have (arbitrary) negative numbers.
<code>attndims</code>	<code>int4</code>		Number of dimensions, if the column is an array type; otherwise 0. (Presently, the number of dimensions of an array is not enforced, so any nonzero value effectively means “it's an array”.)
<code>attcacheoff</code>	<code>int4</code>		Always -1 in storage, but when loaded into a row descriptor in memory this might be updated to cache the offset of the attribute within the row
<code>atttypmod</code>	<code>int4</code>		<code>atttypmod</code> records type-specific data supplied at table creation time (for example, the maximum length of a <code>varchar</code> column). It is passed to type-specific input functions and length coercion functions. The value will generally be -1 for types that do not need <code>atttypmod</code> .
<code>attbyval</code>	<code>bool</code>		A copy of <code>pg_type.typbyval</code> of this column's type
<code>attstorage</code>	<code>char</code>		Normally a copy of <code>pg_type.typstorage</code> of this column's type. For TOAST-able data types, this can be altered after column creation to control storage policy.

Name	Type	References	Description
attalign	char		A copy of <code>pg_type.typalign</code> of this column's type
attnotnull	bool		This represents a not-null constraint.
atthasdef	bool		This column has a default value, in which case there will be a corresponding entry in the <code>pg_attrdef</code> catalog that actually defines the value.
attisdropped	bool		This column has been dropped and is no longer valid. A dropped column is still physically present in the table, but is ignored by the parser and so cannot be accessed via SQL.
attislocal	bool		This column is defined locally in the relation. Note that a column can be locally defined and inherited simultaneously.
attinhcount	int4		The number of direct ancestors this column has. A column with a nonzero number of ancestors cannot be dropped nor renamed.
attcollation	oid	pg_collation .oid	The defined collation of the column, or zero if the column is not of a collatable data type.
attacl	aclitem[]		Column-level access privileges, if any have been granted specifically on this column
attoptions	text[]		Attribute-level options, as “keyword=value” strings
attfdwoptions	text[]		Attribute-level foreign data wrapper options, as “keyword=value” strings

In a dropped column's `pg_attribute` entry, `atttypid` is reset to zero, but `attlen` and the other fields copied from `pg_type` are still valid. This arrangement is needed to cope with the situation where the dropped column's data type was later dropped, and so there is no `pg_type` row anymore. `attlen` and the other fields can be used to interpret the contents of a row of the table.

50.8. pg_authid

The catalog `pg_authid` contains information about database authorization identifiers (roles). A role subsumes the concepts of “users” and “groups”. A user is essentially just a role with the `rolcanlogin` flag set. Any role (with or without `rolcanlogin`) can have other roles as members; see [pg_auth_members](#).

Since this catalog contains passwords, it must not be publicly readable. [pg_roles](#) is a publicly readable view on `pg_authid` that blanks out the password field.

[Chapter 21](#) contains detailed information about user and privilege management.

Because user identities are cluster-wide, `pg_authid` is shared across all databases of a cluster: there is only one copy of `pg_authid` per cluster, not one per database.

Table 50.8. `pg_authid` Columns

Name	Type	Description
<code>oid</code>	<code>oid</code>	Row identifier (hidden attribute; must be explicitly selected)
<code>rolname</code>	<code>name</code>	Role name
<code>rolsuper</code>	<code>bool</code>	Role has superuser privileges
<code>rolinherit</code>	<code>bool</code>	Role automatically inherits privileges of roles it is a member of
<code>rolcreaterole</code>	<code>bool</code>	Role can create more roles
<code>rolcreatedb</code>	<code>bool</code>	Role can create databases
<code>rolcanlogin</code>	<code>bool</code>	Role can log in. That is, this role can be given as the initial session authorization identifier.
<code>rolreplication</code>	<code>bool</code>	Role is a replication role. A replication role can initiate replication connections and create and drop replication slots.
<code>rolbypassrls</code>	<code>bool</code>	Role bypasses every row level security policy, see Section 5.7 for more information.
<code>rolconndef</code>	<code>int4</code>	For roles that can log in, this sets maximum number of concurrent connections this role can make. -1 means no limit.
<code>rolpassword</code>	<code>text</code>	Password (possibly encrypted); null if none. If the password is encrypted with MD5, this column will begin with the string <code>md5</code> followed by a 32-character hexadecimal MD5 hash. The MD5 hash will be of the user's password concatenated to their user name. For example, if user <code>joe</code> has password <code>xyzyzy</code> , Postgres Pro will store the md5 hash of <code>xyzyzyjoe</code> . If the password is encrypted with SCRAM-SHA-256, it is built with 4 fields separated by a colon. The first field is a salt encoded in base-64. The second field is the number of iterations

Name	Type	Description
		used to generate the password. The third field is a stored key, encoded in hexadecimal. The fourth field is a server key encoded in hexadecimal. A password that does not follow any of those formats is assumed to be unencrypted.
rolvaliduntil	timestampz	Password expiry time (only used for password authentication); null if no expiration

50.9. pg_auth_members

The catalog `pg_auth_members` shows the membership relations between roles. Any non-circular set of relationships is allowed.

Because user identities are cluster-wide, `pg_auth_members` is shared across all databases of a cluster: there is only one copy of `pg_auth_members` per cluster, not one per database.

Table 50.9. pg_auth_members Columns

Name	Type	References	Description
roleid	oid	<code>pg_authid</code> .oid	ID of a role that has a member
member	oid	<code>pg_authid</code> .oid	ID of a role that is a member of <code>roleid</code>
grantor	oid	<code>pg_authid</code> .oid	ID of the role that granted this membership
admin_option	bool		True if <code>member</code> can grant membership in <code>roleid</code> to others

50.10. pg_cast

The catalog `pg_cast` stores data type conversion paths, both built-in and user-defined.

It should be noted that `pg_cast` does not represent every type conversion that the system knows how to perform; only those that cannot be deduced from some generic rule. For example, casting between a domain and its base type is not explicitly represented in `pg_cast`. Another important exception is that “automatic I/O conversion casts”, those performed using a data type's own I/O functions to convert to or from `text` or other string types, are not explicitly represented in `pg_cast`.

Table 50.10. pg_cast Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
castsource	oid	<code>pg_type</code> .oid	OID of the source data type
casttarget	oid	<code>pg_type</code> .oid	OID of the target data type
castfunc	oid	<code>pg_proc</code> .oid	The OID of the function to use to perform this

Name	Type	References	Description
			cast. Zero is stored if the cast method doesn't require a function.
castcontext	char		Indicates what contexts the cast can be invoked in. <code>e</code> means only as an explicit cast (using <code>CAST</code> or <code>::</code> syntax). <code>a</code> means implicitly in assignment to a target column, as well as explicitly. <code>i</code> means implicitly in expressions, as well as the other cases.
castmethod	char		Indicates how the cast is performed. <code>f</code> means that the function specified in the <code>castfunc</code> field is used. <code>i</code> means that the input/output functions are used. <code>b</code> means that the types are binary-coercible, thus no conversion is required.

The cast functions listed in `pg_cast` must always take the cast source type as their first argument type, and return the cast destination type as their result type. A cast function can have up to three arguments. The second argument, if present, must be type `integer`; it receives the type modifier associated with the destination type, or -1 if there is none. The third argument, if present, must be type `boolean`; it receives `true` if the cast is an explicit cast, `false` otherwise.

It is legitimate to create a `pg_cast` entry in which the source and target types are the same, if the associated function takes more than one argument. Such entries represent “length coercion functions” that coerce values of the type to be legal for a particular type modifier value.

When a `pg_cast` entry has different source and target types and a function that takes more than one argument, it represents converting from one type to another and applying a length coercion in a single step. When no such entry is available, coercion to a type that uses a type modifier involves two steps, one to convert between data types and a second to apply the modifier.

50.11. pg_class

The catalog `pg_class` catalogs tables and most everything else that has columns or is otherwise similar to a table. This includes indexes (but see also `pg_index`), sequences, views, materialized views, composite types, and TOAST tables; see `relkind`. Below, when we mean all of these kinds of objects we speak of “relations”. Not all columns are meaningful for all relation types.

Table 50.11. pg_class Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
relname	name		Name of the table, index, view, etc.

Name	Type	References	Description
relnamespace	oid	pg_namespace .oid	The OID of the namespace that contains this relation
reltype	oid	pg_type .oid	The OID of the data type that corresponds to this table's row type, if any (zero for indexes, which have no pg_type entry)
reloftype	oid	pg_type .oid	For typed tables, the OID of the underlying composite type, zero for all other relations
relowner	oid	pg_authid .oid	Owner of the relation
relam	oid	pg_am .oid	If this is an index, the access method used (B-tree, hash, etc.)
relfilenode	oid		Name of the on-disk file of this relation; zero means this is a “mapped” relation whose disk file name is determined by low-level state
reltablespace	oid	pg_tablespace .oid	The tablespace in which this relation is stored. If zero, the database's default tablespace is implied. (Not meaningful if the relation has no on-disk file.)
relpages	int4		Size of the on-disk representation of this table in pages (of size <code>BLCKSZ</code>). This is only an estimate used by the planner. It is updated by <code>VACUUM</code> , <code>ANALYZE</code> , and a few DDL commands such as <code>CREATE INDEX</code> .
reltuples	float4		Number of rows in the table. This is only an estimate used by the planner. It is updated by <code>VACUUM</code> , <code>ANALYZE</code> , and a few DDL commands such as <code>CREATE INDEX</code> .
relallvisible	int4		Number of pages that are marked all-visible in the table's visibility map. This is only an estimate used by the planner. It is updated by <code>VACUUM</code> , <code>ANALYZE</code> , and a few

Name	Type	References	Description
			DDL commands such as <code>CREATE INDEX</code> .
<code>reltoastrelid</code>	<code>oid</code>	<code>pg_class</code> . <code>oid</code>	OID of the TOAST table associated with this table, 0 if none. The TOAST table stores large attributes “out of line” in a secondary table.
<code>relhasindex</code>	<code>bool</code>		True if this is a table and it has (or recently had) any indexes
<code>relisshared</code>	<code>bool</code>		True if this table is shared across all databases in the cluster. Only certain system catalogs (such as <code>pg_database</code>) are shared.
<code>relpersistence</code>	<code>char</code>		<code>p</code> = permanent table, <code>u</code> = unlogged table, <code>t</code> = temporary table
<code>relkind</code>	<code>char</code>		<code>r</code> = ordinary table, <code>i</code> = index, <code>s</code> = sequence, <code>v</code> = view, <code>m</code> = materialized view, <code>c</code> = composite type, <code>t</code> = TOAST table, <code>f</code> = foreign table
<code>relnatts</code>	<code>int2</code>		Number of user columns in the relation (system columns not counted). There must be this many corresponding entries in <code>pg_attribute</code> . See also <code>pg_attribute.attnum</code> .
<code>relchecks</code>	<code>int2</code>		Number of <code>CHECK</code> constraints on the table; see <code>pg_constraint</code> catalog
<code>relhasoids</code>	<code>bool</code>		True if we generate an OID for each row of the relation
<code>relhaspkey</code>	<code>bool</code>		True if the table has (or once had) a primary key
<code>relhasrules</code>	<code>bool</code>		True if table has (or once had) rules; see <code>pg_rewrite</code> catalog
<code>relhastriggers</code>	<code>bool</code>		True if table has (or once had) triggers; see <code>pg_trigger</code> catalog
<code>relhassubclass</code>	<code>bool</code>		True if table has (or once had) any inheritance children

Name	Type	References	Description
relrowsecurity	bool		True if table has row level security enabled; see pg_policy catalog
relforcerowsecurity	bool		True if row level security (when enabled) will also apply to table owner; see pg_policy catalog
relispopulated	bool		True if relation is populated (this is true for all relations other than some materialized views)
relreplident	char		Columns used to form “replica identity” for rows: d = default (primary key, if any), n = nothing, f = all columns, i = index with indisreplident set (same as nothing if the index used has been dropped)
relfrozenxid	xid		All transaction IDs before this one have been replaced with a permanent (“frozen”) transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to allow <code>pg_clog</code> to be shrunk. Zero (<code>InvalidTransactionId</code>) if the relation is not a table.
relminmxid	xid		All multixact IDs before this one have been replaced by a transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to allow <code>pg_multixact</code> to be shrunk. Zero (<code>InvalidMultiXactId</code>) if the relation is not a table.
relacl	aclitem[]		Access privileges; see GRANT and REVOKE for details
reloptions	text[]		Access-method-specific options, as “keyword=value” strings

Several of the Boolean flags in `pg_class` are maintained lazily: they are guaranteed to be true if that's the correct state, but may not be reset to false immediately when the condition is no longer true. For example, `relhasindex` is set by `CREATE INDEX`, but it is never cleared by `DROP INDEX`. Instead, `VACUUM` clears `relhasindex` if it finds the table has no indexes. This arrangement avoids race conditions and improves concurrency.

50.12. `pg_collation`

The catalog `pg_collation` describes the available collations, which are essentially mappings from an SQL name to operating system locale categories. See [Section 23.2](#) for more information.

Table 50.12. `pg_collation` Columns

Name	Type	References	Description
<code>oid</code>	<code>oid</code>		Row identifier (hidden attribute; must be explicitly selected)
<code>collname</code>	<code>name</code>		Collation name (unique per namespace and encoding)
<code>collnamespace</code>	<code>oid</code>	<code>pg_namespace .oid</code>	The OID of the namespace that contains this collation
<code>collowner</code>	<code>oid</code>	<code>pg_authid .oid</code>	Owner of the collation
<code>collencoding</code>	<code>int4</code>		Encoding in which the collation is applicable, or -1 if it works for any encoding
<code>collcollate</code>	<code>name</code>		<code>LC_COLLATE</code> for this collation object
<code>collctype</code>	<code>name</code>		<code>LC_CTYPE</code> for this collation object

Note that the unique key on this catalog is (`collname`, `collencoding`, `collnamespace`) not just (`collname`, `collnamespace`). Postgres Pro generally ignores all collations that do not have `collencoding` equal to either the current database's encoding or -1, and creation of new entries with the same name as an entry with `collencoding` = -1 is forbidden. Therefore it is sufficient to use a qualified SQL name (`schema.name`) to identify a collation, even though this is not unique according to the catalog definition. The reason for defining the catalog this way is that `initdb` fills it in at cluster initialization time with entries for all locales available on the system, so it must be able to hold entries for all encodings that might ever be used in the cluster.

In the `template0` database, it could be useful to create collations whose encoding does not match the database encoding, since they could match the encodings of databases later cloned from `template0`. This would currently have to be done manually.

50.13. `pg_constraint`

The catalog `pg_constraint` stores check, primary key, unique, foreign key, and exclusion constraints on tables. (Column constraints are not treated specially. Every column constraint is equivalent to some table constraint.) Not-null constraints are represented in the `pg_attribute` catalog, not here.

User-defined constraint triggers (created with `CREATE CONSTRAINT TRIGGER`) also give rise to an entry in this table.

Check constraints on domains are stored here, too.

Table 50.13. pg_constraint Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
conname	name		Constraint name (not necessarily unique!)
connamespace	oid	pg_namespace .oid	The OID of the namespace that contains this constraint
contype	char		c = check constraint, f = foreign key constraint, p = primary key constraint, u = unique constraint, t = constraint trigger, x = exclusion constraint
condeferrable	bool		Is the constraint deferrable?
condeferred	bool		Is the constraint deferred by default?
convalidated	bool		Has the constraint been validated? Currently, can only be false for foreign keys and CHECK constraints
conrelid	oid	pg_class .oid	The table this constraint is on; 0 if not a table constraint
contypid	oid	pg_type .oid	The domain this constraint is on; 0 if not a domain constraint
conindid	oid	pg_class .oid	The index supporting this constraint, if it's a unique, primary key, foreign key, or exclusion constraint; else 0
confrelid	oid	pg_class .oid	If a foreign key, the referenced table; else 0
confupdtype	char		Foreign key update action code: a = no action, r = restrict, c = cascade, n = set null, d = set default
confdeltype	char		Foreign key deletion action code: a = no action, r = restrict, c = cascade, n = set null, d = set default

Name	Type	References	Description
confmacthype	char		Foreign key match type: f = full, p = partial, s = simple
conislocal	bool		This constraint is defined locally for the relation. Note that a constraint can be locally defined and inherited simultaneously.
coninhcount	int4		The number of direct inheritance ancestors this constraint has. A constraint with a nonzero number of ancestors cannot be dropped nor renamed.
connoinherit	bool		This constraint is defined locally for the relation. It is a non-inheritable constraint.
conkey	int2[]	pg_attribute .attnum	If a table constraint (including foreign keys, but not constraint triggers), list of the constrained columns
confkey	int2[]	pg_attribute .attnum	If a foreign key, list of the referenced columns
conpfeqop	oid[]	pg_operator .oid	If a foreign key, list of the equality operators for PK = FK comparisons
conppeqop	oid[]	pg_operator .oid	If a foreign key, list of the equality operators for PK = PK comparisons
conffeqop	oid[]	pg_operator .oid	If a foreign key, list of the equality operators for FK = FK comparisons
conexclop	oid[]	pg_operator .oid	If an exclusion constraint, list of the per-column exclusion operators
conbin	pg_node_tree		If a check constraint, an internal representation of the expression
consrc	text		If a check constraint, a human-readable representation of the expression

In the case of an exclusion constraint, `conkey` is only useful for constraint elements that are simple column references. For other cases, a zero appears in `conkey` and the associated index must be consulted to discover the expression that is constrained. (`conkey` thus has the same contents as `pg_index.indkey` for the index.)

Note

`consrc` is not updated when referenced objects change; for example, it won't track renaming of columns. Rather than relying on this field, it's best to use `pg_get_constraintdef()` to extract the definition of a check constraint.

Note

`pg_class.relchecks` needs to agree with the number of check-constraint entries found in this table for each relation.

50.14. pg_conversion

The catalog `pg_conversion` describes encoding conversion procedures. See [CREATE CONVERSION](#) for more information.

Table 50.14. pg_conversion Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
conname	name		Conversion name (unique within a namespace)
connamespace	oid	pg_namespace .oid	The OID of the namespace that contains this conversion
conowner	oid	pg_authid .oid	Owner of the conversion
conforencoding	int4		Source encoding ID
contoencoding	int4		Destination encoding ID
conproc	regproc	pg_proc .oid	Conversion procedure
condefault	bool		True if this is the default conversion

50.15. pg_database

The catalog `pg_database` stores information about the available databases. Databases are created with the [CREATE DATABASE](#) command. Consult [Chapter 22](#) for details about the meaning of some of the parameters.

Unlike most system catalogs, `pg_database` is shared across all databases of a cluster: there is only one copy of `pg_database` per cluster, not one per database.

Table 50.15. pg_database Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
datname	name		Database name

Name	Type	References	Description
datdba	oid	<code>pg_authid</code> .oid	Owner of the database, usually the user who created it
encoding	int4		Character encoding for this database (<code>pg_encoding_to_char()</code> can translate this number to the encoding name)
datcollate	name		LC_COLLATE for this database
datctype	name		LC_CTYPE for this database
datistemplate	bool		If true, then this database can be cloned by any user with <code>CREATEDB</code> privileges; if false, then only superusers or the owner of the database can clone it.
datallowconn	bool		If false then no one can connect to this database. This is used to protect the <code>template0</code> database from being altered.
datconndef	int4		Sets maximum number of concurrent connections that can be made to this database. -1 means no limit.
datlastsysoid	oid		Last system OID in the database; useful particularly to <code>pg_dump</code>
datfrozenxid	xid		All transaction IDs before this one have been replaced with a permanent ("frozen") transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to allow <code>pg_clog</code> to be shrunk. It is the minimum of the per-table <code>pg_class</code> .relfrozenxid values.
datminmxid	xid		All multixact IDs before this one have been replaced with

Name	Type	References	Description
			a transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to allow <code>pg_multixact</code> to be shrunk. It is the minimum of the per-table <code>pg_class.relmixmapid</code> values.
<code>dattablespace</code>	<code>oid</code>	<code>pg_tablespace.oid</code>	The default tablespace for the database. Within this database, all tables for which <code>pg_class.reltablespace</code> is zero will be stored in this tablespace; in particular, all the non-shared system catalogs will be there.
<code>dataacl</code>	<code>aclitem[]</code>		Access privileges; see GRANT and REVOKE for details

50.16. `pg_db_role_setting`

The catalog `pg_db_role_setting` records the default values that have been set for run-time configuration variables, for each role and database combination.

Unlike most system catalogs, `pg_db_role_setting` is shared across all databases of a cluster: there is only one copy of `pg_db_role_setting` per cluster, not one per database.

Table 50.16. `pg_db_role_setting` Columns

Name	Type	References	Description
<code>setdatabase</code>	<code>oid</code>	<code>pg_database.oid</code>	The OID of the database the setting is applicable to, or zero if not database-specific
<code>setrole</code>	<code>oid</code>	<code>pg_authid.oid</code>	The OID of the role the setting is applicable to, or zero if not role-specific
<code>setconfig</code>	<code>text[]</code>		Defaults for run-time configuration variables

50.17. `pg_default_acl`

The catalog `pg_default_acl` stores initial privileges to be assigned to newly created objects.

Table 50.17. pg_default_acl Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
defaclrole	oid	pg_authid .oid	The OID of the role associated with this entry
defaclnamespace	oid	pg_namespace .oid	The OID of the namespace associated with this entry, or 0 if none
defaclobjtype	char		Type of object this entry is for: r = relation (table, view), s = sequence, f = function, T = type
defaclacl	aclitem[]		Access privileges that this type of object should have on creation

A `pg_default_acl` entry shows the initial privileges to be assigned to an object belonging to the indicated user. There are currently two types of entry: “global” entries with `defaclnamespace = 0`, and “per-schema” entries that reference a particular schema. If a global entry is present then it *overrides* the normal hard-wired default privileges for the object type. A per-schema entry, if present, represents privileges to be *added to* the global or hard-wired default privileges.

Note that when an ACL entry in another catalog is null, it is taken to represent the hard-wired default privileges for its object, *not* whatever might be in `pg_default_acl` at the moment. `pg_default_acl` is only consulted during object creation.

50.18. pg_depend

The catalog `pg_depend` records the dependency relationships between database objects. This information allows `DROP` commands to find which other objects must be dropped by `DROP CASCADE` or prevent dropping in the `DROP RESTRICT` case.

See also [pg_shdepend](#), which performs a similar function for dependencies involving objects that are shared across a database cluster.

Table 50.18. pg_depend Columns

Name	Type	References	Description
classid	oid	pg_class .oid	The OID of the system catalog the dependent object is in
objid	oid	any OID column	The OID of the specific dependent object
objsubid	int4		For a table column, this is the column number (the <code>objid</code> and <code>classid</code> refer to the table itself). For all other object types, this column is zero.

Name	Type	References	Description
refclassid	oid	pg_class .oid	The OID of the system catalog the referenced object is in
refobjid	oid	any OID column	The OID of the specific referenced object
refobjsubid	int4		For a table column, this is the column number (the refobjid and refclassid refer to the table itself). For all other object types, this column is zero.
deptype	char		A code defining the specific semantics of this dependency relationship; see text

In all cases, a `pg_depend` entry indicates that the referenced object cannot be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

DEPENDENCY_NORMAL (n)

A normal relationship between separately-created objects. The dependent object can be dropped without affecting the referenced object. The referenced object can only be dropped by specifying `CASCADE`, in which case the dependent object is dropped, too. Example: a table column has a normal dependency on its data type.

DEPENDENCY_AUTO (a)

The dependent object can be dropped separately from the referenced object, and should be automatically dropped (regardless of `RESTRICT` or `CASCADE` mode) if the referenced object is dropped. Example: a named constraint on a table is made autodependent on the table, so that it will go away if the table is dropped.

DEPENDENCY_INTERNAL (i)

The dependent object was created as part of creation of the referenced object, and is really just a part of its internal implementation. A `DROP` of the dependent object will be disallowed outright (we'll tell the user to issue a `DROP` against the referenced object, instead). A `DROP` of the referenced object will be propagated through to drop the dependent object whether `CASCADE` is specified or not. Example: a trigger that's created to enforce a foreign-key constraint is made internally dependent on the constraint's `pg_constraint` entry.

DEPENDENCY_EXTENSION (e)

The dependent object is a member of the *extension* that is the referenced object (see [pg_extension](#)). The dependent object can be dropped only via `DROP EXTENSION` on the referenced object. Functionally this dependency type acts the same as an internal dependency, but it's kept separate for clarity and to simplify `pg_dump`.

DEPENDENCY_AUTO_EXTENSION (x)

The dependent object is not a member of the extension that is the referenced object (and so should not be ignored by `pg_dump`), but cannot function without it and should be dropped when the extension itself is. The dependent object may be dropped on its own as well.

DEPENDENCY_PIN (p)

There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by `initdb`. The columns for the dependent object contain zeroes.

Other dependency flavors might be needed in future.

50.19. pg_description

The catalog `pg_description` stores optional descriptions (comments) for each database object. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`'s `\d` commands. Descriptions of many built-in system objects are provided in the initial contents of `pg_description`.

See also `pg_shdescription`, which performs a similar function for descriptions involving objects that are shared across a database cluster.

Table 50.19. pg_description Columns

Name	Type	References	Description
<code>objoid</code>	<code>oid</code>	any OID column	The OID of the object this description pertains to
<code>classoid</code>	<code>oid</code>	<code>pg_class</code> .oid	The OID of the system catalog this object appears in
<code>objsubid</code>	<code>int4</code>		For a comment on a table column, this is the column number (the <code>objoid</code> and <code>classoid</code> refer to the table itself). For all other object types, this column is zero.
<code>description</code>	<code>text</code>		Arbitrary text that serves as the description of this object

50.20. pg_enum

The `pg_enum` catalog contains entries showing the values and labels for each enum type. The internal representation of a given enum value is actually the OID of its associated row in `pg_enum`.

Table 50.20. pg_enum Columns

Name	Type	References	Description
<code>oid</code>	<code>oid</code>		Row identifier (hidden attribute; must be explicitly selected)
<code>enumtypid</code>	<code>oid</code>	<code>pg_type</code> .oid	The OID of the <code>pg_type</code> entry owning this enum value
<code>enumsortorder</code>	<code>float4</code>		The sort position of this enum value within its enum type
<code>enumlabel</code>	<code>name</code>		The textual label for this enum value

The OIDs for `pg_enum` rows follow a special rule: even-numbered OIDs are guaranteed to be ordered in the same way as the sort ordering of their enum type. That is, if two even OIDs belong to the same enum type, the smaller OID must have the smaller `enumsortorder` value. Odd-numbered OID values need bear no relationship to the sort order. This rule allows the enum comparison routines to avoid catalog lookups in many common cases. The routines that create and alter enum types attempt to assign even OIDs to enum values whenever possible.

When an enum type is created, its members are assigned sort-order positions 1..*n*. But members added later might be given negative or fractional values of `enumsortorder`. The only requirement on these values is that they be correctly ordered and unique within each enum type.

50.21. pg_event_trigger

The catalog `pg_event_trigger` stores event triggers. See [Chapter 38](#) for more information.

Table 50.21. pg_event_trigger Columns

Name	Type	References	Description
evtname	name		Trigger name (must be unique)
evtevent	name		Identifies the event for which this trigger fires
evtowner	oid	pg_authid .oid	Owner of the event trigger
evtfoid	oid	pg_proc .oid	The function to be called
evtenabled	char		Controls in which session_replication_role modes the event trigger fires. <code>O</code> = trigger fires in “origin” and “local” modes, <code>D</code> = trigger is disabled, <code>R</code> = trigger fires in “replica” mode, <code>A</code> = trigger fires always.
evttags	text[]		Command tags for which this trigger will fire. If NULL, the firing of this trigger is not restricted on the basis of the command tag.

50.22. pg_extension

The catalog `pg_extension` stores information about the installed extensions. See [Section 36.15](#) for details about extensions.

Table 50.22. pg_extension Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
extname	name		Name of the extension
extowner	oid	pg_authid .oid	Owner of the extension
extnamespace	oid	pg_namespace .oid	Schema containing the extension's exported objects
extrelocatable	bool		True if extension can be relocated to another schema

Name	Type	References	Description
extversion	text		Version name for the extension
extconfig	oid[]	pg_class .oid	Array of regclass OIDs for the extension's configuration table(s), or NULL if none
extcondition	text[]		Array of WHERE-clause filter conditions for the extension's configuration table(s), or NULL if none

Note that unlike most catalogs with a “namespace” column, `extnamespace` is not meant to imply that the extension belongs to that schema. Extension names are never schema-qualified. Rather, `extnamespace` indicates the schema that contains most or all of the extension's objects. If `extrelocatable` is true, then this schema must in fact contain all schema-qualifiable objects belonging to the extension.

50.23. pg_foreign_data_wrapper

The catalog `pg_foreign_data_wrapper` stores foreign-data wrapper definitions. A foreign-data wrapper is the mechanism by which external data, residing on foreign servers, is accessed.

Table 50.23. pg_foreign_data_wrapper Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
fdwname	name		Name of the foreign-data wrapper
fdwowner	oid	pg_authid .oid	Owner of the foreign-data wrapper
fdwhandler	oid	pg_proc .oid	References a handler function that is responsible for supplying execution routines for the foreign-data wrapper. Zero if no handler is provided
fdwvalidator	oid	pg_proc .oid	References a validator function that is responsible for checking the validity of the options given to the foreign-data wrapper, as well as options for foreign servers and user mappings using the foreign-data wrapper. Zero if no validator is provided
fdwacl	aclitem[]		Access privileges; see GRANT and REVOKE for details

Name	Type	References	Description
fdwoptions	text[]		Foreign-data wrapper specific options, as “keyword=value” strings

50.24. pg_foreign_server

The catalog `pg_foreign_server` stores foreign server definitions. A foreign server describes a source of external data, such as a remote server. Foreign servers are accessed via foreign-data wrappers.

Table 50.24. pg_foreign_server Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
srvname	name		Name of the foreign server
srvowner	oid	pg_authid .oid	Owner of the foreign server
srvfdw	oid	pg_foreign_data_wrapper .oid	OID of the foreign-data wrapper of this foreign server
srvtype	text		Type of the server (optional)
srvversion	text		Version of the server (optional)
srvacl	aclitem[]		Access privileges; see GRANT and REVOKE for details
srvoptions	text[]		Foreign server specific options, as “keyword=value” strings

50.25. pg_foreign_table

The catalog `pg_foreign_table` contains auxiliary information about foreign tables. A foreign table is primarily represented by a `pg_class` entry, just like a regular table. Its `pg_foreign_table` entry contains the information that is pertinent only to foreign tables and not any other kind of relation.

Table 50.25. pg_foreign_table Columns

Name	Type	References	Description
ftrelid	oid	pg_class .oid	OID of the <code>pg_class</code> entry for this foreign table
ftserver	oid	pg_foreign_server .oid	OID of the foreign server for this foreign table
ftoptions	text[]		Foreign table options, as “keyword=value” strings

50.26. pg_index

The catalog `pg_index` contains part of the information about indexes. The rest is mostly in `pg_class`.

Table 50.26. pg_index Columns

Name	Type	References	Description
indexrelid	oid	pg_class .oid	The OID of the <code>pg_class</code> entry for this index
indrelid	oid	pg_class .oid	The OID of the <code>pg_class</code> entry for the table this index is for
indnatts	int2		The number of columns in the index (duplicates <code>pg_class.relnatts</code>)
indnkeyatts	int2		The number of key columns in the index. "Key columns" are ordinary index columns in contrast with "included" columns.
indisunique	bool		If true, this is a unique index
indisprimary	bool		If true, this index represents the primary key of the table (<code>indisunique</code> should always be true when this is true)
indisexclusion	bool		If true, this index supports an exclusion constraint
indimmediate	bool		If true, the uniqueness check is enforced immediately on insertion (irrelevant if <code>indisunique</code> is not true)
indisclustered	bool		If true, the table was last clustered on this index
indisvalid	bool		If true, the index is currently valid for queries. False means the index is possibly incomplete: it must still be modified by <code>INSERT/UPDATE</code> operations, but it cannot safely be used for queries. If it is unique, the uniqueness property is not guaranteed true either.
indcheckxmin	bool		If true, queries must not use the index until the <code>xmin</code> of this <code>pg_index</code> row is below their <code>TransactionXmin</code> event horizon, because

Name	Type	References	Description
			the table may contain broken HOT chains with incompatible rows that they can see
indisready	bool		If true, the index is currently ready for inserts. False means the index must be ignored by INSERT/UPDATE operations.
indislive	bool		If false, the index is in process of being dropped, and should be ignored for all purposes (including HOT-safety decisions)
indisreplident	bool		If true this index has been chosen as “replica identity” using ALTER TABLE ... REPLICA IDENTITY USING INDEX ...
indkey	int2vector	pg_attribute .attnum	This is an array of <code>indnatts</code> values that indicate which table columns this index indexes. For example a value of 1 3 would mean that the first and the third table columns make up the index key. A zero in this array indicates that the corresponding index attribute is an expression over the table columns, rather than a simple column reference.
indcollation	oidvector	pg_collation .oid	For each column in the index key, this contains the OID of the collation to use for the index.
indclass	oidvector	pg_opclass .oid	For each column in the index key, this contains the OID of the operator class to use. See pg_opclass for details.
indoption	int2vector		This is an array of <code>indnatts</code> values that store per-column flag bits. The meaning of the bits is defined by the index's access method.

Name	Type	References	Description
indexprs	pg_node_tree		Expression trees (in <code>nodeToString()</code> representation) for index attributes that are not simple column references. This is a list with one element for each zero entry in <code>indkey</code> . Null if all index attributes are simple references.
indpred	pg_node_tree		Expression tree (in <code>nodeToString()</code> representation) for partial index predicate. Null if not a partial index.

50.27. pg_inherits

The catalog `pg_inherits` records information about table inheritance hierarchies. There is one entry for each direct child table in the database. (Indirect inheritance can be determined by following chains of entries.)

Table 50.27. pg_inherits Columns

Name	Type	References	Description
inhrelid	oid	pg_class .oid	The OID of the child table
inhparent	oid	pg_class .oid	The OID of the parent table
inhseqno	int4		If there is more than one direct parent for a child table (multiple inheritance), this number tells the order in which the inherited columns are to be arranged. The count starts at 1.

50.28. pg_init_privs

The catalog `pg_init_privs` records information about the initial privileges of objects in the system. There is one entry for each object in the database which has a non-default (non-NULL) initial set of privileges.

Objects can have initial privileges either by having those privileges set when the system is initialized (by `initdb`) or when the object is created during a `CREATE EXTENSION` and the extension script sets initial privileges using the `GRANT` system. Note that the system will automatically handle recording of the privileges during the extension script and that extension authors need only use the `GRANT` and `REVOKE` statements in their script to have the privileges recorded. The `privtype` column indicates if the initial privilege was set by `initdb` or during a `CREATE EXTENSION` command.

Objects which have initial privileges set by `initdb` will have entries where `privtype` is 'i', while objects which have initial privileges set by `CREATE EXTENSION` will have entries where `privtype` is 'e'.

Table 50.28. pg_init_privs Columns

Name	Type	References	Description
objoid	oid	any OID column	The OID of the specific object
classoid	oid	pg_class .oid	The OID of the system catalog the object is in
objsubid	int4		For a table column, this is the column number (the <code>objoid</code> and <code>classoid</code> refer to the table itself). For all other object types, this column is zero.
privtype	char		A code defining the type of initial privilege of this object; see text
initprivs	aclitem[]		The initial access privileges; see GRANT and REVOKE for details

50.29. pg_language

The catalog `pg_language` registers languages in which you can write functions or stored procedures. See [CREATE LANGUAGE](#) and [Chapter 40](#) for more information about language handlers.

Table 50.29. pg_language Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
lanname	name		Name of the language
lanowner	oid	pg_authid .oid	Owner of the language
lanispl	bool		This is false for internal languages (such as SQL) and true for user-defined languages. Currently, <code>pg_dump</code> still uses this to determine which languages need to be dumped, but this might be replaced by a different mechanism in the future.
lanpltrusted	bool		True if this is a trusted language, which means that it is believed not to grant access to anything outside the normal SQL execution environment. Only superusers can create functions in untrusted languages.
lanplcallfoid	oid	pg_proc .oid	For noninternal languages this

Name	Type	References	Description
			references the language handler, which is a special function that is responsible for executing all functions that are written in the particular language
laninline	oid	pg_proc .oid	This references a function that is responsible for executing “inline” anonymous code blocks (DO blocks). Zero if inline blocks are not supported.
lanvalidator	oid	pg_proc .oid	This references a language validator function that is responsible for checking the syntax and validity of new functions when they are created. Zero if no validator is provided.
lanacl	aclitem[]		Access privileges; see GRANT and REVOKE for details

50.30. pg_largeobject

The catalog `pg_largeobject` holds the data making up “large objects”. A large object is identified by an OID assigned when it is created. Each large object is broken into segments or “pages” small enough to be conveniently stored as rows in `pg_largeobject`. The amount of data per page is defined to be `LOBLKSIZE` (which is currently `BLCKSZ/4`, or typically 2 kB).

Prior to PostgreSQL 9.0, there was no permission structure associated with large objects. As a result, `pg_largeobject` was publicly readable and could be used to obtain the OIDs (and contents) of all large objects in the system. This is no longer the case; use `pg_largeobject_metadata` to obtain a list of large object OIDs.

Table 50.30. `pg_largeobject` Columns

Name	Type	References	Description
loid	oid	pg_largeobject_metadata .oid	Identifier of the large object that includes this page
pageno	int4		Page number of this page within its large object (counting from zero)
data	bytea		Actual data stored in the large object. This will never be more than <code>LOBLKSIZE</code> bytes and might be less.

Each row of `pg_largeobject` holds data for one page of a large object, beginning at byte offset (`pageno * LOBLKSIZE`) within the object. The implementation allows sparse storage: pages might be missing, and might be shorter than `LOBLKSIZE` bytes even if they are not the last page of the object. Missing regions within a large object read as zeroes.

50.31. `pg_largeobject_metadata`

The catalog `pg_largeobject_metadata` holds metadata associated with large objects. The actual large object data is stored in `pg_largeobject`.

Table 50.31. `pg_largeobject_metadata` Columns

Name	Type	References	Description
<code>oid</code>	<code>oid</code>		Row identifier (hidden attribute; must be explicitly selected)
<code>lomowner</code>	<code>oid</code>	<code>pg_authid .oid</code>	Owner of the large object
<code>lomacl</code>	<code>aclitem[]</code>		Access privileges; see GRANT and REVOKE for details

50.32. `pg_namespace`

The catalog `pg_namespace` stores namespaces. A namespace is the structure underlying SQL schemas: each namespace can have a separate collection of relations, types, etc. without name conflicts.

Table 50.32. `pg_namespace` Columns

Name	Type	References	Description
<code>oid</code>	<code>oid</code>		Row identifier (hidden attribute; must be explicitly selected)
<code>nspname</code>	<code>name</code>		Name of the namespace
<code>nspowner</code>	<code>oid</code>	<code>pg_authid .oid</code>	Owner of the namespace
<code>nspacl</code>	<code>aclitem[]</code>		Access privileges; see GRANT and REVOKE for details

50.33. `pg_opclass`

The catalog `pg_opclass` defines index access method operator classes. Each operator class defines semantics for index columns of a particular data type and a particular index access method. An operator class essentially specifies that a particular operator family is applicable to a particular indexable column data type. The set of operators from the family that are actually usable with the indexed column are whichever ones accept the column's data type as their left-hand input.

Operator classes are described at length in [Section 36.14](#).

Table 50.33. `pg_opclass` Columns

Name	Type	References	Description
<code>oid</code>	<code>oid</code>		Row identifier (hidden attribute; must be explicitly selected)
<code>opcmethod</code>	<code>oid</code>	<code>pg_am .oid</code>	Index access method operator class is for

Name	Type	References	Description
opcname	name		Name of this operator class
opcnamespace	oid	pg_namespace .oid	Namespace of this operator class
opowner	oid	pg_authid .oid	Owner of the operator class
opcfamily	oid	pg_opfamily .oid	Operator family containing the operator class
opcintype	oid	pg_type .oid	Data type that the operator class indexes
opcdefault	bool		True if this operator class is the default for opcintype
opckeytype	oid	pg_type .oid	Type of data stored in index, or zero if same as opcintype

An operator class's `opcmethod` must match the `opfmethid` of its containing operator family. Also, there must be no more than one `pg_opclass` row having `opcdefault` true for any given combination of `opcmethod` and `opcintype`.

50.34. pg_operator

The catalog `pg_operator` stores information about operators. See [CREATE OPERATOR](#) and [Section 36.12](#) for more information.

Table 50.34. pg_operator Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
oprname	name		Name of the operator
oprnamespace	oid	pg_namespace .oid	The OID of the namespace that contains this operator
opowner	oid	pg_authid .oid	Owner of the operator
oprkind	char		b = infix (“both”), l = prefix (“left”), r = postfix (“right”)
oprcanmerge	bool		This operator supports merge joins
oprcanhash	bool		This operator supports hash joins
oprleft	oid	pg_type .oid	Type of the left operand
oprright	oid	pg_type .oid	Type of the right operand
oprresult	oid	pg_type .oid	Type of the result
oprcom	oid	pg_operator .oid	Commutator of this operator, if any

Name	Type	References	Description
oprnegate	oid	pg_operator .oid	Negator of this operator, if any
oprcode	regproc	pg_proc .oid	Function that implements this operator
oprrest	regproc	pg_proc .oid	Restriction selectivity estimation function for this operator
oprjoin	regproc	pg_proc .oid	Join selectivity estimation function for this operator

Unused column contain zeroes. For example, `oprleft` is zero for a prefix operator.

50.35. pg_opfamily

The catalog `pg_opfamily` defines operator families. Each operator family is a collection of operators and associated support routines that implement the semantics specified for a particular index access method. Furthermore, the operators in a family are all “compatible”, in a way that is specified by the access method. The operator family concept allows cross-data-type operators to be used with indexes and to be reasoned about using knowledge of access method semantics.

Operator families are described at length in [Section 36.14](#).

Table 50.35. pg_opfamily Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
opfmethod	oid	pg_am .oid	Index access method operator family is for
opfname	name		Name of this operator family
opfnamespace	oid	pg_namespace .oid	Namespace of this operator family
opfowner	oid	pg_authid .oid	Owner of the operator family

The majority of the information defining an operator family is not in its `pg_opfamily` row, but in the associated rows in [pg_amop](#), [pg_amproc](#), and [pg_opclass](#).

50.36. pg_pltemplate

The catalog `pg_pltemplate` stores “template” information for procedural languages. A template for a language allows the language to be created in a particular database by a simple `CREATE LANGUAGE` command, with no need to specify implementation details.

Unlike most system catalogs, `pg_pltemplate` is shared across all databases of a cluster: there is only one copy of `pg_pltemplate` per cluster, not one per database. This allows the information to be accessible in each database as it is needed.

Table 50.36. pg_pltemplate Columns

Name	Type	Description
tmplname	name	Name of the language this template is for

Name	Type	Description
tmpltrusted	boolean	True if language is considered trusted
tmpldbacreate	boolean	True if language may be created by a database owner
tmplhandler	text	Name of call handler function
tmplinline	text	Name of anonymous-block handler function, or null if none
tmplvalidator	text	Name of validator function, or null if none
tmpllibrary	text	Path of shared library that implements language
tmplacl	aclitem[]	Access privileges for template (not actually used)

There are not currently any commands that manipulate procedural language templates; to change the built-in information, a superuser must modify the table using ordinary `INSERT`, `DELETE`, or `UPDATE` commands.

Note

It is likely that `pg_pltemplate` will be removed in some future release of Postgres Pro, in favor of keeping this knowledge about procedural languages in their respective extension installation scripts.

50.37. pg_policy

The catalog `pg_policy` stores row level security policies for tables. A policy includes the kind of command that it applies to (possibly all commands), the roles that it applies to, the expression to be added as a security-barrier qualification to queries that include the table, and the expression to be added as a `WITH CHECK` option for queries that attempt to add new records to the table.

Table 50.37. pg_policy Columns

Name	Type	References	Description
polname	name		The name of the policy
polrelid	oid	pg_class .oid	The table to which the policy applies
polcmd	char		The command type to which the policy is applied: <code>r</code> for <code>SELECT</code> , <code>a</code> for <code>INSERT</code> , <code>w</code> for <code>UPDATE</code> , <code>d</code> for <code>DELETE</code> , or <code>*</code> for all
polroles	oid[]	pg_authid .oid	The roles to which the policy is applied
polqual	pg_node_tree		The expression tree to be added to the security barrier qualifications for queries that use the table
polwithcheck	pg_node_tree		The expression tree to be added to the <code>WITH</code>

Name	Type	References	Description
			CHECK qualifications for queries that attempt to add rows to the table

Note

Policies stored in `pg_policy` are applied only when `pg_class.relrowsecurity` is set for their table.

50.38. pg_proc

The catalog `pg_proc` stores information about functions (or procedures). See [CREATE FUNCTION](#) and [Section 36.3](#) for more information.

The table contains data for aggregate functions as well as plain functions. If `proisagg` is true, there should be a matching row in `pg_aggregate`.

Table 50.38. pg_proc Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
proname	name		Name of the function
pronamespace	oid	pg_namespace .oid	The OID of the namespace that contains this function
proowner	oid	pg_authid .oid	Owner of the function
prolang	oid	pg_language .oid	Implementation language or call interface of this function
procost	float4		Estimated execution cost (in units of cpu_operator_cost); if <code>proretset</code> , this is cost per row returned
prorows	float4		Estimated number of result rows (zero if not <code>proretset</code>)
provariadic	oid	pg_type .oid	Data type of the variadic array parameter's elements, or zero if the function does not have a variadic parameter
protransform	regproc	pg_proc .oid	Calls to this function can be simplified by this other function (see Section 36.9.11)
proisagg	bool		Function is an aggregate function
proiswindow	bool		Function is a window function

Name	Type	References	Description
prosecdef	bool		Function is a security definer (i.e., a “setuid” function)
proleakproof	bool		The function has no side effects. No information about the arguments is conveyed except via the return value. Any function that might throw an error depending on the values of its arguments is not leak-proof.
proisstrict	bool		Function returns null if any call argument is null. In that case the function won't actually be called at all. Functions that are not “strict” must be prepared to handle null inputs.
proretset	bool		Function returns a set (i.e., multiple values of the specified data type)
provolatile	char		provolatile tells whether the function's result depends only on its input arguments, or is affected by outside factors. It is <i>i</i> for “immutable” functions, which always deliver the same result for the same inputs. It is <i>s</i> for “stable” functions, whose results (for fixed inputs) do not change within a scan. It is <i>v</i> for “volatile” functions, whose results might change at any time. (Use <i>v</i> also for functions with side-effects, so that calls to them cannot get optimized away.)
proparallel	char		proparallel tells whether the function can be safely run in parallel mode. It is <i>s</i> for functions which are safe to run in parallel mode without restriction. It is <i>r</i> for functions which can be run in parallel mode,

Name	Type	References	Description
			but their execution is restricted to the parallel group leader; parallel worker processes cannot invoke these functions. It is <code>u</code> for functions which are unsafe in parallel mode; the presence of such a function forces a serial execution plan.
<code>pronargs</code>	<code>int2</code>		Number of input arguments
<code>pronargdefaults</code>	<code>int2</code>		Number of arguments that have defaults
<code>prorettytype</code>	<code>oid</code>	pg_type .oid	Data type of the return value
<code>proargtypes</code>	<code>oidvector</code>	pg_type .oid	An array with the data types of the function arguments. This includes only input arguments (including <code>INOUT</code> and <code>VARIADIC</code> arguments), and thus represents the call signature of the function.
<code>proallargtypes</code>	<code>oid[]</code>	pg_type .oid	An array with the data types of the function arguments. This includes all arguments (including <code>OUT</code> and <code>INOUT</code> arguments); however, if all the arguments are <code>IN</code> arguments, this field will be null. Note that subscripting is 1-based, whereas for historical reasons <code>proargtypes</code> is subscripted from 0.
<code>proargmodes</code>	<code>char[]</code>		An array with the modes of the function arguments, encoded as <code>i</code> for <code>IN</code> arguments, <code>o</code> for <code>OUT</code> arguments, <code>b</code> for <code>INOUT</code> arguments, <code>v</code> for <code>VARIADIC</code> arguments, <code>t</code> for <code>TABLE</code> arguments. If all the arguments are <code>IN</code> arguments, this field will be null. Note that subscripts correspond to positions of <code>proallargtypes</code> not <code>proargtypes</code> .

Name	Type	References	Description
proargnames	text[]		An array with the names of the function arguments. Arguments without a name are set to empty strings in the array. If none of the arguments have a name, this field will be null. Note that subscripts correspond to positions of <code>proallargtypes</code> not <code>proargtypes</code> .
proargdefaults	pg_node_tree		Expression trees (in <code>nodeToString()</code> representation) for default values. This is a list with <code>pronargdefaults</code> elements, corresponding to the last <i>N</i> input arguments (i.e., the last <i>N</i> <code>proargtypes</code> positions). If none of the arguments have defaults, this field will be null.
protrftypes	oid[]		Data type OIDs for which to apply transforms.
prosrc	text		This tells the function handler how to invoke the function. It might be the actual source code of the function for interpreted languages, a link symbol, a file name, or just about anything else, depending on the implementation language/call convention.
probin	text		Additional information about how to invoke the function. Again, the interpretation is language-specific.
proconfig	text[]		Function's local settings for run-time configuration variables
proacl	aclitem[]		Access privileges; see GRANT and REVOKE for details

For compiled functions, both built-in and dynamically loaded, `prosrc` contains the function's C-language name (link symbol). For all other currently-known language types, `prosrc` contains the function's source

text. `probin` is unused except for dynamically-loaded C functions, for which it gives the name of the shared library file containing the function.

50.39. `pg_range`

The catalog `pg_range` stores information about range types. This is in addition to the types' entries in `pg_type`.

Table 50.39. `pg_range` Columns

Name	Type	References	Description
<code>rngtypeid</code>	<code>oid</code>	<code>pg_type</code> .oid	OID of the range type
<code>rngsubtype</code>	<code>oid</code>	<code>pg_type</code> .oid	OID of the element type (subtype) of this range type
<code>rngcollation</code>	<code>oid</code>	<code>pg_collation</code> .oid	OID of the collation used for range comparisons, or 0 if none
<code>rngsubopc</code>	<code>oid</code>	<code>pg_opclass</code> .oid	OID of the subtype's operator class used for range comparisons
<code>rngcanonical</code>	<code>regproc</code>	<code>pg_proc</code> .oid	OID of the function to convert a range value into canonical form, or 0 if none
<code>rngsubdiff</code>	<code>regproc</code>	<code>pg_proc</code> .oid	OID of the function to return the difference between two element values as double precision, or 0 if none

`rngsubopc` (plus `rngcollation`, if the element type is collatable) determines the sort ordering used by the range type. `rngcanonical` is used when the element type is discrete. `rngsubdiff` is optional but should be supplied to improve performance of GiST indexes on the range type.

50.40. `pg_replication_origin`

The `pg_replication_origin` catalog contains all replication origins created. For more on replication origins see [Chapter 48](#).

Table 50.40. `pg_replication_origin` Columns

Name	Type	References	Description
<code>roident</code>	<code>Oid</code>		A unique, cluster-wide identifier for the replication origin. Should never leave the system.
<code>roname</code>	<code>text</code>		The external, user defined, name of a replication origin.

50.41. `pg_rewrite`

The catalog `pg_rewrite` stores rewrite rules for tables and views.

Table 50.41. pg_rewrite Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
rulename	name		Rule name
ev_class	oid	pg_class .oid	The table this rule is for
ev_type	char		Event type that the rule is for: 1 = SELECT, 2 = UPDATE, 3 = INSERT, 4 = DELETE
ev_enabled	char		Controls in which session_replication_role modes the rule fires. O = rule fires in “origin” and “local” modes, D = rule is disabled, R = rule fires in “replica” mode, A = rule fires always.
is_instead	bool		True if the rule is an INSTEAD rule
ev_qual	pg_node_tree		Expression tree (in the form of a <code>nodeToString()</code> representation) for the rule's qualifying condition
ev_action	pg_node_tree		Query tree (in the form of a <code>nodeToString()</code> representation) for the rule's action

Note

`pg_class.relhasrules` must be true if a table has any rules in this catalog.

50.42. pg_seclabel

The catalog `pg_seclabel` stores security labels on database objects. Security labels can be manipulated with the [SECURITY LABEL](#) command. For an easier way to view security labels, see [Section 50.74](#).

See also [pg_shseclabel](#), which performs a similar function for security labels of database objects that are shared across a database cluster.

Table 50.42. pg_seclabel Columns

Name	Type	References	Description
objoid	oid	any OID column	The OID of the object this security label pertains to
classoid	oid	pg_class .oid	The OID of the system catalog this object appears in

Name	Type	References	Description
objsubid	int4		For a security label on a table column, this is the column number (the <code>objoid</code> and <code>classoid</code> refer to the table itself). For all other object types, this column is zero.
provider	text		The label provider associated with this label.
label	text		The security label applied to this object.

50.43. pg_shdepend

The catalog `pg_shdepend` records the dependency relationships between database objects and shared objects, such as roles. This information allows Postgres Pro to ensure that those objects are unreferenced before attempting to delete them.

See also [pg_depend](#), which performs a similar function for dependencies involving objects within a single database.

Unlike most system catalogs, `pg_shdepend` is shared across all databases of a cluster: there is only one copy of `pg_shdepend` per cluster, not one per database.

Table 50.43. pg_shdepend Columns

Name	Type	References	Description
dbid	oid	pg_database .oid	The OID of the database the dependent object is in, or zero for a shared object
classid	oid	pg_class .oid	The OID of the system catalog the dependent object is in
objid	oid	any OID column	The OID of the specific dependent object
objsubid	int4		For a table column, this is the column number (the <code>objid</code> and <code>classid</code> refer to the table itself). For all other object types, this column is zero.
refclassid	oid	pg_class .oid	The OID of the system catalog the referenced object is in (must be a shared catalog)
refobjid	oid	any OID column	The OID of the specific referenced object
deptype	char		A code defining the specific semantics of this dependency relationship; see text

In all cases, a `pg_shdepend` entry indicates that the referenced object cannot be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

`SHARED_DEPENDENCY_OWNER` (o)

The referenced object (which must be a role) is the owner of the dependent object.

`SHARED_DEPENDENCY_ACL` (a)

The referenced object (which must be a role) is mentioned in the ACL (access control list, i.e., privileges list) of the dependent object. (A `SHARED_DEPENDENCY_ACL` entry is not made for the owner of the object, since the owner will have a `SHARED_DEPENDENCY_OWNER` entry anyway.)

`SHARED_DEPENDENCY_POLICY` (r)

The referenced object (which must be a role) is mentioned as the target of a dependent policy object.

`SHARED_DEPENDENCY_PIN` (p)

There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by `initdb`. The columns for the dependent object contain zeroes.

Other dependency flavors might be needed in future. Note in particular that the current definition only supports roles as referenced objects.

50.44. `pg_shdescription`

The catalog `pg_shdescription` stores optional descriptions (comments) for shared database objects. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`'s `\d` commands.

See also `pg_description`, which performs a similar function for descriptions involving objects within a single database.

Unlike most system catalogs, `pg_shdescription` is shared across all databases of a cluster: there is only one copy of `pg_shdescription` per cluster, not one per database.

Table 50.44. `pg_shdescription` Columns

Name	Type	References	Description
<code>objoid</code>	<code>oid</code>	any OID column	The OID of the object this description pertains to
<code>classoid</code>	<code>oid</code>	<code>pg_class.oid</code>	The OID of the system catalog this object appears in
<code>description</code>	<code>text</code>		Arbitrary text that serves as the description of this object

50.45. `pg_shseclabel`

The catalog `pg_shseclabel` stores security labels on shared database objects. Security labels can be manipulated with the `SECURITY LABEL` command. For an easier way to view security labels, see [Section 50.74](#).

See also `pg_seclabel`, which performs a similar function for security labels involving objects within a single database.

Unlike most system catalogs, `pg_shseclabel` is shared across all databases of a cluster: there is only one copy of `pg_shseclabel` per cluster, not one per database.

Table 50.45. pg_shseclabel Columns

Name	Type	References	Description
objoid	oid	any OID column	The OID of the object this security label pertains to
classoid	oid	pg_class .oid	The OID of the system catalog this object appears in
provider	text		The label provider associated with this label.
label	text		The security label applied to this object.

50.46. pg_statistic

The catalog `pg_statistic` stores statistical data about the contents of the database. Entries are created by [ANALYZE](#) and subsequently used by the query planner. Note that all the statistical data is inherently approximate, even assuming that it is up-to-date.

Normally there is one entry, with `stainherit = false`, for each table column that has been analyzed. If the table has inheritance children, a second entry with `stainherit = true` is also created. This row represents the column's statistics over the inheritance tree, i.e., statistics for the data you'd see with `SELECT column FROM table*`, whereas the `stainherit = false` row represents the results of `SELECT column FROM ONLY table`.

`pg_statistic` also stores statistical data about the values of index expressions. These are described as if they were actual data columns; in particular, `starelid` references the index. No entry is made for an ordinary non-expression index column, however, since it would be redundant with the entry for the underlying table column. Currently, entries for index expressions always have `stainherit = false`.

Since different kinds of statistics might be appropriate for different kinds of data, `pg_statistic` is designed not to assume very much about what sort of statistics it stores. Only extremely general statistics (such as nullness) are given dedicated columns in `pg_statistic`. Everything else is stored in “slots”, which are groups of associated columns whose content is identified by a code number in one of the slot's columns. For more information see `src/include/catalog/pg_statistic.h`.

`pg_statistic` should not be readable by the public, since even statistical information about a table's contents might be considered sensitive. (Example: minimum and maximum values of a salary column might be quite interesting.) [pg_stats](#) is a publicly readable view on `pg_statistic` that only exposes information about those tables that are readable by the current user.

Table 50.46. pg_statistic Columns

Name	Type	References	Description
starelid	oid	pg_class .oid	The table or index that the described column belongs to
staattnum	int2	pg_attribute .attnum	The number of the described column
stainherit	bool		If true, the stats include inheritance child columns, not just the values in the specified relation

Name	Type	References	Description
stanullfrac	float4		The fraction of the column's entries that are null
stawidth	int4		The average stored width, in bytes, of nonnull entries
stadistinct	float4		The number of distinct nonnull data values in the column. A value greater than zero is the actual number of distinct values. A value less than zero is the negative of a multiplier for the number of rows in the table; for example, a column in which about 80% of the values are nonnull and each nonnull value appears about twice on average could be represented by <code>stadistinct = -0.4</code> . A zero value means the number of distinct values is unknown.
stakindN	int2		A code number indicating the kind of statistics stored in the <i>N</i> th "slot" of the <code>pg_statistic</code> row.
staopN	oid	pg_operator .oid	An operator used to derive the statistics stored in the <i>N</i> th "slot". For example, a histogram slot would show the <code><</code> operator that defines the sort order of the data.
stanumbersN	float4[]		Numerical statistics of the appropriate kind for the <i>N</i> th "slot", or null if the slot kind does not involve numerical values
stavaluesN	anyarray		Column data values of the appropriate kind for the <i>N</i> th "slot", or null if the slot kind does not store any data values. Each array's element values are actually of the specific column's data type, or a related type such as an array's

Name	Type	References	Description
			element type, so there is no way to define these columns' type more specifically than <code>anyarray</code> .

50.47. `pg_tablespace`

The catalog `pg_tablespace` stores information about the available tablespaces. Tables can be placed in particular tablespaces to aid administration of disk layout.

Unlike most system catalogs, `pg_tablespace` is shared across all databases of a cluster: there is only one copy of `pg_tablespace` per cluster, not one per database.

Table 50.47. `pg_tablespace` Columns

Name	Type	References	Description
<code>oid</code>	<code>oid</code>		Row identifier (hidden attribute; must be explicitly selected)
<code>spcname</code>	<code>name</code>		Tablespace name
<code>spcowner</code>	<code>oid</code>	<code>pg_authid</code> .oid	Owner of the tablespace, usually the user who created it
<code>spcacl</code>	<code>aclitem[]</code>		Access privileges; see GRANT and REVOKE for details
<code>spcoptions</code>	<code>text[]</code>		Tablespace-level options, as “keyword=value” strings

50.48. `pg_transform`

The catalog `pg_transform` stores information about transforms, which are a mechanism to adapt data types to procedural languages. See [CREATE TRANSFORM](#) for more information.

Table 50.48. `pg_transform` Columns

Name	Type	References	Description
<code>trftype</code>	<code>oid</code>	<code>pg_type</code> .oid	OID of the data type this transform is for
<code>trflang</code>	<code>oid</code>	<code>pg_language</code> .oid	OID of the language this transform is for
<code>trffromsql</code>	<code>regproc</code>	<code>pg_proc</code> .oid	The OID of the function to use when converting the data type for input to the procedural language (e.g., function parameters). Zero is stored if this operation is not supported.
<code>trftosql</code>	<code>regproc</code>	<code>pg_proc</code> .oid	The OID of the function to use when converting output from the procedural language

Name	Type	References	Description
			(e.g., return values) to the data type. Zero is stored if this operation is not supported.

50.49. pg_trigger

The catalog `pg_trigger` stores triggers on tables and views. See [CREATE TRIGGER](#) for more information.

Table 50.49. pg_trigger Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
tgrelid	oid	pg_class .oid	The table this trigger is on
tgname	name		Trigger name (must be unique among triggers of same table)
tgfoid	oid	pg_proc .oid	The function to be called
tgtype	int2		Bit mask identifying trigger firing conditions
tgenabled	char		Controls in which session_replication_role modes the trigger fires. <code>O</code> = trigger fires in “origin” and “local” modes, <code>D</code> = trigger is disabled, <code>R</code> = trigger fires in “replica” mode, <code>A</code> = trigger fires always.
tgisinternal	bool		True if trigger is internally generated (usually, to enforce the constraint identified by <code>tgconstraint</code>)
tgconstrrelid	oid	pg_class .oid	The table referenced by a referential integrity constraint
tgconstrindid	oid	pg_class .oid	The index supporting a unique, primary key, referential integrity, or exclusion constraint
tgconstraint	oid	pg_constraint .oid	The <code>pg_constraint</code> entry associated with the trigger, if any
tgdeferrable	bool		True if constraint trigger is deferrable
tginitdeferred	bool		True if constraint trigger is initially deferred

Name	Type	References	Description
tgargs	int2		Number of argument strings passed to trigger function
tgattr	int2vector	pg_attribute .attnum	Column numbers, if trigger is column-specific; otherwise an empty array
tgargs	bytea		Argument strings to pass to trigger, each NULL-terminated
tgqual	pg_node_tree		Expression tree (in <code>nodeToString()</code> representation) for the trigger's WHEN condition, or null if none

Currently, column-specific triggering is supported only for UPDATE events, and so `tgattr` is relevant only for that event type. `tgtype` might contain bits for other event types as well, but those are presumed to be table-wide regardless of what is in `tgattr`.

Note

When `tgconstraint` is nonzero, `tgconstrrelid`, `tgconstrindid`, `tgdeferrable`, and `tginitdeferred` are largely redundant with the referenced `pg_constraint` entry. However, it is possible for a non-deferrable trigger to be associated with a deferrable constraint: foreign key constraints can have some deferrable and some non-deferrable triggers.

Note

`pg_class.relhastriggers` must be true if a relation has any triggers in this catalog.

50.50. pg_ts_config

The `pg_ts_config` catalog contains entries representing text search configurations. A configuration specifies a particular text search parser and a list of dictionaries to use for each of the parser's output token types. The parser is shown in the `pg_ts_config` entry, but the token-to-dictionary mapping is defined by subsidiary entries in [pg_ts_config_map](#).

Postgres Pro's text search features are described at length in [Chapter 12](#).

Table 50.50. `pg_ts_config` Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
cfgname	name		Text search configuration name
cfgnamespace	oid	pg_namespace .oid	The OID of the namespace that contains this configuration

Name	Type	References	Description
cfgowner	oid	pg_authid .oid	Owner of the configuration
cfgparser	oid	pg_ts_parser .oid	The OID of the text search parser for this configuration

50.51. pg_ts_config_map

The `pg_ts_config_map` catalog contains entries showing which text search dictionaries should be consulted, and in what order, for each output token type of each text search configuration's parser.

Postgres Pro's text search features are described at length in [Chapter 12](#).

Table 50.51. pg_ts_config_map Columns

Name	Type	References	Description
mapcfg	oid	pg_ts_config .oid	The OID of the <code>pg_ts_config</code> entry owning this map entry
maptokentype	integer		A token type emitted by the configuration's parser
mapseqno	integer		Order in which to consult this entry (lower <code>mapseqnos</code> first)
mapdict	oid	pg_ts_dict .oid	The OID of the text search dictionary to consult

50.52. pg_ts_dict

The `pg_ts_dict` catalog contains entries defining text search dictionaries. A dictionary depends on a text search template, which specifies all the implementation functions needed; the dictionary itself provides values for the user-settable parameters supported by the template. This division of labor allows dictionaries to be created by unprivileged users. The parameters are specified by a text string `dictinitoption`, whose format and meaning vary depending on the template.

Postgres Pro's text search features are described at length in [Chapter 12](#).

Table 50.52. pg_ts_dict Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
dictname	name		Text search dictionary name
dictnamespace	oid	pg_namespace .oid	The OID of the namespace that contains this dictionary
dictowner	oid	pg_authid .oid	Owner of the dictionary
dicttemplate	oid	pg_ts_template .oid	The OID of the text search template for this dictionary

Name	Type	References	Description
dictinitoption	text		Initialization option string for the template

50.53. pg_ts_parser

The `pg_ts_parser` catalog contains entries defining text search parsers. A parser is responsible for splitting input text into lexemes and assigning a token type to each lexeme. Since a parser must be implemented by C-language-level functions, creation of new parsers is restricted to database superusers.

Postgres Pro's text search features are described at length in [Chapter 12](#).

Table 50.53. pg_ts_parser Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
prsname	name		Text search parser name
prsnamespace	oid	pg_namespace .oid	The OID of the namespace that contains this parser
prsstart	regproc	pg_proc .oid	OID of the parser's startup function
prstoken	regproc	pg_proc .oid	OID of the parser's next-token function
prsend	regproc	pg_proc .oid	OID of the parser's shutdown function
prsheadline	regproc	pg_proc .oid	OID of the parser's headline function
prsllextype	regproc	pg_proc .oid	OID of the parser's lextype function

50.54. pg_ts_template

The `pg_ts_template` catalog contains entries defining text search templates. A template is the implementation skeleton for a class of text search dictionaries. Since a template must be implemented by C-language-level functions, creation of new templates is restricted to database superusers.

Postgres Pro's text search features are described at length in [Chapter 12](#).

Table 50.54. pg_ts_template Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
tmplname	name		Text search template name
tmplnamespace	oid	pg_namespace .oid	The OID of the namespace that contains this template
tmplinit	regproc	pg_proc .oid	OID of the template's initialization function

Name	Type	References	Description
tmpllexize	regproc	pg_proc .oid	OID of the template's lexize function

50.55. pg_type

The catalog `pg_type` stores information about data types. Base types and enum types (scalar types) are created with [CREATE TYPE](#), and domains with [CREATE DOMAIN](#). A composite type is automatically created for each table in the database, to represent the row structure of the table. It is also possible to create composite types with `CREATE TYPE AS`.

Table 50.55. pg_type Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
typname	name		Data type name
typnamespace	oid	pg_namespace .oid	The OID of the namespace that contains this type
typowner	oid	pg_authid .oid	Owner of the type
typlen	int2		For a fixed-size type, <code>typlen</code> is the number of bytes in the internal representation of the type. But for a variable-length type, <code>typlen</code> is negative. -1 indicates a “varlena” type (one that has a length word), -2 indicates a null-terminated C string.
typbyval	bool		<code>typbyval</code> determines whether internal routines pass a value of this type by value or by reference. <code>typbyval</code> had better be false if <code>typlen</code> is not 1, 2, or 4 (or 8 on machines where Datum is 8 bytes). Variable-length types are always passed by reference. Note that <code>typbyval</code> can be false even if the length would allow pass-by-value.
typtype	char		<code>typtype</code> is <code>b</code> for a base type, <code>c</code> for a composite type (e.g., a table's row type), <code>d</code> for a domain, <code>e</code> for an enum type, <code>p</code> for a pseudo-type, or <code>r</code> for a range type.

Name	Type	References	Description
			See also <code>typrelid</code> and <code>typbasetype</code> .
<code>typcategory</code>	<code>char</code>		<code>typcategory</code> is an arbitrary classification of data types that is used by the parser to determine which implicit casts should be “preferred”. See Table 50.56 .
<code>typispreferred</code>	<code>bool</code>		True if the type is a preferred cast target within its <code>typcategory</code>
<code>typisdefined</code>	<code>bool</code>		True if the type is defined, false if this is a placeholder entry for a not-yet-defined type. When <code>typisdefined</code> is false, nothing except the type name, namespace, and OID can be relied on.
<code>typdelim</code>	<code>char</code>		Character that separates two values of this type when parsing array input. Note that the delimiter is associated with the array element data type, not the array data type.
<code>typrelid</code>	<code>oid</code>	pg_class .oid	If this is a composite type (see <code>typtype</code>), then this column points to the <code>pg_class</code> entry that defines the corresponding table. (For a free-standing composite type, the <code>pg_class</code> entry doesn't really represent a table, but it is needed anyway for the type's <code>pg_attribute</code> entries to link to.) Zero for non-composite types.
<code>typelem</code>	<code>oid</code>	pg_type .oid	If <code>typelem</code> is not 0 then it identifies another row in <code>pg_type</code> . The current type can then be subscripted like an array yielding values of type <code>typelem</code> . A “true” array type is variable length (<code>typlen</code> = -1), but some fixed-length (<code>typlen</code> >

Name	Type	References	Description
			0) types also have nonzero <code>typelem</code> , for example <code>name</code> and <code>point</code> . If a fixed-length type has a <code>typelem</code> then its internal representation must be some number of values of the <code>typelem</code> data type with no other data. Variable-length array types have a header defined by the array subroutines.
<code>typarray</code>	<code>oid</code>	<code>pg_type</code> .oid	If <code>typarray</code> is not 0 then it identifies another row in <code>pg_type</code> , which is the “true” array type having this type as element
<code>typinput</code>	<code>regproc</code>	<code>pg_proc</code> .oid	Input conversion function (text format)
<code>typoutput</code>	<code>regproc</code>	<code>pg_proc</code> .oid	Output conversion function (text format)
<code>typreceive</code>	<code>regproc</code>	<code>pg_proc</code> .oid	Input conversion function (binary format), or 0 if none
<code>typsend</code>	<code>regproc</code>	<code>pg_proc</code> .oid	Output conversion function (binary format), or 0 if none
<code>typmodin</code>	<code>regproc</code>	<code>pg_proc</code> .oid	Type modifier input function, or 0 if type does not support modifiers
<code>typmodout</code>	<code>regproc</code>	<code>pg_proc</code> .oid	Type modifier output function, or 0 to use the standard format
<code>typanalyze</code>	<code>regproc</code>	<code>pg_proc</code> .oid	Custom <code>ANALYZE</code> function, or 0 to use the standard function
<code>typalign</code>	<code>char</code>		<code>typalign</code> is the alignment required when storing a value of this type. It applies to storage on disk as well as most representations of the value inside Postgres Pro. When multiple values are stored consecutively, such as in the representation of a complete row on disk, padding is inserted before a datum of this type so that it begins on the specified boundary.

Name	Type	References	Description
			The alignment reference is the beginning of the first datum in the sequence. Possible values are: • <code>c</code> = <code>char</code> alignment, i.e., no alignment needed. • <code>s</code> = <code>short</code> alignment (2 bytes on most machines). • <code>i</code> = <code>int</code> alignment (4 bytes on most machines). • <code>d</code> = <code>double</code> alignment (8 bytes on many machines, but by no means all). Note For types used in system tables, it is critical that the size and alignment defined in <code>pg_type</code> agree with the way that the compiler will lay out the column in a structure representing a table row.
typstorage	char		<code>typstorage</code> tells for <code>varlena</code> types (those with <code>typlen = -1</code>) if the type is prepared for toasting and what the default strategy for attributes of this type should be. Possible values are • <code>p</code>: Value must always be stored plain. • <code>e</code>: Value can be stored in a “secondary” relation (if relation has one, see <code>pg_class.reltoastrelid</code>).

Name	Type	References	Description
			<code>m</code>: Value can be stored compressed inline. <code>x</code>: Value can be stored compressed inline or stored in “secondary” storage. Note that <code>m</code> columns can also be moved out to secondary storage, but only as a last resort (<code>e</code> and <code>x</code> columns are moved first).
<code>typnotnull</code>	<code>bool</code>		<code>typnotnull</code> represents a not-null constraint on a type. Used for domains only.
<code>typbasetype</code>	<code>oid</code>	<code>pg_type.oid</code>	If this is a domain (see <code>typtype</code>), then <code>typbasetype</code> identifies the type that this one is based on. Zero if this type is not a domain.
<code>typtypmod</code>	<code>int4</code>		Domains use <code>typtypmod</code> to record the <code>typmod</code> to be applied to their base type (-1 if base type does not use a <code>typmod</code>). -1 if this type is not a domain.
<code>typndims</code>	<code>int4</code>		<code>typndims</code> is the number of array dimensions for a domain over an array (that is, <code>typbasetype</code> is an array type). Zero for types other than domains over array types.
<code>typcollation</code>	<code>oid</code>	<code>pg_collation.oid</code>	<code>typcollation</code> specifies the collation of the type. If the type does not support collations, this will be zero. A base type that supports collations will have <code>DEFAULT_COLLATION_OID</code> here. A domain over a collatable type can have some other collation OID, if one was specified for the domain.
<code>typdefaultbin</code>	<code>pg_node_tree</code>		If <code>typdefaultbin</code> is not null, it is the <code>nodeToString()</code>

Name	Type	References	Description
			representation of a default expression for the type. This is only used for domains.
typdefault	text		typdefault is null if the type has no associated default value. If typdefaultbin is not null, typdefault must contain a human-readable version of the default expression represented by typdefaultbin. If typdefaultbin is null and typdefault is not, then typdefault is the external representation of the type's default value, which can be fed to the type's input converter to produce a constant.
typacl	aclitem[]		Access privileges; see GRANT and REVOKE for details

[Table 50.56](#) lists the system-defined values of `typcategory`. Any future additions to this list will also be upper-case ASCII letters. All other ASCII characters are reserved for user-defined categories.

Table 50.56. `typcategory` Codes

Code	Category
A	Array types
B	Boolean types
C	Composite types
D	Date/time types
E	Enum types
G	Geometric types
I	Network address types
N	Numeric types
P	Pseudo-types
R	Range types
S	String types
T	Timespan types
U	User-defined types
V	Bit-string types
X	unknown type

50.56. `pg_user_mapping`

The catalog `pg_user_mapping` stores the mappings from local user to remote. Access to this catalog is restricted from normal users, use the view `pg_user_mappings` instead.

Table 50.57. `pg_user_mapping` Columns

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
umuser	oid	<code>pg_authid.oid</code>	OID of the local role being mapped, 0 if the user mapping is public
umserver	oid	<code>pg_foreign_server.oid</code>	The OID of the foreign server that contains this mapping
umoptions	text[]		User mapping specific options, as “keyword=value” strings

50.57. System Views

In addition to the system catalogs, Postgres Pro provides a number of built-in views. Some system views provide convenient access to some commonly used queries on the system catalogs. Other views provide access to internal server state.

The information schema ([Chapter 35](#)) provides an alternative set of views which overlap the functionality of the system views. Since the information schema is SQL-standard whereas the views described here are Postgres Pro-specific, it's usually better to use the information schema if it provides all the information you need.

[Table 50.58](#) lists the system views described here. More detailed documentation of each view follows below. There are some additional views that provide access to the results of the statistics collector; they are described in [Table 28.2](#).

Except where noted, all the views described here are read-only.

Table 50.58. System Views

View Name	Purpose
<code>pg_available_extensions</code>	available extensions
<code>pg_available_extension_versions</code>	available versions of extensions
<code>pg_config</code>	compile-time configuration parameters
<code>pg_cursors</code>	open cursors
<code>pg_file_settings</code>	summary of configuration file contents
<code>pg_group</code>	groups of database users
<code>pg_indexes</code>	indexes
<code>pg_locks</code>	locks currently held or awaited
<code>pg_matviews</code>	materialized views
<code>pg_policies</code>	policies
<code>pg_prepared_statements</code>	prepared statements
<code>pg_prepared_xacts</code>	prepared transactions
<code>pg_replication_origin_status</code>	information about replication origins, including replication progress

View Name	Purpose
pg_replication_slots	replication slot information
pg_roles	database roles
pg_rules	rules
pg_seclabels	security labels
pg_settings	parameter settings
pg_shadow	database users
pg_stats	planner statistics
pg_tables	tables
pg_timezone_abbrevs	time zone abbreviations
pg_timezone_names	time zone names
pg_user	database users
pg_user_mappings	user mappings
pg_views	views

50.58. [pg_available_extensions](#)

The [pg_available_extensions](#) view lists the extensions that are available for installation. See also the [pg_extension](#) catalog, which shows the extensions currently installed.

Table 50.59. [pg_available_extensions](#) Columns

Name	Type	Description
name	name	Extension name
default_version	text	Name of default version, or NULL if none is specified
installed_version	text	Currently installed version of the extension, or NULL if not installed
comment	text	Comment string from the extension's control file

The [pg_available_extensions](#) view is read only.

50.59. [pg_available_extension_versions](#)

The [pg_available_extension_versions](#) view lists the specific extension versions that are available for installation. See also the [pg_extension](#) catalog, which shows the extensions currently installed.

Table 50.60. [pg_available_extension_versions](#) Columns

Name	Type	Description
name	name	Extension name
version	text	Version name
installed	bool	True if this version of this extension is currently installed
superuser	bool	True if only superusers are allowed to install this extension
relocatable	bool	True if extension can be relocated to another schema

Name	Type	Description
schema	name	Name of the schema that the extension must be installed into, or NULL if partially or fully relocatable
requires	name []	Names of prerequisite extensions, or NULL if none
comment	text	Comment string from the extension's control file

The `pg_available_extension_versions` view is read only.

50.60. pg_config

The view `pg_config` describes the compile-time configuration parameters of the currently installed version of Postgres Pro. It is intended, for example, to be used by software packages that want to interface to Postgres Pro to facilitate finding the required header files and libraries. It provides the same basic information as the [pg_config](#) Postgres Pro client application.

By default, the `pg_config` view can be read only by superusers.

Table 50.61. pg_config Columns

Name	Type	Description
name	text	The parameter name
setting	text	The parameter value

50.61. pg_cursors

The `pg_cursors` view lists the cursors that are currently available. Cursors can be defined in several ways:

- via the [DECLARE](#) statement in SQL
- via the Bind message in the frontend/backend protocol, as described in [Section 51.2.3](#)
- via the Server Programming Interface (SPI), as described in [Section 45.1](#)

The `pg_cursors` view displays cursors created by any of these means. Cursors only exist for the duration of the transaction that defines them, unless they have been declared `WITH HOLD`. Therefore non-holdable cursors are only present in the view until the end of their creating transaction.

Note

Cursors are used internally to implement some of the components of Postgres Pro, such as procedural languages. Therefore, the `pg_cursors` view might include cursors that have not been explicitly created by the user.

Table 50.62. pg_cursors Columns

Name	Type	Description
name	text	The name of the cursor
statement	text	The verbatim query string submitted to declare this cursor

Name	Type	Description
is_holdable	boolean	true if the cursor is holdable (that is, it can be accessed after the transaction that declared the cursor has committed); false otherwise
is_binary	boolean	true if the cursor was declared BINARY; false otherwise
is_scrollable	boolean	true if the cursor is scrollable (that is, it allows rows to be retrieved in a nonsequential manner); false otherwise
creation_time	timestampz	The time at which the cursor was declared

The `pg_cursors` view is read only.

50.62. `pg_file_settings`

The view `pg_file_settings` provides a summary of the contents of the server's configuration file(s). A row appears in this view for each “name = value” entry appearing in the files, with annotations indicating whether the value could be applied successfully. Additional row(s) may appear for problems not linked to a “name = value” entry, such as syntax errors in the files.

This view is helpful for checking whether planned changes in the configuration files will work, or for diagnosing a previous failure. Note that this view reports on the *current* contents of the files, not on what was last applied by the server. (The `pg_settings` view is usually sufficient to determine that.)

By default, the `pg_file_settings` view can be read only by superusers.

Table 50.63. `pg_file_settings` Columns

Name	Type	Description
sourcefile	text	Full path name of the configuration file
sourceline	integer	Line number within the configuration file where the entry appears
seqno	integer	Order in which the entries are processed (1.. <i>n</i>)
name	text	Configuration parameter name
setting	text	Value to be assigned to the parameter
applied	boolean	True if the value can be applied successfully
error	text	If not null, an error message indicating why this entry could not be applied

If the configuration file contains syntax errors or invalid parameter names, the server will not attempt to apply any settings from it, and therefore all the `applied` fields will read as false. In such a case there will be one or more rows with non-null `error` fields indicating the problem(s). Otherwise, individual settings will be applied if possible. If an individual setting cannot be applied (e.g., invalid value, or the setting

cannot be changed after server start) it will have an appropriate message in the `error` field. Another way that an entry might have `applied = false` is that it is overridden by a later entry for the same parameter name; this case is not considered an error so nothing appears in the `error` field.

See [Section 19.1](#) for more information about the various ways to change run-time parameters.

50.63. `pg_group`

The view `pg_group` exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1. It shows the names and members of all roles that are marked as not `rolcanlogin`, which is an approximation to the set of roles that are being used as groups.

Table 50.64. `pg_group` Columns

Name	Type	References	Description
<code>groname</code>	<code>name</code>	<code>pg_authid</code> .rolname	Name of the group
<code>grosysid</code>	<code>oid</code>	<code>pg_authid</code> .oid	ID of this group
<code>grolist</code>	<code>oid[]</code>	<code>pg_authid</code> .oid	An array containing the IDs of the roles in this group

50.64. `pg_indexes`

The view `pg_indexes` provides access to useful information about each index in the database.

Table 50.65. `pg_indexes` Columns

Name	Type	References	Description
<code>schemaname</code>	<code>name</code>	<code>pg_namespace</code> .nspname	Name of schema containing table and index
<code>tablename</code>	<code>name</code>	<code>pg_class</code> .relname	Name of table the index is for
<code>indexname</code>	<code>name</code>	<code>pg_class</code> .relname	Name of index
<code>tablespace</code>	<code>name</code>	<code>pg_tablespace</code> .spcname	Name of tablespace containing index (null if default for database)
<code>indexdef</code>	<code>text</code>		Index definition (a reconstructed <code>CREATE INDEX</code> command)

50.65. `pg_locks`

The view `pg_locks` provides access to information about the locks held by active processes within the database server. See [Chapter 13](#) for more discussion of locking.

`pg_locks` contains one row per active lockable object, requested lock mode, and relevant process. Thus, the same lockable object might appear many times, if multiple processes are holding or waiting for locks on it. However, an object that currently has no locks on it will not appear at all.

There are several distinct types of lockable objects: whole relations (e.g., tables), individual pages of relations, individual tuples of relations, transaction IDs (both virtual and permanent IDs), and general database objects (identified by class OID and object OID, in the same way as in `pg_description` or `pg_depend`). Also, the right to extend a relation is represented as a separate lockable object, as is the

right to update `pg_database.datfrozenxid`. Also, “advisory” locks can be taken on numbers that have user-defined meanings.

Table 50.66. `pg_locks` Columns

Name	Type	References	Description
locktype	text		Type of the lockable object: relation, extend, frozenid, page, tuple, transactionid, virtualxid, object, userlock, or advisory
database	oid	<code>pg_database</code> .oid	OID of the database in which the lock target exists, or zero if the target is a shared object, or null if the target is a transaction ID
relation	oid	<code>pg_class</code> .oid	OID of the relation targeted by the lock, or null if the target is not a relation or part of a relation
page	integer		Page number targeted by the lock within the relation, or null if the target is not a relation page or tuple
tuple	smallint		Tuple number targeted by the lock within the page, or null if the target is not a tuple
virtualxid	text		Virtual ID of the transaction targeted by the lock, or null if the target is not a virtual transaction ID
transactionid	xid		ID of the transaction targeted by the lock, or null if the target is not a transaction ID
classid	oid	<code>pg_class</code> .oid	OID of the system catalog containing the lock target, or null if the target is not a general database object
objid	oid	any OID column	OID of the lock target within its system catalog, or null if the target is not a general database object
objsubid	smallint		Column number targeted by the lock (the <code>classid</code> and <code>objid</code> refer to the

Name	Type	References	Description
			table itself), or zero if the target is some other general database object, or null if the target is not a general database object
virtualtransaction	text		Virtual ID of the transaction that is holding or awaiting this lock
pid	integer		Process ID of the server process holding or awaiting this lock, or null if the lock is held by a prepared transaction
mode	text		Name of the lock mode held or desired by this process (see Section 13.3.1 and Section 13.2.3)
granted	boolean		True if lock is held, false if lock is awaited
fastpath	boolean		True if lock was taken via fast path, false if taken via main lock table

`granted` is true in a row representing a lock held by the indicated process. False indicates that this process is currently waiting to acquire this lock, which implies that at least one other process is holding or waiting for a conflicting lock mode on the same lockable object. The waiting process will sleep until the other lock is released (or a deadlock situation is detected). A single process can be waiting to acquire at most one lock at a time.

Throughout running a transaction, a server process holds an exclusive lock on the transaction's virtual transaction ID. If a permanent ID is assigned to the transaction (which normally happens only if the transaction changes the state of the database), it also holds an exclusive lock on the transaction's permanent transaction ID until it ends. When a process finds it necessary to wait specifically for another transaction to end, it does so by attempting to acquire share lock on the other transaction's ID (either virtual or permanent ID depending on the situation). That will succeed only when the other transaction terminates and releases its locks.

Although tuples are a lockable type of object, information about row-level locks is stored on disk, not in memory, and therefore row-level locks normally do not appear in this view. If a process is waiting for a row-level lock, it will usually appear in the view as waiting for the permanent transaction ID of the current holder of that row lock.

Advisory locks can be acquired on keys consisting of either a single `bigint` value or two integer values. A `bigint` key is displayed with its high-order half in the `classid` column, its low-order half in the `objid` column, and `objsubid` equal to 1. The original `bigint` value can be reassembled with the expression `(classid::bigint << 32) | objid::bigint`. Integer keys are displayed with the first key in the `classid` column, the second key in the `objid` column, and `objsubid` equal to 2. The actual meaning of the keys is up to the user. Advisory locks are local to each database, so the `database` column is meaningful for an advisory lock.

`pg_locks` provides a global view of all locks in the database cluster, not only those relevant to the current database. Although its `relation` column can be joined against `pg_class.oid` to identify locked relations,

this will only work correctly for relations in the current database (those for which the `database` column is either the current database's OID or zero).

The `pid` column can be joined to the `pid` column of the `pg_stat_activity` view to get more information on the session holding or awaiting each lock, for example

```
SELECT * FROM pg_locks pl LEFT JOIN pg_stat_activity psa
    ON pl.pid = psa.pid;
```

Also, if you are using prepared transactions, the `virtualtransaction` column can be joined to the `transaction` column of the `pg_prepared_xacts` view to get more information on prepared transactions that hold locks. (A prepared transaction can never be waiting for a lock, but it continues to hold the locks it acquired while running.) For example:

```
SELECT * FROM pg_locks pl LEFT JOIN pg_prepared_xacts ppx
    ON pl.virtualtransaction = '-1/' || ppx.transaction;
```

While it is possible to obtain information about which processes block which other processes by joining `pg_locks` against itself, this is very difficult to get right in detail. Such a query would have to encode knowledge about which lock modes conflict with which others. Worse, the `pg_locks` view does not expose information about which processes are ahead of which others in lock wait queues, nor information about which processes are parallel workers running on behalf of which other client sessions. It is better to use the `pg_blocking_pids()` function (see [Table 9.59](#)) to identify which process(es) a waiting process is blocked behind.

The `pg_locks` view displays data from both the regular lock manager and the predicate lock manager, which are separate systems; in addition, the regular lock manager subdivides its locks into regular and *fast-path* locks. This data is not guaranteed to be entirely consistent. When the view is queried, data on fast-path locks (with `fastpath = true`) is gathered from each backend one at a time, without freezing the state of the entire lock manager, so it is possible for locks to be taken or released while information is gathered. Note, however, that these locks are known not to conflict with any other lock currently in place. After all backends have been queried for fast-path locks, the remainder of the regular lock manager is locked as a unit, and a consistent snapshot of all remaining locks is collected as an atomic action. After unlocking the regular lock manager, the predicate lock manager is similarly locked and all predicate locks are collected as an atomic action. Thus, with the exception of fast-path locks, each lock manager will deliver a consistent set of results, but as we do not lock both lock managers simultaneously, it is possible for locks to be taken or released after we interrogate the regular lock manager and before we interrogate the predicate lock manager.

Locking the regular and/or predicate lock manager could have some impact on database performance if this view is very frequently accessed. The locks are held only for the minimum amount of time necessary to obtain data from the lock managers, but this does not completely eliminate the possibility of a performance impact.

50.66. `pg_matviews`

The view `pg_matviews` provides access to useful information about each materialized view in the database.

Table 50.67. `pg_matviews` Columns

Name	Type	References	Description
<code>schemaname</code>	name	<code>pg_namespace</code> . <code>nspname</code>	Name of schema containing materialized view
<code>matviewname</code>	name	<code>pg_class</code> . <code>relname</code>	Name of materialized view
<code>matviewowner</code>	name	<code>pg_authid</code> . <code>rolname</code>	Name of materialized view's owner

Name	Type	References	Description
tablespace	name	pg_tablespace .spcname	Name of tablespace containing materialized view (null if default for database)
hasindexes	boolean		True if materialized view has (or recently had) any indexes
ispopulated	boolean		True if materialized view is currently populated
definition	text		Materialized view definition (a reconstructed SELECT query)

50.67. pg_policies

The view `pg_policies` provides access to useful information about each row-level security policy in the database.

Table 50.68. pg_policies Columns

Name	Type	References	Description
schemaname	name	pg_namespace .nspname	Name of schema containing table policy is on
tablename	name	pg_class .relname	Name of table policy is on
polycyname	name	pg_policy .polname	Name of policy
roles	name []		The roles to which this policy applies
cmd	text		The command type to which the policy is applied
qual	text		The expression added to the security barrier qualifications for queries that this policy applies to
with_check	text		The expression added to the WITH CHECK qualifications for queries that attempt to add rows to this table

50.68. pg_prepared_statements

The `pg_prepared_statements` view displays all the prepared statements that are available in the current session. See [PREPARE](#) for more information about prepared statements.

`pg_prepared_statements` contains one row for each prepared statement. Rows are added to the view when a new prepared statement is created and removed when a prepared statement is released (for example, via the [DEALLOCATE](#) command).

Table 50.69. pg_prepared_statements Columns

Name	Type	Description
name	text	The identifier of the prepared statement
statement	text	The query string submitted by the client to create this prepared statement. For prepared statements created via SQL, this is the <code>PREPARE</code> statement submitted by the client. For prepared statements created via the frontend/backend protocol, this is the text of the prepared statement itself.
prepare_time	timestampz	The time at which the prepared statement was created
parameter_types	regtype[]	The expected parameter types for the prepared statement in the form of an array of <code>regtype</code> . The OID corresponding to an element of this array can be obtained by casting the <code>regtype</code> value to <code>oid</code> .
from_sql	boolean	<code>true</code> if the prepared statement was created via the <code>PREPARE SQL</code> command; <code>false</code> if the statement was prepared via the frontend/backend protocol

The `pg_prepared_statements` view is read only.

50.69. pg_prepared_xacts

The view `pg_prepared_xacts` displays information about transactions that are currently prepared for two-phase commit (see [PREPARE TRANSACTION](#) for details).

`pg_prepared_xacts` contains one row per prepared transaction. An entry is removed when the transaction is committed or rolled back.

Table 50.70. pg_prepared_xacts Columns

Name	Type	References	Description
transaction	xid		Numeric transaction identifier of the prepared transaction
gid	text		Global transaction identifier that was assigned to the transaction
prepared	timestamp with time zone		Time at which the transaction was prepared for commit
owner	name	pg_authid .rolname	Name of the user that executed the transaction

Name	Type	References	Description
database	name	pg_database .datname	Name of the database in which the transaction was executed

When the `pg_prepared_xacts` view is accessed, the internal transaction manager data structures are momentarily locked, and a copy is made for the view to display. This ensures that the view produces a consistent set of results, while not blocking normal operations longer than necessary. Nonetheless there could be some impact on database performance if this view is frequently accessed.

50.70. `pg_replication_origin_status`

The `pg_replication_origin_status` view contains information about how far replay for a certain origin has progressed. For more on replication origins see [Chapter 48](#).

Table 50.71. `pg_replication_origin_status` Columns

Name	Type	References	Description
local_id	Oid	pg_replication_origin .roident	internal node identifier
external_id	text	pg_replication_origin .roname	external node identifier
remote_lsn	pg_lsn		The origin node's LSN up to which data has been replicated.
local_lsn	pg_lsn		This node's LSN at which <code>remote_lsn</code> has been replicated. Used to flush commit records before persisting data to disk when using asynchronous commits.

50.71. `pg_replication_slots`

The `pg_replication_slots` view provides a listing of all replication slots that currently exist on the database cluster, along with their current state.

For more on replication slots, see [Section 26.2.6](#) and [Chapter 47](#).

Table 50.72. `pg_replication_slots` Columns

Name	Type	References	Description
slot_name	name		A unique, cluster-wide identifier for the replication slot
plugin	name		The base name of the shared object containing the output plugin this logical slot is using, or null for physical slots.
slot_type	text		The slot type - physical or logical

Name	Type	References	Description
datoid	oid	pg_database .oid	The OID of the database this slot is associated with, or null. Only logical slots have an associated database.
database	text	pg_database .datname	The name of the database this slot is associated with, or null. Only logical slots have an associated database.
active	boolean		True if this slot is currently actively being used
active_pid	integer		The process ID of the session using this slot if the slot is currently actively being used. NULL if inactive.
xmin	xid		The oldest transaction that this slot needs the database to retain. VACUUM cannot remove tuples deleted by any later transaction.
catalog_xmin	xid		The oldest transaction affecting the system catalogs that this slot needs the database to retain. VACUUM cannot remove catalog tuples deleted by any later transaction.
restart_lsn	pg_lsn		The address (LSN) of oldest WAL which still might be required by the consumer of this slot and thus won't be automatically removed during checkpoints.
confirmed_flush_lsn	pg_lsn		The address (LSN) up to which the logical slot's consumer has confirmed receiving data. Data older than this is not available anymore. NULL for physical slots.

50.72. pg_roles

The view `pg_roles` provides access to information about database roles. This is simply a publicly readable view of `pg_authid` that blanks out the password field.

This view explicitly exposes the OID column of the underlying table, since that is needed to do joins to other catalogs.

Table 50.73. pg_roles Columns

Name	Type	References	Description
rolname	name		Role name
rolsuper	bool		Role has superuser privileges
rolinherit	bool		Role automatically inherits privileges of roles it is a member of
rolcreaterole	bool		Role can create more roles
rolcreatedb	bool		Role can create databases
rolcanlogin	bool		Role can log in. That is, this role can be given as the initial session authorization identifier
rolreplication	bool		Role is a replication role. A replication role can initiate replication connections and create and drop replication slots.
rolconlimit	int4		For roles that can log in, this sets maximum number of concurrent connections this role can make. -1 means no limit.
rolpassword	text		Not the password (always reads as *****)
rolvaliduntil	timestampz		Password expiry time (only used for password authentication); null if no expiration
rolbypassrls	bool		Role bypasses every row level security policy, see Section 5.7 for more information.
rolconfig	text[]		Role-specific defaults for run-time configuration variables
oid	oid	pg_authid .oid	ID of role

50.73. pg_rules

The view `pg_rules` provides access to useful information about query rewrite rules.

Table 50.74. pg_rules Columns

Name	Type	References	Description
schemaname	name	pg_namespace .nspname	Name of schema containing table

Name	Type	References	Description
tablename	name	pg_class .relname	Name of table the rule is for
rulename	name	pg_rewrite .rulename	Name of rule
definition	text		Rule definition (a reconstructed creation command)

The `pg_rules` view excludes the `ON SELECT` rules of views and materialized views; those can be seen in `pg_views` and `pg_matviews`.

50.74. `pg_seclabels`

The view `pg_seclabels` provides information about security labels. It is an easier-to-query version of the `pg_seclabel` catalog.

Table 50.75. `pg_seclabels` Columns

Name	Type	References	Description
objoid	oid	any OID column	The OID of the object this security label pertains to
classoid	oid	pg_class .oid	The OID of the system catalog this object appears in
objsubid	int4		For a security label on a table column, this is the column number (the <code>objoid</code> and <code>classoid</code> refer to the table itself). For all other object types, this column is zero.
objtype	text		The type of object to which this label applies, as text.
objnamespace	oid	pg_namespace .oid	The OID of the namespace for this object, if applicable; otherwise NULL.
objname	text		The name of the object to which this label applies, as text.
provider	text	pg_seclabel .provider	The label provider associated with this label.
label	text	pg_seclabel .label	The security label applied to this object.

50.75. `pg_settings`

The view `pg_settings` provides access to run-time parameters of the server. It is essentially an alternative interface to the `SHOW` and `SET` commands. It also provides access to some facts about each parameter that are not directly available from `SHOW`, such as minimum and maximum values.

Table 50.76. pg_settings Columns

Name	Type	Description
name	text	Run-time configuration parameter name
setting	text	Current value of the parameter
unit	text	Implicit unit of the parameter
category	text	Logical group of the parameter
short_desc	text	A brief description of the parameter
extra_desc	text	Additional, more detailed, description of the parameter
context	text	Context required to set the parameter's value (see below)
vartype	text	Parameter type (bool, enum, integer, real, or string)
source	text	Source of the current parameter value
min_val	text	Minimum allowed value of the parameter (null for non-numeric values)
max_val	text	Maximum allowed value of the parameter (null for non-numeric values)
enumvals	text[]	Allowed values of an enum parameter (null for non-enum values)
boot_val	text	Parameter value assumed at server startup if the parameter is not otherwise set
reset_val	text	Value that RESET would reset the parameter to in the current session
sourcefile	text	Configuration file the current value was set in (null for values set from sources other than configuration files, or when examined by a non-superuser); helpful when using include directives in configuration files
sourceline	integer	Line number within the configuration file the current value was set at (null for values set from sources other than configuration files, or when examined by a non-superuser)
pending_restart	boolean	true if the value has been changed in the configuration file but needs a restart; or false otherwise.

There are several possible values of `context`. In order of decreasing difficulty of changing the setting, they are:

`internal`

These settings cannot be changed directly; they reflect internally determined values. Some of them may be adjustable by rebuilding the server with different configuration options, or by changing options supplied to `initdb`.

`postmaster`

These settings can only be applied when the server starts, so any change requires restarting the server. Values for these settings are typically stored in the `postgresql.conf` file, or passed on the command line when starting the server. Of course, settings with any of the lower `context` types can also be set at server start time.

`sighup`

Changes to these settings can be made in `postgresql.conf` without restarting the server. Send a `SIGHUP` signal to the postmaster to cause it to re-read `postgresql.conf` and apply the changes. The postmaster will also forward the `SIGHUP` signal to its child processes so that they all pick up the new value.

`superuser-backend`

Changes to these settings can be made in `postgresql.conf` without restarting the server. They can also be set for a particular session in the connection request packet (for example, via libpq's `PGOPTIONS` environment variable), but only if the connecting user is a superuser. However, these settings never change in a session after it is started. If you change them in `postgresql.conf`, send a `SIGHUP` signal to the postmaster to cause it to re-read `postgresql.conf`. The new values will only affect subsequently-launched sessions.

`backend`

Changes to these settings can be made in `postgresql.conf` without restarting the server. They can also be set for a particular session in the connection request packet (for example, via libpq's `PGOPTIONS` environment variable); any user can make such a change for their session. However, these settings never change in a session after it is started. If you change them in `postgresql.conf`, send a `SIGHUP` signal to the postmaster to cause it to re-read `postgresql.conf`. The new values will only affect subsequently-launched sessions.

`superuser`

These settings can be set from `postgresql.conf`, or within a session via the `SET` command; but only superusers can change them via `SET`. Changes in `postgresql.conf` will affect existing sessions only if no session-local value has been established with `SET`.

`user`

These settings can be set from `postgresql.conf`, or within a session via the `SET` command. Any user is allowed to change their session-local value. Changes in `postgresql.conf` will affect existing sessions only if no session-local value has been established with `SET`.

See [Section 19.1](#) for more information about the various ways to change these parameters.

The `pg_settings` view cannot be inserted into or deleted from, but it can be updated. An `UPDATE` applied to a row of `pg_settings` is equivalent to executing the [SET](#) command on that named parameter. The change only affects the value used by the current session. If an `UPDATE` is issued within a transaction that is later aborted, the effects of the `UPDATE` command disappear when the transaction is rolled back. Once the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another `UPDATE` or `SET`.

50.76. `pg_shadow`

The view `pg_shadow` exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1. It shows properties of all roles that are marked as `rolcanlogin` in `pg_authid`.

The name stems from the fact that this table should not be readable by the public since it contains passwords. `pg_user` is a publicly readable view on `pg_shadow` that blanks out the password field.

Table 50.77. `pg_shadow` Columns

Name	Type	References	Description
<code>username</code>	<code>name</code>	<code>pg_authid</code> .rolname	User name
<code>usesysid</code>	<code>oid</code>	<code>pg_authid</code> .oid	ID of this user
<code>usecreatedb</code>	<code>bool</code>		User can create databases
<code>usesuper</code>	<code>bool</code>		User is a superuser
<code>userepl</code>	<code>bool</code>		User can initiate streaming replication and put the system in and out of backup mode.
<code>usebypassrls</code>	<code>bool</code>		User bypasses every row level security policy, see Section 5.7 for more information.
<code>passwd</code>	<code>text</code>		Password (possibly encrypted); null if none. See <code>pg_authid</code> for details of how encrypted passwords are stored.
<code>valuntil</code>	<code>abstime</code>		Password expiry time (only used for password authentication)
<code>useconfig</code>	<code>text []</code>		Session defaults for run-time configuration variables

50.77. `pg_stats`

The view `pg_stats` provides access to the information stored in the `pg_statistic` catalog. This view allows access only to rows of `pg_statistic` that correspond to tables the user has permission to read, and therefore it is safe to allow public read access to this view.

`pg_stats` is also designed to present the information in a more readable format than the underlying catalog — at the cost that its schema must be extended whenever new slot types are defined for `pg_statistic`.

Table 50.78. `pg_stats` Columns

Name	Type	References	Description
<code>schemaname</code>	<code>name</code>	<code>pg_namespace</code> .nspname	Name of schema containing table
<code>tablename</code>	<code>name</code>	<code>pg_class</code> .relname	Name of table
<code>attname</code>	<code>name</code>	<code>pg_attribute</code> .attname	Name of the column described by this row
<code>inherited</code>	<code>bool</code>		If true, this row includes inheritance child columns, not just

Name	Type	References	Description
			the values in the specified table
null_frac	real		Fraction of column entries that are null
avg_width	integer		Average width in bytes of column's entries
n_distinct	real		If greater than zero, the estimated number of distinct values in the column. If less than zero, the negative of the number of distinct values divided by the number of rows. (The negated form is used when ANALYZE believes that the number of distinct values is likely to increase as the table grows; the positive form is used when the column seems to have a fixed number of possible values.) For example, -1 indicates a unique column in which the number of distinct values is the same as the number of rows.
most_common_vals	anyarray		A list of the most common values in the column. (Null if no values seem to be more common than any others.)
most_common_freqs	real[]		A list of the frequencies of the most common values, i.e., number of occurrences of each divided by total number of rows. (Null when most_common_vals is.)
histogram_bounds	anyarray		A list of values that divide the column's values into groups of approximately equal population. The values in most_common_vals, if present, are omitted from this histogram calculation. (This column is null if the column data type does not have a < operator or if the most_common_vals list

Name	Type	References	Description
			accounts for the entire population.)
correlation	real		Statistical correlation between physical row ordering and logical ordering of the column values. This ranges from -1 to +1. When the value is near -1 or +1, an index scan on the column will be estimated to be cheaper than when it is near zero, due to reduction of random access to the disk. (This column is null if the column data type does not have a < operator.)
most_common_elems	anyarray		A list of non-null element values most often appearing within values of the column. (Null for scalar types.)
most_common_elem_freqs	real[]		A list of the frequencies of the most common element values, i.e., the fraction of rows containing at least one instance of the given value. Two or three additional values follow the per-element frequencies; these are the minimum and maximum of the preceding per-element frequencies, and optionally the frequency of null elements. (Null when most_common_elems is.)
elem_count_histogram	real[]		A histogram of the counts of distinct non-null element values within the values of the column, followed by the average number of distinct non-null elements. (Null for scalar types.)

The maximum number of entries in the array fields can be controlled on a column-by-column basis using the `ALTER TABLE SET STATISTICS` command, or globally by setting the [default_statistics_target](#) run-time parameter.

50.78. pg_tables

The view `pg_tables` provides access to useful information about each table in the database.

Table 50.79. pg_tables Columns

Name	Type	References	Description
<code>schemaname</code>	name	<code>pg_namespace .nspname</code>	Name of schema containing table
<code>tablename</code>	name	<code>pg_class .relname</code>	Name of table
<code>tableowner</code>	name	<code>pg_authid .rolname</code>	Name of table's owner
<code>tablespace</code>	name	<code>pg_tablespace .spcname</code>	Name of tablespace containing table (null if default for database)
<code>hasindexes</code>	boolean	<code>pg_class .relhasindex</code>	True if table has (or recently had) any indexes
<code>hasrules</code>	boolean	<code>pg_class .relhasrules</code>	True if table has (or once had) rules
<code>hastriggers</code>	boolean	<code>pg_class .relhastriggers</code>	True if table has (or once had) triggers
<code>rowsecurity</code>	boolean	<code>pg_class .relrowsecurity</code>	True if row security is enabled on the table

50.79. pg_timezone_abbrevs

The view `pg_timezone_abbrevs` provides a list of time zone abbreviations that are currently recognized by the datetime input routines. The contents of this view change when the `timezone_abbreviations` runtime parameter is modified.

Table 50.80. pg_timezone_abbrevs Columns

Name	Type	Description
<code>abbrev</code>	text	Time zone abbreviation
<code>utc_offset</code>	interval	Offset from UTC (positive means east of Greenwich)
<code>is_dst</code>	boolean	True if this is a daylight-savings abbreviation

While most timezone abbreviations represent fixed offsets from UTC, there are some that have historically varied in value (see [Section B.4](#) for more information). In such cases this view presents their current meaning.

50.80. pg_timezone_names

The view `pg_timezone_names` provides a list of time zone names that are recognized by `SET TIMEZONE`, along with their associated abbreviations, UTC offsets, and daylight-savings status. (Technically, Postgres Pro does not use UTC because leap seconds are not handled.) Unlike the abbreviations shown in `pg_timezone_abbrevs`, many of these names imply a set of daylight-savings transition date rules. Therefore, the associated information changes across local DST boundaries. The displayed information is computed based on the current value of `CURRENT_TIMESTAMP`.

Table 50.81. pg_timezone_names Columns

Name	Type	Description
<code>name</code>	text	Time zone name

Name	Type	Description
abbrev	text	Time zone abbreviation
utc_offset	interval	Offset from UTC (positive means east of Greenwich)
is_dst	boolean	True if currently observing daylight savings

50.81. pg_user

The view `pg_user` provides access to information about database users. This is simply a publicly readable view of `pg_shadow` that blanks out the password field.

Table 50.82. pg_user Columns

Name	Type	Description
username	name	User name
usesysid	oid	ID of this user
usecreatedb	bool	User can create databases
usesuper	bool	User is a superuser
userepl	bool	User can initiate streaming replication and put the system in and out of backup mode.
usebypassrls	bool	User bypasses every row level security policy, see Section 5.7 for more information.
passwd	text	Not the password (always reads as *****)
valuntil	abstime	Password expiry time (only used for password authentication)
useconfig	text[]	Session defaults for run-time configuration variables

50.82. pg_user_mappings

The view `pg_user_mappings` provides access to information about user mappings. This is essentially a publicly readable view of `pg_user_mapping` that leaves out the options field if the user has no rights to use it.

Table 50.83. pg_user_mappings Columns

Name	Type	References	Description
umid	oid	pg_user_mapping .oid	OID of the user mapping
srvid	oid	pg_foreign_server .oid	The OID of the foreign server that contains this mapping
srvname	name	pg_foreign_server .srvname	Name of the foreign server
umuser	oid	pg_authid .oid	OID of the local role being mapped, 0 if the user mapping is public
username	name		Name of the local user to be mapped

Name	Type	References	Description
umoptions	text []		User mapping specific options, as “keyword=value” strings

To protect password information stored as a user mapping option, the `umoptions` column will read as null unless one of the following applies:

- current user is the user being mapped, and owns the server or holds `USAGE` privilege on it
- current user is the server owner and mapping is for `PUBLIC`
- current user is a superuser

50.83. pg_views

The view `pg_views` provides access to useful information about each view in the database.

Table 50.84. pg_views Columns

Name	Type	References	Description
schemaname	name	<code>pg_namespace</code> .nspname	Name of schema containing view
viewname	name	<code>pg_class</code> .relname	Name of view
viewowner	name	<code>pg_authid</code> .rolname	Name of view's owner
definition	text		View definition (a reconstructed <code>SELECT</code> query)

Chapter 51. Frontend/Backend Protocol

Postgres Pro uses a message-based protocol for communication between frontends and backends (clients and servers). The protocol is supported over TCP/IP and also over Unix-domain sockets. Port number 5432 has been registered with IANA as the customary TCP port number for servers supporting this protocol, but in practice any non-privileged port number can be used.

This document describes version 3.0 of the protocol, implemented in PostgreSQL 7.4 and later. For descriptions of the earlier protocol versions, see previous releases of the PostgreSQL documentation. A single server can support multiple protocol versions. The initial startup-request message tells the server which protocol version the client is attempting to use. If the major version requested by the client is not supported by the server, the connection will be rejected (for example, this would occur if the client requested protocol version 4.0, which does not exist as of this writing). If the minor version requested by the client is not supported by the server (e.g., the client requests version 3.1, but the server supports only 3.0), the server may either reject the connection or may respond with a `NegotiateProtocolVersion` message containing the highest minor protocol version which it supports. The client may then choose either to continue with the connection using the specified protocol version or to abort the connection.

In order to serve multiple clients efficiently, the server launches a new “backend” process for each client. In the current implementation, a new child process is created immediately after an incoming connection is detected. This is transparent to the protocol, however. For purposes of the protocol, the terms “backend” and “server” are interchangeable; likewise “frontend” and “client” are interchangeable.

51.1. Overview

The protocol has separate phases for startup and normal operation. In the startup phase, the frontend opens a connection to the server and authenticates itself to the satisfaction of the server. (This might involve a single message, or multiple messages depending on the authentication method being used.) If all goes well, the server then sends status information to the frontend, and finally enters normal operation. Except for the initial startup-request message, this part of the protocol is driven by the server.

During normal operation, the frontend sends queries and other commands to the backend, and the backend sends back query results and other responses. There are a few cases (such as `NOTIFY`) wherein the backend will send unsolicited messages, but for the most part this portion of a session is driven by frontend requests.

Termination of the session is normally by frontend choice, but can be forced by the backend in certain cases. In any case, when the backend closes the connection, it will roll back any open (incomplete) transaction before exiting.

Within normal operation, SQL commands can be executed through either of two sub-protocols. In the “simple query” protocol, the frontend just sends a textual query string, which is parsed and immediately executed by the backend. In the “extended query” protocol, processing of queries is separated into multiple steps: parsing, binding of parameter values, and execution. This offers flexibility and performance benefits, at the cost of extra complexity.

Normal operation has additional sub-protocols for special operations such as `COPY`.

51.1.1. Messaging Overview

All communication is through a stream of messages. The first byte of a message identifies the message type, and the next four bytes specify the length of the rest of the message (this length count includes itself, but not the message-type byte). The remaining contents of the message are determined by the message type. For historical reasons, the very first message sent by the client (the startup message) has no initial message-type byte.

To avoid losing synchronization with the message stream, both servers and clients typically read an entire message into a buffer (using the byte count) before attempting to process its contents. This allows

easy recovery if an error is detected while processing the contents. In extreme situations (such as not having enough memory to buffer the message), the receiver can use the byte count to determine how much input to skip before it resumes reading messages.

Conversely, both servers and clients must take care never to send an incomplete message. This is commonly done by marshaling the entire message in a buffer before beginning to send it. If a communications failure occurs partway through sending or receiving a message, the only sensible response is to abandon the connection, since there is little hope of recovering message-boundary synchronization.

51.1.2. Extended Query Overview

In the extended-query protocol, execution of SQL commands is divided into multiple steps. The state retained between steps is represented by two types of objects: *prepared statements* and *portals*. A prepared statement represents the result of parsing and semantic analysis of a textual query string. A prepared statement is not in itself ready to execute, because it might lack specific values for *parameters*. A portal represents a ready-to-execute or already-partially-executed statement, with any missing parameter values filled in. (For `SELECT` statements, a portal is equivalent to an open cursor, but we choose to use a different term since cursors don't handle non-`SELECT` statements.)

The overall execution cycle consists of a *parse* step, which creates a prepared statement from a textual query string; a *bind* step, which creates a portal given a prepared statement and values for any needed parameters; and an *execute* step that runs a portal's query. In the case of a query that returns rows (`SELECT`, `SHOW`, etc), the execute step can be told to fetch only a limited number of rows, so that multiple execute steps might be needed to complete the operation.

The backend can keep track of multiple prepared statements and portals (but note that these exist only within a session, and are never shared across sessions). Existing prepared statements and portals are referenced by names assigned when they were created. In addition, an “unnamed” prepared statement and portal exist. Although these behave largely the same as named objects, operations on them are optimized for the case of executing a query only once and then discarding it, whereas operations on named objects are optimized on the expectation of multiple uses.

51.1.3. Formats and Format Codes

Data of a particular data type might be transmitted in any of several different *formats*. As of PostgreSQL 7.4 the only supported formats are “text” and “binary”, but the protocol makes provision for future extensions. The desired format for any value is specified by a *format code*. Clients can specify a format code for each transmitted parameter value and for each column of a query result. Text has format code zero, binary has format code one, and all other format codes are reserved for future definition.

The text representation of values is whatever strings are produced and accepted by the input/output conversion functions for the particular data type. In the transmitted representation, there is no trailing null character; the frontend must add one to received values if it wants to process them as C strings. (The text format does not allow embedded nulls, by the way.)

Binary representations for integers use network byte order (most significant byte first). For other data types consult the documentation or source code to learn about the binary representation. Keep in mind that binary representations for complex data types might change across server versions; the text format is usually the more portable choice.

51.2. Message Flow

This section describes the message flow and the semantics of each message type. (Details of the exact representation of each message appear in [Section 51.5](#).) There are several different sub-protocols depending on the state of the connection: start-up, query, function call, `COPY`, and termination. There are also special provisions for asynchronous operations (including notification responses and command cancellation), which can occur at any time after the start-up phase.

51.2.1. Start-up

To begin a session, a frontend opens a connection to the server and sends a startup message. This message includes the names of the user and of the database the user wants to connect to; it also identifies the particular protocol version to be used. (Optionally, the startup message can include additional settings for run-time parameters.) The server then uses this information and the contents of its configuration files (such as `pg_hba.conf`) to determine whether the connection is provisionally acceptable, and what additional authentication is required (if any).

The server then sends an appropriate authentication request message, to which the frontend must reply with an appropriate authentication response message (such as a password). For all authentication methods except GSSAPI, SSPI and SASL, there is at most one request and one response. In some methods, no response at all is needed from the frontend, and so no authentication request occurs. For GSSAPI, SSPI and SASL, multiple exchanges of packets may be needed to complete the authentication.

The authentication cycle ends with the server either rejecting the connection attempt (`ErrorResponse`), or sending `AuthenticationOk`.

The possible messages from the server in this phase are:

`ErrorResponse`

The connection attempt has been rejected. The server then immediately closes the connection.

`AuthenticationOk`

The authentication exchange is successfully completed.

`AuthenticationKerberosV5`

The frontend must now take part in a Kerberos V5 authentication dialog (not described here, part of the Kerberos specification) with the server. If this is successful, the server responds with an `AuthenticationOk`, otherwise it responds with an `ErrorResponse`. This is no longer supported.

`AuthenticationCleartextPassword`

The frontend must now send a `PasswordMessage` containing the password in clear-text form. If this is the correct password, the server responds with an `AuthenticationOk`, otherwise it responds with an `ErrorResponse`.

`AuthenticationMD5Password`

The frontend must now send a `PasswordMessage` containing the password (with user name) encrypted via MD5, then encrypted again using the 4-byte random salt specified in the `AuthenticationMD5Password` message. If this is the correct password, the server responds with an `AuthenticationOk`, otherwise it responds with an `ErrorResponse`. The actual `PasswordMessage` can be computed in SQL as `concat('md5', md5(concat(md5(concat(password, username)), random-salt)))`. (Keep in mind the `md5()` function returns its result as a hex string.)

`AuthenticationSCMCredential`

This response is only possible for local Unix-domain connections on platforms that support SCM credential messages. The frontend must issue an SCM credential message and then send a single data byte. (The contents of the data byte are uninteresting; it's only used to ensure that the server waits long enough to receive the credential message.) If the credential is acceptable, the server responds with an `AuthenticationOk`, otherwise it responds with an `ErrorResponse`. (This message type is only issued by pre-9.1 servers. It may eventually be removed from the protocol specification.)

`AuthenticationGSS`

The frontend must now initiate a GSSAPI negotiation. The frontend will send a `PasswordMessage` with the first part of the GSSAPI data stream in response to this. If further messages are needed, the server will respond with `AuthenticationGSSContinue`.

AuthenticationSSPI

The frontend must now initiate a SSPI negotiation. The frontend will send a PasswordMessage with the first part of the SSPI data stream in response to this. If further messages are needed, the server will respond with AuthenticationGSSContinue.

AuthenticationGSSContinue

This message contains the response data from the previous step of GSSAPI or SSPI negotiation (AuthenticationGSS, AuthenticationSSPI or a previous AuthenticationGSSContinue). If the GSSAPI or SSPI data in this message indicates more data is needed to complete the authentication, the frontend must send that data as another PasswordMessage. If GSSAPI or SSPI authentication is completed by this message, the server will next send AuthenticationOk to indicate successful authentication or ErrorResponse to indicate failure.

AuthenticationSASL

The frontend must now initiate a SASL negotiation, using the SASL mechanism specified in the message. The frontend will send a PasswordMessage with the first part of the SASL data stream in response to this. If further messages are needed, the server will respond with AuthenticationSASLContinue.

AuthenticationSASLContinue

This message contains the response data from the previous step of SASL negotiation (AuthenticationSASL, or a previous AuthenticationSASLContinue). If the SASL data in this message indicates more data is needed to complete the authentication, the frontend must send that data as another PasswordMessage. If SASL authentication is completed by this message, the server will next send AuthenticationOk to indicate successful authentication or ErrorResponse to indicate failure.

NegotiateProtocolVersion

The server does not support the minor protocol version requested by the client, but does support an earlier version of the protocol; this message indicates the highest supported minor version. This message will also be sent if the client requested unsupported protocol options (i.e., beginning with `_pq_.`) in the startup packet. This message will be followed by an ErrorResponse or a message indicating the success or failure of authentication.

If the frontend does not support the authentication method requested by the server, then it should immediately close the connection.

After having received AuthenticationOk, the frontend must wait for further messages from the server. In this phase a backend process is being started, and the frontend is just an interested bystander. It is still possible for the startup attempt to fail (ErrorResponse) or the server to decline support for the requested minor protocol version (NegotiateProtocolVersion), but in the normal case the backend will send some ParameterStatus messages, BackendKeyData, and finally ReadyForQuery.

During this phase the backend will attempt to apply any additional run-time parameter settings that were given in the startup message. If successful, these values become session defaults. An error causes ErrorResponse and exit.

The possible messages from the backend in this phase are:

BackendKeyData

This message provides secret-key data that the frontend must save if it wants to be able to issue cancel requests later. The frontend should not respond to this message, but should continue listening for a ReadyForQuery message.

ParameterStatus

This message informs the frontend about the current (initial) setting of backend parameters, such as `client_encoding` or `DateStyle`. The frontend can ignore this message, or record the settings for its

future use; see [Section 51.2.6](#) for more details. The frontend should not respond to this message, but should continue listening for a ReadyForQuery message.

ReadyForQuery

Start-up is completed. The frontend can now issue commands.

ErrorResponse

Start-up failed. The connection is closed after sending this message.

NoticeResponse

A warning message has been issued. The frontend should display the message but continue listening for ReadyForQuery or ErrorResponse.

The ReadyForQuery message is the same one that the backend will issue after each command cycle. Depending on the coding needs of the frontend, it is reasonable to consider ReadyForQuery as starting a command cycle, or to consider ReadyForQuery as ending the start-up phase and each subsequent command cycle.

51.2.2. Simple Query

A simple query cycle is initiated by the frontend sending a Query message to the backend. The message includes an SQL command (or commands) expressed as a text string. The backend then sends one or more response messages depending on the contents of the query command string, and finally a ReadyForQuery response message. ReadyForQuery informs the frontend that it can safely send a new command. (It is not actually necessary for the frontend to wait for ReadyForQuery before issuing another command, but the frontend must then take responsibility for figuring out what happens if the earlier command fails and already-issued later commands succeed.)

The possible response messages from the backend are:

CommandComplete

An SQL command completed normally.

CopyInResponse

The backend is ready to copy data from the frontend to a table; see [Section 51.2.5](#).

CopyOutResponse

The backend is ready to copy data from a table to the frontend; see [Section 51.2.5](#).

RowDescription

Indicates that rows are about to be returned in response to a `SELECT`, `FETCH`, etc query. The contents of this message describe the column layout of the rows. This will be followed by a DataRow message for each row being returned to the frontend.

DataRow

One of the set of rows returned by a `SELECT`, `FETCH`, etc query.

EmptyQueryResponse

An empty query string was recognized.

ErrorResponse

An error has occurred.

ReadyForQuery

Processing of the query string is complete. A separate message is sent to indicate this because the query string might contain multiple SQL commands. (CommandComplete marks the end of

processing one SQL command, not the whole string.) ReadyForQuery will always be sent, whether processing terminates successfully or with an error.

NoticeResponse

A warning message has been issued in relation to the query. Notices are in addition to other responses, i.e., the backend will continue processing the command.

The response to a `SELECT` query (or other queries that return row sets, such as `EXPLAIN` or `SHOW`) normally consists of `RowDescription`, zero or more `DataRow` messages, and then `CommandComplete`. `COPY` to or from the frontend invokes special protocol as described in [Section 51.2.5](#). All other query types normally produce only a `CommandComplete` message.

Since a query string could contain several queries (separated by semicolons), there might be several such response sequences before the backend finishes processing the query string. ReadyForQuery is issued when the entire string has been processed and the backend is ready to accept a new query string.

If a completely empty (no contents other than whitespace) query string is received, the response is `EmptyQueryResponse` followed by ReadyForQuery.

In the event of an error, `ErrorResponse` is issued followed by ReadyForQuery. All further processing of the query string is aborted by `ErrorResponse` (even if more queries remained in it). Note that this might occur partway through the sequence of messages generated by an individual query.

In simple Query mode, the format of retrieved values is always text, except when the given command is a `FETCH` from a cursor declared with the `BINARY` option. In that case, the retrieved values are in binary format. The format codes given in the `RowDescription` message tell which format is being used.

A frontend must be prepared to accept `ErrorResponse` and `NoticeResponse` messages whenever it is expecting any other type of message. See also [Section 51.2.6](#) concerning messages that the backend might generate due to outside events.

Recommended practice is to code frontends in a state-machine style that will accept any message type at any time that it could make sense, rather than wiring in assumptions about the exact sequence of messages.

51.2.3. Extended Query

The extended query protocol breaks down the above-described simple query protocol into multiple steps. The results of preparatory steps can be re-used multiple times for improved efficiency. Furthermore, additional features are available, such as the possibility of supplying data values as separate parameters instead of having to insert them directly into a query string.

In the extended protocol, the frontend first sends a `Parse` message, which contains a textual query string, optionally some information about data types of parameter placeholders, and the name of a destination prepared-statement object (an empty string selects the unnamed prepared statement). The response is either `ParseComplete` or `ErrorResponse`. Parameter data types can be specified by OID; if not given, the parser attempts to infer the data types in the same way as it would do for untyped literal string constants.

Note

A parameter data type can be left unspecified by setting it to zero, or by making the array of parameter type OIDs shorter than the number of parameter symbols (`$n`) used in the query string. Another special case is that a parameter's type can be specified as `void` (that is, the OID of the `void` pseudotype). This is meant to allow parameter symbols to be used for function parameters that are actually OUT parameters. Ordinarily there is no context in which a `void` parameter could be used, but if such a parameter symbol appears in a function's parameter list, it is effectively ignored. For example, a function call such as `foo($1, $2, $3, $4)` could match a function with two IN and two OUT arguments, if `$3` and `$4` are specified as having type `void`.

Note

The query string contained in a Parse message cannot include more than one SQL statement; else a syntax error is reported. This restriction does not exist in the simple-query protocol, but it does exist in the extended protocol, because allowing prepared statements or portals to contain multiple commands would complicate the protocol unduly.

If successfully created, a named prepared-statement object lasts till the end of the current session, unless explicitly destroyed. An unnamed prepared statement lasts only until the next Parse statement specifying the unnamed statement as destination is issued. (Note that a simple Query message also destroys the unnamed statement.) Named prepared statements must be explicitly closed before they can be redefined by another Parse message, but this is not required for the unnamed statement. Named prepared statements can also be created and accessed at the SQL command level, using `PREPARE` and `EXECUTE`.

Once a prepared statement exists, it can be readied for execution using a Bind message. The Bind message gives the name of the source prepared statement (empty string denotes the unnamed prepared statement), the name of the destination portal (empty string denotes the unnamed portal), and the values to use for any parameter placeholders present in the prepared statement. The supplied parameter set must match those needed by the prepared statement. (If you declared any `void` parameters in the Parse message, pass `NULL` values for them in the Bind message.) Bind also specifies the format to use for any data returned by the query; the format can be specified overall, or per-column. The response is either `BindComplete` or `ErrorResponse`.

Note

The choice between text and binary output is determined by the format codes given in Bind, regardless of the SQL command involved. The `BINARY` attribute in cursor declarations is irrelevant when using extended query protocol.

Query planning typically occurs when the Bind message is processed. If the prepared statement has no parameters, or is executed repeatedly, the server might save the created plan and re-use it during subsequent Bind messages for the same prepared statement. However, it will do so only if it finds that a generic plan can be created that is not much less efficient than a plan that depends on the specific parameter values supplied. This happens transparently so far as the protocol is concerned.

If successfully created, a named portal object lasts till the end of the current transaction, unless explicitly destroyed. An unnamed portal is destroyed at the end of the transaction, or as soon as the next Bind statement specifying the unnamed portal as destination is issued. (Note that a simple Query message also destroys the unnamed portal.) Named portals must be explicitly closed before they can be redefined by another Bind message, but this is not required for the unnamed portal. Named portals can also be created and accessed at the SQL command level, using `DECLARE CURSOR` and `FETCH`.

Once a portal exists, it can be executed using an Execute message. The Execute message specifies the portal name (empty string denotes the unnamed portal) and a maximum result-row count (zero meaning "fetch all rows"). The result-row count is only meaningful for portals containing commands that return row sets; in other cases the command is always executed to completion, and the row count is ignored. The possible responses to Execute are the same as those described above for queries issued via simple query protocol, except that Execute doesn't cause `ReadyForQuery` or `RowDescription` to be issued.

If Execute terminates before completing the execution of a portal (due to reaching a nonzero result-row count), it will send a `PortalSuspended` message; the appearance of this message tells the frontend that another Execute should be issued against the same portal to complete the operation. The `CommandComplete` message indicating completion of the source SQL command is not sent until the portal's execution is completed. Therefore, an Execute phase is always terminated by the appearance

of exactly one of these messages: `CommandComplete`, `EmptyQueryResponse` (if the portal was created from an empty query string), `ErrorResponse`, or `PortalSuspended`.

At completion of each series of extended-query messages, the frontend should issue a `Sync` message. This parameterless message causes the backend to close the current transaction if it's not inside a `BEGIN/COMMIT` transaction block ("close" meaning to commit if no error, or roll back if error). Then a `ReadyForQuery` response is issued. The purpose of `Sync` is to provide a resynchronization point for error recovery. When an error is detected while processing any extended-query message, the backend issues `ErrorResponse`, then reads and discards messages until a `Sync` is reached, then issues `ReadyForQuery` and returns to normal message processing. (But note that no skipping occurs if an error is detected *while* processing `Sync` — this ensures that there is one and only one `ReadyForQuery` sent for each `Sync`.)

Note

`Sync` does not cause a transaction block opened with `BEGIN` to be closed. It is possible to detect this situation since the `ReadyForQuery` message includes transaction status information.

In addition to these fundamental, required operations, there are several optional operations that can be used with extended-query protocol.

The `Describe` message (portal variant) specifies the name of an existing portal (or an empty string for the unnamed portal). The response is a `RowDescription` message describing the rows that will be returned by executing the portal; or a `NoData` message if the portal does not contain a query that will return rows; or `ErrorResponse` if there is no such portal.

The `Describe` message (statement variant) specifies the name of an existing prepared statement (or an empty string for the unnamed prepared statement). The response is a `ParameterDescription` message describing the parameters needed by the statement, followed by a `RowDescription` message describing the rows that will be returned when the statement is eventually executed (or a `NoData` message if the statement will not return rows). `ErrorResponse` is issued if there is no such prepared statement. Note that since `Bind` has not yet been issued, the formats to be used for returned columns are not yet known to the backend; the format code fields in the `RowDescription` message will be zeroes in this case.

Tip

In most scenarios the frontend should issue one or the other variant of `Describe` before issuing `Execute`, to ensure that it knows how to interpret the results it will get back.

The `Close` message closes an existing prepared statement or portal and releases resources. It is not an error to issue `Close` against a nonexistent statement or portal name. The response is normally `CloseComplete`, but could be `ErrorResponse` if some difficulty is encountered while releasing resources. Note that closing a prepared statement implicitly closes any open portals that were constructed from that statement.

The `Flush` message does not cause any specific output to be generated, but forces the backend to deliver any data pending in its output buffers. A `Flush` must be sent after any extended-query command except `Sync`, if the frontend wishes to examine the results of that command before issuing more commands. Without `Flush`, messages returned by the backend will be combined into the minimum possible number of packets to minimize network overhead.

Note

The simple `Query` message is approximately equivalent to the series `Parse`, `Bind`, portal `Describe`, `Execute`, `Close`, `Sync`, using the unnamed prepared statement and portal objects and no parameters. One difference is that it will accept multiple SQL statements in the query string, automatically performing the `bind/describe/execute` sequence for each one in succession. Another

difference is that it will not return ParseComplete, BindComplete, CloseComplete, or NoData messages.

51.2.4. Function Call

The Function Call sub-protocol allows the client to request a direct call of any function that exists in the database's `pg_proc` system catalog. The client must have execute permission for the function.

Note

The Function Call sub-protocol is a legacy feature that is probably best avoided in new code. Similar results can be accomplished by setting up a prepared statement that does `SELECT function($1, ...)`. The Function Call cycle can then be replaced with Bind/Execute.

A Function Call cycle is initiated by the frontend sending a `FunctionCall` message to the backend. The backend then sends one or more response messages depending on the results of the function call, and finally a `ReadyForQuery` response message. `ReadyForQuery` informs the frontend that it can safely send a new query or function call.

The possible response messages from the backend are:

ErrorResponse

An error has occurred.

FunctionCallResponse

The function call was completed and returned the result given in the message. (Note that the Function Call protocol can only handle a single scalar result, not a row type or set of results.)

ReadyForQuery

Processing of the function call is complete. `ReadyForQuery` will always be sent, whether processing terminates successfully or with an error.

NoticeResponse

A warning message has been issued in relation to the function call. Notices are in addition to other responses, i.e., the backend will continue processing the command.

51.2.5. COPY Operations

The `COPY` command allows high-speed bulk data transfer to or from the server. Copy-in and copy-out operations each switch the connection into a distinct sub-protocol, which lasts until the operation is completed.

Copy-in mode (data transfer to the server) is initiated when the backend executes a `COPY FROM STDIN` SQL statement. The backend sends a `CopyInResponse` message to the frontend. The frontend should then send zero or more `CopyData` messages, forming a stream of input data. (The message boundaries are not required to have anything to do with row boundaries, although that is often a reasonable choice.) The frontend can terminate the copy-in mode by sending either a `CopyDone` message (allowing successful termination) or a `CopyFail` message (which will cause the `COPY` SQL statement to fail with an error). The backend then reverts to the command-processing mode it was in before the `COPY` started, which will be either simple or extended query protocol. It will next send either `CommandComplete` (if successful) or `ErrorResponse` (if not).

In the event of a backend-detected error during copy-in mode (including receipt of a `CopyFail` message), the backend will issue an `ErrorResponse` message. If the `COPY` command was issued via an extended-query message, the backend will now discard frontend messages until a `Sync` message is received, then

it will issue `ReadyForQuery` and return to normal processing. If the `COPY` command was issued in a simple Query message, the rest of that message is discarded and `ReadyForQuery` is issued. In either case, any subsequent `CopyData`, `CopyDone`, or `CopyFail` messages issued by the frontend will simply be dropped.

The backend will ignore `Flush` and `Sync` messages received during copy-in mode. Receipt of any other non-copy message type constitutes an error that will abort the copy-in state as described above. (The exception for `Flush` and `Sync` is for the convenience of client libraries that always send `Flush` or `Sync` after an `Execute` message, without checking whether the command to be executed is a `COPY FROM STDIN`.)

Copy-out mode (data transfer from the server) is initiated when the backend executes a `COPY TO STDOUT` SQL statement. The backend sends a `CopyOutResponse` message to the frontend, followed by zero or more `CopyData` messages (always one per row), followed by `CopyDone`. The backend then reverts to the command-processing mode it was in before the `COPY` started, and sends `CommandComplete`. The frontend cannot abort the transfer (except by closing the connection or issuing a `Cancel` request), but it can discard unwanted `CopyData` and `CopyDone` messages.

In the event of a backend-detected error during copy-out mode, the backend will issue an `ErrorResponse` message and revert to normal processing. The frontend should treat receipt of `ErrorResponse` as terminating the copy-out mode.

It is possible for `NoticeResponse` and `ParameterStatus` messages to be interspersed between `CopyData` messages; frontends must handle these cases, and should be prepared for other asynchronous message types as well (see [Section 51.2.6](#)). Otherwise, any message type other than `CopyData` or `CopyDone` may be treated as terminating copy-out mode.

There is another Copy-related mode called copy-both, which allows high-speed bulk data transfer to *and* from the server. Copy-both mode is initiated when a backend in `walsender` mode executes a `START_REPLICATION` statement. The backend sends a `CopyBothResponse` message to the frontend. Both the backend and the frontend may then send `CopyData` messages until either end sends a `CopyDone` message. After the client sends a `CopyDone` message, the connection goes from copy-both mode to copy-out mode, and the client may not send any more `CopyData` messages. Similarly, when the server sends a `CopyDone` message, the connection goes into copy-in mode, and the server may not send any more `CopyData` messages. After both sides have sent a `CopyDone` message, the copy mode is terminated, and the backend reverts to the command-processing mode. In the event of a backend-detected error during copy-both mode, the backend will issue an `ErrorResponse` message, discard frontend messages until a `Sync` message is received, and then issue `ReadyForQuery` and return to normal processing. The frontend should treat receipt of `ErrorResponse` as terminating the copy in both directions; no `CopyDone` should be sent in this case. See [Section 51.3](#) for more information on the subprotocol transmitted over copy-both mode.

The `CopyInResponse`, `CopyOutResponse` and `CopyBothResponse` messages include fields that inform the frontend of the number of columns per row and the format codes being used for each column. (As of the present implementation, all columns in a given `COPY` operation will use the same format, but the message design does not assume this.)

51.2.6. Asynchronous Operations

There are several cases in which the backend will send messages that are not specifically prompted by the frontend's command stream. Frontends must be prepared to deal with these messages at any time, even when not engaged in a query. At minimum, one should check for these cases before beginning to read a query response.

It is possible for `NoticeResponse` messages to be generated due to outside activity; for example, if the database administrator commands a “fast” database shutdown, the backend will send a `NoticeResponse` indicating this fact before closing the connection. Accordingly, frontends should always be prepared to accept and display `NoticeResponse` messages, even when the connection is nominally idle.

`ParameterStatus` messages will be generated whenever the active value changes for any of the parameters the backend believes the frontend should know about. Most commonly this occurs in response to a `SET SQL` command executed by the frontend, and this case is effectively synchronous

— but it is also possible for parameter status changes to occur because the administrator changed a configuration file and then sent the SIGHUP signal to the server. Also, if a SET command is rolled back, an appropriate ParameterStatus message will be generated to report the current effective value.

At present there is a hard-wired set of parameters for which ParameterStatus will be generated: they are `server_version`, `server_encoding`, `client_encoding`, `application_name`, `is_superuser`, `session_authorization`, `DateStyle`, `IntervalStyle`, `TimeZone`, `integer_datetimes`, and `standard_conforming_strings`. (`server_encoding`, `TimeZone`, and `integer_datetimes` were not reported by releases before 8.0; `standard_conforming_strings` was not reported by releases before 8.1; `IntervalStyle` was not reported by releases before 8.4; `application_name` was not reported by releases before 9.0.) Note that `server_version`, `server_encoding` and `integer_datetimes` are pseudo-parameters that cannot change after startup. This set might change in the future, or even become configurable. Accordingly, a frontend should simply ignore ParameterStatus for parameters that it does not understand or care about.

If a frontend issues a LISTEN command, then the backend will send a NotificationResponse message (not to be confused with NoticeResponse!) whenever a NOTIFY command is executed for the same channel name.

Note

At present, NotificationResponse can only be sent outside a transaction, and thus it will not occur in the middle of a command-response series, though it might occur just before ReadyForQuery. It is unwise to design frontend logic that assumes that, however. Good practice is to be able to accept NotificationResponse at any point in the protocol.

51.2.7. Canceling Requests in Progress

During the processing of a query, the frontend might request cancellation of the query. The cancel request is not sent directly on the open connection to the backend for reasons of implementation efficiency: we don't want to have the backend constantly checking for new input from the frontend during query processing. Cancel requests should be relatively infrequent, so we make them slightly cumbersome in order to avoid a penalty in the normal case.

To issue a cancel request, the frontend opens a new connection to the server and sends a CancelRequest message, rather than the StartupMessage message that would ordinarily be sent across a new connection. The server will process this request and then close the connection. For security reasons, no direct reply is made to the cancel request message.

A CancelRequest message will be ignored unless it contains the same key data (PID and secret key) passed to the frontend during connection start-up. If the request matches the PID and secret key for a currently executing backend, the processing of the current query is aborted. (In the existing implementation, this is done by sending a special signal to the backend process that is processing the query.)

The cancellation signal might or might not have any effect — for example, if it arrives after the backend has finished processing the query, then it will have no effect. If the cancellation is effective, it results in the current command being terminated early with an error message.

The upshot of all this is that for reasons of both security and efficiency, the frontend has no direct way to tell whether a cancel request has succeeded. It must continue to wait for the backend to respond to the query. Issuing a cancel simply improves the odds that the current query will finish soon, and improves the odds that it will fail with an error message instead of succeeding.

Since the cancel request is sent across a new connection to the server and not across the regular frontend/backend communication link, it is possible for the cancel request to be issued by any process, not just the frontend whose query is to be canceled. This might provide additional flexibility when building multiple-process applications. It also introduces a security risk, in that unauthorized persons

might try to cancel queries. The security risk is addressed by requiring a dynamically generated secret key to be supplied in cancel requests.

51.2.8. Termination

The normal, graceful termination procedure is that the frontend sends a `Terminate` message and immediately closes the connection. On receipt of this message, the backend closes the connection and terminates.

In rare cases (such as an administrator-commanded database shutdown) the backend might disconnect without any frontend request to do so. In such cases the backend will attempt to send an error or notice message giving the reason for the disconnection before it closes the connection.

Other termination scenarios arise from various failure cases, such as core dump at one end or the other, loss of the communications link, loss of message-boundary synchronization, etc. If either frontend or backend sees an unexpected closure of the connection, it should clean up and terminate. The frontend has the option of launching a new backend by recontacting the server if it doesn't want to terminate itself. Closing the connection is also advisable if an unrecognizable message type is received, since this probably indicates loss of message-boundary sync.

For either normal or abnormal termination, any open transaction is rolled back, not committed. One should note however that if a frontend disconnects while a non-`SELECT` query is being processed, the backend will probably finish the query before noticing the disconnection. If the query is outside any transaction block (`BEGIN ... COMMIT` sequence) then its results might be committed before the disconnection is recognized.

51.2.9. SSL Session Encryption

If Postgres Pro was built with SSL support, frontend/backend communications can be encrypted using SSL. This provides communication security in environments where attackers might be able to capture the session traffic. For more information on encrypting Postgres Pro sessions with SSL, see [Section 18.9](#).

To initiate an SSL-encrypted connection, the frontend initially sends an `SSLRequest` message rather than a `StartupMessage`. The server then responds with a single byte containing `S` or `N`, indicating that it is willing or unwilling to perform SSL, respectively. The frontend might close the connection at this point if it is dissatisfied with the response. To continue after `S`, perform an SSL startup handshake (not described here, part of the SSL specification) with the server. If this is successful, continue with sending the usual `StartupMessage`. In this case the `StartupMessage` and all subsequent data will be SSL-encrypted. To continue after `N`, send the usual `StartupMessage` and proceed without encryption.

The frontend should also be prepared to handle an `ErrorMessage` response to `SSLRequest` from the server. This would only occur if the server predates the addition of SSL support to Postgres Pro. (Such servers are now very ancient, and likely do not exist in the wild anymore.) In this case the connection must be closed, but the frontend might choose to open a fresh connection and proceed without requesting SSL.

An initial `SSLRequest` can also be used in a connection that is being opened to send a `CancelRequest` message.

While the protocol itself does not provide a way for the server to force SSL encryption, the administrator can configure the server to reject unencrypted sessions as a byproduct of authentication checking.

51.3. Streaming Replication Protocol

To initiate streaming replication, the frontend sends the `replication` parameter in the startup message. A Boolean value of `true` tells the backend to go into walsender mode, wherein a small set of replication commands can be issued instead of SQL statements. Only the simple query protocol can be used in walsender mode. Replication commands are logged in the server log when [log_replication_commands](#) is enabled. Passing `database` as the value instructs walsender to connect to the database specified in the `dbname` parameter, which will allow the connection to be used for logical replication from that database.

For the purpose of testing replication commands, you can make a replication connection via `psql` or any other `libpq`-using tool with a connection string including the `replication` option, e.g.:

```
psql "dbname=postgres replication=database" -c "IDENTIFY_SYSTEM;"
```

However, it is often more useful to use [pg_receivexlog](#) (for physical replication) or [pg_recvlogical](#) (for logical replication).

The commands accepted in `walsender` mode are:

`IDENTIFY_SYSTEM`

Requests the server to identify itself. Server replies with a result set of a single row, containing four fields:

`systemid` (text)

The unique system identifier identifying the cluster. This can be used to check that the base backup used to initialize the standby came from the same cluster.

`timeline` (int4)

Current timeline ID. Also useful to check that the standby is consistent with the master.

`xlogpos` (text)

Current xlog flush location. Useful to get a known location in the transaction log where streaming can start.

`dbname` (text)

Database connected to or null.

`TIMELINE_HISTORY tli`

Requests the server to send over the timeline history file for timeline `tli`. Server replies with a result set of a single row, containing two fields. While the fields are labeled as `text` and `bytea`, they effectively return raw bytes, with no escaping or encoding conversion:

`filename` (text)

File name of the timeline history file, e.g., `00000002.history`.

`content` (bytea)

Contents of the timeline history file.

`CREATE_REPLICATION_SLOT slot_name { PHYSICAL [ RESERVE_WAL ] | LOGICAL output_plugin }`

Create a physical or logical replication slot. See [Section 26.2.6](#) for more about replication slots.

`slot_name`

The name of the slot to create. Must be a valid replication slot name (see [Section 26.2.6.1](#)).

`output_plugin`

The name of the output plugin used for logical decoding (see [Section 47.6](#)).

`RESERVE_WAL`

Specify that this physical replication slot reserves WAL immediately. Otherwise, WAL is only reserved upon connection from a streaming replication client.

`START_REPLICATION [ SLOT slot_name ] [ PHYSICAL ] XXX/XXX [ TIMELINE tli ]`

Instructs server to start streaming WAL, starting at WAL position `XXX/XXX`. If `TIMELINE` option is specified, streaming starts on timeline `tli`; otherwise, the server's current timeline is selected. The

server can reply with an error, for example if the requested section of WAL has already been recycled. On success, server responds with a `CopyBothResponse` message, and then starts to stream WAL to the frontend.

If a slot's name is provided via `slot_name`, it will be updated as replication progresses so that the server knows which WAL segments, and if `hot_standby_feedback` is on which transactions, are still needed by the standby.

If the client requests a timeline that's not the latest but is part of the history of the server, the server will stream all the WAL on that timeline starting from the requested start point up to the point where the server switched to another timeline. If the client requests streaming at exactly the end of an old timeline, the server responds immediately with `CommandComplete` without entering COPY mode.

After streaming all the WAL on a timeline that is not the latest one, the server will end streaming by exiting the COPY mode. When the client acknowledges this by also exiting COPY mode, the server sends a result set with one row and two columns, indicating the next timeline in this server's history. The first column is the next timeline's ID (type `int8`), and the second column is the WAL position where the switch happened (type `text`). Usually, the switch position is the end of the WAL that was streamed, but there are corner cases where the server can send some WAL from the old timeline that it has not itself replayed before promoting. Finally, the server sends `CommandComplete` message, and is ready to accept a new command.

WAL data is sent as a series of `CopyData` messages. (This allows other information to be intermixed; in particular the server can send an `ErrorResponse` message if it encounters a failure after beginning to stream.) The payload of each `CopyData` message from server to the client contains a message of one of the following formats:

XLogData (B)

Byte1('w')

Identifies the message as WAL data.

Int64

The starting point of the WAL data in this message.

Int64

The current end of WAL on the server.

Int64

The server's system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byten

A section of the WAL data stream.

A single WAL record is never split across two `XLogData` messages. When a WAL record crosses a WAL page boundary, and is therefore already split using continuation records, it can be split at the page boundary. In other words, the first main WAL record and its continuation records can be sent in different `XLogData` messages.

Primary keepalive message (B)

Byte1('k')

Identifies the message as a sender keepalive.

Int64

The current end of WAL on the server.

Int64

The server's system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byte1

1 means that the client should reply to this message as soon as possible, to avoid a timeout disconnect. 0 otherwise.

The receiving process can send replies back to the sender at any time, using one of the following message formats (also in the payload of a CopyData message):

Standby status update (F)

Byte1('r')

Identifies the message as a receiver status update.

Int64

The location of the last WAL byte + 1 received and written to disk in the standby.

Int64

The location of the last WAL byte + 1 flushed to disk in the standby.

Int64

The location of the last WAL byte + 1 applied in the standby.

Int64

The client's system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byte1

If 1, the client requests the server to reply to this message immediately. This can be used to ping the server, to test if the connection is still healthy.

Hot Standby feedback message (F)

Byte1('h')

Identifies the message as a Hot Standby feedback message.

Int64

The client's system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Int32

The standby's current xmin. This may be 0, if the standby is sending notification that Hot Standby feedback will no longer be sent on this connection. Later non-zero messages may reinstate the feedback mechanism.

Int32

The standby's current epoch.

```
START_REPLICATION SLOT slot_name LOGICAL XXX/XXX [ ( option_name [ option_value ] [, ...] ) ]
```

Instructs server to start streaming WAL for logical replication, starting at WAL position *xxx/xxx*. The server can reply with an error, for example if the requested section of WAL has already been

recycled. On success, server responds with a `CopyBothResponse` message, and then starts to stream WAL to the frontend.

The messages inside the `CopyBothResponse` messages are of the same format documented for `START_REPLICATION ... PHYSICAL`.

The output plugin associated with the selected slot is used to process the output for streaming.

`SLOT slot_name`

The name of the slot to stream changes from. This parameter is required, and must correspond to an existing logical replication slot created with `CREATE_REPLICATION_SLOT` in `LOGICAL` mode.

`XXX/XXX`

The WAL position to begin streaming at.

`option_name`

The name of an option passed to the slot's logical decoding plugin.

`option_value`

Optional value, in the form of a string constant, associated with the specified option.

`DROP_REPLICATION_SLOT slot_name`

Drops a replication slot, freeing any reserved server-side resources. If the slot is currently in use by an active connection, this command fails.

`slot_name`

The name of the slot to drop.

`BASE_BACKUP [ LABEL 'label' ] [ PROGRESS ] [ FAST ] [ WAL ] [ NOWAIT ] [ MAX_RATE rate ] [ TABLESPACE_MAP ]`

Instructs the server to start streaming a base backup. The system will automatically be put in backup mode before the backup is started, and taken out of it when the backup is complete. The following options are accepted:

`LABEL 'label'`

Sets the label of the backup. If none is specified, a backup label of `base backup` will be used. The quoting rules for the label are the same as a standard SQL string with [standard_conforming_strings](#) turned on.

`PROGRESS`

Request information required to generate a progress report. This will send back an approximate size in the header of each tablespace, which can be used to calculate how far along the stream is done. This is calculated by enumerating all the file sizes once before the transfer is even started, and might as such have a negative impact on the performance. In particular, it might take longer before the first data is streamed. Since the database files can change during the backup, the size is only approximate and might both grow and shrink between the time of approximation and the sending of the actual files.

`FAST`

Request a fast checkpoint.

`WAL`

Include the necessary WAL segments in the backup. This will include all the files between start and stop backup in the `pg_xlog` directory of the base directory tar file.

NOWAIT

By default, the backup will wait until the last required WAL segment has been archived, or emit a warning if log archiving is not enabled. Specifying **NOWAIT** disables both the waiting and the warning, leaving the client responsible for ensuring the required log is available.

MAX_RATE *rate*

Limit (throttle) the maximum amount of data transferred from server to client per unit of time. The expected unit is kilobytes per second. If this option is specified, the value must either be equal to zero or it must fall within the range from 32 kB through 1 GB (inclusive). If zero is passed or the option is not specified, no restriction is imposed on the transfer.

TABLESPACE_MAP

Include information about symbolic links present in the directory `pg_tblspc` in a file named `tablespace_map`. The tablespace map file includes each symbolic link name as it exists in the directory `pg_tblspc/` and the full path of that symbolic link.

When the backup is started, the server will first send two ordinary result sets, followed by one or more CopyResponse results.

The first ordinary result set contains the starting position of the backup, in a single row with two columns. The first column contains the start position given in XLogRecPtr format, and the second column contains the corresponding timeline ID.

The second ordinary result set has one row for each tablespace. The fields in this row are:

`spcoid (oid)`

The OID of the tablespace, or null if it's the base directory.

`spclocation (text)`

The full path of the tablespace directory, or null if it's the base directory.

`size (int8)`

The approximate size of the tablespace, if progress report has been requested; otherwise it's null.

After the second regular result set, one or more CopyResponse results will be sent, one for the main data directory and one for each additional tablespace other than `pg_default` and `pg_global`. The data in the CopyResponse results will be a tar format (following the “ustar interchange format” specified in the POSIX 1003.1-2008 standard) dump of the tablespace contents, except that the two trailing blocks of zeroes specified in the standard are omitted. After the tar data is complete, a final ordinary result set will be sent, containing the WAL end position of the backup, in the same format as the start position.

The tar archive for the data directory and each tablespace will contain all files in the directories, regardless of whether they are Postgres Pro files or other files added to the same directory. The only excluded files are:

- `postmaster.pid`
- `postmaster.opts`
- various temporary files created during the operation of the Postgres Pro server
- `pg_xlog`, including subdirectories. If the backup is run with WAL files included, a synthesized version of `pg_xlog` will be included, but it will only contain the files necessary for the backup to work, not the rest of the contents.
- `pg_replslot` is copied as an empty directory.
- Files other than regular files and directories, such as symbolic links and special device files, are skipped. (Symbolic links in `pg_tblspc` are maintained.)

Owner, group, and file mode are set if the underlying file system on the server supports it.

51.4. Message Data Types

This section describes the base data types used in messages.

`Int $n$ ( $i$ )`

An n -bit integer in network byte order (most significant byte first). If i is specified it is the exact value that will appear, otherwise the value is variable. Eg. `Int16`, `Int32(42)`.

`Int $n$ [ $k$ ]`

An array of k n -bit integers, each in network byte order. The array length k is always determined by an earlier field in the message. Eg. `Int16[M]`.

`String( $s$ )`

A null-terminated string (C-style string). There is no specific length limitation on strings. If s is specified it is the exact value that will appear, otherwise the value is variable. Eg. `String`, `String("user")`.

Note

There is no predefined limit on the length of a string that can be returned by the backend. Good coding strategy for a frontend is to use an expandable buffer so that anything that fits in memory can be accepted. If that's not feasible, read the full string and discard trailing characters that don't fit into your fixed-size buffer.

`Byte $n$ ( $c$ )`

Exactly n bytes. If the field width n is not a constant, it is always determinable from an earlier field in the message. If c is specified it is the exact value. Eg. `Byte2`, `Byte1('\n')`.

51.5. Message Formats

This section describes the detailed format of each message. Each is marked to indicate that it can be sent by a frontend (F), a backend (B), or both (F & B). Notice that although each message includes a byte count at the beginning, the message format is defined so that the message end can be found without reference to the byte count. This aids validity checking. (The `CopyData` message is an exception, because it forms part of a data stream; the contents of any individual `CopyData` message cannot be interpretable on their own.)

`AuthenticationOk` (B)

`Byte1('R')`

Identifies the message as an authentication request.

`Int32(8)`

Length of message contents in bytes, including self.

`Int32(0)`

Specifies that the authentication was successful.

`AuthenticationKerberosV5` (B)

`Byte1('R')`

Identifies the message as an authentication request.

`Int32(8)`

Length of message contents in bytes, including self.

Int32(2)

Specifies that Kerberos V5 authentication is required.

AuthenticationCleartextPassword (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(3)

Specifies that a clear-text password is required.

AuthenticationMD5Password (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(12)

Length of message contents in bytes, including self.

Int32(5)

Specifies that an MD5-encrypted password is required.

Byte4

The salt to use when encrypting the password.

AuthenticationSCMCredential (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(6)

Specifies that an SCM credentials message is required.

AuthenticationGSS (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(7)

Specifies that GSSAPI authentication is required.

AuthenticationSSPI (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(9)

Specifies that SSPI authentication is required.

AuthenticationGSSContinue (B)

Byte1('R')

Identifies the message as an authentication request.

Int32

Length of message contents in bytes, including self.

Int32(8)

Specifies that this message contains GSSAPI or SSPI data.

Byte_n

GSSAPI or SSPI authentication data.

AuthenticationSASL (B)

Byte1('R')

Identifies the message as an authentication request.

Int32

Length of message contents in bytes, including self.

Int32(10)

Specifies that SASL authentication is started.

String

Name of a SASL authentication mechanism.

AuthenticationSASLContinue (B)

Byte1('R')

Identifies the message as an authentication request.

Int32

Length of message contents in bytes, including self.

Int32(11)

Specifies that this message contains SASL-mechanism specific data.

Byte_n

SASL data, specific to the SASL mechanism being used.

BackendKeyData (B)

Byte1('K')

Identifies the message as cancellation key data. The frontend must save these values if it wishes to be able to issue CancelRequest messages later.

Int32(12)

Length of message contents in bytes, including self.

Int32

The process ID of this backend.

Int32

The secret key of this backend.

Bind (F)

Byte1('B')

Identifies the message as a Bind command.

Int32

Length of message contents in bytes, including self.

String

The name of the destination portal (an empty string selects the unnamed portal).

String

The name of the source prepared statement (an empty string selects the unnamed prepared statement).

Int16

The number of parameter format codes that follow (denoted c below). This can be zero to indicate that there are no parameters or that the parameters all use the default format (text); or one, in which case the specified format code is applied to all parameters; or it can equal the actual number of parameters.

Int16[c]

The parameter format codes. Each must presently be zero (text) or one (binary).

Int16

The number of parameter values that follow (possibly zero). This must match the number of parameters needed by the query.

Next, the following pair of fields appear for each parameter:

Int32

The length of the parameter value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL parameter value. No value bytes follow in the NULL case.

Byte n

The value of the parameter, in the format indicated by the associated format code. n is the above length.

After the last parameter, the following fields appear:

Int16

The number of result-column format codes that follow (denoted R below). This can be zero to indicate that there are no result columns or that the result columns should all use the default format (text); or one, in which case the specified format code is applied to all result columns (if any); or it can equal the actual number of result columns of the query.

Int16[R]

The result-column format codes. Each must presently be zero (text) or one (binary).

BindComplete (B)

Byte1('2')

Identifies the message as a Bind-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

CancelRequest (F)

Int32(16)

Length of message contents in bytes, including self.

Int32(80877102)

The cancel request code. The value is chosen to contain 1234 in the most significant 16 bits, and 5678 in the least significant 16 bits. (To avoid confusion, this code must not be the same as any protocol version number.)

Int32

The process ID of the target backend.

Int32

The secret key for the target backend.

Close (F)

Byte1('C')

Identifies the message as a Close command.

Int32

Length of message contents in bytes, including self.

Byte1

'S' to close a prepared statement; or 'P' to close a portal.

String

The name of the prepared statement or portal to close (an empty string selects the unnamed prepared statement or portal).

CloseComplete (B)

Byte1('3')

Identifies the message as a Close-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

CommandComplete (B)

Byte1('C')

Identifies the message as a command-completed response.

Int32

Length of message contents in bytes, including self.

String

The command tag. This is usually a single word that identifies which SQL command was completed.

For an `INSERT` command, the tag is `INSERT oid rows`, where `rows` is the number of rows inserted. `oid` is the object ID of the inserted row if `rows` is 1 and the target table has OIDs; otherwise `oid` is 0.

For a `DELETE` command, the tag is `DELETE rows` where *rows* is the number of rows deleted.

For an `UPDATE` command, the tag is `UPDATE rows` where *rows* is the number of rows updated.

For a `SELECT` or `CREATE TABLE AS` command, the tag is `SELECT rows` where *rows* is the number of rows retrieved.

For a `MOVE` command, the tag is `MOVE rows` where *rows* is the number of rows the cursor's position has been changed by.

For a `FETCH` command, the tag is `FETCH rows` where *rows* is the number of rows that have been retrieved from the cursor.

For a `COPY` command, the tag is `COPY rows` where *rows* is the number of rows copied. (Note: the row count appears only in PostgreSQL 8.2 and later.)

CopyData (F & B)

Byte1('d')

Identifies the message as `COPY` data.

Int32

Length of message contents in bytes, including self.

Byten

Data that forms part of a `COPY` data stream. Messages sent from the backend will always correspond to single data rows, but messages sent by frontends might divide the data stream arbitrarily.

CopyDone (F & B)

Byte1('c')

Identifies the message as a `COPY`-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

CopyFail (F)

Byte1('f')

Identifies the message as a `COPY`-failure indicator.

Int32

Length of message contents in bytes, including self.

String

An error message to report as the cause of failure.

CopyInResponse (B)

Byte1('G')

Identifies the message as a Start Copy In response. The frontend must now send copy-in data (if not prepared to do so, send a `CopyFail` message).

Int32

Length of message contents in bytes, including self.

Int8

0 indicates the overall `COPY` format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to `DataRow` format). See [COPY](#) for more information.

Int16

The number of columns in the data to be copied (denoted N below).

Int16[N]

The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

CopyOutResponse (B)

Byte1('H')

Identifies the message as a Start Copy Out response. This message will be followed by copy-out data.

Int32

Length of message contents in bytes, including self.

Int8

0 indicates the overall `COPY` format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to `DataRow` format). See [COPY](#) for more information.

Int16

The number of columns in the data to be copied (denoted N below).

Int16[N]

The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

CopyBothResponse (B)

Byte1('W')

Identifies the message as a Start Copy Both response. This message is used only for Streaming Replication.

Int32

Length of message contents in bytes, including self.

Int8

0 indicates the overall `COPY` format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to `DataRow` format). See [COPY](#) for more information.

Int16

The number of columns in the data to be copied (denoted N below).

Int16[N]

The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

DataRow (B)**Byte1('D')**

Identifies the message as a data row.

Int32

Length of message contents in bytes, including self.

Int16

The number of column values that follow (possibly zero).

Next, the following pair of fields appear for each column:

Int32

The length of the column value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL column value. No value bytes follow in the NULL case.

Byte_nThe value of the column, in the format indicated by the associated format code. *n* is the above length.**Describe (F)****Byte1('D')**

Identifies the message as a Describe command.

Int32

Length of message contents in bytes, including self.

Byte1

'S' to describe a prepared statement; or 'P' to describe a portal.

String

The name of the prepared statement or portal to describe (an empty string selects the unnamed prepared statement or portal).

EmptyQueryResponse (B)**Byte1('I')**

Identifies the message as a response to an empty query string. (This substitutes for CommandComplete.)

Int32(4)

Length of message contents in bytes, including self.

ErrorResponse (B)**Byte1('E')**

Identifies the message as an error.

Int32

Length of message contents in bytes, including self.

The message body consists of one or more identified fields, followed by a zero byte as a terminator. Fields can appear in any order. For each field there is the following:

Byte1

A code identifying the field type; if zero, this is the message terminator and no string follows. The presently defined field types are listed in [Section 51.6](#). Since more field types might be added in future, frontends should silently ignore fields of unrecognized type.

String

The field value.

Execute (F)**Byte1('E')**

Identifies the message as an Execute command.

Int32

Length of message contents in bytes, including self.

String

The name of the portal to execute (an empty string selects the unnamed portal).

Int32

Maximum number of rows to return, if portal contains a query that returns rows (ignored otherwise). Zero denotes “no limit”.

Flush (F)**Byte1('H')**

Identifies the message as a Flush command.

Int32(4)

Length of message contents in bytes, including self.

FunctionCall (F)**Byte1('F')**

Identifies the message as a function call.

Int32

Length of message contents in bytes, including self.

Int32

Specifies the object ID of the function to call.

Int16

The number of argument format codes that follow (denoted *c* below). This can be zero to indicate that there are no arguments or that the arguments all use the default format (text); or one, in which case the specified format code is applied to all arguments; or it can equal the actual number of arguments.

Int16[*c*]

The argument format codes. Each must presently be zero (text) or one (binary).

Int16

Specifies the number of arguments being supplied to the function.

Next, the following pair of fields appear for each argument:

Int32

The length of the argument value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL argument value. No value bytes follow in the NULL case.

Byte n

The value of the argument, in the format indicated by the associated format code. n is the above length.

After the last argument, the following field appears:

Int16

The format code for the function result. Must presently be zero (text) or one (binary).

FunctionCallResponse (B)

Byte1('V')

Identifies the message as a function call result.

Int32

Length of message contents in bytes, including self.

Int32

The length of the function result value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL function result. No value bytes follow in the NULL case.

Byte n

The value of the function result, in the format indicated by the associated format code. n is the above length.

NegotiateProtocolVersion (B)

Byte1('v')

Identifies the message as a protocol version negotiation message.

Int32

Length of message contents in bytes, including self.

Int32

Newest minor protocol version supported by the server for the major protocol version requested by the client.

Int32

Number of protocol options not recognized by the server.

Then, for protocol option not recognized by the server, there is the following:

String

The option name.

NoData (B)

Byte1('n')

Identifies the message as a no-data indicator.

Int32(4)

Length of message contents in bytes, including self.

NoticeResponse (B)**Byte1('N')**

Identifies the message as a notice.

Int32

Length of message contents in bytes, including self.

The message body consists of one or more identified fields, followed by a zero byte as a terminator. Fields can appear in any order. For each field there is the following:

Byte1

A code identifying the field type; if zero, this is the message terminator and no string follows. The presently defined field types are listed in [Section 51.6](#). Since more field types might be added in future, frontends should silently ignore fields of unrecognized type.

String

The field value.

NotificationResponse (B)**Byte1('A')**

Identifies the message as a notification response.

Int32

Length of message contents in bytes, including self.

Int32

The process ID of the notifying backend process.

String

The name of the channel that the notify has been raised on.

String

The “payload” string passed from the notifying process.

ParameterDescription (B)**Byte1('t')**

Identifies the message as a parameter description.

Int32

Length of message contents in bytes, including self.

Int16

The number of parameters used by the statement (can be zero).

Then, for each parameter, there is the following:

Int32

Specifies the object ID of the parameter data type.

ParameterStatus (B)**Byte1('S')**

Identifies the message as a run-time parameter status report.

Int32

Length of message contents in bytes, including self.

String

The name of the run-time parameter being reported.

String

The current value of the parameter.

Parse (F)

Byte1('P')

Identifies the message as a Parse command.

Int32

Length of message contents in bytes, including self.

String

The name of the destination prepared statement (an empty string selects the unnamed prepared statement).

String

The query string to be parsed.

Int16

The number of parameter data types specified (can be zero). Note that this is not an indication of the number of parameters that might appear in the query string, only the number that the frontend wants to prespecify types for.

Then, for each parameter, there is the following:

Int32

Specifies the object ID of the parameter data type. Placing a zero here is equivalent to leaving the type unspecified.

ParseComplete (B)

Byte1('1')

Identifies the message as a Parse-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

PasswordMessage (F)

Byte1('p')

Identifies the message as a password response. Note that this is also used for GSSAPI, SSPI and SASL response messages (which is really a design error, since the contained data is not a null-terminated string in that case, but can be arbitrary binary data).

Int32

Length of message contents in bytes, including self.

String

The password (encrypted, if requested).

PortalSuspended (B)

Byte1('s')

Identifies the message as a portal-suspended indicator. Note this only appears if an Execute message's row-count limit was reached.

Int32(4)

Length of message contents in bytes, including self.

Query (F)

Byte1('Q')

Identifies the message as a simple query.

Int32

Length of message contents in bytes, including self.

String

The query string itself.

ReadyForQuery (B)

Byte1('Z')

Identifies the message type. ReadyForQuery is sent whenever the backend is ready for a new query cycle.

Int32(5)

Length of message contents in bytes, including self.

Byte1

Current backend transaction status indicator. Possible values are 'I' if idle (not in a transaction block); 'T' if in a transaction block; or 'E' if in a failed transaction block (queries will be rejected until block is ended).

RowDescription (B)

Byte1('T')

Identifies the message as a row description.

Int32

Length of message contents in bytes, including self.

Int16

Specifies the number of fields in a row (can be zero).

Then, for each field, there is the following:

String

The field name.

Int32

If the field can be identified as a column of a specific table, the object ID of the table; otherwise zero.

Int16

If the field can be identified as a column of a specific table, the attribute number of the column; otherwise zero.

Int32

The object ID of the field's data type.

Int16

The data type size (see `pg_type.typelen`). Note that negative values denote variable-width types.

Int32

The type modifier (see `pg_attribute.atttypmod`). The meaning of the modifier is type-specific.

Int16

The format code being used for the field. Currently will be zero (text) or one (binary). In a `RowDescription` returned from the statement variant of `Describe`, the format code is not yet known and will always be zero.

SSLRequest (F)

Int32(8)

Length of message contents in bytes, including self.

Int32(80877103)

The SSL request code. The value is chosen to contain `1234` in the most significant 16 bits, and `5679` in the least significant 16 bits. (To avoid confusion, this code must not be the same as any protocol version number.)

StartupMessage (F)

Int32

Length of message contents in bytes, including self.

Int32(196608)

The protocol version number. The most significant 16 bits are the major version number (3 for the protocol described here). The least significant 16 bits are the minor version number (0 for the protocol described here).

The protocol version number is followed by one or more pairs of parameter name and value strings. A zero byte is required as a terminator after the last name/value pair. Parameters can appear in any order. `user` is required, others are optional. Each parameter is specified as:

String

The parameter name. Currently recognized names are:

`user`

The database user name to connect as. Required; there is no default.

`database`

The database to connect to. Defaults to the user name.

`options`

Command-line arguments for the backend. (This is deprecated in favor of setting individual run-time parameters.) Spaces within this string are considered to separate arguments, unless escaped with a backslash (`\`); write `\\` to represent a literal backslash.

In addition to the above, other parameters may be listed. Parameter names beginning with `_pg_` are reserved for use as protocol extensions, while others are treated as run-time parameters to be set at backend start time. Such settings will be applied during backend start (after parsing the command-line arguments if any) and will act as session defaults.

String

The parameter value.

Sync (F)

Byte1('S')

Identifies the message as a Sync command.

Int32(4)

Length of message contents in bytes, including self.

Terminate (F)

Byte1('X')

Identifies the message as a termination.

Int32(4)

Length of message contents in bytes, including self.

51.6. Error and Notice Message Fields

This section describes the fields that can appear in ErrorResponse and NoticeResponse messages. Each field type has a single-byte identification token. Note that any given field type should appear at most once per message.

S

Severity: the field contents are `ERROR`, `FATAL`, or `PANIC` (in an error message), or `WARNING`, `NOTICE`, `DEBUG`, `INFO`, or `LOG` (in a notice message), or a localized translation of one of these. Always present.

V

Severity: the field contents are `ERROR`, `FATAL`, or `PANIC` (in an error message), or `WARNING`, `NOTICE`, `DEBUG`, `INFO`, or `LOG` (in a notice message). This is identical to the `S` field except that the contents are never localized. This is present only in messages generated by Postgres Pro versions 9.6 and later.

C

Code: the SQLSTATE code for the error (see [Appendix A](#)). Not localizable. Always present.

M

Message: the primary human-readable error message. This should be accurate but terse (typically one line). Always present.

D

Detail: an optional secondary error message carrying more detail about the problem. Might run to multiple lines.

H

Hint: an optional suggestion what to do about the problem. This is intended to differ from Detail in that it offers advice (potentially inappropriate) rather than hard facts. Might run to multiple lines.

P

Position: the field value is a decimal ASCII integer, indicating an error cursor position as an index into the original query string. The first character has index 1, and positions are measured in characters not bytes.

P

Internal position: this is defined the same as the P field, but it is used when the cursor position refers to an internally generated command rather than the one submitted by the client. The q field will always appear when this field appears.

Q

Internal query: the text of a failed internally-generated command. This could be, for example, a SQL query issued by a PL/pgSQL function.

W

Where: an indication of the context in which the error occurred. Presently this includes a call stack traceback of active procedural language functions and internally-generated queries. The trace is one entry per line, most recent first.

S

Schema name: if the error was associated with a specific database object, the name of the schema containing that object, if any.

T

Table name: if the error was associated with a specific table, the name of the table. (Refer to the schema name field for the name of the table's schema.)

C

Column name: if the error was associated with a specific table column, the name of the column. (Refer to the schema and table name fields to identify the table.)

D

Data type name: if the error was associated with a specific data type, the name of the data type. (Refer to the schema name field for the name of the data type's schema.)

N

Constraint name: if the error was associated with a specific constraint, the name of the constraint. Refer to fields listed above for the associated table or domain. (For this purpose, indexes are treated as constraints, even if they weren't created with constraint syntax.)

F

File: the file name of the source-code location where the error was reported.

L

Line: the line number of the source-code location where the error was reported.

R

Routine: the name of the source-code routine reporting the error.

Note

The fields for schema name, table name, column name, data type name, and constraint name are supplied only for a limited number of error types; see [Appendix A](#). Frontends should not assume that the presence of any of these fields guarantees the presence of another field. Core error sources observe the interrelationships noted above, but user-defined functions may use these fields in other ways. In the same vein, clients should not assume that these fields denote contemporary objects in the current database.

The client is responsible for formatting displayed information to meet its needs; in particular it should break long lines as needed. Newline characters appearing in the error message fields should be treated as paragraph breaks, not line breaks.

51.7. Summary of Changes since Protocol 2.0

This section provides a quick checklist of changes, for the benefit of developers trying to update existing client libraries to protocol 3.0.

The initial startup packet uses a flexible list-of-strings format instead of a fixed format. Notice that session default values for run-time parameters can now be specified directly in the startup packet. (Actually, you could do that before using the `options` field, but given the limited width of `options` and the lack of any way to quote whitespace in the values, it wasn't a very safe technique.)

All messages now have a length count immediately following the message type byte (except for startup packets, which have no type byte). Also note that `PasswordMessage` now has a type byte.

`ErrorResponse` and `NoticeResponse` ('E' and 'N') messages now contain multiple fields, from which the client code can assemble an error message of the desired level of verbosity. Note that individual fields will typically not end with a newline, whereas the single string sent in the older protocol always did.

The `ReadyForQuery` ('Z') message includes a transaction status indicator.

The distinction between `BinaryRow` and `DataRow` message types is gone; the single `DataRow` message type serves for returning data in all formats. Note that the layout of `DataRow` has changed to make it easier to parse. Also, the representation of binary values has changed: it is no longer directly tied to the server's internal representation.

There is a new “extended query” sub-protocol, which adds the frontend message types `Parse`, `Bind`, `Execute`, `Describe`, `Close`, `Flush`, and `Sync`, and the backend message types `ParseComplete`, `BindComplete`, `PortalSuspended`, `ParameterDescription`, `NoData`, and `CloseComplete`. Existing clients do not have to concern themselves with this sub-protocol, but making use of it might allow improvements in performance or functionality.

`COPY` data is now encapsulated into `CopyData` and `CopyDone` messages. There is a well-defined way to recover from errors during `COPY`. The special “\.” last line is not needed anymore, and is not sent during `COPY OUT`. (It is still recognized as a terminator during `COPY IN`, but its use is deprecated and will eventually be removed.) Binary `COPY` is supported. The `CopyInResponse` and `CopyOutResponse` messages include fields indicating the number of columns and the format of each column.

The layout of `FunctionCall` and `FunctionCallResponse` messages has changed. `FunctionCall` can now support passing `NULL` arguments to functions. It also can handle passing parameters and retrieving results in either text or binary format. There is no longer any reason to consider `FunctionCall` a potential security hole, since it does not offer direct access to internal server data representations.

The backend sends `ParameterStatus` ('S') messages during connection startup for all parameters it considers interesting to the client library. Subsequently, a `ParameterStatus` message is sent whenever the active value changes for any of these parameters.

The `RowDescription` ('T') message carries new table OID and column number fields for each column of the described row. It also shows the format code for each column.

The `CursorResponse` ('P') message is no longer generated by the backend.

The `NotificationResponse` ('A') message has an additional string field, which can carry a “payload” string passed from the `NOTIFY` event sender.

The `EmptyQueryResponse` ('I') message used to include an empty string parameter; this has been removed.

Chapter 52. Writing A Procedural Language Handler

All calls to functions that are written in a language other than the current “version 1” interface for compiled languages (this includes functions in user-defined procedural languages, functions written in SQL, and functions using the version 0 compiled language interface) go through a *call handler* function for the specific language. It is the responsibility of the call handler to execute the function in a meaningful way, such as by interpreting the supplied source text. This chapter outlines how a new procedural language's call handler can be written.

The call handler for a procedural language is a “normal” function that must be written in a compiled language such as C, using the version-1 interface, and registered with Postgres Pro as taking no arguments and returning the type `language_handler`. This special pseudotype identifies the function as a call handler and prevents it from being called directly in SQL commands. For more details on C language calling conventions and dynamic loading, see [Section 36.9](#).

The call handler is called in the same way as any other function: It receives a pointer to a `FunctionCallInfoData` struct containing argument values and information about the called function, and it is expected to return a `Datum` result (and possibly set the `isnull` field of the `FunctionCallInfoData` structure, if it wishes to return an SQL null result). The difference between a call handler and an ordinary callee function is that the `flinfo->fn_oid` field of the `FunctionCallInfoData` structure will contain the OID of the actual function to be called, not of the call handler itself. The call handler must use this field to determine which function to execute. Also, the passed argument list has been set up according to the declaration of the target function, not of the call handler.

It's up to the call handler to fetch the entry of the function from the `pg_proc` system catalog and to analyze the argument and return types of the called function. The `AS` clause from the `CREATE FUNCTION` command for the function will be found in the `prosrc` column of the `pg_proc` row. This is commonly source text in the procedural language, but in theory it could be something else, such as a path name to a file, or anything else that tells the call handler what to do in detail.

Often, the same function is called many times per SQL statement. A call handler can avoid repeated lookups of information about the called function by using the `flinfo->fn_extra` field. This will initially be `NULL`, but can be set by the call handler to point at information about the called function. On subsequent calls, if `flinfo->fn_extra` is already non-`NULL` then it can be used and the information lookup step skipped. The call handler must make sure that `flinfo->fn_extra` is made to point at memory that will live at least until the end of the current query, since an `FmgrInfo` data structure could be kept that long. One way to do this is to allocate the extra data in the memory context specified by `flinfo->fn_mcxt`; such data will normally have the same lifespan as the `FmgrInfo` itself. But the handler could also choose to use a longer-lived memory context so that it can cache function definition information across queries.

When a procedural-language function is invoked as a trigger, no arguments are passed in the usual way, but the `FunctionCallInfoData`'s `context` field points at a `TriggerData` structure, rather than being `NULL` as it is in a plain function call. A language handler should provide mechanisms for procedural-language functions to get at the trigger information.

This is a template for a procedural-language handler written in C:

```
#include "postgres.h"
#include "executor/spi.h"
#include "commands/trigger.h"
#include "fmgr.h"
#include "access/heapam.h"
#include "utils/syscache.h"
#include "catalog/pg_proc.h"
#include "catalog/pg_type.h"
```

```
#ifdef PG_MODULE_MAGIC
PG_MODULE_MAGIC;
#endif

PG_FUNCTION_INFO_V1(plsample_call_handler);

Datum
plsample_call_handler(PG_FUNCTION_ARGS)
{
    Datum          retval;

    if (CALLED_AS_TRIGGER(fcinfo))
    {
        /*
         * Called as a trigger procedure
         */
        TriggerData *trigdata = (TriggerData *) fcinfo->context;

        retval = ...
    }
    else
    {
        /*
         * Called as a function
         */

        retval = ...
    }

    return retval;
}
```

Only a few thousand lines of code have to be added instead of the dots to complete the call handler.

After having compiled the handler function into a loadable module (see [Section 36.9.6](#)), the following commands then register the sample procedural language:

```
CREATE FUNCTION plsample_call_handler() RETURNS language_handler
AS 'filename'
LANGUAGE C;
CREATE LANGUAGE plsample
HANDLER plsample_call_handler;
```

Although providing a call handler is sufficient to create a minimal procedural language, there are two other functions that can optionally be provided to make the language more convenient to use. These are a *validator* and an *inline handler*. A validator can be provided to allow language-specific checking to be done during [CREATE FUNCTION](#). An inline handler can be provided to allow the language to support anonymous code blocks executed via the [DO](#) command.

If a validator is provided by a procedural language, it must be declared as a function taking a single parameter of type `oid`. The validator's result is ignored, so it is customarily declared to return `void`. The validator will be called at the end of a `CREATE FUNCTION` command that has created or updated a function written in the procedural language. The passed-in OID is the OID of the function's `pg_proc` row. The validator must fetch this row in the usual way, and do whatever checking is appropriate. First, call `CheckFunctionValidatorAccess()` to diagnose explicit calls to the validator that the user could not achieve through `CREATE FUNCTION`. Typical checks then include verifying that the function's argument and result types are supported by the language, and that the function's body is syntactically correct in the language. If the validator finds the function to be okay, it should just return. If it finds an error, it

should report that via the normal `ereport()` error reporting mechanism. Throwing an error will force a transaction rollback and thus prevent the incorrect function definition from being committed.

Validator functions should typically honor the `check_function_bodies` parameter: if it is turned off then any expensive or context-sensitive checking should be skipped. If the language provides for code execution at compilation time, the validator must suppress checks that would induce such execution. In particular, this parameter is turned off by `pg_dump` so that it can load procedural language functions without worrying about side effects or dependencies of the function bodies on other database objects. (Because of this requirement, the call handler should avoid assuming that the validator has fully checked the function. The point of having a validator is not to let the call handler omit checks, but to notify the user immediately if there are obvious errors in a `CREATE FUNCTION` command.) While the choice of exactly what to check is mostly left to the discretion of the validator function, note that the core `CREATE FUNCTION` code only executes `SET` clauses attached to a function when `check_function_bodies` is on. Therefore, checks whose results might be affected by GUC parameters definitely should be skipped when `check_function_bodies` is off, to avoid false failures when reloading a dump.

If an inline handler is provided by a procedural language, it must be declared as a function taking a single parameter of type `internal`. The inline handler's result is ignored, so it is customarily declared to return `void`. The inline handler will be called when a `DO` statement is executed specifying the procedural language. The parameter actually passed is a pointer to an `InlineCodeBlock` struct, which contains information about the `DO` statement's parameters, in particular the text of the anonymous code block to be executed. The inline handler should execute this code and return.

It's recommended that you wrap all these function declarations, as well as the `CREATE LANGUAGE` command itself, into an *extension* so that a simple `CREATE EXTENSION` command is sufficient to install the language. See [Section 36.15](#) for information about writing extensions.

The procedural languages included in the standard distribution are good references when trying to write your own language handler. Look into the `src/pl` subdirectory of the source tree. The [CREATE LANGUAGE](#) reference page also has some useful details.

Chapter 53. Writing A Foreign Data Wrapper

All operations on a foreign table are handled through its foreign data wrapper, which consists of a set of functions that the core server calls. The foreign data wrapper is responsible for fetching data from the remote data source and returning it to the Postgres Pro executor. If updating foreign tables is to be supported, the wrapper must handle that, too. This chapter outlines how to write a new foreign data wrapper.

The foreign data wrappers included in the standard distribution are good references when trying to write your own. Look into the `contrib` subdirectory of the source tree. The [CREATE FOREIGN DATA WRAPPER](#) reference page also has some useful details.

Note

The SQL standard specifies an interface for writing foreign data wrappers. However, Postgres Pro does not implement that API, because the effort to accommodate it into Postgres Pro would be large, and the standard API hasn't gained wide adoption anyway.

53.1. Foreign Data Wrapper Functions

The FDW author needs to implement a handler function, and optionally a validator function. Both functions must be written in a compiled language such as C, using the version-1 interface. For details on C language calling conventions and dynamic loading, see [Section 36.9](#).

The handler function simply returns a struct of function pointers to callback functions that will be called by the planner, executor, and various maintenance commands. Most of the effort in writing an FDW is in implementing these callback functions. The handler function must be registered with Postgres Pro as taking no arguments and returning the special pseudo-type `fdw_handler`. The callback functions are plain C functions and are not visible or callable at the SQL level. The callback functions are described in [Section 53.2](#).

The validator function is responsible for validating options given in `CREATE` and `ALTER` commands for its foreign data wrapper, as well as foreign servers, user mappings, and foreign tables using the wrapper. The validator function must be registered as taking two arguments, a text array containing the options to be validated, and an OID representing the type of object the options are associated with (in the form of the OID of the system catalog the object would be stored in, either `ForeignDataWrapperRelationId`, `ForeignServerRelationId`, `UserMappingRelationId`, or `ForeignTableRelationId`). If no validator function is supplied, options are not checked at object creation time or object alteration time.

53.2. Foreign Data Wrapper Callback Routines

The FDW handler function returns a `palloc'd` `FdwRoutine` struct containing pointers to the callback functions described below. The scan-related functions are required, the rest are optional.

The `FdwRoutine` struct type is declared in `src/include/foreign/fdwapi.h`, which see for additional details.

53.2.1. FDW Routines For Scanning Foreign Tables

```
void
GetForeignRelSize (PlannerInfo *root,
                  RelOptInfo *baserel,
                  Oid foreigntableid);
```

Obtain relation size estimates for a foreign table. This is called at the beginning of planning for a query that scans a foreign table. `root` is the planner's global information about the query; `baserel` is the

planner's information about this table; and `foreigntableid` is the `pg_class` OID of the foreign table. (`foreigntableid` could be obtained from the planner data structures, but it's passed explicitly to save effort.)

This function should update `baserel->rows` to be the expected number of rows returned by the table scan, after accounting for the filtering done by the restriction quals. The initial value of `baserel->rows` is just a constant default estimate, which should be replaced if at all possible. The function may also choose to update `baserel->width` if it can compute a better estimate of the average result row width. (The initial value is based on column data types and on column average-width values measured by the last `ANALYZE`.) Also, this function may update `baserel->tuples` if it can compute a better estimate of the foreign table's total row count. (The initial value is from `pg_class.reltuples` which represents the total row count seen by the last `ANALYZE`.)

See [Section 53.4](#) for additional information.

```
void
GetForeignPaths (PlannerInfo *root,
                 RelOptInfo *baserel,
                 Oid foreigntableid);
```

Create possible access paths for a scan on a foreign table. This is called during query planning. The parameters are the same as for `GetForeignRelSize`, which has already been called.

This function must generate at least one access path (`ForeignPath` node) for a scan on the foreign table and must call `add_path` to add each such path to `baserel->pathlist`. It's recommended to use `create_foreignscan_path` to build the `ForeignPath` nodes. The function can generate multiple access paths, e.g., a path which has valid `pathkeys` to represent a pre-sorted result. Each access path must contain cost estimates, and can contain any FDW-private information that is needed to identify the specific scan method intended.

See [Section 53.4](#) for additional information.

```
ForeignScan *
GetForeignPlan (PlannerInfo *root,
                RelOptInfo *baserel,
                Oid foreigntableid,
                ForeignPath *best_path,
                List *tlist,
                List *scan_clauses,
                Plan *outer_plan);
```

Create a `ForeignScan` plan node from the selected foreign access path. This is called at the end of query planning. The parameters are as for `GetForeignRelSize`, plus the selected `ForeignPath` (previously produced by `GetForeignPaths`, `GetForeignJoinPaths`, or `GetForeignUpperPaths`), the target list to be emitted by the plan node, the restriction clauses to be enforced by the plan node, and the outer subplan of the `ForeignScan`, which is used for rechecks performed by `RecheckForeignScan`. (If the path is for a join rather than a base relation, `foreigntableid` is `InvalidOid`.)

This function must create and return a `ForeignScan` plan node; it's recommended to use `make_foreignscan` to build the `ForeignScan` node.

See [Section 53.4](#) for additional information.

```
void
BeginForeignScan (ForeignScanState *node,
                 int eflags);
```

Begin executing a foreign scan. This is called during executor startup. It should perform any initialization needed before the scan can start, but not start executing the actual scan (that should be done upon the first call to `IterateForeignScan`). The `ForeignScanState` node has already been created,

but its `fdw_state` field is still `NULL`. Information about the table to scan is accessible through the `ForeignScanState` node (in particular, from the underlying `ForeignScan` plan node, which contains any FDW-private information provided by `GetForeignPlan`). `eflags` contains flag bits describing the executor's operating mode for this plan node.

Note that when `(eflags & EXEC_FLAG_EXPLAIN_ONLY)` is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for `ExplainForeignScan` and `EndForeignScan`.

```
TupleTableSlot *  
IterateForeignScan (ForeignScanState *node);
```

Fetch one row from the foreign source, returning it in a tuple table slot (the node's `ScanTupleSlot` should be used for this purpose). Return `NULL` if no more rows are available. The tuple table slot infrastructure allows either a physical or virtual tuple to be returned; in most cases the latter choice is preferable from a performance standpoint. Note that this is called in a short-lived memory context that will be reset between invocations. Create a memory context in `BeginForeignScan` if you need longer-lived storage, or use the `es_query_cxt` of the node's `EState`.

The rows returned must match the `fdw_scan_tlist` target list if one was supplied, otherwise they must match the row type of the foreign table being scanned. If you choose to optimize away fetching columns that are not needed, you should insert nulls in those column positions, or else generate a `fdw_scan_tlist` list with those columns omitted.

Note that Postgres Pro's executor doesn't care whether the rows returned violate any constraints that were defined on the foreign table — but the planner does care, and may optimize queries incorrectly if there are rows visible in the foreign table that do not satisfy a declared constraint. If a constraint is violated when the user has declared that the constraint should hold true, it may be appropriate to raise an error (just as you would need to do in the case of a data type mismatch).

```
void  
ReScanForeignScan (ForeignScanState *node);
```

Restart the scan from the beginning. Note that any parameters the scan depends on may have changed value, so the new scan does not necessarily return exactly the same rows.

```
void  
EndForeignScan (ForeignScanState *node);
```

End the scan and release resources. It is normally not important to release `palloc'd` memory, but for example open files and connections to remote servers should be cleaned up.

53.2.2. FDW Routines For Scanning Foreign Joins

If an FDW supports performing foreign joins remotely (rather than by fetching both tables' data and doing the join locally), it should provide this callback function:

```
void  
GetForeignJoinPaths (PlannerInfo *root,  
                    RelOptInfo *joinrel,  
                    RelOptInfo *outerrel,  
                    RelOptInfo *innerrel,  
                    JoinType jointype,  
                    JoinPathExtraData *extra);
```

Create possible access paths for a join of two (or more) foreign tables that all belong to the same foreign server. This optional function is called during query planning. As with `GetForeignPaths`, this function should generate `ForeignPath` path(s) for the supplied `joinrel`, and call `add_path` to add these paths to the set of paths considered for the join. But unlike `GetForeignPaths`, it is not necessary that this function succeed in creating at least one path, since paths involving local joining are always possible.

Note that this function will be invoked repeatedly for the same join relation, with different combinations of inner and outer relations; it is the responsibility of the FDW to minimize duplicated work.

If a `ForeignPath` path is chosen for the join, it will represent the entire join process; paths generated for the component tables and subsidiary joins will not be used. Subsequent processing of the join path proceeds much as it does for a path scanning a single foreign table. One difference is that the `scanrelid` of the resulting `ForeignScan` plan node should be set to zero, since there is no single relation that it represents; instead, the `fs_relids` field of the `ForeignScan` node represents the set of relations that were joined. (The latter field is set up automatically by the core planner code, and need not be filled by the FDW.) Another difference is that, because the column list for a remote join cannot be found from the system catalogs, the FDW must fill `fdw_scan_tlist` with an appropriate list of `TargetEntry` nodes, representing the set of columns it will supply at run time in the tuples it returns.

See [Section 53.4](#) for additional information.

53.2.3. FDW Routines For Planning Post-Scan/Join Processing

If an FDW supports performing remote post-scan/join processing, such as remote aggregation, it should provide this callback function:

```
void
GetForeignUpperPaths (PlannerInfo *root,
                     UpperRelationKind stage,
                     RelOptInfo *input_rel,
                     RelOptInfo *output_rel);
```

Create possible access paths for *upper relation* processing, which is the planner's term for all post-scan/join query processing, such as aggregation, window functions, sorting, and table updates. This optional function is called during query planning. Currently, it is called only if all base relation(s) involved in the query belong to the same FDW. This function should generate `ForeignPath` path(s) for any post-scan/join processing that the FDW knows how to perform remotely, and call `add_path` to add these paths to the indicated upper relation. As with `GetForeignJoinPaths`, it is not necessary that this function succeed in creating any paths, since paths involving local processing are always possible.

The `stage` parameter identifies which post-scan/join step is currently being considered. `output_rel` is the upper relation that should receive paths representing computation of this step, and `input_rel` is the relation representing the input to this step. (Note that `ForeignPath` paths added to `output_rel` would typically not have any direct dependency on paths of the `input_rel`, since their processing is expected to be done externally. However, examining paths previously generated for the previous processing step can be useful to avoid redundant planning work.)

See [Section 53.4](#) for additional information.

53.2.4. FDW Routines For Updating Foreign Tables

If an FDW supports writable foreign tables, it should provide some or all of the following callback functions depending on the needs and capabilities of the FDW:

```
void
AddForeignUpdateTargets (Query *parsetree,
                       RangeTblEntry *target_rte,
                       Relation target_relation);
```

UPDATE and DELETE operations are performed against rows previously fetched by the table-scanning functions. The FDW may need extra information, such as a row ID or the values of primary-key columns, to ensure that it can identify the exact row to update or delete. To support that, this function can add extra hidden, or “junk”, target columns to the list of columns that are to be retrieved from the foreign table during an UPDATE or DELETE.

To do that, add `TargetEntry` items to `parsetree->targetList`, containing expressions for the extra values to be fetched. Each such entry must be marked `resjunk = true`, and must have a distinct `resname`

that will identify it at execution time. Avoid using names matching `ctidN`, `wholerow`, or `wholerowN`, as the core system can generate junk columns of these names. If the extra expressions are more complex than simple Vars, they must be run through `eval_const_expressions` before adding them to the targetlist.

Although this function is called during planning, the information provided is a bit different from that available to other planning routines. `parsetree` is the parse tree for the `UPDATE` or `DELETE` command, while `target_rte` and `target_relation` describe the target foreign table.

If the `AddForeignUpdateTargets` pointer is set to `NULL`, no extra target expressions are added. (This will make it impossible to implement `DELETE` operations, though `UPDATE` may still be feasible if the FDW relies on an unchanging primary key to identify rows.)

```
List *
PlanForeignModify (PlannerInfo *root,
                  ModifyTable *plan,
                  Index resultRelation,
                  int subplan_index);
```

Perform any additional planning actions needed for an insert, update, or delete on a foreign table. This function generates the FDW-private information that will be attached to the `ModifyTable` plan node that performs the update action. This private information must have the form of a `List`, and will be delivered to `BeginForeignModify` during the execution stage.

`root` is the planner's global information about the query. `plan` is the `ModifyTable` plan node, which is complete except for the `fdwPrivLists` field. `resultRelation` identifies the target foreign table by its range table index. `subplan_index` identifies which target of the `ModifyTable` plan node this is, counting from zero; use this if you want to index into `plan->plans` or other substructure of the plan node.

See [Section 53.4](#) for additional information.

If the `PlanForeignModify` pointer is set to `NULL`, no additional plan-time actions are taken, and the `fdw_private` list delivered to `BeginForeignModify` will be `NIL`.

```
void
BeginForeignModify (ModifyTableState *mtstate,
                  ResultRelInfo *rinfo,
                  List *fdw_private,
                  int subplan_index,
                  int eflags);
```

Begin executing a foreign table modification operation. This routine is called during executor startup. It should perform any initialization needed prior to the actual table modifications. Subsequently, `ExecForeignInsert`, `ExecForeignUpdate` or `ExecForeignDelete` will be called for each tuple to be inserted, updated, or deleted.

`mtstate` is the overall state of the `ModifyTable` plan node being executed; global data about the plan and execution state is available via this structure. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. (The `ri_FdwState` field of `ResultRelInfo` is available for the FDW to store any private state it needs for this operation.) `fdw_private` contains the private data generated by `PlanForeignModify`, if any. `subplan_index` identifies which target of the `ModifyTable` plan node this is. `eflags` contains flag bits describing the executor's operating mode for this plan node.

Note that when `(eflags & EXEC_FLAG_EXPLAIN_ONLY)` is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for `ExplainForeignModify` and `EndForeignModify`.

If the `BeginForeignModify` pointer is set to `NULL`, no action is taken during executor startup.

```
TupleTableSlot *
ExecForeignInsert (EState *estate,
```

```
ResultRelInfo *rinfo,  
TupleTableSlot *slot,  
TupleTableSlot *planSlot);
```

Insert one tuple into the foreign table. `estate` is global execution state for the query. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. `slot` contains the tuple to be inserted; it will match the row-type definition of the foreign table. `planSlot` contains the tuple that was generated by the `ModifyTable` plan node's subplan; it differs from `slot` in possibly containing additional “junk” columns. (The `planSlot` is typically of little interest for `INSERT` cases, but is provided for completeness.)

The return value is either a slot containing the data that was actually inserted (this might differ from the data supplied, for example as a result of trigger actions), or `NULL` if no row was actually inserted (again, typically as a result of triggers). The passed-in `slot` can be re-used for this purpose.

The data in the returned slot is used only if the `INSERT` query has a `RETURNING` clause or the foreign table has an `AFTER ROW` trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the `RETURNING` clause. Regardless, some slot must be returned to indicate success, or the query's reported row count will be wrong.

If the `ExecForeignInsert` pointer is set to `NULL`, attempts to insert into the foreign table will fail with an error message.

```
TupleTableSlot *  
ExecForeignUpdate (EState *estate,  
                  ResultRelInfo *rinfo,  
                  TupleTableSlot *slot,  
                  TupleTableSlot *planSlot);
```

Update one tuple in the foreign table. `estate` is global execution state for the query. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. `slot` contains the new data for the tuple; it will match the row-type definition of the foreign table. `planSlot` contains the tuple that was generated by the `ModifyTable` plan node's subplan; it differs from `slot` in possibly containing additional “junk” columns. In particular, any junk columns that were requested by `AddForeignUpdateTargets` will be available from this slot.

The return value is either a slot containing the row as it was actually updated (this might differ from the data supplied, for example as a result of trigger actions), or `NULL` if no row was actually updated (again, typically as a result of triggers). The passed-in `slot` can be re-used for this purpose.

The data in the returned slot is used only if the `UPDATE` query has a `RETURNING` clause or the foreign table has an `AFTER ROW` trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the `RETURNING` clause. Regardless, some slot must be returned to indicate success, or the query's reported row count will be wrong.

If the `ExecForeignUpdate` pointer is set to `NULL`, attempts to update the foreign table will fail with an error message.

```
TupleTableSlot *  
ExecForeignDelete (EState *estate,  
                  ResultRelInfo *rinfo,  
                  TupleTableSlot *slot,  
                  TupleTableSlot *planSlot);
```

Delete one tuple from the foreign table. `estate` is global execution state for the query. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. `slot` contains nothing useful upon call, but can be used to hold the returned tuple. `planSlot` contains the tuple that was generated by the `ModifyTable` plan node's subplan; in particular, it will carry any junk columns that were requested by `AddForeignUpdateTargets`. The junk column(s) must be used to identify the tuple to be deleted.

The return value is either a slot containing the row that was deleted, or `NULL` if no row was deleted (typically as a result of triggers). The passed-in `slot` can be used to hold the tuple to be returned.

The data in the returned slot is used only if the `DELETE` query has a `RETURNING` clause or the foreign table has an `AFTER ROW` trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the `RETURNING` clause. Regardless, some slot must be returned to indicate success, or the query's reported row count will be wrong.

If the `ExecForeignDelete` pointer is set to `NULL`, attempts to delete from the foreign table will fail with an error message.

```
void
EndForeignModify (EState *estate,
                 ResultRelInfo *rinfo);
```

End the table update and release resources. It is normally not important to release `palloc'd` memory, but for example open files and connections to remote servers should be cleaned up.

If the `EndForeignModify` pointer is set to `NULL`, no action is taken during executor shutdown.

```
int
IsForeignRelUpdatable (Relation rel);
```

Report which update operations the specified foreign table supports. The return value should be a bit mask of rule event numbers indicating which operations are supported by the foreign table, using the `CmdType` enumeration; that is, $(1 \ll \text{CMD\_UPDATE}) = 4$ for `UPDATE`, $(1 \ll \text{CMD\_INSERT}) = 8$ for `INSERT`, and $(1 \ll \text{CMD\_DELETE}) = 16$ for `DELETE`.

If the `IsForeignRelUpdatable` pointer is set to `NULL`, foreign tables are assumed to be insertable, updatable, or deletable if the FDW provides `ExecForeignInsert`, `ExecForeignUpdate`, or `ExecForeignDelete` respectively. This function is only needed if the FDW supports some tables that are updatable and some that are not. (Even then, it's permissible to throw an error in the execution routine instead of checking in this function. However, this function is used to determine updatability for display in the `information_schema` views.)

Some inserts, updates, and deletes to foreign tables can be optimized by implementing an alternative set of interfaces. The ordinary interfaces for inserts, updates, and deletes fetch rows from the remote server and then modify those rows one at a time. In some cases, this row-by-row approach is necessary, but it can be inefficient. If it is possible for the foreign server to determine which rows should be modified without actually retrieving them, and if there are no local structures which would affect the operation (row-level local triggers or `WITH CHECK OPTION` constraints from parent views), then it is possible to arrange things so that the entire operation is performed on the remote server. The interfaces described below make this possible.

```
bool
PlanDirectModify (PlannerInfo *root,
                 ModifyTable *plan,
                 Index resultRelation,
                 int subplan_index);
```

Decide whether it is safe to execute a direct modification on the remote server. If so, return `true` after performing planning actions needed for that. Otherwise, return `false`. This optional function is called during query planning. If this function succeeds, `BeginDirectModify`, `IterateDirectModify` and `EndDirectModify` will be called at the execution stage, instead. Otherwise, the table modification will be executed using the table-updating functions described above. The parameters are the same as for `PlanForeignModify`.

To execute the direct modification on the remote server, this function must rewrite the target subplan with a `ForeignScan` plan node that executes the direct modification on the remote server. The `operation` field of the `ForeignScan` must be set to the `CmdType` enumeration appropriately; that is, `CMD_UPDATE` for `UPDATE`, `CMD_INSERT` for `INSERT`, and `CMD_DELETE` for `DELETE`.

See [Section 53.4](#) for additional information.

If the `PlanDirectModify` pointer is set to `NULL`, no attempts to execute a direct modification on the remote server are taken.

```
void
BeginDirectModify (ForeignScanState *node,
                  int eflags);
```

Prepare to execute a direct modification on the remote server. This is called during executor startup. It should perform any initialization needed prior to the direct modification (that should be done upon the first call to `IterateDirectModify`). The `ForeignScanState` node has already been created, but its `fdw_state` field is still `NULL`. Information about the table to modify is accessible through the `ForeignScanState` node (in particular, from the underlying `ForeignScan` plan node, which contains any FDW-private information provided by `PlanDirectModify`). `eflags` contains flag bits describing the executor's operating mode for this plan node.

Note that when (`eflags & EXEC_FLAG_EXPLAIN_ONLY`) is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for `ExplainDirectModify` and `EndDirectModify`.

If the `BeginDirectModify` pointer is set to `NULL`, no attempts to execute a direct modification on the remote server are taken.

```
TupleTableSlot *
IterateDirectModify (ForeignScanState *node);
```

When the `INSERT`, `UPDATE` or `DELETE` query doesn't have a `RETURNING` clause, just return `NULL` after a direct modification on the remote server. When the query has the clause, fetch one result containing the data needed for the `RETURNING` calculation, returning it in a tuple table slot (the node's `ScanTupleSlot` should be used for this purpose). The data that was actually inserted, updated or deleted must be stored in the `es_result_relation_info->ri_projectReturning->pi_exprContext->ecxt_scantuple` of the node's `EState`. Return `NULL` if no more rows are available. Note that this is called in a short-lived memory context that will be reset between invocations. Create a memory context in `BeginDirectModify` if you need longer-lived storage, or use the `es_query_cxt` of the node's `EState`.

The rows returned must match the `fdw_scan_tlist` target list if one was supplied, otherwise they must match the row type of the foreign table being updated. If you choose to optimize away fetching columns that are not needed for the `RETURNING` calculation, you should insert nulls in those column positions, or else generate a `fdw_scan_tlist` list with those columns omitted.

Whether the query has the clause or not, the query's reported row count must be incremented by the FDW itself. When the query doesn't have the clause, the FDW must also increment the row count for the `ForeignScanState` node in the `EXPLAIN ANALYZE` case.

If the `IterateDirectModify` pointer is set to `NULL`, no attempts to execute a direct modification on the remote server are taken.

```
void
EndDirectModify (ForeignScanState *node);
```

Clean up following a direct modification on the remote server. It is normally not important to release palloc'd memory, but for example open files and connections to the remote server should be cleaned up.

If the `EndDirectModify` pointer is set to `NULL`, no attempts to execute a direct modification on the remote server are taken.

53.2.5. FDW Routines For Row Locking

If an FDW wishes to support *late row locking* (as described in [Section 53.5](#)), it must provide the following callback functions:

```
RowMarkType
```

```
GetForeignRowMarkType (RangeTblEntry *rte,  
                      LockClauseStrength strength);
```

Report which row-marking option to use for a foreign table. `rte` is the `RangeTblEntry` node for the table and `strength` describes the lock strength requested by the relevant `FOR UPDATE/SHARE` clause, if any. The result must be a member of the `RowMarkType` enum type.

This function is called during query planning for each foreign table that appears in an `UPDATE`, `DELETE`, or `SELECT FOR UPDATE/SHARE` query and is not the target of `UPDATE` or `DELETE`.

If the `GetForeignRowMarkType` pointer is set to `NULL`, the `ROW_MARK_COPY` option is always used. (This implies that `RefetchForeignRow` will never be called, so it need not be provided either.)

See [Section 53.5](#) for more information.

```
HeapTuple  
RefetchForeignRow (EState *estate,  
                  ExecRowMark *erm,  
                  Datum rowid,  
                  bool *updated);
```

Re-fetch one tuple from the foreign table, after locking it if required. `estate` is global execution state for the query. `erm` is the `ExecRowMark` struct describing the target foreign table and the row lock type (if any) to acquire. `rowid` identifies the tuple to be fetched. `updated` is an output parameter.

This function should return a palloc'd copy of the fetched tuple, or `NULL` if the row lock couldn't be obtained. The row lock type to acquire is defined by `erm->markType`, which is the value previously returned by `GetForeignRowMarkType`. (`ROW_MARK_REFERENCE` means to just re-fetch the tuple without acquiring any lock, and `ROW_MARK_COPY` will never be seen by this routine.)

In addition, `*updated` should be set to `true` if what was fetched was an updated version of the tuple rather than the same version previously obtained. (If the FDW cannot be sure about this, always returning `true` is recommended.)

Note that by default, failure to acquire a row lock should result in raising an error; a `NULL` return is only appropriate if the `SKIP LOCKED` option is specified by `erm->waitPolicy`.

The `rowid` is the `ctid` value previously read for the row to be re-fetched. Although the `rowid` value is passed as a `Datum`, it can currently only be a `tid`. The function API is chosen in hopes that it may be possible to allow other data types for row IDs in future.

If the `RefetchForeignRow` pointer is set to `NULL`, attempts to re-fetch rows will fail with an error message.

See [Section 53.5](#) for more information.

```
bool  
RecheckForeignScan (ForeignScanState *node, TupleTableSlot *slot);
```

Recheck that a previously-returned tuple still matches the relevant scan and join qualifiers, and possibly provide a modified version of the tuple. For foreign data wrappers which do not perform join pushdown, it will typically be more convenient to set this to `NULL` and instead set `fdw_recheck_qual` appropriately. When outer joins are pushed down, however, it isn't sufficient to reapply the checks relevant to all the base tables to the result tuple, even if all needed attributes are present, because failure to match some qualifier might result in some attributes going to `NULL`, rather than in no tuple being returned. `RecheckForeignScan` can recheck qualifiers and return `true` if they are still satisfied and `false` otherwise, but it can also store a replacement tuple into the supplied slot.

To implement join pushdown, a foreign data wrapper will typically construct an alternative local join plan which is used only for rechecks; this will become the outer subplan of the `ForeignScan`. When a recheck is required, this subplan can be executed and the resulting tuple can be stored in the slot. This plan need not be efficient since no base table will return more than one row; for example, it may implement all joins

as nested loops. The function `GetExistingLocalJoinPath` may be used to search existing paths for a suitable local join path, which can be used as the alternative local join plan. `GetExistingLocalJoinPath` searches for an unparameterized path in the path list of the specified join relation. (If it does not find such a path, it returns `NULL`, in which case a foreign data wrapper may build the local path by itself or may choose not to create access paths for that join.)

53.2.6. FDW Routines for EXPLAIN

```
void
ExplainForeignScan (ForeignScanState *node,
                   ExplainState *es);
```

Print additional `EXPLAIN` output for a foreign table scan. This function can call `ExplainPropertyText` and related functions to add fields to the `EXPLAIN` output. The flag fields in `es` can be used to determine what to print, and the state of the `ForeignScanState` node can be inspected to provide run-time statistics in the `EXPLAIN ANALYZE` case.

If the `ExplainForeignScan` pointer is set to `NULL`, no additional information is printed during `EXPLAIN`.

```
void
ExplainForeignModify (ModifyTableState *mtstate,
                    ResultRelInfo *rinfo,
                    List *fdw_private,
                    int subplan_index,
                    struct ExplainState *es);
```

Print additional `EXPLAIN` output for a foreign table update. This function can call `ExplainPropertyText` and related functions to add fields to the `EXPLAIN` output. The flag fields in `es` can be used to determine what to print, and the state of the `ModifyTableState` node can be inspected to provide run-time statistics in the `EXPLAIN ANALYZE` case. The first four arguments are the same as for `BeginForeignModify`.

If the `ExplainForeignModify` pointer is set to `NULL`, no additional information is printed during `EXPLAIN`.

```
void
ExplainDirectModify (ForeignScanState *node,
                   ExplainState *es);
```

Print additional `EXPLAIN` output for a direct modification on the remote server. This function can call `ExplainPropertyText` and related functions to add fields to the `EXPLAIN` output. The flag fields in `es` can be used to determine what to print, and the state of the `ForeignScanState` node can be inspected to provide run-time statistics in the `EXPLAIN ANALYZE` case.

If the `ExplainDirectModify` pointer is set to `NULL`, no additional information is printed during `EXPLAIN`.

53.2.7. FDW Routines for ANALYZE

```
bool
AnalyzeForeignTable (Relation relation,
                   AcquireSampleRowsFunc *func,
                   BlockNumber *totalpages);
```

This function is called when `ANALYZE` is executed on a foreign table. If the FDW can collect statistics for this foreign table, it should return `true`, and provide a pointer to a function that will collect sample rows from the table in `func`, plus the estimated size of the table in pages in `totalpages`. Otherwise, return `false`.

If the FDW does not support collecting statistics for any tables, the `AnalyzeForeignTable` pointer can be set to `NULL`.

If provided, the sample collection function must have the signature

```
int
```

```
AcquireSampleRowsFunc (Relation relation, int elevel,
                        HeapTuple *rows, int targrows,
                        double *totalrows,
                        double *totaldeadrows);
```

A random sample of up to *targrows* rows should be collected from the table and stored into the caller-provided *rows* array. The actual number of rows collected must be returned. In addition, store estimates of the total numbers of live and dead rows in the table into the output parameters *totalrows* and *totaldeadrows*. (Set *totaldeadrows* to zero if the FDW does not have any concept of dead rows.)

53.2.8. FDW Routines For IMPORT FOREIGN SCHEMA

```
List *
ImportForeignSchema (ImportForeignSchemaStmt *stmt, Oid serverOid);
```

Obtain a list of foreign table creation commands. This function is called when executing [IMPORT FOREIGN SCHEMA](#), and is passed the parse tree for that statement, as well as the OID of the foreign server to use. It should return a list of C strings, each of which must contain a [CREATE FOREIGN TABLE](#) command. These strings will be parsed and executed by the core server.

Within the `ImportForeignSchemaStmt` struct, `remote_schema` is the name of the remote schema from which tables are to be imported. `list_type` identifies how to filter table names: `FDW_IMPORT_SCHEMA_ALL` means that all tables in the remote schema should be imported (in this case `table_list` is empty), `FDW_IMPORT_SCHEMA_LIMIT_TO` means to include only tables listed in `table_list`, and `FDW_IMPORT_SCHEMA_EXCEPT` means to exclude the tables listed in `table_list`. `options` is a list of options used for the import process. The meanings of the options are up to the FDW. For example, an FDW could use an option to define whether the `NOT NULL` attributes of columns should be imported. These options need not have anything to do with those supported by the FDW as database object options.

The FDW may ignore the `local_schema` field of the `ImportForeignSchemaStmt`, because the core server will automatically insert that name into the parsed `CREATE FOREIGN TABLE` commands.

The FDW does not have to concern itself with implementing the filtering specified by `list_type` and `table_list`, either, as the core server will automatically skip any returned commands for tables excluded according to those options. However, it's often useful to avoid the work of creating commands for excluded tables in the first place. The function `IsImportableForeignTable()` may be useful to test whether a given foreign-table name will pass the filter.

If the FDW does not support importing table definitions, the `ImportForeignSchema` pointer can be set to `NULL`.

53.2.9. FDW Routines for Parallel Execution

A `ForeignScan` node can, optionally, support parallel execution. A parallel `ForeignScan` will be executed in multiple processes and should return each row only once across all cooperating processes. To do this, processes can coordinate through fixed size chunks of dynamic shared memory. This shared memory is not guaranteed to be mapped at the same address in every process, so pointers may not be used. The following callbacks are all optional in general, but required if parallel execution is to be supported.

```
bool
IsForeignScanParallelSafe(PlannerInfo *root, RelOptInfo *rel,
                          RangeTblEntry *rte);
```

Test whether a scan can be performed within a parallel worker. This function will only be called when the planner believes that a parallel plan might be possible, and should return true if it is safe for that scan to run within a parallel worker. This will generally not be the case if the remote data source has transaction semantics, unless the worker's connection to the data can somehow be made to share the same transaction context as the leader.

If this callback is not defined, it is assumed that the scan must take place within the parallel leader. Note that returning true does not mean that the scan itself can be done in parallel, only that the scan

can be performed within a parallel worker. Therefore, it can be useful to define this method even when parallel execution is not supported.

Size

```
EstimateDSMForeignScan(ForeignScanState *node, ParallelContext *pcxt);
```

Estimate the amount of dynamic shared memory that will be required for parallel operation. This may be higher than the amount that will actually be used, but it must not be lower. The return value is in bytes.

void

```
InitializeDSMForeignScan(ForeignScanState *node, ParallelContext *pcxt,  
                        void *coordinate);
```

Initialize the dynamic shared memory that will be required for parallel operation; `coordinate` points to an amount of allocated space equal to the return value of `EstimateDSMForeignScan`.

void

```
InitializeWorkerForeignScan(ForeignScanState *node, shm_toc *toc,  
                           void *coordinate);
```

Initialize a parallel worker's custom state based on the shared state set up in the leader by `InitializeDSMForeignScan`. This callback is optional, and needs only be supplied if this custom path supports parallel execution.

53.3. Foreign Data Wrapper Helper Functions

Several helper functions are exported from the core server so that authors of foreign data wrappers can get easy access to attributes of FDW-related objects, such as FDW options. To use any of these functions, you need to include the header file `foreign/foreign.h` in your source file. That header also defines the struct types that are returned by these functions.

ForeignDataWrapper *

```
GetForeignDataWrapper(Oid fdwid);
```

This function returns a `ForeignDataWrapper` object for the foreign-data wrapper with the given OID. A `ForeignDataWrapper` object contains properties of the FDW (see `foreign/foreign.h` for details).

ForeignServer *

```
GetForeignServer(Oid serverid);
```

This function returns a `ForeignServer` object for the foreign server with the given OID. A `ForeignServer` object contains properties of the server (see `foreign/foreign.h` for details).

UserMapping *

```
GetUserMapping(Oid userid, Oid serverid);
```

This function returns a `UserMapping` object for the user mapping of the given role on the given server. (If there is no mapping for the specific user, it will return the mapping for `PUBLIC`, or throw error if there is none.) A `UserMapping` object contains properties of the user mapping (see `foreign/foreign.h` for details).

ForeignTable *

```
GetForeignTable(Oid relid);
```

This function returns a `ForeignTable` object for the foreign table with the given OID. A `ForeignTable` object contains properties of the foreign table (see `foreign/foreign.h` for details).

List *

```
GetForeignColumnOptions(Oid relid, AttrNumber attnum);
```

This function returns the per-column FDW options for the column with the given foreign table OID and attribute number, in the form of a list of `DefElem`. `NIL` is returned if the column has no options.

Some object types have name-based lookup functions in addition to the OID-based ones:

```
ForeignDataWrapper *  
GetForeignDataWrapperByName(const char *name, bool missing_ok);
```

This function returns a `ForeignDataWrapper` object for the foreign-data wrapper with the given name. If the wrapper is not found, return `NULL` if `missing_ok` is true, otherwise raise an error.

```
ForeignServer *  
GetForeignServerByName(const char *name, bool missing_ok);
```

This function returns a `ForeignServer` object for the foreign server with the given name. If the server is not found, return `NULL` if `missing_ok` is true, otherwise raise an error.

53.4. Foreign Data Wrapper Query Planning

The FDW callback functions `GetForeignRelSize`, `GetForeignPaths`, `GetForeignPlan`, `PlanForeignModify`, `GetForeignJoinPaths`, `GetForeignUpperPaths`, and `PlanDirectModify` must fit into the workings of the Postgres Pro planner. Here are some notes about what they must do.

The information in `root` and `baserel` can be used to reduce the amount of information that has to be fetched from the foreign table (and therefore reduce the cost). `baserel->baserestrictinfo` is particularly interesting, as it contains restriction quals (`WHERE` clauses) that should be used to filter the rows to be fetched. (The FDW itself is not required to enforce these quals, as the core executor can check them instead.) `baserel->reltarget->exprs` can be used to determine which columns need to be fetched; but note that it only lists columns that have to be emitted by the `ForeignScan` plan node, not columns that are used in qual evaluation but not output by the query.

Various private fields are available for the FDW planning functions to keep information in. Generally, whatever you store in FDW private fields should be `palloc'd`, so that it will be reclaimed at the end of planning.

`baserel->fdw_private` is a void pointer that is available for FDW planning functions to store information relevant to the particular foreign table. The core planner does not touch it except to initialize it to `NULL` when the `RelOptInfo` node is created. It is useful for passing information forward from `GetForeignRelSize` to `GetForeignPaths` and/or `GetForeignPaths` to `GetForeignPlan`, thereby avoiding recalculation.

`GetForeignPaths` can identify the meaning of different access paths by storing private information in the `fdw_private` field of `ForeignPath` nodes. `fdw_private` is declared as a `List` pointer, but could actually contain anything since the core planner does not touch it. However, best practice is to use a representation that's dumpable by `nodeToString`, for use with debugging support available in the backend.

`GetForeignPlan` can examine the `fdw_private` field of the selected `ForeignPath` node, and can generate `fdw_exprs` and `fdw_private` lists to be placed in the `ForeignScan` plan node, where they will be available at execution time. Both of these lists must be represented in a form that `copyObject` knows how to copy. The `fdw_private` list has no other restrictions and is not interpreted by the core backend in any way. The `fdw_exprs` list, if not `NIL`, is expected to contain expression trees that are intended to be executed at run time. These trees will undergo post-processing by the planner to make them fully executable.

In `GetForeignPlan`, generally the passed-in target list can be copied into the plan node as-is. The passed `scan_clauses` list contains the same clauses as `baserel->baserestrictinfo`, but may be re-ordered for better execution efficiency. In simple cases the FDW can just strip `RestrictInfo` nodes from the `scan_clauses` list (using `extract_actual_clauses`) and put all the clauses into the plan node's qual list, which means that all the clauses will be checked by the executor at run time. More complex FDWs may be able to check some of the clauses internally, in which case those clauses can be removed from the plan node's qual list so that the executor doesn't waste time rechecking them.

As an example, the FDW might identify some restriction clauses of the form *foreign_variable* = *sub_expression*, which it determines can be executed on the remote server given the locally-evaluated value of the *sub_expression*. The actual identification of such a clause should happen during

`GetForeignPaths`, since it would affect the cost estimate for the path. The path's `fdw_private` field would probably include a pointer to the identified clause's `RestrictInfo` node. Then `GetForeignPlan` would remove that clause from `scan_clauses`, but add the `sub_expression` to `fdw_exprs` to ensure that it gets massaged into executable form. It would probably also put control information into the plan node's `fdw_private` field to tell the execution functions what to do at run time. The query transmitted to the remote server would involve something like `WHERE foreign_variable = $1`, with the parameter value obtained at run time from evaluation of the `fdw_exprs` expression tree.

Any clauses removed from the plan node's qual list must instead be added to `fdw_recheckquals` or rechecked by `RecheckForeignScan` in order to ensure correct behavior at the `READ COMMITTED` isolation level. When a concurrent update occurs for some other table involved in the query, the executor may need to verify that all of the original quals are still satisfied for the tuple, possibly against a different set of parameter values. Using `fdw_recheckquals` is typically easier than implementing checks inside `RecheckForeignScan`, but this method will be insufficient when outer joins have been pushed down, since the join tuples in that case might have some fields go to `NULL` without rejecting the tuple entirely.

Another `ForeignScan` field that can be filled by FDWs is `fdw_scan_tlist`, which describes the tuples returned by the FDW for this plan node. For simple foreign table scans this can be set to `NIL`, implying that the returned tuples have the row type declared for the foreign table. A non-`NIL` value must be a target list (list of `TargetEntry`s) containing `Vars` and/or expressions representing the returned columns. This might be used, for example, to show that the FDW has omitted some columns that it noticed won't be needed for the query. Also, if the FDW can compute expressions used by the query more cheaply than can be done locally, it could add those expressions to `fdw_scan_tlist`. Note that join plans (created from paths made by `GetForeignJoinPaths`) must always supply `fdw_scan_tlist` to describe the set of columns they will return.

The FDW should always construct at least one path that depends only on the table's restriction clauses. In join queries, it might also choose to construct path(s) that depend on join clauses, for example `foreign_variable = local_variable`. Such clauses will not be found in `baserel->baserestrictinfo` but must be sought in the relation's join lists. A path using such a clause is called a "parameterized path". It must identify the other relations used in the selected join clause(s) with a suitable value of `param_info`; use `get_baserel_parampathinfo` to compute that value. In `GetForeignPlan`, the `local_variable` portion of the join clause would be added to `fdw_exprs`, and then at run time the case works the same as for an ordinary restriction clause.

If an FDW supports remote joins, `GetForeignJoinPaths` should produce `ForeignPaths` for potential remote joins in much the same way as `GetForeignPaths` works for base tables. Information about the intended join can be passed forward to `GetForeignPlan` in the same ways described above. However, `baserestrictinfo` is not relevant for join relations; instead, the relevant join clauses for a particular join are passed to `GetForeignJoinPaths` as a separate parameter (`extra->restrictlist`).

An FDW might additionally support direct execution of some plan actions that are above the level of scans and joins, such as grouping or aggregation. To offer such options, the FDW should generate paths and insert them into the appropriate *upper relation*. For example, a path representing remote aggregation should be inserted into the `UPPERREL_GROUP_AGG` relation, using `add_path`. This path will be compared on a cost basis with local aggregation performed by reading a simple scan path for the foreign relation (note that such a path must also be supplied, else there will be an error at plan time). If the remote-aggregation path wins, which it usually would, it will be converted into a plan in the usual way, by calling `GetForeignPlan`. The recommended place to generate such paths is in the `GetForeignUpperPaths` callback function, which is called for each upper relation (i.e., each post-scan/join processing step), if all the base relations of the query come from the same FDW.

`PlanForeignModify` and the other callbacks described in [Section 53.2.4](#) are designed around the assumption that the foreign relation will be scanned in the usual way and then individual row updates will be driven by a local `ModifyTable` plan node. This approach is necessary for the general case where an update requires reading local tables as well as foreign tables. However, if the operation could be executed entirely by the foreign server, the FDW could generate a path representing that and insert it into the `UPPERREL_FINAL` upper relation, where it would compete against the `ModifyTable` approach.

This approach could also be used to implement remote `SELECT FOR UPDATE`, rather than using the row locking callbacks described in [Section 53.2.5](#). Keep in mind that a path inserted into `UPPERREL_FINAL` is responsible for implementing *all* behavior of the query.

When planning an `UPDATE` or `DELETE`, `PlanForeignModify` and `PlanDirectModify` can look up the `RelOptInfo` struct for the foreign table and make use of the `baserel->fdw_private` data previously created by the scan-planning functions. However, in `INSERT` the target table is not scanned so there is no `RelOptInfo` for it. The `List` returned by `PlanForeignModify` has the same restrictions as the `fdw_private` list of a `ForeignScan` plan node, that is it must contain only structures that `copyObject` knows how to copy.

`INSERT` with an `ON CONFLICT` clause does not support specifying the conflict target, as unique constraints or exclusion constraints on remote tables are not locally known. This in turn implies that `ON CONFLICT DO UPDATE` is not supported, since the specification is mandatory there.

53.5. Row Locking in Foreign Data Wrappers

If an FDW's underlying storage mechanism has a concept of locking individual rows to prevent concurrent updates of those rows, it is usually worthwhile for the FDW to perform row-level locking with as close an approximation as practical to the semantics used in ordinary Postgres Pro tables. There are multiple considerations involved in this.

One key decision to be made is whether to perform *early locking* or *late locking*. In early locking, a row is locked when it is first retrieved from the underlying store, while in late locking, the row is locked only when it is known that it needs to be locked. (The difference arises because some rows may be discarded by locally-checked restriction or join conditions.) Early locking is much simpler and avoids extra round trips to a remote store, but it can cause locking of rows that need not have been locked, resulting in reduced concurrency or even unexpected deadlocks. Also, late locking is only possible if the row to be locked can be uniquely re-identified later. Preferably the row identifier should identify a specific version of the row, as Postgres Pro TIDs do.

By default, Postgres Pro ignores locking considerations when interfacing to FDWs, but an FDW can perform early locking without any explicit support from the core code. The API functions described in [Section 53.2.5](#), which were added in Postgres Pro 9.5, allow an FDW to use late locking if it wishes.

An additional consideration is that in `READ COMMITTED` isolation mode, Postgres Pro may need to re-check restriction and join conditions against an updated version of some target tuple. Rechecking join conditions requires re-obtaining copies of the non-target rows that were previously joined to the target tuple. When working with standard Postgres Pro tables, this is done by including the TIDs of the non-target tables in the column list projected through the join, and then re-fetching non-target rows when required. This approach keeps the join data set compact, but it requires inexpensive re-fetch capability, as well as a TID that can uniquely identify the row version to be re-fetched. By default, therefore, the approach used with foreign tables is to include a copy of the entire row fetched from a foreign table in the column list projected through the join. This puts no special demands on the FDW but can result in reduced performance of merge and hash joins. An FDW that is capable of meeting the re-fetch requirements can choose to do it the first way.

For an `UPDATE` or `DELETE` on a foreign table, it is recommended that the `ForeignScan` operation on the target table perform early locking on the rows that it fetches, perhaps via the equivalent of `SELECT FOR UPDATE`. An FDW can detect whether a table is an `UPDATE/DELETE` target at plan time by comparing its `relid` to `root->parse->resultRelation`, or at execution time by using `ExecRelationIsTargetRelation()`. An alternative possibility is to perform late locking within the `ExecForeignUpdate` or `ExecForeignDelete` callback, but no special support is provided for this.

For foreign tables that are specified to be locked by a `SELECT FOR UPDATE/SHARE` command, the `ForeignScan` operation can again perform early locking by fetching tuples with the equivalent of `SELECT FOR UPDATE/SHARE`. To perform late locking instead, provide the callback functions defined in [Section 53.2.5](#). In `GetForeignRowMarkType`, select `rowmark` option `ROW_MARK_EXCLUSIVE`, `ROW_MARK_NOKEYEXCLUSIVE`, `ROW_MARK_SHARE`, or `ROW_MARK_KEYSHARE` depending on the requested lock

strength. (The core code will act the same regardless of which of these four options you choose.) Elsewhere, you can detect whether a foreign table was specified to be locked by this type of command by using `get_plan_rowmark` at plan time, or `ExecFindRowMark` at execution time; you must check not only whether a non-null rowmark struct is returned, but that its `strength` field is not `LCS_NONE`.

Lastly, for foreign tables that are used in an `UPDATE`, `DELETE` or `SELECT FOR UPDATE/SHARE` command but are not specified to be row-locked, you can override the default choice to copy entire rows by having `GetForeignRowMarkType` select option `ROW_MARK_REFERENCE` when it sees lock strength `LCS_NONE`. This will cause `RefetchForeignRow` to be called with that value for `markType`; it should then re-fetch the row without acquiring any new lock. (If you have a `GetForeignRowMarkType` function but don't wish to re-fetch unlocked rows, select option `ROW_MARK_COPY` for `LCS_NONE`.)

See `src/include/nodes/lockoptions.h`, the comments for `RowMarkType` and `PlanRowMark` in `src/include/nodes/plannodes.h`, and the comments for `ExecRowMark` in `src/include/nodes/execnodes.h` for additional information.

Chapter 54. Writing A Table Sampling Method

Postgres Pro's implementation of the `TABLESAMPLE` clause supports custom table sampling methods, in addition to the `BERNOULLI` and `SYSTEM` methods that are required by the SQL standard. The sampling method determines which rows of the table will be selected when the `TABLESAMPLE` clause is used.

At the SQL level, a table sampling method is represented by a single SQL function, typically implemented in C, having the signature

```
method_name(internal) RETURNS tsm_handler
```

The name of the function is the same method name appearing in the `TABLESAMPLE` clause. The `internal` argument is a dummy (always having value zero) that simply serves to prevent this function from being called directly from a SQL command. The result of the function must be a palloc'd struct of type `TsmRoutine`, which contains pointers to support functions for the sampling method. These support functions are plain C functions and are not visible or callable at the SQL level. The support functions are described in [Section 54.1](#).

In addition to function pointers, the `TsmRoutine` struct must provide these additional fields:

`List *parameterTypes`

This is an OID list containing the data type OIDs of the parameter(s) that will be accepted by the `TABLESAMPLE` clause when this sampling method is used. For example, for the built-in methods, this list contains a single item with value `FLOAT4OID`, which represents the sampling percentage. Custom sampling methods can have more or different parameters.

`bool repeatable_across_queries`

If `true`, the sampling method can deliver identical samples across successive queries, if the same parameters and `REPEATABLE` seed value are supplied each time and the table contents have not changed. When this is `false`, the `REPEATABLE` clause is not accepted for use with the sampling method.

`bool repeatable_across_scans`

If `true`, the sampling method can deliver identical samples across successive scans in the same query (assuming unchanging parameters, seed value, and snapshot). When this is `false`, the planner will not select plans that would require scanning the sampled table more than once, since that might result in inconsistent query output.

The `TsmRoutine` struct type is declared in `src/include/access/tsmapi.h`, which see for additional details.

The table sampling methods included in the standard distribution are good references when trying to write your own. Look into the `src/backend/access/tablesample` subdirectory of the source tree for the built-in sampling methods, and into the `contrib` subdirectory for add-on methods.

54.1. Sampling Method Support Functions

The TSM handler function returns a palloc'd `TsmRoutine` struct containing pointers to the support functions described below. Most of the functions are required, but some are optional, and those pointers can be `NULL`.

```
void
SampleScanGetSampleSize (PlannerInfo *root,
                        RelOptInfo *baserel,
                        List *paramexprs,
                        BlockNumber *pages,
```

```
double *tuples);
```

This function is called during planning. It must estimate the number of relation pages that will be read during a sample scan, and the number of tuples that will be selected by the scan. (For example, these might be determined by estimating the sampling fraction, and then multiplying the `basere1->pages` and `basere1->tuples` numbers by that, being sure to round the results to integral values.) The `paramexprs` list holds the expression(s) that are parameters to the `TABLESAMPLE` clause. It is recommended to use `estimate_expression_value()` to try to reduce these expressions to constants, if their values are needed for estimation purposes; but the function must provide size estimates even if they cannot be reduced, and it should not fail even if the values appear invalid (remember that they're only estimates of what the run-time values will be). The `pages` and `tuples` parameters are outputs.

```
void  
InitSampleScan (SampleScanState *node,  
                int eflags);
```

Initialize for execution of a `SampleScan` plan node. This is called during executor startup. It should perform any initialization needed before processing can start. The `SampleScanState` node has already been created, but its `tsm_state` field is `NULL`. The `InitSampleScan` function can `palloc` whatever internal state data is needed by the sampling method, and store a pointer to it in `node->tsm_state`. Information about the table to scan is accessible through other fields of the `SampleScanState` node (but note that the `node->ss.ss_currentScanDesc` scan descriptor is not set up yet). `eflags` contains flag bits describing the executor's operating mode for this plan node.

When `(eflags & EXEC_FLAG_EXPLAIN_ONLY)` is true, the scan will not actually be performed, so this function should only do the minimum required to make the node state valid for `EXPLAIN` and `EndSampleScan`.

This function can be omitted (set the pointer to `NULL`), in which case `BeginSampleScan` must perform all initialization needed by the sampling method.

```
void  
BeginSampleScan (SampleScanState *node,  
                 Datum *params,  
                 int nparams,  
                 uint32 seed);
```

Begin execution of a sampling scan. This is called just before the first attempt to fetch a tuple, and may be called again if the scan needs to be restarted. Information about the table to scan is accessible through fields of the `SampleScanState` node (but note that the `node->ss.ss_currentScanDesc` scan descriptor is not set up yet). The `params` array, of length `nparams`, contains the values of the parameters supplied in the `TABLESAMPLE` clause. These will have the number and types specified in the sampling method's `parameterTypes` list, and have been checked to not be null. `seed` contains a seed to use for any random numbers generated within the sampling method; it is either a hash derived from the `REPEATABLE` value if one was given, or the result of `random()` if not.

This function may adjust the fields `node->use_bulkread` and `node->use_pagemode`. If `node->use_bulkread` is true, which it is by default, the scan will use a buffer access strategy that encourages recycling buffers after use. It might be reasonable to set this to false if the scan will visit only a small fraction of the table's pages. If `node->use_pagemode` is true, which it is by default, the scan will perform visibility checking in a single pass for all tuples on each visited page. It might be reasonable to set this to false if the scan will select only a small fraction of the tuples on each visited page. That will result in fewer tuple visibility checks being performed, though each one will be more expensive because it will require more locking.

If the sampling method is marked `repeatable_across_scans`, it must be able to select the same set of tuples during a rescan as it did originally, that is a fresh call of `BeginSampleScan` must lead to selecting the same tuples as before (if the `TABLESAMPLE` parameters and seed don't change).

```
BlockNumber
```

```
NextSampleBlock (SampleScanState *node);
```

Returns the block number of the next page to be scanned, or `InvalidBlockNumber` if no pages remain to be scanned.

This function can be omitted (set the pointer to `NULL`), in which case the core code will perform a sequential scan of the entire relation. Such a scan can use synchronized scanning, so that the sampling method cannot assume that the relation pages are visited in the same order on each scan.

```
OffsetNumber  
NextSampleTuple (SampleScanState *node,  
                BlockNumber blockno,  
                OffsetNumber maxoffset);
```

Returns the offset number of the next tuple to be sampled on the specified page, or `InvalidOffsetNumber` if no tuples remain to be sampled. `maxoffset` is the largest offset number in use on the page.

Note

`NextSampleTuple` is not explicitly told which of the offset numbers in the range `1 .. maxoffset` actually contain valid tuples. This is not normally a problem since the core code ignores requests to sample missing or invisible tuples; that should not result in any bias in the sample. However, if necessary, the function can examine `node->ss.ss_currentScanDesc->rs_vistuples[]` to identify which tuples are valid and visible. (This requires `node->use_pagemode` to be `true`.)

Note

`NextSampleTuple` must *not* assume that `blockno` is the same page number returned by the most recent `NextSampleBlock` call. It was returned by some previous `NextSampleBlock` call, but the core code is allowed to call `NextSampleBlock` in advance of actually scanning pages, so as to support prefetching. It is OK to assume that once sampling of a given page begins, successive `NextSampleTuple` calls all refer to the same page until `InvalidOffsetNumber` is returned.

```
void  
EndSampleScan (SampleScanState *node);
```

End the scan and release resources. It is normally not important to release `palloc'd` memory, but any externally-visible resources should be cleaned up. This function can be omitted (set the pointer to `NULL`) in the common case where no such resources exist.

Chapter 55. Writing A Custom Scan Provider

Postgres Pro supports a set of experimental facilities which are intended to allow extension modules to add new scan types to the system. Unlike a [foreign data wrapper](#), which is only responsible for knowing how to scan its own foreign tables, a custom scan provider can provide an alternative method of scanning any relation in the system. Typically, the motivation for writing a custom scan provider will be to allow the use of some optimization not supported by the core system, such as caching or some form of hardware acceleration. This chapter outlines how to write a new custom scan provider.

Implementing a new type of custom scan is a three-step process. First, during planning, it is necessary to generate access paths representing a scan using the proposed strategy. Second, if one of those access paths is selected by the planner as the optimal strategy for scanning a particular relation, the access path must be converted to a plan. Finally, it must be possible to execute the plan and generate the same results that would have been generated for any other access path targeting the same relation.

55.1. Creating Custom Scan Paths

A custom scan provider will typically add paths for a base relation by setting the following hook, which is called after the core code has generated all the access paths it can for the relation (except for Gather paths, which are made after this call so that they can use partial paths added by the hook):

```
typedef void (*set_rel_pathlist_hook_type) (PlannerInfo *root,
                                           RelOptInfo *rel,
                                           Index rti,
                                           RangeTblEntry *rte);
extern PGDLLIMPORT set_rel_pathlist_hook_type set_rel_pathlist_hook;
```

Although this hook function can be used to examine, modify, or remove paths generated by the core system, a custom scan provider will typically confine itself to generating `CustomPath` objects and adding them to `rel` using `add_path`. The custom scan provider is responsible for initializing the `CustomPath` object, which is declared like this:

```
typedef struct CustomPath
{
    Path      path;
    uint32    flags;
    List      *custom_paths;
    List      *custom_private;
    const CustomPathMethods *methods;
} CustomPath;
```

`path` must be initialized as for any other path, including the row-count estimate, start and total cost, and sort ordering provided by this path. `flags` is a bit mask, which should include `CUSTOMPATH_SUPPORT_BACKWARD_SCAN` if the custom path can support a backward scan and `CUSTOMPATH_SUPPORT_MARK_RESTORE` if it can support mark and restore. Both capabilities are optional. An optional `custom_paths` is a list of `Path` nodes used by this custom-path node; these will be transformed into `Plan` nodes by planner. `custom_private` can be used to store the custom path's private data. Private data should be stored in a form that can be handled by `nodeToString`, so that debugging routines that attempt to print the custom path will work as designed. `methods` must point to a (usually statically allocated) object implementing the required custom path methods, of which there is currently only one.

A custom scan provider can also provide join paths. Just as for base relations, such a path must produce the same output as would normally be produced by the join it replaces. To do this, the join provider should set the following hook, and then within the hook function, create `CustomPath` path(s) for the join relation.

```
typedef void (*set_join_pathlist_hook_type) (PlannerInfo *root,
                                              RelOptInfo *joinrel,
                                              RelOptInfo *outerrel,
                                              RelOptInfo *innerrel,
                                              JoinType jointype,
```

```
JoinPathExtraData *extra);  
extern PGDLLIMPORT set_join_pathlist_hook_type set_join_pathlist_hook;
```

This hook will be invoked repeatedly for the same join relation, with different combinations of inner and outer relations; it is the responsibility of the hook to minimize duplicated work.

55.1.1. Custom Scan Path Callbacks

```
Plan *(*PlanCustomPath) (PlannerInfo *root,  
                          RelOptInfo *rel,  
                          CustomPath *best_path,  
                          List *tlist,  
                          List *clauses,  
                          List *custom_plans);
```

Convert a custom path to a finished plan. The return value will generally be a `CustomScan` object, which the callback must allocate and initialize. See [Section 55.2](#) for more details.

55.2. Creating Custom Scan Plans

A custom scan is represented in a finished plan tree using the following structure:

```
typedef struct CustomScan  
{  
    Scan        scan;  
    uint32      flags;  
    List        *custom_plans;  
    List        *custom_exprs;  
    List        *custom_private;  
    List        *custom_scan_tlist;  
    Bitmapset   *custom_relids;  
    const CustomScanMethods *methods;  
} CustomScan;
```

`scan` must be initialized as for any other scan, including estimated costs, target lists, qualifications, and so on. `flags` is a bit mask with the same meaning as in `CustomPath`. `custom_plans` can be used to store child `Plan` nodes. `custom_exprs` should be used to store expression trees that will need to be fixed up by `setrefs.c` and `subselect.c`, while `custom_private` should be used to store other private data that is only used by the custom scan provider itself. `custom_scan_tlist` can be `NIL` when scanning a base relation, indicating that the custom scan returns scan tuples that match the base relation's row type. Otherwise it is a target list describing the actual scan tuples. `custom_scan_tlist` must be provided for joins, and could be provided for scans if the custom scan provider can compute some non-Var expressions. `custom_relids` is set by the core code to the set of relations (range table indexes) that this scan node handles; except when this scan is replacing a join, it will have only one member. `methods` must point to a (usually statically allocated) object implementing the required custom scan methods, which are further detailed below.

When a `CustomScan` scans a single relation, `scan.scanrelid` must be the range table index of the table to be scanned. When it replaces a join, `scan.scanrelid` should be zero.

Plan trees must be able to be duplicated using `copyObject`, so all the data stored within the “custom” fields must consist of nodes that that function can handle. Furthermore, custom scan providers cannot substitute a larger structure that embeds a `CustomScan` for the structure itself, as would be possible for a `CustomPath` or `CustomScanState`.

55.2.1. Custom Scan Plan Callbacks

```
Node *(*CreateCustomScanState) (CustomScan *cscan);
```

Allocate a `CustomScanState` for this `CustomScan`. The actual allocation will often be larger than required for an ordinary `CustomScanState`, because many providers will wish to embed that as the first field of

a larger structure. The value returned must have the `node` tag and `methods` set appropriately, but other fields should be left as zeroes at this stage; after `ExecInitCustomScan` performs basic initialization, the `BeginCustomScan` callback will be invoked to give the custom scan provider a chance to do whatever else is needed.

55.3. Executing Custom Scans

When a `CustomScan` is executed, its execution state is represented by a `CustomScanState`, which is declared as follows:

```
typedef struct CustomScanState
{
    ScanState ss;
    uint32    flags;
    const CustomExecMethods *methods;
} CustomScanState;
```

`ss` is initialized as for any other scan state, except that if the scan is for a join rather than a base relation, `ss.ss_currentRelation` is left `NULL`. `flags` is a bit mask with the same meaning as in `CustomPath` and `CustomScan`. `methods` must point to a (usually statically allocated) object implementing the required custom scan state methods, which are further detailed below. Typically, a `CustomScanState`, which need not support `copyObject`, will actually be a larger structure embedding the above as its first member.

55.3.1. Custom Scan Execution Callbacks

```
void (*BeginCustomScan) (CustomScanState *node,
                        EState *estate,
                        int eflags);
```

Complete initialization of the supplied `CustomScanState`. Standard fields have been initialized by `ExecInitCustomScan`, but any private fields should be initialized here.

```
TupleTableSlot *(*ExecCustomScan) (CustomScanState *node);
```

Fetch the next scan tuple. If any tuples remain, it should fill `ps_ResultTupleSlot` with the next tuple in the current scan direction, and then return the tuple slot. If not, `NULL` or an empty slot should be returned.

```
void (*EndCustomScan) (CustomScanState *node);
```

Clean up any private data associated with the `CustomScanState`. This method is required, but it does not need to do anything if there is no associated data or it will be cleaned up automatically.

```
void (*ReScanCustomScan) (CustomScanState *node);
```

Rewind the current scan to the beginning and prepare to rescan the relation.

```
void (*MarkPosCustomScan) (CustomScanState *node);
```

Save the current scan position so that it can subsequently be restored by the `RestrPosCustomScan` callback. This callback is optional, and need only be supplied if the `CUSTOMPATH_SUPPORT_MARK_RESTORE` flag is set.

```
void (*RestrPosCustomScan) (CustomScanState *node);
```

Restore the previous scan position as saved by the `MarkPosCustomScan` callback. This callback is optional, and need only be supplied if the `CUSTOMPATH_SUPPORT_MARK_RESTORE` flag is set.

```
Size (*EstimateDSMCustomScan) (CustomScanState *node,
                               ParallelContext *pcxt);
```

Estimate the amount of dynamic shared memory that will be required for parallel operation. This may be higher than the amount that will actually be used, but it must not be lower. The return value is in bytes. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution.

```
void (*InitializeDSMCustomScan) (CustomScanState *node,  
                                ParallelContext *pcxt,  
                                void *coordinate);
```

Initialize the dynamic shared memory that will be required for parallel operation; `coordinate` points to an amount of allocated space equal to the return value of `EstimateDSMCustomScan`. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution.

```
void (*InitializeWorkerCustomScan) (CustomScanState *node,  
                                    shm_toc *toc,  
                                    void *coordinate);
```

Initialize a parallel worker's custom state based on the shared state set up in the leader by `InitializeDSMCustomScan`. This callback is optional, and needs only be supplied if this custom path supports parallel execution.

```
void (*ExplainCustomScan) (CustomScanState *node,  
                           List *ancestors,  
                           ExplainState *es);
```

Output additional information for EXPLAIN of a custom-scan plan node. This callback is optional. Common data stored in the `ScanState`, such as the target list and scan relation, will be shown even without this callback, but the callback allows the display of additional, private state.

Chapter 56. Genetic Query Optimizer

Author

Written by Martin Utesch (<utesch@aut.tu-freiberg.de>) for the Institute of Automatic Control at the University of Mining and Technology in Freiberg, Germany.

56.1. Query Handling as a Complex Optimization Problem

Among all relational operators the most difficult one to process and optimize is the *join*. The number of possible query plans grows exponentially with the number of joins in the query. Further optimization effort is caused by the support of a variety of *join methods* (e.g., nested loop, hash join, merge join in Postgres Pro) to process individual joins and a diversity of *indexes* (e.g., B-tree, hash, GiST and GIN in Postgres Pro) as access paths for relations.

The normal Postgres Pro query optimizer performs a *near-exhaustive search* over the space of alternative strategies. This algorithm, first introduced in IBM's System R database, produces a near-optimal join order, but can take an enormous amount of time and memory space when the number of joins in the query grows large. This makes the ordinary Postgres Pro query optimizer inappropriate for queries that join a large number of tables.

The Institute of Automatic Control at the University of Mining and Technology, in Freiberg, Germany, encountered some problems when it wanted to use Postgres Pro as the backend for a decision support knowledge based system for the maintenance of an electrical power grid. The DBMS needed to handle large join queries for the inference machine of the knowledge based system. The number of joins in these queries made using the normal query optimizer infeasible.

In the following we describe the implementation of a *genetic algorithm* to solve the join ordering problem in a manner that is efficient for queries involving large numbers of joins.

56.2. Genetic Algorithms

The genetic algorithm (GA) is a heuristic optimization method which operates through randomized search. The set of possible solutions for the optimization problem is considered as a *population* of *individuals*. The degree of adaptation of an individual to its environment is specified by its *fitness*.

The coordinates of an individual in the search space are represented by *chromosomes*, in essence a set of character strings. A *gene* is a subsection of a chromosome which encodes the value of a single parameter being optimized. Typical encodings for a gene could be *binary* or *integer*.

Through simulation of the evolutionary operations *recombination*, *mutation*, and *selection* new generations of search points are found that show a higher average fitness than their ancestors.

According to the comp.ai.genetic FAQ it cannot be stressed too strongly that a GA is not a pure random search for a solution to a problem. A GA uses stochastic processes, but the result is distinctly non-random (better than random).

56.3. Genetic Query Optimization (GEQO) in Postgres Pro

The GEQO module approaches the query optimization problem as though it were the well-known traveling salesman problem (TSP). Possible query plans are encoded as integer strings. Each string represents the join order from one relation of the query to the next. For example, the join tree

$$\begin{array}{c} \diagup \diagdown \\ \diagup \diagdown \quad 2 \\ \diagup \diagdown \quad 3 \\ 4 \quad 1 \end{array}$$

is encoded by the integer string '4-1-3-2', which means, first join relation '4' and '1', then '3', and then '2', where 1, 2, 3, 4 are relation IDs within the Postgres Pro optimizer.

Specific characteristics of the GEQO implementation in Postgres Pro are:

- Usage of a *steady state* GA (replacement of the least fit individuals in a population, not whole-generational replacement) allows fast convergence towards improved query plans. This is essential for query handling with reasonable time;
- Usage of *edge recombination crossover* which is especially suited to keep edge losses low for the solution of the TSP by means of a GA;
- Mutation as genetic operator is deprecated so that no repair mechanisms are needed to generate legal TSP tours.

Parts of the GEOO module are adapted from D. Whitley's Genitor algorithm.

The GEQO module allows the Postgres Pro query optimizer to support large join queries effectively through non-exhaustive search.

56.3.1. Generating Possible Plans with GEQO

The GEQO planning process uses the standard planner code to generate plans for scans of individual relations. Then join plans are developed using the genetic approach. As shown above, each candidate

join plan is represented by a sequence in which to join the base relations. In the initial stage, the GEQO code simply generates some possible join sequences at random. For each join sequence considered, the standard planner code is invoked to estimate the cost of performing the query using that join sequence. (For each step of the join sequence, all three possible join strategies are considered; and all the initially-determined relation scan plans are available. The estimated cost is the cheapest of these possibilities.) Join sequences with lower estimated cost are considered “more fit” than those with higher cost. The genetic algorithm discards the least fit candidates. Then new candidates are generated by combining genes of more-fit candidates — that is, by using randomly-chosen portions of known low-cost join sequences to create new sequences for consideration. This process is repeated until a preset number of join sequences have been considered; then the best one found at any time during the search is used to generate the finished plan.

This process is inherently nondeterministic, because of the randomized choices made during both the initial population selection and subsequent “mutation” of the best candidates. To avoid surprising changes of the selected plan, each run of the GEQO algorithm restarts its random number generator with the current `geqo_seed` parameter setting. As long as `geqo_seed` and the other GEQO parameters are kept fixed, the same plan will be generated for a given query (and other planner inputs such as statistics). To experiment with different search paths, try changing `geqo_seed`.

56.3.2. Future Implementation Tasks for Postgres Pro GEQO

Work is still needed to improve the genetic algorithm parameter settings. In file `src/backend/optimizer/geqo/geqo_main.c`, routines `gimme_pool_size` and `gimme_number_generations`, we have to find a compromise for the parameter settings to satisfy two competing demands:

- Optimality of the query plan
- Computing time

In the current implementation, the fitness of each candidate join sequence is estimated by running the standard planner's join selection and cost estimation code from scratch. To the extent that different candidates use similar sub-sequences of joins, a great deal of work will be repeated. This could be made significantly faster by retaining cost estimates for sub-joins. The problem is to avoid expending unreasonable amounts of memory on retaining that state.

At a more basic level, it is not clear that solving query optimization with a GA algorithm designed for TSP is appropriate. In the TSP case, the cost associated with any substring (partial tour) is independent of the rest of the tour, but this is certainly not true for query optimization. Thus it is questionable whether edge recombination crossover is the most effective mutation procedure.

Chapter 57. Index Access Method Interface Definition

This chapter defines the interface between the core Postgres Pro system and *index access methods*, which manage individual index types. The core system knows nothing about indexes beyond what is specified here, so it is possible to develop entirely new index types by writing add-on code.

All indexes in Postgres Pro are what are known technically as *secondary indexes*; that is, the index is physically separate from the table file that it describes. Each index is stored as its own physical *relation* and so is described by an entry in the `pg_class` catalog. The contents of an index are entirely under the control of its index access method. In practice, all index access methods divide indexes into standard-size pages so that they can use the regular storage manager and buffer manager to access the index contents. (All the existing index access methods furthermore use the standard page layout described in [Section 63.6](#), and most use the same format for index tuple headers; but these decisions are not forced on an access method.)

An index is effectively a mapping from some data key values to *tuple identifiers*, or TIDs, of row versions (tuples) in the index's parent table. A TID consists of a block number and an item number within that block (see [Section 63.6](#)). This is sufficient information to fetch a particular row version from the table. Indexes are not directly aware that under MVCC, there might be multiple extant versions of the same logical row; to an index, each tuple is an independent object that needs its own index entry. Thus, an update of a row always creates all-new index entries for the row, even if the key values did not change. (HOT tuples are an exception to this statement; but indexes do not deal with those, either.) Index entries for dead tuples are reclaimed (by vacuuming) when the dead tuples themselves are reclaimed.

57.1. Basic API Structure for Indexes

Each index access method is described by a row in the `pg_am` system catalog. The `pg_am` entry specifies a name and a *handler function* for the access method. These entries can be created and deleted using the [CREATE ACCESS METHOD](#) and [DROP ACCESS METHOD](#) SQL commands.

An index access method handler function must be declared to accept a single argument of type `internal` and to return the pseudo-type `index_am_handler`. The argument is a dummy value that simply serves to prevent handler functions from being called directly from SQL commands. The result of the function must be a palloc'd struct of type `IndexAmRoutine`, which contains everything that the core code needs to know to make use of the index access method. The `IndexAmRoutine` struct, also called the access method's *API struct*, includes fields specifying assorted fixed properties of the access method, such as whether it can support multicolumn indexes. More importantly, it contains pointers to support functions for the access method, which do all of the real work to access indexes. These support functions are plain C functions and are not visible or callable at the SQL level. The support functions are described in [Section 57.2](#).

The structure `IndexAmRoutine` is defined thus:

```
typedef struct IndexAmRoutine
{
    NodeTag      type;

    /*
     * Total number of strategies (operators) by which we can traverse/search
     * this AM. Zero if AM does not have a fixed set of strategy assignments.
     */
    uint16       amstrategies;
    /* total number of support functions that this AM uses */
    uint16       amsupport;
    /* does AM support ORDER BY indexed column's value? */
    bool         amcanorder;
    /* does AM support ORDER BY result of an operator on indexed column? */
}
```

```

bool            amcanorderbyop;
/* does AM support backward scanning? */
bool            amcanbackward;
/* does AM support UNIQUE indexes? */
bool            amcanunique;
/* does AM support multi-column indexes? */
bool            amcanmulticol;
/* does AM require scans to have a constraint on the first index column? */
bool            amoptionalkey;
/* does AM handle ScalarArrayOpExpr quals? */
bool            amsearcharray;
/* does AM handle IS NULL/IS NOT NULL quals? */
bool            amsearchnulls;
/* can index storage data type differ from column data type? */
bool            amstorage;
/* can an index of this type be clustered on? */
bool            amclusterable;
/* does AM handle predicate locks? */
bool            ampredlocks;
/* does AM support columns included with clause INCLUDE? */
bool            amcaninclude;
/* type of data stored in index, or InvalidOid if variable */
Oid             amkeytype;

/* interface functions */
ambuild_function ambuild;
ambuildempty_function ambuildempty;
aminert_function aminert;
ambulkdelete_function ambulkdelete;
amvacuumcleanup_function amvacuumcleanup;
amcanreturn_function amcanreturn; /* can be NULL */
amcostestimate_function amcostestimate;
amoptions_function amoptions;
amproperty_function amproperty; /* can be NULL */
amvalidate_function amvalidate;
ambeginscan_function ambeginscan;
amrescan_function amrescan;
amgettupple_function amgettupple; /* can be NULL */
amgetbitmap_function amgetbitmap; /* can be NULL */
amendscan_function amendscan;
ammarkpos_function ammarkpos; /* can be NULL */
amrestrpos_function amrestrpos; /* can be NULL */
} IndexAmRoutine;

```

To be useful, an index access method must also have one or more *operator families* and *operator classes* defined in [pg_opfamily](#), [pg_opclass](#), [pg_amop](#), and [pg_amproc](#). These entries allow the planner to determine what kinds of query qualifications can be used with indexes of this access method. Operator families and classes are described in [Section 36.14](#), which is prerequisite material for reading this chapter.

An individual index is defined by a [pg_class](#) entry that describes it as a physical relation, plus a [pg_index](#) entry that shows the logical content of the index — that is, the set of index columns it has and the semantics of those columns, as captured by the associated operator classes. The index columns (key values) can be either simple columns of the underlying table or expressions over the table rows. The index access method normally has no interest in where the index key values come from (it is always handed precomputed key values) but it will be very interested in the operator class information in [pg_index](#). Both of these catalog entries can be accessed as part of the `Relation` data structure that is passed to all operations on the index.

Some of the flag fields of `IndexAmRoutine` have nonobvious implications. The requirements of `amcanunique` are discussed in [Section 57.5](#). The `amcanmulticol` flag asserts that the access method supports multicolumn indexes, while `amoptionalkey` asserts that it allows scans where no indexable restriction clause is given for the first index column. When `amcanmulticol` is false, `amoptionalkey` essentially says whether the access method supports full-index scans without any restriction clause. Access methods that support multiple index columns *must* support scans that omit restrictions on any or all of the columns after the first; however they are permitted to require some restriction to appear for the first index column, and this is signaled by setting `amoptionalkey` false. One reason that an index AM might set `amoptionalkey` false is if it doesn't index null values. Since most indexable operators are strict and hence cannot return true for null inputs, it is at first sight attractive to not store index entries for null values: they could never be returned by an index scan anyway. However, this argument fails when an index scan has no restriction clause for a given index column. In practice this means that indexes that have `amoptionalkey` true must index nulls, since the planner might decide to use such an index with no scan keys at all. A related restriction is that an index access method that supports multiple index columns *must* support indexing null values in columns after the first, because the planner will assume the index can be used for queries that do not restrict these columns. For example, consider an index on (a,b) and a query with `WHERE a = 4`. The system will assume the index can be used to scan for rows with `a = 4`, which is wrong if the index omits rows where `b` is null. It is, however, OK to omit rows where the first indexed column is null. An index access method that does index nulls may also set `amsearchnulls`, indicating that it supports `IS NULL` and `IS NOT NULL` clauses as search conditions.

57.2. Index Access Method Functions

The index construction and maintenance functions that an index access method must provide in `IndexAmRoutine` are:

```
IndexBuildResult *
ambuild (Relation heapRelation,
         Relation indexRelation,
         IndexInfo *indexInfo);
```

Build a new index. The index relation has been physically created, but is empty. It must be filled in with whatever fixed data the access method requires, plus entries for all tuples already existing in the table. Ordinarily the `ambuild` function will call `IndexBuildHeapScan()` to scan the table for existing tuples and compute the keys that need to be inserted into the index. The function must return a palloc'd struct containing statistics about the new index.

```
void
ambuildempty (Relation indexRelation);
```

Build an empty index, and write it to the initialization fork (`INIT_FORKNUM`) of the given relation. This method is called only for unlogged indexes; the empty index written to the initialization fork will be copied over the main relation fork on each server restart.

```
bool
aminert (Relation indexRelation,
         Datum *values,
         bool *isnull,
         ItemPointer heap_tid,
         Relation heapRelation,
         IndexUniqueCheck checkUnique);
```

Insert a new tuple into an existing index. The `values` and `isnull` arrays give the key values to be indexed, and `heap_tid` is the TID to be indexed. If the access method supports unique indexes (its `amcanunique` flag is true) then `checkUnique` indicates the type of uniqueness check to perform. This varies depending on whether the unique constraint is deferrable; see [Section 57.5](#) for details. Normally the access method only needs the `heapRelation` parameter when performing uniqueness checking (since then it will have to look into the heap to verify tuple liveness).

The function's Boolean result value is significant only when `checkUnique` is `UNIQUE_CHECK_PARTIAL`. In this case a TRUE result means the new entry is known unique, whereas FALSE means it might be non-

unique (and a deferred uniqueness check must be scheduled). For other cases a constant FALSE result is recommended.

Some indexes might not index all tuples. If the tuple is not to be indexed, `amininsert` should just return without doing anything.

```
IndexBulkDeleteResult *
ambulkdelete (IndexVacuumInfo *info,
              IndexBulkDeleteResult *stats,
              IndexBulkDeleteCallback callback,
              void *callback_state);
```

Delete tuple(s) from the index. This is a “bulk delete” operation that is intended to be implemented by scanning the whole index and checking each entry to see if it should be deleted. The passed-in `callback` function must be called, in the style `callback(TID, callback_state)` returns `bool`, to determine whether any particular index entry, as identified by its referenced TID, is to be deleted. Must return either NULL or a palloc'd struct containing statistics about the effects of the deletion operation. It is OK to return NULL if no information needs to be passed on to `amvacuumcleanup`.

Because of limited `maintenance_work_mem`, `ambulkdelete` might need to be called more than once when many tuples are to be deleted. The `stats` argument is the result of the previous call for this index (it is NULL for the first call within a VACUUM operation). This allows the AM to accumulate statistics across the whole operation. Typically, `ambulkdelete` will modify and return the same struct if the passed `stats` is not null.

```
IndexBulkDeleteResult *
amvacuumcleanup (IndexVacuumInfo *info,
                 IndexBulkDeleteResult *stats);
```

Clean up after a VACUUM operation (zero or more `ambulkdelete` calls). This does not have to do anything beyond returning index statistics, but it might perform bulk cleanup such as reclaiming empty index pages. `stats` is whatever the last `ambulkdelete` call returned, or NULL if `ambulkdelete` was not called because no tuples needed to be deleted. If the result is not NULL it must be a palloc'd struct. The statistics it contains will be used to update `pg_class`, and will be reported by VACUUM if VERBOSE is given. It is OK to return NULL if the index was not changed at all during the VACUUM operation, but otherwise correct stats should be returned.

As of PostgreSQL 8.4, `amvacuumcleanup` will also be called at completion of an ANALYZE operation. In this case `stats` is always NULL and any return value will be ignored. This case can be distinguished by checking `info->analyze_only`. It is recommended that the access method do nothing except post-insert cleanup in such a call, and that only in an autovacuum worker process.

```
bool
amcanreturn (Relation indexRelation, int attno);
```

Check whether the index can support *index-only scans* on the given column, by returning the indexed column values for an index entry in the form of an `IndexTuple`. The attribute number is 1-based, i.e., the first column's `attno` is 1. Returns TRUE if supported, else FALSE. If the access method does not support index-only scans at all, the `amcanreturn` field in its `IndexAmRoutine` struct can be set to NULL.

```
void
amcostestimate (PlannerInfo *root,
                IndexPath *path,
                double loop_count,
                Cost *indexStartupCost,
                Cost *indexTotalCost,
                Selectivity *indexSelectivity,
                double *indexCorrelation);
```

Estimate the costs of an index scan. This function is described fully in [Section 57.6](#), below.

```
bytea *
```

```
amoptions (ArrayType *reloptions,
          bool validate);
```

Parse and validate the reloptions array for an index. This is called only when a non-null reloptions array exists for the index. *reloptions* is a text array containing entries of the form *name=value*. The function should construct a *bytea* value, which will be copied into the *rd_options* field of the index's relcache entry. The data contents of the *bytea* value are open for the access method to define; most of the standard access methods use struct *StdRdOptions*. When *validate* is true, the function should report a suitable error message if any of the options are unrecognized or have invalid values; when *validate* is false, invalid entries should be silently ignored. (*validate* is false when loading options already stored in *pg_catalog*; an invalid entry could only be found if the access method has changed its rules for options, and in that case ignoring obsolete entries is appropriate.) It is OK to return NULL if default behavior is wanted.

```
bool
amproperty (Oid index_oid, int attno,
            IndexAMProperty prop, const char *propname,
            bool *res, bool *isnull);
```

The *amproperty* method allows index access methods to override the default behavior of *pg_index_column_has_property* and related functions. If the access method does not have any special behavior for index property inquiries, the *amproperty* field in its *IndexAmRoutine* struct can be set to NULL. Otherwise, the *amproperty* method will be called with *index_oid* and *attno* both zero for *pg_indexam_has_property* calls, or with *index_oid* valid and *attno* zero for *pg_index_has_property* calls, or with *index_oid* valid and *attno* greater than zero for *pg_index_column_has_property* calls. *prop* is an enum value identifying the property being tested, while *propname* is the original property name string. If the core code does not recognize the property name then *prop* is *AMPROP_UNKNOWN*. Access methods can define custom property names by checking *propname* for a match (use *pg_strcasecmp* to match, for consistency with the core code); for names known to the core code, it's better to inspect *prop*. If the *amproperty* method returns true then it has determined the property test result: it must set **res* to the boolean value to return, or set **isnull* to true to return a NULL. (Both of the referenced variables are initialized to false before the call.) If the *amproperty* method returns false then the core code will proceed with its normal logic for determining the property test result.

Access methods that support ordering operators should implement *AMPROP_DISTANCE_ORDERABLE* property testing, as the core code does not know how to do that and will return NULL. It may also be advantageous to implement *AMPROP_RETURNABLE* testing, if that can be done more cheaply than by opening the index and calling *amcanreturn*, which is the core code's default behavior. The default behavior should be satisfactory for all other standard properties.

```
bool
amvalidate (Oid opclassoid);
```

Validate the catalog entries for the specified operator class, so far as the access method can reasonably do that. For example, this might include testing that all required support functions are provided. The *amvalidate* function must return false if the opclass is invalid. Problems should be reported with *ereport* messages.

The purpose of an index, of course, is to support scans for tuples matching an indexable *WHERE* condition, often called a *qualifier* or *scan key*. The semantics of index scanning are described more fully in [Section 57.3](#), below. An index access method can support “plain” index scans, “bitmap” index scans, or both. The scan-related functions that an index access method must or may provide are:

```
IndexScanDesc
ambeginscan (Relation indexRelation,
            int nkeys,
            int norderbys);
```

Prepare for an index scan. The *nkeys* and *norderbys* parameters indicate the number of quals and ordering operators that will be used in the scan; these may be useful for space allocation

purposes. Note that the actual values of the scan keys aren't provided yet. The result must be a palloc'd struct. For implementation reasons the index access method *must* create this struct by calling `RelationGetIndexScan()`. In most cases `ambeginscan` does little beyond making that call and perhaps acquiring locks; the interesting parts of index-scan startup are in `amrescan`.

```
void
amrescan (IndexScanDesc scan,
          ScanKey keys,
          int nkeys,
          ScanKey orderbys,
          int norderbys);
```

Start or restart an index scan, possibly with new scan keys. (To restart using previously-passed keys, NULL is passed for `keys` and/or `orderbys`.) Note that it is not allowed for the number of keys or order-by operators to be larger than what was passed to `ambeginscan`. In practice the restart feature is used when a new outer tuple is selected by a nested-loop join and so a new key comparison value is needed, but the scan key structure remains the same.

```
boolean
amgettupple (IndexScanDesc scan,
             ScanDirection direction);
```

Fetch the next tuple in the given scan, moving in the given direction (forward or backward in the index). Returns TRUE if a tuple was obtained, FALSE if no matching tuples remain. In the TRUE case the tuple TID is stored into the `scan` structure. Note that “success” means only that the index contains an entry that matches the scan keys, not that the tuple necessarily still exists in the heap or will pass the caller's snapshot test. On success, `amgettupple` must also set `scan->xs_recheck` to TRUE or FALSE. FALSE means it is certain that the index entry matches the scan keys. TRUE means this is not certain, and the conditions represented by the scan keys must be rechecked against the heap tuple after fetching it. This provision supports “lossy” index operators. Note that rechecking will extend only to the scan conditions; a partial index predicate (if any) is never rechecked by `amgettupple` callers.

If the index supports [index-only scans](#) (i.e., `amcanreturn` returns TRUE for it), then on success the AM must also check `scan->xs_want_itup`, and if that is true it must return the original indexed data for the index entry, in the form of an `IndexTuple` pointer stored at `scan->xs_itup`, with tuple descriptor `scan->xs_itupdesc`. (Management of the data referenced by the pointer is the access method's responsibility. The data must remain good at least until the next `amgettupple`, `amrescan`, or `amendscan` call for the scan.)

The `amgettupple` function need only be provided if the access method supports “plain” index scans. If it doesn't, the `amgettupple` field in its `IndexAmRoutine` struct must be set to NULL.

```
int64
amgetbitmap (IndexScanDesc scan,
             TIDBitmap *tbm);
```

Fetch all tuples in the given scan and add them to the caller-supplied `TIDBitmap` (that is, OR the set of tuple IDs into whatever set is already in the bitmap). The number of tuples fetched is returned (this might be just an approximate count, for instance some AMs do not detect duplicates). While inserting tuple IDs into the bitmap, `amgetbitmap` can indicate that rechecking of the scan conditions is required for specific tuple IDs. This is analogous to the `xs_recheck` output parameter of `amgettupple`. Note: in the current implementation, support for this feature is conflated with support for lossy storage of the bitmap itself, and therefore callers recheck both the scan conditions and the partial index predicate (if any) for recheckable tuples. That might not always be true, however. `amgetbitmap` and `amgettupple` cannot be used in the same index scan; there are other restrictions too when using `amgetbitmap`, as explained in [Section 57.3](#).

The `amgetbitmap` function need only be provided if the access method supports “bitmap” index scans. If it doesn't, the `amgetbitmap` field in its `IndexAmRoutine` struct must be set to NULL.

```
void
```

```
amendscan (IndexScanDesc scan);
```

End a scan and release resources. The `scan` struct itself should not be freed, but any locks or pins taken internally by the access method must be released, as well as any other memory allocated by `ambeginscan` and other scan-related functions.

```
void  
ammarkpos (IndexScanDesc scan);
```

Mark current scan position. The access method need only support one remembered scan position per scan.

The `ammarkpos` function need only be provided if the access method supports ordered scans. If it doesn't, the `ammarkpos` field in its `IndexAmRoutine` struct may be set to `NULL`.

```
void  
amrestrpos (IndexScanDesc scan);
```

Restore the scan to the most recently marked position.

The `amrestrpos` function need only be provided if the access method supports ordered scans. If it doesn't, the `amrestrpos` field in its `IndexAmRoutine` struct may be set to `NULL`.

57.3. Index Scanning

In an index scan, the index access method is responsible for regurgitating the TIDs of all the tuples it has been told about that match the *scan keys*. The access method is *not* involved in actually fetching those tuples from the index's parent table, nor in determining whether they pass the scan's time qualification test or other conditions.

A scan key is the internal representation of a `WHERE` clause of the form *index_key operator constant*, where the index key is one of the columns of the index and the operator is one of the members of the operator family associated with that index column. An index scan has zero or more scan keys, which are implicitly ANDed — the returned tuples are expected to satisfy all the indicated conditions.

The access method can report that the index is *lossy*, or requires rechecks, for a particular query. This implies that the index scan will return all the entries that pass the scan key, plus possibly additional entries that do not. The core system's index-scan machinery will then apply the index conditions again to the heap tuple to verify whether or not it really should be selected. If the recheck option is not specified, the index scan must return exactly the set of matching entries.

Note that it is entirely up to the access method to ensure that it correctly finds all and only the entries passing all the given scan keys. Also, the core system will simply hand off all the `WHERE` clauses that match the index keys and operator families, without any semantic analysis to determine whether they are redundant or contradictory. As an example, given `WHERE x > 4 AND x > 14` where `x` is a b-tree indexed column, it is left to the b-tree `amrescan` function to realize that the first scan key is redundant and can be discarded. The extent of preprocessing needed during `amrescan` will depend on the extent to which the index access method needs to reduce the scan keys to a “normalized” form.

Some access methods return index entries in a well-defined order, others do not. There are actually two different ways that an access method can support sorted output:

- Access methods that always return entries in the natural ordering of their data (such as btree) should set `amcanorder` to `true`. Currently, such access methods must use btree-compatible strategy numbers for their equality and ordering operators.
- Access methods that support ordering operators should set `amcanorderbyop` to `true`. This indicates that the index is capable of returning entries in an order satisfying `ORDER BY index_key operator constant`. Scan modifiers of that form can be passed to `amrescan` as described previously.

The `amgettupple` function has a `direction` argument, which can be either `ForwardScanDirection` (the normal case) or `BackwardScanDirection`. If the first call after `amrescan` specifies

`BackwardScanDirection`, then the set of matching index entries is to be scanned back-to-front rather than in the normal front-to-back direction, so `amgettupple` must return the last matching tuple in the index, rather than the first one as it normally would. (This will only occur for access methods that set `amcanorder` to true.) After the first call, `amgettupple` must be prepared to advance the scan in either direction from the most recently returned entry. (But if `amcanbackward` is false, all subsequent calls will have the same direction as the first one.)

Access methods that support ordered scans must support “marking” a position in a scan and later returning to the marked position. The same position might be restored multiple times. However, only one position need be remembered per scan; a new `ammarkpos` call overrides the previously marked position. An access method that does not support ordered scans need not provide `ammarkpos` and `amrestrpos` functions in `IndexAmRoutine`; set those pointers to NULL instead.

Both the scan position and the mark position (if any) must be maintained consistently in the face of concurrent insertions or deletions in the index. It is OK if a freshly-inserted entry is not returned by a scan that would have found the entry if it had existed when the scan started, or for the scan to return such an entry upon rescanning or backing up even though it had not been returned the first time through. Similarly, a concurrent delete might or might not be reflected in the results of a scan. What is important is that insertions or deletions not cause the scan to miss or multiply return entries that were not themselves being inserted or deleted.

If the index stores the original indexed data values (and not some lossy representation of them), it is useful to support [index-only scans](#), in which the index returns the actual data not just the TID of the heap tuple. This will only avoid I/O if the visibility map shows that the TID is on an all-visible page; else the heap tuple must be visited anyway to check MVCC visibility. But that is no concern of the access method's.

Instead of using `amgettupple`, an index scan can be done with `amgetbitmap` to fetch all tuples in one call. This can be noticeably more efficient than `amgettupple` because it allows avoiding lock/unlock cycles within the access method. In principle `amgetbitmap` should have the same effects as repeated `amgettupple` calls, but we impose several restrictions to simplify matters. First of all, `amgetbitmap` returns all tuples at once and marking or restoring scan positions isn't supported. Secondly, the tuples are returned in a bitmap which doesn't have any specific ordering, which is why `amgetbitmap` doesn't take a `direction` argument. (Ordering operators will never be supplied for such a scan, either.) Also, there is no provision for index-only scans with `amgetbitmap`, since there is no way to return the contents of index tuples. Finally, `amgetbitmap` does not guarantee any locking of the returned tuples, with implications spelled out in [Section 57.4](#).

Note that it is permitted for an access method to implement only `amgetbitmap` and not `amgettupple`, or vice versa, if its internal implementation is unsuited to one API or the other.

57.4. Index Locking Considerations

Index access methods must handle concurrent updates of the index by multiple processes. The core Postgres Pro system obtains `AccessShareLock` on the index during an index scan, and `RowExclusiveLock` when updating the index (including plain `VACUUM`). Since these lock types do not conflict, the access method is responsible for handling any fine-grained locking it might need. An exclusive lock on the index as a whole will be taken only during index creation, destruction, or `REINDEX`.

Building an index type that supports concurrent updates usually requires extensive and subtle analysis of the required behavior.

Aside from the index's own internal consistency requirements, concurrent updates create issues about consistency between the parent table (the *heap*) and the index. Because Postgres Pro separates accesses and updates of the heap from those of the index, there are windows in which the index might be inconsistent with the heap. We handle this problem with the following rules:

- A new heap entry is made before making its index entries. (Therefore a concurrent index scan is likely to fail to see the heap entry. This is okay because the index reader would be uninterested in an uncommitted row anyway. But see [Section 57.5](#).)

- When a heap entry is to be deleted (by `VACUUM`), all its index entries must be removed first.
- An index scan must maintain a pin on the index page holding the item last returned by `amgettuple`, and `ambulkdelete` cannot delete entries from pages that are pinned by other backends. The need for this rule is explained below.

Without the third rule, it is possible for an index reader to see an index entry just before it is removed by `VACUUM`, and then to arrive at the corresponding heap entry after that was removed by `VACUUM`. This creates no serious problems if that item number is still unused when the reader reaches it, since an empty item slot will be ignored by `heap_fetch()`. But what if a third backend has already re-used the item slot for something else? When using an MVCC-compliant snapshot, there is no problem because the new occupant of the slot is certain to be too new to pass the snapshot test. However, with a non-MVCC-compliant snapshot (such as `SnapshotAny`), it would be possible to accept and return a row that does not in fact match the scan keys. We could defend against this scenario by requiring the scan keys to be rechecked against the heap row in all cases, but that is too expensive. Instead, we use a pin on an index page as a proxy to indicate that the reader might still be “in flight” from the index entry to the matching heap entry. Making `ambulkdelete` block on such a pin ensures that `VACUUM` cannot delete the heap entry before the reader is done with it. This solution costs little in run time, and adds blocking overhead only in the rare cases where there actually is a conflict.

This solution requires that index scans be “synchronous”: we have to fetch each heap tuple immediately after scanning the corresponding index entry. This is expensive for a number of reasons. An “asynchronous” scan in which we collect many TIDs from the index, and only visit the heap tuples sometime later, requires much less index locking overhead and can allow a more efficient heap access pattern. Per the above analysis, we must use the synchronous approach for non-MVCC-compliant snapshots, but an asynchronous scan is workable for a query using an MVCC snapshot.

In an `amgetbitmap` index scan, the access method does not keep an index pin on any of the returned tuples. Therefore it is only safe to use such scans with MVCC-compliant snapshots.

When the `ampredlocks` flag is not set, any scan using that index access method within a serializable transaction will acquire a nonblocking predicate lock on the full index. This will generate a read-write conflict with the insert of any tuple into that index by a concurrent serializable transaction. If certain patterns of read-write conflicts are detected among a set of concurrent serializable transactions, one of those transactions may be canceled to protect data integrity. When the flag is set, it indicates that the index access method implements finer-grained predicate locking, which will tend to reduce the frequency of such transaction cancellations.

57.5. Index Uniqueness Checks

Postgres Pro enforces SQL uniqueness constraints using *unique indexes*, which are indexes that disallow multiple entries with identical keys. An access method that supports this feature sets `amcanunique` true. (At present, only b-tree supports it.) Columns which are present in the `INCLUDE` clause are not used to enforce uniqueness.

Because of MVCC, it is always necessary to allow duplicate entries to exist physically in an index: the entries might refer to successive versions of a single logical row. The behavior we actually want to enforce is that no MVCC snapshot could include two rows with equal index keys. This breaks down into the following cases that must be checked when inserting a new row into a unique index:

- If a conflicting valid row has been deleted by the current transaction, it's okay. (In particular, since an `UPDATE` always deletes the old row version before inserting the new version, this will allow an `UPDATE` on a row without changing the key.)
- If a conflicting row has been inserted by an as-yet-uncommitted transaction, the would-be inserter must wait to see if that transaction commits. If it rolls back then there is no conflict. If it commits without deleting the conflicting row again, there is a uniqueness violation. (In practice we just wait for the other transaction to end and then redo the visibility check in toto.)
- Similarly, if a conflicting valid row has been deleted by an as-yet-uncommitted transaction, the would-be inserter must wait for that transaction to commit or abort, and then repeat the test.

Furthermore, immediately before reporting a uniqueness violation according to the above rules, the access method must recheck the liveness of the row being inserted. If it is committed dead then no violation should be reported. (This case cannot occur during the ordinary scenario of inserting a row that's just been created by the current transaction. It can happen during `CREATE UNIQUE INDEX CONCURRENTLY`, however.)

We require the index access method to apply these tests itself, which means that it must reach into the heap to check the commit status of any row that is shown to have a duplicate key according to the index contents. This is without a doubt ugly and non-modular, but it saves redundant work: if we did a separate probe then the index lookup for a conflicting row would be essentially repeated while finding the place to insert the new row's index entry. What's more, there is no obvious way to avoid race conditions unless the conflict check is an integral part of insertion of the new index entry.

If the unique constraint is deferrable, there is additional complexity: we need to be able to insert an index entry for a new row, but defer any uniqueness-violation error until end of statement or even later. To avoid unnecessary repeat searches of the index, the index access method should do a preliminary uniqueness check during the initial insertion. If this shows that there is definitely no conflicting live tuple, we are done. Otherwise, we schedule a recheck to occur when it is time to enforce the constraint. If, at the time of the recheck, both the inserted tuple and some other tuple with the same key are live, then the error must be reported. (Note that for this purpose, “live” actually means “any tuple in the index entry's HOT chain is live”.) To implement this, the `aminert` function is passed a `checkUnique` parameter having one of the following values:

- `UNIQUE_CHECK_NO` indicates that no uniqueness checking should be done (this is not a unique index).
- `UNIQUE_CHECK_YES` indicates that this is a non-deferrable unique index, and the uniqueness check must be done immediately, as described above.
- `UNIQUE_CHECK_PARTIAL` indicates that the unique constraint is deferrable. Postgres Pro will use this mode to insert each row's index entry. The access method must allow duplicate entries into the index, and report any potential duplicates by returning `FALSE` from `aminert`. For each row for which `FALSE` is returned, a deferred recheck will be scheduled.

The access method must identify any rows which might violate the unique constraint, but it is not an error for it to report false positives. This allows the check to be done without waiting for other transactions to finish; conflicts reported here are not treated as errors and will be rechecked later, by which time they may no longer be conflicts.

- `UNIQUE_CHECK_EXISTING` indicates that this is a deferred recheck of a row that was reported as a potential uniqueness violation. Although this is implemented by calling `aminert`, the access method must *not* insert a new index entry in this case. The index entry is already present. Rather, the access method must check to see if there is another live index entry. If so, and if the target row is also still live, report error.

It is recommended that in a `UNIQUE_CHECK_EXISTING` call, the access method further verify that the target row actually does have an existing entry in the index, and report error if not. This is a good idea because the index tuple values passed to `aminert` will have been recomputed. If the index definition involves functions that are not really immutable, we might be checking the wrong area of the index. Checking that the target row is found in the recheck verifies that we are scanning for the same tuple values as were used in the original insertion.

57.6. Index Cost Estimation Functions

The `amcostestimate` function is given information describing a possible index scan, including lists of `WHERE` and `ORDER BY` clauses that have been determined to be usable with the index. It must return estimates of the cost of accessing the index and the selectivity of the `WHERE` clauses (that is, the fraction of parent-table rows that will be retrieved during the index scan). For simple cases, nearly all the work of the cost estimator can be done by calling standard routines in the optimizer; the point of having an `amcostestimate` function is to allow index access methods to provide index-type-specific knowledge, in case it is possible to improve on the standard estimates.

Each `amcostestimate` function must have the signature:

```
void  
amcostestimate (PlannerInfo *root,  
                IndexPath *path,  
                double loop_count,  
                Cost *indexStartupCost,  
                Cost *indexTotalCost,  
                Selectivity *indexSelectivity,  
                double *indexCorrelation);
```

The first three parameters are inputs:

root

The planner's information about the query being processed.

path

The index access path being considered. All fields except cost and selectivity values are valid.

loop_count

The number of repetitions of the index scan that should be factored into the cost estimates. This will typically be greater than one when considering a parameterized scan for use in the inside of a nestloop join. Note that the cost estimates should still be for just one scan; a larger *loop_count* means that it may be appropriate to allow for some caching effects across multiple scans.

The last four parameters are pass-by-reference outputs:

**indexStartupCost*

Set to cost of index start-up processing

**indexTotalCost*

Set to total cost of index processing

**indexSelectivity*

Set to index selectivity

**indexCorrelation*

Set to correlation coefficient between index scan order and underlying table's order

Note that cost estimate functions must be written in C, not in SQL or any available procedural language, because they must access internal data structures of the planner/optimizer.

The index access costs should be computed using the parameters used by `src/backend/optimizer/path/costsize.c`: a sequential disk block fetch has cost `seq_page_cost`, a nonsequential fetch has cost `random_page_cost`, and the cost of processing one index row should usually be taken as `cpu_index_tuple_cost`. In addition, an appropriate multiple of `cpu_operator_cost` should be charged for any comparison operators invoked during index processing (especially evaluation of the `indexquals` themselves).

The access costs should include all disk and CPU costs associated with scanning the index itself, but *not* the costs of retrieving or processing the parent-table rows that are identified by the index.

The “start-up cost” is the part of the total scan cost that must be expended before we can begin to fetch the first row. For most indexes this can be taken as zero, but an index type with a high start-up cost might want to set it nonzero.

The *indexSelectivity* should be set to the estimated fraction of the parent table rows that will be retrieved during the index scan. In the case of a lossy query, this will typically be higher than the fraction of rows that actually pass the given qual conditions.

The *indexCorrelation* should be set to the correlation (ranging between -1.0 and 1.0) between the index order and the table order. This is used to adjust the estimate for the cost of fetching rows from the parent table.

When *loop_count* is greater than one, the returned numbers should be averages expected for any one scan of the index.

Cost Estimation

A typical cost estimator will proceed as follows:

1. Estimate and return the fraction of parent-table rows that will be visited based on the given qual conditions. In the absence of any index-type-specific knowledge, use the standard optimizer function `clauselist_selectivity()`:

```
*indexSelectivity = clauselist_selectivity(root, path->indexquals,
                                           path->indexinfo->rel->relid,
                                           JOIN_INNER, NULL);
```

2. Estimate the number of index rows that will be visited during the scan. For many index types this is the same as *indexSelectivity* times the number of rows in the index, but it might be more. (Note that the index's size in pages and rows is available from the `path->indexinfo` struct.)
3. Estimate the number of index pages that will be retrieved during the scan. This might be just *indexSelectivity* times the index's size in pages.
4. Compute the index access cost. A generic estimator might do this:

```
/*
 * Our generic assumption is that the index pages will be read
 * sequentially, so they cost seq_page_cost each, not random_page_cost.
 * Also, we charge for evaluation of the indexquals at each index row.
 * All the costs are assumed to be paid incrementally during the scan.
 */
cost_qual_eval(&index_qual_cost, path->indexquals, root);
*indexStartupCost = index_qual_cost.startup;
*indexTotalCost = seq_page_cost * numIndexPages +
    (cpu_index_tuple_cost + index_qual_cost.per_tuple) * numIndexTuples;
```

However, the above does not account for amortization of index reads across repeated index scans.

5. Estimate the index correlation. For a simple ordered index on a single field, this can be retrieved from `pg_statistic`. If the correlation is not known, the conservative estimate is zero (no correlation).

Examples of cost estimator functions can be found in `src/backend/utils/adt/selfuncs.c`.

Chapter 58. Generic WAL Records

Although all built-in WAL-logged modules have their own types of WAL records, there is also a generic WAL record type, which describes changes to pages in a generic way. This is useful for extensions that provide custom access methods, because they cannot register their own WAL redo routines.

The API for constructing generic WAL records is defined in `access/generic_xlog.h` and implemented in `access/transam/generic_xlog.c`.

To perform a WAL-logged data update using the generic WAL record facility, follow these steps:

1. `state = GenericXLogStart(relation)` — start construction of a generic WAL record for the given relation.
2. `page = GenericXLogRegisterBuffer(state, buffer, flags)` — register a buffer to be modified within the current generic WAL record. This function returns a pointer to a temporary copy of the buffer's page, where modifications should be made. (Do not modify the buffer's contents directly.) The third argument is a bitmask of flags applicable to the operation. Currently the only such flag is `GENERIC_XLOG_FULL_IMAGE`, which indicates that a full-page image rather than a delta update should be included in the WAL record. Typically this flag would be set if the page is new or has been rewritten completely. `GenericXLogRegisterBuffer` can be repeated if the WAL-logged action needs to modify multiple pages.
3. Apply modifications to the page images obtained in the previous step.
4. `GenericXLogFinish(state)` — apply the changes to the buffers and emit the generic WAL record.

WAL record construction can be canceled between any of the above steps by calling `GenericXLogAbort(state)`. This will discard all changes to the page image copies.

Please note the following points when using the generic WAL record facility:

- No direct modifications of buffers are allowed! All modifications must be done in copies acquired from `GenericXLogRegisterBuffer()`. In other words, code that makes generic WAL records should never call `BufferGetPage()` for itself. However, it remains the caller's responsibility to pin/unpin and lock/unlock the buffers at appropriate times. Exclusive lock must be held on each target buffer from before `GenericXLogRegisterBuffer()` until after `GenericXLogFinish()`.
- Registrations of buffers (step 2) and modifications of page images (step 3) can be mixed freely, i.e., both steps may be repeated in any sequence. Keep in mind that buffers should be registered in the same order in which locks are to be obtained on them during replay.
- The maximum number of buffers that can be registered for a generic WAL record is `MAX_GENERIC_XLOG_PAGES`. An error will be thrown if this limit is exceeded.
- Generic WAL assumes that the pages to be modified have standard layout, and in particular that there is no useful data between `pd_lower` and `pd_upper`.
- Since you are modifying copies of buffer pages, `GenericXLogStart()` does not start a critical section. Thus, you can safely do memory allocation, error throwing, etc. between `GenericXLogStart()` and `GenericXLogFinish()`. The only actual critical section is present inside `GenericXLogFinish()`. There is no need to worry about calling `GenericXLogAbort()` during an error exit, either.
- `GenericXLogFinish()` takes care of marking buffers dirty and setting their LSNs. You do not need to do this explicitly.
- For unlogged relations, everything works the same except that no actual WAL record is emitted. Thus, you typically do not need to do any explicit checks for unlogged relations.
- The generic WAL redo function will acquire exclusive locks to buffers in the same order as they were registered. After redoing all changes, the locks will be released in the same order.
- If `GENERIC_XLOG_FULL_IMAGE` is not specified for a registered buffer, the generic WAL record contains a delta between the old and the new page images. This delta is based on byte-by-byte

comparison. This is not very compact for the case of moving data within a page, and might be improved in the future.

Chapter 59. GiST Indexes

59.1. Introduction

GiST stands for Generalized Search Tree. It is a balanced, tree-structured access method, that acts as a base template in which to implement arbitrary indexing schemes. B-trees, R-trees and many other indexing schemes can be implemented in GiST.

One advantage of GiST is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from the University of California at Berkeley's GiST Indexing Project [web site](#) and Marcel Kornacker's thesis, [Access Methods for Next-Generation Database Systems](#). The GiST implementation in Postgres Pro is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their [web site](#).

59.2. Built-in Operator Classes

The core Postgres Pro distribution includes the GiST operator classes shown in [Table 59.1](#). (Some of the optional modules described in [Appendix F](#) provide additional GiST operator classes.)

Table 59.1. Built-in GiST Operator Classes

Name	Indexed Data Type	Indexable Operators	Ordering Operators
box_ops	box	&& &> &< &< >> << << <@ &> @ &> >> ~ ~=	
circle_ops	circle	&& &> &< &< >> << << <@ &> @ &> >> ~ ~=	<->
inet_ops	inet, cidr	&& >> >>= > >= <> << <<= < <= =	
point_ops	point	>> >^ << <@ <@ <@ <^ ~=	<->
poly_ops	polygon	&& &> &< &< >> << << <@ &> @ &> >> ~ ~=	<->
range_ops	any range type	&& &> &< >> << <@ - - = &> @>	
tsquery_ops	tsquery	<@ @>	
tsvector_ops	tsvector	@@	

For historical reasons, the `inet_ops` operator class is not the default class for types `inet` and `cidr`. To use it, mention the class name in `CREATE INDEX`, for example

```
CREATE INDEX ON my_table USING GIST (my_inet_column inet_ops);
```

59.3. Extensibility

Traditionally, implementing a new index access method meant a lot of difficult work. It was necessary to understand the inner workings of the database, such as the lock manager and Write-Ahead Log. The GiST interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GiST layer itself takes care of concurrency, logging and searching the tree structure.

This extensibility should not be confused with the extensibility of the other standard search trees in terms of the data they can handle. For example, Postgres Pro supports extensible B-trees and hash indexes. That means that you can use Postgres Pro to build a B-tree or hash over any data type you want. But B-trees only support range predicates (`<`, `=`, `>`), and hash indexes only support equality queries.

So if you index, say, an image collection with a Postgres Pro B-tree, you can only issue queries such as “is imagex equal to imagey”, “is imagex less than imagey” and “is imagex greater than imagey”. Depending on how you define “equals”, “less than” and “greater than” in this context, this could be useful. However, by using a GiST based index, you could create ways to ask domain-specific questions, perhaps “find all images of horses” or “find all over-exposed images”.

All it takes to get a GiST access method up and running is to implement several user-defined methods, which define the behavior of keys in the tree. Of course these methods have to be pretty fancy to support fancy queries, but for all the standard queries (B-trees, R-trees, etc.) they're relatively straightforward. In short, GiST combines extensibility along with generality, code reuse, and a clean interface.

There are seven methods that an index operator class for GiST must provide, and two that are optional. Correctness of the index is ensured by proper implementation of the `same`, `consistent` and `union` methods, while efficiency (size and speed) of the index will depend on the `penalty` and `picksplit` methods. The remaining two basic methods are `compress` and `decompress`, which allow an index to have internal tree data of a different type than the data it indexes. The leaves are to be of the indexed data type, while the other tree nodes can be of any C struct (but you still have to follow Postgres Pro data type rules here, see about `varlena` for variable sized data). If the tree's internal data type exists at the SQL level, the `STORAGE` option of the `CREATE OPERATOR CLASS` command can be used. The optional eighth method is `distance`, which is needed if the operator class wishes to support ordered scans (nearest-neighbor searches). The optional ninth method `fetch` is needed if the operator class wishes to support index-only scans.

`consistent`

Given an index entry `p` and a query value `q`, this function determines whether the index entry is “consistent” with the query; that is, could the predicate “`indexed_column indexable_operator q`” be true for any row represented by the index entry? For a leaf index entry this is equivalent to testing the indexable condition, while for an internal tree node this determines whether it is necessary to scan the subtree of the index represented by the tree node. When the result is `true`, a `recheck` flag must also be returned. This indicates whether the predicate is certainly true or only possibly true. If `recheck = false` then the index has tested the predicate condition exactly, whereas if `recheck = true` the row is only a candidate match. In that case the system will automatically evaluate the `indexable_operator` against the actual row value to see if it is really a match. This convention allows GiST to support both lossless and lossy index structures.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_consistent(internal, data_type, smallint, oid,
    internal)
RETURNS bool
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_consistent);

Datum
my_consistent(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    data_type *query = PG_GETARG_DATA_TYPE_P(1);
    StrategyNumber strategy = (StrategyNumber) PG_GETARG_UINT16(2);
    /* Oid subtype = PG_GETARG_OID(3); */
    bool *recheck = (bool *) PG_GETARG_POINTER(4);
    data_type *key = DatumGetDataTypes(entry->key);
    bool retval;

    /*
```

```
* determine return value as a function of strategy, key and query.
*
* Use GIST_LEAF(entry) to know where you're called in the index tree,
* which comes handy when supporting the = operator for example (you could
* check for non empty union() in non-leaf nodes and equality in leaf
* nodes).
*/

*recheck = true;          /* or false if check is exact */

PG_RETURN_BOOL(retval);
}
```

Here, `key` is an element in the index and `query` the value being looked up in the index. The `StrategyNumber` parameter indicates which operator of your operator class is being applied — it matches one of the operator numbers in the `CREATE OPERATOR CLASS` command.

Depending on which operators you have included in the class, the data type of `query` could vary with the operator, since it will be whatever type is on the righthand side of the operator, which might be different from the indexed data type appearing on the lefthand side. (The above code skeleton assumes that only one type is possible; if not, fetching the `query` argument value would have to depend on the operator.) It is recommended that the SQL declaration of the `consistent` function use the opclass's indexed data type for the `query` argument, even though the actual type might be something else depending on the operator.

`union`

This method consolidates information in the tree. Given a set of entries, this function generates a new index entry that represents all the given entries.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_union(internal, internal)
RETURNS storage_type
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_union);

Datum
my_union(PG_FUNCTION_ARGS)
{
    GistEntryVector *entryvec = (GistEntryVector *) PG_GETARG_POINTER(0);
    GISTENTRY *ent = entryvec->vector;
    data_type *out,
               *tmp,
               *old;
    int numranges,
        i = 0;

    numranges = entryvec->n;
    tmp = DatumGetDataTypes(ent[0].key);
    out = tmp;

    if (numranges == 1)
    {
        out = data_type_deep_copy(tmp);

        PG_RETURN_DATA_TYPE_P(out);
    }
}
```

```
    }

    for (i = 1; i < numranges; i++)
    {
        old = out;
        tmp = DatumGetDataTypes(ent[i].key);
        out = my_union_implementation(out, tmp);
    }

    PG_RETURN_DATA_TYPE_P(out);
}
```

As you can see, in this skeleton we're dealing with a data type where `union(X, Y, Z) = union(union(X, Y), Z)`. It's easy enough to support data types where this is not the case, by implementing the proper union algorithm in this GiST support method.

The result of the `union` function must be a value of the index's storage type, whatever that is (it might or might not be different from the indexed column's type). The `union` function should return a pointer to newly `palloc()`ed memory. You can't just return the input value as-is, even if there is no type change.

As shown above, the `union` function's first internal argument is actually a `GistEntryVector` pointer. The second argument is a pointer to an integer variable, which can be ignored. (It used to be required that the `union` function store the size of its result value into that variable, but this is no longer necessary.)

`compress`

Converts the data item into a format suitable for physical storage in an index page.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_compress(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_compress);

Datum
my_compress(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY *retval;

    if (entry->leafkey)
    {
        /* replace entry->key with a compressed version */
        compressed_data_type *compressed_data =
            palloc(sizeof(compressed_data_type));

        /* fill *compressed_data from entry->key ... */

        retval = palloc(sizeof(GISTENTRY));
        gistentryinit(retval, PointerGetDatum(compressed_data),
                      entry->rel, entry->page, entry->offset, FALSE);
    }
    else
    {

```

```
        /* typically we needn't do anything with non-leaf entries */
        retval = entry;
    }

    PG_RETURN_POINTER(retval);
}
```

You have to adapt *compressed_data_type* to the specific type you're converting to in order to compress your leaf nodes, of course.

decompress

The reverse of the *compress* method. Converts the index representation of the data item into a format that can be manipulated by the other GiST methods in the operator class.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_decompress(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_decompress);

Datum
my_decompress(PG_FUNCTION_ARGS)
{
    PG_RETURN_POINTER(PG_GETARG_POINTER(0));
}
```

The above skeleton is suitable for the case where no decompression is needed.

penalty

Returns a value indicating the “cost” of inserting the new entry into a particular branch of the tree. Items will be inserted down the path of least *penalty* in the tree. Values returned by *penalty* should be non-negative. If a negative value is returned, it will be treated as zero.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_penalty(internal, internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT; -- in some cases penalty functions need not be strict
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_penalty);

Datum
my_penalty(PG_FUNCTION_ARGS)
{
    GISTENTRY *origentry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY *newentry = (GISTENTRY *) PG_GETARG_POINTER(1);
    float *penalty = (float *) PG_GETARG_POINTER(2);
    data_type *orig = DatumGetDataType(origentry->key);
    data_type *new = DatumGetDataType(newentry->key);

    *penalty = my_penalty_implementation(orig, new);
    PG_RETURN_POINTER(penalty);
}
```

For historical reasons, the `penalty` function doesn't just return a `float` result; instead it has to store the value at the location indicated by the third argument. The return value per se is ignored, though it's conventional to pass back the address of that argument.

The `penalty` function is crucial to good performance of the index. It'll get used at insertion time to determine which branch to follow when choosing where to add the new entry in the tree. At query time, the more balanced the index, the quicker the lookup.

`picksplit`

When an index page split is necessary, this function decides which entries on the page are to stay on the old page, and which are to move to the new page.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_picksplit(internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_picksplit);

Datum
my_picksplit(PG_FUNCTION_ARGS)
{
    GistEntryVector *entryvec = (GistEntryVector *) PG_GETARG_POINTER(0);
    GIST_SPLITVEC *v = (GIST_SPLITVEC *) PG_GETARG_POINTER(1);
    OffsetNumber maxoff = entryvec->n - 1;
    GISTENTRY *ent = entryvec->vector;
    int i,
        nbytes;
    OffsetNumber *left,
        *right;
    data_type *tmp_union;
    data_type *unionL;
    data_type *unionR;
    GISTENTRY **raw_entryvec;

    maxoff = entryvec->n - 1;
    nbytes = (maxoff + 1) * sizeof(OffsetNumber);

    v->spl_left = (OffsetNumber *) palloc(nbytes);
    left = v->spl_left;
    v->spl_nleft = 0;

    v->spl_right = (OffsetNumber *) palloc(nbytes);
    right = v->spl_right;
    v->spl_nright = 0;

    unionL = NULL;
    unionR = NULL;

    /* Initialize the raw entry vector. */
    raw_entryvec = (GISTENTRY **) malloc(entryvec->n * sizeof(void *));
    for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
        raw_entryvec[i] = &(entryvec->vector[i]);

    for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
    {
```

```
int            real_index = raw_entryvec[i] - entryvec->vector;

tmp_union = DatumGetDataType(entryvec->vector[real_index].key);
Assert(tmp_union != NULL);

/*
 * Choose where to put the index entries and update unionL and unionR
 * accordingly. Append the entries to either v->spl_left or
 * v->spl_right, and care about the counters.
 */

if (my_choice_is_left(unionL, curl, unionR, curr))
{
    if (unionL == NULL)
        unionL = tmp_union;
    else
        unionL = my_union_implementation(unionL, tmp_union);

    *left = real_index;
    ++left;
    ++(v->spl_nleft);
}
else
{
    /*
     * Same on the right
     */
}
}

v->spl_ldatum = DataTypeGetDatum(unionL);
v->spl_rdatum = DataTypeGetDatum(unionR);
PG_RETURN_POINTER(v);
}
```

Notice that the `picksplit` function's result is delivered by modifying the passed-in `v` structure. The return value per se is ignored, though it's conventional to pass back the address of `v`.

Like `penalty`, the `picksplit` function is crucial to good performance of the index. Designing suitable `penalty` and `picksplit` implementations is where the challenge of implementing well-performing GiST indexes lies.

same

Returns true if two index entries are identical, false otherwise. (An “index entry” is a value of the index's storage type, not necessarily the original indexed column's type.)

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_same(storage_type, storage_type, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_same);

Datum
my_same(PG_FUNCTION_ARGS)
{
```

```

prefix_range *v1 = PG_GETARG_PREFIX_RANGE_P(0);
prefix_range *v2 = PG_GETARG_PREFIX_RANGE_P(1);
bool          *result = (bool *) PG_GETARG_POINTER(2);

*result = my_eq(v1, v2);
PG_RETURN_POINTER(result);
}

```

For historical reasons, the `same` function doesn't just return a Boolean result; instead it has to store the flag at the location indicated by the third argument. The return value per se is ignored, though it's conventional to pass back the address of that argument.

`distance`

Given an index entry `p` and a query value `q`, this function determines the index entry's “distance” from the query value. This function must be supplied if the operator class contains any ordering operators. A query using the ordering operator will be implemented by returning index entries with the smallest “distance” values first, so the results must be consistent with the operator's semantics. For a leaf index entry the result just represents the distance to the index entry; for an internal tree node, the result must be the smallest distance that any child entry could have.

The SQL declaration of the function must look like this:

```

CREATE OR REPLACE FUNCTION my_distance(internal, data_type, smallint, oid, internal)
RETURNS float8
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

```

And the matching code in the C module could then follow this skeleton:

```

PG_FUNCTION_INFO_V1(my_distance);

Datum
my_distance(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    data_type *query = PG_GETARG_DATA_TYPE_P(1);
    StrategyNumber strategy = (StrategyNumber) PG_GETARG_UINT16(2);
    /* Oid subtype = PG_GETARG_OID(3); */
    /* bool *recheck = (bool *) PG_GETARG_POINTER(4); */
    data_type *key = DatumGetDataType(entry->key);
    double      retval;

    /*
     * determine return value as a function of strategy, key and query.
     */

    PG_RETURN_FLOAT8(retval);
}

```

The arguments to the `distance` function are identical to the arguments of the `consistent` function.

Some approximation is allowed when determining the distance, so long as the result is never greater than the entry's actual distance. Thus, for example, distance to a bounding box is usually sufficient in geometric applications. For an internal tree node, the distance returned must not be greater than the distance to any of the child nodes. If the returned distance is not exact, the function must set `*recheck` to true. (This is not necessary for internal tree nodes; for them, the calculation is always assumed to be inexact.) In this case the executor will calculate the accurate distance after fetching the tuple from the heap, and reorder the tuples if necessary.

If the distance function returns `*recheck = true` for any leaf node, the original ordering operator's return type must be `float8` or `float4`, and the distance function's result values must be comparable

to those of the original ordering operator, since the executor will sort using both distance function results and recalculated ordering-operator results. Otherwise, the distance function's result values can be any finite `float8` values, so long as the relative order of the result values matches the order returned by the ordering operator. (Infinity and minus infinity are used internally to handle cases such as nulls, so it is not recommended that `distance` functions return these values.)

`fetch`

Converts the compressed index representation of a data item into the original data type, for index-only scans. The returned data must be an exact, non-lossy copy of the originally indexed value.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_fetch(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

The argument is a pointer to a `GISTENTRY` struct. On entry, its `key` field contains a non-NULL leaf datum in compressed form. The return value is another `GISTENTRY` struct, whose `key` field contains the same datum in its original, uncompressed form. If the `opclass`'s `compress` function does nothing for leaf entries, the `fetch` method can return the argument as-is.

The matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_fetch);

Datum
my_fetch(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    input_data_type *in = DatumGetPointer(entry->key);
    fetched_data_type *fetched_data;
    GISTENTRY *retval;

    retval = palloc(sizeof(GISTENTRY));
    fetched_data = palloc(sizeof(fetched_data_type));

    /*
     * Convert 'fetched_data' into the a Datum of the original datatype.
     */

    /* fill *retval from fetched_data. */
    gistentryinit(retval, PointerGetDatum(converted_datum),
                  entry->rel, entry->page, entry->offset, FALSE);

    PG_RETURN_POINTER(retval);
}
```

If the `compress` method is lossy for leaf entries, the operator class cannot support index-only scans, and must not define a `fetch` function.

All the GiST support methods are normally called in short-lived memory contexts; that is, `CurrentMemoryContext` will get reset after each tuple is processed. It is therefore not very important to worry about `pfree`'ing everything you `palloc`. However, in some cases it's useful for a support method to cache data across repeated calls. To do that, allocate the longer-lived data in `fcinfo->flinfo->fn_mcxt`, and keep a pointer to it in `fcinfo->flinfo->fn_extra`. Such data will survive for the life of the index operation (e.g., a single GiST index scan, index build, or index tuple insertion). Be careful to `pfree` the previous value when replacing a `fn_extra` value, or the leak will accumulate for the duration of the operation.

59.4. Implementation

59.4.1. GiST buffering build

Building large GiST indexes by simply inserting all the tuples tends to be slow, because if the index tuples are scattered across the index and the index is large enough to not fit in cache, the insertions need to perform a lot of random I/O. Beginning in version 9.2, PostgreSQL supports a more efficient method to build GiST indexes based on buffering, which can dramatically reduce the number of random I/Os needed for non-ordered data sets. For well-ordered data sets the benefit is smaller or non-existent, because only a small number of pages receive new tuples at a time, and those pages fit in cache even if the index as whole does not.

However, buffering index build needs to call the `penalty` function more often, which consumes some extra CPU resources. Also, the buffers used in the buffering build need temporary disk space, up to the size of the resulting index. Buffering can also influence the quality of the resulting index, in both positive and negative directions. That influence depends on various factors, like the distribution of the input data and the operator class implementation.

By default, a GiST index build switches to the buffering method when the index size reaches [effective_cache_size](#). It can be manually turned on or off by the `buffering` parameter to the `CREATE INDEX` command. The default behavior is good for most cases, but turning buffering off might speed up the build somewhat if the input data is ordered.

59.5. Examples

The Postgres Pro source distribution includes several examples of index methods implemented using GiST. The core system currently provides text search support (indexing for `tsvector` and `tsquery`) as well as R-Tree equivalent functionality for some of the built-in geometric data types (see `src/backend/access/gist/gistproc.c`). The following `contrib` modules also contain GiST operator classes:

`btree_gist`

B-tree equivalent functionality for several data types

`cube`

Indexing for multidimensional cubes

`hstore`

Module for storing (key, value) pairs

`intarray`

RD-Tree for one-dimensional array of int4 values

`ltree`

Indexing for tree-like structures

`pg_trgm`

Text similarity using trigram matching

`seg`

Indexing for “float ranges”

Chapter 60. SP-GiST Indexes

60.1. Introduction

SP-GiST is an abbreviation for space-partitioned GiST. SP-GiST supports partitioned search trees, which facilitate development of a wide range of different non-balanced data structures, such as quad-trees, k-d trees, and radix trees (tries). The common feature of these structures is that they repeatedly divide the search space into partitions that need not be of equal size. Searches that are well matched to the partitioning rule can be very fast.

These popular data structures were originally developed for in-memory usage. In main memory, they are usually designed as a set of dynamically allocated nodes linked by pointers. This is not suitable for direct storing on disk, since these chains of pointers can be rather long which would require too many disk accesses. In contrast, disk-based data structures should have a high fanout to minimize I/O. The challenge addressed by SP-GiST is to map search tree nodes to disk pages in such a way that a search need access only a few disk pages, even if it traverses many nodes.

Like GiST, SP-GiST is meant to allow the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from Purdue University's SP-GiST Indexing Project [web site](#). The SP-GiST implementation in Postgres Pro is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their [web site](#).

60.2. Built-in Operator Classes

The core Postgres Pro distribution includes the SP-GiST operator classes shown in [Table 60.1](#).

Table 60.1. Built-in SP-GiST Operator Classes

Name	Indexed Data Type	Indexable Operators	Ordering Operators
kd_point_ops	point	<< <@ <^ >> >^ ~=	<->
quad_point_ops	point	<< <@ <^ >> >^ ~=	<->
range_ops	any range type	&& &< &> - - << <@ = >> @>	
box_ops	box	<< &< && &> >> ~= @> <@ &< << >> &>	
circle_ops	circle	<< &< && &> >> ~= @> <@ &< << >> &>	<->
poly_ops	polygon	<< &< && &> >> ~= @> <@ &< << >> &>	<->
text_ops	text	< <= = > >= ~<=~ ~<~ ~>=~ ~>~	

Of the two operator classes for type `point`, `quad_point_ops` is the default. `kd_point_ops` supports the same operators but uses a different index data structure that may offer better performance in some applications.

The `quad_point_ops`, `kd_point_ops`, `circle_ops`, and `poly_ops` operator classes support the `<->` ordering operator, which enables the k-nearest neighbor (k-NN) search over indexed point, circle, or polygon datasets.

60.3. Extensibility

SP-GiST offers an interface with a high level of abstraction, requiring the access method developer to implement only methods specific to a given data type. The SP-GiST core is responsible for efficient disk mapping and searching the tree structure. It also takes care of concurrency and logging considerations.

Leaf tuples of an SP-GiST tree contain values of the same data type as the indexed column. Leaf tuples at the root level will always contain the original indexed data value, but leaf tuples at lower levels might contain only a compressed representation, such as a suffix. In that case the operator class support functions must be able to reconstruct the original value using information accumulated from the inner tuples that are passed through to reach the leaf level.

Inner tuples are more complex, since they are branching points in the search tree. Each inner tuple contains a set of one or more *nodes*, which represent groups of similar leaf values. A node contains a downlink that leads either to another, lower-level inner tuple, or to a short list of leaf tuples that all lie on the same index page. Each node normally has a *label* that describes it; for example, in a radix tree the node label could be the next character of the string value. (Alternatively, an operator class can omit the node labels, if it works with a fixed set of nodes for all inner tuples; see [Section 60.4.2](#).) Optionally, an inner tuple can have a *prefix* value that describes all its members. In a radix tree this could be the common prefix of the represented strings. The prefix value is not necessarily really a prefix, but can be any data needed by the operator class; for example, in a quad-tree it can store the central point that the four quadrants are measured with respect to. A quad-tree inner tuple would then also contain four nodes corresponding to the quadrants around this central point.

Some tree algorithms require knowledge of level (or depth) of the current tuple, so the SP-GiST core provides the possibility for operator classes to manage level counting while descending the tree. There is also support for incrementally reconstructing the represented value when that is needed, and for passing down additional data (called *traverse values*) during a tree descent.

Note

The SP-GiST core code takes care of null entries. Although SP-GiST indexes do store entries for nulls in indexed columns, this is hidden from the index operator class code: no null index entries or search conditions will ever be passed to the operator class methods. (It is assumed that SP-GiST operators are strict and so cannot succeed for null values.) Null values are therefore not discussed further here.

There are five user-defined methods that an index operator class for SP-GiST must provide, and one is optional. All five mandatory methods follow the convention of accepting two `internal` arguments, the first of which is a pointer to a C struct containing input values for the support method, while the second argument is a pointer to a C struct where output values must be placed. Four of the mandatory methods just return `void`, since all their results appear in the output struct; but `leaf_consistent` additionally returns a `boolean` result. The methods must not modify any fields of their input structs. In all cases, the output struct is initialized to zeroes before calling the user-defined method. The optional sixth method `compress` accepts `datum` to be indexed as the only argument and returns a value suitable for physical storage in a leaf tuple.

The five mandatory user-defined methods are:

`config`

Returns static information about the index implementation, including the data type OIDs of the prefix and node label data types.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_config(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgConfigIn` C struct, containing input data for the function. The second argument is a pointer to a `spgConfigOut` C struct, which the function must fill with result data.

```
typedef struct spgConfigIn
{
    Oid          attType;          /* Data type to be indexed */
} spgConfigIn;
```

```
typedef struct spgConfigOut
{
    Oid      prefixType;      /* Data type of inner-tuple prefixes */
    Oid      labelType;       /* Data type of inner-tuple node labels */
    Oid      leafType;        /* Data type of leaf-tuple values */
    bool     canReturnData;   /* Opclass can reconstruct original data */
    bool     longValuesOK;    /* Opclass can cope with values > 1 page */
} spgConfigOut;
```

`attType` is passed in order to support polymorphic index operator classes; for ordinary fixed-data-type operator classes, it will always have the same value and so can be ignored.

For operator classes that do not use prefixes, `prefixType` can be set to `VOIDOID`. Likewise, for operator classes that do not use node labels, `labelType` can be set to `VOIDOID`. `canReturnData` should be set true if the operator class is capable of reconstructing the originally-supplied index value. `longValuesOK` should be set true only when the `attType` is of variable length and the operator class is capable of segmenting long values by repeated suffixing (see [Section 60.4.1](#)).

`leafType` is typically the same as `attType`. For the reasons of backward compatibility, method `config` can leave `leafType` uninitialized; that would give the same effect as setting `leafType` equal to `attType`. When `attType` and `leafType` are different, then optional method `compress` must be provided. Method `compress` is responsible for transformation of datums to be indexed from `attType` to `leafType`. Note: both consistent functions will get `scankeys` unchanged, without transformation using `compress`.

`choose`

Chooses a method for inserting a new value into an inner tuple.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_choose(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgChooseIn` C struct, containing input data for the function. The second argument is a pointer to a `spgChooseOut` C struct, which the function must fill with result data.

```
typedef struct spgChooseIn
{
    Datum      datum;          /* original datum to be indexed */
    Datum      leafDatum;      /* current datum to be stored at leaf */
    int        level;          /* current level (counting from zero) */

    /* Data from current inner tuple */
    bool       allTheSame;     /* tuple is marked all-the-same? */
    bool       hasPrefix;      /* tuple has a prefix? */
    Datum      prefixDatum;     /* if so, the prefix value */
    int        nNodes;         /* number of nodes in the inner tuple */
    Datum      *nodeLabels;    /* node label values (NULL if none) */
} spgChooseIn;

typedef enum spgChooseResultType
{
    spgMatchNode = 1,          /* descend into existing node */
    spgAddNode,                /* add a node to the inner tuple */
    spgSplitTuple              /* split inner tuple (change its prefix) */
} spgChooseResultType;

typedef struct spgChooseOut
{
```

```

    spgChooseResultType resultType;      /* action code, see above */
    union
    {
        struct                      /* results for spgMatchNode */
        {
            int          nodeN;      /* descend to this node (index from 0) */
            int          levelAdd;   /* increment level by this much */
            Datum        restDatum;  /* new leaf datum */
        } matchNode;
        struct                      /* results for spgAddNode */
        {
            Datum        nodeLabel;  /* new node's label */
            int          nodeN;      /* where to insert it (index from 0) */
        } addNode;
        struct                      /* results for spgSplitTuple */
        {
            /* Info to form new inner tuple with one node */
            bool          prefixHasPrefix; /* tuple should have a prefix? */
            Datum        prefixPrefixDatum; /* if so, its value */
            Datum        nodeLabel;      /* node's label */

            /* Info to form new lower-level inner tuple with all old nodes */
            bool          postfixHasPrefix; /* tuple should have a prefix? */
            Datum        postfixPrefixDatum; /* if so, its value */
        } splitTuple;
    } result;
} spgChooseOut;

```

`datum` is the original datum of `spgConfigIn.attType` type that was to be inserted into the index. `leafDatum` is a value of `spgConfigOut.leafType` type, which is initially a result of method `compress` applied to `datum` when method `compress` is provided, or the same value as `datum` otherwise. `leafDatum` can change at lower levels of the tree if the `choose` or `picksplit` methods change it. When the insertion search reaches a leaf page, the current value of `leafDatum` is what will be stored in the newly created leaf tuple. `level` is the current inner tuple's level, starting at zero for the root level. `allTheSame` is true if the current inner tuple is marked as containing multiple equivalent nodes (see [Section 60.4.3](#)). `hasPrefix` is true if the current inner tuple contains a prefix; if so, `prefixDatum` is its value. `nNodes` is the number of child nodes contained in the inner tuple, and `nodeLabels` is an array of their label values, or NULL if there are no labels.

The `choose` function can determine either that the new value matches one of the existing child nodes, or that a new child node must be added, or that the new value is inconsistent with the tuple prefix and so the inner tuple must be split to create a less restrictive prefix.

If the new value matches one of the existing child nodes, set `resultType` to `spgMatchNode`. Set `nodeN` to the index (from zero) of that node in the node array. Set `levelAdd` to the increment in `level` caused by descending through that node, or leave it as zero if the operator class does not use levels. Set `restDatum` to equal `datum` if the operator class does not modify datums from one level to the next, or otherwise set it to the modified value to be used as `leafDatum` at the next level.

If a new child node must be added, set `resultType` to `spgAddNode`. Set `nodeLabel` to the label to be used for the new node, and set `nodeN` to the index (from zero) at which to insert the node in the node array. After the node has been added, the `choose` function will be called again with the modified inner tuple; that call should result in an `spgMatchNode` result.

If the new value is inconsistent with the tuple prefix, set `resultType` to `spgSplitTuple`. This action moves all the existing nodes into a new lower-level inner tuple, and replaces the existing inner tuple with a tuple having a single node that links to the new lower-level inner tuple. Set `prefixHasPrefix` to indicate whether the new upper tuple should have a prefix, and if so set `prefixPrefixDatum` to the prefix value. This new prefix value must be sufficiently less restrictive than the original

to accept the new value to be indexed, and it should be no longer than the original prefix. Set `nodeLabel` to the label to be used for the node that will point to the new lower-level inner tuple. Set `postfixHasPrefix` to indicate whether the new lower-level inner tuple should have a prefix, and if so set `postfixPrefixDatum` to the prefix value. The combination of these two prefixes and the additional label must have the same meaning as the original prefix, because there is no opportunity to alter the node labels that are moved to the new lower-level tuple, nor to change any child index entries. After the node has been split, the `choose` function will be called again with the replacement inner tuple. That call will usually result in an `spgAddNode` result, since presumably the node label added in the split step will not match the new value; so after that, there will be a third call that finally returns `spgMatchNode` and allows the insertion to descend to the leaf level.

`picksplit`

Decides how to create a new inner tuple over a set of leaf tuples.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_picksplit(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgPickSplitIn` C struct, containing input data for the function. The second argument is a pointer to a `spgPickSplitOut` C struct, which the function must fill with result data.

```
typedef struct spgPickSplitIn
{
    int          nTuples;          /* number of leaf tuples */
    Datum        *datums;          /* their datums (array of length nTuples) */
    int          level;           /* current level (counting from zero) */
} spgPickSplitIn;

typedef struct spgPickSplitOut
{
    bool          hasPrefix;       /* new inner tuple should have a prefix? */
    Datum         prefixDatum;     /* if so, its value */

    int          nNodes;          /* number of nodes for new inner tuple */
    Datum        *nodeLabels;     /* their labels (or NULL for no labels) */

    int          *mapTuplesToNodes; /* node index for each leaf tuple */
    Datum        *leafTupleDatums; /* datum to store in each new leaf tuple */
} spgPickSplitOut;
```

`nTuples` is the number of leaf tuples provided. `datums` is an array of their datum values of `spgConfigOut.leafType` type. `level` is the current level that all the leaf tuples share, which will become the level of the new inner tuple.

Set `hasPrefix` to indicate whether the new inner tuple should have a prefix, and if so set `prefixDatum` to the prefix value. Set `nNodes` to indicate the number of nodes that the new inner tuple will contain, and set `nodeLabels` to an array of their label values, or to NULL if node labels are not required. Set `mapTuplesToNodes` to an array that gives the index (from zero) of the node that each leaf tuple should be assigned to. Set `leafTupleDatums` to an array of the values to be stored in the new leaf tuples (these will be the same as the input `datums` if the operator class does not modify datums from one level to the next). Note that the `picksplit` function is responsible for `malloc`'ing the `nodeLabels`, `mapTuplesToNodes` and `leafTupleDatums` arrays.

If more than one leaf tuple is supplied, it is expected that the `picksplit` function will classify them into more than one node; otherwise it is not possible to split the leaf tuples across multiple pages, which is the ultimate purpose of this operation. Therefore, if the `picksplit` function ends up placing all the leaf tuples in the same node, the core SP-GiST code will override that decision and generate an inner tuple in which the leaf tuples are assigned at random to several identically-labeled nodes. Such

a tuple is marked `allTheSame` to signify that this has happened. The `choose` and `inner_consistent` functions must take suitable care with such inner tuples. See [Section 60.4.3](#) for more information.

`picksplit` can be applied to a single leaf tuple only in the case that the `config` function set `longValuesOK` to true and a larger-than-a-page input value has been supplied. In this case the point of the operation is to strip off a prefix and produce a new, shorter leaf datum value. The call will be repeated until a leaf datum short enough to fit on a page has been produced. See [Section 60.4.1](#) for more information.

`inner_consistent`

Returns set of nodes (branches) to follow during tree search.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_inner_consistent(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgInnerConsistentIn` C struct, containing input data for the function. The second argument is a pointer to a `spgInnerConsistentOut` C struct, which the function must fill with result data.

```
typedef struct spgInnerConsistentIn
{
    ScanKey      scankeys;          /* array of operators and comparison values */
    ScanKey      orderbyKeys;       /* array of ordering operators and comparison values */
    /*
     *
     */
    int          nkeys;             /* length of array */
    int          norderbys;         /* length of array */

    Datum        reconstructedValue; /* value reconstructed at parent */
    void         *traversalValue;    /* opclass-specific traverse value */
    MemoryContext traversalMemoryContext; /* put new traverse values here */
    int          level;             /* current level (counting from zero) */
    bool         returnData;        /* original data must be returned? */

    /* Data from current inner tuple */
    bool         allTheSame;        /* tuple is marked all-the-same? */
    bool         hasPrefix;         /* tuple has a prefix? */
    Datum        prefixDatum;       /* if so, the prefix value */
    int          nNodes;            /* number of nodes in the inner tuple */
    Datum        *nodeLabels;       /* node label values (NULL if none) */
} spgInnerConsistentIn;

typedef struct spgInnerConsistentOut
{
    int          nNodes;            /* number of child nodes to be visited */
    int          *nodeNumbers;      /* their indexes in the node array */
    int          *levelAdds;        /* increment level by this much for each */
    Datum        *reconstructedValues; /* associated reconstructed values */
    void         **traversalValues; /* opclass-specific traverse values */
    double       **distances;       /* associated distances */
} spgInnerConsistentOut;
```

The array `scankeys`, of length `nkeys`, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them are interesting. (Note that `nkeys = 0` implies that all index entries satisfy the query.) Usually the consistent function only cares about the `sk_strategy` and `sk_argument` fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check `sk_flags` to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions. `orderbyKeys`, of length `norderbys`, describes ordering operators (if any) in the same fashion. `reconstructedValue` is the value reconstructed for the parent tuple; it is (Datum) 0 at the root level

or if the `inner_consistent` function did not provide a value at the parent level. `reconstructedValue` is always of `spgConfigOut.leafType` type. `traversalValue` is a pointer to any traverse data passed down from the previous call of `inner_consistent` on the parent index tuple, or NULL at the root level. `traversalMemoryContext` is the memory context in which to store output traverse values (see below). `level` is the current inner tuple's level, starting at zero for the root level. `returnData` is true if reconstructed data is required for this query; this will only be so if the `config` function asserted `canReturnData`. `allTheSame` is true if the current inner tuple is marked “all-the-same”; in this case all the nodes have the same label (if any) and so either all or none of them match the query (see [Section 60.4.3](#)). `hasPrefix` is true if the current inner tuple contains a prefix; if so, `prefixDatum` is its value. `nNodes` is the number of child nodes contained in the inner tuple, and `nodeLabels` is an array of their label values, or NULL if the nodes do not have labels.

`nNodes` must be set to the number of child nodes that need to be visited by the search, and `nodeNumbers` must be set to an array of their indexes. If the operator class keeps track of levels, set `levelAdds` to an array of the level increments required when descending to each node to be visited. (Often these increments will be the same for all the nodes, but that's not necessarily so, so an array is used.) If value reconstruction is needed, set `reconstructedValues` to an array of the values of `spgConfigOut.leafType` type reconstructed for each child node to be visited; otherwise, leave `reconstructedValues` as NULL. `distances` if the ordered search is carried out, the implementation is supposed to fill them in accordance to the ordering operators provided in `orderByKeys` (nodes with lowest distances will be processed first). Leave it NULL otherwise. If it is desired to pass down additional out-of-band information (“traverse values”) to lower levels of the tree search, set `traversalValues` to an array of the appropriate traverse values, one for each child node to be visited; otherwise, leave `traversalValues` as NULL. Note that the `inner_consistent` function is responsible for `palloc`'ing the `nodeNumbers`, `levelAdds`, `distances`, `reconstructedValues` and `traversalValues` arrays in the current memory context. However, any output traverse values pointed to by the `traversalValues` array should be allocated in `traversalMemoryContext`. Each traverse value must be a single `palloc`'d chunk.

`leaf_consistent`

Returns true if a leaf tuple satisfies a query.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_leaf_consistent(internal, internal) RETURNS bool ...
```

The first argument is a pointer to a `spgLeafConsistentIn` C struct, containing input data for the function. The second argument is a pointer to a `spgLeafConsistentOut` C struct, which the function must fill with result data.

```
typedef struct spgLeafConsistentIn
{
    ScanKey      scankeys;          /* array of operators and comparison values */
    ScanKey      orderbykeys;       /* array of ordering operators and comparison values */
    /*
    int          nkeys;              /* length of scankeys array */
    int          norderbys;         /* length of orderbykeys array */

    void         *traversalValue;    /* opclass-specific traverse value */
    Datum        reconstructedValue; /* value reconstructed at parent */
    int          level;              /* current level (counting from zero) */
    bool         returnData;         /* original data must be returned? */

    Datum        leafDatum;          /* datum in leaf tuple */
} spgLeafConsistentIn;

typedef struct spgLeafConsistentOut
{
    Datum        leafValue;          /* reconstructed original data, if any */
```

```
bool        recheck;           /* set true if operator must be rechecked */
bool        recheckDistances; /* set true if distances must be rechecked */
double      *distances;        /* associated distances */
} spgLeafConsistentOut;
```

The array `scankeys`, of length `nkeys`, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them satisfy the query. (Note that `nkeys = 0` implies that all index entries satisfy the query.) Usually the consistent function only cares about the `sk_strategy` and `sk_argument` fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check `sk_flags` to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions. The array `orderbykeys`, of length `norderbys`, describes the ordering operators in the same fashion. `reconstructedValue` is the value reconstructed for the parent tuple; it is (`Datum`) 0 at the root level or if the `inner_consistent` function did not provide a value at the parent level. `reconstructedValue` is always of `spgConfigOut.leafType` type. `traversalValue` is a pointer to any traverse data passed down from the previous call of `inner_consistent` on the parent index tuple, or NULL at the root level. `level` is the current leaf tuple's level, starting at zero for the root level. `returnData` is true if reconstructed data is required for this query; this will only be so if the `config` function asserted `canReturnData`. `leafDatum` is the key value of `spgConfigOut.leafType` stored in the current leaf tuple.

The function must return `true` if the leaf tuple matches the query, or `false` if not. In the `true` case, if `returnData` is true then `leafValue` must be set to the value of `spgConfigIn.attType` type originally supplied to be indexed for this leaf tuple. Also, `recheck` may be set to `true` if the match is uncertain and so the operator(s) must be re-applied to the actual heap tuple to verify the match. If the ordered search is performed, `distances` should be set in accordance with the ordering operator provided, otherwise implementation is supposed to set it to NULL. If at least one of returned distances is not exact, the function must set `recheckDistances` to true. In this case, the executor calculates the exact distances after fetching the tuple from the heap, and reorders the tuples if necessary.

The optional user-defined method is:

```
Datum compress(Datum in)
```

Converts the data item into a format suitable for physical storage in a leaf tuple of index page. It accepts `spgConfigIn.attType` value and returns `spgConfigOut.leafType` value. Output value should not be toasted.

All the SP-GiST support methods are normally called in a short-lived memory context; that is, `CurrentMemoryContext` will be reset after processing of each tuple. It is therefore not very important to worry about pfree'ing everything you palloc. (The `config` method is an exception: it should try to avoid leaking memory. But usually the `config` method need do nothing but assign constants into the passed parameter struct.)

If the indexed column is of a collatable data type, the index collation will be passed to all the support methods, using the standard `PG_GET_COLLATION()` mechanism.

60.4. Implementation

This section covers implementation details and other tricks that are useful for implementers of SP-GiST operator classes to know.

60.4.1. SP-GiST Limits

Individual leaf tuples and inner tuples must fit on a single index page (8kB by default). Therefore, when indexing values of variable-length data types, long values can only be supported by methods such as radix trees, in which each level of the tree includes a prefix that is short enough to fit on a page, and the final leaf level includes a suffix also short enough to fit on a page. The operator class should set `longValuesOK` to TRUE only if it is prepared to arrange for this to happen. Otherwise, the SP-GiST core will reject any request to index a value that is too large to fit on an index page.

Likewise, it is the operator class's responsibility that inner tuples do not grow too large to fit on an index page; this limits the number of child nodes that can be used in one inner tuple, as well as the maximum size of a prefix value.

Another limitation is that when an inner tuple's node points to a set of leaf tuples, those tuples must all be in the same index page. (This is a design decision to reduce seeking and save space in the links that chain such tuples together.) If the set of leaf tuples grows too large for a page, a split is performed and an intermediate inner tuple is inserted. For this to fix the problem, the new inner tuple *must* divide the set of leaf values into more than one node group. If the operator class's `picksplit` function fails to do that, the SP-GiST core resorts to extraordinary measures described in [Section 60.4.3](#).

60.4.2. SP-GiST Without Node Labels

Some tree algorithms use a fixed set of nodes for each inner tuple; for example, in a quad-tree there are always exactly four nodes corresponding to the four quadrants around the inner tuple's centroid point. In such a case the code typically works with the nodes by number, and there is no need for explicit node labels. To suppress node labels (and thereby save some space), the `picksplit` function can return NULL for the `nodeLabels` array. This will in turn result in `nodeLabels` being NULL during subsequent calls to `choose` and `inner_consistent`. In principle, node labels could be used for some inner tuples and omitted for others in the same index.

When working with an inner tuple having unlabeled nodes, it is an error for `choose` to return `spgAddNode`, since the set of nodes is supposed to be fixed in such cases. Also, there is no provision for generating an unlabeled node in `spgSplitTuple` actions, since it is expected that an `spgAddNode` action will be needed as well.

60.4.3. “All-the-same” Inner Tuples

The SP-GiST core can override the results of the operator class's `picksplit` function when `picksplit` fails to divide the supplied leaf values into at least two node categories. When this happens, the new inner tuple is created with multiple nodes that each have the same label (if any) that `picksplit` gave to the one node it did use, and the leaf values are divided at random among these equivalent nodes. The `allTheSame` flag is set on the inner tuple to warn the `choose` and `inner_consistent` functions that the tuple does not have the node set that they might otherwise expect.

When dealing with an `allTheSame` tuple, a `choose` result of `spgMatchNode` is interpreted to mean that the new value can be assigned to any of the equivalent nodes; the core code will ignore the supplied `nodeN` value and descend into one of the nodes at random (so as to keep the tree balanced). It is an error for `choose` to return `spgAddNode`, since that would make the nodes not all equivalent; the `spgSplitTuple` action must be used if the value to be inserted doesn't match the existing nodes.

When dealing with an `allTheSame` tuple, the `inner_consistent` function should return either all or none of the nodes as targets for continuing the index search, since they are all equivalent. This may or may not require any special-case code, depending on how much the `inner_consistent` function normally assumes about the meaning of the nodes.

60.5. Examples

The Postgres Pro source distribution includes several examples of index operator classes for SP-GiST, as described in [Table 60.1](#). Look into `src/backend/access/spgist/` and `src/backend/utils/adt/` to see the code.

Chapter 61. GIN Indexes

61.1. Introduction

GIN stands for Generalized Inverted Index. GIN is designed for handling cases where the items to be indexed are composite values, and the queries to be handled by the index need to search for element values that appear within the composite items. For example, the items could be documents, and the queries could be searches for documents containing specific words.

We use the word *item* to refer to a composite value that is to be indexed, and the word *key* to refer to an element value. GIN always stores and searches for keys, not item values per se.

A GIN index stores a set of (key, posting list) pairs, where a *posting list* is a set of row IDs in which the key occurs. The same row ID can appear in multiple posting lists, since an item can contain more than one key. Each key value is stored only once, so a GIN index is very compact for cases where the same key appears many times.

GIN is generalized in the sense that the GIN access method code does not need to know the specific operations that it accelerates. Instead, it uses custom strategies defined for particular data types. The strategy defines how keys are extracted from indexed items and query conditions, and how to determine whether a row that contains some of the key values in a query actually satisfies the query.

One advantage of GIN is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert. This is much the same advantage as using GiST.

The GIN implementation in Postgres Pro is primarily maintained by Teodor Sigaev and Oleg Bartunov. There is more information about GIN on their [website](#).

61.2. Built-in Operator Classes

The core Postgres Pro distribution includes the GIN operator classes shown in [Table 61.1](#). (Some of the optional modules described in [Appendix F](#) provide additional GIN operator classes.)

Table 61.1. Built-in GIN Operator Classes

Name	Indexed Data Type	Indexable Operators
<code>_abstime_ops</code>	<code>abstime[]</code>	<code>&& <@ = @></code>
<code>_bit_ops</code>	<code>bit[]</code>	<code>&& <@ = @></code>
<code>_bool_ops</code>	<code>boolean[]</code>	<code>&& <@ = @></code>
<code>_bpchar_ops</code>	<code>character[]</code>	<code>&& <@ = @></code>
<code>_bytea_ops</code>	<code>bytea[]</code>	<code>&& <@ = @></code>
<code>_char_ops</code>	<code>"char"[]</code>	<code>&& <@ = @></code>
<code>_cidr_ops</code>	<code>cidr[]</code>	<code>&& <@ = @></code>
<code>_date_ops</code>	<code>date[]</code>	<code>&& <@ = @></code>
<code>_float4_ops</code>	<code>float4[]</code>	<code>&& <@ = @></code>
<code>_float8_ops</code>	<code>float8[]</code>	<code>&& <@ = @></code>
<code>_inet_ops</code>	<code>inet[]</code>	<code>&& <@ = @></code>
<code>_int2_ops</code>	<code>smallint[]</code>	<code>&& <@ = @></code>
<code>_int4_ops</code>	<code>integer[]</code>	<code>&& <@ = @></code>
<code>_int8_ops</code>	<code>bigint[]</code>	<code>&& <@ = @></code>
<code>_interval_ops</code>	<code>interval[]</code>	<code>&& <@ = @></code>

Name	Indexed Data Type	Indexable Operators
<code>_macaddr_ops</code>	<code>macaddr[]</code>	<code>&& <@ = @></code>
<code>_money_ops</code>	<code>money[]</code>	<code>&& <@ = @></code>
<code>_name_ops</code>	<code>name[]</code>	<code>&& <@ = @></code>
<code>_numeric_ops</code>	<code>numeric[]</code>	<code>&& <@ = @></code>
<code>_oid_ops</code>	<code>oid[]</code>	<code>&& <@ = @></code>
<code>_oidvector_ops</code>	<code>oidvector[]</code>	<code>&& <@ = @></code>
<code>_reltime_ops</code>	<code>reltime[]</code>	<code>&& <@ = @></code>
<code>_text_ops</code>	<code>text[]</code>	<code>&& <@ = @></code>
<code>_time_ops</code>	<code>time[]</code>	<code>&& <@ = @></code>
<code>_timestamp_ops</code>	<code>timestamp[]</code>	<code>&& <@ = @></code>
<code>_timestamptz_ops</code>	<code>timestamp with time zone[]</code>	<code>&& <@ = @></code>
<code>_timetz_ops</code>	<code>time with time zone[]</code>	<code>&& <@ = @></code>
<code>_tinterval_ops</code>	<code>tinterval[]</code>	<code>&& <@ = @></code>
<code>_varbit_ops</code>	<code>bit varying[]</code>	<code>&& <@ = @></code>
<code>_varchar_ops</code>	<code>character varying[]</code>	<code>&& <@ = @></code>
<code>jsonb_ops</code>	<code>jsonb</code>	<code>? ?& ? @></code>
<code>jsonb_path_ops</code>	<code>jsonb</code>	<code>@></code>
<code>tsvector_ops</code>	<code>tsvector</code>	<code>@@ @@@</code>

Of the two operator classes for type `jsonb`, `jsonb_ops` is the default. `jsonb_path_ops` supports fewer operators but offers better performance for those operators. See [Section 8.14.4](#) for details.

61.3. Extensibility

The GIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GIN layer itself takes care of concurrency, logging and searching the tree structure.

All it takes to get a GIN access method working is to implement a few user-defined methods, which define the behavior of keys in the tree and the relationships between keys, indexed items, and indexable queries. In short, GIN combines extensibility with generality, code reuse, and a clean interface.

There are three methods that an operator class for GIN must provide:

```
int compare(Datum a, Datum b)
```

Compares two keys (not indexed items!) and returns an integer less than zero, zero, or greater than zero, indicating whether the first key is less than, equal to, or greater than the second. Null keys are never passed to this function.

```
Datum *extractValue(Datum itemValue, int32 *nkeys, bool **nullFlags)
```

Returns a palloc'd array of keys given an item to be indexed. The number of returned keys must be stored into `*nkeys`. If any of the keys can be null, also palloc an array of `*nkeys` `bool` fields, store its address at `*nullFlags`, and set these null flags as needed. `*nullFlags` can be left `NULL` (its initial value) if all keys are non-null. The return value can be `NULL` if the item contains no keys.

```
Datum *extractQuery(Datum query, int32 *nkeys, StrategyNumber n, bool **pmatch, Pointer
**extra_data, bool **nullFlags, int32 *searchMode)
```

Returns a palloc'd array of keys given a value to be queried; that is, `query` is the value on the right-hand side of an indexable operator whose left-hand side is the indexed column. `n` is the strategy

number of the operator within the operator class (see [Section 36.14.2](#)). Often, `extractQuery` will need to consult `n` to determine the data type of `query` and the method it should use to extract key values. The number of returned keys must be stored into `*nkeys`. If any of the keys can be null, also `palloc` an array of `*nkeys` `bool` fields, store its address at `*nullFlags`, and set these null flags as needed. `*nullFlags` can be left `NULL` (its initial value) if all keys are non-null. The return value can be `NULL` if the `query` contains no keys.

`searchMode` is an output argument that allows `extractQuery` to specify details about how the search will be done. If `*searchMode` is set to `GIN_SEARCH_MODE_DEFAULT` (which is the value it is initialized to before call), only items that match at least one of the returned keys are considered candidate matches. If `*searchMode` is set to `GIN_SEARCH_MODE_INCLUDE_EMPTY`, then in addition to items containing at least one matching key, items that contain no keys at all are considered candidate matches. (This mode is useful for implementing is-subset-of operators, for example.) If `*searchMode` is set to `GIN_SEARCH_MODE_ALL`, then all non-null items in the index are considered candidate matches, whether they match any of the returned keys or not. (This mode is much slower than the other two choices, since it requires scanning essentially the entire index, but it may be necessary to implement corner cases correctly. An operator that needs this mode in most cases is probably not a good candidate for a GIN operator class.) The symbols to use for setting this mode are defined in `access/gin.h`.

`pmatch` is an output argument for use when partial match is supported. To use it, `extractQuery` must allocate an array of `*nkeys` `bool`s and store its address at `*pmatch`. Each element of the array should be set to `TRUE` if the corresponding key requires partial match, `FALSE` if not. If `*pmatch` is set to `NULL` then GIN assumes partial match is not required. The variable is initialized to `NULL` before call, so this argument can simply be ignored by operator classes that do not support partial match.

`extra_data` is an output argument that allows `extractQuery` to pass additional data to the `consistent` and `comparePartial` methods. To use it, `extractQuery` must allocate an array of `*nkeys` pointers and store its address at `*extra_data`, then store whatever it wants to into the individual pointers. The variable is initialized to `NULL` before call, so this argument can simply be ignored by operator classes that do not require extra data. If `*extra_data` is set, the whole array is passed to the `consistent` method, and the appropriate element to the `comparePartial` method.

An operator class must also provide a function to check if an indexed item matches the query. It comes in two flavors, a boolean `consistent` function, and a ternary `triConsistent` function. `triConsistent` covers the functionality of both, so providing `triConsistent` alone is sufficient. However, if the boolean variant is significantly cheaper to calculate, it can be advantageous to provide both. If only the boolean variant is provided, some optimizations that depend on refuting index items before fetching all the keys are disabled.

```
bool consistent(bool check[], StrategyNumber n, Datum query, int32 nkeys, Pointer
extra_data[], bool *recheck, Datum queryKeys[], bool nullFlags[])
```

Returns `TRUE` if an indexed item satisfies the query operator with strategy number `n` (or might satisfy it, if the `recheck` indication is returned). This function does not have direct access to the indexed item's value, since GIN does not store items explicitly. Rather, what is available is knowledge about which key values extracted from the query appear in a given indexed item. The `check` array has length `nkeys`, which is the same as the number of keys previously returned by `extractQuery` for this query datum. Each element of the `check` array is `TRUE` if the indexed item contains the corresponding query key, i.e., if `(check[i] == TRUE)` the *i*-th key of the `extractQuery` result array is present in the indexed item. The original query datum is passed in case the `consistent` method needs to consult it, and so are the `queryKeys[]` and `nullFlags[]` arrays previously returned by `extractQuery`. `extra_data` is the extra-data array returned by `extractQuery`, or `NULL` if none.

When `extractQuery` returns a null key in `queryKeys[]`, the corresponding `check[]` element is `TRUE` if the indexed item contains a null key; that is, the semantics of `check[]` are like `IS NOT DISTINCT FROM`. The `consistent` function can examine the corresponding `nullFlags[]` element if it needs to tell the difference between a regular value match and a null match.

On success, `*recheck` should be set to `TRUE` if the heap tuple needs to be rechecked against the query operator, or `FALSE` if the index test is exact. That is, a `FALSE` return value guarantees that the heap tuple does not match the query; a `TRUE` return value with `*recheck` set to `FALSE` guarantees that the heap tuple does match the query; and a `TRUE` return value with `*recheck` set to `TRUE` means that the heap tuple might match the query, so it needs to be fetched and rechecked by evaluating the query operator directly against the originally indexed item.

```
GinTernaryValue triConsistent(GinTernaryValue check[], StrategyNumber n, Datum query,
int32 nkeys, Pointer extra_data[], Datum queryKeys[], bool nullFlags[])
```

`triConsistent` is similar to `consistent`, but instead of booleans in the `check` vector, there are three possible values for each key: `GIN_TRUE`, `GIN_FALSE` and `GIN_MAYBE`. `GIN_FALSE` and `GIN_TRUE` have the same meaning as regular boolean values, while `GIN_MAYBE` means that the presence of that key is not known. When `GIN_MAYBE` values are present, the function should only return `GIN_TRUE` if the item certainly matches whether or not the index item contains the corresponding query keys. Likewise, the function must return `GIN_FALSE` only if the item certainly does not match, whether or not it contains the `GIN_MAYBE` keys. If the result depends on the `GIN_MAYBE` entries, i.e., the match cannot be confirmed or refuted based on the known query keys, the function must return `GIN_MAYBE`.

When there are no `GIN_MAYBE` values in the `check` vector, a `GIN_MAYBE` return value is the equivalent of setting the `recheck` flag in the boolean `consistent` function.

Optionally, an operator class for GIN can supply the following method:

```
int comparePartial(Datum partial_key, Datum key, StrategyNumber n, Pointer extra_data)
```

Compare a partial-match query key to an index key. Returns an integer whose sign indicates the result: less than zero means the index key does not match the query, but the index scan should continue; zero means that the index key does match the query; greater than zero indicates that the index scan should stop because no more matches are possible. The strategy number `n` of the operator that generated the partial match query is provided, in case its semantics are needed to determine when to end the scan. Also, `extra_data` is the corresponding element of the extra-data array made by `extractQuery`, or `NULL` if none. Null keys are never passed to this function.

To support “partial match” queries, an operator class must provide the `comparePartial` method, and its `extractQuery` method must set the `pmatch` parameter when a partial-match query is encountered. See [Section 61.4.2](#) for details.

The actual data types of the various `Datum` values mentioned above vary depending on the operator class. The item values passed to `extractValue` are always of the operator class's input type, and all key values must be of the class's `STORAGE` type. The type of the `query` argument passed to `extractQuery`, `consistent` and `triConsistent` is whatever is the right-hand input type of the class member operator identified by the strategy number. This need not be the same as the indexed type, so long as key values of the correct type can be extracted from it. However, it is recommended that the SQL declarations of these three support functions use the opclass's indexed data type for the `query` argument, even though the actual type might be something else depending on the operator.

61.4. Implementation

Internally, a GIN index contains a B-tree index constructed over keys, where each key is an element of one or more indexed items (a member of an array, for example) and where each tuple in a leaf page contains either a pointer to a B-tree of heap pointers (a “posting tree”), or a simple list of heap pointers (a “posting list”) when the list is small enough to fit into a single index tuple along with the key value.

As of PostgreSQL 9.1, null key values can be included in the index. Also, placeholder nulls are included in the index for indexed items that are null or contain no keys according to `extractValue`. This allows searches that should find empty items to do so.

Multicolumn GIN indexes are implemented by building a single B-tree over composite values (column number, key value). The key values for different columns can be of different types.

61.4.1. GIN Fast Update Technique

Updating a GIN index tends to be slow because of the intrinsic nature of inverted indexes: inserting or updating one heap row can cause many inserts into the index (one for each key extracted from the indexed item). As of PostgreSQL 8.4, GIN is capable of postponing much of this work by inserting new tuples into a temporary, unsorted list of pending entries. When the table is vacuumed or autoanalyzed, or when `gin_clean_pending_list` function is called, or if the pending list becomes larger than `gin_pending_list_limit`, the entries are moved to the main GIN data structure using the same bulk insert techniques used during initial index creation. This greatly improves GIN index update speed, even counting the additional vacuum overhead. Moreover the overhead work can be done by a background process instead of in foreground query processing.

The main disadvantage of this approach is that searches must scan the list of pending entries in addition to searching the regular index, and so a large list of pending entries will slow searches significantly. Another disadvantage is that, while most updates are fast, an update that causes the pending list to become “too large” will incur an immediate cleanup cycle and thus be much slower than other updates. Proper use of autovacuum can minimize both of these problems.

If consistent response time is more important than update speed, use of pending entries can be disabled by turning off the `fastupdate` storage parameter for a GIN index. See [CREATE INDEX](#) for details.

61.4.2. Partial Match Algorithm

GIN can support “partial match” queries, in which the query does not determine an exact match for one or more keys, but the possible matches fall within a reasonably narrow range of key values (within the key sorting order determined by the `compare` support method). The `extractQuery` method, instead of returning a key value to be matched exactly, returns a key value that is the lower bound of the range to be searched, and sets the `pmatch` flag true. The key range is then scanned using the `comparePartial` method. `comparePartial` must return zero for a matching index key, less than zero for a non-match that is still within the range to be searched, or greater than zero if the index key is past the range that could match.

61.5. GIN Tips and Tricks

Create vs. insert

Insertion into a GIN index can be slow due to the likelihood of many keys being inserted for each item. So, for bulk insertions into a table it is advisable to drop the GIN index and recreate it after finishing bulk insertion.

As of PostgreSQL 8.4, this advice is less necessary since delayed indexing is used (see [Section 61.4.1](#) for details). But for very large updates it may still be best to drop and recreate the index.

`maintenance_work_mem`

Build time for a GIN index is very sensitive to the `maintenance_work_mem` setting; it doesn't pay to skimp on work memory during index creation.

`gin_pending_list_limit`

During a series of insertions into an existing GIN index that has `fastupdate` enabled, the system will clean up the pending-entry list whenever the list grows larger than `gin_pending_list_limit`. To avoid fluctuations in observed response time, it's desirable to have pending-list cleanup occur in the background (i.e., via autovacuum). Foreground cleanup operations can be avoided by increasing `gin_pending_list_limit` or making autovacuum more aggressive. However, enlarging the threshold of the cleanup operation means that if a foreground cleanup does occur, it will take even longer.

`gin_pending_list_limit` can be overridden for individual GIN indexes by changing storage parameters, which allows each GIN index to have its own cleanup threshold. For example, it's possible

to increase the threshold only for the GIN index which can be updated heavily, and decrease it otherwise.

`gin_fuzzy_search_limit`

The primary goal of developing GIN indexes was to create support for highly scalable full-text search in Postgres Pro, and there are often situations when a full-text search returns a very large set of results. Moreover, this often happens when the query contains very frequent words, so that the large result set is not even useful. Since reading many tuples from the disk and sorting them could take a lot of time, this is unacceptable for production. (Note that the index search itself is very fast.)

To facilitate controlled execution of such queries, GIN has a configurable soft upper limit on the number of rows returned: the `gin_fuzzy_search_limit` configuration parameter. It is set to 0 (meaning no limit) by default. If a non-zero limit is set, then the returned set is a subset of the whole result set, chosen at random.

“Soft” means that the actual number of returned results could differ somewhat from the specified limit, depending on the query and the quality of the system's random number generator.

From experience, values in the thousands (e.g., 5000 — 20000) work well.

61.6. Limitations

GIN assumes that indexable operators are strict. This means that `extractValue` will not be called at all on a null item value (instead, a placeholder index entry is created automatically), and `extractQuery` will not be called on a null query value either (instead, the query is presumed to be unsatisfiable). Note however that null key values contained within a non-null composite item or query value are supported.

61.7. Examples

The Postgres Pro source distribution includes GIN operator classes for `tsvector` and for one-dimensional arrays of all internal types. Prefix searching in `tsvector` is implemented using the GIN partial match feature. The following `contrib` modules also contain GIN operator classes:

`btree_gin`

B-tree equivalent functionality for several data types

`hstore`

Module for storing (key, value) pairs

`intarray`

Enhanced support for `int[]`

`pg_trgm`

Text similarity using trigram matching

Chapter 62. BRIN Indexes

62.1. Introduction

BRIN stands for Block Range Index. BRIN is designed for handling very large tables in which certain columns have some natural correlation with their physical location within the table. A *block range* is a group of pages that are physically adjacent in the table; for each block range, some summary info is stored by the index. For example, a table storing a store's sale orders might have a date column on which each order was placed, and most of the time the entries for earlier orders will appear earlier in the table as well; a table storing a ZIP code column might have all codes for a city grouped together naturally.

BRIN indexes can satisfy queries via regular bitmap index scans, and will return all tuples in all pages within each range if the summary info stored by the index is *consistent* with the query conditions. The query executor is in charge of rechecking these tuples and discarding those that do not match the query conditions — in other words, these indexes are lossy. Because a BRIN index is very small, scanning the index adds little overhead compared to a sequential scan, but may avoid scanning large parts of the table that are known not to contain matching tuples.

The specific data that a BRIN index will store, as well as the specific queries that the index will be able to satisfy, depend on the operator class selected for each column of the index. Data types having a linear sort order can have operator classes that store the minimum and maximum value within each block range, for instance; geometrical types might store the bounding box for all the objects in the block range.

The size of the block range is determined at index creation time by the `pages_per_range` storage parameter. The number of index entries will be equal to the size of the relation in pages divided by the selected value for `pages_per_range`. Therefore, the smaller the number, the larger the index becomes (because of the need to store more index entries), but at the same time the summary data stored can be more precise and more data blocks can be skipped during an index scan.

62.1.1. Index Maintenance

At the time of creation, all existing index pages are scanned and a summary index tuple is created for each range, including the possibly-incomplete range at the end. As new pages are filled with data, page ranges that are already summarized will cause the summary information to be updated with data from the new tuples. When a new page is created that does not fall within the last summarized range, that range does not automatically acquire a summary tuple; those tuples remain unsummarized until a summarization run is invoked later, creating initial summaries. This process can be invoked manually using the `brin_summarize_new_values(regclass)` function, or automatically when `VACUUM` processes the table.

62.2. Built-in Operator Classes

The core Postgres Pro distribution includes the BRIN operator classes shown in [Table 62.1](#).

The *minmax* operator classes store the minimum and the maximum values appearing in the indexed column within the range. The *inclusion* operator classes store a value which includes the values in the indexed column within the range.

Table 62.1. Built-in BRIN Operator Classes

Name	Indexed Data Type	Indexable Operators
<code>abstime_minmax_ops</code>	<code>abstime</code>	<code>< <= = >= ></code>
<code>int8_minmax_ops</code>	<code>bigint</code>	<code>< <= = >= ></code>
<code>bit_minmax_ops</code>	<code>bit</code>	<code>< <= = >= ></code>
<code>varbit_minmax_ops</code>	<code>bit varying</code>	<code>< <= = >= ></code>
<code>box_inclusion_ops</code>	<code>box</code>	<code><< &< && &> >> ~= @> <@ &< << >> &></code>

Name	Indexed Data Type	Indexable Operators
bytea_minmax_ops	bytea	< <= = >= >
bpchar_minmax_ops	character	< <= = >= >
char_minmax_ops	"char"	< <= = >= >
date_minmax_ops	date	< <= = >= >
float8_minmax_ops	double precision	< <= = >= >
inet_minmax_ops	inet	< <= = >= >
network_inclusion_ops	inet	&& >= <= = >> <<
int4_minmax_ops	integer	< <= = >= >
interval_minmax_ops	interval	< <= = >= >
macaddr_minmax_ops	macaddr	< <= = >= >
name_minmax_ops	name	< <= = >= >
numeric_minmax_ops	numeric	< <= = >= >
pg_lsn_minmax_ops	pg_lsn	< <= = >= >
oid_minmax_ops	oid	< <= = >= >
range_inclusion_ops	any range type	<< &< && &> >> @> <@ - - = < <= = > >=
float4_minmax_ops	real	< <= = >= >
reltime_minmax_ops	reltime	< <= = >= >
int2_minmax_ops	smallint	< <= = >= >
text_minmax_ops	text	< <= = >= >
tid_minmax_ops	tid	< <= = >= >
timestamp_minmax_ops	timestamp without time zone	< <= = >= >
timestampztz_minmax_ops	timestamp with time zone	< <= = >= >
time_minmax_ops	time without time zone	< <= = >= >
timetz_minmax_ops	time with time zone	< <= = >= >
uuid_minmax_ops	uuid	< <= = >= >

62.3. Extensibility

The BRIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The BRIN layer itself takes care of concurrency, logging and searching the index structure.

All it takes to get a BRIN access method working is to implement a few user-defined methods, which define the behavior of summary values stored in the index and the way they interact with scan keys. In short, BRIN combines extensibility with generality, code reuse, and a clean interface.

There are four methods that an operator class for BRIN must provide:

```
BrinOpcInfo *opcInfo(Oid type_oid)
```

Returns internal information about the indexed columns' summary data. The return value must point to a palloc'd `BrinOpcInfo`, which has this definition:

```
typedef struct BrinOpcInfo
{
    /* Number of columns stored in an index column of this opclass */
    uint16      oi_nstored;
```

```

/* Opaque pointer for the opclass' private use */
void      *oi_opaque;

/* Type cache entries of the stored columns */
TypeCacheEntry *oi_typcache[FLEXIBLE_ARRAY_MEMBER];
} BrinOpcInfo;

```

`BrinOpcInfo.oi_opaque` can be used by the operator class routines to pass information between support procedures during an index scan.

```
bool consistent(BrinDesc *bdesc, BrinValues *column, ScanKey key)
```

Returns whether the `ScanKey` is consistent with the given indexed values for a range. The attribute number to use is passed as part of the scan key.

```
bool addValue(BrinDesc *bdesc, BrinValues *column, Datum newval, bool isnull)
```

Given an index tuple and an indexed value, modifies the indicated attribute of the tuple so that it additionally represents the new value. If any modification was done to the tuple, `true` is returned.

```
bool unionTuples(BrinDesc *bdesc, BrinValues *a, BrinValues *b)
```

Consolidates two index tuples. Given two index tuples, modifies the indicated attribute of the first of them so that it represents both tuples. The second tuple is not modified.

The core distribution includes support for two types of operator classes: minmax and inclusion. Operator class definitions using them are shipped for in-core data types as appropriate. Additional operator classes can be defined by the user for other data types using equivalent definitions, without having to write any source code; appropriate catalog entries being declared is enough. Note that assumptions about the semantics of operator strategies are embedded in the support procedures' source code.

Operator classes that implement completely different semantics are also possible, provided implementations of the four main support procedures described above are written. Note that backwards compatibility across major releases is not guaranteed: for example, additional support procedures might be required in later releases.

To write an operator class for a data type that implements a totally ordered set, it is possible to use the minmax support procedures alongside the corresponding operators, as shown in [Table 62.2](#). All operator class members (procedures and operators) are mandatory.

Table 62.2. Procedure and Support Numbers for Minmax Operator Classes

Operator class member	Object
Support Procedure 1	internal function <code>brin_minmax_opcinfo()</code>
Support Procedure 2	internal function <code>brin_minmax_add_value()</code>
Support Procedure 3	internal function <code>brin_minmax_consistent()</code>
Support Procedure 4	internal function <code>brin_minmax_union()</code>
Operator Strategy 1	operator less-than
Operator Strategy 2	operator less-than-or-equal-to
Operator Strategy 3	operator equal-to
Operator Strategy 4	operator greater-than-or-equal-to
Operator Strategy 5	operator greater-than

To write an operator class for a complex data type which has values included within another type, it's possible to use the inclusion support procedures alongside the corresponding operators, as shown in [Table 62.3](#). It requires only a single additional function, which can be written in any language. More

functions can be defined for additional functionality. All operators are optional. Some operators require other operators, as shown as dependencies on the table.

Table 62.3. Procedure and Support Numbers for Inclusion Operator Classes

Operator class member	Object	Dependency
Support Procedure 1	internal function <code>brin_inclusion_opcinfo()</code>	
Support Procedure 2	internal function <code>brin_inclusion_add_value()</code>	
Support Procedure 3	internal function <code>brin_inclusion_consistent()</code>	
Support Procedure 4	internal function <code>brin_inclusion_union()</code>	
Support Procedure 11	function to merge two elements	
Support Procedure 12	optional function to check whether two elements are mergeable	
Support Procedure 13	optional function to check if an element is contained within another	
Support Procedure 14	optional function to check whether an element is empty	
Operator Strategy 1	operator left-of	Operator Strategy 4
Operator Strategy 2	operator does-not-extend-to-the-right-of	Operator Strategy 5
Operator Strategy 3	operator overlaps	
Operator Strategy 4	operator does-not-extend-to-the-left-of	Operator Strategy 1
Operator Strategy 5	operator right-of	Operator Strategy 2
Operator Strategy 6, 18	operator same-as-or-equal-to	Operator Strategy 7
Operator Strategy 7, 13, 16, 24, 25	operator contains-or-equal-to	
Operator Strategy 8, 14, 26, 27	operator is-contained-by-or-equal-to	Operator Strategy 3
Operator Strategy 9	operator does-not-extend-above	Operator Strategy 11
Operator Strategy 10	operator is-below	Operator Strategy 12
Operator Strategy 11	operator is-above	Operator Strategy 9
Operator Strategy 12	operator does-not-extend-below	Operator Strategy 10
Operator Strategy 20	operator less-than	Operator Strategy 5
Operator Strategy 21	operator less-than-or-equal-to	Operator Strategy 5
Operator Strategy 22	operator greater-than	Operator Strategy 1
Operator Strategy 23	operator greater-than-or-equal-to	Operator Strategy 1

Support procedure numbers 1-10 are reserved for the BRIN internal functions, so the SQL level functions start with number 11. Support function number 11 is the main function required to build the index. It should accept two arguments with the same data type as the operator class, and return the union of them. The inclusion operator class can store union values with different data types if it is defined with the `STORAGE` parameter. The return value of the union function should match the `STORAGE` data type.

Support procedure numbers 12 and 14 are provided to support irregularities of built-in data types. Procedure number 12 is used to support network addresses from different families which are not mergeable. Procedure number 14 is used to support empty ranges. Procedure number 13 is an optional but recommended one, which allows the new value to be checked before it is passed to the union function. As the BRIN framework can shortcut some operations when the union is not changed, using this function can improve index performance.

Both minmax and inclusion operator classes support cross-data-type operators, though with these the dependencies become more complicated. The minmax operator class requires a full set of operators to be defined with both arguments having the same data type. It allows additional data types to be supported by defining extra sets of operators. Inclusion operator class operator strategies are dependent on another operator strategy as shown in [Table 62.3](#), or the same operator strategy as themselves. They require the dependency operator to be defined with the `STORAGE` data type as the left-hand-side argument and the other supported data type to be the right-hand-side argument of the supported operator. See `float4_minmax_ops` as an example of minmax, and `box_inclusion_ops` as an example of inclusion.

Chapter 63. Database Physical Storage

This chapter provides an overview of the physical storage format used by Postgres Pro databases.

63.1. Database File Layout

This section describes the storage format at the level of files and directories.

Traditionally, the configuration and data files used by a database cluster are stored together within the cluster's data directory, commonly referred to as `PGDATA` (after the name of the environment variable that can be used to define it). A common location for `PGDATA` is `/var/lib/pgsql/data`. Multiple clusters, managed by different server instances, can exist on the same machine.

The `PGDATA` directory contains several subdirectories and control files, as shown in [Table 63.1](#). In addition to these required items, the cluster configuration files `postgresql.conf`, `pg_hba.conf`, and `pg_ident.conf` are traditionally stored in `PGDATA`, although it is possible to place them elsewhere.

Table 63.1. Contents of PGDATA

Item	Description
<code>PG_VERSION</code>	A file containing the major version number of Postgres Pro
<code>base</code>	Subdirectory containing per-database subdirectories
<code>global</code>	Subdirectory containing cluster-wide tables, such as <code>pg_database</code>
<code>pg_commit_ts</code>	Subdirectory containing transaction commit timestamp data
<code>pg_clog</code>	Subdirectory containing transaction commit status data
<code>pg_dynshmem</code>	Subdirectory containing files used by the dynamic shared memory subsystem
<code>pg_logical</code>	Subdirectory containing status data for logical decoding
<code>pg_multixact</code>	Subdirectory containing multitransaction status data (used for shared row locks)
<code>pg_notify</code>	Subdirectory containing LISTEN/NOTIFY status data
<code>pg_replslot</code>	Subdirectory containing replication slot data
<code>pg_serial</code>	Subdirectory containing information about committed serializable transactions
<code>pg_snapshots</code>	Subdirectory containing exported snapshots
<code>pg_stat</code>	Subdirectory containing permanent files for the statistics subsystem
<code>pg_stat_tmp</code>	Subdirectory containing temporary files for the statistics subsystem
<code>pg_subtrans</code>	Subdirectory containing subtransaction status data
<code>pg_tblspc</code>	Subdirectory containing symbolic links to tablespaces
<code>pg_twophase</code>	Subdirectory containing state files for prepared transactions

Item	Description
<code>pg_xlog</code>	Subdirectory containing WAL (Write Ahead Log) files
<code>postgresql.auto.conf</code>	A file used for storing configuration parameters that are set by <code>ALTER SYSTEM</code>
<code>postmaster.opts</code>	A file recording the command-line options the server was last started with
<code>postmaster.pid</code>	A lock file recording the current postmaster process ID (PID), cluster data directory path, postmaster start timestamp, port number, Unix-domain socket directory path (empty on Windows), first valid listen address (IP address or *, or empty if not listening on TCP), and shared memory segment ID (this file is not present after server shutdown)

For each database in the cluster there is a subdirectory within `PGDATA/base`, named after the database's OID in `pg_database`. This subdirectory is the default location for the database's files; in particular, its system catalogs are stored there.

Each table and index is stored in a separate file. For ordinary relations, these files are named after the table or index's *filenode* number, which can be found in `pg_class.relfilenode`. But for temporary relations, the file name is of the form `tBBB_FFF`, where *BBB* is the backend ID of the backend which created the file, and *FFF* is the filenode number. In either case, in addition to the main file (a/k/a main fork), each table and index has a *free space map* (see [Section 63.3](#)), which stores information about free space available in the relation. The free space map is stored in a file named with the filenode number plus the suffix `_fsm`. Tables also have a *visibility map*, stored in a fork with the suffix `_vm`, to track which pages are known to have no dead tuples. The visibility map is described further in [Section 63.4](#). Unlogged tables and indexes have a third fork, known as the initialization fork, which is stored in a fork with the suffix `_init` (see [Section 63.5](#)).

Caution

Note that while a table's filenode often matches its OID, this is *not* necessarily the case; some operations, like `TRUNCATE`, `REINDEX`, `CLUSTER` and some forms of `ALTER TABLE`, can change the filenode while preserving the OID. Avoid assuming that filenode and table OID are the same. Also, for certain system catalogs including `pg_class` itself, `pg_class.relfilenode` contains zero. The actual filenode number of these catalogs is stored in a lower-level data structure, and can be obtained using the `pg_relation_filenode()` function.

When a table or index exceeds 1 GB, it is divided into gigabyte-sized *segments*. The first segment's file name is the same as the filenode; subsequent segments are named `filenode.1`, `filenode.2`, etc. This arrangement avoids problems on platforms that have file size limitations. (Actually, 1 GB is just the default segment size. The segment size can be adjusted using the configuration option `--with-segsize` when building Postgres Pro.) In principle, free space map and visibility map forks could require multiple segments as well, though this is unlikely to happen in practice.

A table that has columns with potentially large entries will have an associated *TOAST* table, which is used for out-of-line storage of field values that are too large to keep in the table rows proper. `pg_class.reltoastrelid` links from a table to its TOAST table, if any. See [Section 63.2](#) for more information.

The contents of tables and indexes are discussed further in [Section 63.6](#).

Tablespaces make the scenario more complicated. Each user-defined tablespace has a symbolic link inside the `PGDATA/pg_tblspc` directory, which points to the physical tablespace directory (i.e., the

location specified in the tablespace's `CREATE TABLESPACE` command). This symbolic link is named after the tablespace's OID. Inside the physical tablespace directory there is a subdirectory with a name that depends on the Postgres Pro server version, such as `PG_9.0_201008051`. (The reason for using this subdirectory is so that successive versions of the database can use the same `CREATE TABLESPACE` location value without conflicts.) Within the version-specific subdirectory, there is a subdirectory for each database that has elements in the tablespace, named after the database's OID. Tables and indexes are stored within that directory, using the filenode naming scheme. The `pg_default` tablespace is not accessed through `pg_tblspc`, but corresponds to `PGDATA/base`. Similarly, the `pg_global` tablespace is not accessed through `pg_tblspc`, but corresponds to `PGDATA/global`.

The `pg_relation_filepath()` function shows the entire path (relative to `PGDATA`) of any relation. It is often useful as a substitute for remembering many of the above rules. But keep in mind that this function just gives the name of the first segment of the main fork of the relation — you may need to append a segment number and/or `_fsm`, `_vm`, or `_init` to find all the files associated with the relation.

Temporary files (for operations such as sorting more data than can fit in memory) are created within `PGDATA/base/pgsql_tmp`, or within a `pgsql_tmp` subdirectory of a tablespace directory if a tablespace other than `pg_default` is specified for them. The name of a temporary file has the form `pgsql_tmpPPP.NNN`, where `PPP` is the PID of the owning backend and `NNN` distinguishes different temporary files of that backend.

63.2. TOAST

This section provides an overview of TOAST (The Oversized-Attribute Storage Technique).

Postgres Pro uses a fixed page size (commonly 8 kB), and does not allow tuples to span multiple pages. Therefore, it is not possible to store very large field values directly. To overcome this limitation, large field values are compressed and/or broken up into multiple physical rows. This happens transparently to the user, with only small impact on most of the backend code. The technique is affectionately known as TOAST (or “the best thing since sliced bread”). The TOAST infrastructure is also used to improve handling of large data values in-memory.

Only certain data types support TOAST — there is no need to impose the overhead on data types that cannot produce large field values. To support TOAST, a data type must have a variable-length (*varlena*) representation, in which, ordinarily, the first four-byte word of any stored value contains the total length of the value in bytes (including itself). TOAST does not constrain the rest of the data type's representation. The special representations collectively called *TOASTed values* work by modifying or reinterpreting this initial length word. Therefore, the C-level functions supporting a TOAST-able data type must be careful about how they handle potentially TOASTed input values: an input might not actually consist of a four-byte length word and contents until after it's been *detoasted*. (This is normally done by invoking `PG_DETOAST_DATUM` before doing anything with an input value, but in some cases more efficient approaches are possible. See [Section 36.11.1](#) for more detail.)

TOAST usurps two bits of the *varlena* length word (the high-order bits on big-endian machines, the low-order bits on little-endian machines), thereby limiting the logical size of any value of a TOAST-able data type to 1 GB (2^{30} - 1 bytes). When both bits are zero, the value is an ordinary un-TOASTed value of the data type, and the remaining bits of the length word give the total datum size (including length word) in bytes. When the highest-order or lowest-order bit is set, the value has only a single-byte header instead of the normal four-byte header, and the remaining bits of that byte give the total datum size (including length byte) in bytes. This alternative supports space-efficient storage of values shorter than 127 bytes, while still allowing the data type to grow to 1 GB at need. Values with single-byte headers aren't aligned on any particular boundary, whereas values with four-byte headers are aligned on at least a four-byte boundary; this omission of alignment padding provides additional space savings that is significant compared to short values. As a special case, if the remaining bits of a single-byte header are all zero (which would be impossible for a self-inclusive length), the value is a pointer to out-of-line data, with several possible alternatives as described below. The type and size of such a *TOAST pointer* are determined by a code stored in the second byte of the datum. Lastly, when the highest-order or lowest-order bit is clear but the adjacent bit is set, the content of the datum has been compressed and must be decompressed before

use. In this case the remaining bits of the four-byte length word give the total size of the compressed datum, not the original data. Note that compression is also possible for out-of-line data but the varlena header does not tell whether it has occurred — the content of the TOAST pointer tells that, instead.

As mentioned, there are multiple types of TOAST pointer datums. The oldest and most common type is a pointer to out-of-line data stored in a *TOAST table* that is separate from, but associated with, the table containing the TOAST pointer datum itself. These *on-disk* pointer datums are created by the TOAST management code (in `access/heap/tuptoaster.c`) when a tuple to be stored on disk is too large to be stored as-is. Further details appear in [Section 63.2.1](#). Alternatively, a TOAST pointer datum can contain a pointer to out-of-line data that appears elsewhere in memory. Such datums are necessarily short-lived, and will never appear on-disk, but they are very useful for avoiding copying and redundant processing of large data values. Further details appear in [Section 63.2.2](#).

The compression technique used for either in-line or out-of-line compressed data is a fairly simple and very fast member of the LZ family of compression techniques. See `src/common/pg_lzcompress.c` for the details.

63.2.1. Out-of-line, on-disk TOAST storage

If any of the columns of a table are TOAST-able, the table will have an associated TOAST table, whose OID is stored in the table's `pg_class.reltoastrelid` entry. On-disk TOASTed values are kept in the TOAST table, as described in more detail below.

Out-of-line values are divided (after compression if used) into chunks of at most `TOAST_MAX_CHUNK_SIZE` bytes (by default this value is chosen so that four chunk rows will fit on a page, making it about 2000 bytes). Each chunk is stored as a separate row in the TOAST table belonging to the owning table. Every TOAST table has the columns `chunk_id` (an OID identifying the particular TOASTed value), `chunk_seq` (a sequence number for the chunk within its value), and `chunk_data` (the actual data of the chunk). A unique index on `chunk_id` and `chunk_seq` provides fast retrieval of the values. A pointer datum representing an out-of-line on-disk TOASTed value therefore needs to store the OID of the TOAST table in which to look and the OID of the specific value (its `chunk_id`). For convenience, pointer datums also store the logical datum size (original uncompressed data length) and physical stored size (different if compression was applied). Allowing for the varlena header bytes, the total size of an on-disk TOAST pointer datum is therefore 18 bytes regardless of the actual size of the represented value.

The TOAST management code is triggered only when a row value to be stored in a table is wider than `TOAST_TUPLE_THRESHOLD` bytes (normally 2 kB). The TOAST code will compress and/or move field values out-of-line until the row value is shorter than `TOAST_TUPLE_TARGET` bytes (also normally 2 kB) or no more gains can be had. During an UPDATE operation, values of unchanged fields are normally preserved as-is; so an UPDATE of a row with out-of-line values incurs no TOAST costs if none of the out-of-line values change.

The TOAST management code recognizes four different strategies for storing TOAST-able columns on disk:

- `PLAIN` prevents either compression or out-of-line storage; furthermore it disables use of single-byte headers for varlena types. This is the only possible strategy for columns of non-TOAST-able data types.
- `EXTENDED` allows both compression and out-of-line storage. This is the default for most TOAST-able data types. Compression will be attempted first, then out-of-line storage if the row is still too big.
- `EXTERNAL` allows out-of-line storage but not compression. Use of `EXTERNAL` will make substring operations on wide `text` and `bytea` columns faster (at the penalty of increased storage space) because these operations are optimized to fetch only the required parts of the out-of-line value when it is not compressed.
- `MAIN` allows compression but not out-of-line storage. (Actually, out-of-line storage will still be performed for such columns, but only as a last resort when there is no other way to make the row small enough to fit on a page.)

Each TOAST-able data type specifies a default strategy for columns of that data type, but the strategy for a given table column can be altered with `ALTER TABLE SET STORAGE`.

This scheme has a number of advantages compared to a more straightforward approach such as allowing row values to span pages. Assuming that queries are usually qualified by comparisons against relatively small key values, most of the work of the executor will be done using the main row entry. The big values of TOASTed attributes will only be pulled out (if selected at all) at the time the result set is sent to the client. Thus, the main table is much smaller and more of its rows fit in the shared buffer cache than would be the case without any out-of-line storage. Sort sets shrink also, and sorts will more often be done entirely in memory. A little test showed that a table containing typical HTML pages and their URLs was stored in about half of the raw data size including the TOAST table, and that the main table contained only about 10% of the entire data (the URLs and some small HTML pages). There was no run time difference compared to an un-TOASTed comparison table, in which all the HTML pages were cut down to 7 kB to fit.

63.2.2. Out-of-line, in-memory TOAST storage

TOAST pointers can point to data that is not on disk, but is elsewhere in the memory of the current server process. Such pointers obviously cannot be long-lived, but they are nonetheless useful. There are currently two sub-cases: pointers to *indirect* data and pointers to *expanded* data.

Indirect TOAST pointers simply point at a non-indirect varlena value stored somewhere in memory. This case was originally created merely as a proof of concept, but it is currently used during logical decoding to avoid possibly having to create physical tuples exceeding 1 GB (as pulling all out-of-line field values into the tuple might do). The case is of limited use since the creator of the pointer datum is entirely responsible that the referenced data survives for as long as the pointer could exist, and there is no infrastructure to help with this.

Expanded TOAST pointers are useful for complex data types whose on-disk representation is not especially suited for computational purposes. As an example, the standard varlena representation of a Postgres Pro array includes dimensionality information, a nulls bitmap if there are any null elements, then the values of all the elements in order. When the element type itself is variable-length, the only way to find the N 'th element is to scan through all the preceding elements. This representation is appropriate for on-disk storage because of its compactness, but for computations with the array it's much nicer to have an "expanded" or "deconstructed" representation in which all the element starting locations have been identified. The TOAST pointer mechanism supports this need by allowing a pass-by-reference Datum to point to either a standard varlena value (the on-disk representation) or a TOAST pointer that points to an expanded representation somewhere in memory. The details of this expanded representation are up to the data type, though it must have a standard header and meet the other API requirements given in `src/include/utils/expandeddatum.h`. C-level functions working with the data type can choose to handle either representation. Functions that do not know about the expanded representation, but simply apply `PG_DETOAST_DATUM` to their inputs, will automatically receive the traditional varlena representation; so support for an expanded representation can be introduced incrementally, one function at a time.

TOAST pointers to expanded values are further broken down into *read-write* and *read-only* pointers. The pointed-to representation is the same either way, but a function that receives a read-write pointer is allowed to modify the referenced value in-place, whereas one that receives a read-only pointer must not; it must first create a copy if it wants to make a modified version of the value. This distinction and some associated conventions make it possible to avoid unnecessary copying of expanded values during query execution.

For all types of in-memory TOAST pointer, the TOAST management code ensures that no such pointer datum can accidentally get stored on disk. In-memory TOAST pointers are automatically expanded to normal in-line varlena values before storage — and then possibly converted to on-disk TOAST pointers, if the containing tuple would otherwise be too big.

63.3. Free Space Map

Each heap and index relation, except for hash indexes, has a Free Space Map (FSM) to keep track of available space in the relation. It's stored alongside the main relation data in a separate relation fork,

named after the filenode number of the relation, plus a `_fsm` suffix. For example, if the filenode of a relation is 12345, the FSM is stored in a file called `12345_fsm`, in the same directory as the main relation file.

The Free Space Map is organized as a tree of FSM pages. The bottom level FSM pages store the free space available on each heap (or index) page, using one byte to represent each such page. The upper levels aggregate information from the lower levels.

Within each FSM page is a binary tree, stored in an array with one byte per node. Each leaf node represents a heap page, or a lower level FSM page. In each non-leaf node, the higher of its children's values is stored. The maximum value in the leaf nodes is therefore stored at the root.

The `pg_freespacemap` module can be used to examine the information stored in free space maps.

63.4. Visibility Map

Each heap relation has a Visibility Map (VM) to keep track of which pages contain only tuples that are known to be visible to all active transactions; it also keeps track of which pages contain only frozen tuples. It's stored alongside the main relation data in a separate relation fork, named after the filenode number of the relation, plus a `_vm` suffix. For example, if the filenode of a relation is 12345, the VM is stored in a file called `12345_vm`, in the same directory as the main relation file. Note that indexes do not have VMs.

The visibility map stores two bits per heap page. The first bit, if set, indicates that the page is all-visible, or in other words that the page does not contain any tuples that need to be vacuumed. This information can also be used by *index-only scans* to answer queries using only the index tuple. The second bit, if set, means that all tuples on the page have been frozen.

The map is conservative in the sense that we make sure that whenever a bit is set, we know the condition is true, but if a bit is not set, it might or might not be true. Visibility map bits are only set by vacuum, but are cleared by any data-modifying operations on a page.

The `pg_visibility` module can be used to examine the information stored in the visibility map.

63.5. The Initialization Fork

Each unlogged table, and each index on an unlogged table, has an initialization fork. The initialization fork is an empty table or index of the appropriate type. When an unlogged table must be reset to empty due to a crash, the initialization fork is copied over the main fork, and any other forks are erased (they will be recreated automatically as needed).

63.6. Database Page Layout

This section provides an overview of the page format used within Postgres Pro tables and indexes.¹ Sequences and TOAST tables are formatted just like a regular table.

In the following explanation, a *byte* is assumed to contain 8 bits. In addition, the term *item* refers to an individual data value that is stored on a page. In a table, an item is a row; in an index, an item is an index entry.

Every table and index is stored as an array of *pages* of a fixed size (usually 8 kB, although a different page size can be selected when compiling the server). In a table, all the pages are logically equivalent, so a particular item (row) can be stored in any page. In indexes, the first page is generally reserved as a *metapage* holding control information, and there can be different types of pages within the index, depending on the index access method.

Table 63.2 shows the overall layout of a page. There are five parts to each page.

¹ Actually, index access methods need not use this page format. All the existing index methods do use this basic format, but the data kept on index metapages usually doesn't follow the item layout rules.

Table 63.2. Overall Page Layout

Item	Description
PageHeaderData	24 bytes long. Contains general information about the page, including free space pointers.
ItemIdData	Array of item identifiers pointing to the actual items. Each entry is an (offset,length) pair. 4 bytes per item.
Free space	The unallocated space. New item identifiers are allocated from the start of this area, new items from the end.
Items	The actual items themselves.
Special space	Index access method specific data. Different methods store different data. Additionally, this space is used to store information about 64-bit transaction IDs.

The first 40 bytes of each page consists of a page header (`PageHeaderData`). Its format is detailed in [Table 63.3](#). The first field tracks the most recent WAL entry related to this page. The second field contains the page checksum if [data checksums](#) are enabled. Next is a 2-byte field containing flag bits. This is followed by three 2-byte integer fields (`pd_lower`, `pd_upper`, and `pd_special`). These contain byte offsets from the page start to the start of unallocated space, to the end of unallocated space, and to the start of the special space. Next are two 8-byte fields containing epoch, i. e. an offset, for short (4-byte) transaction IDs in this page. The next 2 bytes of the page header, `pd_pagesize_version`, store both the page size and a version indicator. Beginning with PostgreSQL 8.3 the version number is 4; PostgreSQL 8.1 and 8.2 used version number 3; PostgreSQL 8.0 used version number 2; PostgreSQL 7.3 and 7.4 used version number 1; prior releases used version number 0. (The basic page layout and header format has not changed in most of these versions, but the layout of heap row headers has.) The page size is basically only present as a cross-check; there is no support for having more than one page size in an installation. The last field is a hint that shows whether pruning the page is likely to be profitable: it tracks the oldest un-pruned XMAX on the page.

Table 63.3. PageHeaderData Layout

Field	Type	Length	Description
<code>pd_lsn</code>	<code>PageXLogRecPtr</code>	8 bytes	LSN: next byte after last byte of xlog record for last change to this page
<code>pd_checksum</code>	<code>uint16</code>	2 bytes	Page checksum
<code>pd_flags</code>	<code>uint16</code>	2 bytes	Flag bits
<code>pd_lower</code>	<code>LocationIndex</code>	2 bytes	Offset to start of free space
<code>pd_upper</code>	<code>LocationIndex</code>	2 bytes	Offset to end of free space
<code>pd_special</code>	<code>LocationIndex</code>	2 bytes	Offset to start of special space
<code>pd_pagesize_version</code>	<code>uint16</code>	2 bytes	Page size and layout version number information
<code>pd_xid_epoch</code>	<code>TransactionId</code>	8 bytes	Epoch for short 4-byte transaction IDs in this page
<code>pd_multi_epoch</code>	<code>TransactionId</code>	8 bytes	Epoch for short 4-byte multixact IDs in this page

Field	Type	Length	Description
pd_prune_xid	ShortTransactionId	4 bytes	Oldest unpruned XMAX on page, or zero if none

All the details can be found in `src/include/storage/bufpage.h`.

Following the page header are item identifiers (`ItemIdData`), each requiring four bytes. An item identifier contains a byte-offset to the start of an item, its length in bytes, and a few attribute bits which affect its interpretation. New item identifiers are allocated as needed from the beginning of the unallocated space. The number of item identifiers present can be determined by looking at `pd_lower`, which is increased to allocate a new identifier. Because an item identifier is never moved until it is freed, its index can be used on a long-term basis to reference an item, even when the item itself is moved around on the page to compact free space. In fact, every pointer to an item (`ItemPointer`, also known as `CTID`) created by Postgres Pro consists of a page number and the index of an item identifier.

The items themselves are stored in space allocated backwards from the end of unallocated space. The exact structure varies depending on what the table is to contain. Tables and sequences both use a structure named `HeapTupleHeaderData`, described below.

The final section is the “special section” which can contain anything the access method wishes to store. For example, b-tree indexes store links to the page's left and right siblings, as well as some other data relevant to the index structure. Ordinary tables do not use a special section at all (indicated by setting `pd_special` to equal the page size).

All table rows are structured in the same way. There is a fixed-size header (occupying 40 bytes on most machines), followed by an optional null bitmap, an optional object ID field, and the user data. The header is detailed in [Table 63.4](#). The actual user data (columns of the row) begins at the offset indicated by `t_hoff`, which must always be a multiple of the `MAXALIGN` distance for the platform. The null bitmap is only present if the `HEAP_HASNULL` bit is set in `t_infomask`. If it is present it begins just after the fixed header and occupies enough bytes to have one bit per data column (that is, `t_natts` bits altogether). In this list of bits, a 1 bit indicates not-null, a 0 bit is a null. When the bitmap is not present, all columns are assumed not-null. The object ID is only present if the `HEAP_HASOID` bit is set in `t_infomask`. If present, it appears just before the `t_hoff` boundary. Any padding needed to make `t_hoff` a `MAXALIGN` multiple will appear between the null bitmap and the object ID. (This in turn ensures that the object ID is suitably aligned.)

Table 63.4. HeapTupleHeaderData Layout

Field	Type	Length	Description
t_xmin	ShortTransactionId	4 bytes	insert XID stamp
t_xmax	ShortTransactionId	4 bytes	delete XID stamp
t_cid	CommandId	4 bytes	insert and/or delete CID stamp (overlays with t_xvac)
t_xvac	ShortTransactionId	4 bytes	XID for VACUUM operation moving a row version
t_ctid	ItemPointerData	6 bytes	current TID of this or newer row version
t_infomask2	uint16	2 bytes	number of attributes, plus various flag bits
t_infomask	uint16	2 bytes	various flag bits
t_hoff	uint8	1 byte	offset to user data

All the details can be found in `src/include/access/htup_details.h`.

Interpreting the actual data can only be done with information obtained from other tables, mostly `pg_attribute`. The key values needed to identify field locations are `attlen` and `attalign`. There is no way to directly get a particular attribute, except when there are only fixed width fields and no null values. All this trickery is wrapped up in the functions *heap_getattr*, *fastgetattr* and *heap_getsysattr*.

To read the data you need to examine each attribute in turn. First check whether the field is NULL according to the null bitmap. If it is, go to the next. Then make sure you have the right alignment. If the field is a fixed width field, then all the bytes are simply placed. If it's a variable length field (`attlen = -1`) then it's a bit more complicated. All variable-length data types share the common header structure `struct varlena`, which includes the total length of the stored value and some flag bits. Depending on the flags, the data can be either inline or in a TOAST table; it might be compressed, too (see [Section 63.2](#)).

Chapter 64. BKI Backend Interface

Backend Interface (BKI) files are scripts in a special language that is understood by the Postgres Pro backend when running in the “bootstrap” mode. The bootstrap mode allows system catalogs to be created and filled from scratch, whereas ordinary SQL commands require the catalogs to exist already. BKI files can therefore be used to create the database system in the first place. (And they are probably not useful for anything else.)

initdb uses a BKI file to do part of its job when creating a new database cluster. The input file used by initdb is created as part of building and installing Postgres Pro by a program named `genbki.pl`, which reads some specially formatted C header files in the `src/include/catalog/` directory of the source tree. The created BKI file is called `postgres.bki` and is normally installed in the `share` subdirectory of the installation tree.

Related information can be found in the documentation for initdb.

64.1. BKI File Format

This section describes how the Postgres Pro backend interprets BKI files. This description will be easier to understand if the `postgres.bki` file is at hand as an example.

BKI input consists of a sequence of commands. Commands are made up of a number of tokens, depending on the syntax of the command. Tokens are usually separated by whitespace, but need not be if there is no ambiguity. There is no special command separator; the next token that syntactically cannot belong to the preceding command starts a new one. (Usually you would put a new command on a new line, for clarity.) Tokens can be certain key words, special characters (parentheses, commas, etc.), numbers, or double-quoted strings. Everything is case sensitive.

Lines starting with `#` are ignored.

64.2. BKI Commands

```
create tablename tableoid [bootstrap] [shared_relation] [without_oids] [rowtype_oid oid] (name1 = type1 [FORCE NOT NULL | FORCE NULL ] [, name2 = type2 [FORCE NOT NULL | FORCE NULL ], ...])
```

Create a table named *tablename*, and having the OID *tableoid*, with the columns given in parentheses.

The following column types are supported directly by `bootstrap.c`: `bool`, `bytea`, `char` (1 byte), `name`, `int2`, `int4`, `regproc`, `regclass`, `regtype`, `text`, `oid`, `tid`, `xid`, `cid`, `int2vector`, `oidvector`, `_int4` (array), `_text` (array), `_oid` (array), `_char` (array), `_aclitem` (array). Although it is possible to create tables containing columns of other types, this cannot be done until after `pg_type` has been created and filled with appropriate entries. (That effectively means that only these column types can be used in bootstrapped tables, but non-bootstrap catalogs can contain any built-in type.)

When `bootstrap` is specified, the table will only be created on disk; nothing is entered into `pg_class`, `pg_attribute`, etc, for it. Thus the table will not be accessible by ordinary SQL operations until such entries are made the hard way (with `insert` commands). This option is used for creating `pg_class` etc themselves.

The table is created as shared if `shared_relation` is specified. It will have OIDs unless `without_oids` is specified. The table's row type OID (`pg_type` OID) can optionally be specified via the `rowtype_oid` clause; if not specified, an OID is automatically generated for it. (The `rowtype_oid` clause is useless if `bootstrap` is specified, but it can be provided anyway for documentation.)

```
open tablename
```

Open the table named *tablename* for insertion of data. Any currently open table is closed.

`close [tablename]`

Close the open table. The name of the table can be given as a cross-check, but this is not required.

`insert [OID = oid_value] ( value1 value2 ... )`

Insert a new row into the open table using *value1*, *value2*, etc., for its column values and *oid_value* for its OID. If *oid_value* is zero (0) or the clause is omitted, and the table has OIDs, then the next available OID is assigned.

NULL values can be specified using the special key word `_null_`. Values containing spaces must be double quoted.

`declare [unique] index indexname indexoid on tablename using amname ( opclass1 name1 [, ...] )`

Create an index named *indexname*, having OID *indexoid*, on the table named *tablename*, using the *amname* access method. The fields to index are called *name1*, *name2* etc., and the operator classes to use are *opclass1*, *opclass2* etc., respectively. The index file is created and appropriate catalog entries are made for it, but the index contents are not initialized by this command.

`declare toast toasttableoid toastindexoid on tablename`

Create a TOAST table for the table named *tablename*. The TOAST table is assigned OID *toasttableoid* and its index is assigned OID *toastindexoid*. As with `declare index`, filling of the index is postponed.

`build indices`

Fill in the indices that have previously been declared.

64.3. Structure of the Bootstrap BKI File

The `open` command cannot be used until the tables it uses exist and have entries for the table that is to be opened. (These minimum tables are `pg_class`, `pg_attribute`, `pg_proc`, and `pg_type`.) To allow those tables themselves to be filled, `create` with the `bootstrap` option implicitly opens the created table for data insertion.

Also, the `declare index` and `declare toast` commands cannot be used until the system catalogs they need have been created and filled in.

Thus, the structure of the `postgres.bki` file has to be:

1. `create bootstrap` one of the critical tables
2. `insert` data describing at least the critical tables
3. `close`
4. Repeat for the other critical tables.
5. `create` (without `bootstrap`) a noncritical table
6. `open`
7. `insert` desired data
8. `close`
9. Repeat for the other noncritical tables.
10. Define indexes and toast tables.
11. `build indices`

There are doubtless other, undocumented ordering dependencies.

64.4. Example

The following sequence of commands will create the table `test_table` with OID 420, having two columns `cola` and `colb` of type `int4` and `text`, respectively, and insert two rows into the table:

```
create test_table 420 (cola = int4, colb = text)
open test_table
insert OID=421 ( 1 "value1" )
insert OID=422 ( 2 _null_ )
close test_table
```

Chapter 65. How the Planner Uses Statistics

This chapter builds on the material covered in [Section 14.1](#) and [Section 14.2](#) to show some additional details about how the planner uses the system statistics to estimate the number of rows each part of a query might return. This is a significant part of the planning process, providing much of the raw material for cost calculation.

The intent of this chapter is not to document the code in detail, but to present an overview of how it works. This will perhaps ease the learning curve for someone who subsequently wishes to read the code.

65.1. Row Estimation Examples

The examples shown below use tables in the Postgres Pro regression test database. The outputs shown are taken from version 8.3. The behavior of earlier (or later) versions might vary. Note also that since `ANALYZE` uses random sampling while producing statistics, the results will change slightly after any new `ANALYZE`.

Let's start with a very simple query:

```
EXPLAIN SELECT * FROM tenk1;
```

QUERY PLAN

```
-----  
Seq Scan on tenk1  (cost=0.00..458.00 rows=10000 width=244)
```

How the planner determines the cardinality of `tenk1` is covered in [Section 14.2](#), but is repeated here for completeness. The number of pages and rows is looked up in `pg_class`:

```
SELECT relpages, reltuples FROM pg_class WHERE relname = 'tenk1';
```

```
relpages | reltuples  
-----+-----  
    358 |    10000
```

These numbers are current as of the last `VACUUM` or `ANALYZE` on the table. The planner then fetches the actual current number of pages in the table (this is a cheap operation, not requiring a table scan). If that is different from `relpages` then `reltuples` is scaled accordingly to arrive at a current number-of-rows estimate. In the example above, the value of `relpages` is up-to-date so the rows estimate is the same as `reltuples`.

Let's move on to an example with a range condition in its `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000;
```

QUERY PLAN

```
-----  
Bitmap Heap Scan on tenk1  (cost=24.06..394.64 rows=1007 width=244)  
  Recheck Cond: (unique1 < 1000)  
    -> Bitmap Index Scan on tenk1_unique1  (cost=0.00..23.80 rows=1007 width=0)  
        Index Cond: (unique1 < 1000)
```

The planner examines the `WHERE` clause condition and looks up the selectivity function for the operator `<` in `pg_operator`. This is held in the column `oprrest`, and the entry in this case is `scalarlttsel`. The `scalarlttsel` function retrieves the histogram for `unique1` from `pg_statistics`. For manual queries it is more convenient to look in the simpler `pg_stats` view:

```
SELECT histogram_bounds FROM pg_stats  
WHERE tablename='tenk1' AND attname='unique1';
```

histogram_bounds

```
-----  
{0,993,1997,3050,4040,5036,5957,7057,8029,9016,9995}
```

Next the fraction of the histogram occupied by “< 1000” is worked out. This is the selectivity. The histogram divides the range into equal frequency buckets, so all we have to do is locate the bucket that our value is in and count *part* of it and *all* of the ones before. The value 1000 is clearly in the second bucket (993-1997). Assuming a linear distribution of values inside each bucket, we can calculate the selectivity as:

```
selectivity = (1 + (1000 - bucket[2].min)/(bucket[2].max - bucket[2].min))/num_buckets
            = (1 + (1000 - 993)/(1997 - 993))/10
            = 0.100697
```

that is, one whole bucket plus a linear fraction of the second, divided by the number of buckets. The estimated number of rows can now be calculated as the product of the selectivity and the cardinality of `tenk1`:

```
rows = rel_cardinality * selectivity
      = 10000 * 0.100697
      = 1007 (rounding off)
```

Next let's consider an example with an equality condition in its `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'CRAAAA';
```

QUERY PLAN

```
-----
Seq Scan on tenk1 (cost=0.00..483.00 rows=30 width=244)
  Filter: (stringu1 = 'CRAAAA'::name)
```

Again the planner examines the `WHERE` clause condition and looks up the selectivity function for `=`, which is `eqsel`. For equality estimation the histogram is not useful; instead the list of *most common values* (MCVs) is used to determine the selectivity. Let's have a look at the MCVs, with some additional columns that will be useful later:

```
SELECT null_frac, n_distinct, most_common_vals, most_common_freqs FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';
```

```
null_frac          | 0
n_distinct         | 676
most_common_vals   |
{EJAAAA, BBAAAA, CRAAAA, FCAAAA, FEAAAA, GSAAAA, JOAAAA, MCAAAA, NAAAAA, WGAAAA}
most_common_freqs  | {0.00333333, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003}
```

Since `CRAAAA` appears in the list of MCVs, the selectivity is merely the corresponding entry in the list of most common frequencies (MCFs):

```
selectivity = mcf[3]
            = 0.003
```

As before, the estimated number of rows is just the product of this with the cardinality of `tenk1`:

```
rows = 10000 * 0.003
      = 30
```

Now consider the same query, but with a constant that is not in the MCV list:

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'xxx';
```

QUERY PLAN

```
-----
Seq Scan on tenk1 (cost=0.00..483.00 rows=15 width=244)
  Filter: (stringu1 = 'xxx'::name)
```

This is quite a different problem: how to estimate the selectivity when the value is *not* in the MCV list. The approach is to use the fact that the value is not in the list, combined with the knowledge of the frequencies for all of the MCVs:

```
selectivity = (1 - sum(mvf))/(num_distinct - num_mcv)
            = (1 - (0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 +
                    0.003 + 0.003 + 0.003 + 0.003))/(676 - 10)
            = 0.0014559
```

That is, add up all the frequencies for the MCVs and subtract them from one, then divide by the number of *other* distinct values. This amounts to assuming that the fraction of the column that is not any of the MCVs is evenly distributed among all the other distinct values. Notice that there are no null values so we don't have to worry about those (otherwise we'd subtract the null fraction from the numerator as well). The estimated number of rows is then calculated as usual:

```
rows = 10000 * 0.0014559
      = 15   (rounding off)
```

The previous example with `unique1 < 1000` was an oversimplification of what `scalarltsel` really does; now that we have seen an example of the use of MCVs, we can fill in some more detail. The example was correct as far as it went, because since `unique1` is a unique column it has no MCVs (obviously, no value is any more common than any other value). For a non-unique column, there will normally be both a histogram and an MCV list, and *the histogram does not include the portion of the column population represented by the MCVs*. We do things this way because it allows more precise estimation. In this situation `scalarltsel` directly applies the condition (e.g., “< 1000”) to each value of the MCV list, and adds up the frequencies of the MCVs for which the condition is true. This gives an exact estimate of the selectivity within the portion of the table that is MCVs. The histogram is then used in the same way as above to estimate the selectivity in the portion of the table that is not MCVs, and then the two numbers are combined to estimate the overall selectivity. For example, consider

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 < 'IAAAAA';
```

QUERY PLAN

```
-----
Seq Scan on tenk1   (cost=0.00..483.00 rows=3077 width=244)
  Filter: (stringu1 < 'IAAAAA'::name)
```

We already saw the MCV information for `stringu1`, and here is its histogram:

```
SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';
```

histogram_bounds

```
-----
{AAAAAA,CQAAAA,FRAAAA,IBAAAA,KRAAAA,NFAAAA,PSAAAA,SGAAAA,VAAAAA,XLAAAA,ZZAAAA}
```

Checking the MCV list, we find that the condition `stringu1 < 'IAAAAA'` is satisfied by the first six entries and not the last four, so the selectivity within the MCV part of the population is

```
selectivity = sum(relevant mvfs)
            = 0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003
            = 0.01833333
```

Summing all the MCFs also tells us that the total fraction of the population represented by MCVs is 0.03033333, and therefore the fraction represented by the histogram is 0.96966667 (again, there are no nulls, else we'd have to exclude them here). We can see that the value `IAAAAA` falls nearly at the end of the third histogram bucket. Using some rather cheesy assumptions about the frequency of different characters, the planner arrives at the estimate 0.298387 for the portion of the histogram population that is less than `IAAAAA`. We then combine the estimates for the MCV and non-MCV populations:

```
selectivity = mcv_selectivity + histogram_selectivity * histogram_fraction
            = 0.01833333 + 0.298387 * 0.96966667
            = 0.307669

rows       = 10000 * 0.307669
            = 3077   (rounding off)
```

In this particular example, the correction from the MCV list is fairly small, because the column distribution is actually quite flat (the statistics showing these particular values as being more common than others are mostly due to sampling error). In a more typical case where some values are significantly more common than others, this complicated process gives a useful improvement in accuracy because the selectivity for the most common values is found exactly.

Now let's consider a case with more than one condition in the WHERE clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000 AND stringu1 = 'xxx';
```

QUERY PLAN

```
-----
Bitmap Heap Scan on tenk1  (cost=23.80..396.91 rows=1 width=244)
  Recheck Cond: (unique1 < 1000)
  Filter: (stringu1 = 'xxx'::name)
-> Bitmap Index Scan on tenk1_unique1  (cost=0.00..23.80 rows=1007 width=0)
    Index Cond: (unique1 < 1000)
```

The planner assumes that the two conditions are independent, so that the individual selectivities of the clauses can be multiplied together:

```
selectivity = selectivity(unique1 < 1000) * selectivity(stringu1 = 'xxx')
              = 0.100697 * 0.0014559
              = 0.0001466

rows        = 10000 * 0.0001466
              = 1   (rounding off)
```

Notice that the number of rows estimated to be returned from the bitmap index scan reflects only the condition used with the index; this is important since it affects the cost estimate for the subsequent heap fetches.

Finally we will examine a query that involves a join:

```
EXPLAIN SELECT * FROM tenk1 t1, tenk2 t2
WHERE t1.unique1 < 50 AND t1.unique2 = t2.unique2;
```

QUERY PLAN

```
-----
Nested Loop  (cost=4.64..456.23 rows=50 width=488)
-> Bitmap Heap Scan on tenk1 t1  (cost=4.64..142.17 rows=50 width=244)
    Recheck Cond: (unique1 < 50)
-> Bitmap Index Scan on tenk1_unique1  (cost=0.00..4.63 rows=50 width=0)
    Index Cond: (unique1 < 50)
-> Index Scan using tenk2_unique2 on tenk2 t2  (cost=0.00..6.27 rows=1 width=244)
    Index Cond: (unique2 = t1.unique2)
```

The restriction on `tenk1, unique1 < 50`, is evaluated before the nested-loop join. This is handled analogously to the previous range example. This time the value 50 falls into the first bucket of the `unique1` histogram:

```
selectivity = (0 + (50 - bucket[1].min)/(bucket[1].max - bucket[1].min))/num_buckets
              = (0 + (50 - 0)/(993 - 0))/10
              = 0.005035

rows        = 10000 * 0.005035
              = 50   (rounding off)
```

The restriction for the join is `t2.unique2 = t1.unique2`. The operator is just our familiar `=`, however the selectivity function is obtained from the `oprjoin` column of `pg_operator`, and is `eqjoinsel`. `eqjoinsel` looks up the statistical information for both `tenk2` and `tenk1`:

```
SELECT tablename, null_frac,n_distinct, most_common_vals FROM pg_stats
```

```
WHERE tablename IN ('tenk1', 'tenk2') AND attname='unique2';
```

tablename	null_frac	n_distinct	most_common_vals
tenk1	0	-1	
tenk2	0	-1	

In this case there is no MCV information for `unique2` because all the values appear to be unique, so we use an algorithm that relies only on the number of distinct values for both relations together with their null fractions:

```
selectivity = (1 - null_frac1) * (1 - null_frac2) * min(1/num_distinct1, 1/
num_distinct2)
             = (1 - 0) * (1 - 0) / max(10000, 10000)
             = 0.0001
```

This is, subtract the null fraction from one for each of the relations, and divide by the maximum of the numbers of distinct values. The number of rows that the join is likely to emit is calculated as the cardinality of the Cartesian product of the two inputs, multiplied by the selectivity:

```
rows = (outer_cardinality * inner_cardinality) * selectivity
      = (50 * 10000) * 0.0001
      = 50
```

Had there been MCV lists for the two columns, `eqjoinsel` would have used direct comparison of the MCV lists to determine the join selectivity within the part of the column populations represented by the MCVs. The estimate for the remainder of the populations follows the same approach shown here.

Notice that we showed `inner_cardinality` as 10000, that is, the unmodified size of `tenk2`. It might appear from inspection of the `EXPLAIN` output that the estimate of join rows comes from `50 * 1`, that is, the number of outer rows times the estimated number of rows obtained by each inner index scan on `tenk2`. But this is not the case: the join relation size is estimated before any particular join plan has been considered. If everything is working well then the two ways of estimating the join size will produce about the same answer, but due to round-off error and other factors they sometimes diverge significantly.

For those interested in further details, estimation of the size of a table (before any `WHERE` clauses) is done in `src/backend/optimizer/util/plancat.c`. The generic logic for clause selectivities is in `src/backend/optimizer/path/clausesel.c`. The operator-specific selectivity functions are mostly found in `src/backend/utils/adtselfuncs.c`.

65.2. Planner Statistics and Security

Access to the table `pg_statistic` is restricted to superusers, so that ordinary users cannot learn about the contents of the tables of other users from it. Some selectivity estimation functions will use a user-provided operator (either the operator appearing in the query or a related operator) to analyze the stored statistics. For example, in order to determine whether a stored most common value is applicable, the selectivity estimator will have to run the appropriate `=` operator to compare the constant in the query to the stored value. Thus the data in `pg_statistic` is potentially passed to user-defined operators. An appropriately crafted operator can intentionally leak the passed operands (for example, by logging them or writing them to a different table), or accidentally leak them by showing their values in error messages, in either case possibly exposing data from `pg_statistic` to a user who should not be able to see it.

In order to prevent this, the following applies to all built-in selectivity estimation functions. When planning a query, in order to be able to use stored statistics, the current user must either have `SELECT` privilege on the table or the involved columns, or the operator used must be `LEAKPROOF` (more accurately, the function that the operator is based on). If not, then the selectivity estimator will behave as if no statistics are available, and the planner will proceed with default or fall-back assumptions.

If a user does not have the required privilege on the table or columns, then in many cases the query will ultimately receive a permission-denied error, in which case this mechanism is invisible in practice. But

if the user is reading from a security-barrier view, then the planner might wish to check the statistics of an underlying table that is otherwise inaccessible to the user. In that case, the operator should be leak-proof or the statistics will not be used. There is no direct feedback about that, except that the plan might be suboptimal. If one suspects that this is the case, one could try running the query as a more privileged user, to see if a different plan results.

This restriction applies only to cases where the planner would need to execute a user-defined operator on one or more values from `pg_statistic`. Thus the planner is permitted to use generic statistical information, such as the fraction of null values or the number of distinct values in a column, regardless of access privileges.

Selectivity estimation functions contained in third-party extensions that potentially operate on statistics with user-defined operators should follow the same security rules.

Part VIII. Appendixes

Appendix A. Postgres Pro Error Codes

All messages emitted by the Postgres Pro server are assigned five-character error codes that follow the SQL standard's conventions for “SQLSTATE” codes. Applications that need to know which error condition has occurred should usually test the error code, rather than looking at the textual error message. The error codes are less likely to change across Postgres Pro releases, and also are not subject to change due to localization of error messages. Note that some, but not all, of the error codes produced by Postgres Pro are defined by the SQL standard; some additional error codes for conditions not defined by the standard have been invented or borrowed from other databases.

According to the standard, the first two characters of an error code denote a class of errors, while the last three characters indicate a specific condition within that class. Thus, an application that does not recognize the specific error code might still be able to infer what to do from the error class.

[Table A.1](#) lists all the error codes defined in Postgres Pro Enterprise 9.6.21.1. (Some are not actually used at present, but are defined by the SQL standard.) The error classes are also shown. For each error class there is a “standard” error code having the last three characters 000. This code is used only for error conditions that fall within the class but do not have any more-specific code assigned.

The symbol shown in the column “Condition Name” is the condition name to use in PL/pgSQL. Condition names can be written in either upper or lower case. (Note that PL/pgSQL does not recognize warning, as opposed to error, condition names; those are classes 00, 01, and 02.)

For some types of errors, the server reports the name of a database object (a table, table column, data type, or constraint) associated with the error; for example, the name of the unique constraint that caused a `unique_violation` error. Such names are supplied in separate fields of the error report message so that applications need not try to extract them from the possibly-localized human-readable text of the message. As of PostgreSQL 9.3, complete coverage for this feature exists only for errors in SQLSTATE class 23 (integrity constraint violation), but this is likely to be expanded in future.

Table A.1. Postgres Pro Error Codes

Error Code	Condition Name
Class 00 — Successful Completion	
00000	successful_completion
Class 01 — Warning	
01000	warning
0100C	dynamic_result_sets_returned
01008	implicit_zero_bit_padding
01003	null_value_eliminated_in_set_function
01007	privilege_not_granted
01006	privilege_not_revoked
01004	string_data_right_truncation
01P01	deprecated_feature
Class 02 — No Data (this is also a warning class per the SQL standard)	
02000	no_data
02001	no_additional_dynamic_result_sets_returned
Class 03 — SQL Statement Not Yet Complete	
03000	sql_statement_not_yet_complete
Class 08 — Connection Exception	
08000	connection_exception

Error Code	Condition Name
08003	connection_does_not_exist
08006	connection_failure
08001	sqlclient_unable_to_establish_sqlconnection
08004	sqlserver_rejected_establishment_of_sqlconnection
08007	transaction_resolution_unknown
08P01	protocol_violation
Class 09 — Triggered Action Exception	
09000	triggered_action_exception
Class 0A — Feature Not Supported	
0A000	feature_not_supported
Class 0B — Invalid Transaction Initiation	
0B000	invalid_transaction_initiation
Class 0F — Locator Exception	
0F000	locator_exception
0F001	invalid_locator_specification
Class 0L — Invalid Grantor	
0L000	invalid_grantor
0LP01	invalid_grant_operation
Class 0P — Invalid Role Specification	
0P000	invalid_role_specification
Class 0Z — Diagnostics Exception	
0Z000	diagnostics_exception
0Z002	stacked_diagnostics_accessed_without_active_handler
Class 20 — Case Not Found	
20000	case_not_found
Class 21 — Cardinality Violation	
21000	cardinality_violation
Class 22 — Data Exception	
22000	data_exception
2202E	array_subscript_error
22021	character_not_in_repertoire
22008	datetime_field_overflow
22012	division_by_zero
22005	error_in_assignment
2200B	escape_character_conflict
22022	indicator_overflow
22015	interval_field_overflow
2201E	invalid_argument_for_logarithm

Error Code	Condition Name
22014	invalid_argument_for_ntile_function
22016	invalid_argument_for_nth_value_function
2201F	invalid_argument_for_power_function
2201G	invalid_argument_for_width_bucket_function
22018	invalid_character_value_for_cast
22007	invalid_datetime_format
22019	invalid_escape_character
2200D	invalid_escape_octet
22025	invalid_escape_sequence
22P06	nonstandard_use_of_escape_character
22010	invalid_indicator_parameter_value
22023	invalid_parameter_value
2201B	invalid_regular_expression
2201W	invalid_row_count_in_limit_clause
2201X	invalid_row_count_in_result_offset_clause
2202H	invalid_tablesample_argument
2202G	invalid_tablesample_repeat
22009	invalid_time_zone_displacement_value
2200C	invalid_use_of_escape_character
2200G	most_specific_type_mismatch
22004	null_value_not_allowed
22002	null_value_no_indicator_parameter
22003	numeric_value_out_of_range
22026	string_data_length_mismatch
22001	string_data_right_truncation
22011	substring_error
22027	trim_error
22024	unterminated_c_string
2200F	zero_length_character_string
22P01	floating_point_exception
22P02	invalid_text_representation
22P03	invalid_binary_representation
22P04	bad_copy_file_format
22P05	untranslatable_character
2200L	not_an_xml_document
2200M	invalid_xml_document
2200N	invalid_xml_content
2200S	invalid_xml_comment

Error Code	Condition Name
2200T	invalid_xml_processing_instruction
Class 23 — Integrity Constraint Violation	
23000	integrity_constraint_violation
23001	restrict_violation
23502	not_null_violation
23503	foreign_key_violation
23505	unique_violation

Appendix B. Date/Time Support

Postgres Pro uses an internal heuristic parser for all date/time input support. Dates and times are input as strings, and are broken up into distinct fields with a preliminary determination of what kind of information can be in the field. Each field is interpreted and either assigned a numeric value, ignored, or rejected. The parser contains internal lookup tables for all textual fields, including months, days of the week, and time zones.

This appendix includes information on the content of these lookup tables and describes the steps used by the parser to decode dates and times.

B.1. Date/Time Input Interpretation

Date/time input strings are decoded using the following procedure.

1. Break the input string into tokens and categorize each token as a string, time, time zone, or number.
 - a. If the numeric token contains a colon (:), this is a time string. Include all subsequent digits and colons.
 - b. If the numeric token contains a dash (-), slash (/), or two or more dots (.), this is a date string which might have a text month. If a date token has already been seen, it is instead interpreted as a time zone name (e.g., `America/New_York`).
 - c. If the token is numeric only, then it is either a single field or an ISO 8601 concatenated date (e.g., `19990113` for January 13, 1999) or time (e.g., `141516` for 14:15:16).
 - d. If the token starts with a plus (+) or minus (-), then it is either a numeric time zone or a special field.
2. If the token is an alphabetic string, match up with possible strings:
 - a. See if the token matches any known time zone abbreviation. These abbreviations are supplied by the configuration file described in [Section B.4](#).
 - b. If not found, search an internal table to match the token as either a special string (e.g., `today`), day (e.g., `Thursday`), month (e.g., `January`), or noise word (e.g., `at`, `on`).
 - c. If still not found, throw an error.
3. When the token is a number or number field:
 - a. If there are eight or six digits, and if no other date fields have been previously read, then interpret as a “concatenated date” (e.g., `19990118` or `990118`). The interpretation is `YYYYMMDD` or `YYMMDD`.
 - b. If the token is three digits and a year has already been read, then interpret as day of year.
 - c. If four or six digits and a year has already been read, then interpret as a time (`HHMM` or `HHMMSS`).
 - d. If three or more digits and no date fields have yet been found, interpret as a year (this forces `yy-mm-dd` ordering of the remaining date fields).
 - e. Otherwise the date field ordering is assumed to follow the `DateStyle` setting: `mm-dd-yy`, `dd-mm-yy`, or `yy-mm-dd`. Throw an error if a month or day field is found to be out of range.
4. If BC has been specified, negate the year and add one for internal storage. (There is no year zero in the Gregorian calendar, so numerically 1 BC becomes year zero.)
5. If BC was not specified, and if the year field was two digits in length, then adjust the year to four digits. If the field is less than 70, then add 2000, otherwise add 1900.

Tip

Gregorian years AD 1-99 can be entered by using 4 digits with leading zeros (e.g., 0099 is AD 99).

B.2. Handling of Invalid or Ambiguous Timestamps

Ordinarily, if a date/time string is syntactically valid but contains out-of-range field values, an error will be thrown. For example, input specifying the 31st of February will be rejected.

During a daylight-savings-time transition, it is possible for a seemingly valid timestamp string to represent a nonexistent or ambiguous timestamp. Such cases are not rejected; the ambiguity is resolved by determining which UTC offset to apply. For example, supposing that the [TimeZone](#) parameter is set to `America/New_York`, consider

```
=> SELECT '2018-03-11 02:30'::timestampz;
       timestampz
-----
2018-03-11 03:30:00-04
(1 row)
```

Because that day was a spring-forward transition date in that time zone, there was no civil time instant 2:30AM; clocks jumped forward from 2AM EST to 3AM EDT. Postgres Pro interprets the given time as if it were standard time (UTC-5), which then renders as 3:30AM EDT (UTC-4).

Conversely, consider the behavior during a fall-back transition:

```
=> SELECT '2018-11-04 02:30'::timestampz;
       timestampz
-----
2018-11-04 02:30:00-05
(1 row)
```

On that date, there were two possible interpretations of 2:30AM; there was 2:30AM EDT, and then an hour later after the reversion to standard time, there was 2:30AM EST. Again, Postgres Pro interprets the given time as if it were standard time (UTC-5). We can force the matter by specifying daylight-savings time:

```
=> SELECT '2018-11-04 02:30 EDT'::timestampz;
       timestampz
-----
2018-11-04 01:30:00-05
(1 row)
```

This timestamp could validly be rendered as either 2:30 UTC-4 or 1:30 UTC-5; the timestamp output code chooses the latter.

The precise rule that is applied in such cases is that an invalid timestamp that appears to fall within a jump-forward daylight savings transition is assigned the UTC offset that prevailed in the time zone just before the transition, while an ambiguous timestamp that could fall on either side of a jump-back transition is assigned the UTC offset that prevailed just after the transition. In most time zones this is equivalent to saying that “the standard-time interpretation is preferred when in doubt”.

In all cases, the UTC offset associated with a timestamp can be specified explicitly, using either a numeric UTC offset or a time zone abbreviation that corresponds to a fixed UTC offset. The rule just given applies only when it is necessary to infer a UTC offset for a time zone in which the offset varies.

B.3. Date/Time Key Words

[Table B.1](#) shows the tokens that are recognized as names of months.

Table B.1. Month Names

Month	Abbreviations
January	Jan
February	Feb
March	Mar
April	Apr
May	
June	Jun
July	Jul
August	Aug
September	Sep, Sept
October	Oct
November	Nov
December	Dec

Table B.2 shows the tokens that are recognized as names of days of the week.

Table B.2. Day of the Week Names

Day	Abbreviations
Sunday	Sun
Monday	Mon
Tuesday	Tue, Tues
Wednesday	Wed, Weds
Thursday	Thu, Thur, Thurs
Friday	Fri
Saturday	Sat

Table B.3 shows the tokens that serve various modifier purposes.

Table B.3. Date/Time Field Modifiers

Identifier	Description
AM	Time is before 12:00
AT	Ignored
JULIAN, JD, J	Next field is Julian Date
ON	Ignored
PM	Time is on or after 12:00
T	Next field is time

B.4. Date/Time Configuration Files

Since timezone abbreviations are not well standardized, Postgres Pro provides a means to customize the set of abbreviations accepted by the server. The [timezone_abbreviations](#) run-time parameter determines the active set of abbreviations. While this parameter can be altered by any database user, the possible values for it are under the control of the database administrator — they are in fact names of configuration files stored in `.../share/timezonesets/` of the installation directory. By adding or altering files in that directory, the administrator can set local policy for timezone abbreviations.

`timezone_abbreviations` can be set to any file name found in `.../share/timezonesets/`, if the file's name is entirely alphabetic. (The prohibition against non-alphabetic characters in `timezone_abbreviations` prevents reading files outside the intended directory, as well as reading editor backup files and other extraneous files.)

A timezone abbreviation file can contain blank lines and comments beginning with `#`. Non-comment lines must have one of these formats:

```
zone_abbreviation offset
zone_abbreviation offset D
zone_abbreviation time_zone_name
@INCLUDE file_name
@OVERRIDE
```

A `zone_abbreviation` is just the abbreviation being defined. An `offset` is an integer giving the equivalent offset in seconds from UTC, positive being east from Greenwich and negative being west. For example, `-18000` would be five hours west of Greenwich, or North American east coast standard time. `D` indicates that the zone name represents local daylight-savings time rather than standard time.

Alternatively, a `time_zone_name` can be given, referencing a zone name defined in the IANA timezone database. The zone's definition is consulted to see whether the abbreviation is or has been in use in that zone, and if so, the appropriate meaning is used — that is, the meaning that was currently in use at the timestamp whose value is being determined, or the meaning in use immediately before that if it wasn't current at that time, or the oldest meaning if it was used only after that time. This behavior is essential for dealing with abbreviations whose meaning has historically varied. It is also allowed to define an abbreviation in terms of a zone name in which that abbreviation does not appear; then using the abbreviation is just equivalent to writing out the zone name.

Tip

Using a simple integer `offset` is preferred when defining an abbreviation whose offset from UTC has never changed, as such abbreviations are much cheaper to process than those that require consulting a time zone definition.

The `@INCLUDE` syntax allows inclusion of another file in the `.../share/timezonesets/` directory. Inclusion can be nested, to a limited depth.

The `@OVERRIDE` syntax indicates that subsequent entries in the file can override previous entries (typically, entries obtained from included files). Without this, conflicting definitions of the same timezone abbreviation are considered an error.

In an unmodified installation, the file `Default` contains all the non-conflicting time zone abbreviations for most of the world. Additional files `Australia` and `India` are provided for those regions: these files first include the `Default` file and then add or modify abbreviations as needed.

For reference purposes, a standard installation also contains files `Africa.txt`, `America.txt`, etc, containing information about every time zone abbreviation known to be in use according to the IANA timezone database. The zone name definitions found in these files can be copied and pasted into a custom configuration file as needed. Note that these files cannot be directly referenced as `timezone_abbreviations` settings, because of the dot embedded in their names.

Note

If an error occurs while reading the time zone abbreviation set, no new value is applied and the old set is kept. If the error occurs while starting the database, startup fails.

Caution

Time zone abbreviations defined in the configuration file override non-timezone meanings built into Postgres Pro. For example, the `Australia` configuration file defines `SAT` (for South Australian Standard Time). When this file is active, `SAT` will not be recognized as an abbreviation for Saturday.

Caution

If you modify files in `.../share/timezonesets/`, it is up to you to make backups — a normal database dump will not include this directory.

B.5. POSIX Time Zone Specifications

Postgres Pro can accept time zone specifications that are written according to the POSIX standard's rules for the `TZ` environment variable. POSIX time zone specifications are inadequate to deal with the complexity of real-world time zone history, but there are sometimes reasons to use them.

A POSIX time zone specification has the form

```
STD offset [ DST [ dstoffset ] [ , rule ] ]
```

(For readability, we show spaces between the fields, but spaces should not be used in practice.) The fields are:

- *STD* is the zone abbreviation to be used for standard time.
- *offset* is the zone's standard-time offset from UTC.
- *DST* is the zone abbreviation to be used for daylight-savings time. If this field and the following ones are omitted, the zone uses a fixed UTC offset with no daylight-savings rule.
- *dstoffset* is the daylight-savings offset from UTC. This field is typically omitted, since it defaults to one hour less than the standard-time *offset*, which is usually the right thing.
- *rule* defines the rule for when daylight savings is in effect, as described below.

In this syntax, a zone abbreviation can be a string of letters, such as `EST`, or an arbitrary string surrounded by angle brackets, such as `<UTC-05>`. Note that the zone abbreviations given here are only used for output, and even then only in some timestamp output formats. The zone abbreviations recognized in timestamp input are determined as explained in [Section B.4](#).

The offset fields specify the hours, and optionally minutes and seconds, difference from UTC. They have the format `hh[:mm[:ss]]` optionally with a leading sign (+ or -). The positive sign is used for zones west of Greenwich. (Note that this is the opposite of the ISO-8601 sign convention used elsewhere in Postgres Pro.) *hh* can have one or two digits; *mm* and *ss* (if used) must have two.

The daylight-savings transition *rule* has the format

```
dstdate [ / dsttime ] , stddate [ / stdtime ]
```

(As before, spaces should not be included in practice.) The *dstdate* and *dsttime* fields define when daylight-savings time starts, while *stddate* and *stdtime* define when standard time starts. (In some cases, notably in zones south of the equator, the former might be later in the year than the latter.) The date fields have one of these formats:

n

A plain integer denotes a day of the year, counting from zero to 364, or to 365 in leap years.

Jn

In this form, *n* counts from 1 to 365, and February 29 is not counted even if it is present. (Thus, a transition occurring on February 29 could not be specified this way. However, days after February

have the same numbers whether it's a leap year or not, so that this form is usually more useful than the plain-integer form for transitions on fixed dates.)

Mm.n.d

This form specifies a transition that always happens during the same month and on the same day of the week. *m* identifies the month, from 1 to 12. *n* specifies the *n*'th occurrence of the weekday identified by *d*. *n* is a number between 1 and 4, or 5 meaning the last occurrence of that weekday in the month (which could be the fourth or the fifth). *d* is a number between 0 and 6, with 0 indicating Sunday. For example, `M3.2.0` means “the second Sunday in March”.

Note

The `M` format is sufficient to describe many common daylight-savings transition laws. But note that none of these variants can deal with daylight-savings law changes, so in practice the historical data stored for named time zones (in the IANA time zone database) is necessary to interpret past time stamps correctly.

The time fields in a transition rule have the same format as the offset fields described previously, except that they cannot contain signs. They define the current local time at which the change to the other time occurs. If omitted, they default to `02:00:00`.

If a daylight-savings abbreviation is given but the transition *rule* field is omitted, Postgres Pro attempts to determine the transition times by consulting the `posixrules` file in the IANA time zone database. This file has the same format as a full time zone entry, but only its transition timing rules are used, not its UTC offsets. Typically, this file has the same contents as the `US/Eastern` file, so that POSIX-style time zone specifications follow USA daylight-savings rules. If needed, you can adjust this behavior by replacing the `posixrules` file.

Note

The facility to consult a `posixrules` file has been deprecated by IANA, and it is likely to go away in the future. One bug in this feature, which is unlikely to be fixed before it disappears, is that it fails to apply DST rules to dates after 2038.

If the `posixrules` file is not present, the fallback behavior is to use the rule `M3.2.0,M11.1.0`, which corresponds to USA practice as of 2020 (that is, spring forward on the second Sunday of March, fall back on the first Sunday of November, both transitions occurring at 2AM prevailing time).

As an example, `CET-1CEST,M3.5.0,M10.5.0/3` describes current (as of 2020) timekeeping practice in Paris. This specification says that standard time has the abbreviation `CET` and is one hour ahead (east) of UTC; daylight savings time has the abbreviation `CEST` and is implicitly two hours ahead of UTC; daylight savings time begins on the last Sunday in March at 2AM CET and ends on the last Sunday in October at 3AM CEST.

The four timezone names `EST5EDT`, `CST6CDT`, `MST7MDT`, and `PST8PDT` look like they are POSIX zone specifications. However, they actually are treated as named time zones because (for historical reasons) there are files by those names in the IANA time zone database. The practical implication of this is that these zone names will produce valid historical USA daylight-savings transitions, even when a plain POSIX specification would not due to lack of a suitable `posixrules` file.

One should be wary that it is easy to misspell a POSIX-style time zone specification, since there is no check on the reasonableness of the zone abbreviation(s). For example, `SET TIMEZONE TO FOOBAR0` will work, leaving the system effectively using a rather peculiar abbreviation for UTC.

B.6. History of Units

The SQL standard states that “Within the definition of a ‘datetime literal’, the ‘datetime values’ are constrained by the natural rules for dates and times according to the Gregorian calendar”. Postgres Pro follows the SQL standard's lead by counting dates exclusively in the Gregorian calendar, even for years before that calendar was in use. This rule is known as the *proleptic Gregorian calendar*.

The Julian calendar was introduced by Julius Caesar in 45 BC. It was in common use in the Western world until the year 1582, when countries started changing to the Gregorian calendar. In the Julian calendar, the tropical year is approximated as $365 \frac{1}{4}$ days = 365.25 days. This gives an error of about 1 day in 128 years.

The accumulating calendar error prompted Pope Gregory XIII to reform the calendar in accordance with instructions from the Council of Trent. In the Gregorian calendar, the tropical year is approximated as $365 + 97 / 400$ days = 365.2425 days. Thus it takes approximately 3300 years for the tropical year to shift one day with respect to the Gregorian calendar.

The approximation $365 + 97/400$ is achieved by having 97 leap years every 400 years, using the following rules:

Every year divisible by 4 is a leap year.

However, every year divisible by 100 is not a leap year.

However, every year divisible by 400 is a leap year after all.

So, 1700, 1800, 1900, 2100, and 2200 are not leap years. But 1600, 2000, and 2400 are leap years. By contrast, in the older Julian calendar all years divisible by 4 are leap years.

The papal bull of February 1582 decreed that 10 days should be dropped from October 1582 so that 15 October should follow immediately after 4 October. This was observed in Italy, Poland, Portugal, and Spain. Other Catholic countries followed shortly after, but Protestant countries were reluctant to change, and the Greek Orthodox countries didn't change until the start of the 20th century. The reform was observed by Great Britain and its dominions (including what is now the USA) in 1752. Thus 2 September 1752 was followed by 14 September 1752. This is why Unix systems that have the `cal` program produce the following:

```
$ cal 9 1752
    September 1752
S  M Tu  W Th  F  S
      1  2 14 15 16
17 18 19 20 21 22 23
24 25 26 27 28 29 30
```

But, of course, this calendar is only valid for Great Britain and dominions, not other places. Since it would be difficult and confusing to try to track the actual calendars that were in use in various places at various times, Postgres Pro does not try, but rather follows the Gregorian calendar rules for all dates, even though this method is not historically accurate.

Different calendars have been developed in various parts of the world, many predating the Gregorian system. For example, the beginnings of the Chinese calendar can be traced back to the 14th century BC. Legend has it that the Emperor Huangdi invented that calendar in 2637 BC. The People's Republic of China uses the Gregorian calendar for civil purposes. The Chinese calendar is used for determining festivals.

The *Julian Date* system is another type of calendar, unrelated to the Julian calendar though it is confusingly named similarly to that calendar. The Julian Date system was invented by the French scholar Joseph Justus Scaliger (1540-1609) and probably takes its name from Scaliger's father, the Italian scholar Julius Caesar Scaliger (1484-1558). In the Julian Date system, each day has a sequential number, starting from JD 0 (which is sometimes called *the* Julian Date). JD 0 corresponds to 1 January 4713 BC in the Julian calendar, or 24 November 4714 BC in the Gregorian calendar. Julian Date counting is most often used by astronomers for labeling their nightly observations, and therefore a date runs from noon UTC to the next noon UTC, rather than from midnight to midnight: JD 0 designates the 24 hours from noon UTC on 24 November 4714 BC to noon UTC on 25 November 4714 BC.

Although Postgres Pro supports Julian Date notation for input and output of dates (and also uses Julian dates for some internal datetime calculations), it does not observe the nicety of having dates run from noon to noon. Postgres Pro treats a Julian Date as running from midnight to midnight.

Appendix C. SQL Key Words

[Table C.1](#) lists all tokens that are key words in the SQL standard and in Postgres Pro Enterprise 9.6.21.1. Background information can be found in [Section 4.1.1](#). (For space reasons, only the latest two versions of the SQL standard, and SQL-92 for historical comparison, are included. The differences between those and the other intermediate standard versions are small.)

SQL distinguishes between *reserved* and *non-reserved* key words. According to the standard, reserved key words are the only real key words; they are never allowed as identifiers. Non-reserved key words only have a special meaning in particular contexts and can be used as identifiers in other contexts. Most non-reserved key words are actually the names of built-in tables and functions specified by SQL. The concept of non-reserved key words essentially only exists to declare that some predefined meaning is attached to a word in some contexts.

In the Postgres Pro parser life is a bit more complicated. There are several different classes of tokens ranging from those that can never be used as an identifier to those that have absolutely no special status in the parser as compared to an ordinary identifier. (The latter is usually the case for functions specified by SQL.) Even reserved key words are not completely reserved in Postgres Pro, but can be used as column labels (for example, `SELECT 55 AS CHECK`, even though `CHECK` is a reserved key word).

In [Table C.1](#) in the column for Postgres Pro we classify as “non-reserved” those key words that are explicitly known to the parser but are allowed as column or table names. Some key words that are otherwise non-reserved cannot be used as function or data type names and are marked accordingly. (Most of these words represent built-in functions or data types with special syntax. The function or type is still available but it cannot be redefined by the user.) Labeled “reserved” are those tokens that are not allowed as column or table names. Some reserved key words are allowable as names for functions or data types; this is also shown in the table. If not so marked, a reserved key word is only allowed as an “AS” column label name.

As a general rule, if you get spurious parser errors for commands that contain any of the listed key words as an identifier you should try to quote the identifier to see if the problem goes away.

It is important to understand before studying [Table C.1](#) that the fact that a key word is not reserved in Postgres Pro does not mean that the feature related to the word is not implemented. Conversely, the presence of a key word does not indicate the existence of a feature.

Table C.1. SQL Key Words

Appendix D. SQL Conformance

This section attempts to outline to what extent Postgres Pro conforms to the current SQL standard. The following information is not a full statement of conformance, but it presents the main topics in as much detail as is both reasonable and useful for users.

The formal name of the SQL standard is ISO/IEC 9075 “Database Language SQL”. A revised version of the standard is released from time to time; the most recent update appearing in 2011. The 2011 version is referred to as ISO/IEC 9075:2011, or simply as SQL:2011. The versions prior to that were SQL:2008, SQL:2003, SQL:1999, and SQL-92. Each version replaces the previous one, so claims of conformance to earlier versions have no official merit. Postgres Pro development aims for conformance with the latest official version of the standard where such conformance does not contradict traditional features or common sense. Many of the features required by the SQL standard are supported, though sometimes with slightly differing syntax or function. Further moves towards conformance can be expected over time.

SQL-92 defined three feature sets for conformance: Entry, Intermediate, and Full. Most database management systems claiming SQL standard conformance were conforming at only the Entry level, since the entire set of features in the Intermediate and Full levels was either too voluminous or in conflict with legacy behaviors.

Starting with SQL:1999, the SQL standard defines a large set of individual features rather than the ineffectively broad three levels found in SQL-92. A large subset of these features represents the “Core” features, which every conforming SQL implementation must supply. The rest of the features are purely optional. Some optional features are grouped together to form “packages”, which SQL implementations can claim conformance to, thus claiming conformance to particular groups of features.

The standard versions beginning with SQL:2003 are also split into a number of parts. Each is known by a shorthand name. Note that these parts are not consecutively numbered.

- ISO/IEC 9075-1 Framework (SQL/Framework)
- ISO/IEC 9075-2 Foundation (SQL/Foundation)
- ISO/IEC 9075-3 Call Level Interface (SQL/CLI)
- ISO/IEC 9075-4 Persistent Stored Modules (SQL/PSM)
- ISO/IEC 9075-9 Management of External Data (SQL/MED)
- ISO/IEC 9075-10 Object Language Bindings (SQL/OLB)
- ISO/IEC 9075-11 Information and Definition Schemas (SQL/Schemata)
- ISO/IEC 9075-13 Routines and Types using the Java Language (SQL/JRT)
- ISO/IEC 9075-14 XML-related specifications (SQL/XML)

The Postgres Pro core covers parts 1, 2, 9, 11, and 14. Part 3 is covered by the ODBC driver, and part 13 is covered by the PL/Java plug-in, but exact conformance is currently not being verified for these components. There are currently no implementations of parts 4 and 10 for Postgres Pro.

Postgres Pro supports most of the major features of SQL:2011. Out of 179 mandatory features required for full Core conformance, Postgres Pro conforms to at least 160. In addition, there is a long list of supported optional features. It might be worth noting that at the time of writing, no current version of any database management system claims full conformance to Core SQL:2011.

In the following two sections, we provide a list of those features that Postgres Pro supports, followed by a list of the features defined in SQL:2011 which are not yet supported in Postgres Pro. Both of these

lists are approximate: There might be minor details that are nonconforming for a feature that is listed as supported, and large parts of an unsupported feature might in fact be implemented. The main body of the documentation always contains the most accurate information about what does and does not work.

Note

Feature codes containing a hyphen are subfeatures. Therefore, if a particular subfeature is not supported, the main feature is listed as unsupported even if some other subfeatures are supported.

D.1. Supported Features

Identifier	Package	Description	Comment
B012		Embedded C	
B021		Direct SQL	
E011	Core	Numeric data types	
E011-01	Core	INTEGER and SMALLINT data types	
E011-02	Core	REAL, DOUBLE PRECISION, and FLOAT data types	
E011-03	Core	DECIMAL and NUMERIC data types	
E011-04	Core	Arithmetic operators	
E011-05	Core	Numeric comparison	
E011-06	Core	Implicit casting among the numeric data types	
E021	Core	Character data types	
E021-01	Core	CHARACTER data type	
E021-02	Core	CHARACTER VARYING data type	
E021-03	Core	Character literals	
E021-04	Core	CHARACTER_LENGTH function	trims trailing spaces from CHARACTER values before counting
E021-05	Core	OCTET_LENGTH function	
E021-06	Core	SUBSTRING function	
E021-07	Core	Character concatenation	
E021-08	Core	UPPER and LOWER functions	
E021-09	Core	TRIM function	
E021-10	Core	Implicit casting among the character string types	
E021-11	Core	POSITION function	
E021-12	Core	Character comparison	
E031	Core	Identifiers	

Identifier	Package	Description	Comment
E031-01	Core	Delimited identifiers	
E031-02	Core	Lower case identifiers	
E031-03	Core	Trailing underscore	
E051	Core	Basic query specification	
E051-01	Core	SELECT DISTINCT	
E051-02	Core	GROUP BY clause	
E051-04	Core	GROUP BY can contain columns not in <select list>	
E051-05	Core	Select list items can be renamed	
E051-06	Core	HAVING clause	
E051-07	Core	Qualified * in select list	
E051-08	Core	Correlation names in the FROM clause	
E051-09	Core	Rename columns in the FROM clause	
E061	Core	Basic predicates and search conditions	
E061-01	Core	Comparison predicate	
E061-02	Core	BETWEEN predicate	
E061-03	Core	IN predicate with list of values	
E061-04	Core	LIKE predicate	
E061-05	Core	LIKE predicate ESCAPE clause	
E061-06	Core	NULL predicate	
E061-07	Core	Quantified comparison predicate	
E061-08	Core	EXISTS predicate	
E061-09	Core	Subqueries in comparison predicate	
E061-11	Core	Subqueries in IN predicate	
E061-12	Core	Subqueries in quantified comparison predicate	
E061-13	Core	Correlated subqueries	
E061-14	Core	Search condition	
E071	Core	Basic query expressions	
E071-01	Core	UNION DISTINCT table operator	
E071-02	Core	UNION ALL table operator	
E071-03	Core	EXCEPT DISTINCT table operator	

Identifier	Package	Description	Comment
E071-05	Core	Columns combined via table operators need not have exactly the same data type	
E071-06	Core	Table operators in subqueries	
E081	Core	Basic Privileges	
E081-01	Core	SELECT privilege	
E081-02	Core	DELETE privilege	
E081-03	Core	INSERT privilege at the table level	
E081-04	Core	UPDATE privilege at the table level	
E081-05	Core	UPDATE privilege at the column level	
E081-06	Core	REFERENCES privilege at the table level	
E081-07	Core	REFERENCES privilege at the column level	
E081-08	Core	WITH GRANT OPTION	
E081-09	Core	USAGE privilege	
E081-10	Core	EXECUTE privilege	
E091	Core	Set functions	
E091-01	Core	AVG	
E091-02	Core	COUNT	
E091-03	Core	MAX	
E091-04	Core	MIN	
E091-05	Core	SUM	
E091-06	Core	ALL quantifier	
E091-07	Core	DISTINCT quantifier	
E101	Core	Basic data manipulation	
E101-01	Core	INSERT statement	
E101-03	Core	Searched UPDATE statement	
E101-04	Core	Searched DELETE statement	
E111	Core	Single row SELECT statement	
E121	Core	Basic cursor support	
E121-01	Core	DECLARE CURSOR	
E121-02	Core	ORDER BY columns need not be in select list	
E121-03	Core	Value expressions in ORDER BY clause	
E121-04	Core	OPEN statement	

Identifier	Package	Description	Comment
E121-06	Core	Positioned UPDATE statement	
E121-07	Core	Positioned DELETE statement	
E121-08	Core	CLOSE statement	
E121-10	Core	FETCH statement implicit NEXT	
E121-17	Core	WITH HOLD cursors	
E131	Core	Null value support (nulls in lieu of values)	
E141	Core	Basic integrity constraints	
E141-01	Core	NOT NULL constraints	
E141-02	Core	UNIQUE constraints of NOT NULL columns	
E141-03	Core	PRIMARY KEY constraints	
E141-04	Core	Basic FOREIGN KEY constraint with the NO ACTION default for both referential delete action and referential update action	
E141-06	Core	CHECK constraints	
E141-07	Core	Column defaults	
E141-08	Core	NOT NULL inferred on PRIMARY KEY	
E141-10	Core	Names in a foreign key can be specified in any order	
E151	Core	Transaction support	
E151-01	Core	COMMIT statement	
E151-02	Core	ROLLBACK statement	
E152	Core	Basic SET TRANSACTION statement	
E152-01	Core	SET TRANSACTION statement: ISOLATION LEVEL SERIALIZABLE clause	
E152-02	Core	SET TRANSACTION statement: READ ONLY and READ WRITE clauses	
E153	Core	Updatable queries with subqueries	
E161	Core	SQL comments using leading double minus	

Identifier	Package	Description	Comment
E171	Core	SQLSTATE support	
F021	Core	Basic information schema	
F021-01	Core	COLUMNS view	
F021-02	Core	TABLES view	
F021-03	Core	VIEWS view	
F021-04	Core	TABLE_CONSTRAINTS view	
F021-05	Core	REFERENTIAL_CONSTRAINTS view	
F021-06	Core	CHECK_CONSTRAINTS view	
F031	Core	Basic schema manipulation	
F031-01	Core	CREATE TABLE statement to create persistent base tables	
F031-02	Core	CREATE VIEW statement	
F031-03	Core	GRANT statement	
F031-04	Core	ALTER TABLE statement: ADD COLUMN clause	
F031-13	Core	DROP TABLE statement: RESTRICT clause	
F031-16	Core	DROP VIEW statement: RESTRICT clause	
F031-19	Core	REVOKE statement: RESTRICT clause	
F032		CASCADE drop behavior	
F033		ALTER TABLE statement: DROP COLUMN clause	
F034		Extended REVOKE statement	
F034-01		REVOKE statement performed by other than the owner of a schema object	
F034-02		REVOKE statement: GRANT OPTION FOR clause	
F034-03		REVOKE statement to revoke a privilege that the grantee has WITH GRANT OPTION	
F041	Core	Basic joined table	

Identifier	Package	Description	Comment
F041-01	Core	Inner join (but not necessarily the INNER keyword)	
F041-02	Core	INNER keyword	
F041-03	Core	LEFT OUTER JOIN	
F041-04	Core	RIGHT OUTER JOIN	
F041-05	Core	Outer joins can be nested	
F041-07	Core	The inner table in a left or right outer join can also be used in an inner join	
F041-08	Core	All comparison operators are supported (rather than just =)	
F051	Core	Basic date and time	
F051-01	Core	DATE data type (including support of DATE literal)	
F051-02	Core	TIME data type (including support of TIME literal) with fractional seconds precision of at least 0	
F051-03	Core	TIMESTAMP data type (including support of TIMESTAMP literal) with fractional seconds precision of at least 0 and 6	
F051-04	Core	Comparison predicate on DATE, TIME, and TIMESTAMP data types	
F051-05	Core	Explicit CAST between datetime types and character string types	
F051-06	Core	CURRENT_DATE	
F051-07	Core	LOCALTIME	
F051-08	Core	LOCALTIMESTAMP	
F052	Enhanced facilities	datetime arithmetic	
F053		OVERLAPS predicate	
F081	Core	UNION and EXCEPT in views	
F111		Isolation levels other than SERIALIZABLE	
F111-01		READ UNCOMMITTED isolation level	

Identifier	Package	Description	Comment
F111-02		READ COMMITTED isolation level	
F111-03		REPEATABLE READ isolation level	
F131	Core	Grouped operations	
F131-01	Core	WHERE, GROUP BY, and HAVING clauses supported in queries with grouped views	
F131-02	Core	Multiple tables supported in queries with grouped views	
F131-03	Core	Set functions supported in queries with grouped views	
F131-04	Core	Subqueries with GROUP BY and HAVING clauses and grouped views	
F131-05	Core	Single row SELECT with GROUP BY and HAVING clauses and grouped views	
F171		Multiple schemas per user	
F191	Enhanced integrity management	Referential delete actions	
F200		TRUNCATE TABLE statement	
F201	Core	CAST function	
F221	Core	Explicit defaults	
F222		INSERT statement: DEFAULT VALUES clause	
F231		Privilege tables	
F231-01		TABLE_PRIVILEGES view	
F231-02		COLUMN_PRIVILEGES view	
F231-03		USAGE_PRIVILEGES view	
F251		Domain support	
F261	Core	CASE expression	
F261-01	Core	Simple CASE	
F261-02	Core	Searched CASE	
F261-03	Core	NULLIF	
F261-04	Core	COALESCE	

Identifier	Package	Description	Comment
F262		Extended CASE expression	
F271		Compound character literals	
F281		LIKE enhancements	
F302		INTERSECT table operator	
F302-01		INTERSECT DISTINCT table operator	
F302-02		INTERSECT ALL table operator	
F304		EXCEPT ALL table operator	
F311-01	Core	CREATE SCHEMA	
F311-02	Core	CREATE TABLE for persistent base tables	
F311-03	Core	CREATE VIEW	
F311-04	Core	CREATE VIEW: WITH CHECK OPTION	
F311-05	Core	GRANT statement	
F321		User authorization	
F361		Subprogram support	
F381		Extended schema manipulation	
F381-01		ALTER TABLE statement: ALTER COLUMN clause	
F381-02		ALTER TABLE statement: ADD CONSTRAINT clause	
F381-03		ALTER TABLE statement: DROP CONSTRAINT clause	
F382		Alter column data type	
F383		Set column not null clause	
F391		Long identifiers	
F392		Unicode escapes in identifiers	
F393		Unicode escapes in literals	
F401		Extended joined table	
F401-01		NATURAL JOIN	
F401-02		FULL OUTER JOIN	
F401-04		CROSS JOIN	

Identifier	Package	Description	Comment
F402		Named column joins for LOBs, arrays, and multisets	
F411	Enhanced facilities	datetime Time zone specification	differences regarding literal interpretation
F421		National character	
F431		Read-only scrollable cursors	
F431-01		FETCH with explicit NEXT	
F431-02		FETCH FIRST	
F431-03		FETCH LAST	
F431-04		FETCH PRIOR	
F431-05		FETCH ABSOLUTE	
F431-06		FETCH RELATIVE	
F441		Extended set function support	
F442		Mixed column references in set functions	
F471	Core	Scalar subquery values	
F481	Core	Expanded NULL predicate	
F491	Enhanced management	integrity Constraint management	
F501	Core	Features and conformance views	
F501-01	Core	SQL_FEATURES view	
F501-02	Core	SQL_SIZING view	
F501-03	Core	SQL_LANGUAGES view	
F502		Enhanced documentation tables	
F502-01		SQL_SIZING_PROFILES view	
F502-02		SQL_IMPLEMENTATION_INFO view	
F502-03		SQL_PACKAGES view	
F531		Temporary tables	
F555	Enhanced facilities	datetime Enhanced seconds precision	
F561		Full value expressions	
F571		Truth value tests	
F591		Derived tables	
F611		Indicator data types	

Identifier	Package	Description	Comment
F641		Row and table constructors	
F651		Catalog name qualifiers	
F661		Simple tables	
F672		Retrospective check constraints	
F690		Collation support	but no character set support
F692		Extended collation support	
F701	Enhanced integrity management	Referential update actions	
F711		ALTER domain	
F731		INSERT column privileges	
F751		View CHECK enhancements	
F761		Session management	
F762		CURRENT_CATALOG	
F763		CURRENT_SCHEMA	
F771		Connection management	
F781		Self-referencing operations	
F791		Insensitive cursors	
F801		Full set function	
F850		Top-level <order by clause> in <query expression>	
F851		<order by clause> in subqueries	
F852		Top-level <order by clause> in views	
F855		Nested <order by clause> in <query expression>	
F856		Nested <fetch first clause> in <query expression>	
F857		Top-level <fetch first clause> in <query expression>	
F858		<fetch first clause> in subqueries	
F859		Top-level <fetch first clause> in views	
F860		<fetch first row count> in <fetch first clause>	

Identifier	Package	Description	Comment
F861		Top-level <result offset clause> in <query expression>	
F862		<result offset clause> in subqueries	
F863		Nested <result offset clause> in <query expression>	
F864		Top-level <result offset clause> in views	
F865		<offset row count> in <result offset clause>	
S071	Enhanced object support	SQL paths in function and type name resolution	
S092		Arrays of user-defined types	
S095		Array constructors by query	
S096		Optional array bounds	
S098		ARRAY_AGG	
S111	Enhanced object support	ONLY in query expressions	
S201		SQL-invoked routines on arrays	
S201-01		Array parameters	
S201-02		Array as result type of functions	
S211	Enhanced object support	User-defined cast functions	
S301		Enhanced UNNEST	
T031		BOOLEAN data type	
T071		BIGINT data type	
T121		WITH (excluding RECURSIVE) in query expression	
T122		WITH (excluding RECURSIVE) in subquery	
T131		Recursive query	
T132		Recursive query in subquery	
T141		SIMILAR predicate	
T151		DISTINCT predicate	
T152		DISTINCT predicate with negation	
T171		LIKE clause in table definition	

Identifier	Package	Description	Comment
T172		AS subquery clause in table definition	
T173		Extended LIKE clause in table definition	
T191	Enhanced integrity management	Referential action RESTRICT	
T201	Enhanced integrity management	Comparable data types for referential constraints	
T211-01	Active Enhanced database, integrity management	Triggers activated on UPDATE, INSERT, or DELETE of one base table	
T211-02	Active Enhanced database, integrity management	BEFORE triggers	
T211-03	Active Enhanced database, integrity management	AFTER triggers	
T211-04	Active Enhanced database, integrity management	FOR EACH ROW triggers	
T211-05	Active Enhanced database, integrity management	Ability to specify a search condition that must be true before the trigger is invoked	
T211-07	Active Enhanced database, integrity management	TRIGGER privilege	
T212	Enhanced integrity management	Enhanced trigger capability	
T213		INSTEAD OF triggers	
T231		Sensitive cursors	
T241		START TRANSACTION statement	
T271		Savepoints	
T281		SELECT privilege with column granularity	
T312		OVERLAY function	
T321-01	Core	User-defined functions with no overloading	
T321-03	Core	Function invocation	
T321-06	Core	ROUTINES view	
T321-07	Core	PARAMETERS view	
T323		Explicit security for external routines	
T325		Qualified SQL parameter references	

Identifier	Package	Description	Comment
T331		Basic roles	
T341		Overloading of SQL-invoked functions and procedures	
T351		Bracketed SQL comments (/*...*/ comments)	
T431	OLAP	Extended grouping capabilities	
T432		Nested and concatenated GROUPING SETS	
T433		Multiargument GROUPING function	
T441		ABS and MOD functions	
T461		Symmetric BETWEEN predicate	
T491		LATERAL derived table	
T501		Enhanced EXISTS predicate	
T551		Optional key words for default syntax	
T581		Regular expression substring function	
T591		UNIQUE constraints of possibly null columns	
T611	OLAP	Elementary OLAP operations	
T613		Sampling	
T614		NTILE function	
T615		LEAD and LAG functions	
T617		FIRST_VALUE and LAST_VALUE function	
T621		Enhanced numeric functions	
T631	Core	IN predicate with one list element	
T651		SQL-schema statements in SQL routines	
T655		Cyclically dependent routines	
X010		XML type	
X011		Arrays of XML type	
X016		Persistent XML values	
X020		XMLConcat	
X031		XMLElement	

Identifier	Package	Description	Comment
X032		XMLForest	
X034		XMLAgg	
X035		XMLAgg: ORDER BY option	
X036		XMLComment	
X037		XMLPI	
X040		Basic table mapping	
X041		Basic table mapping: nulls absent	
X042		Basic table mapping: null as nil	
X043		Basic table mapping: table as forest	
X044		Basic table mapping: table as element	
X045		Basic table mapping: with target namespace	
X046		Basic table mapping: data mapping	
X047		Basic table mapping: metadata mapping	
X048		Basic table mapping: base64 encoding of binary strings	
X049		Basic table mapping: hex encoding of binary strings	
X050		Advanced table mapping	
X051		Advanced table mapping: nulls absent	
X052		Advanced table mapping: null as nil	
X053		Advanced table mapping: table as forest	
X054		Advanced table mapping: table as element	
X055		Advanced table mapping: with target namespace	
X056		Advanced table mapping: data mapping	
X057		Advanced table mapping: metadata mapping	
X058		Advanced table mapping: base64	

Identifier	Package	Description	Comment
		encoding of binary strings	
X059		Advanced table mapping: hex encoding of binary strings	
X060		XMLParse: character string input and CONTENT option	
X061		XMLParse: character string input and DOCUMENT option	
X070		XMLSerialize: character string serialization and CONTENT option	
X071		XMLSerialize: character string serialization and DOCUMENT option	
X072		XMLSerialize: character string serialization	
X090		XML document predicate	
X120		XML parameters in SQL routines	
X121		XML parameters in external routines	
X400		Name and identifier mapping	
X410		Alter column data type: XML type	

D.2. Unsupported Features

The following features defined in SQL:2011 are not implemented in this release of Postgres Pro. In a few cases, equivalent functionality is available.

Identifier	Package	Description	Comment
B011		Embedded Ada	
B013		Embedded COBOL	
B014		Embedded Fortran	
B015		Embedded MUMPS	
B016		Embedded Pascal	
B017		Embedded PL/I	
B031		Basic dynamic SQL	
B032		Extended dynamic SQL	
B032-01		<describe input statement>	
B033		Untyped SQL-invoked function arguments	

Identifier	Package	Description	Comment
B034		Dynamic specification of cursor attributes	
B035		Non-extended descriptor names	
B041		Extensions to embedded SQL exception declarations	
B051		Enhanced execution rights	
B111		Module language Ada	
B112		Module language C	
B113		Module language COBOL	
B114		Module language Fortran	
B115		Module language MUMPS	
B116		Module language Pascal	
B117		Module language PL/I	
B121		Routine language Ada	
B122		Routine language C	
B123		Routine language COBOL	
B124		Routine language Fortran	
B125		Routine language MUMPS	
B126		Routine language Pascal	
B127		Routine language PL/I	
B128		Routine language SQL	
B211		Module language Ada: VARCHAR and NUMERIC support	
B221		Routine language Ada: VARCHAR and NUMERIC support	
E182	Core	Module language	
F054		TIMESTAMP in DATE type precedence list	
F121		Basic diagnostics management	
F121-01		GET DIAGNOSTICS statement	
F121-02		SET TRANSACTION statement: DIAGNOSTICS SIZE clause	

Identifier	Package	Description	Comment
F122		Enhanced diagnostics management	
F123		All diagnostics	
F181	Core	Multiple module support	
F202		TRUNCATE TABLE: identity column restart option	
F263		Comma-separated predicates in simple CASE expression	
F291		UNIQUE predicate	
F301		CORRESPONDING in query expressions	
F311	Core	Schema definition statement	
F312		MERGE statement	consider INSERT ... ON CONFLICT DO UPDATE
F313		Enhanced MERGE statement	
F314		MERGE statement with DELETE branch	
F341		Usage tables	no ROUTINE_*_USAGE tables
F384		Drop identity property clause	
F385		Drop column generation expression clause	
F386		Set identity column generation clause	
F394		Optional normal form specification	
F403		Partitioned joined tables	
F451		Character set definition	
F461		Named character sets	
F492		Optional table constraint enforcement	
F521	Enhanced integrity management	Assertions	
F671	Enhanced integrity management	Subqueries in CHECK	intentionally omitted
F693		SQL-session and client module collations	
F695		Translation support	
F696		Additional translation documentation	
F721		Deferrable constraints	foreign and unique keys only

Identifier	Package	Description	Comment
F741		Referential MATCH types	no partial match yet
F812	Core	Basic flagging	
F813		Extended flagging	
F821		Local table references	
F831		Full cursor update	
F831-01		Updatable scrollable cursors	
F831-02		Updatable ordered cursors	
F841		LIKE_REGEX predicate	
F842		OCCURRENCES_REGEX function	
F843		POSITION_REGEX function	
F844		SUBSTRING_REGEX function	
F845		TRANSLATE_REGEX function	
F846		Octet support in regular expression operators	
F847		Nonconstant regular expressions	
F866		FETCH FIRST clause: PERCENT option	
F867		FETCH FIRST clause: WITH TIES option	
S011	Core	Distinct data types	
S011-01	Core	USER_DEFINED_TYPES view	
S023	Basic object support	Basic structured types	
S024	Enhanced object support	Enhanced structured types	
S025		Final structured types	
S026		Self-referencing structured types	
S027		Create method by specific method name	
S028		Permutable UDT options list	
S041	Basic object support	Basic reference types	
S043	Enhanced object support	Enhanced reference types	
S051	Basic object support	Create table of type	partially supported
S081	Enhanced object support	Subtables	

Identifier	Package	Description	Comment
S091		Basic array support	partially supported
S091-01		Arrays of built-in data types	
S091-02		Arrays of distinct types	
S091-03		Array expressions	
S094		Arrays of reference types	
S097		Array element assignment	
S151	Basic object support	Type predicate	
S161	Enhanced object support	Subtype treatment	
S162		Subtype treatment for references	
S202		SQL-invoked routines on multisets	
S231	Enhanced object support	Structured type locators	
S232		Array locators	
S233		Multiset locators	
S241		Transform functions	
S242		Alter transform statement	
S251		User-defined orderings	
S261		Specific type method	
S271		Basic multiset support	
S272		Multisets of user-defined types	
S274		Multisets of reference types	
S275		Advanced multiset support	
S281		Nested collection types	
S291		Unique constraint on entire row	
S401		Distinct types based on array types	
S402		Distinct types based on distinct types	
S403		ARRAY_MAX_CARDINALITY	
S404		TRIM_ARRAY	
T011		Timestamp in Information Schema	
T021		BINARY and VARBINARY data types	

Identifier	Package	Description	Comment
T022		Advanced support for BINARY and VARBINARY data types	
T023		Compound binary literal	
T024		Spaces in binary literals	
T041	Basic object support	Basic LOB data type support	
T041-01	Basic object support	BLOB data type	
T041-02	Basic object support	CLOB data type	
T041-03	Basic object support	POSITION, LENGTH, LOWER, TRIM, UPPER, and SUBSTRING functions for LOB data types	
T041-04	Basic object support	Concatenation of LOB data types	
T041-05	Basic object support	LOB locator: non-holdable	
T042		Extended LOB data type support	
T043		Multiplier T	
T044		Multiplier P	
T051		Row types	
T052		MAX and MIN for row types	
T053		Explicit aliases for all-fields reference	
T061		UCS support	
T101		Enhanced nullability determination	
T111		Updatable joins, unions, and columns	
T174		Identity columns	
T175		Generated columns	
T176		Sequence generator support	
T177		Sequence generator support: simple restart option	
T178		Identity columns: simple restart option	
T180		System-versioned tables	
T181		Application-time period tables	
T211	Active database, Enhanced integrity management	Basic trigger capability	

Identifier	Package	Description	Comment
T211-06	Active database, Enhanced integrity management	Support for run-time rules for the interaction of triggers and constraints	
T211-08	Active database, Enhanced integrity management	Multiple triggers for the same event are executed in the order in which they were created in the catalog	intentionally omitted
T251		SET TRANSACTION statement: LOCAL option	
T261		Chained transactions	
T272		Enhanced savepoint management	
T285		Enhanced derived column names	
T301		Functional dependencies	partially supported
T321	Core	Basic SQL-invoked routines	
T321-02	Core	User-defined stored procedures with no overloading	
T321-04	Core	CALL statement	
T321-05	Core	RETURN statement	
T322	PSM	Declared data type attributes	
T324		Explicit security for SQL routines	
T326		Table functions	
T332		Extended roles	mostly supported
T434		GROUP BY DISTINCT	
T471		Result sets return value	
T472		DESCRIBE CURSOR	
T495		Combined data change and retrieval	different syntax
T502		Period predicates	
T511		Transaction counts	
T521		Named arguments in CALL statement	
T522		Default values for IN parameters of SQL-invoked procedures	supported except DEFAULT key word in invocation
T561		Holdable locators	
T571		Array-returning external SQL-invoked functions	

Identifier	Package	Description	Comment
T572		Multiset-returning external SQL-invoked functions	
T601		Local cursor references	
T612		Advanced OLAP operations	some forms supported
T616		Null treatment option for LEAD and LAG functions	
T618		NTH_VALUE function	function exists, but some options missing
T619		Nested window functions	
T620		WINDOW clause: GROUPS option	
T641		Multiple column assignment	only some syntax variants supported
T652		SQL-dynamic statements in SQL routines	
T653		SQL-schema statements in external routines	
T654		SQL-dynamic statements in external routines	
M001		Datalinks	
M002		Datalinks via SQL/CLI	
M003		Datalinks via Embedded SQL	
M004		Foreign data support	partially supported
M005		Foreign schema support	
M006		GetSQLString routine	
M007		TransmitRequest	
M009		GetOpts and GetStatistics routines	
M010		Foreign data wrapper support	different API
M011		Datalinks via Ada	
M012		Datalinks via C	
M013		Datalinks via COBOL	
M014		Datalinks via Fortran	
M015		Datalinks via M	
M016		Datalinks via Pascal	
M017		Datalinks via PL/I	
M018		Foreign data wrapper interface routines in Ada	
M019		Foreign data wrapper interface routines in C	different API

Appendix E. Release Notes

The release notes contain the significant changes in each Postgres Pro Enterprise release, with major features and migration issues listed at the top. The release notes do not contain changes that affect only a few users or changes that are internal and therefore not user-visible. For example, the optimizer is improved in almost every release, but the improvements are usually observed by users as simply faster queries.

E.1. Postgres Pro Enterprise 9.6.21.1

Release date: 2020-02-26

E.1.1. Overview

This release is based on PostgreSQL 9.6.21 and Postgres Pro Enterprise 9.6.20.1. All improvements inherited from PostgreSQL 9.6.21 are listed in [PostgreSQL 9.6.21 Release Notes](#). As compared with Postgres Pro Enterprise 9.6.20.1, this version also provides the following changes:

- Deprecated the `cfs_compress_small_relations` parameter. Small relations are still compressed by default and will not differ from the bigger ones. Make sure to keep the existing parameter setting intact for the lifetime of your database cluster.
- Fixed a bug in the CFS implementation that resulted in disabling compression for all relations when the `cfs_compress_temp_relations` parameter was set.
- Added the `pg_snapshot_any` function to help superusers explore corrupted databases. See [Section 9.26.11](#) for details.
- Aligned the behavior of the parameters `idle_session_timeout` and `idle_in_transaction_session_timeout` with how they will behave in a future PostgreSQL release. Specifically, the `idle_session_timeout` parameter now applies only when outside a transaction.
- Upgraded `pg_probackup` to the latest version 2.4.10. Major improvements over the previously included version 2.4.2 are as follows:
 - Incremental restore with `--force` flag now allows you to overwrite the contents of the directory specified by `PGDATA` in case of system ID mismatch. Previously this resulted in an error.
 - It is now possible to restore and validate backups from a read-only filesystem.
 - In-place merge is now disabled only if the storage format changed.
 - Non-exclusive backup locks are implemented, which enables concurrent validate and restore. Backup shared locks are now released at the process exit.
 - Streamed WAL segments are now added to the backup filelist on the fly and fsynced to disk at the end of the backup.

See [pg_probackup documentation](#) for details.

- Fixed a bug in [pgpro_scheduler](#) due to which jobs scheduled to run exactly at the start of an hour (but at a two-hour or larger interval) were not executed at all.
- Added [pgpro_controldata](#) utility to display control information of a PostgreSQL/Postgres Pro database cluster and compatibility information for a cluster and/or server.

E.1.2. Migration to Version 9.6.21.1

Depending on your current installation, the upgrade procedure will differ.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro Standard, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#). Besides, make sure to pay special attention to implementation specifics of [64-bit transaction IDs](#). If you have used explicit casts to

32-bit integers when handling transaction IDs, you have to replace them with casts to `bigint` since 64-bit transaction IDs are of the `bigint` type.

While functions `numeric_eq`, `numeric_ne`, `numeric_gt`, `numeric_ge`, `numeric_lt`, and `numeric_le` are actually leakproof, they were not marked as such in Postgres Pro Enterprise 9.6.16.1 or lower, which could lead to incorrect query optimization. In particular, it negatively affected query execution if row-level security policy was in use. Version 9.6.17.1 repairs this issue for new installations by correcting the initial catalog data, but existing installations will still have incorrect markings unless you update `pg_proc` entries for these functions. You can run [pg_upgrade](#) to upgrade your server instance to a version containing the corrected initial data, or manually correct these entries in each database of the installation using the `ALTER FUNCTION` command. For example:

```
ALTER FUNCTION pg_catalog.numeric_eq LEAKPROOF
```

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. It is usually enough to install the new version into the same installation directory. Once the new binaries are installed, the `pgpro_upgrade` script is run automatically to check whether additional setup is required and complete the upgrade.

Since `pg_probackup` delivery model changed in Postgres Pro Enterprise 9.6.12.1, when upgrading from a lower version on ALT Linux and Debian-based systems, run `apt dist-upgrade` (or `apt-get dist-upgrade`) to ensure that all new dependencies are handled correctly. On Windows, you have to run a separate `pg_probackup` installer to complete the upgrade.

When upgrading from versions 9.6.9.1 through 9.6.14.1, you must run the `REINDEX` command to rebuild GIN, GiST, and SP-GiST indexes to fix replication issues that could be observed in these versions. You should also retake all backups for these versions if your database had such indexes.

When upgrading from versions 9.6.8.2 or lower, you have to rebuild indexes that used `mchar` or `mvchar` types.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

When upgrading from version 9.6.1.2 on RPM-based Linux distributions, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

For some Linux distributions, you may be prompted to run `pgpro_upgrade` manually. In this case, you must stop the `postgres` service. The script must be run on behalf of the user owning the database (typically `postgres`) and `PGDATA` environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error. This step is not required when upgrading from version 9.6.4.1 or higher.

E.2. Postgres Pro Enterprise 9.6.20.1

Release date: 2020-11-27

E.2.1. Overview

This release is based on PostgreSQL 9.6.20 and Postgres Pro Enterprise 9.6.19.1. All improvements inherited from PostgreSQL 9.6.20 are listed in [PostgreSQL 9.6.20 Release Notes](#). As compared with Postgres Pro Enterprise 9.6.19.1, this version also provides the following changes:

- Ended support for CentOS 6.
- Fixed a bug in the [pg_variables](#) module. Now you can create a variable in a transaction after removal of a variable with the same name.
- Fixed the [pgpro_upgrade](#) script, which did not behave as described in the documentation on Debian-based operating systems. There, the script previously ignored the `-D/--pgdata` option, to be used to specify the data directory, and the `--check` option did not produce the documented output.

- Upgraded [mamonsu](#) to version 2.6.2.
- Upgraded [pgbouncer](#) to version 1.15.
- Improved the precision of `pgbench` when the `--default-isolation-level` option is used. The default isolation level is now set in the environment variable `PGOPTIONS` so that TPS values are computed consistently, with or without the `--connect` option.
- Fixed [CFS](#) to dramatically speed up `pg_basebackup` for a database that contains a lot of small tables. Previously, nearly 1 MB of zeroes was produced for each relation to be copied.
- Updated [pgpro_scheduler](#):
 - Now `pgpro_scheduler` waits in the suspended state on a standby server to be started when the standby is promoted to a master server. Previously it didn't work on a standby server either and besides generated a lot of error messages.
 - Enhanced the scheduling scale used by `pgpro_scheduler` — jobs can now be scheduled to a precision of seconds. Also some predefined keywords can now be used instead of `crontab` strings.

E.2.2. Migration to Version 9.6.20.1

Depending on your current installation, the upgrade procedure will differ.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro Standard, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#). Besides, make sure to pay special attention to implementation specifics of [64-bit transaction IDs](#). If you have used explicit casts to 32-bit integers when handling transaction IDs, you have to replace them with casts to `bigint` since 64-bit transaction IDs are of the `bigint` type.

While functions `numeric_eq`, `numeric_ne`, `numeric_gt`, `numeric_ge`, `numeric_lt`, and `numeric_le` are actually leakproof, they were not marked as such in Postgres Pro Enterprise 9.6.16.1 or lower, which could lead to incorrect query optimization. In particular, it negatively affected query execution if row-level security policy was in use. Version 9.6.17.1 repairs this issue for new installations by correcting the initial catalog data, but existing installations will still have incorrect markings unless you update `pg_proc` entries for these functions. You can run [pg_upgrade](#) to upgrade your server instance to a version containing the corrected initial data, or manually correct these entries in each database of the installation using the `ALTER FUNCTION` command. For example:

```
ALTER FUNCTION pg_catalog.numeric_eq LEAKPROOF
```

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. It is usually enough to install the new version into the same installation directory. Once the new binaries are installed, the `pgpro_upgrade` script is run automatically to check whether additional setup is required and complete the upgrade.

Since `pg_probackup` delivery model changed in Postgres Pro Enterprise 9.6.12.1, when upgrading from a lower version on ALT Linux and Debian-based systems, run `apt dist-upgrade` (or `apt-get dist-upgrade`) to ensure that all new dependencies are handled correctly. On Windows, you have to run a separate `pg_probackup` installer to complete the upgrade.

When upgrading from versions 9.6.9.1 through 9.6.14.1, you must run the `REINDEX` command to rebuild GIN, GiST, and SP-GiST indexes to fix replication issues that could be observed in these versions. You should also retake all backups for these versions if your database had such indexes.

When upgrading from versions 9.6.8.2 or lower, you have to rebuild indexes that used `mchar` or `mvarchar` types.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

When upgrading from version 9.6.1.2 on RPM-based Linux distributions, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

For some Linux distributions, you may be prompted to run `pgpro_upgrade` manually. In this case, you must stop the `postgres` service. The script must be run on behalf of the user owning the database (typically `postgres`) and `PGDATA` environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error. This step is not required when upgrading from version 9.6.4.1 or higher.

E.3. Postgres Pro Enterprise 9.6.19.1

Release date: 2020-08-24

E.3.1. Overview

This release is based on PostgreSQL 9.6.19 and Postgres Pro Enterprise 9.6.18.1. All improvements inherited from PostgreSQL 9.6.19 are listed in [PostgreSQL 9.6.19 Release Notes](#). As compared with Postgres Pro Enterprise 9.6.18.1, this version also provides the following changes:

- Improved the `rum` extension:
 - Improved full text search for `tsvector` values with the lexeme weights specified. When executing queries with the weight-based constraints, the index search results do not need to be rechecked in table, so these queries perform much faster.
 - Fixed the error which causes result loss when the negation operator is used in such queries.
- Fixed bug in `pgpro_scheduler` that prevented stopping of the running jobs on `schedule.stop()`.
- Fixed the GUC parameter group naming. A `Compressed File System` parameter group name has been omitted previously which caused other group names to be shifted.
- Ended support for SUSE Linux Enterprise Server 11.
- Fixed race conditions in BRIN index that caused errors:
 - "failed to find parent tuple for heap-only tuple ...".

The error could occur when the `brin_summarize_new_values()` function and HOT updates were executed simultaneously in concurrent transactions.
 - "corrupted BRIN index: inconsistent range map".

The error could occur when BRIN index's desummarization and a bitmap scan were executed simultaneously in concurrent transactions.
- Upgraded `pg_probackup` to latest version 2.4.2:
 - New options and flags can now be used to add flexibility to `delete`, `backup`, `restore`, `archive-push` and `set-backup` commands.
 - Incremental restore and support for multi-timeline incremental chains have been added.
 - Postgres Pro parameters `slot_name` and `primary_conninfo` can be used during restore.
 - `archive-push` and `archive-get` commands considerably reworked.
 - Improvements have been achieved in speed and memory consumption.See [pg_probackup documentation](#) for details.
- Upgraded `mamonsu` for Linux systems to version 2.5.1. Now it is based on Python 3. Version 2.3.4 is still provided for Windows systems.

E.3.2. Migration to Version 9.6.19.1

Depending on your current installation, the upgrade procedure will differ.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro Standard, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#). Besides, make sure to pay special attention to implementation specifics of [64-bit transaction IDs](#). If you have used explicit casts to 32-bit integers when handling transaction IDs, you have to replace them with casts to `bigint` since 64-bit transaction IDs are of the `bigint` type.

While functions `numeric_eq`, `numeric_ne`, `numeric_gt`, `numeric_ge`, `numeric_lt`, and `numeric_le` are actually leakproof, they were not marked as such in Postgres Pro Enterprise 9.6.16.1 or lower, which could lead to incorrect query optimization. In particular, it negatively affected query execution if row-level security policy was in use. Version 9.6.17.1 repairs this issue for new installations by correcting the initial catalog data, but existing installations will still have incorrect markings unless you update `pg_proc` entries for these functions. You can run [pg_upgrade](#) to upgrade your server instance to a version containing the corrected initial data, or manually correct these entries in each database of the installation using the `ALTER FUNCTION` command. For example:

```
ALTER FUNCTION pg_catalog.numeric_eq LEAKPROOF
```

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. It is usually enough to install the new version into the same installation directory. Once the new binaries are installed, the `pgpro_upgrade` script is run automatically to check whether additional setup is required and complete the upgrade.

Since `pg_probackup` delivery model changed in Postgres Pro Enterprise 9.6.12.1, when upgrading from a lower version on ALT Linux and Debian-based systems, run `apt dist-upgrade` (or `apt-get dist-upgrade`) to ensure that all new dependencies are handled correctly. On Windows, you have to run a separate `pg_probackup` installer to complete the upgrade.

When upgrading from versions 9.6.9.1 through 9.6.14.1, you must run the `REINDEX` command to rebuild GIN, GiST, and SP-GiST indexes to fix replication issues that could be observed in these versions. You should also retake all backups for these versions if your database had such indexes.

When upgrading from versions 9.6.8.2 or lower, you have to rebuild indexes that used `mchar` or `mvchar` types.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

When upgrading from version 9.6.1.2 on RPM-based Linux distributions, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

For some Linux distributions, you may be prompted to run `pgpro_upgrade` manually. In this case, you must stop the `postgres` service. The script must be run on behalf of the user owning the database (typically `postgres`) and `PGDATA` environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error. This step is not required when upgrading from version 9.6.4.1 or higher.

E.4. Postgres Pro Enterprise 9.6.18.1

Release date: 2020-05-26

E.4.1. Overview

This release is based on PostgreSQL 9.6.18 and Postgres Pro Enterprise 9.6.17.1. All improvements inherited from PostgreSQL 9.6.18 are listed in [PostgreSQL 9.6.18 Release Notes](#). As compared with Postgres Pro Enterprise 9.6.17.1, this version also provides the following changes:

- Fixed an issue that could lead to server failure if autovacuum tried to access a manually dropped temporary namespace.
- Fixed an issue that could lead to losing transactional consistency if multiple autonomous transactions were in use.

- Updated [CFS](#) to allow changing the [cfs_gc_threshold](#) parameter for the current session. Now you can temporarily set it to a smaller value if you would like to manually defragment a relation with a smaller percent of garbage than is currently allowed.
- Added the `--no-data-checksums` option for [initdb](#) to allow initializing Postgres Pro clusters with checksums disabled.
- Upgraded several libraries provided with Postgres Pro on Windows. Now the following libraries are used: OpenSSL 1.1.1g, libzstd 1.4.4, gettext 0.20.2, libiconv 1.16, libxml2 2.9.9, and libxslt 1.1.32. The ICU library has been upgraded from version 56.1 to 56.2.
- Upgraded [pgpro_scheduler](#) to version 2.6. This version introduces several enhancements, including a full rework of cron parser implementation. Besides, [pgpro_scheduler](#) now starts scheduled jobs once a background worker becomes available if there were not enough workers to start the job on time.
- Upgraded [pageinspect](#) to version 1.6 to correctly handle 64-bit transaction IDs.
- Upgraded [pg_pathman](#) to version 1.5.11 to avoid server failure when trying to access child partitions without the required permissions while parent table access is allowed. This issue could previously occur when using [pg_pathman](#) with Postgres Pro 11.7.1 or higher.

E.4.2. Migration to Version 9.6.18.1

Depending on your current installation, the upgrade procedure will differ.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro Standard, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#). Besides, make sure to pay special attention to implementation specifics of [64-bit transaction IDs](#). If you have used explicit casts to 32-bit integers when handling transaction IDs, you have to replace them with casts to `bigint` since 64-bit transaction IDs are of the `bigint` type.

While functions `numeric_eq`, `numeric_ne`, `numeric_gt`, `numeric_ge`, `numeric_lt`, and `numeric_le` are actually leakproof, they were not marked as such in Postgres Pro Enterprise 9.6.16.1 or lower, which could lead to incorrect query optimization. In particular, it negatively affected query execution if row-level security policy was in use. Version 9.6.17.1 repairs this issue for new installations by correcting the initial catalog data, but existing installations will still have incorrect markings unless you update `pg_proc` entries for these functions. You can run [pg_upgrade](#) to upgrade your server instance to a version containing the corrected initial data, or manually correct these entries in each database of the installation using the `ALTER FUNCTION` command. For example:

```
ALTER FUNCTION pg_catalog.numeric_eq LEAKPROOF
```

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. It is usually enough to install the new version into the same installation directory. Once the new binaries are installed, the `pgpro_upgrade` script is run automatically to check whether additional setup is required and complete the upgrade.

Since `pg_probackup` delivery model changed in Postgres Pro Enterprise 9.6.12.1, when upgrading from a lower version on ALT Linux and Debian-based systems, run `apt dist-upgrade` (or `apt-get dist-upgrade`) to ensure that all new dependencies are handled correctly. On Windows, you have to run a separate `pg_probackup` installer to complete the upgrade.

When upgrading from versions 9.6.9.1 through 9.6.14.1, you must run the `REINDEX` command to rebuild GIN, GiST, and SP-GiST indexes to fix replication issues that could be observed in these versions. You should also retake all backups for these versions if your database had such indexes.

When upgrading from versions 9.6.8.2 or lower, you have to rebuild indexes that used `mchar` or `mvchar` types.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

When upgrading from version 9.6.1.2 on RPM-based Linux distributions, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

For some Linux distributions, you may be prompted to run `pgpro_upgrade` manually. In this case, you must stop the `postgres` service. The script must be run on behalf of the user owning the database (typically `postgres`) and `PGDATA` environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error. This step is not required when upgrading from version 9.6.4.1 or higher.

E.5. Postgres Pro Enterprise 9.6.17.1

Release date: 2020-02-21

E.5.1. Overview

This release is based on PostgreSQL 9.6.17 and Postgres Pro Enterprise 9.6.16.1. All improvements inherited from PostgreSQL 9.6.17 are listed in [PostgreSQL 9.6.17 Release Notes](#). As compared with Postgres Pro Enterprise 9.6.16.1, this version also provides the following changes:

- Increased the maximum value of the `track_activity_query_size` parameter to 1MB. In vanilla PostgreSQL, this change is targeted for version 13.
- Fixed planner's optimization to correctly take into account similar `OR` clauses if they reference columns that are different, but have the same position in different indexes.
- Updated [CFS](#) to enhance compression functionality:
 - The `cfs_compress_small_relations` parameter controls whether small tables are compressed. It may be useful to turn off this setting for databases with many relations smaller than 1GB to avoid overhead.
- Improved query performance with row-level security policy enabled by correctly marking numeric comparison functions as leakproof.
- Fixed the `mchar` extension to correctly handle the `ESCAPE` clause in `SIMILAR TO` regular expressions.
- Upgraded `pg_probackup` to version 2.2.7.
- Upgraded `mamonsu` to version 2.4.4.

E.5.2. Migration to Version 9.6.17.1

Depending on your current installation, the upgrade procedure will differ.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro Standard, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#). Besides, make sure to pay special attention to implementation specifics of [64-bit transaction IDs](#). If you have used explicit casts to 32-bit integers when handling transaction IDs, you have to replace them with casts to `bigint` since 64-bit transaction IDs are of the `bigint` type.

While functions `numeric_eq`, `numeric_ne`, `numeric_gt`, `numeric_ge`, `numeric_lt`, and `numeric_le` are actually leakproof, they were not marked as such in Postgres Pro Enterprise 9.6.16.1 or lower, which could lead to incorrect query optimization. In particular, it negatively affected query execution if row-level security policy was in use. Version 9.6.17.1 repairs this issue for new installations by correcting the initial catalog data, but existing installations will still have incorrect markings unless you update `pg_proc` entries for these functions. You can run [pg_upgrade](#) to upgrade your server instance to a version containing the corrected initial data, or manually correct these entries in each database of the installation using the `ALTER FUNCTION` command. For example:

```
ALTER FUNCTION pg_catalog.numeric_eq LEAKPROOF
```

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. It is usually enough to install the new version into the same installation

directory. Once the new binaries are installed, the `pgpro_upgrade` script is run automatically to check whether additional setup is required and complete the upgrade.

Since `pg_probackup` delivery model changed in Postgres Pro Enterprise 9.6.12.1, when upgrading from a lower version on ALT Linux and Debian-based systems, run `apt dist-upgrade` (or `apt-get dist-upgrade`) to ensure that all new dependencies are handled correctly. On Windows, you have to run a separate `pg_probackup` installer to complete the upgrade.

When upgrading from versions 9.6.9.1 through 9.6.14.1, you must run the `REINDEX` command to rebuild GIN, GiST, and SP-GiST indexes to fix replication issues that could be observed in these versions. You should also retake all backups for these versions if your database had such indexes.

When upgrading from versions 9.6.8.2 or lower, you have to rebuild indexes that used `mchar` or `mvchar` types.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

When upgrading from version 9.6.1.2 on RPM-based Linux distributions, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

For some Linux distributions, you may be prompted to run `pgpro_upgrade` manually. In this case, you must stop the `postgres` service. The script must be run on behalf of the user owning the database (typically `postgres`) and `PGDATA` environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error. This step is not required when upgrading from version 9.6.4.1 or higher.

E.6. Postgres Pro Enterprise 9.6.16.1

Release date: 2019-12-02

E.6.1. Overview

This release is based on PostgreSQL 9.6.16 and Postgres Pro Enterprise 9.6.15.2. All improvements inherited from PostgreSQL 9.6.16 are listed in [PostgreSQL 9.6.16 Release Notes](#). As compared with Postgres Pro Enterprise 9.6.15.2, this version also provides the following changes:

- Ended support for SLES 12. If you would like to use Postgres Pro on this operating system, install Postgres Pro Enterprise 10 or higher.
- Fixed handling of NULL distance values when using k-NN search with SP-GiST.
- Fixed handling of temporary tables by autonomous transactions.
- Ensured that `pg_visibility` is compatible with 64-bit transaction IDs.
- Forbade access to tables that belong to partition hierarchies in which both `pg_pathman` and standard PostgreSQL inheritance have been used for partitioning. Mixing different partitioning mechanisms in a single table hierarchy is unsupported and should have never been attempted. Previously, you could get duplicated query results from such table hierarchies.
- Updated `pgpro_scheduler`:
 - Added the `schedule.auto_enabled` configuration parameter that specifies whether to enable `pgpro_scheduler` at the server start. By default, `pgpro_scheduler` is not automatically restarted if you reload the server.
 - Added the `schedule.is_enabled()` function that allows to check whether `pgpro_scheduler` is currently running. The `schedule.enabled` configuration parameter that could previously serve this purpose is now deprecated.
 - Changing `pgpro_scheduler` parameters on the fly does not cause server failures anymore.

- `pgpro_scheduler` stability has been improved for several other corner cases.
- Updated the [mamonsu](#) module to version 2.4.1. You can now convert all system and Postgres Pro metrics definitions provided by `mamonsu` to the format supported by the native Zabbix agent.
- Upgraded `pgbouncer` to version 1.11.0.
- Upgraded `pg_probackup` to version 2.2.5.

E.6.2. Migration to Version 9.6.16.1

Depending on your current installation, the upgrade procedure will differ.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro Standard, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#).

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. It is usually enough to install the new version into the same installation directory. Once the new binaries are installed, the `pgpro_upgrade` script is run automatically to check whether additional setup is required and complete the upgrade.

Since `pg_probackup` delivery model changed in Postgres Pro Enterprise 9.6.12.1, when upgrading from a lower version on ALT Linux and Debian-based systems, run `apt dist-upgrade` (or `apt-get dist-upgrade`) to ensure that all new dependencies are handled correctly. On Windows, you have to run a separate `pg_probackup` installer to complete the upgrade.

When upgrading from versions 9.6.9.1 through 9.6.14.1, you must run the `REINDEX` command to rebuild GIN, GiST, and SP-GiST indexes to fix replication issues that could be observed in these versions. You should also retake all backups for these versions if your database had such indexes.

When upgrading from versions 9.6.8.2 or lower, you have to rebuild indexes that used `mchar` or `mvchar` types.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

When upgrading from version 9.6.1.2 on RPM-based Linux distributions, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

For some Linux distributions, you may be prompted to run `pgpro_upgrade` manually. In this case, you must stop the `postgres` service. The script must be run on behalf of the user owning the database (typically `postgres`) and `PGDATA` environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error. This step is not required when upgrading from version 9.6.4.1 or higher.

E.7. Postgres Pro Enterprise 9.6.15.2

Release date: 2019-10-10

E.7.1. Overview

This release is based on Postgres Pro Enterprise 9.6.15.1 and provides the following improvement:

- The expression comparison function has been reworked to fix bugs and improve support in the future.

E.7.2. Migration to Version 9.6.15.2

Depending on your current installation, the upgrade procedure will differ.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro Standard, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#).

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. It is usually enough to install the new version into the same installation directory. Once the new binaries are installed, the `pgpro_upgrade` script is run automatically to check whether additional setup is required and complete the upgrade.

Since `pg_probackup` delivery model changed in Postgres Pro Enterprise 9.6.12.1, when upgrading from a lower version on ALT Linux and Debian-based systems, run `apt dist-upgrade` (or `apt-get dist-upgrade`) to ensure that all new dependencies are handled correctly. On Windows, you have to run a separate `pg_probackup` installer to complete the upgrade.

When upgrading from versions 9.6.9.1 through 9.6.14.1, you must run the `REINDEX` command to rebuild GIN, GiST, and SP-GiST indexes to fix replication issues that could be observed in these versions. You should also retake all backups for these versions if your database had such indexes.

When upgrading from versions 9.6.8.2 or lower, you have to rebuild indexes that used `mchar` or `mvchar` types.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

When upgrading from version 9.6.1.2 on RPM-based Linux distributions, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

For some Linux distributions, you may be prompted to run `pgpro_upgrade` manually. In this case, you must stop the `postgres` service. The script must be run on behalf of the user owning the database (typically `postgres`) and `PGDATA` environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error. This step is not required when upgrading from version 9.6.4.1 or higher.

E.8. Postgres Pro Enterprise 9.6.15.1

Release date: 2019-08-13

E.8.1. Overview

This release is based on PostgreSQL 9.6.15 and Postgres Pro Enterprise 9.6.14.1. All improvements inherited from PostgreSQL 9.6.15 are listed in [PostgreSQL 9.6.15 Release Notes](#). As compared with Postgres Pro Enterprise 9.6.14.1, this version also provides the following changes:

- Added support for Debian 10.
- Fixed `VACUUM` logic for truncating multixact members as required for 64-bit transaction and multixact IDs. It resolves a bloating issue that could affect the `pg_multixact` directory.
- Fixed replication issues that could occur with newly created GIN, GiST and SP-GiST indexes. Previously, the metapage of such indexes was not copied to standby after `CREATE INDEX` or `REINDEX`, which caused an error if this index was accessed on standby before any other metapage updates.
- Improved planning accuracy for queries with `OR` clauses. Now sorting is performed correctly for such queries.
- Fixed implementation of greater than (`>`) and not equal to (`<>`) operators for the `jsquery` type.
- Fixed a deadlock issue in the `pg_wait_sampling` module. Previously, a deadlock could occur if clients got disconnected before receiving the requested statistics on wait events. Now statistics collector releases the exclusive lock in such cases and logs the following message:
`pg_wait_sampling collector: receiver of message queue has been detached.`

E.8.2. Migration to Version 9.6.15.1

Depending on your current installation, the upgrade procedure will differ.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro Standard, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#).

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. It is usually enough to install the new version into the same installation directory. Once the new binaries are installed, the `pgpro_upgrade` script is run automatically to check whether additional setup is required and complete the upgrade.

Since `pg_probackup` delivery model changed in Postgres Pro Enterprise 9.6.12.1, when upgrading from a lower version on ALT Linux and Debian-based systems, run `apt dist-upgrade` (or `apt-get dist-upgrade`) to ensure that all new dependencies are handled correctly. On Windows, you have to run a separate `pg_probackup` installer to complete the upgrade.

When upgrading from versions 9.6.9.1 through 9.6.14.1, you must run the `REINDEX` command to rebuild GIN, GiST, and SP-GiST indexes to fix replication issues that could be observed in these versions. You should also retake all backups for these versions if your database had such indexes.

When upgrading from versions 9.6.8.2 or lower, you have to rebuild indexes that used `mchar` or `mvchar` types.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

When upgrading from version 9.6.1.2 on RPM-based Linux distributions, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

For some Linux distributions, you may be prompted to run `pgpro_upgrade` manually. In this case, you must stop the `postgres` service. The script must be run on behalf of the user owning the database (typically `postgres`) and `PGDATA` environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error. This step is not required when upgrading from version 9.6.4.1 or higher.

E.9. Postgres Pro Enterprise 9.6.14.1

Release date: 2019-07-10

E.9.1. Overview

This release is based on PostgreSQL 9.6.14 and Postgres Pro Enterprise 9.6.12.1. All improvements inherited from PostgreSQL 9.6.14 are listed in [PostgreSQL 9.6.14 Release Notes](#). As compared with Postgres Pro Enterprise 9.6.12.1, this version also provides the following changes:

- Added support for Rosa Enterprise Linux Server 7 and ROSA COBALT 7 (server edition). The previous versions of these operating systems are no longer supported.
- Added support for SUSE Linux Enterprise Server 12 SP3.
- Fixed an issue that could cause server failures when using non-strict aggregate functions.
- Fixed processing of queries with multiple `OR` clauses to eliminate duplicate results and ensure the correct sort order.
- Updated `pg_probackup` module to version 2.1.3. As compared with version 2.0.26, it offers the following major improvements:
 - Backup and restore of a remote Postgres Pro instance via SSH.
 - Merging incremental backups with their expired parent backups to satisfy retention policy.
 - Backing up files and directories located outside of Postgres Pro data directory, such as configuration or log files.
 - The `checkdb` command for validating all data files in the Postgres Pro instance and logical verification of indexes using [amcheck](#).

For a full list of changes, see [pg_probackup Wiki](#).

- Updated `pg_pathman` module to version 1.5.8. As compared to version 1.5.5 provided in the previous Postgres Pro releases, the following enhancements were introduced:
 - Fixed handling of tables with multilevel partitioning. Previously, `SELECT FOR SHARE` and `SELECT FOR UPDATE` commands for such tables could return the following error: `ERROR: variable not found in subplan target lists`.
 - Enhanced `pg_pathman` stability.

E.9.2. Migration to Version 9.6.14.1

Depending on your current installation, the upgrade procedure will differ.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro Standard, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#).

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. It is usually enough to install the new version into the same installation directory. Once the new binaries are installed, the `pgpro_upgrade` script is run automatically to check whether additional setup is required and complete the upgrade.

Since `pg_probackup` delivery model changed in Postgres Pro Enterprise 9.6.12.1, when upgrading from a lower version on ALT Linux and Debian-based systems, run `apt dist-upgrade` (or `apt-get dist-upgrade`) to ensure that all new dependencies are handled correctly. On Windows, you have to run a separate `pg_probackup` installer to complete the upgrade.

When upgrading from versions 9.6.8.2 or lower, you have to rebuild indexes that used `mchar` or `mvchar` types.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

When upgrading from version 9.6.1.2 on RPM-based Linux distributions, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

For some Linux distributions, you may be prompted to run `pgpro_upgrade` manually. In this case, you must stop the `postgres` service. The script must be run on behalf of the user owning the database (typically `postgres`) and `PGDATA` environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error. This step is not required when upgrading from version 9.6.4.1 or higher.

E.10. Postgres Pro Enterprise 9.6.12.1

Release date: 2019-03-20

E.10.1. Overview

This release is based on PostgreSQL 9.6.12 and Postgres Pro Enterprise 9.6.11.1. All improvements inherited from PostgreSQL 9.6.12 are listed in [PostgreSQL 9.6.12 Release Notes](#). As compared with Postgres Pro Enterprise 9.6.11.1, this version also provides the following changes:

- Changed the default authentication method for installations on SUSE Linux Enterprise Server systems, as well as Red Hat Enterprise Linux 7 and its derivatives. Now local connections use the `peer` method, while network connections use `md5`. For details on supported authentication methods, see [Section 20.3](#).
- Backported the patch that addresses `dsm_attach()` race condition when DSM handles are reused; in vanilla PostgreSQL, this fix is targeted for the future updates only. The patch is hoped to resolve

issues when the server reports the following error message: `ERROR: dsa_area could not attach to segment.`

- Changed delivery model for `pg_probackup` utility:
 - On Linux, `pg_probackup` is now provided in the `pg-probackup-ent-9.6` package. On ALT Linux and Debian-based systems, when upgrading from Postgres Pro Enterprise 9.6.11.1 or lower, run `apt dist-upgrade` (or `apt-get dist-upgrade`) to ensure that all new dependencies are handled correctly.
 - On Windows, `pg_probackup` now has a separate installer. You have to install core components of the current Postgres Pro version before installing `pg_probackup`.
- Started delivering `pg_hint_plan` separately:
 - On Linux, `pg_hint_plan` is now provided in the `pg-hint-plan-ent-9.6` package.
 - On Windows, `pg_hint_plan` now has a separate installer that should be run after the core components of the current Postgres Pro version are installed.
- Added new options to Postgres Pro interactive installer for Windows. Now you can:
 - Choose `icu` or `libc` as the default collation provider. Previously, Postgres Pro Enterprise always used `icu` by default.
 - Select a Windows user that starts Postgres Pro service. By default, Postgres Pro service is started on behalf of `NT AUTHORITY\NetworkService`.
- Provided multiple improvements for [autonomous transactions](#):
 - Added support for sharing PL/pgSQL variables between parent and autonomous transaction blocks.
 - Improved SQL syntax consistency: the `AUTONOMOUS` keyword can now be used with `START`, `COMMIT/END`, and `ROLLBACK/ABORT` transaction statements. Previously, only `BEGIN` allowed this keyword.
 - Fixed miscellaneous bugs to improve stability of autonomous transactions.
- Implemented periodic client-server connection checks to detect broken connections earlier and free server resources upon disconnection. By default, the checks are performed every second. You can change this interval using the [client_connection_check_interval](#) configuration parameter.
- Fixed `amcheck` to eliminate false-positive reports of invalid index structure, which were manifested by the following error message: `ERROR: heap tuple lacks matching index tuple within index.`
- Fixed performance degradation for index-only scans over wide indexes.
- Ended support for ALT Linux SPT 6.0 and Windows 7 SP1.
- Changes in `rum` and `bloom` indexes are now tracked correctly by `pg_probackup` in the `PTRACK` mode.
- Updated `pg_pathman` module to version 1.5.5. As compared to version 1.5.2 provided in the previous Postgres Pro releases, the following enhancements were introduced:
 - Fixed `pg_pathman` upgrade scripts to avoid issues caused by a different the number of `pg_config` attributes in `pg_pathman` 1.4 and 1.5 major versions.
 - Improved `pg_pathman` stability:
 - Trying to call `pg_pathman` functions when this extension is disabled does not cause server failures anymore; now an error is raised instead.
 - Different partitioning strategies can now be successfully applied to the same table.
- Updated `pg_variables` module to version 1.2. As compared to the version provided in the previous Postgres Pro releases, the following enhancements were introduced:
 - Added support for array types.

- Improved module stability.
- Changed empty package handling. An empty package is now removed only after the transaction that emptied it has ended.

(See [Section F.49.](#))

E.10.2. Migration to Version 9.6.12.1

Depending on your current installation, the upgrade procedure will differ.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro Standard, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#).

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. It is usually enough to install the new version into the same installation directory. Once the new binaries are installed, the `pgpro_upgrade` script is run automatically to check whether additional setup is required and complete the upgrade.

Since `pg_probackup` delivery model changed in Postgres Pro Enterprise 9.6.12.1, when upgrading from a lower version on ALT Linux and Debian-based systems, run `apt dist-upgrade` (or `apt-get dist-upgrade`) to ensure that all new dependencies are handled correctly. On Windows, you have to run a separate `pg_probackup` installer to complete the upgrade.

When upgrading from versions 9.6.8.2 or lower, you have to rebuild indexes that used `mchar` or `mvchar` types.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

When upgrading from version 9.6.1.2 on RPM-based Linux distributions, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

For some Linux distributions, you may be prompted to run `pgpro_upgrade` manually. In this case, you must stop the `postgres` service. The script must be run on behalf of the user owning the database (typically `postgres`) and `PGDATA` environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error. This step is not required when upgrading from version 9.6.4.1 or higher.

E.11. Postgres Pro Enterprise 9.6.11.1

Release date: 2018-11-20

E.11.1. Overview

This release is based on PostgreSQL 9.6.11 and Postgres Pro Enterprise 9.6.10.3. All improvements inherited from PostgreSQL 9.6.11 are listed in [PostgreSQL 9.6.11 Release Notes](#). As compared with Postgres Pro Enterprise 9.6.10.3, this version also provides the following changes:

- Added support for Astra Linux Smolensk 1.6.
- Improved stability of [autonomous transactions](#).
- For Windows systems, fixed an issue with reloading dictionaries provided by the `shared_iscspell` module.
- Improved planning for queries with multiple `OR` operators in the `WHERE` clause.
- Fixed an issue in index search that caused a slowdown when using complex `jsquery` values.
- Improved [plantuner](#) stability and fixed a memory leak.
- Added [seq_scan_startup_cost_first_row](#) parameter that allows to better prioritize sequential and index scans.

- Added `lwlock_shared_limit` parameter that enables fair lightweight lock scheduling after the specified number of shared locks is acquired.
- Updated `pg_pathman` module to version 1.5.2. As compared to version 1.4.14 provided in the previous Postgres Pro releases, the following enhancements were introduced:
 - Added support for multilevel partitioning.
 - Eliminated update triggers and added `pg_pathman.enable_partitionrouter` parameter to enable/disable cross-partition updates.
 - Renamed `get_pathman_lib_version()` to `pathman_version()`.
 - Provided other miscellaneous bug fixes and improvements. For a full list of changes, see [pg_pathman Wiki](#).
- Updated `pg_probackup` module to version 2.0.24. As compared to version 2.0.19 provided in the previous Postgres Pro releases, the following enhancements were introduced:
 - If unchanged since the previous backup, files that do not store relation data are now skipped in incremental backups.
 - Version number specified in `pg_probackup.conf` is now preserved when this file gets updated, which allows to correctly identify `pg_probackup` version used to take the backup.
 - Fixed an issue with restoring compressed file blocks and enhanced checks for compression errors. Previously, `pg_probackup` could not restore file blocks that the `zlib` algorithm failed to compress during backup. This issue could not be detected by the built-in `pg_probackup` validation mechanism as it occurs on a lower level than validation itself. You are recommended to re-validate existing backups using this `pg_probackup` version.
 - Improved validation algorithm. Files are now validated block by block by default, not only in case of file-level checksum mismatch. You can disable this behavior using the `--skip-block-validation` option.
 - Allowed restarting a backup merge if the previous attempt has been interrupted.
 - Allowed taking backups from standby servers without connecting to the master. Besides, `pg_probackup` now uses its built-in mechanism to determine the consistency point, so there is no risk that backups from standby contain any inconsistent data.
- Updated `pgpro_scheduler` to version 2.3, which implements logging of all scheduling changes. To enable this functionality, you have to set the `schedule.enable_history` parameter to `true`.
- Introduced the following changes for Windows version of Postgres Pro:
 - PL/Perl now requires ActivePerl 5.26.
 - 32-bit Postgres Pro version is no longer provided.

E.11.2. Migration to Version 9.6.11.1

Depending on your current installation, the upgrade procedure will differ.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro Standard, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#).

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. It is usually enough to install the new version into the same installation directory. Once the new binaries are installed, the `pgpro_upgrade` script is run automatically to check whether additional setup is required and complete the upgrade.

When upgrading from versions 9.6.8.2 or lower, you have to rebuild indexes that used `mchar` or `mvchar` types.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

When upgrading from version 9.6.1.2 on RPM-based Linux distributions, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

For some Linux distributions, you may be prompted to run `pgpro_upgrade` manually. In this case, you must stop the `postgres` service. The script must be run on behalf of the user owning the database (typically `postgres`) and `PGDATA` environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error. This step is not required when upgrading from version 9.6.4.1 or higher.

E.12. Postgres Pro Enterprise 9.6.10.3

Release date: 2018-10-11

E.12.1. Overview

This release is based on Postgres Pro Enterprise 9.6.10.2 and provides the following improvements:

- `pgbadger` now supports the extended log format of Postgres Pro Enterprise. Its package got renamed to `pgpro-pgbadger`.
- Added a fix for incorrect calculation of the minimum recovery point on standby servers, which could cause incorrect page references.
- Updated the `online_analyze` module, so that now it forbids nested `ANALYZE` calls.
- Increased the number of partitions of the shared buffer mapping hash table to 1024, which can improve performance on multi-core systems.
- Added `amcheck` module that allows you to verify logical consistency of the structure of indexes. (See [amcheck](#) for details.)
- Fixed backup restore on a master server to avoid race conditions when applying two-phase transactions.
- For Windows systems, fixed an issue with reloading dictionaries provided by the `shared_ispell` module.
- Updated [pg_probackup](#) to version 2.0.21, which provides the following bug fixes:
 - Issues related to restoring backups taken on standbys are resolved.
 - The `log-rotation-size` and `log-rotation-age` parameters are now parsed correctly.
 - The `show` command now dynamically changes width of the displayed output to improve readability for large tables.
 - The `restore` command now correctly restores all symbolic links to tablespaces.
 - If checksums are enabled, the `validate` command now verifies checksums for blocks.

E.12.2. Migration to Version 9.6.10.3

Depending on your current installation, the upgrade procedure will differ.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#).

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. It is usually enough to install the new version into the same installation directory. Once the new binaries are installed, the `pgpro_upgrade` script is run automatically to check whether additional setup is required and complete the upgrade.

When upgrading from versions 9.6.8.2 or lower, you have to rebuild indexes that used `mchar` or `mvarchar` types.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

When upgrading from version 9.6.1.2 on RPM-based Linux distributions, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

For some Linux distributions, you may be prompted to run `pgpro_upgrade` manually. In this case, you must stop the `postgres` service. The script must be run on behalf of the user owning the database (typically `postgres`) and `PGDATA` environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error. This step is not required when upgrading from version 9.6.4.1 or higher.

E.13. Postgres Pro Enterprise 9.6.10.2

Release date: 2018-09-17

E.13.1. Overview

This release is based on Postgres Pro Enterprise 9.6.10.1 and provides the following bug fixes and improvements:

- Implemented the following changes in `pgbench`:
 - `pgbench` now supports compound commands.
 - You can now limit the time allotted for transaction retries using the `--latency-limit` option. If this option is used together with `--max-tries` set to zero, transactions can be retried as many times as `--latency-limit` permits.
 - The reported TPS and the number of processed transactions now exclude skipped and failed transactions.
- Updated `pg_pathman` module to version 1.4.14 to improve stability.
- Fixed `pgpro_upgrade` script for Red Hat Enterprise Linux and SUSE systems so that it can be launched using a relative path.

E.13.2. Migration to Version 9.6.10.2

Depending on your current installation, the upgrade procedure will differ.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#).

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. It is usually enough to install the new version into the same installation directory. Once the new binaries are installed, the `pgpro_upgrade` script is run automatically to check whether additional setup is required and complete the upgrade.

When upgrading from versions 9.6.8.2 or lower, you have to rebuild indexes that used `mchar` or `mvchar` types.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

When upgrading from version 9.6.1.2 on RPM-based Linux distributions, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

For some Linux distributions, you may be prompted to run `pgpro_upgrade` manually. In this case, you must stop the `postgres` service. The script must be run on behalf of the user owning the database (typically `postgres`) and `PGDATA` environment variable should be set to the directory where database

resides. Running `pgpro_upgrade` as root will result in an error. This step is not required when upgrading from version 9.6.4.1 or higher.

E.14. Postgres Pro Enterprise 9.6.10.1

Release date: 2018-08-31

E.14.1. Overview

This release is based on PostgreSQL 9.6.10 and Postgres Pro Enterprise 9.6.9.2. All improvements inherited from PostgreSQL 9.6.10 are listed in [PostgreSQL 9.6.10 Release Notes](#).

Main changes over Postgres Pro Enterprise 9.6.9.2 are as follows:

- On Debian-based systems, library packages `libecpg-compat3`, `libecpg6`, `libecpg-dev`, `libpgtypes3`, `libpq5`, `libpq-dev` provided with Postgres Pro Enterprise got renamed and now have a `postgrespro-` prefix. When upgrading from a previous version of Postgres Pro Enterprise, run `apt-get dist-upgrade` to handle this change in an automated way, or install the new packages manually.
- Updated `pg_pathman` module to version 1.4.13. For a full list of changes, see [pg_pathman Wiki](#).
- Log files now include the number of rows and the size of the data passed to the client if `log_duration` is enabled or if the query runs longer than `log_min_duration_statement`.
- The `cfs_compress_temp_relations` variable enables/disables compression of temporary tables.
- The `pg_variables` module now supports transactional variables. (See [Section F.49](#).)
- The `auto_explain` module can now display planning time.
- Autovacuum now immediately drops orphaned temporary tables to prevent `pg_class` bloating.
- Fixed a bug that made unusable some Hunspell dictionaries with `FLAG num` affixes, such as `ru_aot`.
- Updated `pg_probackup` module to version 2.0.19, which includes the following new features:
 - If one of its parent backups is corrupt, the incremental backup is marked with the `ORPHAN` status.
 - The `show-config` command now shows both modified `pg_probackup` parameters and the default settings that remained unchanged. The output can be formatted as JSON for better readability.
 - The `restore` command can now skip backup validation to speed up cluster recovery.
 - Parallel execution of incremental backups has been improved.
 - You can merge incremental backups to their parent full backup to save disk space. This is an experimental feature that can cause backup corruption if the merge is interrupted.
- Postgres Pro Enterprise version for Windows has been improved:
 - Lifted an implicit restriction on the number of simultaneously open files for each server subprocess.
 - Added an option to disable data checksums for your cluster. By default, Postgres Pro is installed with data checksums enabled.
- Miscellaneous bug fixes.

E.14.2. Migration to Version 9.6.10.1

Depending on your current installation, the upgrade procedure will differ.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#).

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. It is usually enough to install the new version into the same installation

directory. Once the new binaries are installed, the `pgpro_upgrade` script is run automatically to check whether additional setup is required and complete the upgrade.

When upgrading from versions 9.6.8.2 or lower, you have to rebuild indexes that used `mchar` or `mvchar` types.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

When upgrading from version 9.6.1.2 on RPM-based Linux distributions, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

For some Linux distributions, you may be prompted to run `pgpro_upgrade` manually. In this case, you must stop the `postgres` service. The script must be run on behalf of the user owning the database (typically `postgres`) and `PGDATA` environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error. This step is not required when upgrading from version 9.6.4.1 or higher.

E.15. Postgres Pro Enterprise 9.6.9.2

Release date: 2018-07-03

E.15.1. Overview

This release is based on Postgres Pro Enterprise 9.6.9.1. It enables WAL reader to track timeline switches and use the up-to-date timeline, which is required for successful standby promotion.

E.15.2. Migration to Version 9.6.9.2

Depending on your current installation, the upgrade procedure will differ.

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. Instead of the `pg_upgrade`, you must use the `pgpro_upgrade` script provided in this distribution. This script updates metadata information to handle catalog number format change introduced in Postgres Pro Enterprise 9.6.4.1. If you are upgrading your Postgres Pro Enterprise installation from a binary package, the `pgpro_upgrade` script is run automatically, or you are prompted to run it manually.

Important

If you run `pgpro_upgrade` manually, you must stop `postgres` service. The script must be run on behalf of the user owning the database (typically `postgres`) and `PGDATA` environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error.

When upgrading from versions 9.6.8.2 or lower, you have to rebuild indexes that used `mchar` or `mvchar` types.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

Note

On RPM-based Linux distributions, if you are upgrading from version 9.6.1.2, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#).

E.16. Postgres Pro Enterprise 9.6.9.1

Release date: 2018-06-01

E.16.1. Overview

This release is based on PostgreSQL 9.6.9 and Postgres Pro Enterprise 9.6.8.2. All improvements inherited from PostgreSQL 9.6.9 are listed in [PostgreSQL 9.6.9 Release Notes](#). Main changes over Postgres Pro Enterprise 9.6.8.2 include:

- Fixed escaping rules for configuration variables in `multimaster`.
- Updated `pg_wait_sampling` module to fix possible memory corruption on Windows.
- Fixed memory issues of `aqo` module.
- Fixed wrong calculation of delta during epoch shift.
- Updated the `mchar` module to fix the sorting order for Cyrillic letters Yo and short I. Make sure to run the `REINDEX` command to rebuild indexes that use `mchar` or `mvchar` types.
- Updated the `pg_probackup` utility to version 2.0.17, which includes the following new features:
 - `DELTA` mode for incremental backups that reads all data files in the data directory and creates an incremental backup for pages that have changed since the previous backup.
 - New options for `restore` and `validate` commands:
 - `--immediate` option ends recovery as soon as a consistent state is reached.
 - `--recovery-target-action` option specifies the action the server should take when the recovery target is reached.
 - `--recovery-target-name` specifies a named savepoint up to which to restore the cluster data.
 - `--write-recovery-conf` writes a minimal `recovery.conf` in the output directory to facilitate setting up a standby server.

For details, see [pg_probackup](#).

- Updated PTRACK to version 1.6:
 - Now `ptrack` doesn't track unlogged relations.
- Updated `jsquery` module.
- Updated `pg_pathman` module to version 1.4.11. As compared to version 1.4.9, the following enhancements were introduced:
 - Fixed an issue with duplicate entries in query results for inherited tables. In general, `pg_pathman` does not support multilevel partitioning.
 - Fixed a spurious `table is being partitioned now error` raised by `partition_table_concurrently()`.
 - Relaxed check constraint handling.
 - Fixed incorrect usage of `memcpy()` in `start_bgworker()`.
 - For a full list of changes, see [pg_pathman Wiki](#).
- Performed multiple bug fixes in the `shared_ispell` module.
- Improved Postgres Pro Enterprise version for Windows:
 - Fixed an issue with pasting strings that include symbols of different character sets from clipboard to `psql` on Windows systems.

- Updated optimization algorithm for default database configuration.
- You can now turn off configuration optimization when installing Postgres Pro from the command line by setting the `needoptimization` option in the INI file to 0.

E.16.2. Migration to Version 9.6.9.1

Depending on your current installation, the upgrade procedure will differ.

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. Instead of the `pg_upgrade`, you must use the `pgpro_upgrade` script provided in this distribution. This script updates metadata information to handle catalog number format change introduced in Postgres Pro Enterprise 9.6.4.1. If you are upgrading your Postgres Pro Enterprise installation from a binary package, the `pgpro_upgrade` script is run automatically, or you are prompted to run it manually.

Important

If you run `pgpro_upgrade` manually, you must stop postgres service. The script must be run on behalf of the user owning the database (typically postgres) and PGDATA environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error.

When upgrading from versions 9.6.8.2 or lower, you have to rebuild indexes that used `mchar` or `mvchar` types.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

Note

On RPM-based Linux distributions, if you are upgrading from version 9.6.1.2, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#).

E.17. Postgres Pro Enterprise 9.6.8.2

Release date: 2018-03-20

E.17.1. Overview

This release is based on Postgres Pro Enterprise 9.6.8.1. Main changes over Postgres Pro Enterprise 9.6.8.1 include:

- Fixed and re-enabled the `pg_wait_sampling` module on Windows systems.
- Updated the [pg_probackup](#) utility from version 2.0.11 to 2.0.16, which includes the following new features:
 - Fixed an infinite loop that could happen during page validation.
 - Fixed segfault for the case of parallel `PTRACK` connections.
 - Allowed to use the `delete-wal` option without `delete-expired`.
 - Fixed CVE-2018-1058. Schema name is now explicitly used on every function call.

- You can now use `pgpro_build` function to get the latest commit ID for the source files of the current release.
- Fixed an issue with sort ordering of some Russian letters in the `mchar` module. Use `REINDEX DATABASE` command to update indexes.

E.17.2. Migration to Version 9.6.8.2

Depending on your current installation, the upgrade procedure will differ.

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. Instead of the `pg_upgrade`, you must use the `pgpro_upgrade` script provided in this distribution. This script updates metadata information to handle catalog number format change introduced in Postgres Pro Enterprise 9.6.4.1. If you are upgrading your Postgres Pro Enterprise installation from a binary package, the `pgpro_upgrade` script is run automatically, or you are prompted to run it manually.

Important

If you run `pgpro_upgrade` manually, you must stop postgres service. The script must be run on behalf of the user owning the database (typically postgres) and PGDATA environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

Note

On RPM-based Linux distributions, if you are upgrading from version 9.6.1.2, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#).

E.18. Postgres Pro Enterprise 9.6.8.1

Release date: 2018-03-01

E.18.1. Overview

This release is based on PostgreSQL 9.6.8 and Postgres Pro Enterprise 9.6.7.1. All improvements inherited from PostgreSQL 9.6.8 are listed in [PostgreSQL 9.6.8 Release Notes](#). Main changes over Postgres Pro Enterprise 9.6.7.1 include:

- Excluded the `pg_wait_sampling` module from Windows builds to avoid server crashes.

E.18.2. Migration to Version 9.6.8.1

Depending on your current installation, the upgrade procedure will differ.

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. Instead of the `pg_upgrade`, you must use the `pgpro_upgrade` script provided in this distribution. This script updates metadata information to handle catalog number format change introduced in Postgres Pro Enterprise 9.6.4.1, as well as renames the `pgpro_build` function to `pgpro_source_id`. If you are upgrading your Postgres Pro Enterprise installation from a binary package, the `pgpro_upgrade` script is run automatically, or you are prompted to run it manually.

Important

If you run `pgpro_upgrade` manually, you must stop postgres service. The script must be run on behalf of the user owning the database (typically postgres) and PGDATA environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

Note

On RPM-based Linux distributions, if you are upgrading from version 9.6.1.2, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#).

E.19. Postgres Pro Enterprise 9.6.7.1

Release date: 2018-02-16

E.19.1. Overview

This release is based on PostgreSQL 9.6.7 and Postgres Pro Enterprise 9.6.6.3. All improvements inherited from PostgreSQL 9.6.7 are listed in [PostgreSQL 9.6.7 Release Notes](#). Major enhancements over Postgres Pro Enterprise 9.6.6.3 include:

- Fixed handling of autonomous transactions in PL/Python.
- Fixed compatibility of autonomous transactions with multimaster.
- Added additional checks for suspend/resume functions in autonomous transactions.
- Updated `pgpro_scheduler` module from to version 2.2. (See [pgpro_scheduler](#).)
- Fixed run-time plan statistics.
- Fixed counting of parallel nodes.
- Updated `pg_wait_sampling` module to version 1.1
- Fixed `DescribeLockTag()` for 64-bit transaction identifiers.
- Updated `dump_stat` module to version 1.1 that provides several bug fixes. (See [dump_stat](#).)
- Updated the PTRACK patch to version 1.4.
- Implemented dynamic prepare of the `psql` history path on Windows systems.
- Added support for TOAST to INCLUDED attributes for B-tree indexes.

E.19.2. Migration to Version 9.6.7.1

Depending on your current installation, the upgrade procedure will differ.

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. Instead of the `pg_upgrade`, you must use the `pgpro_upgrade` script provided in this distribution. This script updates metadata information to handle catalog number format change introduced in Postgres Pro Enterprise 9.6.4.1, as well as renames the `pgpro_build` function to `pgpro_source_id`. If you are upgrading your Postgres Pro Enterprise installation from a binary package, the `pgpro_upgrade` script is run automatically, or you are prompted to run it manually.

Important

If you run `pgpro_upgrade` manually, you must stop postgres service. The script must be run on behalf of the user owning the database (typically postgres) and PGDATA environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

Note

On RPM-based Linux distributions, if you are upgrading from version 9.6.1.2, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#).

E.20. Postgres Pro Enterprise 9.6.6.3

Release date: 2018-01-17

E.20.1. Overview

This release is based on Postgres Pro Enterprise 9.6.6.2. Major enhancements over Postgres Pro Enterprise 9.6.6.2 include:

- Improved multimaster extension. In particular, the following changes were introduced:
 - Fixed rules of resolving stale prepared transactions after a node failure.
 - Fixed errors that occurred when selecting transactions to apply during automatic recovery process.
 - `TRUNCATE` operations now do not cause global cluster locks.
 - Sped up node status switches.
 - Referee decision is now preserved after rebooting the nodes that won the referee voting.
- Updated `pg_pathman` module to version 1.4.9. For a full list of changes, see [pg_pathman Wiki](#).
- Added several fixes for 64-bit XIDs.
- Improved k-NN support:
 - Fixed the execution of the following query types with a btree index:

```
SELECT * FROM tab WHERE col IN (1,2,3) ORDER BY col <-> 4
```
 - Added cross-type distance operators, such as `int2 <-> int4`, `float4 <-> float8`, `date <-> timestamp`, etc.
 - Added the `ammatchorderbyop` method.
 - Enabled distance recheck for SP-GiST indexes. For details, see the description of the `leaf_consistent` function in [Section 60.3](#).
- Updated RUM index to version 1.2 (See [Section F.55](#).)
 - Added support for the `anyarray` type via `rum_anyarray_ops` and `rum_anyarray_addon_ops` operator classes.
- Updated `pg_probackup` utility to version 2.0.14.
 - Fixed race conditions in `ptrack` and page backups.

- Fixed parallel `ptrack` backup interruption.
- Added new backup state `ORPHAN`, which indicates that one of previous backups is corrupted.

E.20.2. Migration to Version 9.6.6.3

Depending on your current installation, the upgrade procedure will differ.

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. Instead of the `pg_upgrade`, you must use the `pgpro_upgrade` script provided in this distribution. This script updates metadata information to handle catalog number format change introduced in Postgres Pro Enterprise 9.6.4.1, as well as renames the `pgpro_build` function to `pgpro_source_id`. If you are upgrading your Postgres Pro Enterprise installation from a binary package, the `pgpro_upgrade` script is run automatically, or you are prompted to run it manually.

Important

If you run `pgpro_upgrade` manually, you must stop postgres service. The script must be run on behalf of the user owning the database (typically postgres) and PGDATA environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

Note

On RPM-based Linux distributions, if you are upgrading from version 9.6.1.2, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#).

E.21. Postgres Pro Enterprise 9.6.6.2

Release date: 2017-12-01

E.21.1. Overview

This release is based on Postgres Pro Enterprise 9.6.6.1. Major enhancements over Postgres Pro Enterprise 9.6.6.1 include:

- Updated `pg_probackup` utility to version 2.0.13.
- Updated PTRACK functionality used by `pg_probackup`.
- Fixed issues with Compressed File System (CFS) on Windows:
 - Enabled updates of compressed tables.
 - Added support for zstd compression.
- Fixed a minor bug in autonomous transactions.

E.21.2. Migration to Version 9.6.6.2

Depending on your current installation, the upgrade procedure will differ.

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. Instead of the `pg_upgrade`, you must use the `pgpro_upgrade` script

provided in this distribution. This script updates metadata information to handle catalog number format change introduced in Postgres Pro Enterprise 9.6.4.1, as well as renames the `pgpro_build` function to `pgpro_source_id`. If you are upgrading your Postgres Pro Enterprise installation from a binary package, the `pgpro_upgrade` script is run automatically, or you are prompted to run it manually.

Important

If you run `pgpro_upgrade` manually, you must stop postgres service. The script must be run on behalf of the user owning the database (typically postgres) and PGDATA environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

Note

On RPM-based Linux distributions, if you are upgrading from version 9.6.1.2, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#).

E.22. Postgres Pro Enterprise 9.6.6.1

Release date: 2017-11-15

E.22.1. Overview

This release is based on PostgreSQL 9.6.6 and Postgres Pro Enterprise 9.6.5.2. All improvements inherited from PostgreSQL 9.6.6 are listed in [PostgreSQL 9.6.6 Release Notes](#). Major enhancements over Postgres Pro Enterprise 9.6.5.2 include:

- Improved multimaster extension. In particular, the following changes were introduced:
 - Added a new extension (referee) for managing quorum settings. With this extension, you can set up a standalone referee node for your cluster to assign the quorum status to a subset of nodes that constitutes half of the cluster. For details, see [Section F.31.3.3.1](#).
 - Added a new parameter for choosing a major node in two-node clusters. You can now set up a major node that continues working even if there is no quorum. For details, see [Section F.31.3.3.2](#).
- Updated `pg_pathman` module to version 1.4.8. (See [pg_pathman](#) and [Section F.39.1.1](#).) As compared to version 1.4.3, the following enhancements were introduced:
 - Improved cache invalidation mechanisms.
 - Disabled `COPY partitioned_table TO` command. Use `COPY (SELECT * FROM partitioned_table) TO` instead.
 - Fixed `INSTEAD OF` triggers on views selected from partitioned tables.
 - `ALTER TABLE partitioned_table RENAME TO` now also renames auto naming sequences.
 - Disabled some dangerous optimizations for `SELECT ... FOR SHARE/UPDATE` on PostgreSQL 9.5.
 - Improved error handling in concurrent partitioning background worker.
 - Prohibited execution of queries `DELETE FROM partitioned_table_1 USING partitioned_table_2...` and `UPDATE partitioned_table_1 FROM partitioned_table_2...` if such queries touch more than one partition of `partitioned_table_1`.
 - Fixed a bug causing crashes on `RESET ALL`.
 - Fixed `WHERE` conditions that point to gaps between partitions.

- Restored compatibility with `pg_repack`.
- For the full list of changes, see [pg_pathman Wiki](#).
- Updated the [pg_probackup](#) utility to version 2.0.11, which includes the following new features:
 - Password prompt interruption is now handled correctly.
 - The provided passwords are checked to be non-empty.
 - The files that have not changed since the previous backup are not included into the next incremental backup.
 - Database version is now added into backup meta information.
 - Other miscellaneous bugfixes.

E.22.2. Migration to Version 9.6.6.1

Depending on your current installation, the upgrade procedure will differ.

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. Instead of the `pg_upgrade`, you must use the `pgpro_upgrade` script provided in this distribution. This script updates metadata information to handle catalog number format change introduced in Postgres Pro Enterprise 9.6.4.1, as well as renames the `pgpro_build` function to `pgpro_source_id`. If you are upgrading your Postgres Pro Enterprise installation from a binary package, the `pgpro_upgrade` script is run automatically, or you are prompted to run it manually.

Important

If you run `pgpro_upgrade` manually, you must stop postgres service. The script must be run on behalf of the user owning the database (typically postgres) and PGDATA environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

Note

On RPM-based Linux distributions, if you are upgrading from version 9.6.1.2, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#).

E.23. Postgres Pro Enterprise 9.6.5.2

Release date: 2017-10-16

E.23.1. Overview

This release is based on Postgres Pro Enterprise [9.6.5.1](#). Major enhancements over Postgres Pro Enterprise 9.6.5.1 include:

- Updated `pg_pathman` module to version 1.4.7.
- Updated `pg_probackup` utility to version 2.0.8.
- Fixed a problem in compressed tablespace garbage collection with incompressible data.
- Fixed handling of SIGTERM in `pgpro_scheduler` extension.

- Fixed bugs in the aqo extension.
- pgbench utility now continues to execute the script if a transaction is rolled back, and has an option to retry failed transactions several times.
- Fixed incompatibility between pg_pathman and online_analyze extensions.

E.23.2. Migration to Version 9.6.5.2

Depending on your current installation, the upgrade procedure will differ.

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. Instead of the `pg_upgrade`, you must use the `pgpro_upgrade` script provided in this distribution. This script updates metadata information to handle catalog number format change introduced in Postgres Pro Enterprise 9.6.4.1, as well as renames the `pgpro_build` function to `pgpro_source_id`. If you are upgrading your Postgres Pro Enterprise installation from a binary package, the `pgpro_upgrade` script is run automatically, or you are prompted to run it manually.

Important

If you run `pgpro_upgrade` manually, you must stop postgres service. The script must be run on behalf of the user owning the database (typically postgres) and PGDATA environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

Note

On RPM-based Linux distributions, if you are upgrading from version 9.6.1.2, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#).

E.24. Postgres Pro Enterprise 9.6.5.1

Release date: 2017-08-31

E.24.1. Overview

This release is based on Postgres Pro Enterprise [9.6.4.1](#) and PostgreSQL [9.6.5](#). Major enhancements over Postgres Pro Enterprise 9.6.4.1 include:

- Enhanced the [pg_controldata](#) utility to enable automatic Postgres Pro upgrades using the `pgpro_upgrade` script.
- Fixed the following CFS issues:
 - CFS garbage collector now traverses only the tablespace directory corresponding to the current postgres instance. Subdirectories for other postgres instances are ignored.
 - *.cfm files are now copied by `pg_upgrade`.
- Updated `pg_pathman` module to version 1.4.3. (See [pg_pathman](#) and [Section F.39.1.1](#).) As compared to version 1.4.2, the following enhancements were introduced:
 - Disabled dangerous optimizations for `UPDATE` and `DELETE` on PostgreSQL 9.5.

- Fixed the following type of query: `DELETE FROM single_table USING partitioned_table`.
- Fixed the output of the `EXPLAIN INSERT INTO partitioned_table` command when verbose mode is activated.

For a full list of changes, see [pg_pathman Wiki](#).

- Enhanced the [pg_controldata](#) utility to enable automatic Postgres Pro upgrades using the `pgpro_upgrade` script.

E.24.2. Migration to Version 9.6.5.1

Depending on your current installation, the upgrade procedure will differ.

To upgrade from a Postgres Pro Enterprise version based on the same PostgreSQL major release, a dump/restore is not required. Instead of the `pg_upgrade`, you must use the `pgpro_upgrade` script provided in this distribution. This script updates metadata information to handle catalog number format change introduced in Postgres Pro Enterprise 9.6.4.1. If you are upgrading your Postgres Pro Enterprise installation from a binary package, the `pgpro_upgrade` script is run automatically, or you are prompted to run it manually.

Important

If you run `pgpro_upgrade` manually, you must stop postgres service. The script must be run on behalf of the user owning the database (typically postgres) and PGDATA environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

Note

On RPM-based Linux distributions, if you are upgrading from version 9.6.1.2, make sure to move the data directory from `pgsql` to the `pgproee` directory before running the `pgpro_upgrade` script.

To migrate from vanilla PostgreSQL 9.6.x or Postgres Pro, make sure you have installed its latest minor version and then perform a dump/restore using [pg_dumpall](#).

E.25. Postgres Pro Enterprise 9.6.4.1

Release date: 2017-08-16

E.25.1. Overview

This release is based on Postgres Pro Enterprise [9.6.3.2](#) and PostgreSQL [9.6.4](#). Major enhancements over Postgres Pro Enterprise 9.6.3.2 include:

- Module [pg_pathman](#) updated to version 1.4.2
- In Compressed File System implementation, fixed a memory leak.
- Fixed potential data corruption in the `online_analyze` contrib module.
- Fixed `ALTER COLUMN` operation for tables with indexes.
- Improved multimaster extension:
 - Fixed `ALTER SYSTEM SET` command.
 - Fixed unexpected timeout of asynchronous connection.

- Fixed invalid transaction state while walsender is executing snapshot.
- Added primary key to schedule tables for the support of multimaster in `pgpro_scheduler`.
- Fixed an incorrect catalog check in `pg_dump` that has been added with the previous release.
- Added distribution for Ubuntu 17.10 and Debian 9.
- Fix potential data corruption in the `online_analyze` contrib module
- Updated the `pg_probackup` backup manager to version 2.0 that includes the following new features:
 - Saving backups for different databases in a single backup catalog
 - Storing backup data in a compressed state to save disk space
 - Extended logging settings
- Added upstream patches that fix potential data corruption during freeze.

E.25.2. Migration to Version 9.6.4.1

A dump/restore using `pg_dumpall`, or use of `pg_upgrade`, is required for those wishing to migrate data from any previous major release.

A dump/restore is required for those running Postgres Pro Enterprise 9.6.3.2, because catalog number format has been changed for better Postgres Pro Enterprise identification.

Dump/restore is necessary when migrating from PostgreSQL, Postgres Pro Standard, or Postgres Pro Enterprise edition.

For upgrades from previous releases of Postgres Pro Enterprise, Postgres Pro Standard, or PostgreSQL 9.6.x, some catalog changes should be applied.

If you use binary packages, and your database is in the default location, this upgrade should be performed automatically. If you've created your database in a non-default location, running `initdb` manually, you should run the `pgpro_upgrade` script provided in this distribution.

Before running the script, you should stop the `postgres` service. The script should be run on behalf of the user owning the database (typically `postgres`), and the `PGDATA` environment variable should be set to the directory where the database resides.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

E.26. Postgres Pro Enterprise 9.6.3.2

Release date: 2017-06-28

E.26.1. Overview

This release is based on Postgres Pro Enterprise 9.6.3.1. Major enhancements over Postgres Pro Enterprise 9.6.3.1 include:

- Updated RUM index to version 1.1 (See [Section F.55.](#))
- In Compressed File System (CFS), fixed a bug caused by invalid merge, as well as included many other fixes.
- Improved multimaster extension:
 - Fixed replication issues and other issues caused by running the `mtm.make_table_local` function.

- Added the `multimaster.major_node` variable. With this variable set to `true` the cluster node can continue working even if connection to the majority of the nodes is lost.
- Fixed an issue with `pgpro_scheduler` background worker hanging at the scheduled job startup for cases when one of the critical tables is locked.
- Fixed an issue with deleting functions declared in languages that do not have the `validate` method (for example, in PL/TCL).

E.26.2. Migration to Version 9.6.3.2

A dump/restore using [pg_dumpall](#), or use of [pg_upgrade](#), is required for those wishing to migrate data from any previous major release.

Dump/restore is necessary when migrating from PostgreSQL, Postgres Pro Standard, or Postgres Pro Enterprise edition.

For upgrades from previous releases of Postgres Pro Enterprise, Postgres Pro Standard, or PostgreSQL 9.6.x, some catalog changes should be applied.

If you use binary packages, and your database is in the default location, this upgrade should be performed automatically. If you've created your database in a non-default location, running `initdb` manually, you should run the `pgpro_upgrade` script provided in this distribution.

Before running the script, you should stop the `postgres` service. The script should be run on behalf of the user owning the database (typically `postgres`), and the `PGDATA` environment variable should be set to the directory where the database resides.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

E.27. Postgres Pro Enterprise 9.6.3.1

Release date: 2017-05-25

E.27.1. Overview

This release is based on Postgres Pro Enterprise [9.6.2.1](#) and PostgreSQL [9.6.3](#) Major enhancements over Postgres Pro Enterprise 9.6.2.1 include:

- Fixed an issue with GiST indexes on columns of the `intarray` type. Make sure to run the `REINDEX` command to rebuild such indexes.
- Updated the [pg_probackup](#) backup manager to version 1.1.11. Command-line interface has been changed.
- Improved multimaster extension:
 - Added support for savepoints.
 - Extended support for DDL statements.

(See [Section F.31](#).)

- Enabled support for multiple data types in RUM index, such as `int`, `bigint`, `float`, `time`, `interval`, `bytea`, `text`, and more. You can now store `tsvector` type together with other types in a single index.

(See [Section F.55](#).)

- Improved autonomous transaction support:
 - Fixed handling of multixact IDs.

- Speeded up execution of autonomous transactions.

(See [Chapter 16](#).)

- Added [pg_tsparser](#) extension for text search.

In addition to separate word parts returned by default, `pg_tsparser` also returns the whole word if this word includes:

- underscores
- numbers and letters separated by the hyphen character
- Updated the [pg_pathman](#) module to version 1.3.2. This version provides compatibility fixes for this release.
- The [sr_plan](#) module is now working with non-default `search_path` variable.
- Fixed WAL inconsistency bug in covering indexes.
- Added distribution for SUSE Linux Enterprise Server 12 SP1 and Ubuntu 17.04.
- Applied patches to optimize inheritance.
- Updated PTRACK patch to version 1.2.
- Provided performance improvements for queries typical for 1C solutions.

E.27.2. Migration to Version 9.6.3.1

A dump/restore using [pg_dumpall](#), or use of [pg_upgrade](#), is required for those wishing to migrate data from any previous major release.

Dump/restore is necessary when migrating from PostgreSQL, Postgres Pro Standard, or Postgres Pro Enterprise edition.

For upgrades from previous releases of Postgres Pro Enterprise, Postgres Pro Standard, or PostgreSQL 9.6.x, some catalog changes should be applied.

If you use binary packages, and your database is in the default location, this upgrade should be performed automatically. If you've created your database in a non-default location, running `initdb` manually, you should run the `pgpro_upgrade` script provided in this distribution.

Before running the script, you should stop the `postgres` service. The script should be run on behalf of the user owning the database (typically `postgres`), and the `PGDATA` environment variable should be set to the directory where the database resides.

When upgrading from versions 9.6.2.1 or lower, you have to rebuild GiST indexes built over columns of the `intarray` type.

E.28. Postgres Pro Enterprise 9.6.2.1

Release date: 2017-03-24

E.28.1. Overview

This release is based on Postgres Pro Enterprise [9.6.1.2](#) and PostgreSQL [9.6.2](#). Major enhancements over Postgres Pro Enterprise 9.6.1.2 include:

- Added multimaster extension.

This extension enables you to set up shared-nothing clusters with synchronous multi-master replication. Such clusters provide OLTP scalability for read transactions, ensure fault tolerance and automatic node recovery, and enable Postgres Pro Enterprise online upgrades. (See [Section F.31](#).)

- Added failover algorithm for libpq connections.
- Added aqo extension for adaptive query optimization.

Based on the collected statistics on query execution, aqo improves cardinality estimation, which can speed up subsequent queries. (See [Section F.2](#).)

- Implemented declarative syntax for partitioning.

The `pg_pathman` extension can now perform range and hash partitioning as part of the `CREATE TABLE` query. Partition management can be done with various forms of `ALTER TABLE`. (See [Section F.39.2.6](#).)

- Added mamonsu monitoring service, which is implemented as a Zabbix agent.

Using mamonsu, you can monitor multiple PostgreSQL and system metrics and visualize the collected data in comprehensive graphs. If required, you can extend mamonsu with your own custom plugins. (See [mamonsu](#).)

- Added `pg_wait_sampling` extension for sampling-based statistics of wait events.

With this extension, you can get an insight into the server activity, including the current wait events for all processes and background workers. (See [Section F.51](#).)

- Added support for timestamp output in the `pg_xlogdump` application.
- Added support for one-time background jobs in `pgpro_scheduler`.

You can now submit jobs for immediate or delayed one-time execution in parallel with the scheduled jobs. (See [pgpro_scheduler](#).)

- Updated the [pg_probackup](#) backup manager to version 1.1.0, which offers the following enhancements:
 - Added `retention show` and `retention purge` commands to implement retention policy.
 - Added support for incremental backup of compressed page files. Compressed files are the feature of the Postgres Pro Enterprise.
 - Fixed `validate` command. The `backup_id` parameter is optional now.
 - Added other miscellaneous cleanup and portability fixes.
- Improved compressed tablespaces:
 - Added function `cfs_garbage_ratio`, which returns garbage ratio for a given relation.
 - Improved stability on the server hard reset or process killed by `SIGTERM`.
- Bug Fixes:
 - Added a fix for WAL optimization on creating indexes.
 - Fixed incorrect `xmin`, `xmax` values in autonomous transactions.
 - Fixed `submit_job` and `set_job_attribute` `pgpro_scheduler` functions on Microsoft Windows systems.
 - Resolved the issue of data corruption in compressed tablespaces.
- Module [pg_pathman](#) has been updated to version 1.3 (see [Section F.39.1.1](#)).
- The [sr_plan](#) module is now initialized independently for each database instance.
- Syntax for covering indexes has been changed. Now the keyword `INCLUDING` is replaced by `INCLUDE`. The previous syntax still works, but is deprecated (see [Section 11.6](#)).
- RHEL-based distributions are installed in a separate location, so the Postgres Pro database can be installed in parallel with an existing PostgreSQL database.

- Improved the algorithm of automatic TCP-port selection for the case of parallel installation of different versions of the product on Windows systems.

E.28.2. Migration to Version 9.6.2.1

A dump/restore using [pg_dumpall](#), or use of [pg_upgrade](#), is required for those wishing to migrate data from any previous major release.

Dump/restore is necessary when migrating from PostgreSQL or Postgres Pro Standard edition.

For upgrades from previous releases of Postgres Pro Standard or PostgreSQL 9.6.x, some catalog changes should be applied.

If you use binary packages, and your database is in the default location, this upgrade should be performed automatically. If you've created your database in a non-default location, running `initdb` manually, you should run the `pgpro_upgrade` script provided in this distribution.

Before running the script, you should stop the `postgres` service. The script should be run on behalf of the user owning the database (typically `postgres`), and the `PGDATA` environment variable should be set to the directory where the database resides.

E.29. Postgres Pro Enterprise 9.6.1.2

Release date: 2016-12-15

E.29.1. Overview

This release is based on PostgreSQL [9.6.1](#) and offers the following major enhancements:

- Added k-nearest neighbors algorithm (KNN) for SP-GiST and B-tree (See [Chapter 60](#))
- Added RUM index, based on GIN, as separate module (See [Section F.55](#))
- WAL size has been reduced on `CREATE INDEX` operation in the GiST, GIN, SP-GiST
- Added timeout for idle sessions on the server side (See [idle_session_timeout](#))
- Added SHA-2 algorithm for password encryption (See [Section 20.3.2](#))
- Added page level compression (CFS) (See [Chapter 31](#))
- Added support of autonomous transactions (See [Chapter 16](#))
- Added new optional background worker to schedule tasks by rules (See [pgpro_scheduler](#))
- Added support for relocatable tables (See [pg_transfer](#))
- Extension `pg_hint_plan` has been added (See [Section F.38](#))
- Transaction IDs on 64-bit platforms use 64-bit data type
- Lazy placement of temporary tables on disk
- Consistent read on standby servers (wait for WAL apply, see [WAITLSN](#))
- Utility `pg_repack` has been added (See [pg_repack](#))
- Backup manager `pg_arman` available in Postgres Pro Standard 9.5 has been replaced by `pg_probackup` 1.0 (See [pg_probackup](#)).
- Added a fix for `pg_buffercache` module to improve database response in the case of connected monitoring tools.
- Added `pgpro_edition()` function, which returns the name of Postgres Pro edition, i.e. `standard` or `enterprise`.

Several modules to support 1C Enterprise have been added:

- mchar (See [Section F.30](#))
- fulleq (See [Section F.20](#))
- fasttrun (See [Section F.18](#))
- online_analyze (See [Section F.32](#))
- plantuner (See [Section F.52](#))

Also, following core changes have been added to support 1C:

- Application level locks
- Optimization of range conditions in the WHERE clause

Core patches from Postgres Pro Standard 9.5 have been applied:

- Covering indices patch by Anastasia Lubennikova (Commit: 91b4e25614247833d7960c49d783f69b90c0c149) (Details: <http://www.postgresql.org/message-id/f90aa60a-b67f-95b5-d9f5-f5d8ced178c6@postgrespro.ru/>)

ICU patch (Commit: ee711324f31cc039e656ea45c54abd0cf8ea3e41)

Fixes to win32 build system (Commit: 84fa653ee00ebe54f591b18e3664fa6d5889224f)

Added pgpro_version SQL function and appropriate defines into pg_config.h (Commit: 671a7525541aa3eece366dae4249aa43a56a2168)

Integrated PTRACK patch (Commit: cea0987364070600fe640df0050d285b53cafb00)

Added order by to index_including test to make 32-bit FreeBSD happy (Commit: fd9fc27d40b5dd4db611418bb848760154ec9f55)

The following modules have been ported from Postgres Pro Standard 9.5:

- hunspell-dict (See [Hunspell Dictionaries Modules](#))
- jsquery (See [Section F.27](#))
- pg_variables (See [Section F.49](#))
- pg_pathman (See [pg_pathman](#))

This module has also been updated to version 1.2.2

- pg_query_state (See [Section F.42](#))
- shared-ispell (See [shared_ispell](#))
- sr_plan (See [sr_plan](#))
- dump_stat (See [dump_stat](#))

E.29.2. Migration to Version 9.6.1.2

A dump/restore using [pg_dumpall](#), or use of [pg_upgrade](#), is required for those wishing to migrate data from any previous major release.

Dump/restore is necessary when migrating from PostgreSQL or Postgres Pro Standard edition.

For upgrades from previous releases of Postgres Pro Standard or from PostgreSQL 9.6.x, some catalog changes should be applied.

If you use binary packages, and your database is in the default location, this upgrade should be performed automatically. If you have created your database in non-default location, running `initdb` manually, you should run `pgpro_upgrade` script provided in this distribution.

Before running script, you should stop postgres service. Script should be run as user, owning the database (typically postgres) and PGDATA environment variable should be set to the directory where database resides.

E.30. Release 9.6.21

Release date: 2021-02-11

This release contains a variety of fixes from 9.6.20. For information about new features in the 9.6 major release, see [Section E.51](#).

The PostgreSQL community will stop releasing updates for the 9.6.X release series in November 2021. Users are encouraged to update to a newer release branch soon.

E.30.1. Migration to Version 9.6.21

A dump/restore is not required for those running 9.6.X.

However, see the first changelog item below, which describes cases in which reindexing indexes after the upgrade may be advisable.

Also, if you are upgrading from a version earlier than 9.6.16, see [Section E.35](#).

E.30.2. Changes

- Fix `CREATE INDEX CONCURRENTLY` to wait for concurrent prepared transactions (Andrey Borodin)

At the point where `CREATE INDEX CONCURRENTLY` waits for all concurrent transactions to complete so that it can see rows they inserted, it must also wait for all prepared transactions to complete, for the same reason. Its failure to do so meant that rows inserted by prepared transactions might be omitted from the new index, causing queries relying on the index to miss such rows. In installations that have enabled prepared transactions (`max_prepared_transactions > 0`), it's recommended to reindex any concurrently-built indexes in case this problem occurred when they were built.

- Avoid incorrect results when `WHERE CURRENT OF` is applied to a cursor whose plan contains a MergeAppend node (Tom Lane)

This case is unsupported (in general, a cursor using `ORDER BY` is not guaranteed to be simply updatable); but the code previously did not reject it, and could silently give false matches.

- Fix crash when `WHERE CURRENT OF` is applied to a cursor whose plan contains a custom scan node (David Geier)
- Fix planner's handling of a placeholder that is computed at some join level and used only at that same level (Tom Lane)

This oversight could lead to “failed to build any *N*-way joins” planner errors.

- Be more careful about whether index AMs support mark/restore (Andrew Gierth)

This prevents errors about missing support functions in rare edge cases.

- Fix `ALTER DEFAULT PRIVILEGES` to handle duplicated arguments safely (Michael Paquier)

Duplicate role or schema names within the same command could lead to “tuple already updated by self” errors or unique-constraint violations.

- Flush ACL-related caches when `pg_authid` changes (Noah Misch)

This change ensures that permissions-related decisions will promptly reflect the results of `ALTER ROLE ... [NO] INHERIT`.

- Prevent misprocessing of ambiguous `CREATE TABLE LIKE` clauses (Tom Lane)

A `LIKE` clause is re-examined after initial creation of the new table, to handle importation of indexes and such. It was possible for this re-examination to find a different table of the same name, causing unexpected behavior; one example is where the new table is a temporary table of the same name as the `LIKE` target.

- Rearrange order of operations in `CREATE TABLE LIKE` so that indexes are cloned before building foreign key constraints (Tom Lane)

This fixes the case where a self-referential foreign key constraint declared in the outer `CREATE TABLE` depends on an index that's coming from the `LIKE` clause.

- Disallow converting an inheritance child table to a view (Tom Lane)
- Ensure that disk space allocated for a dropped relation is released promptly at commit (Thomas Munro)

Previously, if the dropped relation spanned multiple 1GB segments, only the first segment was truncated immediately. Other segments were simply unlinked, which doesn't authorize the kernel to release the storage so long as any other backends still have the files open.

- Fix handling of backslash-escaped multibyte characters in `COPY FROM` (Heikki Linnakangas)

A backslash followed by a multibyte character was not handled correctly. In some client character encodings, this could lead to misinterpreting part of a multibyte character as a field separator or end-of-copy-data marker.

- Avoid preallocating executor hash tables in `EXPLAIN` without `ANALYZE` (Alexey Bashtanov)
- Fix recently-introduced race conditions in `LISTEN/NOTIFY` queue handling (Tom Lane)

A newly-listening backend could attempt to read SLRU pages that were in process of being truncated, possibly causing an error.

The queue tail pointer could become set to a value that's not equal to the queue position of any backend, resulting in effective disabling of the queue truncation logic. Continued use of `NOTIFY` then led to queue-fill warnings, and eventually to inability to send any more notifies until the server is restarted.

- Allow the `jsonb` concatenation operator to handle all combinations of JSON data types (Tom Lane)

We can concatenate two JSON objects or two JSON arrays. Handle other cases by wrapping non-array inputs in one-element arrays, then performing an array concatenation. Previously, some combinations of inputs followed this rule but others arbitrarily threw an error.

- Fix use of uninitialized value while parsing a `*` quantifier in a BRE-mode regular expression (Tom Lane)

This error could cause the quantifier to act non-greedy, that is behave like a `*?` quantifier would do in full regular expressions.

- Fix numeric `power()` for the case where the exponent is exactly `INT_MIN` (-2147483648) (Dean Rasheed)

Previously, a result with no significant digits was produced.

- Prevent possible data loss from incorrect detection of the wraparound point of an SLRU log (Noah Misch)

The wraparound point typically falls in the middle of a page, which must be rounded off to a page boundary, and that was not done correctly. No issue could arise unless an installation had gotten to within one page of SLRU overflow, which is unlikely in a properly-functioning system. If this did happen, it would manifest in later "apparent wraparound" or "could not access status of transaction" errors.

- Fix memory leak in walsender processes while sending new snapshots for logical decoding (Amit Kapila)
- Fix walsender to accept additional commands after terminating replication (Jeff Davis)
- Ensure detection of deadlocks between hot standby backends and the startup (WAL-application) process (Fujii Masao)

The startup process did not run the deadlock detection code, so that in situations where the startup process is last to join a circular wait situation, the deadlock might never be recognized.

- Fix portability problem in parsing of `recovery_target_xid` values (Michael Paquier)

The target XID is potentially 64 bits wide, but it was parsed with `strtoul()`, causing misbehavior on platforms where `long` is 32 bits (such as Windows).

- Avoid assertion failure in `pg_get_functiondef()` when examining a function with a `TRANSFORM` option (Tom Lane)
- In `psql`, re-allow including a password in a `connection_string` argument of a `\connect` command (Tom Lane)

This used to work, but a recent bug fix caused the password to be ignored (resulting in prompting for a password).

- Fix assorted bugs in `psql`'s `\help` command (Kyotaro Horiguchi, Tom Lane)

`\help` with two argument words failed to find a command description using only the first word, for example `\help reset all` should show the help for `RESET` but did not. Also, `\help` often failed to invoke the pager when it should. It also leaked memory.

- Fix `pg_dump` to handle `WITH GRANT OPTION` in an extension's initial privileges (Noah Misch)

If an extension's script creates an object and grants privileges on it with grant option, then later the user revokes such privileges, `pg_dump` would generate incorrect SQL for reproducing the situation. (Few if any extensions do this today.)

- In `pg_rewind`, ensure that all WAL is accounted for when rewinding a standby server (Ian Barwick, Heikki Linnakangas)
- Report the correct database name in connection failure error messages from some client programs (Álvaro Herrera)

If the database name was defaulted rather than given on the command line, `pg_dumpall`, `pgbench`, `oid2name`, and `vacuumlo` would produce misleading error messages after a connection failure.

- Fix memory leak in `contrib/auto_explain` (Japin Li)

Memory consumed while producing the `EXPLAIN` output was not freed until the end of the current transaction (for a top-level statement) or the end of the surrounding statement (for a nested statement). This was particularly a problem with `log_nested_statements` enabled.

- In `contrib/postgres_fdw`, avoid leaking open connections to remote servers when a user mapping or foreign server object is dropped (Bharath Rupireddy)

Open connections that depend on a dropped user mapping or foreign server can no longer be referenced, but formerly they were kept around anyway for the duration of the local session.

- In `contrib/pgcrypto`, check for error returns from OpenSSL's EVP functions (Michael Paquier)

We do not really expect errors here, but this change silences warnings from static analysis tools.

- In `contrib/pg_trgm`'s GiST index support, avoid crash in the rare case that `picksplit` is called on exactly two index items (Andrew Gierth, Alexander Korotkov)
- Fix miscalculation of timeouts in `contrib/pg_prewarm` and `contrib/postgres_fdw` (Alexey Kondratov, Tom Lane)

The main loop in `contrib/pg_prewarm`'s `autoprewarm` parent process underestimated its desired sleep time by a factor of 1000, causing it to consume much more CPU than intended. When waiting for a result from a remote server, `contrib/postgres_fdw` overestimated the desired timeout by a factor of 1000 (though this error had been mitigated by imposing a clamp to 60 seconds).

Both of these errors stemmed from incorrectly converting seconds-and-microseconds to milliseconds. Introduce a new API `TimestampDifferenceMilliseconds()` to make it easier to get this right in the future.

- Improve `configure`'s heuristics for selecting `PG_SYSROOT` on macOS (Tom Lane)

The new method is more likely to produce desirable results when Xcode is newer than the underlying operating system. Choosing a sysroot that does not match the OS version may result in nonfunctional executables.

- While building on macOS, specify `-isysroot` in link steps as well as compile steps (James Hilliard)

This likewise improves the results when Xcode is out of sync with the operating system.

- Update time zone data files to `tzdata` release 2021a for DST law changes in Russia (Volgograd zone) and South Sudan, plus historical corrections for Australia, Bahamas, Belize, Bermuda, Ghana, Israel, Kenya, Nigeria, Palestine, Seychelles, and Vanuatu.

Notably, the Australia/Currie zone has been corrected to the point where it is identical to Australia/Hobart.

E.31. Release 9.6.20

Release date: 2020-11-12

This release contains a variety of fixes from 9.6.19. For information about new features in the 9.6 major release, see [Section E.51](#).

E.31.1. Migration to Version 9.6.20

A dump/restore is not required for those running 9.6.X.

However, if you are upgrading from a version earlier than 9.6.16, see [Section E.35](#).

E.31.2. Changes

- Block `DECLARE CURSOR ... WITH HOLD` and firing of deferred triggers within index expressions and materialized view queries (Noah Misch)

This is essentially a leak in the “security restricted operation” sandbox mechanism. An attacker having permission to create non-temporary SQL objects could parlay this leak to execute arbitrary SQL code as a superuser.

The PostgreSQL Project thanks Etienne Stalmans for reporting this problem. (CVE-2020-25695)

- Fix usage of complex connection-string parameters in `pg_dump`, `pg_restore`, `clusterdb`, `reindexdb`, and `vacuumdb` (Tom Lane)

The `-d` parameter of `pg_dump` and `pg_restore`, or the `--maintenance-db` parameter of the other programs mentioned, can be a “connection string” containing multiple connection parameters rather than just a database name. In cases where these programs need to initiate additional connections, such as parallel processing or processing of multiple databases, the connection string was forgotten and just the basic connection parameters (database name, host, port, and username) were used for the additional connections. This could lead to connection failures if the connection string included any other essential information, such as non-default SSL or GSS parameters. Worse, the connection might succeed but not be encrypted as intended, or be vulnerable to man-in-the-middle attacks that the intended connection parameters would have prevented. (CVE-2020-25694)

- When `psql's \connect` command re-uses connection parameters, ensure that all non-overridden parameters from a previous connection string are re-used (Tom Lane)

This avoids cases where reconnection might fail due to omission of relevant parameters, such as non-default SSL or GSS options. Worse, the reconnection might succeed but not be encrypted as intended, or be vulnerable to man-in-the-middle attacks that the intended connection parameters would have prevented. This is largely the same problem as just cited for `pg_dump` et al, although `psql's` behavior is more complex since the user may intentionally override some connection parameters. (CVE-2020-25694)

- Prevent `psql's \gset` command from modifying specially-treated variables (Noah Misch)

`\gset` without a prefix would overwrite whatever variables the server told it to. Thus, a compromised server could set specially-treated variables such as `PROMPT1`, giving the ability to execute arbitrary shell code in the user's session.

The PostgreSQL Project thanks Nick Cleaton for reporting this problem. (CVE-2020-25696)

- Prevent possible data loss from concurrent truncations of SLRU logs (Noah Misch)

This rare problem would manifest in later “apparent wraparound” or “could not access status of transaction” errors.

- Ensure that SLRU directories are properly `fsync'd` during checkpoints (Thomas Munro)

This prevents possible data loss in a subsequent operating system crash.

- Fix `ALTER ROLE` for users with the `BYPASSRLS` attribute (Tom Lane, Stephen Frost)

The `BYPASSRLS` attribute is only allowed to be changed by superusers, but other `ALTER ROLE` operations, such as password changes, should be allowed with only ordinary permission checks. The previous coding erroneously restricted all changes on such a role to superusers.

- Fix handling of expressions in `CREATE TABLE LIKE` with inheritance (Tom Lane)

If a `CREATE TABLE` command uses both `LIKE` and traditional inheritance, column references in `CHECK` constraints and expression indexes that came from a `LIKE` parent table tended to get mis-numbered, resulting in wrong answers and/or bizarre error messages. The same could happen in `GENERATED` expressions, in branches that have that feature.

- Fix off-by-one conversion of negative years to BC dates in `to_date()` and `to_timestamp()` (Dar Alathar-Yemen, Tom Lane)

Also, arrange for the combination of a negative year and an explicit “BC” marker to cancel out and produce AD.

- Ensure that standby servers will archive WAL timeline history files when `archive_mode` is set to `always` (Grigory Smolkin, Fujii Masao)

This oversight could lead to failure of subsequent PITR recovery attempts.

- During “smart” shutdown, don't terminate background processes until all client (foreground) sessions are done (Tom Lane)

The previous behavior broke parallel query processing, since the postmaster would terminate parallel workers and refuse to launch any new ones. It also caused autovacuum to cease functioning, which could have dire long-term effects if the surviving client sessions make a lot of data changes.

- Avoid recursive consumption of stack space while processing signals in the postmaster (Tom Lane)

Heavy use of parallel processing has been observed to cause postmaster crashes due to too many concurrent signals requesting creation of a parallel worker process.

- Avoid running `atexit` handlers when exiting due to `SIGQUIT` (Kyotaro Horiguchi, Tom Lane)

Most server processes followed this practice already, but the archiver process was overlooked. Backends that were still waiting for a client startup packet got it wrong, too.

- Avoid misoptimization of subquery qualifications that reference apparently-constant grouping columns (Tom Lane)

A “constant” subquery output column isn't really constant if it is a grouping column that appears in only some of the grouping sets.

- Avoid failure when SQL function inlining changes the shape of a potentially-hashable subplan comparison expression (Tom Lane)
- While building or re-building an index, tolerate the appearance of new HOT chains due to concurrent updates (Anastasia Lubennikova, Álvaro Herrera)

This oversight could lead to “failed to find parent tuple for heap-only tuple” errors.

- Ensure that data is detoasted before being inserted into a BRIN index (Tomas Vondra)

Index entries are not supposed to contain out-of-line TOAST pointers, but BRIN didn't get that memo. This could lead to errors like “missing chunk number 0 for toast value NNN”. (If you are faced with such an error from an existing index, `REINDEX` should be enough to fix it.)

- Handle concurrent desummarization correctly during BRIN index scans (Alexander Lakhin, Álvaro Herrera)

Previously, if a page range was desummarized at just the wrong time, an index scan might falsely raise an error indicating index corruption.

- Fix rare “lost saved point in index” errors in scans of multicolumn GIN indexes (Tom Lane)
- Fix use-after-free hazard when an event trigger monitors an `ALTER TABLE` operation (Jehan-Guillaume de Rorthais)
- Fix incorrect error message about inconsistent moving-aggregate data types (Jeff Janes)
- Avoid lockup when a parallel worker reports a very long error message (Vignesh C)
- Avoid unnecessary failure when transferring very large payloads through shared memory queues (Markus Wanner)
- Fix relation cache memory leaks with RLS policies (Tom Lane)
- Fix small memory leak when `SIGHUP` processing decides that a new GUC variable value cannot be applied without a restart (Tom Lane)
- Make `libpq` support arbitrary-length lines in `.pgpass` files (Tom Lane)

This is mostly useful to allow using very long security tokens as passwords.

- In `libpq` for Windows, call `WSAStartup()` once per process and `WSACleanup()` not at all (Tom Lane, Alexander Lakhin)

Previously, `libpq` invoked `WSAStartup()` at connection start and `WSACleanup()` at connection cleanup. However, it appears that calling `WSACleanup()` can interfere with other program operations; notably, we have observed rare failures to emit expected output to `stdout`. There appear to be no ill effects from omitting the call, so do that. (This also eliminates a performance issue from repeated DLL loads and unloads when a program performs a series of database connections.)

- Fix `ecpg` library's per-thread initialization logic for Windows (Tom Lane, Alexander Lakhin)

Multi-threaded `ecpg` applications could suffer rare misbehavior due to incorrect locking.

- On Windows, make `psql` read the output of a backtick command in text mode, not binary mode (Tom Lane)

This ensures proper handling of newlines.

- Ensure that `pg_dump` collects per-column information about extension configuration tables (Fabrizio de Royes Mello, Tom Lane)

Failure to do this led to crashes when specifying `--inserts`, or underspecified (though usually correct) `COPY` commands when using `COPY` to reload the tables' data.

- Make `pg_upgrade` check for pre-existence of tablespace directories in the target cluster (Bruce Momjian)
- Fix potential memory leak in `contrib/pgcrypto` (Michael Paquier)
- Add check for an unlikely failure case in `contrib/pgcrypto` (Daniel Gustafsson)
- Use `return not exit()` in `configure`'s test programs (Peter Eisentraut)

This avoids failures with pickier compilers.

- Update time zone data files to `tzdata` release 2020d for DST law changes in Fiji, Morocco, Palestine, the Canadian Yukon, Macquarie Island, and Casey Station (Antarctica); plus historical corrections for France, Hungary, Monaco, and Palestine.
- Sync our copy of the timezone library with IANA `tzcode` release 2020d (Tom Lane)

This absorbs upstream's change of `zic`'s default output option from “fat” to “slim”. That's just cosmetic for our purposes, as we continue to select the “fat” mode in pre-v13 branches. This change also ensures that `strftime()` does not change `errno` unless it fails.

E.32. Release 9.6.19

Release date: 2020-08-13

This release contains a variety of fixes from 9.6.18. For information about new features in the 9.6 major release, see [Section E.51](#).

E.32.1. Migration to Version 9.6.19

A dump/restore is not required for those running 9.6.X.

However, if you are upgrading from a version earlier than 9.6.16, see [Section E.35](#).

E.32.2. Changes

- Make contrib modules' installation scripts more secure (Tom Lane)

Attacks similar to those described in CVE-2018-1058 could be carried out against an extension installation script, if the attacker can create objects in either the extension's target schema or the schema of some prerequisite extension. Since extensions often require superuser privilege to install, this can open a path to obtaining superuser privilege. To mitigate this risk, be more careful about the `search_path` used to run an installation script; disable `check_function_bodies` within the script; and fix catalog-adjustment queries used in some contrib modules to ensure they are secure. Also provide documentation to help third-party extension authors make their installation scripts secure. This is not a complete solution; extensions that depend on other extensions can still be at risk if installed carelessly. (CVE-2020-14350)

- In logical replication walsender, fix failure to send feedback messages after sending a keepalive message (Álvaro Herrera)

This is a relatively minor problem when using built-in logical replication, because the built-in walreceiver will send a feedback reply (which clears the incorrect state) fairly frequently anyway. But with some other replication systems, such as `pglogical`, it causes significant performance issues.

- Fix slow execution of `ts_headline()` (Tom Lane)

The phrase-search fix added in our previous set of minor releases could cause `ts_headline()` to take unreasonable amounts of time for long documents; to make matters worse, the query was not cancellable within the troublesome loop.

- Ensure the `repeat()` function can be interrupted by query cancel (Joe Conway)
- Fix mis-handling of NaN inputs during parallel aggregation on numeric-type columns (Tom Lane)

If some partial aggregation workers found only NaNs while others found only non-NaNs, the results were combined incorrectly, possibly leading to the wrong overall result (i.e., not NaN when it should be).

- Undo double-quoting of index names in `EXPLAIN`'s non-text output formats (Tom Lane, Euler Taveira)
- Fix timing of constraint revalidation in `ALTER TABLE` (David Rowley)

If `ALTER TABLE` needs to fully rewrite the table's contents (for example, due to change of a column's data type) and also needs to scan the table to re-validate foreign keys or `CHECK` constraints, it sometimes did things in the wrong order, leading to odd errors such as "could not read block 0 in file "base/nnnnn/nnnnn": read only 0 of 8192 bytes".

- Cope with `LATERAL` references in restriction clauses attached to an un-flattened sub-`SELECT` in the `FROM` clause (Tom Lane)

This oversight could result in assertion failures or crashes at query execution.

- Avoid believing that a never-analyzed foreign table has zero tuples (Tom Lane)

This primarily affected the planner's estimate of the number of groups that would be obtained by `GROUP BY`.

- Improve error handling in the server's `buffile` module (Thomas Munro)

Fix some cases where I/O errors were indistinguishable from reaching EOF, or were not reported at all. Also add details such as block numbers and byte counts where appropriate.

- Fix conflict-checking anomalies in `SERIALIZABLE` isolation mode (Peter Geoghegan)

If a concurrently-inserted tuple was updated by a different concurrent transaction, and neither tuple version was visible to the current transaction's snapshot, serialization conflict checking could draw the wrong conclusions about whether the tuple was relevant to the results of the current transaction. This could allow a serializable transaction to commit when it should have failed with a serialization error.

- Avoid repeated marking of dead btree index entries as dead (Masahiko Sawada)

While functionally harmless, this led to useless WAL traffic when checksums are enabled or `wal_log_hints` is on.

- Fix failure of some code paths to acquire the correct lock before modifying `pg_control` (Nathan Bossart, Fujii Masao)

This oversight could allow `pg_control` to be written out with an inconsistent checksum, possibly causing trouble later, including inability to restart the database if it crashed before the next `pg_control` update.

- Fix errors in `currtid()` and `currtid2()` (Michael Paquier)

These functions (which are undocumented and used only by ancient versions of the ODBC driver) contained coding errors that could result in crashes, or in confusing error messages such as "could not open file" when applied to a relation having no storage.

- Avoid calling `elog()` or `palloc()` while holding a spinlock (Michael Paquier, Tom Lane)

Logic associated with replication slots had several violations of this coding rule. While the odds of trouble are quite low, an error in the called function would lead to a stuck spinlock.

- Report out-of-disk-space errors properly in `pg_dump` and `pg_basebackup` (Justin Pryzby, Tom Lane, Alvaro Herrera)

Some code paths could produce silly reports like “could not write file: Success”.

- Fix parallel restore of tables having both table-level privileges and per-column privileges (Tom Lane)

The table-level privilege grants have to be applied first, but a parallel restore did not reliably order them that way; this could lead to “tuple concurrently updated” errors, or to disappearance of some per-column privilege grants. The fix for this is to include dependency links between such entries in the archive file, meaning that a new dump has to be taken with a corrected `pg_dump` to ensure that the problem will not recur.

- Ensure that `pg_upgrade` runs with `vacuum_defer_cleanup_age` set to zero in the target cluster (Bruce Momjian)

If the target cluster's configuration has been modified to set `vacuum_defer_cleanup_age` to a nonzero value, that prevented freezing of the system catalogs from working properly, which caused the upgrade to fail in confusing ways. Ensure that any such setting is overridden for the duration of the upgrade.

- Fix `pg_recvlogical` to drain pending messages before exiting (Noah Misch)

Without this, the replication sender might detect a send failure and exit without making the expected final update to the replication slot's LSN position. That led to re-transmitting data after the next connection. It was also possible to miss error messages sent after the last data that `pg_recvlogical` wants to consume.

- Fix `pg_rewind`'s handling of just-deleted files in the source data directory (Justin Pryzby, Michael Paquier)

When working with an on-line source database, concurrent file deletions are possible, but `pg_rewind` would get confused if deletion happened between seeing a file's directory entry and examining it with `stat()`.

- Make `pg_test_fsync` use binary I/O mode on Windows (Michael Paquier)

Previously it wrote the test file in text mode, which is not an accurate reflection of PostgreSQL's actual usage.

- Fix failure to initialize local state correctly in `contrib/dblink` (Joe Conway)

With the right combination of circumstances, this could lead to `dblink_close()` issuing an unexpected remote `COMMIT`.

- Fix `contrib/pgcrypto`'s misuse of `deflate()` (Tom Lane)

The `pgp_sym_encrypt` functions could produce incorrect compressed data due to mishandling of zlib's API requirements. We have no reports of this error manifesting with stock zlib, but it can be seen when using IBM's zlibNX implementation.

- Fix corner case in decompression logic in `contrib/pgcrypto`'s `pgp_sym_decrypt` functions (Kyotaro Horiguchi, Michael Paquier)

A compressed stream can validly end with an empty packet, but the decompressor failed to handle this and would complain about corrupt data.

- Use POSIX-standard `strsignal()` in place of the BSD-ish `sys_siglist[]` (Tom Lane)

This avoids build failures with very recent versions of glibc.

- Support building our NLS code with Microsoft Visual Studio 2015 or later (Juan José Santamaría Flecha, Davinder Singh, Amit Kapila)
- Avoid possible failure of our MSVC install script when there is a file named `configure` several levels above the source code tree (Arnold Müller)

This could confuse some logic that looked for `configure` to identify the top level of the source tree.

E.33. Release 9.6.18

Release date: 2020-05-14

This release contains a variety of fixes from 9.6.17. For information about new features in the 9.6 major release, see [Section E.51](#).

E.33.1. Migration to Version 9.6.18

A dump/restore is not required for those running 9.6.X.

However, if you are upgrading from a version earlier than 9.6.16, see [Section E.35](#).

E.33.2. Changes

- Preserve the `indisclustered` setting of indexes rewritten by `ALTER TABLE` (Amit Langote, Justin Pryzby)

Previously, `ALTER TABLE` lost track of which index had been used for `CLUSTER`.

- Preserve the replica identity properties of indexes rewritten by `ALTER TABLE` (Quan Zongliang, Peter Eisentraut)
- Lock objects sooner during `DROP OWNED BY` (Álvaro Herrera)

This avoids failures in race-condition cases where another session is deleting some of the same objects.

- Fix error-case processing for `CREATE ROLE ... IN ROLE` (Andrew Gierth)

Some error cases would be reported as “unexpected node type” or the like, instead of the intended message.

- Fix full text search to handle NOT above a phrase search correctly (Tom Lane)

Queries such as `!(foo<->bar)` failed to find matching rows when implemented as a GiST or GIN index search.

- Fix full text search for cases where a phrase search includes an item with both prefix matching and a weight restriction (Tom Lane)
- Fix `ts_headline()` to make better headline selections when working with phrase queries (Tom Lane)
- Fix bugs in `gin_fuzzy_search_limit` processing (Adé Heyward, Tom Lane)

A small value of `gin_fuzzy_search_limit` could result in unexpected slowness due to unintentionally rescanning the same index page many times. Another code path failed to apply the intended filtering at all, possibly returning too many values.

- Allow input of type `circle` to accept the format “ $(x, y), r$ ” as the documentation says it does (David Zhang)
- Make the `get_bit()` and `set_bit()` functions cope with `bytea` strings longer than 256MB (Movead Li)

Since the bit number argument is only `int4`, it's impossible to use these functions to access bits beyond the first 256MB of a long `bytea`. We'll widen the argument to `int8` in v13, but in the meantime, allow these functions to work on the initial substring of a long `bytea`.

- Avoid possibly leaking an open-file descriptor for a directory in `pg_ls_dir()`, `pg_timezone_names()`, `pg_tablespace_databases()`, and allied functions (Justin Pryzby)
- Fix polymorphic-function type resolution to correctly infer the actual type of an `anyarray` output when given only an `anyrange` input (Tom Lane)
- Avoid unlikely crash when `REINDEX` is terminated by a session-shutdown signal (Tom Lane)
- Prevent printout of possibly-incorrect hash join table statistics in `EXPLAIN` (Konstantin Knizhnik, Tom Lane, Thomas Munro)
- Fix reporting of elapsed time for heap truncation steps in `VACUUM VERBOSE` (Tatsuhito Kasahara)
- Avoid possibly showing “waiting” twice in a process's PS status (Masahiko Sawada)
- Avoid premature recycling of WAL segments during crash recovery (Jehan-Guillaume de Rorthais)

WAL segments that become ready to be archived during crash recovery were potentially recycled without being archived.

- Avoid scanning irrelevant timelines during archive recovery (Kyotaro Horiguchi)

This can eliminate many attempts to fetch non-existent WAL files from archive storage, which is helpful if archive access is slow.

- Remove bogus “subtransaction logged without previous top-level txn record” error check in logical decoding (Arseny Sher, Amit Kapila)

This condition is legitimately reachable in various scenarios, so remove the check.

- Ensure that a replication slot's `io_in_progress_lock` is released in failure code paths (Pavan Deolasee)

This could result in a `walsender` later becoming stuck waiting for the lock.

- Fix race conditions in synchronous standby management (Tom Lane)

During a change in the `synchronous_standby_names` setting, there was a window in which wrong decisions could be made about whether it is OK to release transactions that are waiting for synchronous commit. Another hazard for similarly wrong decisions existed if a `walsender` process exited and was immediately replaced by another.

- Ensure `nextXid` can't go backwards on a standby server (Eka Palamadaï)

This race condition could allow incorrect hot standby feedback messages to be sent back to the primary server, potentially allowing `VACUUM` to run too soon on the primary.

- Add missing `SQLSTATE` values to a few error reports (Sawada Masahiko)
- Fix PL/pgSQL to reliably refuse to execute an event trigger function as a plain function (Tom Lane)
- Fix memory leak in `libpq` when using `sslmode=verify-full` (Roman Peshkurov)

Certificate verification during connection startup could leak some memory. This would become an issue if a client process opened many database connections during its lifetime.

- Fix `ecpg` to treat an argument of just “-” as meaning “read from stdin” on all platforms (Tom Lane)
- Add `pg_dump` support for `ALTER ... DEPENDS ON EXTENSION` (Álvaro Herrera)

`pg_dump` previously ignored dependencies added this way, causing them to be forgotten during dump/restore or `pg_upgrade`.

- Fix `pg_dump` to dump comments on RLS policy objects (Tom Lane)

- In `pg_dump`, postpone restore of event triggers till the end (Fabrízio de Royes Mello, Hamid Akhtar, Tom Lane)

This minimizes the risk that an event trigger could interfere with the restoration of other objects.

- Fix quoting of `--encoding`, `--lc-ctype` and `--lc-collate` values in `createdb` utility (Michael Paquier)
- `contrib/lo`'s `lo_manage()` function crashed if called directly rather than as a trigger (Tom Lane)
- In `contrib/ltree`, protect against overflow of `ltree` and `lquery` length fields (Nikita Glukhov)
- Fix cache reference leak in `contrib/sepgsql` (Michael Luo)
- Avoid failures when dealing with Unix-style locale names on Windows (Juan José Santamaría Flecha)
- In MSVC builds, cope with spaces in the path name for Python (Victor Wagner)
- In MSVC builds, fix detection of Visual Studio version to work with more language settings (Andrew Dunstan)
- In MSVC builds, use `-Wno-deprecated` with bison versions newer than 3.0, as non-Windows builds already do (Andrew Dunstan)
- Update time zone data files to `tzdata` release 2020a for DST law changes in Morocco and the Canadian Yukon, plus historical corrections for Shanghai.

The America/Godthab zone has been renamed to America/Nuuk to reflect current English usage; however, the old name remains available as a compatibility link.

Also, update `initdb`'s list of known Windows time zone names to include recent additions, improving the odds that it will correctly translate the system time zone setting on that platform.

E.34. Release 9.6.17

Release date: 2020-02-13

This release contains a variety of fixes from 9.6.16. For information about new features in the 9.6 major release, see [Section E.51](#).

E.34.1. Migration to Version 9.6.17

A dump/restore is not required for those running 9.6.X.

However, if you are upgrading from a version earlier than 9.6.16, see [Section E.35](#).

E.34.2. Changes

- Add missing permissions checks for `ALTER ... DEPENDS ON EXTENSION` (Álvaro Herrera)

Marking an object as dependent on an extension did not have any privilege check whatsoever. This oversight allowed any user to mark routines, triggers, materialized views, or indexes as droppable by anyone able to drop an extension. Require that the calling user own the specified object (and hence have privilege to drop it). (CVE-2020-1720)

- Avoid failure in logical decoding when a large transaction must be spilled into many separate temporary files (Amit Khandekar)
- Fix failure in logical replication publisher after a database crash and restart (Vignesh C)
- Prevent premature shutdown of a Gather or GatherMerge plan node that is underneath a Limit node (Amit Kapila)

This avoids failure if such a plan node needs to be scanned more than once, as for instance if it is on the inside of a nestloop.

- Avoid memory leak when there are no free dynamic shared memory slots (Thomas Munro)
- Ignore the `CONCURRENTLY` option when performing an index creation, drop, or rebuild on a temporary table (Michael Paquier, Heikki Linnakangas, Andres Freund)

This avoids strange failures if the temporary table has an `ON COMMIT` action. There is no benefit in using `CONCURRENTLY` for a temporary table anyway, since other sessions cannot access the table, making the extra processing pointless.

- Fix possible failure when resetting expression indexes on temporary tables that are marked `ON COMMIT DELETE ROWS` (Tom Lane)
- Fix possible crash in BRIN index operations with `box`, `range` and `inet` data types (Heikki Linnakangas)
- Fix handling of deleted pages in GIN indexes (Alexander Korotkov)

Avoid possible deadlocks, incorrect updates of a deleted page's state, and failure to traverse through a recently-deleted page.

- Fix possible crash with a SubPlan (sub-SELECT) within a multi-row `VALUES` list (Tom Lane)
- Fix unlikely crash with pass-by-reference aggregate transition states (Andres Freund, Teodor Sigaev)
- Improve error reporting in `to_date()` and `to_timestamp()` (Tom Lane, Álvaro Herrera)

Reports about incorrect month or day names in input strings could truncate the input in the middle of a multi-byte character, leading to an improperly encoded error message that could cause follow-on failures. Truncate at the next whitespace instead.

- Fix off-by-one result for `EXTRACT(ISOYEAR FROM timestamp)` for BC dates (Tom Lane)
- Avoid stack overflow in `information_schema` views when a self-referential view exists in the system catalogs (Tom Lane)

A self-referential view can't work; it will always result in infinite recursion. We handled that situation correctly when trying to execute the view, but not when inquiring whether it is automatically updatable.

- Improve performance of hash joins with very large inner relations (Thomas Munro)
- Fix edge-case crashes and misestimations in selectivity calculations for the `<@` and `@>` range operators (Michael Paquier, Andrey Borodin, Tom Lane)
- Improve error reporting for attempts to use automatic updating of views with conditional `INSTEAD` rules (Dean Rasheed)

This has never been supported, but previously the error was thrown only at execution time, so that it could be masked by planner errors.

- Prevent a composite type from being included in itself indirectly via a range type (Tom Lane, Julien Rouhaud)
- Fix error reporting for index expressions of prohibited types (Amit Langote)
- Fix dumping of views that contain only a `VALUES` list to handle cases where a view output column has been renamed (Tom Lane)
- Transmit incoming `NOTIFY` messages to the client before sending `ReadyForQuery`, rather than after (Tom Lane)

This change ensures that, with `libpq` and other client libraries that act similarly to it, any notifications received during a transaction will be available by the time the client thinks the transaction is complete. This probably makes no difference in practical applications (which would need to cope with asynchronous notifications in any case); but it makes it easier to build test cases with reproducible behavior.

- Allow `libpq` to parse all GSS-related connection parameters even when the GSSAPI code hasn't been compiled in (Tom Lane)

This makes the behavior similar to our SSL support, where it was long ago deemed to be a good idea to always accept all the related parameters, even if some are ignored or restricted due to lack of the feature in a particular build.

- Fix incorrect handling of `%b` and `%B` format codes in `ecpg`'s `PGTYPEStimestamp_fmt_asc()` function (Tomas Vondra)

Due to an off-by-one error, these codes would print the wrong month name, or possibly crash.

- Fix parallel `pg_dump/pg_restore` to more gracefully handle failure to create worker processes (Tom Lane)
- Prevent possible crash or lockup when attempting to terminate a parallel `pg_dump/pg_restore` run via a signal (Tom Lane)
- In `pg_upgrade`, look inside arrays and ranges while searching for non-upgradable data types in tables (Tom Lane)
- Apply more thorough syntax checking to `createuser`'s `--connection-limit` option (Álvaro Herrera)
- Avoid crash in `postgres_fdw` when trying to send a command like `UPDATE remote_tab SET (x,y) = (SELECT ...)` to the remote server (Tom Lane)
- In `contrib/dict_int`, reject `maxlen` settings less than one (Tomas Vondra)

This prevents a possible crash with silly settings for that parameter.

- Disallow NULL category values in `contrib/tablefunc`'s `crosstab()` function (Joe Conway)

This case never worked usefully, and it would crash on some platforms.

- Mark some timeout and statistics-tracking GUC variables as `PGDLLIMPORT`, to allow extensions to access them on Windows (Pascal Legrand)

This applies to `idle_in_transaction_session_timeout`, `lock_timeout`, `statement_timeout`, `track_activities`, `track_counts`, and `track_functions`.

- Fix race condition that led to delayed delivery of interprocess signals on Windows (Amit Kapila)

This caused visible timing oddities in `NOTIFY`, and perhaps other misbehavior.

- On Windows, retry a few times after an `ERROR_ACCESS_DENIED` file access failure (Alexander Lakhin, Tom Lane)

This helps cope with cases where a file open attempt fails because the targeted file is flagged for deletion but not yet actually gone. `pg_ctl`, for example, frequently failed with such an error when probing to see if the postmaster had shut down yet.

E.35. Release 9.6.16

Release date: 2019-11-14

This release contains a variety of fixes from 9.6.15. For information about new features in the 9.6 major release, see [Section E.51](#).

E.35.1. Migration to Version 9.6.16

A dump/restore is not required for those running 9.6.X.

However, if you use the `contrib/intarray` extension with a GiST index, and you rely on indexed searches for the `<@` operator, see the entry below about that.

Also, if you are upgrading from a version earlier than 9.6.9, see [Section E.42](#).

E.35.2. Changes

- Fix failure of `ALTER TABLE SET` with a custom relation option (Michael Paquier)
- Disallow changing a multiply-inherited column's type if not all parent tables were changed (Tom Lane)

Previously, this was allowed, whereupon queries on the now-out-of-sync parent would fail.

- Prevent `VACUUM` from trying to freeze an old multixact ID involving a still-running transaction (Nathan Bossart, Jeremy Schneider)

This case would lead to `VACUUM` failing until the old transaction terminates.

- Ensure that offset expressions in `WINDOW` clauses are processed when a query's expressions are manipulated (Andrew Gierth)

This oversight could result in assorted failures when the offsets are nontrivial expressions. One example is that a function parameter reference in such an expression would fail if the function was inlined.

- Fix handling of whole-row variables in `WITH CHECK OPTION` expressions and row-level-security policy expressions (Andres Freund)

Previously, such usage might result in bogus errors about row type mismatches.

- Avoid postmaster failure if a parallel query requests a background worker when no postmaster child process array slots remain free (Tom Lane)
- Prevent possible double-free if a `BEFORE UPDATE` trigger returns the old tuple as-is, and it is not the last such trigger (Thomas Munro)
- Provide a relevant error context line when an error occurs while setting GUC parameters during parallel worker startup (Thomas Munro)
- In serializable mode, ensure that row-level predicate locks are acquired on the correct version of the row (Thomas Munro, Heikki Linnakangas)

If the visible version of the row is HOT-updated, the lock might be taken on its now-dead predecessor, resulting in subtle failures to guarantee serialization.

- Ensure that `fsync()` is applied only to files that are opened read/write (Andres Freund, Michael Paquier)

Some code paths tried to do this after opening a file read-only, but on some platforms that causes “bad file descriptor” or similar errors.

- Allow encoding conversion to succeed on longer strings than before (Álvaro Herrera, Tom Lane)

Previously, there was a hard limit of 0.25GB on the input string, but now it will work as long as the converted output is not over 1GB.

- Avoid creating unnecessarily-bulky tuple stores for window functions (Andrew Gierth)

In some cases the tuple storage would include all columns of the source table(s), not just the ones that are needed by the query.

- Allow `repalloc()` to give back space when a large chunk is reduced in size (Tom Lane)
- Ensure that temporary WAL and history files are removed at the end of archive recovery (Sawada Masahiko)
- Avoid failure in archive recovery if `recovery_min_apply_delay` is enabled (Fujii Masao)

`recovery_min_apply_delay` is not typically used in this configuration, but it should work.

- Avoid unwanted delay during shutdown of a logical replication walsender (Craig Ringer, Álvaro Herrera)

- Correctly time-stamp replication messages for logical decoding (Jeff Janes)

This oversight resulted, for example, in `pg_stat_subscription.last_msg_send_time` usually reading as NULL.

- In logical decoding, ensure that sub-transactions are correctly accounted for when reconstructing a snapshot (Masahiko Sawada)

This error leads to assertion failures; it's unclear whether any bad effects exist in production builds.

- Fix race condition during backend exit, when the backend process has previously waited for synchronous replication to occur (Dongming Liu)
- Fix `ALTER SYSTEM` to cope with duplicate entries in `postgresql.auto.conf` (Ian Barwick)

`ALTER SYSTEM` itself will not generate such a state, but external tools that modify `postgresql.auto.conf` could do so. Duplicate entries for the target variable will now be removed, and then the new setting (if any) will be appended at the end.

- Reject include directives with empty file names in configuration files, and report include-file recursion more clearly (Ian Barwick, Tom Lane)
- Avoid logging complaints about abandoned connections when using PAM authentication (Tom Lane)

libpq-based clients will typically make two connection attempts when a password is required, since they don't prompt their user for a password until their first connection attempt fails. Therefore the server is coded not to generate useless log spam when a client closes the connection upon being asked for a password. However, the PAM authentication code hadn't gotten that memo, and would generate several messages about a phantom authentication failure.

- Fix some cases where an incomplete date specification is not detected in `time with time zone` input (Alexander Lakhin)

If a time zone with a time-varying UTC offset is specified, then a date must be as well, so that the offset can be resolved. Depending on the syntax used, this check was not enforced in some cases, allowing bogus output to be produced.

- Fix misbehavior of `bitshiftright()` (Tom Lane)

The bitstring right shift operator failed to zero out padding space that exists in the last byte of the result when the bitstring length is not a multiple of 8. While invisible to most operations, any nonzero bits there would result in unexpected comparison behavior, since bitstring comparisons don't bother to ignore the extra bits, expecting them to always be zero.

If you have inconsistent data as a result of saving the output of `bitshiftright()` in a table, it's possible to fix it with something like

```
UPDATE mytab SET bitcol = ~(~bitcol) WHERE bitcol != ~(~bitcol);
```

- Fix detection of edge-case integer overflow in interval multiplication (Yuya Watari)
- Avoid crashes if `ispell` text search dictionaries contain wrong affix data (Arthur Zakirov)
- Fix incorrect compression logic for GIN posting lists (Heikki Linnakangas)

A GIN posting list item can require 7 bytes if the distance between adjacent indexed TIDs exceeds 16TB. One step in the logic was out of sync with that, and might try to write the value into a 6-byte buffer. In principle this could cause a stack overrun, but on most architectures it's likely that the next byte would be unused alignment padding, making the bug harmless. In any case the bug would be very difficult to hit.

- Fix handling of infinity, NaN, and NULL values in KNN-GiST (Alexander Korotkov)

The query's output order could be wrong (different from a plain sort's result) if some distances computed for non-null column values are infinity or NaN.

- Fix handling of searches for NULL in KNN-SP-GiST (Nikita Glukhov)
- On Windows, recognize additional spellings of the “Norwegian (Bokmål)” locale name (Tom Lane)
- Avoid compile failure if an ECPG client includes `ecpglib.h` while having `ENABLE_NLS` defined (Tom Lane)

This risk was created by a misplaced declaration: `ecpg_gettext()` should not be visible to client code.

- In `psql`, resynchronize internal state about the server after an unexpected connection loss and successful reconnection (Peter Billen, Tom Lane)

Ordinarily this is unnecessary since the state would be the same anyway. But it can matter in corner cases, such as where the connection might lead to one of several servers. This change causes `psql` to re-issue any interactive messages that it would have issued at startup, for example about whether SSL is in use.

- Avoid platform-specific null pointer dereference in `psql` (Quentin Rameau)
- Fix `pg_dump`'s handling of circular dependencies in views (Tom Lane)

In some cases a view may depend on an object that `pg_dump` needs to dump later than the view; the most common example is that a query using `GROUP BY` on a primary-key column may be semantically invalid without the primary key. This is now handled by emitting a dummy `CREATE VIEW` command that just establishes the view's column names and types, and then later emitting `CREATE OR REPLACE VIEW` with the full view definition. Previously, the dummy definition was actually a `CREATE TABLE` command, and this was automatically converted to a view by a later `CREATE RULE` command. The new approach has been used successfully in PostgreSQL version 10 and later. We are back-patching it into older releases now because of reports that the previous method causes bogus error messages about the view's replica identity status. This change also avoids problems when trying to use the `--clean` option during a restore involving such a view.

- In `pg_dump`, ensure stable output order for similarly-named triggers and row-level-security policy objects (Benjie Gillam)

Previously, if two triggers on different tables had the same names, they would be sorted in OID-based order, which is less desirable than sorting them by table name. Likewise for RLS policies.

- Fix `pg_dump` to work again with pre-8.3 source servers (Tom Lane)

A previous fix caused `pg_dump` to always try to query `pg_opfamily`, but that catalog doesn't exist before version 8.3.

- In `pg_restore`, treat `-f -` as meaning “output to stdout” (Álvaro Herrera)

This synchronizes `pg_restore`'s behavior with some other applications, and in particular makes pre-v12 branches act similarly to version 12's `pg_restore`, simplifying creation of dump/restore scripts that work across multiple PostgreSQL versions. Before this change, `pg_restore` interpreted such a switch as meaning “output to a file named `-`”, but few people would want that.

- Improve `pg_upgrade`'s checks for the use of a data type that has changed representation, such as `line` (Tomas Vondra)

The previous coding could be fooled by cases where the data type of interest underlies a stored column of a domain or composite type.

- Detect file read errors during `pg_basebackup` (Jeevan Chalke)
- In `pg_rewind` with an online source cluster, disable timeouts, much as `pg_dump` does (Alexander Kukushkin)
- Fix failure in `pg_waldump` with the `-s` option, when a continuation WAL record ends exactly at a page boundary (Andrey Lepikhov)
- In `pg_waldump`, include the `newitemoff` field in btree page split records (Peter Geoghegan)

- In `pg_waldump` with the `--bkp-details` option, avoid emitting extra newlines for WAL records involving full-page writes (Andres Freund)
- Fix small memory leak in `pg_waldump` (Andres Freund)
- Fix `vacuumdb` with a high `--jobs` option to handle running out of file descriptors better (Michael Paquier)
- Fix `contrib/intarray`'s GiST opclasses to not fail for empty arrays with `<@` (Tom Lane)

A clause like `array_column <@ constant_array` is considered indexable, but the index search may not find empty array values; of course, such entries should trivially match the search.

The only practical back-patchable fix for this requires making `<@` index searches scan the whole index, which is what this patch does. This is unfortunate: it means that the query performance is likely worse than a plain sequential scan would be.

Applications whose performance is adversely impacted by this change have a couple of options. They could switch to a GIN index, which doesn't have this bug, or they could replace `array_column <@ constant_array` with `array_column <@ constant_array AND array_column && constant_array`. That will provide about the same performance as before, and it will find all non-empty subsets of the given constant array, which is all that could reliably be expected of the query before.

- Allow `configure --with-python` to succeed when only `python3` or only `python2` can be found (Peter Eisentraut, Tom Lane)

Search for `python`, then `python3`, then `python2`, so that `configure` can succeed in the increasingly-more-common situation where there is no executable named simply `python`. It's still possible to override this choice by setting the `PYTHON` environment variable.

- Fix `configure`'s test for presence of `libperl` so that it works on recent Red Hat releases (Tom Lane)

Previously, it could fail if the user sets `CFLAGS` to `-O0`.

- Ensure correct code generation for spinlocks on PowerPC (Noah Misch)

The previous spinlock coding allowed the compiler to select register zero for use with an assembly instruction that does not accept that register, causing a build failure. We have seen only one long-ago report that matches this bug, but it could cause problems for people trying to build modified PostgreSQL code or use atypical compiler options.

- On PowerPC, avoid depending on the `xlc` compiler's `__fetch_and_add()` function (Noah Misch)

`xlc 13` and newer interpret this function in a way incompatible with our usage, resulting in an unusable build of PostgreSQL. Fix by using custom assembly code instead.

- On AIX, don't use the compiler option `-qsrcmsg` (Noah Misch)

This avoids an internal compiler error with `xlc v16.1.0`, with little consequence other than changing the format of compiler error messages.

- Fix MSVC build process to cope with spaces in the file path of OpenSSL (Andrew Dunstan)
- Update time zone data files to `tzdata` release 2019c for DST law changes in Fiji and Norfolk Island, plus historical corrections for Alberta, Austria, Belgium, British Columbia, Cambodia, Hong Kong, Indiana (Perry County), Kaliningrad, Kentucky, Michigan, Norfolk Island, South Korea, and Turkey.

E.36. Release 9.6.15

Release date: 2019-08-08

This release contains a variety of fixes from 9.6.14. For information about new features in the 9.6 major release, see [Section E.51](#).

E.36.1. Migration to Version 9.6.15

A dump/restore is not required for those running 9.6.X.

However, if you are upgrading from a version earlier than 9.6.9, see [Section E.42](#).

E.36.2. Changes

- Require schema qualification to cast to a temporary type when using functional cast syntax (Noah Misch)

We have long required invocations of temporary functions to explicitly specify the temporary schema, that is `pg_temp.func_name(args)`. Require this as well for casting to temporary types using functional notation, for example `pg_temp.type_name(arg)`. Otherwise it's possible to capture a function call using a temporary object, allowing privilege escalation in much the same ways that we blocked in CVE-2007-2138. (CVE-2019-10208)

- Fix failure of `ALTER TABLE ... ALTER COLUMN TYPE` when altering multiple columns' types in one command (Tom Lane)

This fixes a regression introduced in the most recent minor releases: indexes using the altered columns were not processed correctly, leading to strange failures during `ALTER TABLE`.

- Don't optimize away `GROUP BY` columns when the table involved is an inheritance parent (David Rowley)

Normally, if a table's primary key column(s) are included in `GROUP BY`, it's safe to drop any other grouping columns, since the primary key columns are enough to make the groups unique. This rule does not work if the query is also reading inheritance child tables, though; the parent's uniqueness does not extend to the children.

- Avoid using unnecessary sort steps for some queries with `GROUPING SETS` (Andrew Gierth, Richard Guo)
- Fix mishandling of multi-column foreign keys when rebuilding a foreign key constraint (Tom Lane)

`ALTER TABLE` could make an incorrect decision about whether revalidation of a foreign key is necessary, if not all columns of the key are of the same type. It seems likely that the error would always have been in the conservative direction, that is revalidating unnecessarily.

- Avoid spurious deadlock errors when upgrading a tuple lock (Oleksii Kliukin)

When two or more transactions are waiting for a transaction T1 to release a tuple-level lock, and T1 upgrades its lock to a higher level, a spurious deadlock among the waiting transactions could be reported when T1 finishes.

- Fix failure to resolve deadlocks involving multiple parallel worker processes (Rui Hai Jiang)

It is not clear whether this bug is reachable with non-artificial queries, but if it did happen, the queries involved in an otherwise-resolvable deadlock would block until canceled.

- Prevent incorrect canonicalization of date ranges with `infinity` endpoints (Laurenz Albe)

It's incorrect to try to convert an open range to a closed one or vice versa by incrementing or decrementing the endpoint value, if the endpoint is infinite; so leave the range alone in such cases.

- Fix loss of fractional digits when converting very large `money` values to `numeric` (Tom Lane)
- Fix spinlock assembly code for MIPS CPUs so that it works on MIPS r6 (YunQiang Su)
- Make libpq ignore carriage return (`\r`) in connection service files (Tom Lane, Michael Paquier)

In some corner cases, service files containing Windows-style newlines could be mis-parsed, resulting in connection failures.

- In `psql`, avoid offering incorrect tab completion options after `SET variable =` (Tom Lane)

- Fix `pg_dump` to ensure that custom operator classes are dumped in the right order (Tom Lane)
If a user-defined opclass is the subtype opclass of a user-defined range type, related objects were dumped in the wrong order, producing an unrestorable dump. (The underlying failure to handle opclass dependencies might manifest in other cases too, but this is the only known case.)
- Fix `contrib/passwordcheck` to coexist with other users of `check_password_hook` (Michael Paquier)
- Fix `contrib/sepysql` tests to work under recent SELinux releases (Mike Palmiotto)
- Improve stability of `src/test/recovery` regression tests (Michael Paquier)
- Reduce stderr output from `pg_upgrade`'s test script (Tom Lane)
- Fix TAP tests to work with `msys` Perl, in cases where the build directory is on a non-root `msys` mount point (Noah Misch)
- Support building Postgres with Microsoft Visual Studio 2019 (Haribabu Kommi)
- In Visual Studio builds, honor `WindowsSDKVersion` environment variable, if that's set (Peifeng Qiu)

This fixes build failures in some configurations.

- Support OpenSSL 1.1.0 and newer in Visual Studio builds (Juan José Santamaría Flecha, Michael Paquier)
- Allow make options to be passed down to `gmake` when non-GNU make is invoked at the top level (Thomas Munro)
- Avoid choosing `localtime` or `posixrules` as `TimeZone` during `initdb` (Tom Lane)

In some cases `initdb` would choose one of these artificial zone names over the “real” zone name. Prefer any other match to the C library's timezone behavior over these two.

- Adjust `pg_timezone_names` view to show the `Factory` time zone if and only if it has a short abbreviation (Tom Lane)

Historically, IANA set up this artificial zone with an “abbreviation” like `Local time zone must be set--see zic manual page`. Modern versions of the `tzdb` database show `-00` instead, but some platforms alter the data to show one or another of the historical phrases. Show this zone only if it uses the modern abbreviation.

- Sync our copy of the timezone library with IANA `tzcode` release 2019b (Tom Lane)

This adds support for `zic`'s new `-b slim` option to reduce the size of the installed zone files. We are not currently using that, but may enable it in future.

- Update time zone data files to `tzdata` release 2019b for DST law changes in Brazil, plus historical corrections for Hong Kong, Italy, and Palestine.

E.37. Release 9.6.14

Release date: 2019-06-20

This release contains a variety of fixes from 9.6.13. For information about new features in the 9.6 major release, see [Section E.51](#).

E.37.1. Migration to Version 9.6.14

A dump/restore is not required for those running 9.6.X.

However, if you are upgrading from a version earlier than 9.6.9, see [Section E.42](#).

E.37.2. Changes

- Fix failure of `ALTER TABLE ... ALTER COLUMN TYPE` when the table has a partial exclusion constraint (Tom Lane)

- Fix failure of `COMMENT` command for comments on domain constraints (Daniel Gustafsson, Michael Paquier)
- Fix faulty generation of merge-append plans (Tom Lane)

This mistake could lead to “could not find pathkey item to sort” errors.

- Fix incorrect printing of queries with duplicate join names (Philip Dubé)

This oversight caused a dump/restore failure for views containing such queries.

- Fix misoptimization of `{1, 1}` quantifiers in regular expressions (Tom Lane)

Such quantifiers were treated as no-ops and optimized away; but the documentation specifies that they impose greediness, or non-greediness in the case of the non-greedy variant `{1, 1}?`, on the subexpression they're attached to, and this did not happen. The misbehavior occurred only if the subexpression contained capturing parentheses or a back-reference.

- Avoid possible failures while initializing a new process's `pg_stat_activity` data (Tom Lane)

Certain operations that could fail, such as converting strings extracted from an SSL certificate into the database encoding, were being performed inside a critical section. Failure there would result in database-wide lockup due to violating the access protocol for shared `pg_stat_activity` data.

- Fix race condition in check to see whether a pre-existing shared memory segment is still in use by a conflicting postmaster (Tom Lane)
- Avoid attempting to do database accesses for parameter checking in processes that are not connected to a specific database (Vignesh C, Andres Freund)

This error could result in failures like “cannot read `pg_class` without having selected a database”.

- Avoid possible hang in `libpq` if using SSL and OpenSSL's pending-data buffer contains an exact multiple of 256 bytes (David Binderman)
- Improve `initdb`'s handling of multiple equivalent names for the system time zone (Tom Lane, Andrew Gierth)

Make `initdb` examine the `/etc/localtime` symbolic link, if that exists, to break ties between equivalent names for the system time zone. This makes `initdb` more likely to select the time zone name that the user would expect when multiple identical time zones exist. It will not change the behavior if `/etc/localtime` is not a symlink to a zone data file, nor if the time zone is determined from the `TZ` environment variable.

Separately, prefer UTC over other spellings of that time zone, when neither `TZ` nor `/etc/localtime` provide a hint. This fixes an annoyance introduced by `tzdata 2019a`'s change to make the UTC and UTC zone names equivalent: `initdb` was then preferring UTC, which almost nobody wants.

- Fix ordering of `GRANT` commands emitted by `pg_dump` and `pg_dumpall` for databases and tablespaces (Nathan Bossart, Michael Paquier)

If cascading grants had been issued, restore might fail due to the `GRANT` commands being given in an order that didn't respect their interdependencies.

- Fix misleading error reports from `reindexdb` (Julien Rouhaud)
- Ensure that `vacuumdb` returns correct status if an error occurs while using parallel jobs (Julien Rouhaud)
- Fix `contrib/auto_explain` to not cause problems in parallel queries (Tom Lane)

Previously, a parallel worker might try to log its query even if the parent query were not being logged by `auto_explain`. This would work sometimes, but it's confusing, and in some cases it resulted in failures like “could not find key N in shm TOC”.

Also, fix an off-by-one error that resulted in not necessarily logging every query even when the sampling rate is set to 1.0.

- In `contrib/postgres_fdw`, account for possible data modifications by local `BEFORE ROW UPDATE` triggers (Shohei Mochizuki)

If a trigger modified a column that was otherwise not changed by the `UPDATE`, the new value was not transmitted to the remote server.

- On Windows, avoid failure when the database encoding is set to `SQL_ASCII` and we attempt to log a non-ASCII string (Noah Misch)

The code had been assuming that such strings must be in UTF-8, and would throw an error if they didn't appear to be validly encoded. Now, just transmit the untranslated bytes to the log.

- Make PL/pgsql's header files C++-safe (George Tarasov)

E.38. Release 9.6.13

Release date: 2019-05-09

This release contains a variety of fixes from 9.6.12. For information about new features in the 9.6 major release, see [Section E.51](#).

E.38.1. Migration to Version 9.6.13

A dump/restore is not required for those running 9.6.X.

However, if you are upgrading from a version earlier than 9.6.9, see [Section E.42](#).

E.38.2. Changes

- Prevent row-level security policies from being bypassed via selectivity estimators (Dean Rasheed)

Some of the planner's selectivity estimators apply user-defined operators to values found in `pg_statistic` (e.g., most-common values). A leaky operator therefore can disclose some of the entries in a data column, even if the calling user lacks permission to read that column. In CVE-2017-7484 we added restrictions to forestall that, but we failed to consider the effects of row-level security. A user who has SQL permission to read a column, but who is forbidden to see certain rows due to RLS policy, might still learn something about those rows' contents via a leaky operator. This patch further tightens the rules, allowing leaky operators to be applied to statistics data only when there is no relevant RLS policy. (CVE-2019-10130)

- Fix behavior for an `UPDATE` or `DELETE` on an inheritance tree or partitioned table in which every table can be excluded (Amit Langote, Tom Lane)

In such cases, the query did not report the correct set of output columns when a `RETURNING` clause was present, and if there were any statement-level triggers that should be fired, it didn't fire them.

- Fix handling of explicit `DEFAULT` items in an `INSERT ... VALUES` command with multiple `VALUES` rows, if the target relation is an updatable view (Amit Langote, Dean Rasheed)

When the updatable view has no default for the column but its underlying table has one, a single-row `INSERT ... VALUES` will use the underlying table's default. In the multi-row case, however, `NULL` was always used. Correct it to act like the single-row case.

- Fix `CREATE VIEW` to allow zero-column views (Ashutosh Sharma)

We should allow this for consistency with allowing zero-column tables. Since a table can be converted to a view, zero-column views could be created even with the restriction in place, leading to dump/reload failures.

- Add missing support for `CREATE TABLE IF NOT EXISTS ... AS EXECUTE ...` (Andreas Karlsson)

The combination of `IF NOT EXISTS` and `EXECUTE` should work, but the grammar omitted it.

- Ensure that sub-`SELECTs` appearing in row-level-security policy expressions are executed with the correct user's permissions (Dean Rasheed)

Previously, if the table having the RLS policy was accessed via a view, such checks might be executed as the user calling the view, not as the view owner as they should be.

- Accept XML documents as valid values of type `xml` when `xmloption` is set to `content`, as required by SQL:2006 and later (Chapman Flack)

Previously PostgreSQL followed the SQL:2003 definition, which doesn't allow this. But that creates a serious problem for dump/restore: there is no setting of `xmloption` that will accept all valid XML data. Hence, switch to the 2006 definition.

`pg_dump` is also modified to emit `SET xmloption = content` while restoring data, ensuring that dump/restore works even if the prevailing setting is `document`.

- Improve server's startup-time checks for whether a pre-existing shared memory segment is still in use (Noah Misch)

The postmaster is now more likely to detect that there are still active processes from a previous postmaster incarnation, even if the `postmaster.pid` file has been removed.

- Avoid counting parallel workers' transactions as separate transactions (Haribabu Kommi)
- Fix incompatibility of GIN-index WAL records (Alexander Korotkov)

A fix applied in February's minor releases was not sufficiently careful about backwards compatibility, leading to problems if a standby server of that vintage reads GIN page-deletion WAL records generated by a primary server of a previous minor release.

- Tolerate `EINVAL` and `ENOSYS` error results, where appropriate, for `fsync` and `sync_file_range` calls (Thomas Munro, James Sewell)

The previous change to panic on file synchronization failures turns out to have been excessively paranoid for certain cases where a failure is predictable and essentially means “operation not supported”.

- Fix “failed to build any *N*-way joins” planner failures with lateral references leading out of `FULL` outer joins (Tom Lane)
- Check the appropriate user's permissions when enforcing rules about letting a leaky operator see `pg_statistic` data (Dean Rasheed)

When an underlying table is being accessed via a view, consider the privileges of the view owner while deciding whether leaky operators may be applied to the table's statistics data, rather than the privileges of the user making the query. This makes the planner's rules about what data is visible match up with the executor's, avoiding unnecessarily-poor plans.

- Speed up planning when there are many equality conditions and many potentially-relevant foreign key constraints (David Rowley)
- Avoid $O(N^2)$ performance issue when rolling back a transaction that created many tables (Tomas Vondra)
- Fix race conditions in management of dynamic shared memory (Thomas Munro)

These could lead to “`dsa_area could not attach to segment`” or “`cannot unpin a segment that is not pinned`” errors.

- Fix race condition in which a hot-standby postmaster could fail to shut down after receiving a smart-shutdown request (Tom Lane)
- Fix possible crash when `pg_identify_object_as_address()` is given invalid input (Álvaro Herrera)

- Tighten validation of encoded SCRAM-SHA-256 and MD5 passwords (Jonathan Katz)

A password string that had the right initial characters could be mistaken for one that is correctly hashed into SCRAM-SHA-256 or MD5 format. The password would be accepted but would be unusable later.

- Fix handling of `lc_time` settings that imply an encoding different from the database's encoding (Juan José Santamaría Flecha, Tom Lane)

Localized month or day names that include non-ASCII characters previously caused unexpected errors or wrong output in such locales.

- Fix incorrect `operator_precedence_warning` checks involving unary minus operators (Rikard Falkeborn)
- Disallow `NaN` as a value for floating-point server parameters (Tom Lane)
- Rearrange `REINDEX` processing to avoid assertion failures when reindexing individual indexes of `pg_class` (Andres Freund, Tom Lane)
- Fix planner assertion failure for parameterized dummy paths (Tom Lane)
- Insert correct test function in the result of `SnapBuildInitialSnapshot()` (Antonin Houska)

No core code cares about this, but some extensions do.

- Fix intermittent “could not reattach to shared memory” session startup failures on Windows (Noah Misch)

A previously unrecognized source of these failures is creation of thread stacks for a process's default thread pool. Arrange for such stacks to be allocated in a different memory region.

- Fix error detection in directory scanning on Windows (Konstantin Knizhnik)

Errors, such as lack of permissions to read the directory, were not detected or reported correctly; instead the code silently acted as though the directory were empty.

- Fix grammar problems in `ecpg` (Tom Lane)

A missing semicolon led to mistranslation of `SET variable = DEFAULT` (but not `SET variable TO DEFAULT`) in `ecpg` programs, producing syntactically invalid output that the server would reject. Additionally, in a `DROP TYPE` or `DROP DOMAIN` command that listed multiple type names, only the first type name was actually processed.

- Sync `ecpg`'s syntax for `CREATE TABLE AS` with the server's (Daisuke Higuchi)
- Fix possible buffer overruns in `ecpg`'s processing of include filenames (Liu Huailing, Fei Wu)
- Avoid crash in `contrib/vacuumlo` if an `lo_unlink()` call failed (Tom Lane)
- Sync our copy of the `timezone` library with IANA `tzcode` release 2019a (Tom Lane)

This corrects a small bug in `zic` that caused it to output an incorrect year-2440 transition in the `Africa/Casablanca` zone, and adds support for `zic`'s new `-r` option.

- Update time zone data files to `tzdata` release 2019a for DST law changes in Palestine and Metlakatla, plus historical corrections for Israel.

`Etc/UCT` is now a backward-compatibility link to `Etc/UTC`, instead of being a separate zone that generates the abbreviation `UCT`, which nowadays is typically a typo. PostgreSQL will still accept `UCT` as an input zone abbreviation, but it won't output it.

E.39. Release 9.6.12

Release date: 2019-02-14

This release contains a variety of fixes from 9.6.11. For information about new features in the 9.6 major release, see [Section E.51](#).

E.39.1. Migration to Version 9.6.12

A dump/restore is not required for those running 9.6.X.

However, if you are upgrading from a version earlier than 9.6.9, see [Section E.42](#).

E.39.2. Changes

- By default, panic instead of retrying after `fsync()` failure, to avoid possible data corruption (Craig Ringer, Thomas Munro)

Some popular operating systems discard kernel data buffers when unable to write them out, reporting this as `fsync()` failure. If we reissue the `fsync()` request it will succeed, but in fact the data has been lost, so continuing risks database corruption. By raising a panic condition instead, we can replay from WAL, which may contain the only remaining copy of the data in such a situation. While this is surely ugly and inefficient, there are few alternatives, and fortunately the case happens very rarely.

A new server parameter [data_sync_retry](#) has been added to control this; if you are certain that your kernel does not discard dirty data buffers in such scenarios, you can set `data_sync_retry` to `on` to restore the old behavior.

- Include each major release branch's release notes in the documentation for only that branch, rather than that branch and all later ones (Tom Lane)

The duplication induced by the previous policy was getting out of hand. Our plan is to provide a full archive of release notes on the project's web site, but not duplicate it within each release.

- Avoid possible deadlock when acquiring multiple buffer locks (Nishant Fnu)
- Avoid deadlock between hot-standby queries and replay of GIN index page deletion (Alexander Korotkov)
- Fix possible crashes in logical replication when index expressions or predicates are in use (Peter Eisentraut)
- Avoid useless and expensive logical decoding of TOAST data during a table rewrite (Tomas Vondra)
- Fix logic for stopping a subset of WAL senders when synchronous replication is enabled (Paul Guo, Michael Paquier)
- Avoid possibly writing an incorrect replica identity field in a tuple deletion WAL record (Stas Kelvich)
- Make the archiver prioritize WAL history files over WAL data files while choosing which file to archive next (David Steele)
- Fix possible crash in `UPDATE` with a multiple `SET` clause using a sub-`SELECT` as source (Tom Lane)
- Avoid crash if `libxml2` returns a null error message (Sergio Conde Gómez)
- Fix spurious grouping-related parser errors caused by inconsistent handling of collation assignment (Andrew Gierth)

In some cases, expressions that should be considered to match were not seen as matching, if they included operations on collatable data types.

- Check whether the comparison function underlying `LEAST()` or `GREATEST()` is leakproof, rather than just assuming it is (Tom Lane)

Actual information leaks from btree comparison functions are typically hard to provoke, but in principle they could happen.

- Fix incorrect planning of queries involving nested loops both above and below a Gather plan node (Tom Lane)

If both levels of nestloop needed to pass the same variable into their right-hand sides, an incorrect plan would be generated.

- Fix incorrect planning of queries in which a lateral reference must be evaluated at a foreign table scan (Tom Lane)
- Fix corner-case underestimation of the cost of a merge join (Tom Lane)

The planner could prefer a merge join when the outer key range is much smaller than the inner key range, even if there are so many duplicate keys on the inner side that this is a poor choice.

- Avoid $O(N^2)$ planning time growth when a query contains many thousand indexable clauses (Tom Lane)
- Improve `ANALYZE`'s handling of concurrently-updated rows (Jeff Janes, Tom Lane)

Previously, rows deleted by an in-progress transaction were omitted from `ANALYZE`'s sample, but this has been found to lead to more inconsistency than including them would do. In effect, the sample now corresponds to an MVCC snapshot as of `ANALYZE`'s start time.

- Make `TRUNCATE` ignore inheritance child tables that are temporary tables of other sessions (Amit Langote, Michael Paquier)

This brings `TRUNCATE` into line with the behavior of other commands. Previously, such cases usually ended in failure.

- Fix `TRUNCATE` to update the statistics counters for the right table (Tom Lane)

If the truncated table had a `TOAST` table, that table's counters were reset instead.

- Process `ALTER TABLE ONLY ADD COLUMN IF NOT EXISTS` correctly (Greg Stark)
- Allow `UNLISTEN` in hot-standby mode (Shay Rojansky)

This is necessarily a no-op, because `LISTEN` isn't allowed in hot-standby mode; but allowing the dummy operation simplifies session-state-reset logic in clients.

- Fix missing role dependencies in some schema and data type permissions lists (Tom Lane)

In some cases it was possible to drop a role to which permissions had been granted. This caused no immediate problem, but a subsequent dump/reload or upgrade would fail, with symptoms involving attempts to grant privileges to all-numeric role names.

- Ensure relation caches are updated properly after adding or removing foreign key constraints (Álvaro Herrera)

This oversight could result in existing sessions failing to enforce a newly-created constraint, or continuing to enforce a dropped one.

- Ensure relation caches are updated properly after renaming constraints (Amit Langote)
- Make autovacuum more aggressive about removing leftover temporary tables, and also remove leftover temporary tables during `DISCARD TEMP` (Álvaro Herrera)

This helps ensure that remnants from a crashed session are cleaned up more promptly.

- Fix replay of GiST index micro-vacuum operations so that concurrent hot-standby queries do not see inconsistent state (Alexander Korotkov)
- Prevent empty GIN index pages from being reclaimed too quickly, causing failures of concurrent searches (Andrey Borodin, Alexander Korotkov)
- Fix edge-case failures in float-to-integer coercions (Andrew Gierth, Tom Lane)

Values very slightly above the maximum valid integer value might not be rejected, and then would overflow, producing the minimum valid integer instead. Also, values that should round to the minimum or maximum integer value might be incorrectly rejected.

- When making a PAM authentication request, don't set the `PAM_RHOST` variable if the connection is via a Unix socket (Thomas Munro)

Previously that variable would be set to `[local]`, which is at best unhelpful, since it's supposed to be a host name.

- Disallow setting `client_min_messages` higher than `ERROR` (Jonah Harris, Tom Lane)

Previously, it was possible to set this variable to `FATAL` or `PANIC`, which had the effect of suppressing transmission of ordinary error messages to the client. However, that's contrary to guarantees that are given in the PostgreSQL wire protocol specification, and it caused some clients to become very confused. In released branches, fix this by silently treating such settings as meaning `ERROR` instead. Version 12 and later will reject those alternatives altogether.

- Fix `ecpglib` to use `uselocale()` or `_configthreadlocale()` in preference to `setlocale()` (Michael Meskes, Tom Lane)

Since `setlocale()` is not thread-local, and might not even be thread-safe, the previous coding caused problems in multi-threaded `ecpg` applications.

- Fix incorrect results for numeric data passed through an `ecpg` SQLDA (SQL Descriptor Area) (Daisuke Higuchi)

Values with leading zeroes were not copied correctly.

- Fix `psql`'s `\g target` meta-command to work with `COPY TO STDOUT` (Daniel Vérité)

Previously, the `target` option was ignored, so that the copy data always went to the current query output target.

- Make `psql`'s LaTeX output formats render special characters properly (Tom Lane)

Backslash and some other ASCII punctuation characters were not rendered correctly, leading to document syntax errors or wrong characters in the output.

- Fix `pg_dump`'s handling of materialized views with indirect dependencies on primary keys (Tom Lane)

This led to mis-labeling of such views' dump archive entries, causing harmless warnings about "archive items not in correct section order"; less harmlessly, selective-restore options depending on those labels, such as `--section`, might misbehave.

- Avoid null-pointer-dereference crash on some platforms when `pg_dump` or `pg_restore` tries to report an error (Tom Lane)
- Fix `contrib/hstore` to calculate correct hash values for empty `hstore` values that were created in version 8.4 or before (Andrew Gierth)

The previous coding did not give the same result as for an empty `hstore` value created by a newer version, thus potentially causing wrong results in hash joins or hash aggregation. It is advisable to reindex any hash indexes built on `hstore` columns, if the table might contain data that was originally stored as far back as 8.4 and was never dumped/reloaded since then.

- Avoid crashes and excessive runtime with large inputs to `contrib/intarray`'s `gist__int_ops` index support (Andrew Gierth)
- Support new Makefile variables `PG_CFLAGS`, `PG_CXXFLAGS`, and `PG_LDFLAGS` in `pgxs` builds (Christoph Berg)

This simplifies customization of extension build processes.

- Fix Perl-coded build scripts to not assume “.” is in the search path, since recent Perl versions don't include that (Andrew Dunstan)
- Fix server command-line option parsing problems on OpenBSD (Tom Lane)
- Relocate call of `set_rel_pathlist_hook` so that extensions can use it to supply partial paths for parallel queries (KaiGai Kohei)

This is not expected to affect existing use-cases.

- Update time zone data files to tzdata release 2018i for DST law changes in Kazakhstan, Metlakatla, and Sao Tome and Principe. Kazakhstan's Qyzylorda zone is split in two, creating a new zone Asia/Qostanay, as some areas did not change UTC offset. Historical corrections for Hong Kong and numerous Pacific islands.

E.40. Release 9.6.11

Release date: 2018-11-08

This release contains a variety of fixes from 9.6.10. For information about new features in the 9.6 major release, see [Section E.51](#).

E.40.1. Migration to Version 9.6.11

A dump/restore is not required for those running 9.6.X.

However, if you are upgrading from a version earlier than 9.6.9, see [Section E.42](#).

E.40.2. Changes

- Fix corner-case failures in `has_foo_privilege()` family of functions (Tom Lane)

Return NULL rather than throwing an error when an invalid object OID is provided. Some of these functions got that right already, but not all. `has_column_privilege()` was additionally capable of crashing on some platforms.

- Avoid $O(N^2)$ slowdown in regular expression match/split functions on long strings (Andrew Gierth)
- Fix parsing of standard multi-character operators that are immediately followed by a comment or + or - (Andrew Gierth)

This oversight could lead to parse errors, or to incorrect assignment of precedence.

- Avoid $O(N^3)$ slowdown in lexer for long strings of + or - characters (Andrew Gierth)
- Fix mis-execution of SubPlans when the outer query is being scanned backwards (Andrew Gierth)
- Fix failure of `UPDATE/DELETE ... WHERE CURRENT OF ...` after rewinding the referenced cursor (Tom Lane)

A cursor that scans multiple relations (particularly an inheritance tree) could produce wrong behavior if rewound to an earlier relation.

- Fix `EvalPlanQual` to handle conditionally-executed `InitPlans` properly (Andrew Gierth, Tom Lane)

This resulted in hard-to-reproduce crashes or wrong answers in concurrent updates, if they contained code such as an uncorrelated sub-SELECT inside a CASE construct.

- Fix character-class checks to not fail on Windows for Unicode characters above U+FFFF (Tom Lane, Kenji Uno)

This bug affected full-text-search operations, as well as `contrib/ltree` and `contrib/pg_trgm`.

- Disallow pushing sub-SELECTs containing window functions, `LIMIT`, or `OFFSET` to parallel workers (Amit Kapila)

Such cases could result in inconsistent behavior due to different workers getting different answers, as a result of indeterminacy due to row-ordering variations.

- Ensure that sequences owned by a foreign table are processed by `ALTER OWNER` on the table (Peter Eisentraut)

The ownership change should propagate to such sequences as well, but this was missed for foreign tables.

- Ensure that the server will process already-received `NOTIFY` and `SIGTERM` interrupts before waiting for client input (Jeff Janes, Tom Lane)
- Fix over-allocation of space for `array_out()`'s result string (Keiichi Hirobe)
- Fix memory leak in repeated SP-GiST index scans (Tom Lane)

This is only known to amount to anything significant in cases where an exclusion constraint using SP-GiST receives many new index entries in a single command.

- Ensure that `ApplyLogicalMappingFile()` closes the mapping file when done with it (Tomas Vondra)

Previously, the file descriptor was leaked, eventually resulting in failures during logical decoding.

- Fix logical decoding to handle cases where a mapped catalog table is repeatedly rewritten, e.g., by `VACUUM FULL` (Andres Freund)
- Prevent starting the server with `wal_level` set to too low a value to support an existing replication slot (Andres Freund)
- Avoid crash if a utility command causes infinite recursion (Tom Lane)
- When initializing a hot standby, cope with duplicate XIDs caused by two-phase transactions on the master (Michael Paquier, Konstantin Knizhnik)
- Fix event triggers to handle nested `ALTER TABLE` commands (Michael Paquier, Álvaro Herrera)
- Propagate parent process's transaction and statement start timestamps to parallel workers (Konstantin Knizhnik)

This prevents misbehavior of functions such as `transaction_timestamp()` when executed in a worker.

- Fix transfer of expanded datums to parallel workers so that alignment is preserved, preventing crashes on alignment-picky platforms (Tom Lane, Amit Kapila)
- Fix WAL file recycling logic to work correctly on standby servers (Michael Paquier)

Depending on the setting of `archive_mode`, a standby might fail to remove some WAL files that could be removed.

- Fix handling of commit-timestamp tracking during recovery (Masahiko Sawada, Michael Paquier)

If commit timestamp tracking has been turned on or off, recovery might fail due to trying to fetch the commit timestamp for a transaction that did not record it.

- Randomize the `random()` seed in bootstrap and standalone backends, and in `initdb` (Noah Misch)

The main practical effect of this change is that it avoids a scenario where `initdb` might mistakenly conclude that POSIX shared memory is not available, due to name collisions caused by always using the same random seed.

- Allow DSM allocation to be interrupted (Chris Travers)
- Avoid failure in a parallel worker when loading an extension that tries to access system caches within its `init` function (Thomas Munro)

We don't consider that to be good extension coding practice, but it mostly worked before parallel query, so continue to support it for now.

- Properly handle turning `full_page_writes` on dynamically (Kyotaro Horiguchi)
- Fix possible crash due to double `free()` during SP-GiST rescan (Andrew Gierth)
- Avoid possible buffer overrun when replaying GIN page recompression from WAL (Alexander Korotkov, Sivasubramanian Ramasubramanian)
- Fix missed `fsync` of a replication slot's directory (Konstantin Knizhnik, Michael Paquier)
- Fix unexpected timeouts when using `wal_sender_timeout` on a slow server (Noah Misch)
- Ensure that hot standby processes use the correct WAL consistency point (Alexander Kukushkin, Michael Paquier)

This prevents possible misbehavior just after a standby server has reached a consistent database state during WAL replay.

- Ensure background workers are stopped properly when the postmaster receives a fast-shutdown request before completing database startup (Alexander Kukushkin)
- Update the free space map during WAL replay of page all-visible/frozen flag changes (Álvaro Herrera)

Previously we were not careful about this, reasoning that the FSM is not critical data anyway. However, if it's sufficiently out of date, that can result in significant performance degradation after a standby has been promoted to primary. The FSM will eventually be healed by updates, but we'd like it to be good sooner, so work harder at maintaining it during WAL replay.

- Avoid premature release of parallel-query resources when query end or tuple count limit is reached (Amit Kapila)

It's only okay to shut down the executor at this point if the caller cannot demand backwards scan afterwards.

- Don't run `atexit` callbacks when servicing `SIGQUIT` (Heikki Linnakangas)
- Don't record foreign-server user mappings as members of extensions (Tom Lane)

If `CREATE USER MAPPING` is executed in an extension script, an extension dependency was created for the user mapping, which is unexpected. Roles can't be extension members, so user mappings shouldn't be either.

- Make `syslogger` more robust against failures in opening CSV log files (Tom Lane)
- Fix `psql`, as well as documentation examples, to call `PQconsumeInput()` before each `PQnotifies()` call (Tom Lane)

This fixes cases in which `psql` would not report receipt of a `NOTIFY` message until after the next command.

- Fix possible inconsistency in `pg_dump`'s sorting of dissimilar object names (Jacob Champion)
- Ensure that `pg_restore` will schema-qualify the table name when emitting `DISABLE/ENABLE TRIGGER` commands (Tom Lane)

This avoids failures due to the new policy of running restores with restrictive search path.

- Fix `pg_upgrade` to handle event triggers in extensions correctly (Haribabu Kommi)

`pg_upgrade` failed to preserve an event trigger's extension-membership status.

- Fix `pg_upgrade`'s cluster state check to work correctly on a standby server (Bruce Momjian)
- Enforce type `cube`'s dimension limit in all `contrib/cube` functions (Andrey Borodin)

Previously, some cube-related functions could construct values that would be rejected by `cube_in()`, leading to dump/reload failures.

- In `contrib/postgres_fdw`, don't try to ship a variable-free `ORDER BY` clause to the remote server (Andrew Gierth)
- Fix `contrib/unaccent`'s `unaccent()` function to use the `unaccent` text search dictionary that is in the same schema as the function (Tom Lane)

Previously it tried to look up the dictionary using the search path, which could fail if the search path has a restrictive value.

- Fix build problems on macOS 10.14 (Mojave) (Tom Lane)

Adjust `configure` to add an `-isysroot` switch to `CPPFLAGS`; without this, PL/Perl and PL/Tcl fail to configure or build on macOS 10.14. The specific `sysroot` used can be overridden at configure time or build time by setting the `PG_SYSROOT` variable in the arguments of `configure` or `make`.

It is now recommended that Perl-related extensions write `$(perl_includespec)` rather than `-I$(perl_archlibexp)/CORE` in their compiler flags. The latter continues to work on most platforms, but not recent macOS.

Also, it should no longer be necessary to specify `--with-tclconfig` manually to get PL/Tcl to build on recent macOS releases.

- Fix MSVC build and regression-test scripts to work on recent Perl versions (Andrew Dunstan)

Perl no longer includes the current directory in its search path by default; work around that.

- On Windows, allow the regression tests to be run by an Administrator account (Andrew Dunstan)

To do this safely, `pg_regress` now gives up any such privileges at startup.

- Allow btree comparison functions to return `INT_MIN` (Tom Lane)

Up to now, we've forbidden datatype-specific comparison functions from returning `INT_MIN`, which allows callers to invert the sort order just by negating the comparison result. However, this was never safe for comparison functions that directly return the result of `memcmp()`, `strcmp()`, etc, as POSIX doesn't place any such restriction on those functions. At least some recent versions of `memcmp()` can return `INT_MIN`, causing incorrect sort ordering. Hence, we've removed this restriction. Callers must now use the `INVERT_COMPARE_RESULT()` macro if they wish to invert the sort order.

- Fix recursion hazard in shared-invalidation message processing (Tom Lane)

This error could, for example, result in failure to access a system catalog or index that had just been processed by `VACUUM FULL`.

This change adds a new result code for `LockAcquire`, which might possibly affect external callers of that function, though only very unusual usage patterns would have an issue with it. The API of `LockAcquireExtended` is also changed.

- Save and restore SPI's global variables during `SPI_connect()` and `SPI_finish()` (Chapman Flack, Tom Lane)

This prevents possible interference when one SPI-using function calls another.

- Avoid using potentially-under-aligned page buffers (Tom Lane)

Invent new union types `PGAlignedBlock` and `PGAlignedXLogBlock`, and use these in place of plain char arrays, ensuring that the compiler can't place the buffer at a misaligned start address. This fixes potential core dumps on alignment-picky platforms, and may improve performance even on platforms that allow misalignment.

- Make `src/port/snprintf.c` follow the C99 standard's definition of `snprintf()`'s result value (Tom Lane)

On platforms where this code is used (mostly Windows), its pre-C99 behavior could lead to failure to detect buffer overrun, if the calling code assumed C99 semantics.

- When building on i386 with the clang compiler, require `-msse2` to be used (Andres Freund)

This avoids problems with missed floating point overflow checks.

- Fix configure's detection of the result type of `strerror_r()` (Tom Lane)

The previous coding got the wrong answer when building with `icc` on Linux (and perhaps in other cases), leading to `libpq` not returning useful error messages for system-reported errors.

- Update time zone data files to tzdata release 2018g for DST law changes in Chile, Fiji, Morocco, and Russia (Volgograd), plus historical corrections for China, Hawaii, Japan, Macau, and North Korea.

E.41. Release 9.6.10

Release date: 2018-08-09

This release contains a variety of fixes from 9.6.9. For information about new features in the 9.6 major release, see [Section E.51](#).

E.41.1. Migration to Version 9.6.10

A dump/restore is not required for those running 9.6.X.

However, if you are upgrading from a version earlier than 9.6.9, see [Section E.42](#).

E.41.2. Changes

- Fix failure to reset `libpq`'s state fully between connection attempts (Tom Lane)

An unprivileged user of `dblink` or `postgres_fdw` could bypass the checks intended to prevent use of server-side credentials, such as a `~/.pgpass` file owned by the operating-system user running the server. Servers allowing peer authentication on local connections are particularly vulnerable. Other attacks such as SQL injection into a `postgres_fdw` session are also possible. Attacking `postgres_fdw` in this way requires the ability to create a foreign server object with selected connection parameters, but any user with access to `dblink` could exploit the problem. In general, an attacker with the ability to select the connection parameters for a `libpq`-using application could cause mischief, though other plausible attack scenarios are harder to think of. Our thanks to Andrew Krasichkov for reporting this issue. (CVE-2018-10915)

- Fix `INSERT ... ON CONFLICT UPDATE` through a view that isn't just `SELECT * FROM ...` (Dean Rasheed, Amit Langote)

Erroneous expansion of an updatable view could lead to crashes or “attribute ... has the wrong type” errors, if the view's `SELECT` list doesn't match one-to-one with the underlying table's columns. Furthermore, this bug could be leveraged to allow updates of columns that an attacking user lacks `UPDATE` privilege for, if that user has `INSERT` and `UPDATE` privileges for some other column(s) of the table. Any user could also use it for disclosure of server memory. (CVE-2018-10925)

- Ensure that updates to the `relfrozenxid` and `relminmxid` values for “nailed” system catalogs are processed in a timely fashion (Andres Freund)

Overoptimistic caching rules could prevent these updates from being seen by other sessions, leading to spurious errors and/or data corruption. The problem was significantly worse for shared catalogs, such as `pg_authid`, because the stale cache data could persist into new sessions as well as existing ones.

- Fix case where a freshly-promoted standby crashes before having completed its first post-recovery checkpoint (Michael Paquier, Kyotaro Horiguchi, Pavan Deolasee, Álvaro Herrera)

This led to a situation where the server did not think it had reached a consistent database state during subsequent WAL replay, preventing restart.

- Avoid emitting a bogus WAL record when recycling an all-zero btree page (Amit Kapila)

This mistake has been seen to cause assertion failures, and potentially it could result in unnecessary query cancellations on hot standby servers.

- During WAL replay, guard against corrupted record lengths exceeding 1GB (Michael Paquier)

Treat such a case as corrupt data. Previously, the code would try to allocate space and get a hard error, making recovery impossible.

- When ending recovery, delay writing the timeline history file as long as possible (Heikki Linnakangas)

This avoids some situations where a failure during recovery cleanup (such as a problem with a two-phase state file) led to inconsistent timeline state on-disk.

- Improve performance of WAL replay for transactions that drop many relations (Fujii Masao)

This change reduces the number of times that shared buffers are scanned, so that it is of most benefit when that setting is large.

- Improve performance of lock releasing in standby server WAL replay (Thomas Munro)
- Make logical WAL senders report streaming state correctly (Simon Riggs, Sawada Masahiko)

The code previously mis-detected whether or not it had caught up with the upstream server.

- Fix bugs in snapshot handling during logical decoding, allowing wrong decoding results in rare cases (Arseny Sher, Álvaro Herrera)
- Ensure a table's cached index list is correctly rebuilt after an index creation fails partway through (Peter Geoghegan)

Previously, the failed index's OID could remain in the list, causing problems later in the same session.

- Fix mishandling of empty uncompressed posting list pages in GIN indexes (Sivasubramanian Ramasubramanian, Alexander Korotkov)

This could result in an assertion failure after `pg_upgrade` of a pre-9.4 GIN index (9.4 and later will not create such pages).

- Ensure that `VACUUM` will respond to signals within btree page deletion loops (Andres Freund)

Corrupted btree indexes could result in an infinite loop here, and that previously wasn't interruptible without forcing a crash.

- Fix misoptimization of equivalence classes involving composite-type columns (Tom Lane)

This resulted in failure to recognize that an index on a composite column could provide the sort order needed for a mergejoin on that column.

- Fix planner to avoid "ORDER/GROUP BY expression not found in targetlist" errors in some queries with set-returning functions (Tom Lane)
- Fix SQL-standard `FETCH FIRST` syntax to allow parameters ($\$n$), as the standard expects (Andrew Gierth)
- Fix `EXPLAIN`'s accounting for resource usage, particularly buffer accesses, in parallel workers (Amit Kapila, Robert Haas)

- Fix failure to schema-qualify some object names in `getObjectDescription` output (Kyotaro Horiguchi, Tom Lane)

Names of collations, conversions, and text search objects were not schema-qualified when they should be.

- Fix `CREATE AGGREGATE` type checking so that parallelism support functions can be attached to variadic aggregates (Alexey Bashtanov)
- Widen `COPY FROM`'s current-line-number counter from 32 to 64 bits (David Rowley)

This avoids two problems with input exceeding 4G lines: `COPY FROM WITH HEADER` would drop a line every 4G lines, not only the first line, and error reports could show a wrong line number.

- Add a string freeing function to ecpg's `pgtypes` library, so that cross-module memory management problems can be avoided on Windows (Takayuki Tsunakawa)

On Windows, crashes can ensue if the `free` call for a given chunk of memory is not made from the same DLL that `malloc`'ed the memory. The `pgtypes` library sometimes returns strings that it expects the caller to free, making it impossible to follow this rule. Add a `PGTYPESchar_free()` function that just wraps `free`, allowing applications to follow this rule.

- Fix ecpg's support for `long long` variables on Windows, as well as other platforms that declare `strtoll/strtoull` nonstandardly or not at all (Dang Minh Huong, Tom Lane)
- Fix misidentification of SQL statement type in PL/pgSQL, when a rule change causes a change in the semantics of a statement intra-session (Tom Lane)

This error led to assertion failures, or in rare cases, failure to enforce the `INTO STRICT` option as expected.

- Fix password prompting in client programs so that `echo` is properly disabled on Windows when `stdin` is not the terminal (Matthew Stickney)
- Further fix mis-quoting of values for list-valued GUC variables in dumps (Tom Lane)

The previous fix for quoting of `search_path` and other list-valued variables in `pg_dump` output turned out to misbehave for empty-string list elements, and it risked truncation of long file paths.

- Fix `pg_dump`'s failure to dump `REPLICA IDENTITY` properties for constraint indexes (Tom Lane)

Manually created unique indexes were properly marked, but not those created by declaring `UNIQUE` or `PRIMARY KEY` constraints.

- Make `pg_upgrade` check that the old server was shut down cleanly (Bruce Momjian)

The previous check could be fooled by an immediate-mode shutdown.

- Fix `contrib/hstore_plperl` to look through Perl scalar references, and to not crash if it doesn't find a hash reference where it expects one (Tom Lane)
- Fix crash in `contrib/ltree`'s `lca()` function when the input array is empty (Pierre Ducroquet)
- Fix various error-handling code paths in which an incorrect error code might be reported (Michael Paquier, Tom Lane, Magnus Hagander)
- Rearrange makefiles to ensure that programs link to freshly-built libraries (such as `libpq.so`) rather than ones that might exist in the system library directories (Tom Lane)

This avoids problems when building on platforms that supply old copies of PostgreSQL libraries.

- Update time zone data files to tzdata release 2018e for DST law changes in North Korea, plus historical corrections for Czechoslovakia.

This update includes a redefinition of “daylight savings” in Ireland, as well as for some past years in Namibia and Czechoslovakia. In those jurisdictions, legally standard time is observed in summer, and daylight savings time in winter, so that the daylight savings offset is one hour behind

standard time not one hour ahead. This does not affect either the actual UTC offset or the timezone abbreviations in use; the only known effect is that the `is_dst` column in the `pg_timezone_names` view will now be true in winter and false in summer in these cases.

E.42. Release 9.6.9

Release date: 2018-05-10

This release contains a variety of fixes from 9.6.8. For information about new features in the 9.6 major release, see [Section E.51](#).

E.42.1. Migration to Version 9.6.9

A dump/restore is not required for those running 9.6.X.

However, if you use the `adminpack` extension, you should update it as per the first changelog entry below.

Also, if the function marking mistakes mentioned in the second and third changelog entries below affect you, you will want to take steps to correct your database catalogs.

Also, if you are upgrading from a version earlier than 9.6.8, see [Section E.43](#).

E.42.2. Changes

- Remove public execute privilege from `contrib/adminpack's pg_logfile_rotate()` function (Stephen Frost)

`pg_logfile_rotate()` is a deprecated wrapper for the core function `pg_rotate_logfile()`. When that function was changed to rely on SQL privileges for access control rather than a hard-coded superuser check, `pg_logfile_rotate()` should have been updated as well, but the need for this was missed. Hence, if `adminpack` is installed, any user could request a logfile rotation, creating a minor security issue.

After installing this update, administrators should update `adminpack` by performing `ALTER EXTENSION adminpack UPDATE` in each database in which `adminpack` is installed. (CVE-2018-1115)

- Fix incorrect volatility markings on a few built-in functions (Thomas Munro, Tom Lane)

The functions `query_to_xml`, `cursor_to_xml`, `cursor_to_xmlschema`, `query_to_xmlschema`, and `query_to_xml_and_xmlschema` should be marked volatile because they execute user-supplied queries that might contain volatile operations. They were not, leading to a risk of incorrect query optimization. This has been repaired for new installations by correcting the initial catalog data, but existing installations will continue to contain the incorrect markings. Practical use of these functions seems to pose little hazard, but in case of trouble, it can be fixed by manually updating these functions' `pg_proc` entries, for example `ALTER FUNCTION pg_catalog.query_to_xml(text, boolean, boolean, text) VOLATILE`. (Note that that will need to be done in each database of the installation.) Another option is to `pg_upgrade` the database to a version containing the corrected initial data.

- Fix incorrect parallel-safety markings on a few built-in functions (Thomas Munro, Tom Lane)

The functions `brin_summarize_new_values`, `gin_clean_pending_list`, `cursor_to_xml`, `cursor_to_xmlschema`, `ts_rewrite`, `ts_stat`, and `binary_upgrade_create_empty_extension` should be marked parallel-unsafe; some because they perform database modifications directly, and others because they execute user-supplied queries that might do so. They were marked parallel-restricted instead, leading to a risk of unexpected query errors. This has been repaired for new installations by correcting the initial catalog data, but existing installations will continue to contain the incorrect markings. Practical use of these functions seems to pose little hazard unless `force_parallel_mode` is turned on. In case of trouble, it can be fixed by manually updating these functions' `pg_proc` entries, for example `ALTER FUNCTION pg_catalog.brin_summarize_new_values(regclass) PARALLEL UNSAFE`. (Note that that will need

to be done in each database of the installation.) Another option is to `pg_upgrade` the database to a version containing the corrected initial data.

- Avoid re-using TOAST value OIDs that match dead-but-not-yet-vacuumed TOAST entries (Pavan Deolasee)

Once the OID counter has wrapped around, it's possible to assign a TOAST value whose OID matches a previously deleted entry in the same TOAST table. If that entry were not yet vacuumed away, this resulted in “unexpected chunk number 0 (expected 1) for toast value `nnnnn`” errors, which would persist until the dead entry was removed by `VACUUM`. Fix by not selecting such OIDs when creating a new TOAST entry.

- Change `ANALYZE`'s algorithm for updating `pg_class.reltuples` (David Gould)

Previously, pages not actually scanned by `ANALYZE` were assumed to retain their old tuple density. In a large table where `ANALYZE` samples only a small fraction of the pages, this meant that the overall tuple density estimate could not change very much, so that `reltuples` would change nearly proportionally to changes in the table's physical size (`relpages`) regardless of what was actually happening in the table. This has been observed to result in `reltuples` becoming so much larger than reality as to effectively shut off autovacuuming. To fix, assume that `ANALYZE`'s sample is a statistically unbiased sample of the table (as it should be), and just extrapolate the density observed within those pages to the whole table.

- Avoid deadlocks in concurrent `CREATE INDEX CONCURRENTLY` commands that are run under `SERIALIZABLE` or `REPEATABLE READ` transaction isolation (Tom Lane)
- Fix possible slow execution of `REFRESH MATERIALIZED VIEW CONCURRENTLY` (Thomas Munro)
- Fix `UPDATE/DELETE ... WHERE CURRENT OF` to not fail when the referenced cursor uses an index-only-scan plan (Yugo Nagata, Tom Lane)
- Fix incorrect planning of join clauses pushed into parameterized paths (Andrew Gierth, Tom Lane)

This error could result in misclassifying a condition as a “join filter” for an outer join when it should be a plain “filter” condition, leading to incorrect join output.

- Fix possibly incorrect generation of an index-only-scan plan when the same table column appears in multiple index columns, and only some of those index columns use operator classes that can return the column value (Kyotaro Horiguchi)
- Fix misoptimization of `CHECK` constraints having provably-NULL subclauses of top-level `AND/OR` conditions (Tom Lane, Dean Rasheed)

This could, for example, allow constraint exclusion to exclude a child table that should not be excluded from a query.

- Fix executor crash due to double free in some `GROUPING SET` usages (Peter Geoghegan)
- Avoid crash if a table rewrite event trigger is added concurrently with a command that could call such a trigger (Álvaro Herrera, Andrew Gierth, Tom Lane)
- Avoid failure if a query-cancel or session-termination interrupt occurs while committing a prepared transaction (Stas Kelvich)
- Fix query-lifespan memory leakage in repeatedly executed hash joins (Tom Lane)
- Fix possible leak or double free of visibility map buffer pins (Amit Kapila)
- Avoid spuriously marking pages as all-visible (Dan Wood, Pavan Deolasee, Álvaro Herrera)

This could happen if some tuples were locked (but not deleted). While queries would still function correctly, vacuum would normally ignore such pages, with the long-term effect that the tuples were never frozen. In recent releases this would eventually result in errors such as “found multixact `nnnnn` from before `relminmxid nnnnn`”.

- Fix overly strict sanity check in `heap_prepare_freeze_tuple` (Álvaro Herrera)

This could result in incorrect “cannot freeze committed xmax” failures in databases that have been `pg_upgrade`d from 9.2 or earlier.

- Prevent dangling-pointer dereference when a C-coded before-update row trigger returns the “old” tuple (Rushabh Lathia)
- Reduce locking during autovacuum worker scheduling (Jeff Janes)

The previous behavior caused drastic loss of potential worker concurrency in databases with many tables.

- Ensure client hostname is copied while copying `pg_stat_activity` data to local memory (Edmund Horner)

Previously the supposedly-local snapshot contained a pointer into shared memory, allowing the client hostname column to change unexpectedly if any existing session disconnected.

- Fix incorrect processing of multiple compound affixes in `ispell` dictionaries (Arthur Zakirov)
- Fix collation-aware searches (that is, indexscans using inequality operators) in SP-GiST indexes on text columns (Tom Lane)

Such searches would return the wrong set of rows in most non-C locales.

- Prevent query-lifespan memory leakage with SP-GiST operator classes that use traversal values (Anton Dignös)
- Count the number of index tuples correctly during initial build of an SP-GiST index (Tomas Vondra)

Previously, the tuple count was reported to be the same as that of the underlying table, which is wrong if the index is partial.

- Count the number of index tuples correctly during vacuuming of a GiST index (Andrey Borodin)

Previously it reported the estimated number of heap tuples, which might be inaccurate, and is certainly wrong if the index is partial.

- Fix a corner case where a streaming standby gets stuck at a WAL continuation record (Kyotaro Horiguchi)
- In logical decoding, avoid possible double processing of WAL data when a walsender restarts (Craig Ringer)
- Allow `scalarltset` and `scalargtsel` to be used on non-core datatypes (Tomas Vondra)
- Reduce libpq's memory consumption when a server error is reported after a large amount of query output has been collected (Tom Lane)

Discard the previous output before, not after, processing the error message. On some platforms, notably Linux, this can make a difference in the application's subsequent memory footprint.

- Fix double-free crashes in `ecpg` (Patrick Kreckler, Jeevan Ladhe)
- Fix `ecpg` to handle `long long int` variables correctly in MSVC builds (Michael Meskes, Andrew Gierth)
- Fix mis-quoting of values for list-valued GUC variables in dumps (Michael Paquier, Tom Lane)

The `local_preload_libraries`, `session_preload_libraries`, `shared_preload_libraries`, and `temp_tablespace` variables were not correctly quoted in `pg_dump` output. This would cause problems if settings for these variables appeared in `CREATE FUNCTION ... SET` or `ALTER DATABASE/ROLE ... SET` clauses.

- Fix `pg_recvlogical` to not fail against pre-v10 PostgreSQL servers (Michael Paquier)

A previous fix caused `pg_recvlogical` to issue a command regardless of server version, but it should only be issued to v10 and later servers.

- Ensure that `pg_rewind` deletes files on the target server if they are deleted from the source server during the run (Takayuki Tsunakawa)

Failure to do this could result in data inconsistency on the target, particularly if the file in question is a WAL segment.

- Fix `pg_rewind` to handle tables in non-default tablespaces correctly (Takayuki Tsunakawa)
- Fix overflow handling in PL/pgSQL integer `FOR` loops (Tom Lane)

The previous coding failed to detect overflow of the loop variable on some non-gcc compilers, leading to an infinite loop.

- Adjust PL/Python regression tests to pass under Python 3.7 (Peter Eisentraut)
- Support testing PL/Python and related modules when building with Python 3 and MSVC (Andrew Dunstan)
- Fix errors in initial build of `contrib/bloom` indexes (Tomas Vondra, Tom Lane)

Fix possible omission of the table's last tuple from the index. Count the number of index tuples correctly, in case it is a partial index.

- Rename internal `b64_encode` and `b64_decode` functions to avoid conflict with Solaris 11.4 built-in functions (Rainer Orth)
- Sync our copy of the timezone library with IANA tzcode release 2018e (Tom Lane)

This fixes the `zic` timezone data compiler to cope with negative daylight-savings offsets. While the PostgreSQL project will not immediately ship such timezone data, `zic` might be used with timezone data obtained directly from IANA, so it seems prudent to update `zic` now.

- Update time zone data files to `tzdata` release 2018d for DST law changes in Palestine and Antarctica (Casey Station), plus historical corrections for Portugal and its colonies, as well as Enderbury, Jamaica, Turks & Caicos Islands, and Uruguay.

E.43. Release 9.6.8

Release date: 2018-03-01

This release contains a variety of fixes from 9.6.7. For information about new features in the 9.6 major release, see [Section E.51](#).

E.43.1. Migration to Version 9.6.8

A dump/restore is not required for those running 9.6.X.

However, if you run an installation in which not all users are mutually trusting, or if you maintain an application or extension that is intended for use in arbitrary situations, it is strongly recommended that you read the documentation changes described in the first changelog entry below, and take suitable steps to ensure that your installation or code is secure.

Also, the changes described in the second changelog entry below may cause functions used in index expressions or materialized views to fail during auto-analyze, or when reloading from a dump. After upgrading, monitor the server logs for such problems, and fix affected functions.

Also, if you are upgrading from a version earlier than 9.6.7, see [Section E.44](#).

E.43.2. Changes

- Document how to configure installations and applications to guard against search-path-dependent trojan-horse attacks from other users (Noah Misch)

Using a `search_path` setting that includes any schemas writable by a hostile user enables that user to capture control of queries and then run arbitrary SQL code with the permissions of the attacked user. While it is possible to write queries that are proof against such hijacking, it is notationally

tedious, and it's very easy to overlook holes. Therefore, we now recommend configurations in which no untrusted schemas appear in one's search path. Relevant documentation appears in [Section 5.8.6](#) (for database administrators and users), [Section 32.1](#) (for application authors), [Section 36.15.5](#) (for extension authors), and [CREATE FUNCTION](#) (for authors of `SECURITY DEFINER` functions). (CVE-2018-1058)

- Avoid use of insecure `search_path` settings in `pg_dump` and other client programs (Noah Misch, Tom Lane)

`pg_dump`, `pg_upgrade`, `vacuumdb` and other PostgreSQL-provided applications were themselves vulnerable to the type of hijacking described in the previous changelog entry; since these applications are commonly run by superusers, they present particularly attractive targets. To make them secure whether or not the installation as a whole has been secured, modify them to include only the `pg_catalog` schema in their `search_path` settings. Autovacuum worker processes now do the same, as well.

In cases where user-provided functions are indirectly executed by these programs — for example, user-provided functions in index expressions — the tighter `search_path` may result in errors, which will need to be corrected by adjusting those user-provided functions to not assume anything about what search path they are invoked under. That has always been good practice, but now it will be necessary for correct behavior. (CVE-2018-1058)

- Fix misbehavior of concurrent-update rechecks with CTE references appearing in subplans (Tom Lane)

If a CTE (`WITH` clause reference) is used in an `InitPlan` or `SubPlan`, and the query requires a recheck due to trying to update or lock a concurrently-updated row, incorrect results could be obtained.

- Fix planner failures with overlapping mergejoin clauses in an outer join (Tom Lane)

These mistakes led to “left and right pathkeys do not match in mergejoin” or “outer pathkeys do not match mergeclauses” planner errors in corner cases.

- Repair `pg_upgrade`'s failure to preserve `relfrozenxid` for materialized views (Tom Lane, Andres Freund)

This oversight could lead to data corruption in materialized views after an upgrade, manifesting as “could not access status of transaction” or “found xmin from before relfrozenxid” errors. The problem would be more likely to occur in seldom-refreshed materialized views, or ones that were maintained only with `REFRESH MATERIALIZED VIEW CONCURRENTLY`.

If such corruption is observed, it can be repaired by refreshing the materialized view (without `CONCURRENTLY`).

- Fix incorrect reporting of PL/Python function names in error `CONTEXT` stacks (Tom Lane)

An error occurring within a nested PL/Python function call (that is, one reached via a SPI query from another PL/Python function) would result in a stack trace showing the inner function's name twice, rather than the expected results. Also, an error in a nested PL/Python `DO` block could result in a null pointer dereference crash on some platforms.

- Allow `contrib/auto_explain`'s `log_min_duration` setting to range up to `INT_MAX`, or about 24 days instead of 35 minutes (Tom Lane)
- Mark assorted GUC variables as `PGDLLIMPORT`, to ease porting extension modules to Windows (Metin Doslu)

E.44. Release 9.6.7

Release date: 2018-02-08

This release contains a variety of fixes from 9.6.6. For information about new features in the 9.6 major release, see [Section E.51](#).

E.44.1. Migration to Version 9.6.7

A dump/restore is not required for those running 9.6.X.

However, if you use `contrib/cube's ~>` operator, see the entry below about that.

Also, if you are upgrading from a version earlier than 9.6.6, see [Section E.45](#).

E.44.2. Changes

- Ensure that all temporary files made by `pg_upgrade` are non-world-readable (Tom Lane, Noah Misch)

`pg_upgrade` normally restricts its temporary files to be readable and writable only by the calling user. But the temporary file containing `pg_dumpall -g` output would be group- or world-readable, or even writable, if the user's `umask` setting allows. In typical usage on multi-user machines, the `umask` and/or the working directory's permissions would be tight enough to prevent problems; but there may be people using `pg_upgrade` in scenarios where this oversight would permit disclosure of database passwords to unfriendly eyes. (CVE-2018-1053)

- Fix vacuuming of tuples that were updated while key-share locked (Andres Freund, Álvaro Herrera)

In some cases `VACUUM` would fail to remove such tuples even though they are now dead, leading to assorted data corruption scenarios.

- Ensure that vacuum will always clean up the pending-insertions list of a GIN index (Masahiko Sawada)

This is necessary to ensure that dead index entries get removed. The old code got it backwards, allowing vacuum to skip the cleanup if some other process were running cleanup concurrently, thus risking invalid entries being left behind in the index.

- Fix inadequate buffer locking in some LSN fetches (Jacob Champion, Asim Praveen, Ashwin Agrawal)

These errors could result in misbehavior under concurrent load. The potential consequences have not been characterized fully.

- Fix incorrect query results from cases involving flattening of subqueries whose outputs are used in `GROUPING SETS` (Heikki Linnakangas)
- Avoid unnecessary failure in a query on an inheritance tree that occurs concurrently with some child table being removed from the tree by `ALTER TABLE NO INHERIT` (Tom Lane)
- Fix spurious deadlock failures when multiple sessions are running `CREATE INDEX CONCURRENTLY` (Jeff Janes)
- Fix failures when an inheritance tree contains foreign child tables (Etsuro Fujita)

A mix of regular and foreign tables in an inheritance tree resulted in creation of incorrect plans for `UPDATE` and `DELETE` queries. This led to visible failures in some cases, notably when there are row-level triggers on a foreign child table.

- Repair failure with correlated sub-`SELECT` inside `VALUES` inside a `LATERAL` subquery (Tom Lane)
- Fix “could not devise a query plan for the given query” planner failure for some cases involving nested `UNION ALL` inside a lateral subquery (Tom Lane)
- Fix logical decoding to correctly clean up disk files for crashed transactions (Atsushi Torikoshi)

Logical decoding may spill WAL records to disk for transactions generating many WAL records. Normally these files are cleaned up after the transaction's commit or abort record arrives; but if no such record is ever seen, the removal code misbehaved.

- Fix walsender timeout failure and failure to respond to interrupts when processing a large transaction (Petr Jelinek)

- Fix `has_sequence_privilege()` to support `WITH GRANT OPTION` tests, as other privilege-testing functions do (Joe Conway)
- In databases using UTF8 encoding, ignore any XML declaration that asserts a different encoding (Pavel Stehule, Noah Misch)

We always store XML strings in the database encoding, so allowing libxml to act on a declaration of another encoding gave wrong results. In encodings other than UTF8, we don't promise to support non-ASCII XML data anyway, so retain the previous behavior for bug compatibility. This change affects only `xpath()` and related functions; other XML code paths already acted this way.

- Provide for forward compatibility with future minor protocol versions (Robert Haas, Badrul Chowdhury)

Up to now, PostgreSQL servers simply rejected requests to use protocol versions newer than 3.0, so that there was no functional difference between the major and minor parts of the protocol version number. Allow clients to request versions 3.x without failing, sending back a message showing that the server only understands 3.0. This makes no difference at the moment, but back-patching this change should allow speedier introduction of future minor protocol upgrades.

- Cope with failure to start a parallel worker process (Amit Kapila, Robert Haas)

Parallel query previously tended to hang indefinitely if a worker could not be started, as the result of `fork()` failure or other low-probability problems.

- Fix collection of `EXPLAIN` statistics from parallel workers (Amit Kapila, Thomas Munro)
- Avoid unsafe alignment assumptions when working with `__int128` (Tom Lane)

Typically, compilers assume that `__int128` variables are aligned on 16-byte boundaries, but our memory allocation infrastructure isn't prepared to guarantee that, and increasing the setting of `MAXALIGN` seems infeasible for multiple reasons. Adjust the code to allow use of `__int128` only when we can tell the compiler to assume lesser alignment. The only known symptom of this problem so far is crashes in some parallel aggregation queries.

- Prevent stack-overflow crashes when planning extremely deeply nested set operations (`UNION/INTERSECT/EXCEPT`) (Tom Lane)
- Fix null-pointer crashes for some types of LDAP URLs appearing in `pg_hba.conf` (Thomas Munro)
- Fix sample `INSTR()` functions in the PL/pgSQL documentation (Yugo Nagata, Tom Lane)

These functions are stated to be Oracle® compatible, but they weren't exactly. In particular, there was a discrepancy in the interpretation of a negative third parameter: Oracle thinks that a negative value indicates the last place where the target substring can begin, whereas our functions took it as the last place where the target can end. Also, Oracle throws an error for a zero or negative fourth parameter, whereas our functions returned zero.

The sample code has been adjusted to match Oracle's behavior more precisely. Users who have copied this code into their applications may wish to update their copies.

- Fix `pg_dump` to make ACL (permissions), comment, and security label entries reliably identifiable in archive output formats (Tom Lane)

The “tag” portion of an ACL archive entry was usually just the name of the associated object. Make it start with the object type instead, bringing ACLs into line with the convention already used for comment and security label archive entries. Also, fix the comment and security label entries for the whole database, if present, to make their tags start with `DATABASE` so that they also follow this convention. This prevents false matches in code that tries to identify large-object-related entries by seeing if the tag starts with `LARGE OBJECT`. That could have resulted in misclassifying entries as data rather than schema, with undesirable results in a schema-only or data-only dump.

Note that this change has user-visible results in the output of `pg_restore --list`.

- Rename `pg_rewind`'s `copy_file_range` function to avoid conflict with new Linux system call of that name (Andres Freund)

This change prevents build failures with newer glibc versions.

- In `ecpg`, detect indicator arrays that do not have the correct length and report an error (David Rader)
- Change the behavior of `contrib/cube`'s `cube ~> int` operator to make it compatible with KNN search (Alexander Korotkov)

The meaning of the second argument (the dimension selector) has been changed to make it predictable which value is selected even when dealing with cubes of varying dimensionalities.

This is an incompatible change, but since the point of the operator was to be used in KNN searches, it seems rather useless as-is. After installing this update, any expression indexes or materialized views using this operator will need to be reindexed/refreshed.

- Avoid triggering a libc assertion in `contrib/hstore`, due to use of `memcpy()` with equal source and destination pointers (Tomas Vondra)
- Fix incorrect display of tuples' null bitmaps in `contrib/pageinspect` (Maksim Milyutin)
- In `contrib/postgres_fdw`, avoid “outer pathkeys do not match mergeclauses” planner error when constructing a plan involving a remote join (Robert Haas)
- Provide modern examples of how to auto-start Postgres on macOS (Tom Lane)

The scripts in `contrib/start-scripts/osx` use infrastructure that's been deprecated for over a decade, and which no longer works at all in macOS releases of the last couple of years. Add a new subdirectory `contrib/start-scripts/macos` containing scripts that use the newer `launchd` infrastructure.

- Fix incorrect selection of configuration-specific libraries for OpenSSL on Windows (Andrew Dunstan)
- Support linking to MinGW-built versions of `libperl` (Noah Misch)

This allows building PL/Perl with some common Perl distributions for Windows.

- Fix MSVC build to test whether 32-bit `libperl` needs `-D_USE_32BIT_TIME_T` (Noah Misch)

Available Perl distributions are inconsistent about what they expect, and lack any reliable means of reporting it, so resort to a build-time test on what the library being used actually does.

- On Windows, install the crash dump handler earlier in postmaster startup (Takayuki Tsunakawa)

This may allow collection of a core dump for some early-startup failures that did not produce a dump before.

- On Windows, avoid encoding-conversion-related crashes when emitting messages very early in postmaster startup (Takayuki Tsunakawa)
- Use our existing Motorola 68K spinlock code on OpenBSD as well as NetBSD (David Carlier)
- Add support for spinlocks on Motorola 88K (David Carlier)
- Update time zone data files to `tzdata` release 2018c for DST law changes in Brazil, Sao Tome and Principe, plus historical corrections for Bolivia, Japan, and South Sudan. The `US/Pacific-New` zone has been removed (it was only an alias for `America/Los_Angeles` anyway).

E.45. Release 9.6.6

Release date: 2017-11-09

This release contains a variety of fixes from 9.6.5. For information about new features in the 9.6 major release, see [Section E.51](#).

E.45.1. Migration to Version 9.6.6

A dump/restore is not required for those running 9.6.X.

However, if you use BRIN indexes, see the fourth changelog entry below.

Also, if you are upgrading from a version earlier than 9.6.4, see [Section E.47](#).

E.45.2. Changes

- Ensure that `INSERT ... ON CONFLICT DO UPDATE` checks table permissions and RLS policies in all cases (Dean Rasheed)

The update path of `INSERT ... ON CONFLICT DO UPDATE` requires `SELECT` permission on the columns of the arbiter index, but it failed to check for that in the case of an arbiter specified by constraint name. In addition, for a table with row level security enabled, it failed to check updated rows against the table's `SELECT` policies (regardless of how the arbiter index was specified). (CVE-2017-15099)

- Fix crash due to rowtype mismatch in `json{b}_populate_recordset()` (Michael Paquier, Tom Lane)

These functions used the result rowtype specified in the `FROM ... AS` clause without checking that it matched the actual rowtype of the supplied tuple value. If it didn't, that would usually result in a crash, though disclosure of server memory contents seems possible as well. (CVE-2017-15098)

- Fix sample server-start scripts to become `$PGUSER` before opening `$PGLOG` (Noah Misch)

Previously, the postmaster log file was opened while still running as root. The database owner could therefore mount an attack against another system user by making `$PGLOG` be a symbolic link to some other file, which would then become corrupted by appending log messages.

By default, these scripts are not installed anywhere. Users who have made use of them will need to manually recopy them, or apply the same changes to their modified versions. If the existing `$PGLOG` file is root-owned, it will need to be removed or renamed out of the way before restarting the server with the corrected script. (CVE-2017-12172)

- Fix BRIN index summarization to handle concurrent table extension correctly (Álvaro Herrera)

Previously, a race condition allowed some table rows to be omitted from the index. It may be necessary to reindex existing BRIN indexes to recover from past occurrences of this problem.

- Fix possible failures during concurrent updates of a BRIN index (Tom Lane)

These race conditions could result in errors like “invalid index offnum” or “inconsistent range map”.

- Fix crash when logical decoding is invoked from a SPI-using function, in particular any function written in a PL language (Tom Lane)
- Fix incorrect query results when multiple `GROUPING SETS` columns contain the same simple variable (Tom Lane)
- Fix incorrect parallelization decisions for nested queries (Amit Kapila, Kuntal Ghosh)
- Fix parallel query handling to not fail when a recently-used role is dropped (Amit Kapila)
- Fix `json_build_array()`, `json_build_object()`, and their `jsonb` equivalents to handle explicit `VARIADIC` arguments correctly (Michael Paquier)
- Properly reject attempts to convert infinite float values to type `numeric` (Tom Lane, KaiGai Kohei)

Previously the behavior was platform-dependent.

- Fix corner-case crashes when columns have been added to the end of a view (Tom Lane)

- Record proper dependencies when a view or rule contains `FieldSelect` or `FieldStore` expression nodes (Tom Lane)

Lack of these dependencies could allow a column or data type `DROP` to go through when it ought to fail, thereby causing later uses of the view or rule to get errors. This patch does not do anything to protect existing views/rules, only ones created in the future.

- Correctly detect hashability of range data types (Tom Lane)

The planner mistakenly assumed that any range type could be hashed for use in hash joins or hash aggregation, but actually it must check whether the range's subtype has hash support. This does not affect any of the built-in range types, since they're all hashable anyway.

- Correctly ignore `RelabelType` expression nodes when determining relation distinctness (David Rowley)

This allows the intended optimization to occur when a subquery has a result column of type `varchar`.

- Prevent sharing transition states between ordered-set aggregates (David Rowley)

This causes a crash with the built-in ordered-set aggregates, and probably with user-written ones as well. v11 and later will include provisions for dealing with such cases safely, but in released branches, just disable the optimization.

- Prevent `idle_in_transaction_session_timeout` from being ignored when a `statement_timeout` occurred earlier (Lukas Fittl)
- Fix low-probability loss of `NOTIFY` messages due to XID wraparound (Marko Tiikkaja, Tom Lane)

If a session executed no queries, but merely listened for notifications, for more than 2 billion transactions, it started to miss some notifications from concurrently-committing transactions.

- Avoid `SIGBUS` crash on Linux when a DSM memory request exceeds the space available in `tmpfs` (Thomas Munro)
- Reduce the frequency of data flush requests during bulk file copies to avoid performance problems on macOS, particularly with its new APFS file system (Tom Lane)
- Prevent low-probability crash in processing of nested trigger firings (Tom Lane)
- Allow `COPY`'s `FREEZE` option to work when the transaction isolation level is `REPEATABLE READ` or higher (Noah Misch)

This case was unintentionally broken by a previous bug fix.

- Correctly restore the `umask` setting when file creation fails in `COPY` or `lo_export()` (Peter Eisentraut)
- Give a better error message for duplicate column names in `ANALYZE` (Nathan Bossart)
- Add missing cases in `GetCommandLogLevel()`, preventing errors when certain SQL commands are used while `log_statement` is set to `ddl` (Michael Paquier)
- Fix mis-parsing of the last line in a non-newline-terminated `pg_hba.conf` file (Tom Lane)
- Fix `AggGetAggref()` to return the correct `Aggref` nodes to aggregate final functions whose transition calculations have been merged (Tom Lane)
- Fix `pg_dump` to ensure that it emits `GRANT` commands in a valid order (Stephen Frost)
- Fix `pg_basebackup`'s matching of tablespace paths to canonicalize both paths before comparing (Michael Paquier)

This is particularly helpful on Windows.

- Fix `libpq` to not require user's home directory to exist (Tom Lane)

In v10, failure to find the home directory while trying to read `~/.pgpass` was treated as a hard error, but it should just cause that file to not be found. Both v10 and previous release branches made the same mistake when reading `~/.pg_service.conf`, though this was less obvious since that file is not sought unless a service name is specified.

- Fix libpq to guard against integer overflow in the row count of a `PGresult` (Michael Paquier)
- Fix ecpg's handling of out-of-scope cursor declarations with pointer or array variables (Michael Meskes)
- In ecpglib, correctly handle backslashes in string literals depending on whether `standard_conforming_strings` is set (Tsunakawa Takayuki)
- Make ecpglib's Informix-compatibility mode ignore fractional digits in integer input strings, as expected (Gao Zengqi, Michael Meskes)
- Fix ecpg's regression tests to work reliably on Windows (Christian Ullrich, Michael Meskes)
- Fix missing temp-install prerequisites for `check`-like Make targets (Noah Misch)

Some non-default test procedures that are meant to work like `make check` failed to ensure that the temporary installation was up to date.

- Sync our copy of the timezone library with IANA release `tzcode2017c` (Tom Lane)

This fixes various issues; the only one likely to be user-visible is that the default DST rules for a POSIX-style zone name, if no `posixrules` file exists in the timezone data directory, now match current US law rather than what it was a dozen years ago.

- Update time zone data files to `tzdata` release 2017c for DST law changes in Fiji, Namibia, Northern Cyprus, Sudan, Tonga, and Turks & Caicos Islands, plus historical corrections for Alaska, Apia, Burma, Calcutta, Detroit, Ireland, Namibia, and Pago Pago.

E.46. Release 9.6.5

Release date: 2017-08-31

This release contains a small number of fixes from 9.6.4. For information about new features in the 9.6 major release, see [Section E.51](#).

E.46.1. Migration to Version 9.6.5

A dump/restore is not required for those running 9.6.X.

However, if you are upgrading from a version earlier than 9.6.4, see [Section E.47](#).

E.46.2. Changes

- Show foreign tables in `information_schema.table_privileges` view (Peter Eisentraut)

All other relevant `information_schema` views include foreign tables, but this one ignored them.

Since this view definition is installed by `initdb`, merely upgrading will not fix the problem. If you need to fix this in an existing installation, you can, as a superuser, do this in `psql`:

```
SET search_path TO information_schema;
CREATE OR REPLACE VIEW table_privileges AS
    SELECT CAST(u_grantor.rolname AS sql_identifier) AS grantor,
           CAST(grantee.rolname AS sql_identifier) AS grantee,
           CAST(current_database() AS sql_identifier) AS table_catalog,
           CAST(nc.nspname AS sql_identifier) AS table_schema,
           CAST(c.relname AS sql_identifier) AS table_name,
```

```
CAST(c.prtype AS character_data) AS privilege_type,
CAST(
    CASE WHEN
        -- object owner always has grant options
        pg_has_role(grantee.oid, c.relowner, 'USAGE')
        OR c.grantable
        THEN 'YES' ELSE 'NO' END AS yes_or_no) AS is_grantable,
CAST(CASE WHEN c.prtype = 'SELECT' THEN 'YES' ELSE 'NO' END AS yes_or_no)
AS with_hierarchy

FROM (
    SELECT oid, relname, relnamespace, relkind, relowner,
    (aclexplode(coalesce(relacl, acldefault('r', relowner)))).* FROM pg_class
    ) AS c (oid, relname, relnamespace, relkind, relowner, grantor, grantee,
prtype, grantable),
pg_namespace nc,
pg_authid u_grantor,
(
    SELECT oid, rolname FROM pg_authid
    UNION ALL
    SELECT 0::oid, 'PUBLIC'
) AS grantee (oid, rolname)

WHERE c.relnamespace = nc.oid
AND c.relkind IN ('r', 'v', 'f')
AND c.grantee = grantee.oid
AND c.grantor = u_grantor.oid
AND c.prtype IN ('INSERT', 'SELECT', 'UPDATE', 'DELETE', 'TRUNCATE',
'REFERENCES', 'TRIGGER')
AND (pg_has_role(u_grantor.oid, 'USAGE')
OR pg_has_role(grantee.oid, 'USAGE')
OR grantee.rolname = 'PUBLIC');
```

This must be repeated in each database to be fixed, including `template0`.

- Clean up handling of a fatal exit (e.g., due to receipt of SIGTERM) that occurs while trying to execute a `ROLLBACK` of a failed transaction (Tom Lane)

This situation could result in an assertion failure. In production builds, the exit would still occur, but it would log an unexpected message about “cannot drop active portal”.

- Remove assertion that could trigger during a fatal exit (Tom Lane)
- Correctly identify columns that are of a range type or domain type over a composite type or domain type being searched for (Tom Lane)

Certain `ALTER` commands that change the definition of a composite type or domain type are supposed to fail if there are any stored values of that type in the database, because they lack the infrastructure needed to update or check such values. Previously, these checks could miss relevant values that are wrapped inside range types or sub-domains, possibly allowing the database to become inconsistent.

- Prevent crash when passing fixed-length pass-by-reference data types to parallel worker processes (Tom Lane)
- Fix crash in `pg_restore` when using parallel mode and using a list file to select a subset of items to restore (Fabrício de Royes Mello)
- Change `ecpg`'s parser to allow `RETURNING` clauses without attached C variables (Michael Meskes)

This allows `ecpg` programs to contain SQL constructs that use `RETURNING` internally (for example, inside a CTE) rather than using it to define values to be returned to the client.

- Change `ecpg`'s parser to recognize backslash continuation of C preprocessor command lines (Michael Meskes)
- Improve selection of compiler flags for PL/Perl on Windows (Tom Lane)

This fix avoids possible crashes of PL/Perl due to inconsistent assumptions about the width of `time_t` values. A side-effect that may be visible to extension developers is that `_USE_32BIT_TIME_T` is no longer defined globally in PostgreSQL Windows builds. This is not expected to cause problems, because type `time_t` is not used in any PostgreSQL API definitions.

- Fix `make check` to behave correctly when invoked via a non-GNU make program (Thomas Munro)

E.47. Release 9.6.4

Release date: 2017-08-10

This release contains a variety of fixes from 9.6.3. For information about new features in the 9.6 major release, see [Section E.51](#).

E.47.1. Migration to Version 9.6.4

A dump/restore is not required for those running 9.6.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.6.3, see [Section E.48](#).

E.47.2. Changes

- Further restrict visibility of `pg_user_mappings.umoptions`, to protect passwords stored as user mapping options (Noah Misch)

The fix for CVE-2017-7486 was incorrect: it allowed a user to see the options in her own user mapping, even if she did not have `USAGE` permission on the associated foreign server. Such options might include a password that had been provided by the server owner rather than the user herself. Since `information_schema.user_mapping_options` does not show the options in such cases, `pg_user_mappings` should not either. (CVE-2017-7547)

By itself, this patch will only fix the behavior in newly initdb'd databases. If you wish to apply this change in an existing database, you will need to do the following:

1. Restart the postmaster after adding `allow_system_table_mods = true` to `postgresql.conf`. (In versions supporting `ALTER SYSTEM`, you can use that to make the configuration change, but you'll still need a restart.)
2. In *each* database of the cluster, run the following commands as superuser:

```
SET search_path = pg_catalog;
CREATE OR REPLACE VIEW pg_user_mappings AS
SELECT
    U.oid          AS umid,
    S.oid          AS srvid,
    S.srvname      AS srvname,
    U.umuser       AS umuser,
    CASE WHEN U.umuser = 0 THEN
        'public'
    ELSE
        A.rolname
    END AS username,
    CASE WHEN (U.umuser <> 0 AND A.rolname = current_user
```

```
        AND (pg_has_role(S.srvowner, 'USAGE')
              OR has_server_privilege(S.oid, 'USAGE'))
        OR (U.umuser = 0 AND pg_has_role(S.srvowner, 'USAGE'))
        OR (SELECT rolsuper FROM pg_authid WHERE rolname =
current_user)

        THEN U.umoptions
        ELSE NULL END AS umoptions
FROM pg_user_mapping U
     LEFT JOIN pg_authid A ON (A.oid = U.umuser) JOIN
     pg_foreign_server S ON (U.umserver = S.oid);
```

3. Do not forget to include the `template0` and `template1` databases, or the vulnerability will still exist in databases you create later. To fix `template0`, you'll need to temporarily make it accept connections. In PostgreSQL 9.5 and later, you can use

```
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS true;
```

and then after fixing `template0`, undo that with

```
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS false;
```

In prior versions, instead use

```
UPDATE pg_database SET datallowconn = true WHERE datname = 'template0';
UPDATE pg_database SET datallowconn = false WHERE datname = 'template0';
```

4. Finally, remove the `allow_system_table_mods` configuration setting, and again restart the postmaster.

- Disallow empty passwords in all password-based authentication methods (Heikki Linnakangas)

`libpq` ignores empty password specifications, and does not transmit them to the server. So, if a user's password has been set to the empty string, it's impossible to log in with that password via `psql` or other `libpq`-based clients. An administrator might therefore believe that setting the password to empty is equivalent to disabling password login. However, with a modified or non-`libpq`-based client, logging in could be possible, depending on which authentication method is configured. In particular the most common method, `md5`, accepted empty passwords. Change the server to reject empty passwords in all cases. (CVE-2017-7546)

- Make `lo_put()` check for `UPDATE` privilege on the target large object (Tom Lane, Michael Paquier)

`lo_put()` should surely require the same permissions as `lowrite()`, but the check was missing, allowing any user to change the data in a large object. (CVE-2017-7548)

- Correct the documentation about the process for upgrading standby servers with `pg_upgrade` (Bruce Momjian)

The previous documentation instructed users to start/stop the primary server after running `pg_upgrade` but before syncing the standby servers. This sequence is unsafe.

- Fix concurrent locking of tuple update chains (Álvaro Herrera)

If several sessions concurrently lock a tuple update chain with nonconflicting lock modes using an old snapshot, and they all succeed, it was possible for some of them to nonetheless fail (and conclude there is no live tuple version) due to a race condition. This had consequences such as foreign-key checks failing to see a tuple that definitely exists but is being updated concurrently.

- Fix potential data corruption when freezing a tuple whose XMAX is a multixact with exactly one still-interesting member (Teodor Sigaev)
- Avoid integer overflow and ensuing crash when sorting more than one billion tuples in-memory (Sergey Kopysov)
- On Windows, retry process creation if we fail to reserve the address range for our shared memory in the new process (Tom Lane, Amit Kapila)

This is expected to fix infrequent child-process-launch failures that are probably due to interference from antivirus products.

- Fix low-probability corruption of shared predicate-lock hash table in Windows builds (Thomas Munro, Tom Lane)
- Avoid logging clean closure of an SSL connection as though it were a connection reset (Michael Paquier)
- Prevent sending SSL session tickets to clients (Tom Lane)

This fix prevents reconnection failures with ticket-aware client-side SSL code.

- Fix code for setting `tcp_keepalives_idle` on Solaris (Tom Lane)
- Fix statistics collector to honor inquiry messages issued just after a postmaster shutdown and immediate restart (Tom Lane)

Statistics inquiries issued within half a second of the previous postmaster shutdown were effectively ignored.

- Ensure that the statistics collector's receive buffer size is at least 100KB (Tom Lane)

This reduces the risk of dropped statistics data on older platforms whose default receive buffer size is less than that.

- Fix possible creation of an invalid WAL segment when a standby is promoted just after it processes an `XLOG_SWITCH` WAL record (Andres Freund)
- Fix walsender to exit promptly when client requests shutdown (Tom Lane)
- Fix SIGHUP and SIGUSR1 handling in walsender processes (Petr Jelinek, Andres Freund)
- Prevent walsender-triggered panics during shutdown checkpoints (Andres Freund, Michael Paquier)
- Fix unnecessarily slow restarts of walreceiver processes due to race condition in postmaster (Tom Lane)
- Fix leakage of small subtransactions spilled to disk during logical decoding (Andres Freund)

This resulted in temporary files consuming excessive disk space.

- Reduce the work needed to build snapshots during creation of logical-decoding slots (Andres Freund, Petr Jelinek)

The previous algorithm was infeasibly expensive on a server with a lot of open transactions.

- Fix race condition that could indefinitely delay creation of logical-decoding slots (Andres Freund, Petr Jelinek)
- Reduce overhead in processing syscache invalidation events (Tom Lane)

This is particularly helpful for logical decoding, which triggers frequent cache invalidation.

- Remove incorrect heuristic used in some cases to estimate join selectivity based on the presence of foreign-key constraints (David Rowley)

In some cases where a multi-column foreign key constraint existed but did not exactly match a query's join structure, the planner used an estimation heuristic that turns out not to work well at all. Revert such cases to the way they were estimated before 9.6.

- Fix cases where an `INSERT` or `UPDATE` assigns to more than one element of a column that is of domain-over-array type (Tom Lane)
- Allow window functions to be used in sub-`SELECT`s that are within the arguments of an aggregate function (Tom Lane)

- Ensure that a view's `CHECK OPTIONS` clause is enforced properly when the underlying table is a foreign table (Etsuro Fujita)

Previously, the update might get pushed entirely to the foreign server, but the need to verify the view conditions was missed if so.

- Move autogenerated array types out of the way during `ALTER ... RENAME` (Vik Fearing)

Previously, we would rename a conflicting autogenerated array type out of the way during `CREATE`; this fix extends that behavior to renaming operations.

- Fix dangling pointer in `ALTER TABLE` when there is a comment on a constraint belonging to the table (David Rowley)

Re-applying the comment to the reconstructed constraint could fail with a weird error message, or even crash.

- Ensure that `ALTER USER ... SET` accepts all the syntax variants that `ALTER ROLE ... SET` does (Peter Eisentraut)
- Allow a foreign table's `CHECK` constraints to be initially `NOT VALID` (Amit Langote)

`CREATE TABLE` silently drops `NOT VALID` specifiers for `CHECK` constraints, reasoning that the table must be empty so the constraint can be validated immediately. But this is wrong for `CREATE FOREIGN TABLE`, where there's no reason to suppose that the underlying table is empty, and even if it is it's no business of ours to decide that the constraint can be treated as valid going forward. Skip this “optimization” for foreign tables.

- Properly update dependency info when changing a datatype I/O function's argument or return type from `opaque` to the correct type (Heikki Linnakangas)

`CREATE TYPE` updates I/O functions declared in this long-obsolete style, but it forgot to record a dependency on the type, allowing a subsequent `DROP TYPE` to leave broken function definitions behind.

- Allow parallelism in the query plan when `COPY` copies from a query's result (Andres Freund)
- Reduce memory usage when `ANALYZE` processes a `tsvector` column (Heikki Linnakangas)
- Fix unnecessary precision loss and sloppy rounding when multiplying or dividing `money` values by integers or floats (Tom Lane)
- Tighten checks for whitespace in functions that parse identifiers, such as `regprocedurein()` (Tom Lane)

Depending on the prevailing locale, these functions could misinterpret fragments of multibyte characters as whitespace.

- Use relevant `#define` symbols from Perl while compiling PL/Perl (Ashutosh Sharma, Tom Lane)

This avoids portability problems, typically manifesting as a “handshake” mismatch during library load, when working with recent Perl versions.

- In `libpq`, reset GSS/SASL and SSPI authentication state properly after a failed connection attempt (Michael Paquier)

Failure to do this meant that when falling back from SSL to non-SSL connections, a GSS/SASL failure in the SSL attempt would always cause the non-SSL attempt to fail. SSPI did not fail, but it leaked memory.

- In `psql`, fix failure when `COPY FROM STDIN` is ended with a keyboard EOF signal and then another `COPY FROM STDIN` is attempted (Thomas Munro)

This misbehavior was observed on BSD-derived platforms (including macOS), but not on most others.

- Fix `pg_dump` and `pg_restore` to emit `REFRESH MATERIALIZED VIEW` commands last (Tom Lane)

This prevents errors during dump/restore when a materialized view refers to tables owned by a different user.

- Improve `pg_dump/pg_restore`'s reporting of error conditions originating in `zlib` (Vladimir Kunschikov, Álvaro Herrera)
- Fix `pg_dump` with the `--clean` option to drop event triggers as expected (Tom Lane)

It also now correctly assigns ownership of event triggers; before, they were restored as being owned by the superuser running the restore script.

- Fix `pg_dump` with the `--clean` option to not fail when the `public` schema doesn't exist (Stephen Frost)
- Fix `pg_dump` to not emit invalid SQL for an empty operator class (Daniel Gustafsson)
- Fix `pg_dump` output to stdout on Windows (Kuntal Ghosh)

A compressed plain-text dump written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.

- Fix `pg_get_ruledef()` to print correct output for the `ON SELECT` rule of a view whose columns have been renamed (Tom Lane)

In some corner cases, `pg_dump` relies on `pg_get_ruledef()` to dump views, so that this error could result in dump/reload failures.

- Fix dumping of outer joins with empty constraints, such as the result of a `NATURAL LEFT JOIN` with no common columns (Tom Lane)
- Fix dumping of function expressions in the `FROM` clause in cases where the expression does not deparse into something that looks like a function call (Tom Lane)
- Fix `pg_basebackup` output to stdout on Windows (Haribabu Kommi)

A backup written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.

- Fix `pg_rewind` to correctly handle files exceeding 2GB (Kuntal Ghosh, Michael Paquier)

Ordinarily such files won't appear in PostgreSQL data directories, but they could be present in some cases.

- Fix `pg_upgrade` to ensure that the ending WAL record does not have `wal_level = minimum` (Bruce Momjian)

This condition could prevent upgraded standby servers from reconnecting.

- Fix `pg_xlogdump`'s computation of WAL record length (Andres Freund)
- In `postgres_fdw`, re-establish connections to remote servers after `ALTER SERVER` or `ALTER USER MAPPING` commands (Kyotaro Horiguchi)

This ensures that option changes affecting connection parameters will be applied promptly.

- In `postgres_fdw`, allow cancellation of remote transaction control commands (Robert Haas, Rafia Sabih)

This change allows us to quickly escape a wait for an unresponsive remote server in many more cases than previously.

- Increase `MAX_SYSCACHE_CALLBACKS` to provide more room for extensions (Tom Lane)
- Always use `-fPIC`, not `-fpic`, when building shared libraries with `gcc` (Tom Lane)

This supports larger extension libraries on platforms where it makes a difference.

- In MSVC builds, handle the case where the openssl library is not within a `vc` subdirectory (Andrew Dunstan)
- In MSVC builds, add proper include path for libxml2 header files (Andrew Dunstan)

This fixes a former need to move things around in standard Windows installations of libxml2.

- In MSVC builds, recognize a Tcl library that is named `tcl86.lib` (Noah Misch)
- In MSVC builds, honor `PROVE_FLAGS` settings on `vc regress.pl`'s command line (Andrew Dunstan)

E.48. Release 9.6.3

Release date: 2017-05-11

This release contains a variety of fixes from 9.6.2. For information about new features in the 9.6 major release, see [Section E.51](#).

E.48.1. Migration to Version 9.6.3

A dump/restore is not required for those running 9.6.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are using third-party replication tools that depend on “logical decoding”, see the fourth changelog entry below.

Also, if you are upgrading from a version earlier than 9.6.2, see [Section E.49](#).

E.48.2. Changes

- Restrict visibility of `pg_user_mappings.umoptions`, to protect passwords stored as user mapping options (Michael Paquier, Feike Steenbergen)

The previous coding allowed the owner of a foreign server object, or anyone he has granted server `USAGE` permission to, to see the options for all user mappings associated with that server. This might well include passwords for other users. Adjust the view definition to match the behavior of `information_schema.user_mapping_options`, namely that these options are visible to the user being mapped, or if the mapping is for `PUBLIC` and the current user is the server owner, or if the current user is a superuser. (CVE-2017-7486)

By itself, this patch will only fix the behavior in newly initdb'd databases. If you wish to apply this change in an existing database, follow the corrected procedure shown in the changelog entry for CVE-2017-7547, in [Section E.47](#).

- Prevent exposure of statistical information via leaky operators (Peter Eisentraut)

Some selectivity estimation functions in the planner will apply user-defined operators to values obtained from `pg_statistic`, such as most common values and histogram entries. This occurs before table permissions are checked, so a nefarious user could exploit the behavior to obtain these values for table columns he does not have permission to read. To fix, fall back to a default estimate if the operator's implementation function is not certified leak-proof and the calling user does not have permission to read the table column whose statistics are needed. At least one of these criteria is satisfied in most cases in practice. (CVE-2017-7484)

- Restore libpq's recognition of the `PGREQUIRESSL` environment variable (Daniel Gustafsson)

Processing of this environment variable was unintentionally dropped in PostgreSQL 9.3, but its documentation remained. This creates a security hazard, since users might be relying on the environment variable to force SSL-encrypted connections, but that would no longer be guaranteed. Restore handling of the variable, but give it lower priority than `PGSSLMODE`, to avoid breaking configurations that work correctly with post-9.3 code. (CVE-2017-7485)

- Fix possibly-invalid initial snapshot during logical decoding (Petr Jelinek, Andres Freund)

The initial snapshot created for a logical decoding replication slot was potentially incorrect. This could cause third-party tools that use logical decoding to copy incomplete/inconsistent initial data. This was more likely to happen if the source server was busy at the time of slot creation, or if another logical slot already existed.

If you are using a replication tool that depends on logical decoding, and it should have copied a nonempty data set at the start of replication, it is advisable to recreate the replica after installing this update, or to verify its contents against the source server.

- Fix possible corruption of “init forks” of unlogged indexes (Robert Haas, Michael Paquier)

This could result in an unlogged index being set to an invalid state after a crash and restart. Such a problem would persist until the index was dropped and rebuilt.

- Fix incorrect reconstruction of `pg_subtrans` entries when a standby server replays a prepared but uncommitted two-phase transaction (Tom Lane)

In most cases this turned out to have no visible ill effects, but in corner cases it could result in circular references in `pg_subtrans`, potentially causing infinite loops in queries that examine rows modified by the two-phase transaction.

- Avoid possible crash in `walsender` due to failure to initialize a string buffer (Stas Kelvich, Fujii Masao)
- Fix possible crash when rescanning a nearest-neighbor index-only scan on a GiST index (Tom Lane)
- Prevent delays in postmaster's launching of multiple parallel worker processes (Tom Lane)

There could be a significant delay (up to tens of seconds) before satisfying a query's request for more than one worker process, or when multiple queries requested workers simultaneously. On most platforms this required unlucky timing, but on some it was the typical case.

- Fix postmaster's handling of `fork()` failure for a background worker process (Tom Lane)

Previously, the postmaster updated portions of its state as though the process had been launched successfully, resulting in subsequent confusion.

- Fix possible “no relation entry for relid 0” error when planning nested set operations (Tom Lane)
- Fix assorted minor issues in planning of parallel queries (Robert Haas)
- Avoid applying “physical targetlist” optimization to custom scans (Dmitry Ivanov, Tom Lane)

This optimization supposed that retrieving all columns of a tuple is inexpensive, which is true for ordinary Postgres tuples; but it might not be the case for a custom scan provider.

- Use the correct sub-expression when applying a `FOR ALL` row-level-security policy (Stephen Frost)

In some cases the `WITH CHECK` restriction would be applied when the `USING` restriction is more appropriate.

- Ensure parsing of queries in extension scripts sees the results of immediately-preceding DDL (Julien Rouhaud, Tom Lane)

Due to lack of a cache flush step between commands in an extension script file, non-utility queries might not see the effects of an immediately preceding catalog change, such as `ALTER TABLE ... RENAME`.

- Skip tablespace privilege checks when `ALTER TABLE ... ALTER COLUMN TYPE` rebuilds an existing index (Noah Misch)

The command failed if the calling user did not currently have `CREATE` privilege for the tablespace containing the index. That behavior seems unhelpful, so skip the check, allowing the index to be rebuilt where it is.

- Fix `ALTER TABLE ... VALIDATE CONSTRAINT` to not recurse to child tables when the constraint is marked `NO INHERIT` (Amit Langote)

This fix prevents unwanted “constraint does not exist” failures when no matching constraint is present in the child tables.

- Avoid dangling pointer in `COPY ... TO` when row-level security is active for the source table (Tom Lane)

Usually this had no ill effects, but sometimes it would cause unexpected errors or crashes.

- Avoid accessing an already-closed relcache entry in `CLUSTER` and `VACUUM FULL` (Tom Lane)

With some bad luck, this could lead to indexes on the target relation getting rebuilt with the wrong persistence setting.

- Fix `VACUUM` to account properly for pages that could not be scanned due to conflicting page pins (Andrew Gierth)

This tended to lead to underestimation of the number of tuples in the table. In the worst case of a small heavily-contended table, `VACUUM` could incorrectly report that the table contained no tuples, leading to very bad planning choices.

- Ensure that bulk-tuple-transfer loops within a hash join are interruptible by query cancel requests (Tom Lane, Thomas Munro)
- Fix incorrect support for certain `box` operators in SP-GiST (Nikita Glukhov)

SP-GiST index scans using the operators `&< &>` `&<|` and `|&>` would yield incorrect answers.

- Fix integer-overflow problems in `interval` comparison (Kyotaro Horiguchi, Tom Lane)

The comparison operators for type `interval` could yield wrong answers for intervals larger than about 296000 years. Indexes on columns containing such large values should be reindexed, since they may be corrupt.

- Fix `cursor_to_xml()` to produce valid output with `tableforest = false` (Thomas Munro, Peter Eisentraut)

Previously it failed to produce a wrapping `<table>` element.

- Fix roundoff problems in `float8_timestampz()` and `make_interval()` (Tom Lane)

These functions truncated, rather than rounded, when converting a floating-point value to integer microseconds; that could cause unexpectedly off-by-one results.

- Fix `pg_get_object_address()` to handle members of operator families correctly (Álvaro Herrera)
- Fix cancelling of `pg_stop_backup()` when attempting to stop a non-exclusive backup (Michael Paquier, David Steele)

If `pg_stop_backup()` was cancelled while waiting for a non-exclusive backup to end, related state was left inconsistent; a new exclusive backup could not be started, and there were other minor problems.

- Improve performance of `pg_timezone_names` view (Tom Lane, David Rowley)
- Reduce memory management overhead for contexts containing many large blocks (Tom Lane)
- Fix sloppy handling of corner-case errors from `lseek()` and `close()` (Tom Lane)

Neither of these system calls are likely to fail in typical situations, but if they did, `fd.c` could get quite confused.

- Fix incorrect check for whether postmaster is running as a Windows service (Michael Paquier)

This could result in attempting to write to the event log when that isn't accessible, so that no logging happens at all.

- Fix `ecpg` to support `COMMIT PREPARED` and `ROLLBACK PREPARED` (Masahiko Sawada)
- Fix a double-free error when processing dollar-quoted string literals in `ecpg` (Michael Meskes)
- Fix `pgbench` to handle the combination of `--connect` and `--rate` options correctly (Fabien Coelho)
- Fix `pgbench` to honor the long-form option spelling `--builtin`, as per its documentation (Tom Lane)
- Fix `pg_dump/pg_restore` to correctly handle privileges for the `public` schema when using `--clean` option (Stephen Frost)

Other schemas start out with no privileges granted, but `public` does not; this requires special-case treatment when it is dropped and restored due to the `--clean` option.

- In `pg_dump`, fix incorrect schema and owner marking for comments and security labels of some types of database objects (Giuseppe Broccolo, Tom Lane)

In simple cases this caused no ill effects; but for example, a schema-selective restore might omit comments it should include, because they were not marked as belonging to the schema of their associated object.

- Fix typo in `pg_dump`'s query for initial privileges of a procedural language (Peter Eisentraut)

This resulted in `pg_dump` always believing that the language had no initial privileges. Since that's true for most procedural languages, ill effects from this bug are probably rare.

- Avoid emitting an invalid list file in `pg_restore -l` when SQL object names contain newlines (Tom Lane)

Replace newlines by spaces, which is sufficient to make the output valid for `pg_restore -L`'s purposes.

- Fix `pg_upgrade` to transfer comments and security labels attached to “large objects” (blobs) (Stephen Frost)

Previously, blobs were correctly transferred to the new database, but any comments or security labels attached to them were lost.

- Improve error handling in `contrib/adminpack`'s `pg_file_write()` function (Noah Misch)

Notably, it failed to detect errors reported by `fclose()`.

- In `contrib/dblink`, avoid leaking the previous unnamed connection when establishing a new unnamed connection (Joe Conway)
- Fix `contrib/pg_trgm`'s extraction of trigrams from regular expressions (Tom Lane)

In some cases it would produce a broken data structure that could never match anything, leading to GIN or GiST indexscans that use a trigram index not finding any matches to the regular expression.

- In `contrib/postgres_fdw`, allow join conditions that contain shippable extension-provided functions to be pushed to the remote server (David Rowley, Ashutosh Bapat)
- Support Tcl 8.6 in MSVC builds (Álvaro Herrera)
- Sync our copy of the timezone library with IANA release `tzcode2017b` (Tom Lane)

This fixes a bug affecting some DST transitions in January 2038.

- Update time zone data files to `tzdata` release 2017b for DST law changes in Chile, Haiti, and Mongolia, plus historical corrections for Ecuador, Kazakhstan, Liberia, and Spain. Switch to

numeric abbreviations for numerous time zones in South America, the Pacific and Indian oceans, and some Asian and Middle Eastern countries.

The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the `pg_timezone_names` view nor used for output.

- Use correct daylight-savings rules for POSIX-style time zone names in MSVC builds (David Rowley)

The Microsoft MSVC build scripts neglected to install the `posixrules` file in the `timezone` directory tree. This resulted in the `timezone` code falling back to its built-in rule about what DST behavior to assume for a POSIX-style time zone name. For historical reasons that still corresponds to the DST rules the USA was using before 2007 (i.e., change on first Sunday in April and last Sunday in October). With this fix, a POSIX-style zone name will use the current and historical DST transition dates of the `US/Eastern` zone. If you don't want that, remove the `posixrules` file, or replace it with a copy of some other zone file (see [Section 8.5.3](#)). Note that due to caching, you may need to restart the server to get such changes to take effect.

E.49. Release 9.6.2

Release date: 2017-02-09

This release contains a variety of fixes from 9.6.1. For information about new features in the 9.6 major release, see [Section E.51](#).

E.49.1. Migration to Version 9.6.2

A dump/restore is not required for those running 9.6.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted indexes.

Also, if you are upgrading from a version earlier than 9.6.1, see [Section E.50](#).

E.49.2. Changes

- Fix a race condition that could cause indexes built with `CREATE INDEX CONCURRENTLY` to be corrupt (Pavan Deolasee, Tom Lane)

If `CREATE INDEX CONCURRENTLY` was used to build an index that depends on a column not previously indexed, then rows updated by transactions that ran concurrently with the `CREATE INDEX` command could have received incorrect index entries. If you suspect this may have happened, the most reliable solution is to rebuild affected indexes after installing this update.

- Ensure that the special snapshot used for catalog scans is not invalidated by premature data pruning (Tom Lane)

Backends failed to account for this snapshot when advertising their oldest `xmin`, potentially allowing concurrent vacuuming operations to remove data that was still needed. This led to transient failures along the lines of “cache lookup failed for relation 1255”.

- Fix incorrect WAL logging for BRIN indexes (Kuntal Ghosh)

The WAL record emitted for a BRIN “revmap” page when moving an index tuple to a different page was incorrect. Replay would make the related portion of the index useless, forcing it to be recomputed.

- Unconditionally WAL-log creation of the “init fork” for an unlogged table (Michael Paquier)

Previously, this was skipped when `wal_level = minimal`, but actually it's necessary even in that case to ensure that the unlogged table is properly reset to empty after a crash.

- If the stats collector dies during hot standby, restart it (Takayuki Tsunakawa)
- Ensure that hot standby feedback works correctly when it's enabled at standby server start (Ants Aasma, Craig Ringer)
- Check for interrupts while hot standby is waiting for a conflicting query (Simon Riggs)
- Avoid constantly respawning the autovacuum launcher in a corner case (Amit Khandekar)

This fix avoids problems when autovacuum is nominally off and there are some tables that require freezing, but all such tables are already being processed by autovacuum workers.

- Disallow setting the `num_sync` field to zero in `synchronous_standby_names` (Fujii Masao)

The correct way to disable synchronous standby is to set the whole value to an empty string.

- Don't count background worker processes against a user's connection limit (David Rowley)
- Fix check for when an extension member object can be dropped (Tom Lane)

Extension upgrade scripts should be able to drop member objects, but this was disallowed for serial-column sequences, and possibly other cases.

- Fix tracking of initial privileges for extension member objects so that it works correctly with `ALTER EXTENSION ... ADD/DROP` (Stephen Frost)

An object's current privileges at the time it is added to the extension will now be considered its default privileges; only later changes in its privileges will be dumped by subsequent `pg_dump` runs.

- Make sure `ALTER TABLE` preserves index tablespace assignments when rebuilding indexes (Tom Lane, Michael Paquier)

Previously, non-default settings of `default_tablespace` could result in broken indexes.

- Fix incorrect updating of trigger function properties when changing a foreign-key constraint's deferrability properties with `ALTER TABLE ... ALTER CONSTRAINT` (Tom Lane)

This led to odd failures during subsequent exercise of the foreign key, as the triggers were fired at the wrong times.

- Prevent dropping a foreign-key constraint if there are pending trigger events for the referenced relation (Tom Lane)

This avoids “could not find trigger *NNN*” or “relation *NNN* has no triggers” errors.

- Fix `ALTER TABLE ... SET DATA TYPE ... USING` when child table has different column ordering than the parent (Álvaro Herrera)

Failure to adjust the column numbering in the `USING` expression led to errors, typically “attribute *N* has wrong type”.

- Fix processing of OID column when a table with OIDs is associated to a parent with OIDs via `ALTER TABLE ... INHERIT` (Amit Langote)

The OID column should be treated the same as regular user columns in this case, but it wasn't, leading to odd behavior in later inheritance changes.

- Ensure that `CREATE TABLE ... LIKE ... WITH OIDS` creates a table with OIDs, whether or not the `LIKE`-referenced table(s) have OIDs (Tom Lane)
- Fix `CREATE OR REPLACE VIEW` to update the view query before attempting to apply the new view options (Dean Rasheed)

Previously the command would fail if the new options were inconsistent with the old view definition.

- Report correct object identity during `ALTER TEXT SEARCH CONFIGURATION` (Artur Zakirov)

The wrong catalog OID was reported to extensions such as logical decoding.

- Fix commit timestamp mechanism to not fail when queried about the special XIDs `FrozenTransactionId` and `BootstrapTransactionId` (Craig Ringer)
- Fix incorrect use of view reloptions as regular table reloptions (Tom Lane)

The symptom was spurious “ON CONFLICT is not supported on table ... used as a catalog table” errors when the target of `INSERT ... ON CONFLICT` is a view with cascade option.

- Fix incorrect “target lists can have at most *N* entries” complaint when using `ON CONFLICT` with wide tables (Tom Lane)
- Fix spurious “query provides a value for a dropped column” errors during `INSERT` or `UPDATE` on a table with a dropped column (Tom Lane)
- Prevent multicolumn expansion of `foo.*` in an `UPDATE` source expression (Tom Lane)

This led to “UPDATE target count mismatch --- internal error”. Now the syntax is understood as a whole-row variable, as it would be in other contexts.

- Ensure that column typmods are determined accurately for multi-row `VALUES` constructs (Tom Lane)

This fixes problems occurring when the first value in a column has a determinable typmod (e.g., length for a `varchar` value) but later values don't share the same limit.

- Throw error for an unfinished Unicode surrogate pair at the end of a Unicode string (Tom Lane)

Normally, a Unicode surrogate leading character must be followed by a Unicode surrogate trailing character, but the check for this was missed if the leading character was the last character in a Unicode string literal (`U&'...'`) or Unicode identifier (`U&"..."`).

- Fix execution of `DISTINCT` and ordered aggregates when multiple such aggregates are able to share the same transition state (Heikki Linnakangas)
- Fix implementation of phrase search operators in `tsquery` (Tom Lane)

Remove incorrect, and inconsistently-applied, rewrite rules that tried to transform away `AND/OR/NOT` operators appearing below a `PHRASE` operator; instead upgrade the execution engine to handle such cases correctly. This fixes assorted strange behavior and possible crashes for text search queries containing such combinations. Also fix nested `PHRASE` operators to work sanely in combinations other than simple left-deep trees, correct the behavior when removing stopwords from a phrase search clause, and make sure that index searches behave consistently with simple sequential-scan application of such queries.

- Ensure that a purely negative text search query, such as `!foo`, matches empty `tsvectors` (Tom Dunstan)

Such matches were found by GIN index searches, but not by sequential scans or GiST index searches.

- Prevent crash when `ts_rewrite()` replaces a non-top-level subtree with an empty query (Artur Zakirov)
- Fix performance problems in `ts_rewrite()` (Tom Lane)
- Fix `ts_rewrite()`'s handling of nested `NOT` operators (Tom Lane)
- Improve speed of user-defined aggregates that use `array_append()` as transition function (Tom Lane)

- Fix `array_fill()` to handle empty arrays properly (Tom Lane)
- Fix possible crash in `array_position()` or `array_positions()` when processing arrays of records (Junseok Yang)
- Fix one-byte buffer overrun in `quote_literal_cstr()` (Heikki Linnakangas)

The overrun occurred only if the input consisted entirely of single quotes and/or backslashes.

- Prevent multiple calls of `pg_start_backup()` and `pg_stop_backup()` from running concurrently (Michael Paquier)

This avoids an assertion failure, and possibly worse things, if someone tries to run these functions in parallel.

- Disable transform that attempted to remove no-op `AT TIME ZONE` conversions (Tom Lane)

This resulted in wrong answers when the simplified expression was used in an index condition.

- Avoid discarding `interval-to-interval` casts that aren't really no-ops (Tom Lane)

In some cases, a cast that should result in zeroing out low-order `interval` fields was mistakenly deemed to be a no-op and discarded. An example is that casting from `INTERVAL MONTH` to `INTERVAL YEAR` failed to clear the months field.

- Fix crash if the number of workers available to a parallel query decreases during a rescan (Andreas Seltenreich)
- Fix bugs in transmitting GUC parameter values to parallel workers (Michael Paquier, Tom Lane)
- Allow statements prepared with `PREPARE` to be given parallel plans (Amit Kapila, Tobias Bussmann)
- Fix incorrect generation of parallel plans for semi-joins (Tom Lane)
- Fix planner's cardinality estimates for parallel joins (Robert Haas)

Ensure that these estimates reflect the number of rows predicted to be seen by each worker, rather than the total.

- Fix planner to avoid trying to parallelize plan nodes containing `initplans` or `subplans` (Tom Lane, Amit Kapila)
- Ensure that cached plans are invalidated by changes in foreign-table options (Amit Langote, Etsuro Fujita, Ashutosh Bapat)
- Fix the plan generated for sorted partial aggregation with a constant `GROUP BY` clause (Tom Lane)
- Fix “could not find plan for CTE” planner error when dealing with a `UNION ALL` containing CTE references (Tom Lane)
- Fix mishandling of `initplans` when forcibly adding a Material node to a subplan (Tom Lane)

The typical consequence of this mistake was a “plan should not reference subplan's variable” error.

- Fix foreign-key-based join selectivity estimation for semi-joins and anti-joins, as well as inheritance cases (Tom Lane)

The new code for taking the existence of a foreign key relationship into account did the wrong thing in these cases, making the estimates worse not better than the pre-9.6 code.

- Fix `pg_dump` to emit the data of a sequence that is marked as an extension configuration table (Michael Paquier)
- Fix mishandling of `ALTER DEFAULT PRIVILEGES ... REVOKE` in `pg_dump` (Stephen Frost)

`pg_dump` missed issuing the required `REVOKE` commands in cases where `ALTER DEFAULT PRIVILEGES` had been used to reduce privileges to less than they would normally be.

- Fix `pg_dump` to dump user-defined casts and transforms that use built-in functions (Stephen Frost)
- Fix `pg_restore` with `--create --if-exists` to behave more sanely if an archive contains unrecognized `DROP` commands (Tom Lane)

This doesn't fix any live bug, but it may improve the behavior in future if `pg_restore` is used with an archive generated by a later `pg_dump` version.

- Fix `pg_basebackup`'s rate limiting in the presence of slow I/O (Antonin Houska)

If disk I/O was transiently much slower than the specified rate limit, the calculation overflowed, effectively disabling the rate limit for the rest of the run.

- Fix `pg_basebackup`'s handling of symlinked `pg_stat_tmp` and `pg_replslot` subdirectories (Magnus Hagander, Michael Paquier)
- Fix possible `pg_basebackup` failure on standby server when including WAL files (Amit Kapila, Robert Haas)
- Improve `initdb` to insert the correct platform-specific default values for the `xxx_flush_after` parameters into `postgresql.conf` (Fabien Coelho, Tom Lane)

This is a cleaner way of documenting the default values than was used previously.

- Fix possible mishandling of expanded arrays in domain check constraints and `CASE` execution (Tom Lane)

It was possible for a PL/pgSQL function invoked in these contexts to modify or even delete an array value that needs to be preserved for additional operations.

- Fix nested uses of PL/pgSQL functions in contexts such as domain check constraints evaluated during assignment to a PL/pgSQL variable (Tom Lane)
- Ensure that the Python exception objects we create for PL/Python are properly reference-counted (Rafa de la Torre, Tom Lane)

This avoids failures if the objects are used after a Python garbage collection cycle has occurred.

- Fix PL/Tcl to support triggers on tables that have `.tupno` as a column name (Tom Lane)

This matches the (previously undocumented) behavior of PL/Tcl's `spi_exec` and `spi_execp` commands, namely that a magic `.tupno` column is inserted only if there isn't a real column named that.

- Allow DOS-style line endings in `~/.pgpass` files, even on Unix (Vik Fearing)

This change simplifies use of the same password file across Unix and Windows machines.

- Fix one-byte buffer overrun if `ecpg` is given a file name that ends with a dot (Takayuki Tsunakawa)
- Fix incorrect error reporting for duplicate data in `psql`'s `\crosstabview` (Tom Lane)

`psql` sometimes quoted the wrong row and/or column values when complaining about multiple entries for the same crosstab cell.

- Fix `psql`'s tab completion for `ALTER DEFAULT PRIVILEGES` (Gilles Darold, Stephen Frost)
- Fix `psql`'s tab completion for `ALTER TABLE t ALTER c DROP ...` (Kyotaro Horiguchi)
- In `psql`, treat an empty or all-blank setting of the `PAGER` environment variable as meaning “no pager” (Tom Lane)

Previously, such a setting caused output intended for the pager to vanish entirely.

- Improve `contrib/dblink`'s reporting of low-level libpq errors, such as out-of-memory (Joe Conway)
- Teach `contrib/dblink` to ignore irrelevant server options when it uses a `contrib/postgres_fdw` foreign server as the source of connection options (Corey Huinker)

Previously, if the foreign server object had options that were not also libpq connection options, an error occurred.

- Fix portability problems in `contrib/pageinspect`'s functions for GIN indexes (Peter Eisentraut, Tom Lane)
- Fix possible miss of socket read events while waiting on Windows (Amit Kapila)

This error was harmless for most uses, but it is known to cause hangs when trying to use the `pldebugger` extension.

- On Windows, ensure that environment variable changes are propagated to DLLs built with debug options (Christian Ullrich)
- Sync our copy of the timezone library with IANA release `tzcode2016j` (Tom Lane)

This fixes various issues, most notably that timezone data installation failed if the target directory didn't support hard links.

- Update time zone data files to `tzdata` release 2016j for DST law changes in northern Cyprus (adding a new zone Asia/Famagusta), Russia (adding a new zone Europe/Saratov), Tonga, and Antarctica/Casey. Historical corrections for Italy, Kazakhstan, Malta, and Palestine. Switch to preferring numeric zone abbreviations for Tonga.

E.50. Release 9.6.1

Release date: 2016-10-27

This release contains a variety of fixes from 9.6.0. For information about new features in the 9.6 major release, see [Section E.51](#).

E.50.1. Migration to Version 9.6.1

A dump/restore is not required for those running 9.6.X.

However, if your installation has been affected by the bugs described in the first two changelog entries below, then after updating you may need to take action to repair corrupted free space maps and/or visibility maps.

E.50.2. Changes

- Fix WAL-logging of truncation of relation free space maps and visibility maps (Pavan Deolasee, Heikki Linnakangas)

It was possible for these files to not be correctly restored during crash recovery, or to be written incorrectly on a standby server. Bogus entries in a free space map could lead to attempts to access pages that have been truncated away from the relation itself, typically producing errors like “could not read block `xxx`: read only 0 of 8192 bytes”. Checksum failures in the visibility map are also possible, if checksumming is enabled.

Procedures for determining whether there is a problem and repairing it if so are discussed at https://wiki.postgresql.org/wiki/Free_Space_Map_Problems.

- Fix possible data corruption when `pg_upgrade` rewrites a relation visibility map into 9.6 format (Tom Lane)

On big-endian machines, bytes of the new visibility map were written in the wrong order, leading to a completely incorrect map. On Windows, the old map was read using text mode, leading to incorrect results if the map happened to contain consecutive bytes that matched a carriage return/line feed sequence. The latter error would almost always lead to a `pg_upgrade` failure due to the map file appearing to be the wrong length.

If you are using a big-endian machine (many non-Intel architectures are big-endian) and have used `pg_upgrade` to upgrade from a pre-9.6 release, you should assume that all visibility maps are incorrect and need to be regenerated. It is sufficient to truncate each relation's visibility map with `contrib/pg_visibility's pg_truncate_visibility_map()` function. For more information see https://wiki.postgresql.org/wiki/Visibility_Map_Problems.

- Don't throw serialization errors for self-conflicting insertions in `INSERT ... ON CONFLICT` (Thomas Munro, Peter Geoghegan)
- Fix use-after-free hazard in execution of aggregate functions using `DISTINCT` (Peter Geoghegan)

This could lead to a crash or incorrect query results.

- Fix incorrect handling of polymorphic aggregates used as window functions (Tom Lane)

The aggregate's transition function was told that its first argument and result were of the aggregate's output type, rather than the state type. This led to errors or crashes with polymorphic transition functions.

- Fix `COPY` with a column name list from a table that has row-level security enabled (Adam Brightwell)
- Fix `EXPLAIN` to emit valid XML when `track_io_timing` is on (Markus Winand)

Previously the XML output-format option produced syntactically invalid tags such as `<I/O-Read-Time>`. That is now rendered as `<I-O-Read-Time>`.

- Fix statistics update for `TRUNCATE` in a prepared transaction (Stas Kelvich)
- Fix bugs in merging inherited `CHECK` constraints while creating or altering a table (Tom Lane, Amit Langote)

Allow identical `CHECK` constraints to be added to a parent and child table in either order. Prevent merging of a valid constraint from the parent table with a `NOT VALID` constraint on the child. Likewise, prevent merging of a `NO INHERIT` child constraint with an inherited constraint.

- Show a sensible value in `pg_settings.unit` for `min_wal_size` and `max_wal_size` (Tom Lane)
- Fix replacement of array elements in `jsonb_set()` (Tom Lane)

If the target is an existing JSON array element, it got deleted instead of being replaced with a new value.

- Avoid very-low-probability data corruption due to testing tuple visibility without holding buffer lock (Thomas Munro, Peter Geoghegan, Tom Lane)
- Preserve commit timestamps across server restart (Julien Rouhaud, Craig Ringer)

With `track_commit_timestamp` turned on, old commit timestamps became inaccessible after a clean server restart.

- Fix logical WAL decoding to work properly when a subtransaction's WAL output is large enough to spill to disk (Andres Freund)
- Fix dangling-pointer problem in logical WAL decoding (Stas Kelvich)
- Round shared-memory allocation request to a multiple of the actual huge page size when attempting to use huge pages on Linux (Tom Lane)

This avoids possible failures during `munmap()` on systems with atypical default huge page sizes. Except in crash-recovery cases, there were no ill effects other than a log message.

- Don't try to share SSL contexts across multiple connections in `libpq` (Heikki Linnakangas)

This led to assorted corner-case bugs, particularly when trying to use different SSL parameters for different connections.

- Avoid corner-case memory leak in libpq (Tom Lane)

The reported problem involved leaking an error report during `PQreset()`, but there might be related cases.

- In `pg_upgrade`, check library loadability in name order (Tom Lane)

This is a workaround to deal with cross-extension dependencies from language transform modules to their base language and data type modules.

- Fix `pg_upgrade` to work correctly for extensions containing index access methods (Tom Lane)

To allow this, the server has been extended to support `ALTER EXTENSION ADD/DROP ACCESS METHOD`. That functionality should have been included in the original patch to support dynamic creation of access methods, but it was overlooked.

- Improve error reporting in `pg_upgrade`'s file copying/linking/rewriting steps (Tom Lane, Álvaro Herrera)
- Fix `pg_dump` to work against pre-7.4 servers (Amit Langote, Tom Lane)
- Disallow specifying both `--source-server` and `--source-target` options to `pg_rewind` (Michael Banck)
- Make `pg_rewind` turn off `synchronous_commit` in its session on the source server (Michael Banck, Michael Paquier)

This allows `pg_rewind` to work even when the source server is using synchronous replication that is not working for some reason.

- In `pg_xlogdump`, retry opening new WAL segments when using `--follow` option (Magnus Hagander)

This allows for a possible delay in the server's creation of the next segment.

- Fix `contrib/pg_visibility` to report the correct TID for a corrupt tuple that has been the subject of a rolled-back update (Tom Lane)
- Fix makefile dependencies so that parallel make of PL/Python by itself will succeed reliably (Pavel Raiskup)
- Update time zone data files to tzdata release 2016h for DST law changes in Palestine and Turkey, plus historical corrections for Turkey and some regions of Russia. Switch to numeric abbreviations for some time zones in Antarctica, the former Soviet Union, and Sri Lanka.

The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the `pg_timezone_names` view nor used for output.

In this update, `AMT` is no longer shown as being in use to mean Armenia Time. Therefore, we have changed the `Default` abbreviation set to interpret it as Amazon Time, thus UTC-4 not UTC+4.

E.51. Release 9.6

Release date: 2016-09-29

E.51.1. Overview

Major enhancements in PostgreSQL 9.6 include:

- Parallel execution of sequential scans, joins and aggregates

- Avoid scanning pages unnecessarily during vacuum freeze operations
- Synchronous replication now allows multiple standby servers for increased reliability
- Full-text search can now search for phrases (multiple adjacent words)
- `postgres_fdw` now supports remote joins, sorts, `UPDATES`, and `DELETES`
- Substantial performance improvements, especially in the area of scalability on multi-CPU-socket servers

The above items are explained in more detail in the sections below.

E.51.2. Migration to Version 9.6

A dump/restore using [pg_dumpall](#), or use of [pg_upgrade](#), is required for those wishing to migrate data from any previous release.

Version 9.6 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

- Improve the `pg_stat_activity` view's information about what a process is waiting for (Amit Kapila, Ildus Kurbangaliev)

Historically a process has only been shown as waiting if it was waiting for a heavyweight lock. Now waits for lightweight locks and buffer pins are also shown in `pg_stat_activity`. Also, the type of lock being waited for is now visible. These changes replace the `waiting` column with `wait_event_type` and `wait_event`.

- In `to_char()`, do not count a minus sign (when needed) as part of the field width for time-related fields (Bruce Momjian)

For example, `to_char('-4 years'::interval, 'YY')` now returns `-04`, rather than `-4`.

- Make `extract()` behave more reasonably with infinite inputs (Vitaly Burovoy)

Historically the `extract()` function just returned zero given an infinite timestamp, regardless of the given field name. Make it return `infinity` or `-infinity` as appropriate when the requested field is one that is monotonically increasing (e.g., `year`, `epoch`), or `NULL` when it is not (e.g., `day`, `hour`). Also, throw the expected error for bad field names.

- Remove PL/pgSQL's "feature" that suppressed the innermost line of `CONTEXT` for messages emitted by `RAISE` commands (Pavel Stehule)

This ancient backwards-compatibility hack was agreed to have outlived its usefulness.

- Fix the default text search parser to allow leading digits in `email` and `host` tokens (Artur Zakirov)

In most cases this will result in few changes in the parsing of text. But if you have data where such addresses occur frequently, it may be worth rebuilding dependent `tsvector` columns and indexes so that addresses of this form will be found properly by text searches.

- Extend `contrib/unaccent`'s standard `unaccent.rules` file to handle all diacritics known to Unicode, and to expand ligatures correctly (Thomas Munro, Léonard Benedetti)

The previous version neglected to convert some less-common letters with diacritic marks. Also, ligatures are now expanded into separate letters. Installations that use this rules file may wish to rebuild `tsvector` columns and indexes that depend on the result.

- Remove the long-deprecated `CREATEUSER/NOCREATEUSER` options from `CREATE ROLE` and allied commands (Tom Lane)

`CREATEUSER` actually meant `SUPERUSER`, for ancient backwards-compatibility reasons. This has been a constant source of confusion for people who (reasonably) expect it to mean `CREATEROLE`. It has been deprecated for ten years now, so fix the problem by removing it.

- Treat role names beginning with `pg_` as reserved (Stephen Frost)

User creation of such role names is now disallowed. This prevents conflicts with built-in roles created by `initdb`.

- Change a column name in the `information_schema.routines` view from `result_cast_character_set_name` to `result_cast_char_set_name` (Clément Prévost)

The SQL:2011 standard specifies the longer name, but that appears to be a mistake, because adjacent column names use the shorter style, as do other `information_schema` views.

- `psql`'s `-c` option no longer implies `--no-psqlrc` (Pavel Stehule, Catalin Iacob)

Write `--no-psqlrc` (or its abbreviation `-x`) explicitly to obtain the old behavior. Scripts so modified will still work with old versions of `psql`.

- Improve `pg_restore`'s `-t` option to match all types of relations, not only plain tables (Craig Ringer)
- Change the display format used for `NextXID` in `pg_controldata` and related places (Joe Conway, Bruce Momjian)

Display epoch-and-transaction-ID values in the format `number:number`. The previous format `number/number` was confusingly similar to that used for LSNs.

- Update extension functions to be marked parallel-safe where appropriate (Andreas Karlsson)

Many of the standard extensions have been updated to allow their functions to be executed within parallel query worker processes. These changes will not take effect in databases `pg_upgrade`'d from prior versions unless you apply `ALTER EXTENSION UPDATE` to each such extension (in each database of a cluster).

E.51.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 9.6 and the previous major release.

E.51.3.1. Server

E.51.3.1.1. Parallel Queries

- Parallel queries (Robert Haas, Amit Kapila, David Rowley, many others)

With 9.6, PostgreSQL introduces initial support for parallel execution of large queries. Only strictly read-only queries where the driving table is accessed via a sequential scan can be parallelized. Hash joins and nested loops can be performed in parallel, as can aggregation (for supported aggregates). Much remains to be done, but this is already a useful set of features.

Parallel query execution is not (yet) enabled by default. To allow it, set the new configuration parameter `max_parallel_workers_per_gather` to a value larger than zero. Additional control over use of parallelism is available through other new configuration parameters `force_parallel_mode`, `parallel_setup_cost`, `parallel_tuple_cost`, and `min_parallel_relation_size`.

- Provide infrastructure for marking the parallel-safety status of functions (Robert Haas, Amit Kapila)

E.51.3.1.2. Indexes

- Allow `GIN` index builds to make effective use of `maintenance_work_mem` settings larger than 1 GB (Robert Abraham, Teodor Sigaev)
- Add pages deleted from a `GIN` index's pending list to the free space map immediately (Jeff Janes, Teodor Sigaev)

This reduces bloat if the table is not vacuumed often.

- Add `gin_clean_pending_list()` function to allow manual invocation of pending-list cleanup for a GIN index (Jeff Janes)

Formerly, such cleanup happened only as a byproduct of vacuuming or analyzing the parent table.

- Improve handling of dead index tuples in **GiST** indexes (Anastasia Lubennikova)

Dead index tuples are now marked as such when an index scan notices that the corresponding heap tuple is dead. When inserting tuples, marked-dead tuples will be removed if needed to make space on the page.

- Add an **SP-GiST** operator class for type `box` (Alexander Lebedev)

E.51.3.1.3. Sorting

- Improve sorting performance by using quicksort, not replacement selection sort, when performing external sort steps (Peter Geoghegan)

The new approach makes better use of the CPU cache for typical cache sizes and data volumes. Where necessary, the behavior can be adjusted via the new configuration parameter `replacement_sort_tuples`.

- Speed up text sorts where the same string occurs multiple times (Peter Geoghegan)
- Speed up sorting of `uuid`, `bytea`, and `char(n)` fields by using “abbreviated” keys (Peter Geoghegan)

Support for abbreviated keys has also been added to the non-default operator classes `text_pattern_ops`, `varchar_pattern_ops`, and `bpchar_pattern_ops`. Processing of ordered-set aggregates can also now exploit abbreviated keys.

- Speed up `CREATE INDEX CONCURRENTLY` by treating TIDs as 64-bit integers during sorting (Peter Geoghegan)

E.51.3.1.4. Locking

- Reduce contention for the `ProcArrayLock` (Amit Kapila, Robert Haas)
- Improve performance by moving buffer content locks into the buffer descriptors (Andres Freund, Simon Riggs)
- Replace shared-buffer header spinlocks with atomic operations to improve scalability (Alexander Korotkov, Andres Freund)
- Use atomic operations, rather than a spinlock, to protect an `LWLock`'s wait queue (Andres Freund)
- Partition the shared hash table freelist to reduce contention on multi-CPU-socket servers (Aleksander Alekseev)
- Reduce interlocking on standby servers during the replay of btree index vacuuming operations (Simon Riggs)

This change avoids substantial replication delays that sometimes occurred while replaying such operations.

E.51.3.1.5. Optimizer Statistics

- Improve `ANALYZE`'s estimates for columns with many nulls (Tomas Vondra, Alex Shulgin)

Previously `ANALYZE` tended to underestimate the number of non-NULL distinct values in a column with many NULLs, and was also inaccurate in computing the most-common values.

- Improve planner's estimate of the number of distinct values in a query result (Tomas Vondra)
- Use foreign key relationships to infer selectivity for join predicates (Tomas Vondra, David Rowley)

If a table `t` has a foreign key restriction, say `(a,b) REFERENCES r (x,y)`, then a `WHERE` condition such as `t.a = r.x AND t.b = r.y` cannot select more than one `r` row per `t` row. The planner

formerly considered these `AND` conditions to be independent and would often drastically misestimate selectivity as a result. Now it compares the `WHERE` conditions to applicable foreign key constraints and produces better estimates.

E.51.3.1.6. VACUUM

- Avoid re-vacuuming pages containing only frozen tuples (Masahiko Sawada, Robert Haas, Andres Freund)

Formerly, anti-wraparound vacuum had to visit every page of a table, even pages where there was nothing to do. Now, pages containing only already-frozen tuples are identified in the table's visibility map, and can be skipped by vacuum even when doing transaction wraparound prevention. This should greatly reduce the cost of maintaining large tables containing mostly-unchanging data.

If necessary, vacuum can be forced to process all-frozen pages using the new `DISABLE_PAGE_SKIPPING` option. Normally this should never be needed, but it might help in recovering from visibility-map corruption.

- Avoid useless heap-truncation attempts during `VACUUM` (Jeff Janes, Tom Lane)

This change avoids taking an exclusive table lock in some cases where no truncation is possible. The main benefit comes from avoiding unnecessary query cancellations on standby servers.

E.51.3.1.7. General Performance

- Allow old MVCC snapshots to be invalidated after a configurable timeout (Kevin Grittner)

Normally, deleted tuples cannot be physically removed by vacuuming until the last transaction that could “see” them is gone. A transaction that stays open for a long time can thus cause considerable table bloat because space cannot be recycled. This feature allows setting a time-based limit, via the new configuration parameter `old_snapshot_threshold`, on how long an MVCC snapshot is guaranteed to be valid. After that, dead tuples are candidates for removal. A transaction using an outdated snapshot will get an error if it attempts to read a page that potentially could have contained such data.

- Ignore `GROUP BY` columns that are functionally dependent on other columns (David Rowley)

If a `GROUP BY` clause includes all columns of a non-deferred primary key, as well as other columns of the same table, those other columns are redundant and can be dropped from the grouping. This saves computation in many common cases.

- Allow use of an `index-only scan` on a partial index when the index's `WHERE` clause references columns that are not indexed (Tomas Vondra, Kyotaro Horiguchi)

For example, an index defined by `CREATE INDEX tidx_partial ON t(b) WHERE a > 0` can now be used for an index-only scan by a query that specifies `WHERE a > 0` and does not otherwise use `a`. Previously this was disallowed because `a` is not listed as an index column.

- Perform checkpoint writes in sorted order (Fabien Coelho, Andres Freund)

Previously, checkpoints wrote out dirty pages in whatever order they happen to appear in shared buffers, which usually is nearly random. That performs poorly, especially on rotating media. This change causes checkpoint-driven writes to be done in order by file and block number, and to be balanced across tablespaces.

- Where feasible, trigger kernel writeback after a configurable number of writes, to prevent accumulation of dirty data in kernel disk buffers (Fabien Coelho, Andres Freund)

PostgreSQL writes data to the kernel's disk cache, from where it will be flushed to physical storage in due time. Many operating systems are not smart about managing this and allow large amounts of dirty data to accumulate before deciding to flush it all at once, causing long delays for new I/O requests until the flushing finishes. This change attempts to alleviate this problem by explicitly requesting data flushes after a configurable interval.

On Linux, `sync_file_range()` is used for this purpose, and the feature is on by default on Linux because that function has few downsides. This flushing capability is also available on other platforms if they have `msync()` or `posix_fadvise()`, but those interfaces have some undesirable side-effects so the feature is disabled by default on non-Linux platforms.

The new configuration parameters `backend_flush_after`, `bgwriter_flush_after`, `checkpoint_flush_after`, and `wal_writer_flush_after` control this behavior.

- Improve aggregate-function performance by sharing calculations across multiple aggregates if they have the same arguments and transition functions (David Rowley)

For example, `SELECT AVG(x), VARIANCE(x) FROM tab` can use a single per-row computation for both aggregates.

- Speed up visibility tests for recently-created tuples by checking the current transaction's snapshot, not `pg_clog`, to decide if the source transaction should be considered committed (Jeff Janes, Tom Lane)
- Allow tuple hint bits to be set sooner than before (Andres Freund)
- Improve performance of short-lived prepared transactions (Stas Kelvich, Simon Riggs, Pavan Deolasee)

Two-phase commit information is now written only to WAL during `PREPARE TRANSACTION`, and will be read back from WAL during `COMMIT PREPARED` if that happens soon thereafter. A separate state file is created only if the pending transaction does not get committed or aborted by the time of the next checkpoint.

- Improve performance of memory context destruction (Jan Wieck)
- Improve performance of resource owners with many tracked objects (Aleksander Alekseev)
- Improve speed of the output functions for `timestamp`, `time`, and `date` data types (David Rowley, Andres Freund)
- Avoid some unnecessary cancellations of hot-standby queries during replay of actions that take `AccessExclusive` locks (Jeff Janes)
- Extend relations multiple blocks at a time when there is contention for the relation's extension lock (Dilip Kumar)

This improves scalability by decreasing contention.

- Increase the number of clog buffers for better scalability (Amit Kapila, Andres Freund)
- Speed up expression evaluation in PL/pgSQL by keeping `ParamListInfo` entries for simple variables valid at all times (Tom Lane)
- Avoid reducing the `SO_SNDBUF` setting below its default on recent Windows versions (Chen Huajun)
- Disable `update_process_title` by default on Windows (Takayuki Tsunakawa)

The overhead of updating the process title is much larger on Windows than most other platforms, and it is also less useful to do it since most Windows users do not have tools that can display process titles.

E.51.3.1.8. Monitoring

- Add `pg_stat_progress_vacuum` system view to provide progress reporting for `VACUUM` operations (Amit Langote, Robert Haas, Vinayak Pokale, Rahila Syed)
- Add `pg_control_system()`, `pg_control_checkpoint()`, `pg_control_recovery()`, and `pg_control_init()` functions to expose fields of `pg_control` to SQL (Joe Conway, Michael Paquier)
- Add `pg_config` system view (Joe Conway)

This view exposes the same information available from the `pg_config` command-line utility, namely assorted compile-time configuration information for PostgreSQL.

- Add a `confirmed_flush_lsn` column to the `pg_replication_slots` system view (Marko Tiikkaja)
- Add `pg_stat_wal_receiver` system view to provide information about the state of a hot-standby server's WAL receiver process (Michael Paquier)
- Add `pg_blocking_pids()` function to reliably identify which sessions block which others (Tom Lane)

This function returns an array of the process IDs of any sessions that are blocking the session with the given process ID. Historically users have obtained such information using a self-join on the `pg_locks` view. However, it is unreasonably tedious to do it that way with any modicum of correctness, and the addition of parallel queries has made the old approach entirely impractical, since locks might be held or awaited by child worker processes rather than the session's main process.

- Add function `pg_current_xlog_flush_location()` to expose the current transaction log flush location (Tomas Vondra)
- Add function `pg_notification_queue_usage()` to report how full the `NOTIFY` queue is (Brendan Jurd)
- Limit the verbosity of memory context statistics dumps (Tom Lane)

The memory usage dump that is output to the postmaster log during an out-of-memory failure now summarizes statistics when there are a large number of memory contexts, rather than possibly generating a very large report. There is also a “grand total” summary line now.

E.51.3.1.9. Authentication

- Add a [BSD authentication method](#) to allow use of the BSD Authentication service for PostgreSQL client authentication (Marisa Emerson)

BSD Authentication is currently only available on OpenBSD.

- When using [PAM authentication](#), provide the client IP address or host name to PAM modules via the `PAM_RHOST` item (Grzegorz Sampolski)
- Provide detail in the postmaster log for more types of password authentication failure (Tom Lane)

All ordinarily-reachable password authentication failure cases should now provide specific `DETAIL` fields in the log.

- Support [RADIUS passwords](#) up to 128 characters long (Marko Tiikkaja)
- Add new [SSPI authentication](#) parameters `compat_realm` and `upn_username` to control whether NetBIOS or Kerberos realm names and user names are used during SSPI authentication (Christian Ullrich)

E.51.3.1.10. Server Configuration

- Allow sessions to be terminated automatically if they are in idle-in-transaction state for too long (Vik Fearing)

This behavior is controlled by the new configuration parameter [idle_in_transaction_session_timeout](#). It can be useful to prevent forgotten transactions from holding locks or preventing vacuum cleanup for too long.

- Raise the maximum allowed value of [checkpoint_timeout](#) to 24 hours (Simon Riggs)
- Allow `effective_io_concurrency` to be set per-tablespace to support cases where different tablespaces have different I/O characteristics (Julien Rouhaud)
- Add [log_line_prefix](#) option `%n` to print the current time in Unix epoch form, with milliseconds (Tomas Vondra, Jeff Davis)

- Add `syslog_sequence_numbers` and `syslog_split_messages` configuration parameters to provide more control over the message format when logging to syslog (Peter Eisentraut)
- Merge the `archive` and `hot_standby` values of the `wal_level` configuration parameter into a single new value `replica` (Peter Eisentraut)

Making a distinction between these settings is no longer useful, and merging them is a step towards a planned future simplification of replication setup. The old names are still accepted but are converted to `replica` internally.

- Add configure option `--with-systemd` to enable calling `sd_notify()` at server start and stop (Peter Eisentraut)

This allows the use of systemd service units of type `notify`, which greatly simplifies the management of PostgreSQL under systemd.

- Allow the server's SSL key file to have group read access if it is owned by `root` (Christoph Berg)

Formerly, we insisted the key file be owned by the user running the PostgreSQL server, but that is inconvenient on some systems (such as Debian) that are configured to manage certificates centrally. Therefore, allow the case where the key file is owned by `root` and has group read access. It is up to the operating system administrator to ensure that the group does not include any untrusted users.

E.51.3.1.11. Reliability

- Force backends to exit if the postmaster dies (Rajeev Rastogi, Robert Haas)

Under normal circumstances the postmaster should always outlive its child processes. If for some reason the postmaster dies, force backend sessions to exit with an error. Formerly, existing backends would continue to run until their clients disconnect, but that is unsafe and inefficient. It also prevents a new postmaster from being started until the last old backend has exited. Backends will detect postmaster death when waiting for client I/O, so the exit will not be instantaneous, but it should happen no later than the end of the current query.

- Check for serializability conflicts before reporting constraint-violation failures (Thomas Munro)

When using serializable transaction isolation, it is desirable that any error due to concurrent transactions should manifest as a serialization failure, thereby cueing the application that a retry might succeed. Unfortunately, this does not reliably happen for duplicate-key failures caused by concurrent insertions. This change ensures that such an error will be reported as a serialization error if the application explicitly checked for the presence of a conflicting key (and did not find it) earlier in the transaction.

- Ensure that invalidation messages are recorded in WAL even when issued by a transaction that has no XID assigned (Andres Freund)

This fixes some corner cases in which transactions on standby servers failed to notice changes, such as new indexes.

- Prevent multiple processes from trying to clean a GIN index's pending list concurrently (Teodor Sigaev, Jeff Janes)

This had been intentionally allowed, but it causes race conditions that can result in vacuum missing index entries it needs to delete.

E.51.3.2. Replication and Recovery

- Allow synchronous replication to support multiple simultaneous synchronous standby servers, not just one (Masahiko Sawada, Beena Emerson, Michael Paquier, Fujii Masao, Kyotaro Horiguchi)

The number of standby servers that must acknowledge a commit before it is considered complete is now configurable as part of the `synchronous_standby_names` parameter.

- Add new setting `remote_apply` for configuration parameter `synchronous_commit` (Thomas Munro)

In this mode, the master waits for the transaction to be *applied* on the standby server, not just written to disk. That means that you can count on a transaction started on the standby to see all commits previously acknowledged by the master.

- Add a feature to the replication protocol, and a corresponding option to `pg_create_physical_replication_slot()`, to allow reserving WAL immediately when creating a replication slot (Gurjeet Singh, Michael Paquier)

This allows the creation of a replication slot to guarantee that all the WAL needed for a base backup will be available.

- Add a `--slot` option to `pg_basebackup` (Peter Eisentraut)

This lets `pg_basebackup` use a replication slot defined for WAL streaming. After the base backup completes, selecting the same slot for regular streaming replication allows seamless startup of the new standby server.

- Extend `pg_start_backup()` and `pg_stop_backup()` to support non-exclusive backups (Magnus Hagander)

E.51.3.3. Queries

- Allow functions that return sets of tuples to return simple `NULLs` (Andrew Gierth, Tom Lane)

In the context of `SELECT FROM function(...)`, a function that returned a set of composite values was previously not allowed to return a plain `NULL` value as part of the set. Now that is allowed and interpreted as a row of `NULLs`. This avoids corner-case errors with, for example, unnesting an array of composite values.

- Fully support array subscripts and field selections in the target column list of an `INSERT` with multiple `VALUES` rows (Tom Lane)

Previously, such cases failed if the same target column was mentioned more than once, e.g., `INSERT INTO tab (x[1], x[2]) VALUES (...)`.

- When appropriate, postpone evaluation of `SELECT` output expressions until after an `ORDER BY` sort (Konstantin Knizhnik)

This change ensures that volatile or expensive functions in the output list are executed in the order suggested by `ORDER BY`, and that they are not evaluated more times than required when there is a `LIMIT` clause. Previously, these properties held if the ordering was performed by an index scan or pre-merge-join sort, but not if it was performed by a top-level sort.

- Widen counters recording the number of tuples processed to 64 bits (Andreas Scherbaum)

This change allows command tags, e.g., `SELECT`, to correctly report tuple counts larger than 4 billion. This also applies to PL/pgSQL's `GET DIAGNOSTICS ... ROW_COUNT` command.

- Avoid doing encoding conversions by converting through the `MULE_INTERNAL` encoding (Tom Lane)

Previously, many conversions for Cyrillic and Central European single-byte encodings were done by converting to a related `MULE_INTERNAL` coding scheme and then to the destination encoding. Aside from being inefficient, this meant that when the conversion encountered an untranslatable character, the error message would confusingly complain about failure to convert to or from `MULE_INTERNAL`, rather than the user-visible encoding.

- Consider performing joins of foreign tables remotely only when the tables will be accessed under the same role ID (Shigeru Hanada, Ashutosh Bapat, Etsuro Fujita)

Previously, the foreign join pushdown infrastructure left the question of security entirely up to individual foreign data wrappers, but that made it too easy for an FDW to inadvertently create

subtle security holes. So, make it the core code's job to determine which role ID will access each table, and do not attempt join pushdown unless the role is the same for all relevant relations.

E.51.3.4. Utility Commands

- Allow `COPY` to copy the output of an `INSERT/UPDATE/DELETE ... RETURNING` query (Marko Tiikkaja)

Previously, an intermediate CTE had to be written to get this result.

- Introduce `ALTER object DEPENDS ON EXTENSION` (Abhijit Menon-Sen)

This command allows a database object to be marked as depending on an extension, so that it will be dropped automatically if the extension is dropped (without needing `CASCADE`). However, the object is not part of the extension, and thus will be dumped separately by `pg_dump`.

- Make `ALTER object SET SCHEMA` do nothing when the object is already in the requested schema, rather than throwing an error as it historically has for most object types (Marti Raudsepp)
- Add options to `ALTER OPERATOR` to allow changing the selectivity functions associated with an existing operator (Yury Zhuravlev)
- Add an `IF NOT EXISTS` option to `ALTER TABLE ADD COLUMN` (Fabrízio de Royes Mello)
- Reduce the lock strength needed by `ALTER TABLE` when setting fillfactor and autovacuum-related relation options (Fabrízio de Royes Mello, Simon Riggs)
- Introduce `CREATE ACCESS METHOD` to allow extensions to create index access methods (Alexander Korotkov, Petr Jelínek)
- Add a `CASCADE` option to `CREATE EXTENSION` to automatically create any extensions the requested one depends on (Petr Jelínek)
- Make `CREATE TABLE ... LIKE` include an `OID` column if any source table has one (Bruce Momjian)
- If a `CHECK` constraint is declared `NOT VALID` in a table creation command, automatically mark it as valid (Amit Langote, Amul Sul)

This is safe because the table has no existing rows. This matches the longstanding behavior of `FOREIGN KEY` constraints.

- Fix `DROP OPERATOR` to clear `pg_operator.oprcom` and `pg_operator.oprnegate` links to the dropped operator (Roma Sokolov)

Formerly such links were left as-is, which could pose a problem in the somewhat unlikely event that the dropped operator's `OID` was reused for another operator.

- Do not show the same subplan twice in `EXPLAIN` output (Tom Lane)

In certain cases, typically involving `SubPlan` nodes in index conditions, `EXPLAIN` would print data for the same subplan twice.

- Disallow creation of indexes on system columns, except for `OID` columns (David Rowley)

Such indexes were never considered supported, and would very possibly misbehave since the system might change the system-column fields of a tuple without updating indexes. However, previously there were no error checks to prevent them from being created.

E.51.3.5. Permissions Management

- Use the privilege system to manage access to sensitive functions (Stephen Frost)

Formerly, many security-sensitive functions contained hard-wired checks that would throw an error if they were called by a non-superuser. This forced the use of superuser roles for some relatively pedestrian tasks. The hard-wired error checks are now gone in favor of making `initdb` revoke the default public `EXECUTE` privilege on these functions. This allows installations to choose to grant usage of such functions to trusted roles that do not need all superuser privileges.

- Create some [built-in roles](#) that can be used to grant access to what were previously superuser-only functions (Stephen Frost)

Currently the only such role is `pg_signal_backend`, but more are expected to be added in future.

E.51.3.6. Data Types

- Improve [full-text search](#) to support searching for phrases, that is, lexemes appearing adjacent to each other in a specific order, or with a specified distance between them (Teodor Sigaev, Oleg Bartunov, Dmitry Ivanov)

A phrase-search query can be specified in `tsquery` input using the new operators `<->` and `<N>`. The former means that the lexemes before and after it must appear adjacent to each other in that order. The latter means they must be exactly *N* lexemes apart.

- Allow omitting one or both boundaries in an array slice specifier, e.g., `array_col[3:]` (Yury Zhuravlev)

Omitted boundaries are taken as the upper or lower limit of the corresponding array subscript. This allows simpler specification for many common use-cases.

- Be more careful about out-of-range dates and timestamps (Vitaly Burovoy)

This change prevents unexpected out-of-range errors for `timestamp with time zone` values very close to the implementation limits. Previously, the “same” value might be accepted or not depending on the `timezone` setting, meaning that a dump and reload could fail on a value that had been accepted when presented. Now the limits are enforced according to the equivalent UTC time, not local time, so as to be independent of `timezone`.

Also, PostgreSQL is now more careful to detect overflow in operations that compute new date or timestamp values, such as `date + integer`.

- For geometric data types, make sure `infinity` and `NaN` component values are treated consistently during input and output (Tom Lane)

Such values will now always print the same as they would in a simple `float8` column, and be accepted the same way on input. Previously the behavior was platform-dependent.

- Upgrade the [ispell](#) dictionary type to handle modern Hunspell files and support more languages (Artur Zakirov)
- Implement look-behind constraints in [regular expressions](#) (Tom Lane)

A look-behind constraint is like a lookahead constraint in that it consumes no text; but it checks for existence (or nonexistence) of a match ending at the current point in the string, rather than one starting at the current point. Similar features exist in many other regular-expression engines.

- In regular expressions, if an apparent three-digit octal escape `\nnn` would exceed 377 (255 decimal), assume it is a two-digit octal escape instead (Tom Lane)

This makes the behavior match current Tcl releases.

- Add transaction ID operators `xid <> xid` and `xid <> int4`, for consistency with the corresponding equality operators (Michael Paquier)

E.51.3.7. Functions

- Add `jsonb_insert()` function to insert a new element into a `jsonb` array, or a not-previously-existing key into a `jsonb` object (Dmitry Dolgov)
- Improve the accuracy of the `ln()`, `log()`, `exp()`, and `pow()` functions for type `numeric` (Dean Rasheed)
- Add a [scale\(numeric\)](#) function to extract the display scale of a `numeric` value (Marko Tiikkaja)
- Add trigonometric functions that work in degrees (Dean Rasheed)

For example, `sind()` measures its argument in degrees, whereas `sin()` measures in radians. These functions go to some lengths to deliver exact results for values where an exact result can be expected, for instance `sind(30) = 0.5`.

- Ensure that trigonometric functions handle `infinity` and `NaN` inputs per the POSIX standard (Dean Rasheed)

The POSIX standard says that these functions should return `NaN` for `NaN` input, and should throw an error for out-of-range inputs including `infinity`. Previously our behavior varied across platforms.

- Make `to_timestamp(float8)` convert float `infinity` to timestamp `infinity` (Vitaly Burovoy)

Formerly it just failed on an infinite input.

- Add new functions for `tsvector` data (Stas Kelvich)

The new functions are `ts_delete()`, `ts_filter()`, `unnest()`, `tsvector_to_array()`, `array_to_tsvector()`, and a variant of `setweight()` that sets the weight only for specified lexeme(s).

- Allow `ts_stat()` and `tsvector_update_trigger()` to operate on values that are of types binary-compatible with the expected argument type, not just exactly that type; for example allow `citext` where `text` is expected (Teodor Sigaev)
- Add variadic functions `num_nulls()` and `num_nonnulls()` that count the number of their arguments that are null or non-null (Marko Tiikkaja)

An example usage is `CHECK(num_nonnulls(a,b,c) = 1)` which asserts that exactly one of `a,b,c` is not `NULL`. These functions can also be used to count the number of null or nonnull elements in an array.

- Add function `parse_ident()` to split a qualified, possibly quoted SQL identifier into its parts (Pavel Stehule)
- In `to_number()`, interpret a `v` format code as dividing by 10 to the power of the number of digits following `v` (Bruce Momjian)

This makes it operate in an inverse fashion to `to_char()`.

- Make the `to_reg*` functions accept type `text` not `cstring` (Petr Korobeinikov)

This avoids the need to write an explicit cast in most cases where the argument is not a simple literal constant.

- Add `pg_size_bytes()` function to convert human-readable size strings to numbers (Pavel Stehule, Vitaly Burovoy, Dean Rasheed)

This function converts strings like those produced by `pg_size_pretty()` into bytes. An example usage is `SELECT oid::regclass FROM pg_class WHERE pg_total_relation_size(oid) > pg_size_bytes('10 GB')`.

- In `pg_size_pretty()`, format negative numbers similarly to positive ones (Adrian Vondendriesch)

Previously, negative numbers were never abbreviated, just printed in bytes.

- Add an optional `missing_ok` argument to the `current_setting()` function (David Christensen)

This allows avoiding an error for an unrecognized parameter name, instead returning a `NULL`.

- Change various catalog-inspection functions to return `NULL` for invalid input (Michael Paquier)

`pg_get_viewdef()` now returns `NULL` if given an invalid view `OID`, and several similar functions likewise return `NULL` for bad input. Previously, such cases usually led to “cache lookup failed” errors, which are not meant to occur in user-facing cases.

- Fix `pg_replication_origin_xact_reset()` to not have any arguments (Fujii Masao)

The documentation said that it has no arguments, and the C code did not expect any arguments, but the entry in `pg_proc` mistakenly specified two arguments.

E.51.3.8. Server-Side Languages

- In `PL/pgSQL`, detect mismatched `CONTINUE` and `EXIT` statements while compiling a function, rather than at execution time (Jim Nasby)
- Extend `PL/Python`'s error-reporting and message-reporting functions to allow specifying additional message fields besides the primary error message (Pavel Stehule)
- Allow `PL/Python` functions to call themselves recursively via SPI, and fix the behavior when multiple set-returning `PL/Python` functions are called within one query (Alexey Grishchenko, Tom Lane)
- Fix session-lifespan memory leaks in `PL/Python` (Heikki Linnakangas, Haribabu Kommi, Tom Lane)
- Modernize `PL/Tcl` to use Tcl's "object" APIs instead of simple strings (Jim Nasby, Karl Lehenbauer)

This can improve performance substantially in some cases. Note that `PL/Tcl` now requires Tcl 8.4 or later.

- In `PL/Tcl`, make database-reported errors return additional information in Tcl's `errorCode` global variable (Jim Nasby, Tom Lane)

This feature follows the Tcl convention for returning auxiliary data about an error.

- Fix `PL/Tcl` to perform encoding conversion between the database encoding and UTF-8, which is what Tcl expects (Tom Lane)

Previously, strings were passed through without conversion, leading to misbehavior with non-ASCII characters when the database encoding was not UTF-8.

E.51.3.9. Client Interfaces

- Add a nonlocalized version of the `severity field` in error and notice messages (Tom Lane)

This change allows client code to determine severity of an error or notice without having to worry about localized variants of the severity strings.

- Introduce a feature in `libpq` whereby the `CONTEXT` field of messages can be suppressed, either always or only for non-error messages (Pavel Stehule)

The default behavior of `PQerrorMessage()` is now to print `CONTEXT` only for errors. The new function `PQsetErrorContextVisibility()` can be used to adjust this.

- Add support in `libpq` for regenerating an error message with a different verbosity level (Alex Shulgin)

This is done with the new function `PQresultVerboseErrorMessage()`. This supports `psql`'s new `\errverbose` feature, and may be useful for other clients as well.

- Improve `libpq`'s `PQhost()` function to return useful data for default Unix-socket connections (Tom Lane)

Previously it would return `NULL` if no explicit host specification had been given; now it returns the default socket directory path.

- Fix `ecpg`'s lexer to handle line breaks within comments starting on preprocessor directive lines (Michael Meskes)

E.51.3.10. Client Applications

- Add a `--strict-names` option to `pg_dump` and `pg_restore` (Pavel Stehule)

This option causes the program to complain if there is no match for a `-t` or `-n` option, rather than silently doing nothing.

- In `pg_dump`, dump locally-made changes of privilege assignments for system objects (Stephen Frost)

While it has always been possible for a superuser to change the privilege assignments for built-in or extension-created objects, such changes were formerly lost in a dump and reload. Now, `pg_dump` recognizes and dumps such changes. (This works only when dumping from a 9.6 or later server, however.)

- Allow `pg_dump` to dump non-extension-owned objects that are within an extension-owned schema (Martín Marqués)

Previously such objects were ignored because they were mistakenly assumed to belong to the extension owning their schema.

- In `pg_dump` output, include the table name in object tags for object types that are only uniquely named per-table (for example, triggers) (Peter Eisentraut)
- Support multiple `-c` and `-f` command-line options (Pavel Stehule, Catalin Iacob)

The specified operations are carried out in the order in which the options are given, and then `psql` terminates.

- Add a `\crosstabview` command that prints the results of a query in a cross-tabulated display (Daniel Vérité)

In the crosstab display, data values from one query result column are placed in a grid whose column and row headers come from other query result columns.

- Add an `\errverbose` command that shows the last server error at full verbosity (Alex Shulgin)

This is useful after getting an unexpected error — you no longer need to adjust the `VERBOSITY` variable and recreate the failure in order to see error fields that are not shown by default.

- Add `\ev` and `\sv` commands for editing and showing view definitions (Petr Korobeinikov)

These are parallel to the existing `\ef` and `\sf` commands for functions.

- Add a `\gexec` command that executes a query and re-submits the result(s) as new queries (Corey Huinker)
- Allow `\pset C string` to set the table title, for consistency with `\C string` (Bruce Momjian)
- In `\pset expanded auto mode`, do not use expanded format for query results with only one column (Andreas Karlsson, Robert Haas)
- Improve the headers output by the `\watch` command (Michael Paquier, Tom Lane)

Include the `\pset title string` if one has been set, and shorten the prefabricated part of the header to be `timestamp (every Ns)`. Also, the timestamp format now obeys `psql`'s locale environment.

- Improve tab-completion logic to consider the entire input query, not only the current line (Tom Lane)

Previously, breaking a command into multiple lines defeated any tab completion rules that needed to see words on earlier lines.

- Numerous minor improvements in tab-completion behavior (Peter Eisentraut, Vik Fearing, Kevin Grittner, Kyotaro Horiguchi, Jeff Janes, Andreas Karlsson, Fujii Masao, Thomas Munro, Masahiko Sawada, Pavel Stehule)
- Add a `PROMPT` option `%p` to insert the process ID of the connected backend (Julien Rouhaud)

- Introduce a feature whereby the `CONTEXT` field of messages can be suppressed, either always or only for non-error messages (Pavel Stehule)

Printing `CONTEXT` only for errors is now the default behavior. This can be changed by setting the special variable `SHOW_CONTEXT`.

- Make `\df+` show function access privileges and parallel-safety attributes (Michael Paquier)
- SQL commands in `pgbench` scripts are now ended by semicolons, not newlines (Kyotaro Horiguchi, Tom Lane)

This change allows SQL commands in scripts to span multiple lines. Existing custom scripts will need to be modified to add a semicolon at the end of each line that does not have one already. (Doing so does not break the script for use with older versions of `pgbench`.)

- Support floating-point arithmetic, as well as some [built-in functions](#), in expressions in backslash commands (Fabien Coelho)
- Replace `\setrandom` with built-in functions (Fabien Coelho)

The new built-in functions include `random()`, `random_exponential()`, and `random_gaussian()`, which perform the same work as `\setrandom`, but are easier to use since they can be embedded in larger expressions. Since these additions have made `\setrandom` obsolete, remove it.

- Allow invocation of multiple copies of the built-in scripts, not only custom scripts (Fabien Coelho)

This is done with the new `-b` switch, which works similarly to `-f` for custom scripts.

- Allow changing the selection probabilities (weights) for scripts (Fabien Coelho)

When multiple scripts are specified, each `pgbench` transaction randomly chooses one to execute. Formerly this was always done with uniform probability, but now different selection probabilities can be specified for different scripts.

- Collect statistics for each script in a multi-script run (Fabien Coelho)

This feature adds an intermediate level of detail to existing global and per-command statistics printouts.

- Add a `--progress-timestamp` option to report progress with Unix epoch timestamps, instead of time since the run started (Fabien Coelho)
- Allow the number of client connections (`-c`) to not be an exact multiple of the number of threads (`-j`) (Fabien Coelho)
- When the `-T` option is used, stop promptly at the end of the specified time (Fabien Coelho)

Previously, specifying a low transaction rate could cause `pgbench` to wait significantly longer than specified.

E.51.3.11. Server Applications

- Improve error reporting during `initdb`'s post-bootstrap phase (Tom Lane)

Previously, an error here led to reporting the entire input file as the “failing query”; now just the current query is reported. To get the desired behavior, queries in `initdb`'s input files must be separated by blank lines.

- Speed up `initdb` by using just one standalone-backend session for all the post-bootstrap steps (Tom Lane)
- Improve [pg_rewind](#) so that it can work when the target timeline changes (Alexander Korotkov)

This allows, for example, rewinding a promoted standby back to some state of the old master's timeline.

E.51.3.12. Source Code

- Remove obsolete `heap_formtuple/heap_modifytuple/heap_deformtuple` functions (Peter Geoghegan)
- Add macros to make `AllocSetContextCreate()` calls simpler and safer (Tom Lane)

Writing out the individual sizing parameters for a memory context is now deprecated in favor of using one of the new macros `ALLOCSET_DEFAULT_SIZES`, `ALLOCSET_SMALL_SIZES`, or `ALLOCSET_START_SMALL_SIZES`. Existing code continues to work, however.

- Unconditionally use `static inline` functions in header files (Andres Freund)

This may result in warnings and/or wasted code space with very old compilers, but the notational improvement seems worth it.

- Improve TAP testing infrastructure (Michael Paquier, Craig Ringer, Álvaro Herrera, Stephen Frost)

Notably, it is now possible to test recovery scenarios using this infrastructure.

- Make `trace_lwlocks` identify individual locks by name (Robert Haas)
- Improve `psql`'s tab-completion code infrastructure (Thomas Munro, Michael Paquier)

Tab-completion rules are now considerably easier to write, and more compact.

- Nail the `pg_shseclabel` system catalog into cache, so that it is available for access during connection authentication (Adam Brightwell)

The core code does not use this catalog for authentication, but extensions might wish to consult it.

- Restructure [index access method API](#) to hide most of it at the C level (Alexander Korotkov, Andrew Gierth)

This change modernizes the index AM API to look more like the designs we have adopted for foreign data wrappers and `tablesample` handlers. This simplifies the C code and makes it much more practical to define index access methods in installable extensions. A consequence is that most of the columns of the `pg_am` system catalog have disappeared. New [inspection functions](#) have been added to allow SQL queries to determine index AM properties that used to be discoverable from `pg_am`.

- Add `pg_init_privs` system catalog to hold original privileges of `initdb`-created and extension-created objects (Stephen Frost)

This infrastructure allows `pg_dump` to dump changes that an installation may have made in privileges attached to system objects. Formerly, such changes would be lost in a dump and reload, but now they are preserved.

- Change the way that extensions allocate custom `LWLocks` (Amit Kapila, Robert Haas)

The `RequestAddinLWLocks()` function is removed, and replaced by `RequestNamedLWLockTranche()`. This allows better identification of custom `LWLocks`, and is less error-prone.

- Improve the isolation tester to allow multiple sessions to wait concurrently, allowing testing of deadlock scenarios (Robert Haas)
- Introduce extensible node types (KaiGai Kohei)

This change allows FDWs or custom scan providers to store data in a plan tree in a more convenient format than was previously possible.

- Make the planner deal with post-scan/join query steps by generating and comparing `Paths`, replacing a lot of ad-hoc logic (Tom Lane)

This change provides only marginal user-visible improvements today, but it enables future work on a lot of upper-planner improvements that were impractical to tackle using the old code structure.

- Support partial aggregation (David Rowley, Simon Riggs)

This change allows the computation of an aggregate function to be split into separate parts, for example so that parallel worker processes can cooperate on computing an aggregate. In future it might allow aggregation across local and remote data to occur partially on the remote end.

- Add a generic command progress reporting facility (Vinayak Pokale, Rahila Syed, Amit Langote, Robert Haas)
- Separate out `psql`'s flex lexer to make it usable by other client programs (Tom Lane, Kyotaro Horiguchi)

This eliminates code duplication for programs that need to be able to parse SQL commands well enough to identify command boundaries. Doing that in full generality is more painful than one could wish, and up to now only `psql` has really gotten it right among our supported client programs.

A new source-code subdirectory `src/fe_utils/` has been created to hold this and other code that is shared across our client programs. Formerly such sharing was accomplished by symbolic linking or copying source files at build time, which was ugly and required duplicate compilation.

- Introduce `WaitEventSet` API to allow efficient waiting for event sets that usually do not change from one wait to the next (Andres Freund, Amit Kapila)
- Add a generic interface for writing WAL records (Alexander Korotkov, Petr Jelínek, Markus Nullmeier)

This change allows extensions to write WAL records for changes to pages using a standard layout. The problem of needing to replay WAL without access to the extension is solved by having generic replay code. This allows extensions to implement, for example, index access methods and have WAL support for them.

- Support generic WAL messages for logical decoding (Petr Jelínek, Andres Freund)

This feature allows extensions to insert data into the WAL stream that can be read by logical-decoding plugins, but is not connected to physical data restoration.

- Allow SP-GiST operator classes to store an arbitrary “traversal value” while descending the index (Alexander Lebedev, Teodor Sigaev)

This is somewhat like the “reconstructed value”, but it could be any arbitrary chunk of data, not necessarily of the same data type as the indexed column.

- Introduce a `LOG_SERVER_ONLY` message level for `ereport()` (David Steele)

This level acts like `LOG` except that the message is never sent to the client. It is meant for use in auditing and similar applications.

- Provide a `Makefile` target to build all generated headers (Michael Paquier, Tom Lane)

`submake-generated-headers` can now be invoked to ensure that generated backend header files are up-to-date. This is useful in subdirectories that might be built “standalone”.

- Support OpenSSL 1.1.0 (Andreas Karlsson, Heikki Linnakangas)

E.51.3.13. Additional Modules

- Add configuration parameter `auto_explain.sample_rate` to allow `contrib/auto_explain` to capture just a configurable fraction of all queries (Craig Ringer, Julien Rouhaud)

This allows reduction of overhead for heavy query traffic, while still getting useful information on average.

- Add `contrib/bloom` module that implements an index access method based on Bloom filtering (Teodor Sigaev, Alexander Korotkov)

This is primarily a proof-of-concept for non-core index access methods, but it could be useful in its own right for queries that search many columns.

- In `contrib/cube`, introduce distance operators for cubes, and support kNN-style searches in GiST indexes on cube columns (Stas Kelvich)
- Make `contrib/hstore`'s `hstore_to_jsonb_loose()` and `hstore_to_json_loose()` functions agree on what is a number (Tom Lane)

Previously, `hstore_to_jsonb_loose()` would convert numeric-looking strings to JSON numbers, rather than strings, even if they did not exactly match the JSON syntax specification for numbers. This was inconsistent with `hstore_to_json_loose()`, so tighten the test to match the JSON syntax.

- Add selectivity estimation functions for `contrib/intarray` operators to improve plans for queries using those operators (Yury Zhuravlev, Alexander Korotkov)
- Make `contrib/pageinspect`'s `heap_page_items()` function show the raw data in each tuple, and add new functions `tuple_data_split()` and `heap_page_item_attrs()` for inspection of individual tuple fields (Nikolay Shaplov)
- Add an optional S2K iteration count parameter to `contrib/pgcrypto`'s `pgp_sym_encrypt()` function (Jeff Janes)
- Add support for “word similarity” to `contrib/pg_trgm` (Alexander Korotkov, Artur Zakirov)

These functions and operators measure the similarity between one string and the most similar single word of another string.

- Add configuration parameter `pg_trgm.similarity_threshold` for `contrib/pg_trgm`'s similarity threshold (Artur Zakirov)

This threshold has always been configurable, but formerly it was controlled by special-purpose functions `set_limit()` and `show_limit()`. Those are now deprecated.

- Improve `contrib/pg_trgm`'s GIN operator class to speed up index searches in which both common and rare keys appear (Jeff Janes)
- Improve performance of similarity searches in `contrib/pg_trgm` GIN indexes (Christophe Fornaroli)
- Add `contrib/pg_visibility` module to allow examining table visibility maps (Robert Haas)
- Add `ssl_extension_info()` function to `contrib/sslinfo`, to print information about SSL extensions present in the X509 certificate used for the current connection (Dmitry Voronin)

E.51.3.13.1. `postgres_fdw`

- Allow extension-provided operators and functions to be sent for remote execution, if the extension is whitelisted in the foreign server's options (Paul Ramsey)

Users can enable this feature when the extension is known to exist in a compatible version in the remote database. It allows more efficient execution of queries involving extension operators.

- Consider performing sorts on the remote server (Ashutosh Bapat)
- Consider performing joins on the remote server (Shigeru Hanada, Ashutosh Bapat)
- When feasible, perform `UPDATE` or `DELETE` entirely on the remote server (Etsuro Fujita)

Formerly, remote updates involved sending a `SELECT FOR UPDATE` command and then updating or deleting the selected rows one-by-one. While that is still necessary if the operation requires any local processing, it can now be done remotely if all elements of the query are safe to send to the remote server.

- Allow the fetch size to be set as a server or table option (Corey Huinker)

Formerly, `postgres_fdw` always fetched 100 rows at a time from remote queries; now that behavior is configurable.

- Use a single foreign-server connection for local user IDs that all map to the same remote user (Ashutosh Bapat)
- Transmit query cancellation requests to the remote server (Michael Paquier, Etsuro Fujita)

Previously, a local query cancellation request did not cause an already-sent remote query to terminate early.

Appendix F. Additional Supplied Modules

This appendix and the next one contain information regarding additional modules available in the Postgres Pro Enterprise distribution. These include porting tools, analysis utilities, and plug-in features that are not part of the core Postgres Pro system, mainly because they address a limited audience or are too experimental to be part of the main source tree. This does not preclude their usefulness.

This appendix covers the extensions and other server plug-in modules. [Appendix G](#) covers the utility programs.

In Postgres Pro Enterprise, these modules are made available as a separate subpackage, such as `postgrespro-contrib-9.6`. You can find the exact name of the package available for your Linux system in [Chapter 17](#).

Many modules supply new user-defined functions, operators, or types. To make use of one of these modules, after you have installed the code you need to register the new SQL objects in the database system. In Postgres Pro, and PostgreSQL 9.1 and later, this is done by executing a [CREATE EXTENSION](#) command. In a fresh database, you can simply do

```
CREATE EXTENSION module_name;
```

This command must be run by a database superuser. This registers the new SQL objects in the current database only, so you need to run this command in each database that you want the module's facilities to be available in. Alternatively, run it in database `template1` so that the extension will be copied into subsequently-created databases by default.

Many modules allow you to install their objects in a schema of your choice. To do that, add `SCHEMA schema_name` to the `CREATE EXTENSION` command. By default, the objects will be placed in your current creation target schema, which in turn defaults to `public`.

If your database was brought forward by dump and reload from a pre-9.1 version of PostgreSQL, and you had been using the pre-9.1 version of the module in it, you should instead do

```
CREATE EXTENSION module_name FROM unpackaged;
```

This will update the pre-9.1 objects of the module into a proper *extension* object. Future updates to the module will be managed by [ALTER EXTENSION](#). For more information about extension updates, see [Section 36.15](#).

Note, however, that some of these modules are not “extensions” in this sense, but are loaded into the server in some other way, for instance by way of [shared_preload_libraries](#). See the documentation of each module for details.

F.1. adminpack

`adminpack` provides a number of support functions which pgAdmin and other administration and management tools can use to provide additional functionality, such as remote management of server log files. Use of all these functions is restricted to superusers.

The functions shown in [Table F.1](#) provide write access to files on the machine hosting the server. (See also the functions in [Table 9.86](#), which provide read-only access.) Only files within the database cluster directory can be accessed, but either a relative or absolute path is allowable.

Table F.1. adminpack Functions

Name	Return Type	Description
<code>pg_catalog.pg_file_write(</code> <code>filename text, data text,</code> <code>append boolean)</code>	<code>bigint</code>	Write, or append to, a text file

Name	Return Type	Description
<code>pg_catalog.pg_file_rename(oldname text, newname text [, archivename text])</code>	boolean	Rename a file
<code>pg_catalog.pg_file_unlink(filename text)</code>	boolean	Remove a file
<code>pg_catalog.pg_logdir_ls()</code>	setof record	List the log files in the log_directory directory

`pg_file_write` writes the specified *data* into the file named by *filename*. If *append* is false, the file must not already exist. If *append* is true, the file can already exist, and will be appended to if so. Returns the number of bytes written.

`pg_file_rename` renames a file. If *archivename* is omitted or NULL, it simply renames *oldname* to *newname* (which must not already exist). If *archivename* is provided, it first renames *newname* to *archivename* (which must not already exist), and then renames *oldname* to *newname*. In event of failure of the second rename step, it will try to rename *archivename* back to *newname* before reporting the error. Returns true on success, false if the source file(s) are not present or not writable; other cases throw errors.

`pg_file_unlink` removes the specified file. Returns true on success, false if the specified file is not present or the `unlink()` call fails; other cases throw errors.

`pg_logdir_ls` returns the start timestamps and path names of all the log files in the [log_directory](#) directory. The [log_filename](#) parameter must have its default setting (`postgresql-%Y-%m-%d_%H%M%S.log`) to use this function.

The functions shown in [Table F.2](#) are deprecated and should not be used in new applications; instead use those shown in [Table 9.77](#) and [Table 9.86](#). These functions are provided in `adminpack` only for compatibility with old versions of pgAdmin.

Table F.2. Deprecated adminpack Functions

Name	Return Type	Description
<code>pg_catalog.pg_file_read(filename text, offset bigint, nbytes bigint)</code>	text	Alternate name for <code>pg_read_file()</code>
<code>pg_catalog.pg_file_length(filename text)</code>	bigint	Same as <code>size</code> column returned by <code>pg_stat_file()</code>
<code>pg_catalog.pg_logfile_rotate()</code>	integer	Alternate name for <code>pg_rotate_logfile()</code> , but note that it returns integer 0 or 1 rather than boolean

F.2. aqo

The `aqo` module is a Postgres Pro Enterprise extension for cost-based query optimization. Using machine learning methods, more precisely, a modification of the k-NN algorithm, `aqo` improves cardinality estimation, which can optimize execution plans and, consequently, speed up query execution.

The `aqo` module can collect statistics on all the executed queries, excluding the queries that access system relations. The collected statistics is classified by query type. If the queries differ in their constants only, they belong to the same type. For each type, `aqo` stores the cardinality quality, planning time,

execution time, and execution statistics for machine learning. Based on this data, `aqo` builds a new query plan and uses it for the next query of the same type. `aqo` test runs have shown significant performance improvements for complex queries.

F.2.1. Installation and Setup

The `aqo` extension is included into Postgres Pro Enterprise. Once you have Postgres Pro Enterprise installed, complete the following steps to enable `aqo`:

1. Add `aqo` to the `shared_preload_libraries` parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'aqo'
```

The `aqo` library must be preloaded at the server startup, since adaptive query optimization needs to be enabled per cluster. Otherwise, `aqo` will only be used for the session in which you created the `aqo` extension.

2. Create the `aqo` extension using the following query:

```
CREATE EXTENSION aqo;
```

Once the extension is created, you can start optimizing queries.

To disable `aqo` at the cluster level and remove all the collected statistics, run:

```
DROP EXTENSION aqo;
```

F.2.1.1. Configuration

By default, `aqo` does not affect query performance. To enable adaptive query optimization for your database, add the `aqo.mode` variable to your `postgresql.conf` file and reload the cluster. Depending on your database usage model, you can choose between the following modes:

- `intelligent` — this mode auto-tunes your queries based on statistics collected per query type.
- `forced` — this mode tries to optimize all new queries together, regardless of the query type.
- `controlled` — this mode uses the default planner for all new queries, but continues using the previously specified planning settings for already known query types, if any.
- `disabled` — this mode disables `aqo` for all queries, even for the known query types. You can use this mode to temporarily disable `aqo` without losing the collected statistics and configuration.

To dynamically change the `aqo` settings in your current session, run the following command:

```
SET aqo.mode = 'mode';
```

where `mode` is the name of the optimization mode to use.

Important

The `intelligent` mode of `aqo` may not work well if the queries in your workload are of multiple different types. In this case, you can try resetting the optimization mode to `controlled`.

F.2.2. Usage

F.2.2.1. Choosing Query Optimization Modes

If you often run queries of the same type, for example, your application limits the number of possible query types, you can use the `intelligent` mode to improve planning for these queries. In this mode, `aqo` analyzes each query execution and stores statistics. Statistics on queries of different types is stored separately. If performance is not improved after 50 iterations, the `aqo` extension falls back to the default query planner.

Note

You can view the current query plan using the standard Postgres Pro `EXPLAIN` command with the `ANALYZE` option. For details, see the [Section 14.1](#).

Since the `intelligent` mode tries to learn separately for different query types, `aqo` may fail to provide performance improvements if the types of the queries in the workload are constantly changing. For such dynamic workloads, reset the `aqo` extension to the `controlled` mode, or try using the `forced` mode.

In the `forced` mode, `aqo` does not classify the collected statistics by query types and tries to optimize all queries together. This mode can help you optimize workloads with multiple different query types, and it consumes less memory than the `intelligent` mode. However, since the `forced` mode lacks intelligent tuning, performance may decrease for some queries. If you see performance issues in this mode, switch `aqo` to the `controlled` mode.

In the `controlled` mode, `aqo` does not collect statistics for new query types, so they will not be optimized. For known query types, `aqo` will continue collecting statistics and using optimized planning algorithms.

If you want to fully disable `aqo`, you can switch `aqo` to the `disabled` mode. In this case, the default planner is used for all queries, but the collected statistics and `aqo` settings are saved and can be used in the future.

F.2.2.2. Fine-Tuning aqo

You must have superuser rights to access `aqo` tables and configure advanced query settings.

When run in the `intelligent` mode, `aqo` assigns a unique hash value to each query type to separate the collected statistics. If you switch to the `forced` mode, the statistics for all untracked query types is stored in a common query type with hash 0. You can view all the processed query types and their corresponding hash values in the `aqo_query_texts` table:

```
SELECT * FROM aqo_query_texts;
```

Each query type has its own optimization settings. These settings are stored in the `aqo_queries` table:

```
SELECT * FROM aqo_queries;
```

For each query type, the following settings are available:

- `query_hash` stores the hash value that uniquely identifies the query type.
- `learn_aqo` enables statistics collection for this query type.
- `use_aqo` enables `aqo` cardinality prediction for the next execution of this query type.
- `fspace_hash` is a unique identifier of the separate space in which the statistics for this query type is collected. By default, `fspace_hash` is equal to `query_hash`.
- `auto_tuning` shows whether `aqo` tries to change other settings for the given query. By default, auto-tuning is enabled in the `intelligent` mode.

You can manually change these settings to adjust optimization for a particular query type. For example:

```
-- Add a new query type into the aqo_queries table:
```

```
SET aqo.mode='intelligent';
SELECT * FROM a, b WHERE a.id=b.id;
SET aqo.mode='controlled';
```

```
-- Disable auto_tuning, enable both learn_aqo and use_aqo
-- for this query type:
```

```
UPDATE aqo_queries SET use_aqo=true, learn_aqo=true, auto_tuning=false
WHERE query_hash = (SELECT query_hash from aqo_query_texts
```

```
WHERE query_text LIKE 'SELECT * FROM a, b WHERE a.id=b.id;');

-- Run EXPLAIN ANALYZE until the plan changes:

EXPLAIN ANALYZE SELECT * FROM a, b WHERE a.id=b.id;
EXPLAIN ANALYZE SELECT * FROM a, b WHERE a.id=b.id;

-- Disable learning to stop statistics collection
-- and use the optimized plan:

UPDATE aqo_queries SET learn_aqo=false
WHERE query_hash = (SELECT query_hash from aqo_query_texts
WHERE query_text LIKE 'SELECT * FROM a, b WHERE a.id=b.id;');
```

If your data or query distribution is rapidly changing, learning new statistics will take longer than usual. In this case, obsolete statistics may affect performance. To speed up aqo learning, reset the statistics. To remove all the collected machine learning statistics, run the following command:

```
DELETE FROM aqo_data;
```

Alternatively, you can specify a particular query type to reset by providing its hash value in the `fspace_hash` option. For example:

```
DELETE FROM aqo_data WHERE fspace_hash = (SELECT fspace_hash FROM aqo_queries
WHERE query_hash = (SELECT query_hash from aqo_query_texts
WHERE query_text LIKE 'SELECT * FROM a, b WHERE a.id=b.id;'));
```

To stop intelligent tuning for a particular query type, disable the `auto_tuning` setting:

```
UPDATE aqo_queries SET auto_tuning=false WHERE query_hash = 'hash';
```

where *hash* is the hash value for this query type. As a result, aqo disables automatic changing of the `learn_aqo` and `use_aqo` settings.

To disable further learning for a particular query type, use the following command:

```
UPDATE aqo_queries SET learn_aqo=false WHERE query_hash = 'hash';
```

where *hash* is the hash value for this query type.

To fully disable aqo for all queries and use the default PostgreSQL query planner, run:

```
UPDATE aqo_queries SET use_aqo=false, learn_aqo=false, auto_tuning=false;
```

F.2.2.3. Using aqo on Standby

In master-standby configurations, aqo statistics on standby is inherited from master in read-only mode. Standby queries do not update aqo statistics, regardless of the current aqo settings. If you would like to update the statistics on standby for one or more query types, you must run these queries on master and synchronize the standby.

You can define whether to use aqo statistics for standby queries independent of the master configuration, toggling aqo modes as required. By default, aqo optimizes queries on standby as follows:

- In intelligent and controlled modes, aqo statistics is only used for the already known query types.
- In the forced mode, aqo tries to optimize the unknown queries based on the common statistics collected in the forced mode on master, if any. If the common statistics is not found, aqo falls back to the default query planner. All the known query types continue using the available statistics.
- The disabled mode switches off the collected statistics completely, relying on the default query planner for all queries.

If you fine-tuned optimization settings for specific query types on master, these settings override the default aqo behavior, unless you choose the disabled mode. For details, see [Section F.2.2.2](#).

F.2.3. Reference

F.2.3.1. Configuration Variables

F.2.3.1.1. `aqo.mode`

Defines `aqo` optimization modes.

Table F.3. `aqo.mode` Options

Option	Description
<code>intelligent</code>	Auto-tunes your queries based on statistics collected per query type.
<code>forced</code>	Optimizes all queries together, regardless of the query type.
<code>controlled</code>	Default. Uses the default planner for all new queries, but can reuse the collected statistics for already known query types, if any.
<code>disabled</code>	Fully disables <code>aqo</code> for all queries. The collected statistics and <code>aqo</code> settings are saved and can be used in the future.

F.2.3.2. Tables

Important

You can manually change optimization settings in the `aqo_queries` table. Avoid modifying other tables as it may lead to unexpected results.

F.2.3.2.1. `aqo_query_texts` Table

The `aqo_query_texts` table classifies all the query types processed by `aqo`.

Table F.4. `aqo_query_texts` Table

Column Name	Description
<code>query_hash</code>	Stores the hash value that uniquely identifies the query type.
<code>query_text</code>	Provides a sample query of the given type.

F.2.3.2.2. `aqo_queries` Table

The `aqo_queries` table stores optimization settings for different query types.

Table F.5. `aqo_queries` Table

Setting	Description
<code>query_hash</code>	Stores the hash value that uniquely identifies the query type.
<code>learn_aqo</code>	Enables statistics collection for this query type.
<code>use_aqo</code>	Enables <code>aqo</code> cardinality prediction for the next execution of this query type. If cost estimation model is incomplete, this may slow down query execution.
<code>fspace_hash</code>	Provides a unique identifier of the separate space in which the statistics for this query type is collected.

Setting	Description
	By default, <code>fspace_hash</code> is equal to <code>query_hash</code> . You can change this setting to a different <code>query_hash</code> to optimize different query types together. It may decrease the amount of memory for models and even improve query execution performance. However, changing this setting may cause unexpected <code>aqo</code> behavior, so make sure to use it only if you know what you are doing.
<code>auto_tuning</code>	Shows whether <code>aqo</code> tries to tune other settings for the given query. By default, auto-tuning is enabled in the intelligent mode. In other modes, new queries are not appended to <code>aqo_queries</code> automatically. You can change this behavior by setting the <code>auto_tuning</code> variable to <code>true</code> .

F.2.3.2.3. `aqo_data` Table

The `aqo_data` table contains machine learning data for cardinality estimation refinement. To forget all the collected statistics for a particular query type, you can delete all rows from `aqo_data` with the corresponding `fspace_hash`.

F.2.3.2.4. `aqo_query_stat` Table

The `aqo_query_stat` table stores statistics on query execution, by query type. The `aqo` extension uses this data when the `auto_tuning` option is enabled for a particular query type.

Table F.6. `aqo_query_stat` Table

Data	Description
<code>execution_time_with_aqo</code>	Execution time for queries run with <code>aqo</code> enabled.
<code>execution_time_without_aqo</code>	Execution time for queries run with <code>aqo</code> disabled.
<code>planning_time_with_aqo</code>	Planning time for queries run with <code>aqo</code> enabled.
<code>planning_time_without_aqo</code>	Planning time for queries run with <code>aqo</code> disabled.
<code>cardinality_error_with_aqo</code>	Cardinality estimation error in the selected query plans with <code>aqo</code> enabled.
<code>cardinality_error_without_aqo</code>	Cardinality estimation error in the selected query plans with <code>aqo</code> disabled.
<code>executions_with_aqo</code>	Number of queries run with <code>aqo</code> enabled.
<code>executions_without_aqo</code>	Number of queries run with <code>aqo</code> disabled.

F.2.4. Author

Oleg Ivanov

F.3. `amcheck`

The `amcheck` module provides functions that allow you to verify the logical consistency of the structure of relations. If the structure appears to be valid, no error is raised.

The functions verify various *invariants* in the structure of the representation of particular relations. The correctness of the access method functions behind index scans and other important operations relies on these invariants always holding. For example, certain functions verify, among other things, that all B-Tree pages have items in “logical” order (e.g., for B-Tree indexes on `text`, index tuples should be in collated lexical order). If that particular invariant somehow fails to hold, we can expect binary searches on the affected page to incorrectly guide index scans, resulting in wrong answers to SQL queries.

Verification is performed using the same procedures as those used by index scans themselves, which may be user-defined operator class code. For example, B-Tree index verification relies on comparisons made with one or more B-Tree support function 1 routines. See [Section 36.14.3](#) for details of operator class support functions.

`amcheck` functions may only be used by superusers.

F.3.1. Functions

`bt_index_check(index regclass, heapallindexed boolean)` returns void

`bt_index_check` tests that its target, a B-Tree index, respects a variety of invariants. Example usage:

```
test=# SELECT bt_index_check(index => c.oid, heapallindexed => i.indisunique),
           c.relname,
           c.relpages
```

```
FROM pg_index i
JOIN pg_opclass op ON i.indclass[0] = op.oid
JOIN pg_am am ON op.opcmethod = am.oid
JOIN pg_class c ON i.indexrelid = c.oid
JOIN pg_namespace n ON c.relnamespace = n.oid
WHERE am.amname = 'btree' AND n.nspname = 'pg_catalog'
-- Don't check temp tables, which may be from another session:
AND c.relpersistence != 't'
-- Function may throw an error when this is omitted:
AND c.relkind = 'i' AND i.indisready AND i.indisvalid
ORDER BY c.relpages DESC LIMIT 10;
```

bt_index_check	relname	relpages
	pg_depend_reference_index	43
	pg_depend_depender_index	40
	pg_proc_proname_args_nsp_index	31
	pg_description_o_c_o_index	21
	pg_attribute_relid_attnam_index	14
	pg_proc_oid_index	10
	pg_attribute_relid_attnum_index	9
	pg_amproc_fam_proc_index	5
	pg_amop_opr_fam_index	5
	pg_amop_fam_strat_index	5

(10 rows)

This example shows a session that performs verification of the 10 largest catalog indexes in the database “test”. Verification of the presence of heap tuples as index tuples is requested for the subset that are unique indexes. Since no error is raised, all indexes tested appear to be logically consistent. Naturally, this query could easily be changed to call `bt_index_check` for every index in the database where verification is supported.

`bt_index_check` acquires an `AccessShareLock` on the target index and the heap relation it belongs to. This lock mode is the same lock mode acquired on relations by simple `SELECT` statements. `bt_index_check` does not verify invariants that span child/parent relationships, but will verify the presence of all heap tuples as index tuples within the index when `heapallindexed` is `true`. When a routine, lightweight test for corruption is required in a live production environment, using `bt_index_check` often provides the best trade-off between thoroughness of verification and limiting the impact on application performance and availability.

`bt_index_parent_check(index regclass, heapallindexed boolean)` returns void

`bt_index_parent_check` tests that its target, a B-Tree index, respects a variety of invariants. Optionally, when the `heapallindexed` argument is `true`, the function verifies the presence of all heap tuples that should be found within the index, and that there are no missing downlinks in the index structure. The checks that can be performed by `bt_index_parent_check` are a superset of the

checks that can be performed by `bt_index_check`. `bt_index_parent_check` can be thought of as a more thorough variant of `bt_index_check`: unlike `bt_index_check`, `bt_index_parent_check` also checks invariants that span parent/child relationships. `bt_index_parent_check` follows the general convention of raising an error if it finds a logical inconsistency or other problem.

A `ShareLock` is required on the target index by `bt_index_parent_check` (a `ShareLock` is also acquired on the heap relation). These locks prevent concurrent data modification from `INSERT`, `UPDATE`, and `DELETE` commands. The locks also prevent the underlying relation from being concurrently processed by `VACUUM`, as well as all other utility commands. Note that the function holds locks only while running, not for the entire transaction.

`bt_index_parent_check`'s additional verification is more likely to detect various pathological cases. These cases may involve an incorrectly implemented B-Tree operator class used by the index that is checked, or, hypothetically, undiscovered bugs in the underlying B-Tree index access method code. Note that `bt_index_parent_check` cannot be used when Hot Standby mode is enabled (i.e., on read-only physical replicas), unlike `bt_index_check`.

F.3.2. Optional *heapallindexed* verification

When the *heapallindexed* argument to verification functions is `true`, an additional phase of verification is performed against the table associated with the target index relation. This consists of a “dummy” `CREATE INDEX` operation, which checks for the presence of all hypothetical new index tuples against a temporary, in-memory summarizing structure (this is built when needed during the basic first phase of verification). The summarizing structure “fingerprints” every tuple found within the target index. The high level principle behind *heapallindexed* verification is that a new index that is equivalent to the existing, target index must only have entries that can be found in the existing structure.

The additional *heapallindexed* phase adds significant overhead: verification will typically take several times longer. However, there is no change to the relation-level locks acquired when *heapallindexed* verification is performed.

The summarizing structure is bound in size by `maintenance_work_mem`. In order to ensure that there is no more than a 2% probability of failure to detect an inconsistency for each heap tuple that should be represented in the index, approximately 2 bytes of memory are needed per tuple. As less memory is made available per tuple, the probability of missing an inconsistency slowly increases. This approach limits the overhead of verification significantly, while only slightly reducing the probability of detecting a problem, especially for installations where verification is treated as a routine maintenance task. Any single absent or malformed tuple has a new opportunity to be detected with each new verification attempt.

F.3.3. Using *amcheck* effectively

amcheck can be effective at detecting various types of failure modes that [data page checksums](#) will always fail to catch. These include:

- Structural inconsistencies caused by incorrect operator class implementations.

This includes issues caused by the comparison rules of operating system collations changing. Comparisons of datums of a collatable type like `text` must be immutable (just as all comparisons used for B-Tree index scans must be immutable), which implies that operating system collation rules must never change. Though rare, updates to operating system collation rules can cause these issues. More commonly, an inconsistency in the collation order between a master server and a standby server is implicated, possibly because the *major* operating system version in use is inconsistent. Such inconsistencies will generally only arise on standby servers, and so can generally only be detected on standby servers.

If a problem like this arises, it may not affect each individual index that is ordered using an affected collation, simply because *indexed* values might happen to have the same absolute ordering regardless of the behavioral inconsistency. See [Section 23.1](#) and [Section 23.2](#) for further details about how Postgres Pro uses operating system locales and collations.

- Structural inconsistencies between indexes and the heap relations that are indexed (when *heapallindexed* verification is performed).

There is no cross-checking of indexes against their heap relation during normal operation. Symptoms of heap corruption can be subtle.

- Corruption caused by hypothetical undiscovered bugs in the underlying Postgres Pro access method code, sort code, or transaction management code.

Automatic verification of the structural integrity of indexes plays a role in the general testing of new or proposed Postgres Pro features that could plausibly allow a logical inconsistency to be introduced. Verification of table structure and associated visibility and transaction status information plays a similar role. One obvious testing strategy is to call `amcheck` functions continuously when running the standard regression tests.

- File system or storage subsystem faults where checksums happen to simply not be enabled.

Note that `amcheck` examines a page as represented in some shared memory buffer at the time of verification if there is only a shared buffer hit when accessing the block. Consequently, `amcheck` does not necessarily examine data read from the file system at the time of verification. Note that when checksums are enabled, `amcheck` may raise an error due to a checksum failure when a corrupt block is read into a buffer.

- Corruption caused by faulty RAM, or the broader memory subsystem.

Postgres Pro does not protect against correctable memory errors and it is assumed you will operate using RAM that uses industry standard Error Correcting Codes (ECC) or better protection. However, ECC memory is typically only immune to single-bit errors, and should not be assumed to provide *absolute* protection against failures that result in memory corruption.

When *heapallindexed* verification is performed, there is generally a greatly increased chance of detecting single-bit errors, since strict binary equality is tested, and the indexed attributes within the heap are tested.

In general, `amcheck` can only prove the presence of corruption; it cannot prove its absence.

F.3.4. Repairing corruption

No error concerning corruption raised by `amcheck` should ever be a false positive. `amcheck` raises errors in the event of conditions that, by definition, should never happen, and so careful analysis of `amcheck` errors is often required.

There is no general method of repairing problems that `amcheck` detects. An explanation for the root cause of an invariant violation should be sought. `pageinspect` may play a useful role in diagnosing corruption that `amcheck` detects. A `REINDEX` may not be effective in repairing corruption.

F.4. `auth_delay`

`auth_delay` causes the server to pause briefly before reporting authentication failure, to make brute-force attacks on database passwords more difficult. Note that it does nothing to prevent denial-of-service attacks, and may even exacerbate them, since processes that are waiting before reporting authentication failure will still consume connection slots.

In order to function, this module must be loaded via `shared_preload_libraries` in `postgresql.conf`.

F.4.1. Configuration Parameters

`auth_delay.milliseconds (int)`

The number of milliseconds to wait before reporting an authentication failure. The default is 0.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'auth_delay'

auth_delay.milliseconds = '500'
```

F.4.2. Author

KaiGai Kohei <kaigai@ak.jp.nec.com>

F.5. auto_explain

The `auto_explain` module provides a means for logging execution plans of slow statements automatically, without having to run `EXPLAIN` by hand. This is especially helpful for tracking down unoptimized queries in large applications.

The module provides no SQL-accessible functions. To use it, simply load it into the server. You can load it into an individual session:

```
LOAD 'auto_explain';
```

(You must be superuser to do that.) More typical usage is to preload it into some or all sessions by including `auto_explain` in `session_preload_libraries` or `shared_preload_libraries` in `postgresql.conf`. Then you can track unexpectedly slow queries no matter when they happen. Of course there is a price in overhead for that.

F.5.1. Configuration Parameters

There are several configuration parameters that control the behavior of `auto_explain`. Note that the default behavior is to do nothing, so you must set at least `auto_explain.log_min_duration` if you want any results.

`auto_explain.log_min_duration` (integer)

`auto_explain.log_min_duration` is the minimum statement execution time, in milliseconds, that will cause the statement's plan to be logged. Setting this to zero logs all plans. Minus-one (the default) disables logging of plans. For example, if you set it to `250ms` then all statements that run 250ms or longer will be logged. Only superusers can change this setting.

`auto_explain.log_analyze` (boolean)

`auto_explain.log_analyze` causes `EXPLAIN ANALYZE` output, rather than just `EXPLAIN` output, to be printed when an execution plan is logged. This parameter is off by default. Only superusers can change this setting.

Note

When this parameter is on, per-plan-node timing occurs for all statements executed, whether or not they run long enough to actually get logged. This can have an extremely negative impact on performance. Turning off `auto_explain.log_timing` ameliorates the performance cost, at the price of obtaining less information.

`auto_explain.log_buffers` (boolean)

`auto_explain.log_buffers` controls whether buffer usage statistics are printed when an execution plan is logged; it's equivalent to the `BUFFERS` option of `EXPLAIN`. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_timing` (boolean)

`auto_explain.log_timing` controls whether per-node timing information is printed when an execution plan is logged; it's equivalent to the `TIMING` option of `EXPLAIN`. The overhead of repeatedly

reading the system clock can slow down queries significantly on some systems, so it may be useful to set this parameter to off when only actual row counts, and not exact times, are needed. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is on by default. Only superusers can change this setting.

`auto_explain.log_triggers` (boolean)

`auto_explain.log_triggers` causes trigger execution statistics to be included when an execution plan is logged. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_verbose` (boolean)

`auto_explain.log_verbose` controls whether verbose details are printed when an execution plan is logged; it's equivalent to the `VERBOSE` option of `EXPLAIN`. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_format` (enum)

`auto_explain.log_format` selects the `EXPLAIN` output format to be used. The allowed values are `text`, `xml`, `json`, and `yaml`. The default is `text`. Only superusers can change this setting.

`auto_explain.log_nested_statements` (boolean)

`auto_explain.log_nested_statements` causes nested statements (statements executed inside a function) to be considered for logging. When it is off, only top-level query plans are logged. This parameter is off by default. Only superusers can change this setting.

`auto_explain.sample_rate` (real)

`auto_explain.sample_rate` causes `auto_explain` to only explain a fraction of the statements in each session. The default is 1, meaning explain all the queries. In case of nested statements, either all will be explained or none. Only superusers can change this setting.

In ordinary usage, these parameters are set in `postgresql.conf`, although superusers can alter them on-the-fly within their own sessions. Typical usage might be:

```
# postgresql.conf
session_preload_libraries = 'auto_explain'

auto_explain.log_min_duration = '3s'
```

F.5.2. Example

```
postgres=# LOAD 'auto_explain';
postgres=# SET auto_explain.log_min_duration = 0;
postgres=# SET auto_explain.log_analyze = true;
postgres=# SELECT count(*)
           FROM pg_class, pg_index
           WHERE oid = indrelid AND indisunique;
```

This might produce log output such as:

```
LOG:  duration: 3.651 ms  plan:
      Query Text: SELECT count(*)
                  FROM pg_class, pg_index
                  WHERE oid = indrelid AND indisunique;
Aggregate  (cost=16.79..16.80 rows=1 width=0) (actual time=3.626..3.627 rows=1
loops=1)
  -> Hash Join  (cost=4.17..16.55 rows=92 width=0) (actual time=3.349..3.594 rows=92
loops=1)
        Hash Cond: (pg_class.oid = pg_index.indrelid)
        -> Seq Scan on pg_class  (cost=0.00..9.55 rows=255 width=4) (actual
time=0.016..0.140 rows=255 loops=1)
```

```
-> Hash (cost=3.02..3.02 rows=92 width=4) (actual time=3.238..3.238 rows=92
loops=1)
      Buckets: 1024 Batches: 1 Memory Usage: 4kB
      -> Seq Scan on pg_index (cost=0.00..3.02 rows=92 width=4) (actual
time=0.008..3.187 rows=92 loops=1)
          Filter: indisunique
```

F.5.3. Author

Takahiro Itagaki <itagaki.takahiro@oss.ntt.co.jp>

F.6. bloom

`bloom` provides an index access method based on *Bloom filters*.

A Bloom filter is a space-efficient data structure that is used to test whether an element is a member of a set. In the case of an index access method, it allows fast exclusion of non-matching tuples via signatures whose size is determined at index creation.

A signature is a lossy representation of the indexed attribute(s), and as such is prone to reporting false positives; that is, it may be reported that an element is in the set, when it is not. So index search results must always be rechecked using the actual attribute values from the heap entry. Larger signatures reduce the odds of a false positive and thus reduce the number of useless heap visits, but of course also make the index larger and hence slower to scan.

This type of index is most useful when a table has many attributes and queries test arbitrary combinations of them. A traditional btree index is faster than a bloom index, but it can require many btree indexes to support all possible queries where one needs only a single bloom index. Note however that bloom indexes only support equality queries, whereas btree indexes can also perform inequality and range searches.

F.6.1. Parameters

A `bloom` index accepts the following parameters in its `WITH` clause:

`length`

Length of each signature (index entry) in bits. It is rounded up to the nearest multiple of 16. The default is 80 bits and the maximum is 4096.

`col1 - col32`

Number of bits generated for each index column. Each parameter's name refers to the number of the index column that it controls. The default is 2 bits and the maximum is 4095. Parameters for index columns not actually used are ignored.

F.6.2. Examples

This is an example of creating a bloom index:

```
CREATE INDEX bloomidx ON tbloom USING bloom (i1,i2,i3)
WITH (length=80, col1=2, col2=2, col3=4);
```

The index is created with a signature length of 80 bits, with attributes `i1` and `i2` mapped to 2 bits, and attribute `i3` mapped to 4 bits. We could have omitted the `length`, `col1`, and `col2` specifications since those have the default values.

Here is a more complete example of bloom index definition and usage, as well as a comparison with equivalent btree indexes. The bloom index is considerably smaller than the btree index, and can perform better.

```
=# CREATE TABLE tbloom AS
SELECT
  (random() * 1000000)::int as i1,
```

```

        (random() * 1000000)::int as i2,
        (random() * 1000000)::int as i3,
        (random() * 1000000)::int as i4,
        (random() * 1000000)::int as i5,
        (random() * 1000000)::int as i6
    FROM
    generate_series(1,10000000);
SELECT 10000000

```

A sequential scan over this large table takes a long time:

```

=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
                                QUERY PLAN

```

```

-----
Seq Scan on tbloom  (cost=0.00..2137.14 rows=3 width=24) (actual time=19.059..19.060
rows=0 loops=1)
  Filter: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Filter: 100000
Planning time: 0.269 ms
Execution time: 19.077 ms
(5 rows)

```

Even with the btree index defined the result will still be a sequential scan:

```

=# CREATE INDEX btreeidx ON tbloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('btreeidx'));
pg_size_pretty
-----
3992 kB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
                                QUERY PLAN

```

```

-----
Seq Scan on tbloom  (cost=0.00..2137.00 rows=2 width=24) (actual time=15.070..15.070
rows=0 loops=1)
  Filter: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Filter: 100000
Planning time: 0.130 ms
Execution time: 15.083 ms
(5 rows)

```

Having the bloom index defined on the table is better than btree in handling this type of search:

```

=# CREATE INDEX bloomidx ON tbloom USING bloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('bloomidx'));
pg_size_pretty
-----
1584 kB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
                                QUERY PLAN

```

```

-----
Bitmap Heap Scan on tbloom  (cost=1792.00..1799.69 rows=2 width=24) (actual
time=0.456..0.456 rows=0 loops=1)
  Recheck Cond: ((i2 = 898732) AND (i5 = 123451))

```

```
Rows Removed by Index Recheck: 29
Heap Blocks: exact=27
-> Bitmap Index Scan on bloomidx  (cost=0.00..1792.00 rows=2 width=0) (actual
time=0.422..0.423 rows=29 loops=1)
    Index Cond: ((i2 = 898732) AND (i5 = 123451))
Planning time: 0.105 ms
Execution time: 0.477 ms
(8 rows)
```

Now, the main problem with the btree search is that btree is inefficient when the search conditions do not constrain the leading index column(s). A better strategy for btree is to create a separate index on each column. Then the planner will choose something like this:

```
=# CREATE INDEX btreeidx1 ON tbloom (i1);
CREATE INDEX
=# CREATE INDEX btreeidx2 ON tbloom (i2);
CREATE INDEX
=# CREATE INDEX btreeidx3 ON tbloom (i3);
CREATE INDEX
=# CREATE INDEX btreeidx4 ON tbloom (i4);
CREATE INDEX
=# CREATE INDEX btreeidx5 ON tbloom (i5);
CREATE INDEX
=# CREATE INDEX btreeidx6 ON tbloom (i6);
CREATE INDEX
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
                                QUERY PLAN
```

```
-----
Bitmap Heap Scan on tbloom  (cost=24.34..32.03 rows=2 width=24) (actual
time=0.029..0.029 rows=0 loops=1)
    Recheck Cond: ((i5 = 123451) AND (i2 = 898732))
    -> BitmapAnd  (cost=24.34..24.34 rows=2 width=0) (actual time=0.028..0.028 rows=0
loops=1)
        -> Bitmap Index Scan on btreeidx5  (cost=0.00..12.04 rows=500 width=0)
(actual time=0.027..0.027 rows=0 loops=1)
            Index Cond: (i5 = 123451)
        -> Bitmap Index Scan on btreeidx2  (cost=0.00..12.04 rows=500 width=0) (never
executed)
            Index Cond: (i2 = 898732)
Planning time: 0.389 ms
Execution time: 0.054 ms
(9 rows)
```

Although this query runs much faster than with either of the single indexes, we pay a penalty in index size. Each of the single-column btree indexes occupies 2 MB, so the total space needed is 12 MB, eight times the space used by the bloom index.

F.6.3. Operator Class Interface

An operator class for bloom indexes requires only a hash function for the indexed data type and an equality operator for searching. This example shows the operator class definition for the `text` data type:

```
CREATE OPERATOR CLASS text_ops
DEFAULT FOR TYPE text USING bloom AS
    OPERATOR      1      =(text, text),
    FUNCTION      1      hashtext(text);
```

F.6.4. Limitations

- Only operator classes for `int4` and `text` are included with the module.

- Only the = operator is supported for search. But it is possible to add support for arrays with union and intersection operations in the future.
- bloom access method doesn't support UNIQUE indexes.
- bloom access method doesn't support searching for NULL values.

F.6.5. Authors

Teodor Sigaev <teodor@postgrespro.ru>, Postgres Professional, Moscow, Russia

Alexander Korotkov <a.korotkov@postgrespro.ru>, Postgres Professional, Moscow, Russia

Oleg Bartunov <obartunov@postgrespro.ru>, Postgres Professional, Moscow, Russia

F.7. btree_gin

`btree_gin` provides sample GIN operator classes that implement B-tree equivalent behavior for the data types `int2`, `int4`, `int8`, `float4`, `float8`, `timestamp with time zone`, `timestamp without time zone`, `time with time zone`, `time without time zone`, `date`, `interval`, `oid`, `money`, `"char"`, `varchar`, `text`, `bytea`, `bit`, `varbit`, `macaddr`, `inet`, and `cidr`.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they are useful for GIN testing and as a base for developing other GIN operator classes. Also, for queries that test both a GIN-indexable column and a B-tree-indexable column, it might be more efficient to create a multicolumn GIN index that uses one of these operator classes than to create two separate indexes that would have to be combined via bitmap ANDing.

F.7.1. Example Usage

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIN (a);
-- query
SELECT * FROM test WHERE a < 10;
```

F.7.2. Authors

Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megera/oddmuse/index.cgi/Gin> for additional information.

F.8. btree_gist

`btree_gist` provides GiST index operator classes that implement B-tree equivalent behavior for the data types `int2`, `int4`, `int8`, `float4`, `float8`, `numeric`, `timestamp with time zone`, `timestamp without time zone`, `time with time zone`, `time without time zone`, `date`, `interval`, `oid`, `money`, `char`, `varchar`, `text`, `bytea`, `bit`, `varbit`, `macaddr`, `inet`, and `cidr`.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they provide some other features that are not available with a B-tree index, as described below. Also, these operator classes are useful when a multicolumn GiST index is needed, wherein some of the columns are of data types that are only indexable with GiST but other columns are just simple data types. Lastly, these operator classes are useful for GiST testing and as a base for developing other GiST operator classes.

In addition to the typical B-tree search operators, `btree_gist` also provides index support for `<>` ("not equals"). This may be useful in combination with an [exclusion constraint](#), as described below.

Also, for data types for which there is a natural distance metric, `btree_gist` defines a distance operator `<->`, and provides GiST index support for nearest-neighbor searches using this operator. Distance operators are provided for `int2`, `int4`, `int8`, `float4`, `float8`, `timestamp with time zone`, `timestamp without time zone`, `time without time zone`, `date`, `interval`, `oid`, and `money`.

F.8.1. Example Usage

Simple example using `btree_gist` instead of `btree`:

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIST (a);
-- query
SELECT * FROM test WHERE a < 10;
-- nearest-neighbor search: find the ten entries closest to "42"
SELECT *, a <-> 42 AS dist FROM test ORDER BY a <-> 42 LIMIT 10;
```

Use an [exclusion constraint](#) to enforce the rule that a cage at a zoo can contain only one kind of animal:

```
=> CREATE TABLE zoo (
    cage    INTEGER,
    animal  TEXT,
    EXCLUDE USING GIST (cage WITH =, animal WITH <>)
);

=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'lion');
ERROR:  conflicting key value violates exclusion constraint "zoo_cage_animal_excl"
DETAIL:  Key (cage, animal)=(123, lion) conflicts with existing key (cage,
        animal)=(123, zebra).
=> INSERT INTO zoo VALUES(124, 'lion');
INSERT 0 1
```

F.8.2. Authors

Teodor Sigaev (<teodor@stack.net>), Oleg Bartunov (<oleg@sai.msu.su>), and Janko Richter (<jankorichter@yahoo.de>). See <http://www.sai.msu.su/~megera/postgres/gist/> for additional information.

F.9. chkpass

This module implements a data type `chkpass` that is designed for storing encrypted passwords. Each password is automatically converted to encrypted form upon entry, and is always stored encrypted. To compare, simply compare against a clear text password and the comparison function will encrypt it before comparing.

There are provisions in the code to report an error if the password is determined to be easily crackable. However, this is currently just a stub that does nothing.

If you precede an input string with a colon, it is assumed to be an already-encrypted password, and is stored without further encryption. This allows entry of previously-encrypted passwords.

On output, a colon is prepended. This makes it possible to dump and reload passwords without re-encrypting them. If you want the encrypted password without the colon then use the `raw()` function. This allows you to use the type with things like Apache's `Auth_PostgreSQL` module.

The encryption uses the standard Unix function `crypt()`, and so it suffers from all the usual limitations of that function; notably that only the first eight characters of a password are considered.

Note that the `chkpass` data type is not indexable.

Sample usage:

```
test=# create table test (p chkpass);
```

```
CREATE TABLE
test=# insert into test values ('hello');
INSERT 0 1
test=# select * from test;
      p
-----
:dVGkpXdOrE3ko
(1 row)

test=# select raw(p) from test;
      raw
-----
dVGkpXdOrE3ko
(1 row)

test=# select p = 'hello' from test;
?column?
-----
t
(1 row)

test=# select p = 'goodbye' from test;
?column?
-----
f
(1 row)
```

F.9.1. Author

D'Arcy J.M. Cain (<darcy@druid.net>)

F.10. citext

The `citext` module provides a case-insensitive character string type, `citext`. Essentially, it internally calls `lower` when comparing values. Otherwise, it behaves almost exactly like `text`.

F.10.1. Rationale

The standard approach to doing case-insensitive matches in Postgres Pro has been to use the `lower` function when comparing values, for example

```
SELECT * FROM tab WHERE lower(col) = LOWER(?);
```

This works reasonably well, but has a number of drawbacks:

- It makes your SQL statements verbose, and you always have to remember to use `lower` on both the column and the query value.
- It won't use an index, unless you create a functional index using `lower`.
- If you declare a column as `UNIQUE` or `PRIMARY KEY`, the implicitly generated index is case-sensitive. So it's useless for case-insensitive searches, and it won't enforce uniqueness case-insensitively.

The `citext` data type allows you to eliminate calls to `lower` in SQL queries, and allows a primary key to be case-insensitive. `citext` is locale-aware, just like `text`, which means that the matching of upper case and lower case characters is dependent on the rules of the database's `LC_CTYPE` setting. Again, this behavior is identical to the use of `lower` in queries. But because it's done transparently by the data type, you don't have to remember to do anything special in your queries.

F.10.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE users (  
    nick CITEXT PRIMARY KEY,  
    pass TEXT NOT NULL  
);  
  
INSERT INTO users VALUES ( 'larry', md5(random()::text) );  
INSERT INTO users VALUES ( 'Tom', md5(random()::text) );  
INSERT INTO users VALUES ( 'Damian', md5(random()::text) );  
INSERT INTO users VALUES ( 'NEAL', md5(random()::text) );  
INSERT INTO users VALUES ( 'Bjørn', md5(random()::text) );  
  
SELECT * FROM users WHERE nick = 'Larry';
```

The `SELECT` statement will return one tuple, even though the `nick` column was set to `larry` and the query was for `Larry`.

F.10.3. String Comparison Behavior

`citext` performs comparisons by converting each string to lower case (as though `lower` were called) and then comparing the results normally. Thus, for example, two strings are considered equal if `lower` would produce identical results for them.

In order to emulate a case-insensitive collation as closely as possible, there are `citext`-specific versions of a number of string-processing operators and functions. So, for example, the regular expression operators `~` and `~*` exhibit the same behavior when applied to `citext`: they both match case-insensitively. The same is true for `!~` and `!~*`, as well as for the `LIKE` operators `~~` and `~~*`, and `!~~` and `!~~*`. If you'd like to match case-sensitively, you can cast the operator's arguments to `text`.

Similarly, all of the following functions perform matching case-insensitively if their arguments are `citext`:

- `regexp_matches()`
- `regexp_replace()`
- `regexp_split_to_array()`
- `regexp_split_to_table()`
- `replace()`
- `split_part()`
- `strpos()`
- `translate()`

For the `regexp` functions, if you want to match case-sensitively, you can specify the “`c`” flag to force a case-sensitive match. Otherwise, you must cast to `text` before using one of these functions if you want case-sensitive behavior.

F.10.4. Limitations

- `citext`'s case-folding behavior depends on the `LC_CTYPE` setting of your database. How it compares values is therefore determined when the database is created. It is not truly case-insensitive in the terms defined by the Unicode standard. Effectively, what this means is that, as long as you're happy with your collation, you should be happy with `citext`'s comparisons. But if you have data in different languages stored in your database, users of one language may find their query results are not as expected if the collation is for another language.
- As of PostgreSQL 9.1, you can attach a `COLLATE` specification to `citext` columns or data values. Currently, `citext` operators will honor a non-default `COLLATE` specification while comparing case-folded strings, but the initial folding to lower case is always done according to the database's `LC_CTYPE` setting (that is, as though `COLLATE "default"` were given). This may be changed in a future release so that both steps follow the input `COLLATE` specification.

- `citext` is not as efficient as `text` because the operator functions and the B-tree comparison functions must make copies of the data and convert it to lower case for comparisons. It is, however, slightly more efficient than using `lower` to get case-insensitive matching.
- `citext` doesn't help much if you need data to compare case-sensitively in some contexts and case-insensitively in other contexts. The standard answer is to use the `text` type and manually use the `lower` function when you need to compare case-insensitively; this works all right if case-insensitive comparison is needed only infrequently. If you need case-insensitive behavior most of the time and case-sensitive infrequently, consider storing the data as `citext` and explicitly casting the column to `text` when you want case-sensitive comparison. In either situation, you will need two indexes if you want both types of searches to be fast.
- The schema containing the `citext` operators must be in the current `search_path` (typically `public`); if it is not, the normal case-sensitive `text` operators will be invoked instead.

F.10.5. Author

David E. Wheeler <david@kineticcode.com>

Inspired by the original `citext` module by Donald Fraser.

F.11. spi

The `spi` module provides several workable examples of using the [Server Programming Interface](#) (SPI) and triggers. While these functions are of some value in their own right, they are even more useful as examples to modify for your own purposes. The functions are general enough to be used with any table, but you have to specify table and field names (as described below) while creating a trigger.

Each of the groups of functions described below is provided as a separately-installable extension.

F.11.1. refint — Functions for Implementing Referential Integrity

`check_primary_key()` and `check_foreign_key()` are used to check foreign key constraints. (This functionality is long since superseded by the built-in foreign key mechanism, of course, but the module is still useful as an example.)

`check_primary_key()` checks the referencing table. To use, create a `BEFORE INSERT OR UPDATE` trigger using this function on a table referencing another table. Specify as the trigger arguments: the referencing table's column name(s) which form the foreign key, the referenced table name, and the column names in the referenced table which form the primary/unique key. To handle multiple foreign keys, create a trigger for each reference.

`check_foreign_key()` checks the referenced table. To use, create a `BEFORE DELETE OR UPDATE` trigger using this function on a table referenced by other table(s). Specify as the trigger arguments: the number of referencing tables for which the function has to perform checking, the action if a referencing key is found (`cascade` — to delete the referencing row, `restrict` — to abort transaction if referencing keys exist, `setnull` — to set referencing key fields to null), the triggered table's column names which form the primary/unique key, then the referencing table name and column names (repeated for as many referencing tables as were specified by first argument). Note that the primary/unique key columns should be marked `NOT NULL` and should have a unique index.

There are examples in `refint.example`.

F.11.2. timetravel — Functions for Implementing Time Travel

Long ago, Postgres Pro had a built-in time travel feature that kept the insert and delete times for each tuple. This can be emulated using these functions. To use these functions, you must add to a table two columns of `abstime` type to store the date when a tuple was inserted (`start_date`) and changed/deleted (`stop_date`):

```
CREATE TABLE mytab (  
    ...  
    start_date      abstime,  
    ...
```

```
        stop_date      abstime
        ...            ...
    );
```

The columns can be named whatever you like, but in this discussion we'll call them `start_date` and `stop_date`.

When a new row is inserted, `start_date` should normally be set to current time, and `stop_date` to `infinity`. The trigger will automatically substitute these values if the inserted data contains nulls in these columns. Generally, inserting explicit non-null data in these columns should only be done when re-loading dumped data.

Tuples with `stop_date` equal to `infinity` are “valid now”, and can be modified. Tuples with a finite `stop_date` cannot be modified anymore — the trigger will prevent it. (If you need to do that, you can turn off time travel as shown below.)

For a modifiable row, on update only the `stop_date` in the tuple being updated will be changed (to current time) and a new tuple with the modified data will be inserted. `Start_date` in this new tuple will be set to current time and `stop_date` to `infinity`.

A delete does not actually remove the tuple but only sets its `stop_date` to current time.

To query for tuples “valid now”, include `stop_date = 'infinity'` in the query's WHERE condition. (You might wish to incorporate that in a view.) Similarly, you can query for tuples valid at any past time with suitable conditions on `start_date` and `stop_date`.

`timetravel()` is the general trigger function that supports this behavior. Create a `BEFORE INSERT OR UPDATE OR DELETE` trigger using this function on each time-traveled table. Specify two trigger arguments: the actual names of the `start_date` and `stop_date` columns. Optionally, you can specify one to three more arguments, which must refer to columns of type `text`. The trigger will store the name of the current user into the first of these columns during `INSERT`, the second column during `UPDATE`, and the third during `DELETE`.

`set_timetravel()` allows you to turn time-travel on or off for a table. `set_timetravel('mytab', 1)` will turn TT ON for table `mytab`. `set_timetravel('mytab', 0)` will turn TT OFF for table `mytab`. In both cases the old status is reported. While TT is off, you can modify the `start_date` and `stop_date` columns freely. Note that the on/off status is local to the current database session — fresh sessions will always start out with TT ON for all tables.

`get_timetravel()` returns the TT state for a table without changing it.

There is an example in `timetravel.example`.

F.11.3. `autoinc` — Functions for Autoincrementing Fields

`autoinc()` is a trigger that stores the next value of a sequence into an integer field. This has some overlap with the built-in “serial column” feature, but it is not the same: `autoinc()` will override attempts to substitute a different field value during inserts, and optionally it can be used to increment the field during updates, too.

To use, create a `BEFORE INSERT` (or optionally `BEFORE INSERT OR UPDATE`) trigger using this function. Specify two trigger arguments: the name of the integer column to be modified, and the name of the sequence object that will supply values. (Actually, you can specify any number of pairs of such names, if you'd like to update more than one autoincrementing column.)

There is an example in `autoinc.example`.

F.11.4. `insert_username` — Functions for Tracking Who Changed a Table

`insert_username()` is a trigger that stores the current user's name into a text field. This can be useful for tracking who last modified a particular row within a table.

To use, create a `BEFORE INSERT` and/or `UPDATE` trigger using this function. Specify a single trigger argument: the name of the text column to be modified.

There is an example in `insert_username.example`.

F.11.5. moddatetime — Functions for Tracking Last Modification Time

`moddatetime()` is a trigger that stores the current time into a `timestamp` field. This can be useful for tracking the last modification time of a particular row within a table.

To use, create a `BEFORE UPDATE` trigger using this function. Specify a single trigger argument: the name of the column to be modified. The column must be of type `timestamp` or `timestamp with time zone`.

There is an example in `moddatetime.example`.

F.12. cube

This module implements a data type `cube` for representing multidimensional cubes.

F.12.1. Syntax

Table F.7 shows the valid external representations for the `cube` type. x , y , etc. denote floating-point numbers.

Table F.7. Cube External Representations

External Syntax	Meaning
x	A one-dimensional point (or, zero-length one-dimensional interval)
(x)	Same as above
$x1, x2, \dots, xn$	A point in n -dimensional space, represented internally as a zero-volume cube
$(x1, x2, \dots, xn)$	Same as above
$(x), (y)$	A one-dimensional interval starting at x and ending at y or vice versa; the order does not matter
$[(x), (y)]$	Same as above
$(x1, \dots, xn), (y1, \dots, yn)$	An n -dimensional cube represented by a pair of its diagonally opposite corners
$[(x1, \dots, xn), (y1, \dots, yn)]$	Same as above

It does not matter which order the opposite corners of a cube are entered in. The `cube` functions automatically swap values if needed to create a uniform “lower left — upper right” internal representation. When the corners coincide, `cube` stores only one corner along with an “is point” flag to avoid wasting space.

White space is ignored on input, so $[(x), (y)]$ is the same as $[(x), (y)]$.

F.12.2. Precision

Values are stored internally as 64-bit floating point numbers. This means that numbers with more than about 16 significant digits will be truncated.

F.12.3. Usage

Table F.8 shows the operators provided for type `cube`.

Table F.8. Cube Operators

Operator	Result	Description
<code>a = b</code>	boolean	The cubes a and b are identical.
<code>a && b</code>	boolean	The cubes a and b overlap.
<code>a @> b</code>	boolean	The cube a contains the cube b.
<code>a <@ b</code>	boolean	The cube a is contained in the cube b.
<code>a < b</code>	boolean	The cube a is less than the cube b.
<code>a <= b</code>	boolean	The cube a is less than or equal to the cube b.
<code>a > b</code>	boolean	The cube a is greater than the cube b.
<code>a >= b</code>	boolean	The cube a is greater than or equal to the cube b.
<code>a <> b</code>	boolean	The cube a is not equal to the cube b.
<code>a -> n</code>	float8	Get <i>n</i> -th coordinate of cube (counting from 1).
<code>a ~> n</code>	float8	Get <i>n</i> -th coordinate of cube in following way: $n = 2 * k - 1$ means lower bound of <i>k</i> -th dimension, $n = 2 * k$ means upper bound of <i>k</i> -th dimension. This operator is designed for KNN-GiST support.
<code>a <-> b</code>	float8	Euclidean distance between a and b.
<code>a <#> b</code>	float8	Taxicab (L-1 metric) distance between a and b.
<code>a <=> b</code>	float8	Chebyshev (L-inf metric) distance between a and b.

(Before PostgreSQL 8.2, the containment operators `@>` and `<@` were respectively called `@` and `~`. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!)

The scalar ordering operators (`<`, `>=`, etc) do not make a lot of sense for any practical purpose but sorting. These operators first compare the first coordinates, and if those are equal, compare the second coordinates, etc. They exist mainly to support the b-tree index operator class for `cube`, which can be useful for example if you would like a `UNIQUE` constraint on a `cube` column.

The `cube` module also provides a GiST index operator class for `cube` values. A `cube` GiST index can be used to search for values using the `=`, `&&`, `@>`, and `<@` operators in `WHERE` clauses.

In addition, a `cube` GiST index can be used to find nearest neighbors using the metric operators `<->`, `<#>`, and `<=>` in `ORDER BY` clauses. For example, the nearest neighbor of the 3-D point (0.5, 0.5, 0.5) could be found efficiently with:

```
SELECT c FROM test ORDER BY c <-> cube(array[0.5,0.5,0.5]) LIMIT 1;
```

The `~>` operator can also be used in this way to efficiently retrieve the first few values sorted by a selected coordinate. For example, to get the first few cubes ordered by the first coordinate (lower left corner) ascending one could use the following query:

```
SELECT c FROM test ORDER BY c ~> 1 LIMIT 5;
```

And to get 2-D cubes ordered by the first coordinate of the upper right corner descending:

```
SELECT c FROM test ORDER BY c ~> 3 DESC LIMIT 5;
```

Table F.9 shows the available functions.

Table F.9. Cube Functions

Function	Result	Description	Example
<code>cube(float8)</code>	cube	Makes a one dimensional cube with both coordinates the same.	<code>cube(1) == '(1)'</code>
<code>cube(float8, float8)</code>	cube	Makes a one dimensional cube.	<code>cube(1,2) == '(1), (2)'</code>
<code>cube(float8[])</code>	cube	Makes a zero-volume cube using the coordinates defined by the array.	<code>cube(ARRAY[1,2]) == '(1,2)'</code>
<code>cube(float8[], float8[])</code>	cube	Makes a cube with upper right and lower left coordinates as defined by the two arrays, which must be of the same length.	<code>cube(ARRAY[1,2], ARRAY[3,4]) == '(1,2), (3,4)'</code>
<code>cube(cube, float8)</code>	cube	Makes a new cube by adding a dimension on to an existing cube, with the same values for both endpoints of the new coordinate. This is useful for building cubes piece by piece from calculated values.	<code>cube('(1,2), (3,4)')::cube, 5) == '(1,2,5), (3,4,5)'</code>
<code>cube(cube, float8, float8)</code>	cube	Makes a new cube by adding a dimension on to an existing cube. This is useful for building cubes piece by piece from calculated values.	<code>cube('(1,2), (3,4)')::cube, 5, 6) == '(1,2,5), (3,4,6)'</code>
<code>cube_dim(cube)</code>	integer	Returns the number of dimensions of the cube.	<code>cube_dim('(1,2), (3,4)') == '2'</code>
<code>cube_ll_coord(cube, integer)</code>	float8	Returns the <i>n</i> -th coordinate value for the lower left corner of the cube.	<code>cube_ll_coord('(1,2), (3,4)', 2) == '2'</code>
<code>cube_ur_coord(cube, integer)</code>	float8	Returns the <i>n</i> -th coordinate value for the upper right corner of the cube.	<code>cube_ur_coord('(1,2), (3,4)', 2) == '4'</code>
<code>cube_is_point(cube)</code>	boolean	Returns true if the cube is a point, that is, the two defining corners are the same.	
<code>cube_distance(cube, cube)</code>	float8	Returns the distance between two cubes. If	

Function	Result	Description	Example
		both cubes are points, this is the normal distance function.	
<code>cube_subset(cube, integer[])</code>	cube	Makes a new cube from an existing cube, using a list of dimension indexes from an array. Can be used to extract the endpoints of a single dimension, or to drop dimensions, or to reorder them as desired.	<code>cube_subset(cube(' (1, 3, 5), (6, 7, 8) '), ARRAY[2]) == '(3), (7)'</code> <code>cube_subset(cube(' (1, 3, 5), (6, 7, 8) '), ARRAY[3, 2, 1, 1]) == '(5, 3, 1, 1), (8, 7, 6, 6)'</code>
<code>cube_union(cube, cube)</code>	cube	Produces the union of two cubes.	
<code>cube_inter(cube, cube)</code>	cube	Produces the intersection of two cubes.	
<code>cube_enlarge(cube, r double, n integer)</code>	cube	Increases the size of the cube by the specified radius r in at least n dimensions. If the radius is negative the cube is shrunk instead. All defined dimensions are changed by the radius r . Lower-left coordinates are decreased by r and upper-right coordinates are increased by r . If a lower-left coordinate is increased to more than the corresponding upper-right coordinate (this can only happen when $r < 0$) then both coordinates are set to their average. If n is greater than the number of defined dimensions and the cube is being enlarged ($r > 0$), then extra dimensions are added to make n altogether; 0 is used as the initial value for the extra coordinates. This function is useful for creating bounding boxes around a point for searching for nearby points.	<code>cube_enlarge('(1, 2), (3, 4)', 0.5, 3) == '(0.5, 1.5, -0.5), (3.5, 4.5, 0.5)'</code>

F.12.4. Defaults

I believe this union:

```
select cube_union('(0,5,2),(2,3,1)', '0');
cube_union
-----
(0, 0, 0),(2, 5, 2)
(1 row)
```

does not contradict common sense, neither does the intersection

```
select cube_inter('(0,-1),(1,1)', '(-2),(2)');
cube_inter
-----
(0, 0),(1, 0)
(1 row)
```

In all binary operations on differently-dimensioned cubes, I assume the lower-dimensional one to be a Cartesian projection, i. e., having zeroes in place of coordinates omitted in the string representation. The above examples are equivalent to:

```
cube_union('(0,5,2),(2,3,1)', '(0,0,0),(0,0,0)');
cube_inter('(0,-1),(1,1)', '(-2,0),(2,0)');
```

The following containment predicate uses the point syntax, while in fact the second argument is internally represented by a box. This syntax makes it unnecessary to define a separate point type and functions for (box,point) predicates.

```
select cube_contains('(0,0),(1,1)', '0.5,0.5');
cube_contains
-----
t
(1 row)
```

F.12.5. Notes

For examples of usage, see the regression test `sql/cube.sql`.

To make it harder for people to break things, there is a limit of 100 on the number of dimensions of cubes. This is set in `cubedata.h` if you need something bigger.

F.12.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (<https://dsf.berkeley.edu/jmh/>) for elucidating the gist of the GiST (<http://gist.cs.berkeley.edu/>), and to his former student Andy Dong for his example written for Illustra. I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

Minor updates to this package were made by Bruno Wolff III <bruno@wolff.to> in August/September of 2002. These include changing the precision from single precision to double precision and adding some new functions.

Additional updates were made by Joshua Reich <josh@root.net> in July 2006. These include `cube(float8[], float8[])` and cleaning up the code to use the V1 call protocol instead of the deprecated V0 protocol.

F.13. dblink

`dblink` is a module that supports connections to other Postgres Pro databases from within a database session.

See also [postgres_fdw](#), which provides roughly the same functionality using a more modern and standards-compliant infrastructure.

dblink_connect

`dblink_connect` — opens a persistent connection to a remote database

Synopsis

```
dblink_connect(text connstr) returns text
dblink_connect(text connname, text connstr) returns text
```

Description

`dblink_connect()` establishes a connection to a remote Postgres Pro database. The server and database to be contacted are identified through a standard libpq connection string. Optionally, a name can be assigned to the connection. Multiple named connections can be open at once, but only one unnamed connection is permitted at a time. The connection will persist until closed or until the database session is ended.

The connection string may also be the name of an existing foreign server. It is recommended to use the foreign-data wrapper `dblink_fdw` when defining the foreign server. See the example below, as well as [CREATE SERVER](#) and [CREATE USER MAPPING](#).

Arguments

connname

The name to use for this connection; if omitted, an unnamed connection is opened, replacing any existing unnamed connection.

connstr

libpq-style connection info string, for example `hostaddr=127.0.0.1 port=5432 dbname=mydb user=postgres password=mypasswd options=-csearch_path=`. For details see [Section 32.1.1](#). Alternatively, the name of a foreign server.

Return Value

Returns status, which is always OK (since any error causes the function to throw an error instead of returning).

Notes

If untrusted users have access to a database that has not adopted a [secure schema usage pattern](#), begin each session by removing publicly-writable schemas from `search_path`. One could, for example, add `options=-csearch_path=` to *connstr*. This consideration is not specific to `dblink`; it applies to every interface for executing arbitrary SQL commands.

Only superusers may use `dblink_connect` to create non-password-authenticated connections. If non-superusers need this capability, use `dblink_connect_u` instead.

It is unwise to choose connection names that contain equal signs, as this opens a risk of confusion with connection info strings in other `dblink` functions.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
 dblink_connect
-----
      OK
(1 row)

SELECT dblink_connect('myconn', 'dbname=postgres options=-csearch_path=');
```

```

dblink_connect
-----
OK
(1 row)

-- FOREIGN DATA WRAPPER functionality
-- Note: local connection must require password authentication for this to work
properly
--      Otherwise, you will receive the following error from dblink_connect():
--      -----
--      ERROR:  password is required
--      DETAIL:  Non-superuser cannot connect if the server does not request a
password.
--      HINT:   Target server's authentication method must be changed.

CREATE SERVER fdtest FOREIGN DATA WRAPPER dblink_fdw OPTIONS (hostaddr '127.0.0.1',
    dbname 'contrib_regression');

CREATE USER regress_dblink_user WITH PASSWORD 'secret';
CREATE USER MAPPING FOR regress_dblink_user SERVER fdtest OPTIONS (user
    'regress_dblink_user', password 'secret');
GRANT USAGE ON FOREIGN SERVER fdtest TO regress_dblink_user;
GRANT SELECT ON TABLE foo TO regress_dblink_user;

\set ORIGINAL_USER :USER
\c - regress_dblink_user
SELECT dblink_connect('myconn', 'fdtest');
dblink_connect
-----
OK
(1 row)

SELECT * FROM dblink('myconn', 'SELECT * FROM foo') AS t(a int, b text, c text[]);
 a | b |      c
-----+-----+-----
 0 | a | {a0,b0,c0}
 1 | b | {a1,b1,c1}
 2 | c | {a2,b2,c2}
 3 | d | {a3,b3,c3}
 4 | e | {a4,b4,c4}
 5 | f | {a5,b5,c5}
 6 | g | {a6,b6,c6}
 7 | h | {a7,b7,c7}
 8 | i | {a8,b8,c8}
 9 | j | {a9,b9,c9}
10 | k | {a10,b10,c10}
(11 rows)

\c - :ORIGINAL_USER
REVOKE USAGE ON FOREIGN SERVER fdtest FROM regress_dblink_user;
REVOKE SELECT ON TABLE foo FROM regress_dblink_user;
DROP USER MAPPING FOR regress_dblink_user SERVER fdtest;
DROP USER regress_dblink_user;
DROP SERVER fdtest;

```

dblink_connect_u

`dblink_connect_u` — opens a persistent connection to a remote database, insecurely

Synopsis

```
dblink_connect_u(text connstr) returns text  
dblink_connect_u(text connname, text connstr) returns text
```

Description

`dblink_connect_u()` is identical to `dblink_connect()`, except that it will allow non-superusers to connect using any authentication method.

If the remote server selects an authentication method that does not involve a password, then impersonation and subsequent escalation of privileges can occur, because the session will appear to have originated from the user as which the local Postgres Pro server runs. Also, even if the remote server does demand a password, it is possible for the password to be supplied from the server environment, such as a `~/.pgpass` file belonging to the server's user. This opens not only a risk of impersonation, but the possibility of exposing a password to an untrustworthy remote server. Therefore, `dblink_connect_u()` is initially installed with all privileges revoked from `PUBLIC`, making it un-callable except by superusers. In some situations it may be appropriate to grant `EXECUTE` permission for `dblink_connect_u()` to specific users who are considered trustworthy, but this should be done with care. It is also recommended that any `~/.pgpass` file belonging to the server's user *not* contain any records specifying a wildcard host name.

For further details see `dblink_connect()`.

dblink_disconnect

`dblink_disconnect` — closes a persistent connection to a remote database

Synopsis

```
dblink_disconnect() returns text
dblink_disconnect(text connname) returns text
```

Description

`dblink_disconnect()` closes a connection previously opened by `dblink_connect()`. The form with no arguments closes an unnamed connection.

Arguments

connname

The name of a named connection to be closed.

Return Value

Returns status, which is always `OK` (since any error causes the function to throw an error instead of returning).

Examples

```
SELECT dblink_disconnect();
 dblink_disconnect
-----
OK
(1 row)

SELECT dblink_disconnect('myconn');
 dblink_disconnect
-----
OK
(1 row)
```

dblink

`dblink` — executes a query in a remote database

Synopsis

```
dblink(text connname, text sql [, bool fail_on_error]) returns setof record
dblink(text connstr, text sql [, bool fail_on_error]) returns setof record
dblink(text sql [, bool fail_on_error]) returns setof record
```

Description

`dblink` executes a query (usually a `SELECT`, but it can be any SQL statement that returns rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

connstr

A connection info string, as previously described for `dblink_connect`.

sql

The SQL query that you wish to execute in the remote database, for example `select * from foo`.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a `NOTICE`, and the function returns no rows.

Return Value

The function returns the row(s) produced by the query. Since `dblink` can be used with any query, it is declared to return `record`, rather than specifying any particular set of columns. This means that you must specify the expected set of columns in the calling query — otherwise Postgres Pro would not know what to expect. Here is an example:

```
SELECT *
FROM dblink('dbname=mydb options=-csearch_path=',
            'select pronomame, prosrc from pg_proc')
AS t1(pronomame name, prosrc text)
WHERE pronomame LIKE 'bytea%';
```

The “alias” part of the `FROM` clause must specify the column names and types that the function will return. (Specifying column names in an alias is actually standard SQL syntax, but specifying column types is a Postgres Pro extension.) This allows the system to understand what `*` should expand to, and what `pronomame` in the `WHERE` clause refers to, in advance of trying to execute the function. At run time, an error will be thrown if the actual query result from the remote database does not have the same number of columns shown in the `FROM` clause. The column names need not match, however, and `dblink` does not insist on exact type matches either. It will succeed so long as the returned data strings are valid input for the column type declared in the `FROM` clause.

Notes

A convenient way to use `dblink` with predetermined queries is to create a view. This allows the column type information to be buried in the view, instead of having to spell it out in every query. For example,

```
CREATE VIEW myremote_pg_proc AS
  SELECT *
    FROM dblink('dbname=postgres options=-csearch_path=',
                'select proname, prosrc from pg_proc')
    AS t1(proname name, prosrc text);

SELECT * FROM myremote_pg_proc WHERE proname LIKE 'bytea%';
```

Examples

```
SELECT * FROM dblink('dbname=postgres options=-csearch_path=',
                    'select proname, prosrc from pg_proc')
  AS t1(proname name, prosrc text) WHERE proname LIKE 'bytea%';
 proname | prosrc
```

```

(14 rows)

dblink_exec

`dblink_exec` — executes a command in a remote database

Synopsis

```
dblink_exec(text connname, text sql [, bool fail_on_error]) returns text
dblink_exec(text connstr, text sql [, bool fail_on_error]) returns text
dblink_exec(text sql [, bool fail_on_error]) returns text
```

Description

`dblink_exec` executes a command (that is, any SQL statement that doesn't return rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

connstr

A connection info string, as previously described for `dblink_connect`.

sql

The SQL command that you wish to execute in the remote database, for example `insert into foo values (0, 'a', '{"a0","b0","c0"}')`.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

Return Value

Returns status, either the command's status string or `ERROR`.

Examples

```
SELECT dblink_connect('dbname=dblink_test_standby');
 dblink_connect
-----
 OK
(1 row)

SELECT dblink_exec('insert into foo values(21, ''z'', ''{"a0","b0","c0"}'');');
 dblink_exec
-----
 INSERT 943366 1
(1 row)

SELECT dblink_connect('myconn', 'dbname=regression');
 dblink_connect
```

OK
(1 row)

```
SELECT dblink_exec('myconn', 'insert into foo values(21, ''z'',
''{"a0","b0","c0"}'');');
      dblink_exec
```

INSERT 6432584 1
(1 row)

```
SELECT dblink_exec('myconn', 'insert into pg_class values (''foo''),false);
NOTICE:  sql error
DETAIL:  ERROR:  null value in column "relnamespace" violates not-null constraint
```

dblink_exec

ERROR
(1 row)

dblink_open

`dblink_open` — opens a cursor in a remote database

Synopsis

```
dblink_open(text cursorname, text sql [, bool fail_on_error]) returns text
dblink_open(text connname, text cursorname, text sql [, bool fail_on_error]) returns
text
```

Description

`dblink_open()` opens a cursor in a remote database. The cursor can subsequently be manipulated with `dblink_fetch()` and `dblink_close()`.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

cursorname

The name to assign to this cursor.

sql

The `SELECT` statement that you wish to execute in the remote database, for example `select * from pg_class`.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

Return Value

Returns status, either `OK` or `ERROR`.

Notes

Since a cursor can only persist within a transaction, `dblink_open` starts an explicit transaction block (`BEGIN`) on the remote side, if the remote side was not already within a transaction. This transaction will be closed again when the matching `dblink_close` is executed. Note that if you use `dblink_exec` to change data between `dblink_open` and `dblink_close`, and then an error occurs or you use `dblink_disconnect` before `dblink_close`, your change *will be lost* because the transaction will be aborted.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
-----
OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
dblink_open
-----
OK
```

Additional Supplied Modules

(1 row)

dblink_fetch

`dblink_fetch` — returns rows from an open cursor in a remote database

Synopsis

```
dblink_fetch(text cursorname, int howmany [, bool fail_on_error]) returns setof record
dblink_fetch(text connname, text cursorname, int howmany [, bool fail_on_error])
returns setof record
```

Description

`dblink_fetch` fetches rows from a cursor previously established by `dblink_open`.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

cursorname

The name of the cursor to fetch from.

howmany

The maximum number of rows to retrieve. The next *howmany* rows are fetched, starting at the current cursor position, moving forward. Once the cursor has reached its end, no more rows are produced.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

Return Value

The function returns the row(s) fetched from the cursor. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

Notes

On a mismatch between the number of return columns specified in the `FROM` clause, and the actual number of columns returned by the remote cursor, an error will be thrown. In this event, the remote cursor is still advanced by as many rows as it would have been if the error had not occurred. The same is true for any other error occurring in the local query after the remote `FETCH` has been done.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
```

```
-----
OK
(1 row)
```

```
SELECT dblink_open('foo', 'select proname, prosrc from pg_proc where proname like
''bytea%'');
dblink_open
```

```
-----
OK
(1 row)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
 funcname | source
-----+-----
 byteacat | byteacat
 byteacmp | byteacmp
 byteaeq  | byteaeq
 byteage  | byteage
 byteagt  | byteagt
(5 rows)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
 funcname | source
-----+-----
 byteain  | byteain
 byteale  | byteale
 bytealike| bytealike
 bytealt  | bytealt
 byteane  | byteane
(5 rows)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
 funcname | source
-----+-----
 byteanlike| byteanlike
 byteaout  | byteaout
(2 rows)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
 funcname | source
-----+-----
(0 rows)
```

dblink_close

`dblink_close` — closes a cursor in a remote database

Synopsis

```
dblink_close(text cursorname [, bool fail_on_error]) returns text
dblink_close(text connname, text cursorname [, bool fail_on_error]) returns text
```

Description

`dblink_close` closes a cursor previously opened with `dblink_open`.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

cursorname

The name of the cursor to close.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

Return Value

Returns status, either `OK` or `ERROR`.

Notes

If `dblink_open` started an explicit transaction block, and this is the last remaining open cursor in this connection, `dblink_close` will issue the matching `COMMIT`.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
 dblink_connect
-----
 OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
 dblink_open
-----
 OK
(1 row)

SELECT dblink_close('foo');
 dblink_close
-----
 OK
(1 row)
```

dblink_get_connections

`dblink_get_connections` — returns the names of all open named dblink connections

Synopsis

```
dblink_get_connections() returns text[]
```

Description

`dblink_get_connections` returns an array of the names of all open named dblink connections.

Return Value

Returns a text array of connection names, or NULL if none.

Examples

```
SELECT dblink_get_connections();
```

dblink_error_message

`dblink_error_message` — gets last error message on the named connection

Synopsis

`dblink_error_message(text connname)` returns text

Description

`dblink_error_message` fetches the most recent remote error message for a given connection.

Arguments

connname

Name of the connection to use.

Return Value

Returns last error message, or OK if there has been no error in this connection.

Notes

When asynchronous queries are initiated by `dblink_send_query`, the error message associated with the connection might not get updated until the server's response message is consumed. This typically means that `dblink_is_busy` or `dblink_get_result` should be called prior to `dblink_error_message`, so that any error generated by the asynchronous query will be visible.

Examples

```
SELECT dblink_error_message('dtest1');
```

dblink_send_query

`dblink_send_query` — sends an async query to a remote database

Synopsis

```
dblink_send_query(text connname, text sql) returns int
```

Description

`dblink_send_query` sends a query to be executed asynchronously, that is, without immediately waiting for the result. There must not be an async query already in progress on the connection.

After successfully dispatching an async query, completion status can be checked with `dblink_is_busy`, and the results are ultimately collected with `dblink_get_result`. It is also possible to attempt to cancel an active async query using `dblink_cancel_query`.

Arguments

connname

Name of the connection to use.

sql

The SQL statement that you wish to execute in the remote database, for example `select * from pg_class`.

Return Value

Returns 1 if the query was successfully dispatched, 0 otherwise.

Examples

```
SELECT dblink_send_query('dtest1', 'SELECT * FROM foo WHERE f1 < 3');
```

dblink_is_busy

`dblink_is_busy` — checks if connection is busy with an async query

Synopsis

```
dblink_is_busy(text connname) returns int
```

Description

`dblink_is_busy` tests whether an async query is in progress.

Arguments

connname

Name of the connection to check.

Return Value

Returns 1 if connection is busy, 0 if it is not busy. If this function returns 0, it is guaranteed that `dblink_get_result` will not block.

Examples

```
SELECT dblink_is_busy('dtest1');
```

dblink_get_notify

dblink_get_notify — retrieve async notifications on a connection

Synopsis

```
dblink_get_notify() returns setof (notify_name text, be_pid int, extra text)
dblink_get_notify(text connname) returns setof (notify_name text, be_pid int, extra
text)
```

Description

dblink_get_notify retrieves notifications on either the unnamed connection, or on a named connection if specified. To receive notifications via dblink, LISTEN must first be issued, using dblink_exec. For details see [LISTEN](#) and [NOTIFY](#).

Arguments

connname

The name of a named connection to get notifications on.

Return Value

Returns setof (notify_name text, be_pid int, extra text), or an empty set if none.

Examples

```
SELECT dblink_exec('LISTEN virtual');
 dblink_exec
-----
LISTEN
(1 row)
```

```
SELECT * FROM dblink_get_notify();
 notify_name | be_pid | extra
-----+-----+-----
(0 rows)
```

```
NOTIFY virtual;
NOTIFY
```

```
SELECT * FROM dblink_get_notify();
 notify_name | be_pid | extra
-----+-----+-----
virtual      |    1229 |
(1 row)
```

dblink_get_result

`dblink_get_result` — gets an async query result

Synopsis

```
dblink_get_result(text connname [, bool fail_on_error]) returns setof record
```

Description

`dblink_get_result` collects the results of an asynchronous query previously sent with `dblink_send_query`. If the query is not already completed, `dblink_get_result` will wait until it is.

Arguments

connname

Name of the connection to use.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

Return Value

For an async query (that is, a SQL statement returning rows), the function returns the row(s) produced by the query. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

For an async command (that is, a SQL statement not returning rows), the function returns a single row with a single text column containing the command's status string. It is still necessary to specify that the result will have a single text column in the calling `FROM` clause.

Notes

This function *must* be called if `dblink_send_query` returned 1. It must be called once for each query sent, and one additional time to obtain an empty set result, before the connection can be used again.

When using `dblink_send_query` and `dblink_get_result`, `dblink` fetches the entire remote query result before returning any of it to the local query processor. If the query returns a large number of rows, this can result in transient memory bloat in the local session. It may be better to open such a query as a cursor with `dblink_open` and then fetch a manageable number of rows at a time. Alternatively, use plain `dblink()`, which avoids memory bloat by spooling large result sets to disk.

Examples

```
contrib_regression=# SELECT dblink_connect('dtest1', 'dbname=contrib_regression');
dblink_connect
-----
OK
(1 row)

contrib_regression=# SELECT * FROM
contrib_regression-# dblink_send_query('dtest1', 'select * from foo where f1 < 3') AS
t1;
t1
----
1
(1 row)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
```

```
f1 | f2 |      f3
----+-----+-----
 0 | a  | {a0,b0,c0}
 1 | b  | {a1,b1,c1}
 2 | c  | {a2,b2,c2}
(3 rows)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
```

```
f1 | f2 | f3
----+-----+-----
(0 rows)
```

```
contrib_regression=# SELECT * FROM
contrib_regression=# dblink_send_query('dtest1', 'select * from foo where f1 < 3;
select * from foo where f1 > 6') AS t1;
```

```
t1
----
 1
(1 row)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
```

```
f1 | f2 |      f3
----+-----+-----
 0 | a  | {a0,b0,c0}
 1 | b  | {a1,b1,c1}
 2 | c  | {a2,b2,c2}
(3 rows)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
```

```
f1 | f2 |      f3
----+-----+-----
 7 | h  | {a7,b7,c7}
 8 | i  | {a8,b8,c8}
 9 | j  | {a9,b9,c9}
10 | k  | {a10,b10,c10}
(4 rows)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
```

```
f1 | f2 | f3
----+-----+-----
(0 rows)
```

dblink_cancel_query

`dblink_cancel_query` — cancels any active query on the named connection

Synopsis

```
dblink_cancel_query(text connname) returns text
```

Description

`dblink_cancel_query` attempts to cancel any query that is in progress on the named connection. Note that this is not certain to succeed (since, for example, the remote query might already have finished). A cancel request simply improves the odds that the query will fail soon. You must still complete the normal query protocol, for example by calling `dblink_get_result`.

Arguments

connname

Name of the connection to use.

Return Value

Returns `OK` if the cancel request has been sent, or the text of an error message on failure.

Examples

```
SELECT dblink_cancel_query('dtest1');
```

dblink_get_pkey

`dblink_get_pkey` — returns the positions and field names of a relation's primary key fields

Synopsis

`dblink_get_pkey(text relname)` returns `setof dblink_pkey_results`

Description

`dblink_get_pkey` provides information about the primary key of a relation in the local database. This is sometimes useful in generating queries to be sent to remote databases.

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

Return Value

Returns one row for each primary key field, or no rows if the relation has no primary key. The result row type is defined as

```
CREATE TYPE dblink_pkey_results AS (position int, colname text);
```

The `position` column simply runs from 1 to *N*; it is the number of the field within the primary key, not the number within the table's columns.

Examples

```
CREATE TABLE foobar (  
    f1 int,  
    f2 int,  
    f3 int,  
    PRIMARY KEY (f1, f2, f3)  
);  
CREATE TABLE  
  
SELECT * FROM dblink_get_pkey('foobar');  
 position | colname  
-----+-----  
        1 | f1  
        2 | f2  
        3 | f3  
(3 rows)
```

dblink_build_sql_insert

`dblink_build_sql_insert` — builds an `INSERT` statement using a local tuple, replacing the primary key field values with alternative supplied values

Synopsis

```
dblink_build_sql_insert(text relname,
                        int2vector primary_key_attnums,
                        integer num_primary_key_atts,
                        text[] src_pk_att_vals_array,
                        text[] tgt_pk_att_vals_array) returns text
```

Description

`dblink_build_sql_insert` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds a SQL `INSERT` command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.)

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

primary_key_attnums

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

num_primary_key_atts

The number of primary key fields.

src_pk_att_vals_array

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

tgt_pk_att_vals_array

Values of the primary key fields to be placed in the resulting `INSERT` command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in *primary_key_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_insert('foo', '1 2', 2, '{"1", "a"}', '{"1", "b''a"}');
       dblink_build_sql_insert
```

```
INSERT INTO foo(f1,f2,f3) VALUES('1','b' 'a','1')
(1 row)
```

dblink_build_sql_delete

`dblink_build_sql_delete` — builds a DELETE statement using supplied values for primary key field values

Synopsis

```
dblink_build_sql_delete(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] tgt_pk_att_vals_array) returns text
```

Description

`dblink_build_sql_delete` can be useful in doing selective replication of a local table to a remote database. It builds a SQL DELETE command that will delete the row with the given primary key values.

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

primary_key_attnums

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

num_primary_key_atts

The number of primary key fields.

tgt_pk_att_vals_array

Values of the primary key fields to be used in the resulting DELETE command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in *primary_key_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_delete('MyFoo', '1 2', 2, '{"1", "b"}');  
      dblink_build_sql_delete  
-----  
DELETE FROM "MyFoo" WHERE f1='1' AND f2='b'  
(1 row)
```

dblink_build_sql_update

`dblink_build_sql_update` — builds an UPDATE statement using a local tuple, replacing the primary key field values with alternative supplied values

Synopsis

```
dblink_build_sql_update(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] src_pk_att_vals_array,  
                        text[] tgt_pk_att_vals_array) returns text
```

Description

`dblink_build_sql_update` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds a SQL UPDATE command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.) The UPDATE command always assigns all fields of the row — the main difference between this and `dblink_build_sql_insert` is that it's assumed that the target row already exists in the remote table.

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

primary_key_attnums

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

num_primary_key_atts

The number of primary key fields.

src_pk_att_vals_array

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

tgt_pk_att_vals_array

Values of the primary key fields to be placed in the resulting UPDATE command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in *primary_key_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_update('foo', '1 2', 2, '{"1", "a"}', '{"1", "b"}');  
       dblink_build_sql_update
```

```
-----  
UPDATE foo SET f1='1',f2='b',f3='1' WHERE f1='1' AND f2='b'  
(1 row)
```

F.14. dict_int

`dict_int` is an example of an add-on dictionary template for full-text search. The motivation for this example dictionary is to control the indexing of integers (signed and unsigned), allowing such numbers to be indexed while preventing excessive growth in the number of unique words, which greatly affects the performance of searching.

F.14.1. Configuration

The dictionary accepts two options:

- The `maxlen` parameter specifies the maximum number of digits allowed in an integer word. The default value is 6.
- The `rejectlong` parameter specifies whether an overlength integer should be truncated or ignored. If `rejectlong` is `false` (the default), the dictionary returns the first `maxlen` digits of the integer. If `rejectlong` is `true`, the dictionary treats an overlength integer as a stop word, so that it will not be indexed. Note that this also means that such an integer cannot be searched for.

F.14.2. Usage

Installing the `dict_int` extension creates a text search template `intdict_template` and a dictionary `intdict` based on it, with the default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY intdict (MAXLEN = 4, REJECTLONG = true);  
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb# select ts_lexize('intdict', '12345678');  
ts_lexize  
-----  
{123456}
```

but real-world usage will involve including it in a text search configuration as described in [Chapter 12](#). That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english  
    ALTER MAPPING FOR int, uint WITH intdict;
```

F.15. dict_xsyn

`dict_xsyn` (Extended Synonym Dictionary) is an example of an add-on dictionary template for full-text search. This dictionary type replaces words with groups of their synonyms, and so makes it possible to search for a word using any of its synonyms.

F.15.1. Configuration

A `dict_xsyn` dictionary accepts the following options:

- `matchorig` controls whether the original word is accepted by the dictionary. Default is `true`.
- `matchsynonyms` controls whether the synonyms are accepted by the dictionary. Default is `false`.
- `keeporig` controls whether the original word is included in the dictionary's output. Default is `true`.
- `keepsynonyms` controls whether the synonyms are included in the dictionary's output. Default is `true`.

- `rules` is the base name of the file containing the list of synonyms. This file must be stored in `$$SHAREDIR/tsearch_data/` (where `$$SHAREDIR` means the Postgres Pro installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `rules` parameter).

The rules file has the following format:

- Each line represents a group of synonyms for a single word, which is given first on the line. Synonyms are separated by whitespace, thus:

```
word syn1 syn2 syn3
```
- The sharp (#) sign is a comment delimiter. It may appear at any position in a line. The rest of the line will be skipped.

Look at `xsyn_sample.rules`, which is installed in `$$SHAREDIR/tsearch_data/`, for an example.

F.15.2. Usage

Installing the `dict_xsyn` extension creates a text search template `xsyn_template` and a dictionary `xsyn` based on it, with default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false);
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb=# SELECT ts_lexize('xsyn', 'word');
       ts_lexize
-----
{syn1,syn2,syn3}
```

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true);
ALTER TEXT SEARCH DICTIONARY
```

```
mydb=# SELECT ts_lexize('xsyn', 'word');
       ts_lexize
-----
{word,syn1,syn2,syn3}
```

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false,
MATCHSYNONYMS=true);
ALTER TEXT SEARCH DICTIONARY
```

```
mydb=# SELECT ts_lexize('xsyn', 'syn1');
       ts_lexize
-----
{syn1,syn2,syn3}
```

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true,
MATCHORIG=false, KEEPSYNONYMS=false);
ALTER TEXT SEARCH DICTIONARY
```

```
mydb=# SELECT ts_lexize('xsyn', 'syn1');
       ts_lexize
-----
{word}
```

Real-world usage will involve including it in a text search configuration as described in [Chapter 12](#). That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
```

```
ALTER MAPPING FOR word, asciiword WITH xsyn, english_stem;
```

F.16. dump_stat

The `dump_stat` module provides functions that allow you to backup and recover the contents of the `pg_statistic` table. When performing a dump/restore, you can use `dump_stat` to migrate the original statistics to the new server instead of running the `ANALYZE` command for the whole database cluster, which can significantly reduce downtime for large databases. The `dump_statistic` function generates `INSERT` statements which can later be applied to a compatible database. To successfully restore statistical data, you must install the extension on both the original and the recipient servers since these statements rely on the provided `dump_stat` functions.

Note that the definition of the `pg_statistic` table might change occasionally, which means that generated dump might be incompatible with future releases of Postgres Pro.

F.16.1. Installation

The `dump_stat` extension is included into Postgres Pro. Once you have Postgres Pro installed, you must execute the `CREATE EXTENSION` command to enable `dump_stat`, as follows:

```
CREATE EXTENSION dump_stat;
```

F.16.2. Functions

`anyarray_to_text(array anyarray)` returns text

Returns the given array as text.

`dump_statistic()` returns setof text

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic`, excluding the ones that contain statistical data for tables in the `information_schema` and `pg_catalog` schemas.

The `INSERT` statement takes form of

```
WITH upsert as (  
  UPDATE pg_catalog.pg_statistic SET column_name = expression [, ...]  
  WHERE starelid = t_relname::regclass  
    AND to_attnum(t_relname, staattnum) = t_attnum  
    AND to_atttype(t_relname, staattnum) = t_atttype  
    AND stainherit = t_stainherit  
  RETURNING *)  
ins as (  
  SELECT expression [, ...]  
  WHERE NOT EXISTS (SELECT * FROM upsert)  
    AND to_attnum(t_relname, t_attnum) IS NOT NULL  
    AND to_atttype(t_relname, t_attnum) = t_atttype)  
INSERT INTO pg_catalog.pg_statistic SELECT * FROM ins;
```

where *expression* can be one of:

```
array_in(array_text, type_name::regtype::oid, -1)  
value::type_name
```

To save the produced statements, redirect the `psql` output into a file using standard `psql` options. For details on the available `psql` options, see [psql](#). Meta-commands starting with a backslash are not supported.

For example, to save statistics for the `dbname` database into a `dump_stat.sql` file, run:

```
$ psql -XAtq -c "SELECT dump_statistic()" dbname > dump_stat.sql
```

`dump_statistic(schema_name text)` returns `setof text`

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic` that relates to some table in the `schema_name` schema.

`dump_statistic(schema_name text, table_name text)` returns `setof text`

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic` that relates to the specified `schema_name.table_name` table.

`dump_statistic(relation regclass)` returns `setof text`

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic` that contains statistical data for the specified relation.

`to_schema_qualified_operator(opid oid)` returns `text`

Fetches the schema-qualified operator name by operator id `opid`. For example:

```
test=# SELECT to_schema_qualified_operator('+(int,int)::regoperator');
           to_schema_qualified_operator
-----
pg_catalog.+(pg_catalog.int4, pg_catalog.int4)
(1 row)
```

`to_schema_qualified_type(typid oid)` returns `text`

Fetches the schema-qualified type name by type id `typid`.

`to_schema_qualified_relation(relid oid)` returns `text`

Fetches the schema-qualified relation name by relation id `relid`.

`anyarray_elemtype(arr anyarray)` returns `oid`

Returns the element type of the given array as `oid`. For example:

```
test=# SELECT anyarray_elemtype(array_in('{1,2,3}', 'int'::regtype, -1));
           anyarray_elemtype
-----
23
(1 row)
```

`to_attname(relation regclass, colnum int2)` returns `text`

Given a relation name `relation` and a column number `colnum`, returns the column name as `text`.

`to_attnum(relation regclass, col text)` returns `int2`

Given a relation name `relation` and a column name `col`, returns the column number as `int2`.

`to_atttype(relation regclass, col text)` returns `text`

Given a relation name `relation` and a column name `col`, returns the schema-qualified column type as `text`.

`to_atttype(relation regclass, colnum int2)` returns `text`

Given a relation name `relation` and a column number `colnum`, returns the schema-qualified column type as `text`.

`to_namespace(nsp text)` returns `oid`

`to_namespace` duplicates the behavior of the cast to the `regnamespace` type, which is not present in the PostgreSQL 9.4 release (and prior releases). This function returns the `oid` of the given schema.

`get_namespace(relation oid)` returns `oid`

`get_namespace` returns the schema of the given relation as `oid`.

F.17. earthdistance

The `earthdistance` module provides two different approaches to calculating great circle distances on the surface of the Earth. The one described first depends on the `cube` module. The second one is based on the built-in `point` data type, using longitude and latitude for the coordinates.

In this module, the Earth is assumed to be perfectly spherical. (If that's too inaccurate for you, you might want to look at the [PostGIS](#) project.)

The `cube` module must be installed before `earthdistance` can be installed (although you can use the `CASCADE` option of `CREATE EXTENSION` to install both in one command).

Caution

It is strongly recommended that `earthdistance` and `cube` be installed in the same schema, and that that schema be one for which `CREATE` privilege has not been and will not be granted to any untrusted users. Otherwise there are installation-time security hazards if `earthdistance`'s schema contains objects defined by a hostile user. Furthermore, when using `earthdistance`'s functions after installation, the entire search path should contain only trusted schemas.

F.17.1. Cube-based Earth Distances

Data is stored in cubes that are points (both corners are the same) using 3 coordinates representing the `x`, `y`, and `z` distance from the center of the Earth. A domain `earth` over `cube` is provided, which includes constraint checks that the value meets these restrictions and is reasonably close to the actual surface of the Earth.

The radius of the Earth is obtained from the `earth()` function. It is given in meters. But by changing this one function you can change the module to use some other units, or to use a different value of the radius that you feel is more appropriate.

This package has applications to astronomical databases as well. Astronomers will probably want to change `earth()` to return a radius of `180/pi()` so that distances are in degrees.

Functions are provided to support input in latitude and longitude (in degrees), to support output of latitude and longitude, to calculate the great circle distance between two points and to easily specify a bounding box usable for index searches.

The provided functions are shown in [Table F.10](#).

Table F.10. Cube-based Earthdistance Functions

Function	Returns	Description
<code>earth()</code>	<code>float8</code>	Returns the assumed radius of the Earth.
<code>sec_to_gc(float8)</code>	<code>float8</code>	Converts the normal straight line (secant) distance between two points on the surface of the Earth to the great circle distance between them.
<code>gc_to_sec(float8)</code>	<code>float8</code>	Converts the great circle distance between two points on the surface of the Earth to the normal straight

Function	Returns	Description
		line (secant) distance between them.
<code>ll_to_earth(float8, float8)</code>	<code>earth</code>	Returns the location of a point on the surface of the Earth given its latitude (argument 1) and longitude (argument 2) in degrees.
<code>latitude(earth)</code>	<code>float8</code>	Returns the latitude in degrees of a point on the surface of the Earth.
<code>longitude(earth)</code>	<code>float8</code>	Returns the longitude in degrees of a point on the surface of the Earth.
<code>earth_distance(earth, earth)</code>	<code>float8</code>	Returns the great circle distance between two points on the surface of the Earth.
<code>earth_box(earth, float8)</code>	<code>cube</code>	Returns a box suitable for an indexed search using the <code>cube @></code> operator for points within a given great circle distance of a location. Some points in this box are further than the specified great circle distance from the location, so a second check using <code>earth_distance</code> should be included in the query.

F.17.2. Point-based Earth Distances

The second part of the module relies on representing Earth locations as values of type `point`, in which the first component is taken to represent longitude in degrees, and the second component is taken to represent latitude in degrees. Points are taken as (longitude, latitude) and not vice versa because longitude is closer to the intuitive idea of x-axis and latitude to y-axis.

A single operator is provided, shown in [Table F.11](#).

Table F.11. Point-based Earthdistance Operators

Operator	Returns	Description
<code>point <@> point</code>	<code>float8</code>	Gives the distance in statute miles between two points on the Earth's surface.

Note that unlike the `cube`-based part of the module, units are hardwired here: changing the `earth()` function will not affect the results of this operator.

One disadvantage of the longitude/latitude representation is that you need to be careful about the edge conditions near the poles and near +/- 180 degrees of longitude. The `cube`-based representation avoids these discontinuities.

F.18. fasttrun

The `fasttrun` module provides transaction unsafe function to truncate temporary tables without growing `pg_class` size.

This module is required for 1C Enterprise support.

Fast truncate operation is not transactional, so its results cannot be rolled back and become immediately visible in all sessions regardless of isolation level.

F.18.1. Function

There is a function call example:

```
select fasttruncate('TABLE_NAME');
```

F.18.2. Test example

For tests you can use this example:

```
create or replace function f() returns void as $$
begin
  for i in 1..1000
  loop
    PERFORM fasttruncate('tt1');
  end loop;
end;
$$ language plpgsql;
```

F.18.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

F.19. file_fdw

The `file_fdw` module provides the foreign-data wrapper `file_fdw`, which can be used to access data files in the server's file system. Data files must be in a format that can be read by `COPY FROM`; see [COPY](#) for details. Access to such data files is currently read-only.

A foreign table created using this wrapper can have the following options:

`filename`

Specifies the file to be read. Required. Relative paths are relative to the data directory.

`format`

Specifies the file's format, the same as `COPY`'s `FORMAT` option.

`header`

Specifies whether the file has a header line, the same as `COPY`'s `HEADER` option.

`delimiter`

Specifies the file's delimiter character, the same as `COPY`'s `DELIMITER` option.

`quote`

Specifies the file's quote character, the same as `COPY`'s `QUOTE` option.

`escape`

Specifies the file's escape character, the same as `COPY`'s `ESCAPE` option.

`null`

Specifies the file's null string, the same as `COPY`'s `NULL` option.

`encoding`

Specifies the file's encoding, the same as `COPY`'s `ENCODING` option.

Note that while `COPY` allows options such as `oids` and `header` to be specified without a corresponding value, the foreign data wrapper syntax requires a value to be present in all cases. To activate `COPY` options normally supplied without a value, you can instead pass the value `TRUE`.

A column of a foreign table created using this wrapper can have the following options:

`force_not_null`

This is a Boolean option. If true, it specifies that values of the column should not be matched against the null string (that is, the file-level `null` option). This has the same effect as listing the column in `COPY`'s `FORCE_NOT_NULL` option.

`force_null`

This is a Boolean option. If true, it specifies that values of the column which match the null string are returned as `NULL` even if the value is quoted. Without this option, only unquoted values matching the null string are returned as `NULL`. This has the same effect as listing the column in `COPY`'s `FORCE_NULL` option.

`COPY`'s `oids` and `FORCE_QUOTE` options are currently not supported by `file_fdw`.

These options can only be specified for a foreign table or its columns, not in the options of the `file_fdw` foreign-data wrapper, nor in the options of a server or user mapping using the wrapper.

Changing table-level options requires superuser privileges, for security reasons: only a superuser should be able to determine which file is read. In principle non-superusers could be allowed to change the other options, but that's not supported at present.

For a foreign table using `file_fdw`, `EXPLAIN` shows the name of the file to be read. Unless `COSTS OFF` is specified, the file size (in bytes) is shown as well.

Example F.1. Create a Foreign Table for Postgres Pro CSV Logs

One of the obvious uses for `file_fdw` is to make the Postgres Pro activity log available as a table for querying. To do this, first you must be [logging to a CSV file](#), which here we will call `pglog.csv`. First, install `file_fdw` as an extension:

```
CREATE EXTENSION file_fdw;
```

Then create a foreign server:

```
CREATE SERVER pglog FOREIGN DATA WRAPPER file_fdw;
```

Now you are ready to create the foreign data table. Using the `CREATE FOREIGN TABLE` command, you will need to define the columns for the table, the CSV file name, and its format:

```
CREATE FOREIGN TABLE pglog (  
    log_time timestamp(3) with time zone,  
    user_name text,  
    database_name text,  
    process_id integer,  
    connection_from text,  
    session_id text,  
    session_line_num bigint,  
    command_tag text,  
    session_start_time timestamp with time zone,  
    virtual_transaction_id text,  
    transaction_id bigint,  
    error_severity text,  
    sql_state_code text,  
    message text,  
    detail text,  
    hint text,
```

```
internal_query text,  
internal_query_pos integer,  
context text,  
query text,  
query_pos integer,  
location text,  
application_name text  
) SERVER pglog  
OPTIONS ( filename '/home/josh/9.1/data/pg_log/pglog.csv', format 'csv' );
```

That's it — now you can query your log directly. In production, of course, you would need to define some way to deal with log rotation.

F.20. fulleq

The `fulleq` module provides additional equivalence operator for compatibility with Microsoft SQL Server.

This module is required for 1C Enterprise support.

F.20.1. Overview

The Postgres Pro equivalence operator is defined to return NULL when both operands are NULLs. However, the Microsoft SQL Servers family traditionally defines other semantic for equivalence operator, where operator returns TRUE in the case of both nulled operands. This module provides such operator with MS SQL semantic.

F.20.2. Operator `fulleq`

The `==` operator is defined for the following data types:

- `bool`
- `bytea`
- `char`
- `name`
- `int2`
- `int4`
- `int8`
- `int2vector`
- `text`
- `oid`
- `xid`
- `cid`
- `oidvector`
- `float4`
- `float8`
- `abstime`
- `reltime`
- `macaddr`
- `inet`
- `cidr`
- `varchar`

- date
- time
- timestamp
- timestamptz
- interval
- timetz

F.20.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

F.21. fuzzystmatch

The `fuzzystmatch` module provides several functions to determine similarities and distance between strings.

Caution

At present, the `soundex`, `metaphone`, `dmetaphone`, and `dmetaphone_alt` functions do not work well with multibyte encodings (such as UTF-8).

F.21.1. Soundex

The Soundex system is a method of matching similar-sounding names by converting them to the same code. It was initially used by the United States Census in 1880, 1900, and 1910. Note that Soundex is not very useful for non-English names.

The `fuzzystmatch` module provides two functions for working with Soundex codes:

```
soundex(text) returns text
difference(text, text) returns int
```

The `soundex` function converts a string to its Soundex code. The `difference` function converts two strings to their Soundex codes and then reports the number of matching code positions. Since Soundex codes have four characters, the result ranges from zero to four, with zero being no match and four being an exact match. (Thus, the function is misnamed — *similarity* would have been a better name.)

Here are some usage examples:

```
SELECT soundex('hello world!');

SELECT soundex('Anne'), soundex('Ann'), difference('Anne', 'Ann');
SELECT soundex('Anne'), soundex('Andrew'), difference('Anne', 'Andrew');
SELECT soundex('Anne'), soundex('Margaret'), difference('Anne', 'Margaret');

CREATE TABLE s (nm text);

INSERT INTO s VALUES ('john');
INSERT INTO s VALUES ('joan');
INSERT INTO s VALUES ('wobbly');
INSERT INTO s VALUES ('jack');

SELECT * FROM s WHERE soundex(nm) = soundex('john');

SELECT * FROM s WHERE difference(s.nm, 'john') > 2;
```

F.21.2. Levenshtein

This function calculates the Levenshtein distance between two strings:

```
levenshtein(text source, text target, int ins_cost, int del_cost, int sub_cost) returns
  int
levenshtein(text source, text target) returns int
levenshtein_less_equal(text source, text target, int ins_cost, int del_cost, int
  sub_cost, int max_d) returns int
levenshtein_less_equal(text source, text target, int max_d) returns int
```

Both `source` and `target` can be any non-null string, with a maximum of 255 characters. The cost parameters specify how much to charge for a character insertion, deletion, or substitution, respectively. You can omit the cost parameters, as in the second version of the function; in that case they all default to 1.

`levenshtein_less_equal` is an accelerated version of the Levenshtein function for use when only small distances are of interest. If the actual distance is less than or equal to `max_d`, then `levenshtein_less_equal` returns the correct distance; otherwise it returns some value greater than `max_d`. If `max_d` is negative then the behavior is the same as `levenshtein`.

Examples:

```
test=# SELECT levenshtein('GUMBO', 'GAMBOL');
 levenshtein
-----
          2
(1 row)

test=# SELECT levenshtein('GUMBO', 'GAMBOL', 2,1,1);
 levenshtein
-----
          3
(1 row)

test=# SELECT levenshtein_less_equal('extensive', 'exhaustive',2);
 levenshtein_less_equal
-----
          3
(1 row)

test=# SELECT levenshtein_less_equal('extensive', 'exhaustive',4);
 levenshtein_less_equal
-----
          4
(1 row)
```

F.21.3. Metaphone

Metaphone, like Soundex, is based on the idea of constructing a representative code for an input string. Two strings are then deemed similar if they have the same codes.

This function calculates the metaphone code of an input string:

```
metaphone(text source, int max_output_length) returns text
```

`source` has to be a non-null string with a maximum of 255 characters. `max_output_length` sets the maximum length of the output metaphone code; if longer, the output is truncated to this length.

Example:

```
test=# SELECT metaphone('GUMBO', 4);
 metaphone
-----
 KM
(1 row)
```

F.21.4. Double Metaphone

The Double Metaphone system computes two “sounds like” strings for a given input string — a “primary” and an “alternate”. In most cases they are the same, but for non-English names especially they can be a bit different, depending on pronunciation. These functions compute the primary and alternate codes:

```
dmetaphone(text source) returns text
dmetaphone_alt(text source) returns text
```

There is no length limit on the input strings.

Example:

```
test=# select dmetaphone('gumbo');
 dmetaphone
-----
 KMP
(1 row)
```

F.22. hstore

This module implements the `hstore` data type for storing sets of key/value pairs within a single Postgres Pro value. This can be useful in various scenarios, such as rows with many attributes that are rarely examined, or semi-structured data. Keys and values are simply text strings.

F.22.1. hstore External Representation

The text representation of an `hstore`, used for input and output, includes zero or more `key => value` pairs separated by commas. Some examples:

```
k => v
foo => bar, baz => whatever
"1-a" => "anything at all"
```

The order of the pairs is not significant (and may not be reproduced on output). Whitespace between pairs or around the `=>` sign is ignored. Double-quote keys and values that include whitespace, commas, `=`s or `>`s. To include a double quote or a backslash in a key or value, escape it with a backslash.

Each key in an `hstore` is unique. If you declare an `hstore` with duplicate keys, only one will be stored in the `hstore` and there is no guarantee as to which will be kept:

```
SELECT 'a=>1,a=>2'::hstore;
 hstore
-----
 "a"=>"1"
```

A value (but not a key) can be an SQL `NULL`. For example:

```
key => NULL
```

The `NULL` keyword is case-insensitive. Double-quote the `NULL` to treat it as the ordinary string “`NULL`”.

Note

Keep in mind that the `hstore` text format, when used for input, applies *before* any required quoting or escaping. If you are passing an `hstore` literal via a parameter, then no additional processing is needed. But if you're passing it as a quoted literal constant, then any single-quote characters

and (depending on the setting of the `standard_conforming_strings` configuration parameter) backslash characters need to be escaped correctly. See [Section 4.1.2.1](#) for more on the handling of string constants.

On output, double quotes always surround keys and values, even when it's not strictly necessary.

F.22.2. hstore Operators and Functions

The operators provided by the `hstore` module are shown in [Table F.12](#), the functions in [Table F.13](#).

Table F.12. hstore Operators

Operator	Description	Example	Result
<code>hstore -> text</code>	get value for key (NULL if not present)	<code>'a=>x, b=>y'::hstore -> 'a'</code>	<code>x</code>
<code>hstore -> text[]</code>	get values for keys (NULL if not present)	<code>'a=>x, b=>y, c=>z'::hstore -> ARRAY['c','a']</code>	<code>{"z","x"}</code>
<code>hstore hstore</code>	concatenate hstores	<code>'a=>b, c=>d'::hstore 'c=>x, d=>q'::hstore</code>	<code>"a"=>"b", "c"=>"x", "d"=>"q"</code>
<code>hstore ? text</code>	does hstore contain key?	<code>'a=>1'::hstore ? 'a'</code>	<code>t</code>
<code>hstore ?& text[]</code>	does hstore contain all specified keys?	<code>'a=>1, b=>2'::hstore ?& ARRAY['a','b']</code>	<code>t</code>
<code>hstore ? text[]</code>	does hstore contain any of the specified keys?	<code>'a=>1, b=>2'::hstore ? ARRAY['b','c']</code>	<code>t</code>
<code>hstore @> hstore</code>	does left operand contain right?	<code>'a=>b, c=>NULL'::hstore @> 'b=>1'</code>	<code>t</code>
<code>hstore <@ hstore</code>	is left operand contained in right?	<code>'a=>c'::hstore <@ 'a=>b, b=>1, c=>NULL'</code>	<code>f</code>
<code>hstore - text</code>	delete key from left operand	<code>'a=>1, b=>2, c=>3'::hstore - 'b'::text</code>	<code>"a"=>"1", "c"=>"3"</code>
<code>hstore - text[]</code>	delete keys from left operand	<code>'a=>1, b=>2, c=>3'::hstore - ARRAY['a','b']</code>	<code>"c"=>"3"</code>
<code>hstore - hstore</code>	delete matching pairs from left operand	<code>'a=>1, b=>2, c=>3'::hstore - 'a=>4, b=>2'::hstore</code>	<code>"a"=>"1", "c"=>"3"</code>
<code>record #= hstore</code>	replace fields in record with matching values from hstore	see Examples section	
<code>%% hstore</code>	convert hstore to array of alternating keys and values	<code>%% 'a=>foo, b=>bar'::hstore</code>	<code>{a,foo,b,bar}</code>
<code>%# hstore</code>	convert hstore to two-dimensional key/value array	<code>%# 'a=>foo, b=>bar'::hstore</code>	<code>{{a,foo},{b,bar}}</code>

Note

Prior to PostgreSQL 8.2, the containment operators @> and <@ were called @ and ~, respectively. These names are still available, but are deprecated and will eventually be removed. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!

Table F.13. hstore Functions

Function	Return Type	Description	Example	Result
hstore(record)	hstore	construct an hstore from a record or row	hstore(ROW(1, 2))	f1=>1, f2=>2
hstore(text[])	hstore	construct an hstore from an array, which may be either a key/value array, or a two-dimensional array	hstore(ARRAY['a', '1', 'b', '2']) hstore(ARRAY[['c', '3'], ['d', '4']])	a=>1, b=>2, c=>3, d=>4
hstore(text[], text[])	hstore	construct an hstore from separate key and value arrays	hstore(ARRAY['a', 'b'], ARRAY['1', '2'])	"a"=>"1", "b"=>"2"
hstore(text, text)	hstore	make single-item hstore	hstore('a', 'b')	"a"=>"b"
akeys(hstore)	text[]	get hstore's keys as an array	akeys('a=>1, b=>2')	{a,b}
skeys(hstore)	setof text	get hstore's keys as a set	skeys('a=>1, b=>2')	a b
avals(hstore)	text[]	get hstore's values as an array	avals('a=>1, b=>2')	{1,2}
svals(hstore)	setof text	get hstore's values as a set	svals('a=>1, b=>2')	1 2
hstore_to_array(hstore)	text[]	get hstore's keys and values as an array of alternating keys and values	hstore_to_array('a=>1, b=>2')	{a,1,b,2}
hstore_to_matrix(hstore)	text[]	get hstore's keys and values as a two-dimensional array	hstore_to_matrix('a=>1, b=>2')	{{a,1},{b,2}}
hstore_to_json(hstore)	json	get hstore as a json value, converting all non-null values to JSON strings	hstore_to_json('a key=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4')	{"a key": "1", "b": "t", "c": null, "d": "12345", "e": "012345", "f": "1.234", "g": "2.345e+4"}
hstore_to_jsonb(hstore)	jsonb	get hstore as a jsonb value,	hstore_to_jsonb('a	{"a key": "1", "b": "t",

Function	Return Type	Description	Example	Result
		converting all non-null values to JSON strings	key=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4')	"c": null, "d": "12345", "e": "012345", "f": "1.234", "g": "2.345e+4"}
hstore_to_json_loose(hstore)	json	get hstore as a json value, but attempt to distinguish numerical and Boolean values so they are unquoted in the JSON	hstore_to_json_loose('a key=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4')	{ "a key": 1, "b": true, "c": null, "d": 12345, "e": "012345", "f": 1.234, "g": 2.345e+4 }
hstore_to_jsonb_loose(hstore)	jsonb	get hstore as a jsonb value, but attempt to distinguish numerical and Boolean values so they are unquoted in the JSON	hstore_to_jsonb_loose('a key=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4')	{ "a key": 1, "b": true, "c": null, "d": 12345, "e": "012345", "f": 1.234, "g": 2.345e+4 }
slice(hstore, text[])	hstore	extract a subset of an hstore	slice('a=>1, b=>2, c=>3'::hstore, ARRAY['b','c','x'])	"b"=>"2", "c"=>"3"
each(hstore)	setof(key text, value text)	get hstore's keys and values as a set	select * from each('a=>1, b=>2')	key value -----+----- a 1 b 2
exist(hstore, text)	boolean	does hstore contain key?	exist('a=>1', 'a')	t
defined(hstore, text)	boolean	does hstore contain non-NULL value for key?	defined('a=>NULL', 'a')	f
delete(hstore, text)	hstore	delete pair with matching key	delete('a=>1, b=>2', 'b')	"a"=>"1"
delete(hstore, text[])	hstore	delete pairs with matching keys	delete('a=>1, b=>2, c=>3', ARRAY['a', 'b'])	"c"=>"3"
delete(hstore, hstore)	hstore	delete pairs matching those in the second argument	delete('a=>1, b=>2', 'a=>4, b=>2'::hstore)	"a"=>"1"
populate_record(record, hstore)	record	replace fields in record with matching values from hstore	see Examples section	

Note

The function `hstore_to_json` is used when an `hstore` value is cast to `json`. Likewise, `hstore_to_jsonb` is used when an `hstore` value is cast to `jsonb`.

Note

The function `populate_record` is actually declared with `anyelement`, not `record`, as its first argument, but it will reject non-record types with a run-time error.

F.22.3. Indexes

`hstore` has GiST and GIN index support for the `@>`, `?`, `?&` and `?|` operators. For example:

```
CREATE INDEX hidx ON testhstore USING GIST (h);
```

```
CREATE INDEX hidx ON testhstore USING GIN (h);
```

`hstore` also supports `btree` or `hash` indexes for the `=` operator. This allows `hstore` columns to be declared `UNIQUE`, or to be used in `GROUP BY`, `ORDER BY` or `DISTINCT` expressions. The sort ordering for `hstore` values is not particularly useful, but these indexes may be useful for equivalence lookups. Create indexes for `=` comparisons as follows:

```
CREATE INDEX hidx ON testhstore USING BTREE (h);
```

```
CREATE INDEX hidx ON testhstore USING HASH (h);
```

F.22.4. Examples

Add a key, or update an existing key with a new value:

```
UPDATE tab SET h = h || hstore('c', '3');
```

Delete a key:

```
UPDATE tab SET h = delete(h, 'k1');
```

Convert a record to an `hstore`:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');
```

```
SELECT hstore(t) FROM test AS t;
           hstore
```

```
-----
"col1"=>"123", "col2"=>"foo", "col3"=>"bar"
(1 row)
```

Convert an `hstore` to a predefined record type:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
```

```
SELECT * FROM populate_record(null::test,
                               '"col1"=>"456", "col2"=>"zzz"');
```

```
 col1 | col2 | col3
-----+-----+-----
  456 | zzz  |
(1 row)
```

Modify an existing record using the values from an `hstore`:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');

SELECT (r).* FROM (SELECT t #= '"col3"=>"baz"' AS r FROM test t) s;
 col1 | col2 | col3
-----+-----+-----
  123 | foo  | baz
(1 row)
```

F.22.5. Statistics

The `hstore` type, because of its intrinsic liberality, could contain a lot of different keys. Checking for valid keys is the task of the application. The following examples demonstrate several techniques for checking keys and obtaining statistics.

Simple example:

```
SELECT * FROM each('aaa=>bq, b=>NULL, ""=>1');
```

Using a table:

```
SELECT (each(h)).key, (each(h)).value INTO stat FROM testhstore;
```

Online statistics:

```
SELECT key, count(*) FROM
  (SELECT (each(h)).key FROM testhstore) AS stat
GROUP BY key
ORDER BY count DESC, key;
```

key	count
line	883
query	207
pos	203
node	202
space	197
status	195
public	194
title	190
org	189
.....	

F.22.6. Compatibility

As of PostgreSQL 9.0, `hstore` uses a different internal representation than previous versions. This presents no obstacle for dump/restore upgrades since the text representation (used in the dump) is unchanged.

In the event of a binary upgrade, upward compatibility is maintained by having the new code recognize old-format data. This will entail a slight performance penalty when processing data that has not yet been modified by the new code. It is possible to force an upgrade of all values in a table column by doing an `UPDATE` statement as follows:

```
UPDATE tablename SET hstorecol = hstorecol || '';
```

Another way to do it is:

```
ALTER TABLE tablename ALTER hstorecol TYPE hstore USING hstorecol || '';
```

The `ALTER TABLE` method requires an exclusive lock on the table, but does not result in bloating the table with old row versions.

F.22.7. Transforms

Additional extensions are available that implement transforms for the `hstore` type for the languages PL/Perl and PL/Python. The extensions for PL/Perl are called `hstore_plperl` and `hstore_plperl_u`, for trusted and untrusted PL/Perl. If you install these transforms and specify them when creating a function, `hstore` values are mapped to Perl hashes. The extensions for PL/Python are called `hstore_plpythonu`, `hstore_plpython2u`, and `hstore_plpython3u` (see [Section 44.1](#) for the PL/Python naming convention). If you use them, `hstore` values are mapped to Python dictionaries.

Caution

It is strongly recommended that the transform extensions be installed in the same schema as `hstore`. Otherwise there are installation-time security hazards if a transform extension's schema contains objects defined by a hostile user.

F.22.8. Authors

Oleg Bartunov <oleg@sai.msu.su>, Moscow, Moscow University, Russia

Teodor Sigaev <teodor@sigaev.ru>, Moscow, Delta-Soft Ltd., Russia

Additional enhancements by Andrew Gierth <andrew@tao11.riddles.org.uk>, United Kingdom

F.23. Hunspell Dictionaries Modules

These modules provide Hunspell dictionaries for various languages. Upon installation of the module into database using `CREATE EXTENSION` command, text search dictionary and configuration objects in the public schema appear.

Table F.14. Modules

Language	Extension name	Dictionary name	Configuration name
American English	<code>hunspell_en_us</code>	<code>english_hunspell</code>	<code>english_hunspell</code>
Dutch	<code>hunspell_nl_nl</code>	<code>dutch_hunspell</code>	<code>dutch_hunspell</code>
French	<code>hunspell_fr</code>	<code>french_hunspell</code>	<code>french_hunspell</code>
Russian	<code>hunspell_ru_ru</code>	<code>russian_hunspell</code>	<code>russian_hunspell</code>

F.23.1. Examples

Text search objects will be created after installation of a dictionary module. We can test created configuration:

```
SELECT * FROM ts_debug('english_hunspell', 'abilities');
  alias | description | token | dictionaries |
  dictionary | lexemes
-----+-----+-----+-----+-----
asciword | Word, all ASCII | abilities | {english_hunspell,english_stem} |
english_hunspell | {ability}
(1 row)
```

Or you can create your own text search configuration. For example, with the created dictionaries and with the `Snowball` dictionary you can create mixed russian-english configuration:

```
CREATE TEXT SEARCH CONFIGURATION russian_en (
  COPY = simple
);
```

```
ALTER TEXT SEARCH CONFIGURATION russian_en
  ALTER MAPPING FOR asciiword, asciihword, hword_asciipart
  WITH english_hunspell, english_stem;
```

```
ALTER TEXT SEARCH CONFIGURATION russian_en
  ALTER MAPPING FOR word, hword, hword_part
  WITH russian_hunspell, russian_stem;
```

You can create mixed dictionaries only for languages with different alphabets. If languages have similar alphabets then Postgres Pro can not decide which dictionary should be used.

A text search configuration which is created with a dictionary module is ready to use. For example, in this text you can search some words:

```
SELECT to_tsvector('english_hunspell', 'The blue whale is the largest animal');
           to_tsvector
-----
'animal':7 'blue':2 'large':6 'whale':3
(1 row)
```

Search query might looks like this:

```
SELECT to_tsvector('english_hunspell', 'The blue whale is the largest animal')
  @@ to_tsquery('english_hunspell', 'large & whale');
   ?column?
-----
t
(1 row)
```

With this configurations you can search a text using GIN or GIST indexes. For example, there is a table with GIN index:

```
CREATE TABLE table1 (t varchar);
INSERT INTO table1 VALUES ('The blue whale is the largest animal');
CREATE INDEX t_idx ON table1 USING GIN (to_tsvector('english_hunspell', "t"));
```

For this table you can execute the following query:

```
SELECT * FROM table1 where to_tsvector('english_hunspell', t)
  @@ to_tsquery('english_hunspell', 'blue & animal');
           t
-----
The blue whale is the largest animal
(1 row)
```

F.24. intagg

The `intagg` module provides an integer aggregator and an enumerator. `intagg` is now obsolete, because there are built-in functions that provide a superset of its capabilities. However, the module is still provided as a compatibility wrapper around the built-in functions.

F.24.1. Functions

The aggregator is an aggregate function `int_array_aggregate(integer)` that produces an integer array containing exactly the integers it is fed. This is a wrapper around `array_agg`, which does the same thing for any array type.

The enumerator is a function `int_array_enum(integer[])` that returns `setof integer`. It is essentially the reverse operation of the aggregator: given an array of integers, expand it into a set of rows. This is a wrapper around `unnest`, which does the same thing for any array type.

F.24.2. Sample Uses

Many database systems have the notion of a one to many table. Such a table usually sits between two indexed tables, for example:

```
CREATE TABLE left (id INT PRIMARY KEY, ...);
CREATE TABLE right (id INT PRIMARY KEY, ...);
CREATE TABLE one_to_many(left INT REFERENCES left, right INT REFERENCES right);
```

It is typically used like this:

```
SELECT right.* from right JOIN one_to_many ON (right.id = one_to_many.right)
WHERE one_to_many.left = item;
```

This will return all the items in the right hand table for an entry in the left hand table. This is a very common construct in SQL.

Now, this methodology can be cumbersome with a very large number of entries in the `one_to_many` table. Often, a join like this would result in an index scan and a fetch for each right hand entry in the table for a particular left hand entry. If you have a very dynamic system, there is not much you can do. However, if you have some data which is fairly static, you can create a summary table with the aggregator.

```
CREATE TABLE summary AS
  SELECT left, int_array_aggregate(right) AS right
  FROM one_to_many
  GROUP BY left;
```

This will create a table with one row per left item, and an array of right items. Now this is pretty useless without some way of using the array; that's why there is an array enumerator. You can do

```
SELECT left, int_array_enum(right) FROM summary WHERE left = item;
```

The above query using `int_array_enum` produces the same results as

```
SELECT left, right FROM one_to_many WHERE left = item;
```

The difference is that the query against the summary table has to get only one row from the table, whereas the direct query against `one_to_many` must index scan and fetch a row for each entry.

On one system, an `EXPLAIN` showed a query with a cost of 8488 was reduced to a cost of 329. The original query was a join involving the `one_to_many` table, which was replaced by:

```
SELECT right, count(right) FROM
  ( SELECT left, int_array_enum(right) AS right
    FROM summary JOIN (SELECT left FROM left_table WHERE left = item) AS lefts
    ON (summary.left = lefts.left)
  ) AS list
GROUP BY right
ORDER BY count DESC;
```

F.25. intarray

The `intarray` module provides a number of useful functions and operators for manipulating null-free arrays of integers. There is also support for indexed searches using some of the operators.

All of these operations will throw an error if a supplied array contains any `NULL` elements.

Many of these operations are only sensible for one-dimensional arrays. Although they will accept input arrays of more dimensions, the data is treated as though it were a linear array in storage order.

F.25.1. intarray Functions and Operators

The functions provided by the `intarray` module are shown in [Table F.15](#), the operators in [Table F.16](#).

Table F.15. intarray Functions

Function	Return Type	Description	Example	Result
<code>icount(int[])</code>	<code>int</code>	number of elements in array	<code>icount('{1,2,3}'::int[])</code>	3
<code>sort(int[], text dir)</code>	<code>int[]</code>	sort array — <i>dir</i> must be <code>asc</code> or <code>desc</code>	<code>sort('{1,2,3}'::int[], 'desc')</code>	{3,2,1}
<code>sort(int[])</code>	<code>int[]</code>	sort in ascending order	<code>sort(array[11,77,44])</code>	{11,44,77}
<code>sort_asc(int[])</code>	<code>int[]</code>	sort in ascending order		
<code>sort_desc(int[])</code>	<code>int[]</code>	sort in descending order		
<code>uniq(int[])</code>	<code>int[]</code>	remove adjacent duplicates	<code>uniq(sort('{1,2,3,2,1}'::int[]))</code>	{1,2,3}
<code>idx(int[], int item)</code>	<code>int</code>	index of first element matching <i>item</i> (0 if none)	<code>idx(array[11,22,33,22,11], 22)</code>	2
<code>subarray(int[], int start, int len)</code>	<code>int[]</code>	portion of array starting at position <i>start</i> , <i>len</i> elements	<code>subarray('{1,2,3,2,1}'::int[], 2, 3)</code>	{2,3,2}
<code>subarray(int[], int start)</code>	<code>int[]</code>	portion of array starting at position <i>start</i>	<code>subarray('{1,2,3,2,1}'::int[], 2)</code>	{2,3,2,1}
<code>intset(int)</code>	<code>int[]</code>	make single-element array	<code>intset(42)</code>	{42}

Table F.16. intarray Operators

Operator	Returns	Description
<code>int[] && int[]</code>	boolean	overlap — true if arrays have at least one common element
<code>int[] @> int[]</code>	boolean	contains — true if left array contains right array
<code>int[] <@ int[]</code>	boolean	contained — true if left array is contained in right array
<code># int[]</code>	<code>int</code>	number of elements in array
<code>int[] # int</code>	<code>int</code>	index (same as <code>idx</code> function)
<code>int[] + int</code>	<code>int[]</code>	push element onto array (add it to end of array)
<code>int[] + int[]</code>	<code>int[]</code>	array concatenation (right array added to the end of left one)
<code>int[] - int</code>	<code>int[]</code>	remove entries matching right argument from array
<code>int[] - int[]</code>	<code>int[]</code>	remove elements of right array from left
<code>int[] int</code>	<code>int[]</code>	union of arguments

Operator	Returns	Description
<code>int[] int[]</code>	<code>int[]</code>	union of arrays
<code>int[] & int[]</code>	<code>int[]</code>	intersection of arrays
<code>int[] @@ query_int</code>	<code>boolean</code>	true if array satisfies query (see below)
<code>query_int ~~ int[]</code>	<code>boolean</code>	true if array satisfies query (commutator of @@)

(Before PostgreSQL 8.2, the containment operators `@>` and `<@` were respectively called `@` and `~`. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!)

The operators `&&`, `@>` and `<@` are equivalent to Postgres Pro's built-in operators of the same names, except that they work only on integer arrays that do not contain nulls, while the built-in operators work for any array type. This restriction makes them faster than the built-in operators in many cases.

The `@@` and `~~` operators test whether an array satisfies a *query*, which is expressed as a value of a specialized data type `query_int`. A *query* consists of integer values that are checked against the elements of the array, possibly combined using the operators `&` (AND), `|` (OR), and `!` (NOT). Parentheses can be used as needed. For example, the query `1 & (2 | 3)` matches arrays that contain 1 and also contain either 2 or 3.

F.25.2. Index Support

`intarray` provides index support for the `&&`, `@>`, `<@`, and `@@` operators, as well as regular array equality.

Two GiST index operator classes are provided: `gist__int_ops` (used by default) is suitable for small- to medium-size data sets, while `gist__intbig_ops` uses a larger signature and is more suitable for indexing large data sets (i.e., columns containing a large number of distinct array values). The implementation uses an RD-tree data structure with built-in lossy compression.

There is also a non-default GIN operator class `gin__int_ops` supporting the same operators.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

F.25.3. Example

```
-- a message can be in one or more "sections"
CREATE TABLE message (mid INT PRIMARY KEY, sections INT[], ...);

-- create specialized index
CREATE INDEX message_rdtree_idx ON message USING GIST (sections gist__int_ops);

-- select messages in section 1 OR 2 - OVERLAP operator
SELECT message.mid FROM message WHERE message.sections && '{1,2}';

-- select messages in sections 1 AND 2 - CONTAINS operator
SELECT message.mid FROM message WHERE message.sections @> '{1,2}';

-- the same, using QUERY operator
SELECT message.mid FROM message WHERE message.sections @@ '1&2'::query_int;
```

F.25.4. Benchmark

The source directory `contrib/intarray/bench` contains a benchmark test suite, which can be run against an installed Postgres Pro server. (It also requires `DBD::Pg` to be installed.) To run:

```
cd .../contrib/intarray/bench
createdb TEST
psql -c "CREATE EXTENSION intarray" TEST
./create_test.pl | psql TEST
./bench.pl
```

The `bench.pl` script has numerous options, which are displayed when it is run without any arguments.

F.25.5. Authors

All work was done by Teodor Sigaev (<teodor@sigaev.ru>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megeera/postgres/gist/> for additional information. Andrey Oktyabrski did a great work on adding new functions and operations.

F.26. isn

The `isn` module provides data types for the following international product numbering standards: EAN13, UPC, ISBN (books), ISMN (music), and ISSN (serials). Numbers are validated on input according to a hard-coded list of prefixes; this list of prefixes is also used to hyphenate numbers on output. Since new prefixes are assigned from time to time, the list of prefixes may be out of date. It is hoped that a future version of this module will obtain the prefix list from one or more tables that can be easily updated by users as needed; however, at present, the list can only be updated by modifying the source code and recompiling. Alternatively, prefix validation and hyphenation support may be dropped from a future version of this module.

F.26.1. Data Types

Table F.17 shows the data types provided by the `isn` module.

Table F.17. `isn` Data Types

Data Type	Description
EAN13	European Article Numbers, always displayed in the EAN13 display format
ISBN13	International Standard Book Numbers to be displayed in the new EAN13 display format
ISMN13	International Standard Music Numbers to be displayed in the new EAN13 display format
ISSN13	International Standard Serial Numbers to be displayed in the new EAN13 display format
ISBN	International Standard Book Numbers to be displayed in the old short display format
ISMN	International Standard Music Numbers to be displayed in the old short display format
ISSN	International Standard Serial Numbers to be displayed in the old short display format
UPC	Universal Product Codes

Some notes:

1. ISBN13, ISMN13, ISSN13 numbers are all EAN13 numbers.
2. EAN13 numbers aren't always ISBN13, ISMN13 or ISSN13 (some are).
3. Some ISBN13 numbers can be displayed as ISBN.
4. Some ISMN13 numbers can be displayed as ISMN.
5. Some ISSN13 numbers can be displayed as ISSN.

6. UPC numbers are a subset of the EAN13 numbers (they are basically EAN13 without the first 0 digit).
7. All UPC, ISBN, ISMN and ISSN numbers can be represented as EAN13 numbers.

Internally, all these types use the same representation (a 64-bit integer), and all are interchangeable. Multiple types are provided to control display formatting and to permit tighter validity checking of input that is supposed to denote one particular type of number.

The `ISBN`, `ISMN`, and `ISSN` types will display the short version of the number (ISxN 10) whenever it's possible, and will show ISxN 13 format for numbers that do not fit in the short version. The `EAN13`, `ISBN13`, `ISMN13` and `ISSN13` types will always display the long version of the ISxN (EAN13).

F.26.2. Casts

The `isn` module provides the following pairs of type casts:

- `ISBN13 <=> EAN13`
- `ISMN13 <=> EAN13`
- `ISSN13 <=> EAN13`
- `ISBN <=> EAN13`
- `ISMN <=> EAN13`
- `ISSN <=> EAN13`
- `UPC <=> EAN13`
- `ISBN <=> ISBN13`
- `ISMN <=> ISMN13`
- `ISSN <=> ISSN13`

When casting from `EAN13` to another type, there is a run-time check that the value is within the domain of the other type, and an error is thrown if not. The other casts are simply relabelings that will always succeed.

F.26.3. Functions and Operators

The `isn` module provides the standard comparison operators, plus B-tree and hash indexing support for all these data types. In addition there are several specialized functions; shown in [Table F.18](#). In this table, `isn` means any one of the module's data types.

Table F.18. `isn` Functions

Function	Returns	Description
<code>isn_weak(boolean)</code>	<code>boolean</code>	Sets the weak input mode (returns new setting)
<code>isn_weak()</code>	<code>boolean</code>	Gets the current status of the weak mode
<code>make_valid(isn)</code>	<code>isn</code>	Validates an invalid number (clears the invalid flag)
<code>is_valid(isn)</code>	<code>boolean</code>	Checks for the presence of the invalid flag

Weak mode is used to be able to insert invalid data into a table. Invalid means the check digit is wrong, not that there are missing numbers.

Why would you want to use the weak mode? Well, it could be that you have a huge collection of ISBN numbers, and that there are so many of them that for weird reasons some have the wrong check digit (perhaps the numbers were scanned from a printed list and the OCR got the numbers wrong, perhaps

the numbers were manually captured... who knows). Anyway, the point is you might want to clean the mess up, but you still want to be able to have all the numbers in your database and maybe use an external tool to locate the invalid numbers in the database so you can verify the information and validate it more easily; so for example you'd want to select all the invalid numbers in the table.

When you insert invalid numbers in a table using the weak mode, the number will be inserted with the corrected check digit, but it will be displayed with an exclamation mark (!) at the end, for example 0-11-000322-5!. This invalid marker can be checked with the `is_valid` function and cleared with the `make_valid` function.

You can also force the insertion of invalid numbers even when not in the weak mode, by appending the `!` character at the end of the number.

Another special feature is that during input, you can write `?` in place of the check digit, and the correct check digit will be inserted automatically.

F.26.4. Examples

```
--Using the types directly:
SELECT isbn('978-0-393-04002-9');
SELECT isbn13('0901690546');
SELECT issn('1436-4522');

--Casting types:
-- note that you can only cast from ean13 to another type when the
-- number would be valid in the realm of the target type;
-- thus, the following will NOT work: select isbn(ean13('0220356483481'));
-- but these will:
SELECT upc(ean13('0220356483481'));
SELECT ean13(upc('220356483481'));

--Create a table with a single column to hold ISBN numbers:
CREATE TABLE test (id isbn);
INSERT INTO test VALUES('9780393040029');

--Automatically calculate check digits (observe the '?'):
INSERT INTO test VALUES('220500896?');
INSERT INTO test VALUES('978055215372?');

SELECT issn('3251231?');
SELECT ismn('979047213542?');

--Using the weak mode:
SELECT isn_weak(true);
INSERT INTO test VALUES('978-0-11-000533-4');
INSERT INTO test VALUES('9780141219307');
INSERT INTO test VALUES('2-205-00876-X');
SELECT isn_weak(false);

SELECT id FROM test WHERE NOT is_valid(id);
UPDATE test SET id = make_valid(id) WHERE id = '2-205-00876-X!';

SELECT * FROM test;

SELECT isbn13(id) FROM test;
```

F.26.5. Bibliography

The information to implement this module was collected from several sites, including:

- <https://www.isbn-international.org/>
- <https://www.issn.org/>
- <https://www.ismn-international.org/>
- <https://www.wikipedia.org/>

The prefixes used for hyphenation were also compiled from:

- http://www.gs1.org/productssolutions/idkeys/support/prefix_list.html
- http://en.wikipedia.org/wiki/List_of_ISBN_identifier_groups
- <https://www.isbn-international.org/content/isbn-users-manual>
- http://en.wikipedia.org/wiki/International_Standard_Music_Number
- <http://www.ismn-international.org/ranges.html>

Care was taken during the creation of the algorithms and they were meticulously verified against the suggested algorithms in the official ISBN, ISMN, ISSN User Manuals.

F.26.6. Author

Germán Méndez Bravo (Kronuz), 2004 - 2006

This module was inspired by Garrett A. Wollman's `isbn_issn` code.

F.27. jquery

jQuery is a language to query `jsonb` data type. Its primary goal is to provide an additional functionality for `jsonb`, such as a simple and effective way for search in nested objects and arrays, as well as additional comparison operators with index support.

jQuery is implemented by means of a `jquery` data type (similar to `tsquery`) and the `@@` match operator for `jsonb`.

F.27.1. Installation

Postgres Pro distribution includes `jquery` as a contrib module. Once you complete Postgres Pro Enterprise installation, create the `jquery` extension, as follows:

```
CREATE EXTENSION jquery;
```

F.27.2. JSON query language

jQuery extension contains `jquery` datatype which represents whole JSON query as a single value (like `tsquery` does for fulltext search). The query is an expression on JSON-document values.

Simple expression is specified as *path binary_operator value* or *path unary_operator*. See the following examples.

- `x = "abc"` - value of key "x" is equal to "abc";
- `$ @> [4, 5, "zzz"]` - the JSON document is an array containing values 4, 5 and "zzz";
- `"abc xyz" >= 10` - value of key "abc xyz" is greater than or equal to 10;
- `volume IS NUMERIC` - type of key "volume" is numeric.
- `$ = true` - the whole JSON document is just a true.
- `similar_ids.@# > 5` - `similar_ids` is an array or object of length greater than 5;
- `similar_product_ids.# = "0684824396"` - array `similar_product_ids` contains string "0684824396".
- `*.color = "red"` - there is object somewhere which key "color" has value "red".

- `foo = *` - key "foo" exists in object.

Path selects set of JSON values to be checked using given operators. In the simplest case, path is just a key name. In general, path is key names and placeholders combined by dot signs. Path can use the following placeholders:

- `#` - any index of array;
- `#N` - Nth index of array;
- `%` - any key of object;
- `*` - any sequence of array indexes and object keys;
- `@#` - length of array or object, could be only used as last component of path;
- `$` - the whole JSON document as single value, could be only the whole path.

Expression is true when operator is true against at least one value selected by path.

Key names could be given either with or without double quotes. Key names without double quotes shouldn't contain spaces, start with number, or concur with `jquery` keyword.

The supported binary operators are:

- Equality operator: `=`;
- Numeric comparison operators: `>`, `>=`, `<`, `<=`;
- Search in the list of scalar values using `IN` operator;
- Array comparison operators: `&&` (overlap), `@>` (contains), `<@` (contained in).
- Filtering operator: `~~`. Taking `jsonb` data as the left operand and a `jquery` expression as the right operand, this operator checks that `jsonb` data contains any entries that satisfy the condition provided in a `jquery` expression and returns an array of such entries, if any.

The supported unary operators are:

- Check for existence operator: `= *`;
- Check for type operators: `IS ARRAY`, `IS NUMERIC`, `IS OBJECT`, `IS STRING` and `IS BOOLEAN`.

Expressions could be complex. Complex expression is a set of expressions combined by logical operators (`AND`, `OR`, `NOT`) and grouped using parentheses.

Examples of complex expressions are given below.

- `a = 1 AND (b = 2 OR c = 3) AND NOT d = 1`
- `x.% = true OR x.# = true`

Prefix expressions are expressions given in the form `path (subexpression)`. In this case path selects JSON values to be checked using given subexpression. Check results are aggregated in the same way as in simple expressions.

- `#(a = 1 AND b = 2)` - an array contains an element where the `a` key is 1 and the `b` key is 2
- `%($ >= 10 AND $ <= 20)` - an object contains a key with a value between 10 and 20

Path also could contain the following special placeholders with "every" semantics:

- `#:` - every index of array;
- `%:` - every key of object;
- `*:` - every sequence of array indexes and object keys.

Consider the following example.

```
%.#: ($ >= 0 AND $ <= 1)
```

This example could be read as follows: there is at least one key for which the value is an array of numerics between 0 and 1.

We can rewrite this example in the following form with extra parentheses.

```
%(#:( $ >= 0 AND $ <= 1))
```

The first placeholder `%` checks that expression in parentheses is true for at least one value in object. The second placeholder `#:` checks that the value is an array and all its elements satisfy expressions in parentheses.

We can rewrite this example without `#:` placeholder as follows.

```
%(NOT #(NOT ( $ >= 0 AND $ <= 1)) AND $ IS ARRAY)
```

In this example we transform assertion that every element of array satisfies some condition to assertion that there is no one element which doesn't satisfy the same condition.

Some examples of using paths are given below.

- `numbers.#: IS NUMERIC` - every element of "numbers" array is numeric.
- `*:( $ IS OBJECT OR $ IS BOOLEAN)` - JSON is a structure of nested objects with booleans as leaf values.
- `#.%.%:( $ >= 0 AND $ <= 1)` - each element of array is object containing only numeric values between 0 and 1.
- `documents.#:.% = *` - "documents" is an array of objects containing at least one key.
- `%.#:( $ IS STRING)` - JSON object contains at least one array of strings.
- `#.% = true` - at least one array element is an object that contains at least one "true" value.

Usage of path operators and parentheses needs some explanation. When same path operators are used multiple times they may refer to different values while you can refer to the same value multiple times by using parentheses and `$` operator. See the following examples.

- `# < 10 AND # > 20` - there is an element less than 10 and another element greater than 20.
- `#( $ < 10 AND $ > 20)` - there is an element that is both less than 10 and greater than 20 (impossible).
- `#( $ >= 10 AND $ <= 20)` - there is an element between 10 and 20.
- `# >= 10 AND # <= 20` - there is an element greater than or equal to 10 and another element less than or equal to 20. The query can be satisfied by an array with no elements between 10 and 20, for instance `[0,30]`.

Same rules apply when you search inside objects and branchy structures.

Type checking operators and "every" placeholders are useful for document schema validation. JQuery matching operator `@@` is immutable and can be used in CHECK constraint. See the following example.

```
CREATE TABLE js (  
  id serial,  
  data jsonb,  
  CHECK (data @@ '  
    name IS STRING AND  
    similar_ids.#: IS NUMERIC AND  
    points.#:(x IS NUMERIC AND y IS NUMERIC)':'::jquery));
```

In this example check constraint validates that in "data" jsonb column: value of "name" key is string, value of "similar_ids" key is array of numerics, value of "points" key is array of objects which contain numeric values in "x" and "y" keys.

See our [pgconf.eu presentation](http://pgconf.eu/presentation) for more examples.

F.27.3. GIN indexes

JQuery extension contains two operator classes (opclasses) for GIN which provide different kinds of query optimization.

- `jsonb_path_value_ops`

- `jsonb_value_path_ops`

In each of two GIN opclasses `jsonb` documents are decomposed into entries. Each entry is associated with a particular value and its path. Difference between opclasses is in the entry representation, comparison, and usage for search optimization.

For example, `jsonb` document `{"a": [{ "b": "xyz", "c": true }, 10], "d": { "e": [7, false] }}` would be decomposed into the following entries:

- `"a".#."b"."xyz"`
- `"a".#."c".true`
- `"a".#.10`
- `"d"."e".#.7`
- `"d"."e".#.false`

Since `JsQuery` doesn't support search in a particular array index, we consider all array elements to be equivalent. Thus, each array element is marked with the same `#` sign in the path.

Major problem in the entries representation is its size. In the given example key `"a"` is presented three times. In the large branchy documents with long keys size of naive entries representation becomes unreasonable. Both opclasses address this issue but in a slightly different way.

F.27.3.1. `jsonb_path_value_ops`

`jsonb_path_value_ops` represents entry as pair of path hash and value. The following pseudocode illustrates it.

```
(hash(path_item_1.path_item_2. ... .path_item_n); value)
```

In comparison of entries path hash is the higher part of entry and value is its lower part. This determines the features of this opclass. Since path is hashed and it is higher part of entry we need to know the full path to the value in order to use it for search. However, once path is specified we can use both exact and range searches very efficiently.

F.27.3.2. `jsonb_value_path_ops`

`jsonb_value_path_ops` represents entry as pair of value and bloom filter of path.

```
(value; bloom(path_item_1) | bloom(path_item_2) | ... | bloom(path_item_n))
```

In comparison of entries value is the higher part of entry and bloom filter of path is its lower part. This determines the features of this opclass. Since value is the higher part of entry we can perform only exact value search efficiently. Range value search is possible as well but we would have to filter all the different paths where matching values occur. Bloom filter over path items allows index usage for conditions containing `%` and `*` in their paths.

F.27.3.3. Query optimization

`JsQuery` opclasses perform complex query optimization. Thus it's valuable for developer or administrator to see the result of such optimization. Unfortunately, opclasses aren't allowed to do any custom output to the `EXPLAIN`. That's why `JsQuery` provides the following functions which allows to see how particular opclass optimizes given query.

- `gin_debug_query_path_value(jsquery)` - for `jsonb_path_value_ops`
- `gin_debug_query_value_path(jsquery)` - for `jsonb_value_path_ops`

Result of these functions is a textual representation of query tree which leaves are GIN search entries. The following examples show different results of query optimization by different opclasses.

```
# SELECT gin_debug_query_path_value('x = 1 AND (*.y = 1 OR y = 2)');
gin_debug_query_path_value
```

```
-----
x = 1 , entry 0          +

# SELECT gin_debug_query_value_path('x = 1 AND (*.y = 1 OR y = 2)');
gin_debug_query_value_path
-----
AND                      +
  x = 1 , entry 0        +
  OR                    +
    *.y = 1 , entry 1    +
    y = 2 , entry 2      +
```

Unfortunately, jsonb has no statistics yet. That's why JQuery optimizer has to do imperative decision while selecting conditions to be evaluated using index. This decision is made by assumption that some condition types are less selective than others. Optimizer divides conditions into the following selectivity class (listed by descending of selectivity).

1. Equality ($x = c$)
2. Range ($c1 < x < c2$)
3. Inequality ($x > c$)
4. Is (x is type)
5. Any ($x = *$)

Optimizer evades index evaluation of less selective conditions when possible. For example, in the $x = 1$ AND $y > 0$ query $x = 1$ is assumed to be more selective than $y > 0$. That's why index isn't used for evaluation of $y > 0$.

```
# SELECT gin_debug_query_path_value('x = 1 AND y > 0');
gin_debug_query_path_value
-----
x = 1 , entry 0          +
```

With lack of statistics decisions made by optimizer can be inaccurate. That's why JQuery supports hints. Comments `/*-- index */` and `/*-- noindex */` placed in the conditions force optimizer to use and not to use index correspondingly.

```
SELECT gin_debug_query_path_value('x = 1 AND y /*-- index */ > 0');
gin_debug_query_path_value
-----
AND                      +
  x = 1 , entry 0        +
  y > 0 , entry 1        +

SELECT gin_debug_query_path_value('x /*-- noindex */ = 1 AND y > 0');
gin_debug_query_path_value
-----
y > 0 , entry 0          +
```

F.28. Io

The `lo` module provides support for managing Large Objects (also called LOs or BLOBs). This includes a data type `lo` and a trigger `lo_manage`.

F.28.1. Rationale

One of the problems with the JDBC driver (and this affects the ODBC driver also), is that the specification assumes that references to BLOBs (Binary Large Objects) are stored within a table, and if that entry is changed, the associated BLOB is deleted from the database.

As Postgres Pro stands, this doesn't occur. Large objects are treated as objects in their own right; a table entry can reference a large object by OID, but there can be multiple table entries referencing the same large object OID, so the system doesn't delete the large object just because you change or remove one such entry.

Now this is fine for Postgres Pro-specific applications, but standard code using JDBC or ODBC won't delete the objects, resulting in orphan objects — objects that are not referenced by anything, and simply occupy disk space.

The `lo` module allows fixing this by attaching a trigger to tables that contain LO reference columns. The trigger essentially just does a `lo_unlink` whenever you delete or modify a value referencing a large object. When you use this trigger, you are assuming that there is only one database reference to any large object that is referenced in a trigger-controlled column!

The module also provides a data type `lo`, which is really just a domain of the `oid` type. This is useful for differentiating database columns that hold large object references from those that are OIDs of other things. You don't have to use the `lo` type to use the trigger, but it may be convenient to use it to keep track of which columns in your database represent large objects that you are managing with the trigger. It is also rumored that the ODBC driver gets confused if you don't use `lo` for BLOB columns.

F.28.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE image (title TEXT, raster lo);

CREATE TRIGGER t_raster BEFORE UPDATE OR DELETE ON image
    FOR EACH ROW EXECUTE PROCEDURE lo_manage(raster);
```

For each column that will contain unique references to large objects, create a `BEFORE UPDATE OR DELETE` trigger, and give the column name as the sole trigger argument. You can also restrict the trigger to only execute on updates to the column by using `BEFORE UPDATE OF column_name`. If you need multiple `lo` columns in the same table, create a separate trigger for each one, remembering to give a different name to each trigger on the same table.

F.28.3. Limitations

- Dropping a table will still orphan any objects it contains, as the trigger is not executed. You can avoid this by preceding the `DROP TABLE` with `DELETE FROM table`.

`TRUNCATE` has the same hazard.

If you already have, or suspect you have, orphaned large objects, see the [vacuumlo](#) module to help you clean them up. It's a good idea to run `vacuumlo` occasionally as a back-stop to the `lo_manage` trigger.

- Some frontends may create their own tables, and will not create the associated trigger(s). Also, users may not remember (or know) to create the triggers.

F.28.4. Author

Peter Mount <peter@retep.org.uk>

F.29. ltree

This module implements a data type `ltree` for representing labels of data stored in a hierarchical tree-like structure. Extensive facilities for searching through label trees are provided.

F.29.1. Definitions

A *label* is a sequence of alphanumeric characters and underscores (for example, in C locale the characters `A-Za-z0-9_` are allowed). Labels must be less than 256 characters long.

Examples: `42`, `Personal_Services`

A *label path* is a sequence of zero or more labels separated by dots, for example `L1.L2.L3`, representing a path from the root of a hierarchical tree to a particular node. The length of a label path cannot exceed 65535 labels.

Example: `Top.Countries.Europe.Russia`

The `ltree` module provides several data types:

- `ltree` stores a label path.
- `lquery` represents a regular-expression-like pattern for matching `ltree` values. A simple word matches that label within a path. A star symbol (`*`) matches zero or more labels. For example:

<code>foo</code>	<i>Match the exact label path foo</i>
<code>*.foo.*</code>	<i>Match any label path containing the label foo</i>
<code>*.foo</code>	<i>Match any label path whose last label is foo</i>

Star symbols can also be quantified to restrict how many labels they can match:

<code>*{n}</code>	<i>Match exactly n labels</i>
<code>*{n,}</code>	<i>Match at least n labels</i>
<code>*{n,m}</code>	<i>Match at least n but not more than m labels</i>
<code>*{,m}</code>	<i>Match at most m labels – same as <code>*{0,m}</code></i>

There are several modifiers that can be put at the end of a non-star label in `lquery` to make it match more than just the exact match:

<code>@</code>	<i>Match case-insensitively, for example <code>a@</code> matches <code>A</code></i>
<code>*</code>	<i>Match any label with this prefix, for example <code>foo*</code> matches <code>foobar</code></i>
<code>%</code>	<i>Match initial underscore-separated words</i>

The behavior of `%` is a bit complicated. It tries to match words rather than the entire label. For example `foo_bar%` matches `foo_bar_baz` but not `foo_barbaz`. If combined with `*`, prefix matching applies to each word separately, for example `foo_bar%*` matches `foo1_bar2_baz` but not `foo1_br2_baz`.

Also, you can write several possibly-modified labels separated with `|` (OR) to match any of those labels, and you can put `!` (NOT) at the start to match any label that doesn't match any of the alternatives.

Here's an annotated example of `lquery`:

```
Top.*{0,2}.sport*@.!football|tennis.Russ*|Spain
a.  b.      c.      d.      e.
```

This query will match any label path that:

- begins with the label `Top`
- and next has zero to two labels before
- a label beginning with the case-insensitive prefix `sport`

d. then a label not matching `football` nor `tennis`

e. and then ends with a label beginning with `Russ` or exactly matching `Spain`.

- `ltxquery` represents a full-text-search-like pattern for matching `ltree` values. An `ltxquery` value contains words, possibly with the modifiers `@`, `*`, `%` at the end; the modifiers have the same meanings as in `lquery`. Words can be combined with `&` (AND), `|` (OR), `!` (NOT), and parentheses. The key difference from `lquery` is that `ltxquery` matches words without regard to their position in the label path.

Here's an example `ltxquery`:

```
Europe & Russia*@ & !Transportation
```

This will match paths that contain the label `Europe` and any label beginning with `Russia` (case-insensitive), but not paths containing the label `Transportation`. The location of these words within the path is not important. Also, when `%` is used, the word can be matched to any underscore-separated word within a label, regardless of position.

Note: `ltxquery` allows whitespace between symbols, but `ltree` and `lquery` do not.

F.29.2. Operators and Functions

Type `ltree` has the usual comparison operators `=`, `<>`, `<`, `>`, `<=`, `>=`. Comparison sorts in the order of a tree traversal, with the children of a node sorted by label text. In addition, the specialized operators shown in [Table F.19](#) are available.

Table F.19. `ltree` Operators

Operator	Returns	Description
<code>ltree @> ltree</code>	boolean	is left argument an ancestor of right (or equal)?
<code>ltree <@ ltree</code>	boolean	is left argument a descendant of right (or equal)?
<code>ltree ~ lquery</code>	boolean	does <code>ltree</code> match <code>lquery</code> ?
<code>lquery ~ ltree</code>	boolean	does <code>ltree</code> match <code>lquery</code> ?
<code>ltree ? lquery[]</code>	boolean	does <code>ltree</code> match any <code>lquery</code> in array?
<code>lquery[] ? ltree</code>	boolean	does <code>ltree</code> match any <code>lquery</code> in array?
<code>ltree @ ltxquery</code>	boolean	does <code>ltree</code> match <code>ltxquery</code> ?
<code>ltxquery @ ltree</code>	boolean	does <code>ltree</code> match <code>ltxquery</code> ?
<code>ltree ltree</code>	<code>ltree</code>	concatenate <code>ltree</code> paths
<code>ltree text</code>	<code>ltree</code>	convert text to <code>ltree</code> and concatenate
<code>text ltree</code>	<code>ltree</code>	convert text to <code>ltree</code> and concatenate
<code>ltree[] @> ltree</code>	boolean	does array contain an ancestor of <code>ltree</code> ?
<code>ltree <@ ltree[]</code>	boolean	does array contain an ancestor of <code>ltree</code> ?
<code>ltree[] <@ ltree</code>	boolean	does array contain a descendant of <code>ltree</code> ?
<code>ltree @> ltree[]</code>	boolean	does array contain a descendant of <code>ltree</code> ?

Operator	Returns	Description
<code>ltree[] ~ lquery</code>	boolean	does array contain any path matching <code>lquery</code> ?
<code>lquery ~ ltree[]</code>	boolean	does array contain any path matching <code>lquery</code> ?
<code>ltree[] ? lquery[]</code>	boolean	does <code>ltree</code> array contain any path matching any <code>lquery</code> ?
<code>lquery[] ? ltree[]</code>	boolean	does <code>ltree</code> array contain any path matching any <code>lquery</code> ?
<code>ltree[] @ ltxtquery</code>	boolean	does array contain any path matching <code>ltxtquery</code> ?
<code>ltxtquery @ ltree[]</code>	boolean	does array contain any path matching <code>ltxtquery</code> ?
<code>ltree[] ?@> ltree</code>	ltree	first array entry that is an ancestor of <code>ltree</code> ; NULL if none
<code>ltree[] ?<@ ltree</code>	ltree	first array entry that is a descendant of <code>ltree</code> ; NULL if none
<code>ltree[] ?~ lquery</code>	ltree	first array entry that matches <code>lquery</code> ; NULL if none
<code>ltree[] ?@ ltxtquery</code>	ltree	first array entry that matches <code>ltxtquery</code> ; NULL if none

The operators `<@`, `@>`, `@` and `~` have analogues `^<@`, `^@>`, `^@`, `^~`, which are the same except they do not use indexes. These are useful only for testing purposes.

The available functions are shown in [Table F.20](#).

Table F.20. ltree Functions

Function	Return Type	Description	Example	Result
<code>subltree(ltree, int start, int end)</code>	ltree	subpath of <code>ltree</code> from position <i>start</i> to position <i>end-1</i> (counting from 0)	<code>subltree('Top.Child1.Child2', 1, 2)</code>	Child1
<code>subpath(ltree, int offset, int len)</code>	ltree	subpath of <code>ltree</code> starting at position <i>offset</i> , length <i>len</i> . If <i>offset</i> is negative, subpath starts that far from the end of the path. If <i>len</i> is negative, leaves that many labels off the end of the path.	<code>subpath('Top.Child1.Child2', 0, 2)</code>	Top.Child1
<code>subpath(ltree, int offset)</code>	ltree	subpath of <code>ltree</code> starting at position <i>offset</i> , extending to end of path. If <i>offset</i> is negative, subpath starts that	<code>subpath('Top.Child1.Child2', 1)</code>	Child1.Child2

Function	Return Type	Description	Example	Result
		far from the end of the path.		
nlevel(ltree)	integer	number of labels in path	nlevel('Top.Child1.Child2')	3
index(ltree a, ltree b)	integer	position of first occurrence of <i>b</i> in <i>a</i> ; -1 if not found	index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6')	6
index(ltree a, ltree b, int offset)	integer	position of first occurrence of <i>b</i> in <i>a</i> , searching starting at <i>offset</i> ; negative <i>offset</i> means start <i>-offset</i> labels from the end of the path	index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6', -4)	9
text2ltree(text)	ltree	cast text to ltree		
ltree2text(ltree)	text	cast ltree to text		
lca(ltree, ltree, ...)	ltree	longest common ancestor of paths (up to 8 arguments supported)	lca('1.2.3', '1.2.3.4.5.6')	1.2
lca(ltree[])	ltree	longest common ancestor of paths in array	lca(array['1.2.3'::ltree, '1.2.3.4'])	1.2

F.29.3. Indexes

ltree supports several types of indexes that can speed up the indicated operators:

- B-tree index over ltree: <, <=, =, >=, >
- GiST index over ltree: <, <=, =, >=, >, @>, <@, @, ~, ?

Example of creating such an index:

```
CREATE INDEX path_gist_idx ON test USING GIST (path);
```

- GiST index over ltree[]: ltree[] <@ ltree, ltree @> ltree[], @, ~, ?

Example of creating such an index:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path);
```

Note: This index type is lossy.

F.29.4. Example

This example uses the following data (also available in file contrib/ltree/ltreetest.sql in the source distribution):

```
CREATE TABLE test (path ltree);
INSERT INTO test VALUES ('Top');
INSERT INTO test VALUES ('Top.Science');
INSERT INTO test VALUES ('Top.Science.Astronomy');
INSERT INTO test VALUES ('Top.Science.Astronomy.Astrophysics');
```

```
INSERT INTO test VALUES ('Top.Science.Astronomy.Cosmology');
INSERT INTO test VALUES ('Top.Hobbies');
INSERT INTO test VALUES ('Top.Hobbies.Amateurs_Astronomy');
INSERT INTO test VALUES ('Top.Collections');
INSERT INTO test VALUES ('Top.Collections.Pictures');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Stars');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Galaxies');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Astronauts');
CREATE INDEX path_gist_idx ON test USING GIST (path);
CREATE INDEX path_idx ON test USING BTREE (path);
```

Now, we have a table `test` populated with data describing the hierarchy shown below:

We can do inheritance:

```
ltreetest=> SELECT path FROM test WHERE path <@ 'Top.Science';
           path
-----
Top.Science
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(4 rows)
```

Here are some examples of path matching:

```
ltreetest=> SELECT path FROM test WHERE path ~ '*.Astronomy.*';
           path
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
Top.Collections.Pictures.Astronomy
Top.Collections.Pictures.Astronomy.Stars
Top.Collections.Pictures.Astronomy.Galaxies
Top.Collections.Pictures.Astronomy.Astronauts
(7 rows)

ltreetest=> SELECT path FROM test WHERE path ~ '*.!pictures@.*.Astronomy.*';
           path
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(3 rows)
```

Here are some examples of full text search:

```
ltreetest=> SELECT path FROM test WHERE path @ 'Astro*% & !pictures@';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
Top.Hobbies.Amateurs_Astronomy
(4 rows)
```

```
ltreetest=> SELECT path FROM test WHERE path @ 'Astro*' & '!pictures@';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(3 rows)
```

Path construction using functions:

```
ltreetest=> SELECT subpath(path,0,2)||'Space'||subpath(path,2) FROM test WHERE path <@
'Top.Science.Astronomy';
           ?column?
```

```
-----
Top.Science.Space.Astronomy
Top.Science.Space.Astronomy.Astrophysics
Top.Science.Space.Astronomy.Cosmology
(3 rows)
```

We could simplify this by creating a SQL function that inserts a label at a specified position in a path:

```
CREATE FUNCTION ins_label(ltree, int, text) RETURNS ltree
AS 'select subpath($1,0,$2) || $3 || subpath($1,$2);'
LANGUAGE SQL IMMUTABLE;
```

```
ltreetest=> SELECT ins_label(path,2,'Space') FROM test WHERE path <@
'Top.Science.Astronomy';
           ins_label
```

```
-----
Top.Science.Space.Astronomy
Top.Science.Space.Astronomy.Astrophysics
Top.Science.Space.Astronomy.Cosmology
(3 rows)
```

F.29.5. Transforms

Additional extensions are available that implement transforms for the `ltree` type for PL/Python. The extensions are called `ltree_plpythonu`, `ltree_plpython2u`, and `ltree_plpython3u` (see [Section 44.1](#) for the PL/Python naming convention). If you install these transforms and specify them when creating a function, `ltree` values are mapped to Python lists. (The reverse is currently not supported, however.)

Caution

It is strongly recommended that the transform extensions be installed in the same schema as `ltree`. Otherwise there are installation-time security hazards if a transform extension's schema contains objects defined by a hostile user.

F.29.6. Authors

All work was done by Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megeera/postgres/gist/> for additional information. Authors would like to thank Eugeny Rodichev for helpful discussions. Comments and bug reports are welcome.

F.30. mchar

The `mchar` module provides additional data types for compatibility with Microsoft SQL Server (MS SQL).

F.30.1. Overview

This module has been designed to improve 1C Enterprise support, most popular Russian CRM and ERP system.

It implements types `MCHAR` and `MVARCHAR`, which are bug-to-bug compatible with MS SQL `CHAR` and `VARCHAR` respectively. Additionally, these types use `libc` for comparison and case conversion, so their behavior is identical across different operating systems.

Postgres Pro also includes `citext` extension which provides types similar to `MCHAR`. But this extension doesn't emulate MS-SQL behavior concerning end-of-value whitespace.

Differences from Postgres Pro standard `CHAR` and `VARCHAR` are:

- Case insensitive comparison
- Handling of the whitespace at the end of string
- These types are always stored as two-byte unicode value regardless of database encoding.

F.30.2. Additional types

- `mchar` — analog of the MS SQL `char` type
- `mvarchar` — analog of the MS SQL `varchar` type

F.30.3. MCHAR and MVARCHAR features

- Defines `length(str)` function
- Defines `substr(str, pos[, length])` function
- Defines `||` operator, which would be applied to concatenate any (`mchar` and `mvarchar`) arguments
- Defines set of operators: `<`, `<=`, `=`, `>=`, `>` for case-insensitive comparison (LibICU)
- Defines set of operators: `&<`, `&<=`, `&=`, `&>=`, `&>` to case-sensitive comparison (LibICU)
- Implicit cast between `mchar` and `mvarchar` types
- B-tree and Hash-index support
- The `LIKE [ESCAPE]` operator support
- The `SIMILAR TO [ESCAPE]` operator support
- The `~` operator (POSIX regexp) support
- Index support for the `LIKE` operator

F.30.4. Authors

Teodor Sigaev <teodor@sigaev.ru>

F.31. multimaster

`multimaster` is a Postgres Pro Enterprise extension with a set of patches that turns Postgres Pro Enterprise into a synchronous shared-nothing cluster to provide Online Transaction Processing (OLTP) scalability for read transactions and high availability with automatic disaster recovery.

As compared to a standard PostgreSQL master-standby cluster, a cluster configured with the `multimaster` extension offers the following benefits:

- Cluster-wide transaction isolation
- Synchronous logical replication and DDL replication
- Working with temporary tables on each cluster node
- Fault tolerance and automatic node recovery
- PostgreSQL online upgrades

The `multimaster` extension replicates your database to all nodes of the cluster and allows write transactions on each node. To ensure data consistency in the case of concurrent updates, `multimaster` enforces transaction isolation cluster-wide, using multiversion concurrency control (MVCC) at the [read committed](#) or [repeatable read](#) isolation levels. Any write transaction is synchronously replicated to all nodes, which increases commit latency for the time required for synchronization. Read-only transactions and queries are executed locally, without any measurable overhead.

To ensure high availability and fault tolerance of the cluster, `multimaster` uses three-phase commit protocol and heartbeats for failure discovery. A multi-master cluster of N nodes can continue working while the majority of the nodes are alive and reachable by other nodes. To be configured with `multimaster`, the cluster must include at least two nodes. In most cases, three cluster nodes are enough to ensure high availability. Since the data on all cluster nodes is the same, you do not typically need more than five cluster nodes.

When a failed node is reconnected to the cluster, `multimaster` can automatically fast-forward the node to the actual state based on the Write-Ahead Log (WAL) data in the corresponding replication slot. If WAL data is no longer available for the time when the node was excluded from the cluster, you can [restore the node using pg_basebackup](#).

Important

When using `multimaster`, make sure to take its replication restrictions into account. For details, see [Section F.31.1](#).

To learn more about the `multimaster` internals, see [Section F.31.2](#).

F.31.1. Limitations

The `multimaster` extension takes care of the database replication in a fully automated way. You can perform write transactions on any node and work with temporary tables on each cluster node simultaneously. However, make sure to take the following replication restrictions into account:

- Microsoft Windows operating system is not supported.
- `multimaster` can only replicate one database per cluster. This database must be specified in the `multimaster.conn_strings` variable. If you connect to a different database, all operations will fail with the corresponding error message.
- The replicated tables must have primary keys or replica identity because of logical replication restrictions. Although tables without primary keys can be replicated, `multimaster` does not allow `UPDATE` and `DELETE` operations on such tables. For details, see [multimaster.ignore_tables_without_pk](#). Unlogged tables are not replicated, as in the standard PostgreSQL.
- Isolation level. The `multimaster` extension supports `read committed` and `repeatable read` isolation levels. `Serializable` isolation level is currently not supported.

Important

Using `repeatable read` isolation level increases the probability of serialization failure at commit time. Unlike in the standard PostgreSQL, `read committed` level can also cause serialization failures on a multi-master cluster (with an SQLSTATE code '40001').

When performing a write transaction, `multimaster` blocks the affected objects only on the node on which the transaction is performed. However, since write transactions are allowed on all nodes, other transactions can try to change the same objects on the neighbor nodes at the same time. In this case, the replication of the first transaction can fail because the affected objects on the neighbor nodes are already blocked by another transaction. Similarly, the latter transaction cannot be replicated to the first node. In this case, a distributed deadlock occurs. As a result, one of the transactions is automatically rolled back and needs to be repeated. The application must be ready to retry transactions.

If your typical workload has too many rollbacks, it is recommended to use `read committed` isolation level. However, the `read committed` still does not guarantee the absence of deadlocks on a multi-master cluster. If using the `read committed` level does not help, you can try directing all the write transactions to a single node.

- In a multi-master cluster, the `ALTER SYSTEM` command only affects the configuration of the current node. If you would like to change configuration parameters across the whole database cluster, you need to run this command on each node.
- Sequence generation. To avoid conflicts between unique identifiers on different nodes, `multimaster` modifies the default behavior of sequence generators. By default, ID generation on each node is started with this node number and is incremented by the number of nodes. For example, in a three-node cluster, 1, 4, and 7 IDs are allocated to the objects written onto the first node, while 2, 5, and 8 IDs are reserved for the second node. If you change the number of nodes in the cluster, the incrementation interval for new IDs is adjusted accordingly. Thus, the generated sequence values are not monotonic. If it is critical to get a monotonically increasing sequence cluster-wide, you can set the `multimaster.monotonic_sequences` to `true`.
- DDL replication. While `multimaster` replicates data on the logical level, DDL is replicated on the statement level, which results in distributed commits of the same statement on different nodes. As a result, complex DDL scenarios, such as stored procedures and temporary tables, may work differently as compared to the standard PostgreSQL.
- Commit latency. In the current implementation of logical replication, `multimaster` sends data to subscriber nodes only after the local commit, so you have to wait for transaction processing twice: first on the local node, and then on all the other nodes simultaneously. In the case of a heavy-write transaction, this may result in a noticeable delay.

If you have any data that must be present on one of the nodes only, you can exclude a particular table from replication, as follows:

```
SELECT mtm.make_table_local('table_name')
```

F.31.2. Architecture

F.31.2.1. Replication

Since each server in a multi-master cluster can accept writes, any server can abort a transaction because of a concurrent update — in the same way as it happens on a single server between different backends. To ensure high availability and data consistency on all cluster nodes, `multimaster` uses [logical replication](#) and the [three-phase E3PC commit protocol](#).

When Postgres Pro Enterprise loads the `multimaster` shared library, `multimaster` sets up a logical replication producer and consumer for each node, and hooks into the transaction commit pipeline. The typical data replication workflow consists of the following phases:

1. **PREPARE phase.** `multimaster` captures and implicitly transforms each `COMMIT` statement to a `PREPARE` statement. All the nodes that get the transaction via the replication protocol (*the cohort nodes*) send their vote for approving or declining the transaction to the arbiter process on the initiating node. This ensures that all the cohort can accept the transaction, and no write conflicts occur. For details on `PREPARE` transactions support in PostgreSQL, see the [PREPARE TRANSACTION](#) topic.

2. **PRECOMMIT phase.** If all the cohort nodes approve the transaction, the arbiter process sends a `PRECOMMIT` message to all the cohort nodes to express an intention to commit the transaction. The cohort nodes respond to the arbiter with the `PRECOMMITTED` message. In case of a failure, all the nodes can use this information to complete the transaction using a quorum-based voting procedure.
3. **COMMIT phase.** If `PRECOMMIT` is successful, the arbiter commits the transaction to all nodes.

Important

`multimaster` currently supports the `read committed` and `repeatable read` isolation levels only, which can cause unexpected serialization failures in your workload. For details, see [Section F.31.1](#).

If a node crashes or gets disconnected from the cluster between the `PREPARE` and `COMMIT` phases, the `PRECOMMIT` phase ensures that the survived nodes have enough information to complete the prepared transaction. The `PRECOMMITTED` messages help avoid the situation when the crashed node has already committed or aborted the transaction, but has not notified other nodes about the transaction status. In a two-phase commit (2PC), such a transaction would block resources (hold locks) until the recovery of the crashed node. Otherwise, you could get data inconsistencies in the database when the failed node is recovered. For example, if the failed node committed the transaction but the survived node aborted it.

To complete the transaction, the arbiter must receive a response from the majority of the nodes. For example, for a cluster of $2N+1$ nodes, at least $N+1$ responses are required. Thus, `multimaster` ensures that your cluster is available for reads and writes while the majority of the nodes are connected, and no data inconsistencies occur in case of a node or connection failure. For details on the failure detection mechanism, see [Section F.31.2.2](#).

F.31.2.2. Failure Detection and Recovery

Since `multimaster` allows writes to each node, it has to wait for responses about transaction acknowledgment from all the other nodes. Without special actions in case of a node failure, each commit would have to wait until the failed node recovery. To deal with such situations, `multimaster` periodically sends heartbeats to check the node state and the connectivity between nodes. When several heartbeats to the node are lost in a row, this node is kicked out of the cluster to allow writes to the remaining alive nodes. You can configure the heartbeat frequency and the response timeout in the `multimaster.heartbeat_send_timeout` and `multimaster.heartbeat_rcv_timeout` parameters, respectively.

For alive nodes, there is no way to distinguish between a failed node that stopped serving requests and a network-partitioned node that can be accessed by database users, but is unreachable for other nodes. To avoid conflicting writes to nodes in different network partitions, `multimaster` only allows writes to the nodes that see the majority of other nodes.

For example, suppose a five-node multi-master cluster experienced a network failure that split the network into two isolated subnets, with two and three cluster nodes. Based on heartbeats propagation information, `multimaster` will continue accepting writes at each node in the bigger partition, and deny all writes in the smaller one. Thus, a cluster consisting of $2N+1$ nodes can tolerate N node failures and stay alive if any $N+1$ nodes are alive and connected to each other.

Tip

For clusters with an even number of nodes, you can override this behavior. For details, see [Section F.31.3.3](#).

In case of a partial network split when different nodes have different connectivity, `multimaster` finds a fully connected subset of nodes and disconnects other nodes. For example, in a three-node cluster,

if node A can access both B and C, but node B cannot access node C, `multimaster` isolates node C to ensure data consistency on nodes A and B.

If you try to access a disconnected node, `multimaster` returns an error message indicating the current status of the node. To prevent stale reads, read-only queries are also forbidden. Additionally, you can break connections between the disconnected node and the clients using the `multimaster.break_connection` variable.

Each node maintains a data structure that keeps the information about the state of all nodes in relation to this node. You can get this data in the `mtm.get_nodes_state()` view.

When a failed node connects back to the cluster, `multimaster` starts automatic recovery:

1. The reconnected node selects a random cluster node and starts catching up with the current state of the cluster based on the Write-Ahead Log (WAL).
2. When the node gets synchronized up to the minimum recovery lag, all the cluster nodes get locked for write transactions to allow the recovery process to finish. By default, the minimum recovery lag is 10KB. You can change this value in the `multimaster.min_recovery_lag` variable.
3. When the recovery is complete, `multimaster` promotes the reconnected node to the online state and includes it into the replication scheme.

Note

Automatic recovery is only possible if the failed node WAL lag behind the working ones does not exceed the `multimaster.max_recovery_lag` value. When the WAL lag is bigger than `multimaster.max_recovery_lag`, you can manually restore the node from one of the working nodes using `pg_basebackup`.

[Restoring a Cluster Node](#)

F.31.3. Installation and Setup

To use `multimaster`, you need to install Postgres Pro Enterprise on all nodes of your cluster. Postgres Pro Enterprise includes all the required dependencies and extensions.

F.31.3.1. Setting up a Multi-Master Cluster

After installing Postgres Pro Enterprise on all nodes, you need to configure the cluster with `multimaster`.

Suppose you are setting up a cluster of three nodes, with `node1`, `node2`, and `node3` domain names. First, set up the database to be replicated, and make sure you have a DBMS user with superuser rights to perform replication:

- If you are starting from scratch, initialize a cluster, create an empty database `mydb` and a new DBMS user `myuser` with superuser rights, on each node of the cluster. For details, see [Section 18.2](#).
- If you already have a database `mydb` running on `node1`, create a new DBMS user `myuser` with superuser rights and initialize new nodes from the working node using `pg_basebackup` on behalf of this user. Run the following command on each node you are going to add:

```
pg_basebackup -D datadir -h node1 -U myuser
```

where `datadir` is the directory containing the database cluster. This directory is specified at the cluster initialization stage, or set in the `PGDATA` environment variable. You can also use any other DBMS user with superuser rights instead of `myuser` to perform this task.

For details on using `pg_basebackup`, see [pg_basebackup](#).

Once the database is set up, complete the following steps on each cluster node:

1. Allow replication of the `mydb` database to each cluster node on behalf of `myuser`, as explained in [Section 20.1](#). Make sure to use the [authentication method](#) that satisfies your security requirements.
2. Modify the `postgresql.conf` configuration file, as follows:

- Add `multimaster` to the `shared_preload_libraries` variable:

```
shared_preload_libraries = 'multimaster'
```

Tip

If the `shared_preload_libraries` variable is already defined in `postgresql.auto.conf`, you will need to modify its value using the [ALTER SYSTEM](#) command. For details, see [Section 19.1.2](#). Note that in a multi-master cluster, the `ALTER SYSTEM` command only affects the configuration of the node from which it was run.

- Specify the transaction isolation level for your cluster. `multimaster` currently supports [read committed](#) and [repeatable read](#) isolation levels.

```
default_transaction_isolation = 'read committed'
```

Important

Using `repeatable read` isolation level increases the probability of serialization failure at commit time. If such cases are not handled by your application, you are recommended to use `read committed` isolation level.

- Set up PostgreSQL parameters related to replication.

```
wal_level = logical
max_connections = 100
max_prepared_transactions = 300
max_wal_senders = 10      # at least the number of nodes
max_replication_slots = 10 # at least the number of nodes
```

You must change the replication level to `logical` as `multimaster` relies on logical replication. For a cluster of N nodes, enable at least N WAL sender processes and replication slots. Since `multimaster` implicitly adds a `PREPARE` phase to each `COMMIT` transaction, make sure to set the number of prepared transactions to $N \times \text{max\_connections}$. Otherwise, prepared transactions may be queued.

- Make sure you have enough background workers allocated for each node:

```
max_worker_processes = 250
```

For example, for a three-node cluster with `max_connections = 100`, `multimaster` may need up to 206 background workers at peak times: 200 workers for connections from the neighbor nodes, two workers for WAL sender processes, two workers for WAL receiver processes, and two workers for the arbiter sender and receiver processes. When setting this parameter, remember that other modules may also use background workers at the same time.

- Add `multimaster`-specific options:

```
multimaster.max_nodes = 3  # cluster size
multimaster.node_id = 1    # the 1-based index of this node
```

```
                                # in the cluster
multimaster.conn_strings = 'dbname=mydb user=myuser host=node1 port=5432
                             arbiter_port=5433,dbname=mydb user=myuser host=node2 port=5432
                             arbiter_port=5433,dbname=mydb user=myuser host=node3 port=5432 arbiter_port=5433'
                                # comma-separated list
                                # of connection strings
                                # to neighbor nodes
multimaster.arbiter_port = 5433
```

The `multimaster.max_nodes` variable defines the maximum cluster size. If you plan to add new nodes to your cluster, the `multimaster.max_nodes` value should exceed the initial number of nodes. In this case, you can add new nodes without restarting Postgres Pro Enterprise until the specified number of nodes is reached.

In most cases, three cluster nodes are enough to ensure high availability. Since the data on all cluster nodes is the same, you do not typically need more than five cluster nodes.

Important

The `multimaster.node_id` variable takes natural numbers starting from 1, without any gaps in numbering. For example, for a cluster of five nodes, set node IDs to 1, 2, 3, 4, and 5. In the `multimaster.conn_strings` variable, make sure to list the nodes in the order of their IDs. The `multimaster.conn_strings` variable must be the same on all nodes.

You can customize connection parameters by adding other [libpq connection options](#) to connection strings in the `multimaster.conn_strings` variable. By default, `multimaster` uses port 5432 to establish connections between the nodes and port 5433 for the arbiter process to listen for connections. If these ports are already in use, you must specify other ports in `port` and `arbiter_port` options in each connection string in the `multimaster.conn_strings` variable.

If you change the `arbiter_port` option, you must also specify this port in the `multimaster.arbiter_port` variable. For details, see [multimaster.arbiter_port](#) and [multimaster.conn_strings](#).

To check whether the default ports are available, you can run the following command:

```
netstat -ln | grep -E '5432|5433'
```

Make sure these ports are not blocked by firewall.

Depending on your network environment and usage patterns, you may want to tune other `multimaster` parameters. For details, see [Section F.31.3.2](#).

3. On behalf of an OS superuser, restart Postgres Pro Enterprise:

```
pg_ctl -D datadir -l pg.log restart
```

When Postgres Pro Enterprise is started on all nodes, connect to any node on behalf of the `postgres` OS user and create the `multimaster` extension in the `mydb` database that will be replicated:

```
psql -h node1 -d mydb
CREATE EXTENSION multimaster;
```

The `CREATE EXTENSION` query is replicated to all the cluster nodes.

To ensure that `multimaster` is enabled, check the `mtm.get_cluster_state()` view:

```
SELECT mtm.get_cluster_state();
```

If `liveNodes` is equal to `allNodes`, your cluster is successfully configured and ready to use.

See Also

Tuning Configuration Parameters

F.31.3.1.1. Sample Cluster Configuration for CentOS, Oracle Linux, and RHEL

This section shows a sample configuration of a three-node cluster with host names `node1`, `node2` and `node3`. The name of the database to be replicated is `mydb`. The name of DBMS user with superuser rights to perform database replication is `myuser`.

1. First, run the following commands on behalf of OS user `postgres`, on all cluster nodes:

```
# Configure each node, and then create the myuser user
# and mydb database owned by myuser.
export PATH=/usr/pgproee-9.6/bin:$PATH
export PGDATA=/var/lib/pgproee/9.6/data

for i in `seq 1 3`; do
echo "host replication myuser node$i md5" >> $PGDATA/pg_hba.conf
echo "host mydb myuser node$i md5" >> $PGDATA/pg_hba.conf
echo "node$i:5432:mydb:myuser:myuserpassword" >> ~/.pgpass
done
chmod 0600 ~/.pgpass

cat << EOF | psql --dbname=postgres --username=postgres --port=5432
ALTER SYSTEM SET default_transaction_isolation = 'read committed';
ALTER SYSTEM SET wal_level = logical;
ALTER SYSTEM SET max_connections = 100;
ALTER SYSTEM SET max_prepared_transactions = 300;
ALTER SYSTEM SET max_wal_senders = 10;
ALTER SYSTEM SET max_replication_slots = 10;
ALTER SYSTEM SET max_worker_processes = 250;
ALTER SYSTEM SET shared_preload_libraries = 'multimaster';
CREATE USER myuser WITH SUPERUSER PASSWORD 'myuserpassword';
CREATE DATABASE mydb OWNER myuser;
EOF

# Define the number of nodes in the cluster, assign node IDs,
# and connection strings to the nodes. This example assumes
# that node hostnames are node1, node2, and node3, and their
# IDs are the corresponding numbers starting with 1.
cat << EOF >> $PGDATA/postgresql.conf
multimaster.max_nodes = 3
multimaster.node_id = `hostname | awk '{ print substr($1,5,1) }'`
multimaster.arbiter_port = 5433
multimaster.conn_strings = 'dbname=mydb user=myuser host=node1 port=5432
  arbiter_port=5433,dbname=mydb user=myuser host=node2 port=5432
  arbiter_port=5433,dbname=mydb user=myuser host=node3 port=5432 arbiter_port=5433'
EOF
```

2. On behalf of an OS user with superuser privileges, restart Postgres Pro Enterprise service on all cluster nodes:

```
sudo service postgrespro-enterprise-9.6 restart
```

3. Now create the `multimaster` extension on one of the cluster nodes, on behalf of OS user `postgres`. It will be replicated to all the other nodes automatically. The following example illustrates extension creation on `node1`.

```
psql --dbname=mydb --username=myuser --host=node1 --port=5432 -c "CREATE EXTENSION IF
NOT EXISTS multimaster"
```

The cluster is set up and ready to use.

F.31.3.2. Tuning Configuration Parameters

While you can use `multimaster` in the default configuration, you may want to tune several parameters for faster failure detection or more reliable automatic recovery.

F.31.3.2.1. Setting Timeout for Failure Detection

To check availability of the neighbor nodes, `multimaster` periodically sends heartbeat packets to all nodes. You can define the timeout for failure detection with the following variables:

- The `multimaster.heartbeat_send_timeout` variable defines the time interval between the heartbeats. By default, this variable is set to 200ms.
- The `multimaster.heartbeat_recv_timeout` variable sets the timeout for the response. If no heartbeats are received during this time, the node is assumed to be disconnected and is excluded from the cluster. By default, this variable is set to 1000ms.

It's a good idea to set `multimaster.heartbeat_send_timeout` based on typical ping latencies between the nodes. Small `recv/send` ratio decreases the time of failure detection, but increases the probability of false-positive failure detection. When setting this parameter, take into account the typical packet loss ratio between your cluster nodes.

F.31.3.2.2. Configuring Automatic Recovery Parameters

If a cluster node fails, `multimaster` can automatically restore it based on the WAL collected on other cluster nodes. To control the recovery settings, use the following variables:

- `multimaster.min_recovery_lag` — sets the minimal WAL lag between the node to be restored and the current cluster state. By default, `multimaster.min_recovery_lag` is set to 10KB. When the disconnected node is fast-forwarded up to the `multimaster.min_recovery_lag` threshold, `multimaster` stops all new commits to the alive nodes until the node fully catches up with the current state of the cluster. When the data is fully synchronized, the disconnected node is promoted to the online state, and the cluster resumes its work.
- `multimaster.max_recovery_lag` — sets the maximum size of WAL. Upon reaching the `multimaster.max_recovery_lag` threshold, WAL for the disconnected node is overwritten. At this point, automatic recovery is no longer possible. In this case, you can [restore the node manually](#) by cloning the data from one of the alive nodes using `pg_basebackup`.

By default, `multimaster.max_recovery_lag` is set to 1GB. Setting `multimaster.max_recovery_lag` to a larger value increases the timeframe for automatic recovery, but requires more disk space for WAL collection.

[GUC Variables](#)

F.31.3.3. Defining Quorum Settings for Clusters with an Even Number of Nodes

By default, `multimaster` uses a majority-based algorithm to determine whether the cluster nodes have a quorum: a cluster can only continue working if the majority of its nodes are alive and can access each other. For clusters with an even number of nodes, this approach is not optimal. For example, if a network failure splits the cluster into equal parts, or one of the nodes fails in a two-node cluster, all the nodes stop accepting queries, even though at least half of the cluster nodes are running normally.

To enable a smooth failover for such cases, you can modify the `multimaster` majority-based behavior using one of the following options:

- [Set up a standalone referee node](#) to assign the quorum status to a subset of nodes that constitutes half of the cluster.
- [Choose the major node](#) that continues working regardless of the status of other nodes. Use this option in two-node cluster configurations only.

Important

To avoid split-brain problems, do not use the major node together with a referee in the same cluster.

F.31.3.3.1. Setting up a Standalone Referee Node

A *referee* is a voting node used to determine which subset of nodes has a quorum if the cluster is split into equal parts. The referee node does not store any cluster data, so it is not resource-intensive and can be configured on virtually any system with Postgres Pro Enterprise installed.

To set up a referee for your cluster:

1. Install Postgres Pro Enterprise on the node you are going to make a referee and create the `referee` extension:

```
CREATE EXTENSION referee;
```

2. Make sure the `pg_hba.conf` file allows access to the referee node.

3. On all your cluster nodes, specify the referee connection string in the `postgresql.conf` file:

```
multimaster.referee_connstring = connstring
```

where `connstring` holds [libpq options](#) required to access the referee.

The first subset of nodes that gets connected to the referee wins the voting and continues working. The referee keeps the voting result until all the other cluster nodes get online again. Then the result is discarded, and a new winner can be chosen in case of another network failure.

To avoid split-brain problems, you can only have a single referee in your cluster. Do not set up a referee if you have already [configured the major node](#).

F.31.3.3.2. Configuring the Major Node

If you configure one of the nodes to be the major one, this node will continue accepting queries even if it is isolated by a network failure, or other nodes get broken. This setting is useful in a two-node cluster configuration, or to quickly restore a single node in a broken cluster.

Important

If your cluster has more than two nodes, promoting one of the nodes to the major status can lead to split-brain problems in case of network failures, and reduce the number of possible failover options. Consider [setting up a standalone referee](#) instead.

To make one of the nodes major, enable the `multimaster.major_node` parameter on this node:

```
ALTER SYSTEM SET multimaster.major_node TO on
SELECT pg_reload_conf();
```

Do not set the `major_node` parameter on more than one cluster node. When enabled on several nodes, it can cause the split-brain problem. If you have already set up a referee for your cluster, the `major_node` option is forbidden.

F.31.4. Multi-Master Cluster Administration

- [Monitoring the Cluster Status](#)
- [Adding New Nodes to the Cluster](#)
- [Removing Nodes from the Cluster](#)
- [Restoring a Cluster Node](#)

F.31.4.1. Monitoring Cluster Status

`multimaster` provides several views to check the current cluster state.

To check node-specific information, use `mtm.get_nodes_state()`:

```
SELECT mtm.get_nodes_state();
```

To check the status of the whole cluster, use the `mtm.get_cluster_state()` view:

```
SELECT mtm.get_cluster_state();
```

For details on all the returned information, see [Section F.31.5.2](#).

F.31.4.2. Adding New Nodes to the Cluster

With the `multimaster` extension, you can add or drop cluster nodes without stopping the database service.

To add a new node, you need to change the cluster configuration on alive nodes, load all the data to the new node using `pg_basebackup`, and start the node.

Suppose we have a working cluster of three nodes, with `node1`, `node2`, and `node3` domain names. To add `node4`, follow these steps:

1. Check whether the current number of cluster nodes has reached the value specified in the `multimaster.max_nodes` variable. If this value is reached, increase the `multimaster.max_nodes` value on each node and restart all nodes. You can restart the nodes one by one, without stopping the database. If the maximum number of nodes is not reached, proceed to the next step.
2. Figure out the required connection string to access the new node. For example, for the database `mydb`, user `myuser`, and the new node `node4`, the connection string can be "`dbname=mydb user=myuser host=node4`". For details, see [multimaster.conn_strings](#).
3. In `psql` connected to any alive node, run:

```
SELECT mtm.add_node('dbname=mydb user=myuser host=node4');
```

This command changes the cluster configuration on all nodes and starts replication slots for the new node.

4. Connect to the new node and clone all the data from one of the alive nodes to the new node:

```
pg_basebackup -D datadir -h node1 -x
```

`pg_basebackup` copies the entire data directory from `node1`, together with configuration settings.

5. Update `postgresql.conf` settings on `node4`:

```
multimaster.node_id = 4
multimaster.conn_strings = 'dbname=mydb user=myuser host=node1,
                             dbname=mydb user=myuser host=node2,
                             dbname=mydb user=myuser host=node3,
                             dbname=mydb user=myuser host=node4'
```

6. Start Postgres Pro on the new node:

```
pg_ctl -D datadir -l pg.log start
```

When the node gets synchronized up to the minimum recovery lag, all the cluster nodes get locked for write transactions until the new node retrieves all the updates. When data recovery is complete, `multimaster` promotes the new node to the online state and includes it into the replication scheme.

To ensure that the new configuration is loaded in the case of PostgreSQL restart, update configuration settings on all the cluster nodes:

1. Change `multimaster.conn_strings` to include the new node.

2. Make sure the `pg_hba.conf` file allows replication to the new node.

See Also

[Setting up a Multi-Master Cluster](#)

[Monitoring Cluster Status](#)

F.31.4.3. Removing Nodes from the Cluster

`multimaster` provides the `mtm.stop_node()` function that can temporarily or permanently remove nodes from the cluster.

To temporarily exclude a node from the cluster, run the `mtm.stop_node()` function specifying the node ID. For example, to exclude node 3, run the following command on any other node of the cluster:

```
SELECT mtm.stop_node(3);
```

This command excludes node 3 from the cluster and stops replication to this node.

While the WAL lag between the node and the current cluster state is less than the `multimaster.max_recovery_lag` value, you can restore the node by running the following command:

```
SELECT mtm.recover_node(3);
```

Otherwise, follow the procedure described in [Section F.31.4.4](#).

Note

If you simply shut down a node, it will be excluded from the cluster as well. However, all transactions in the cluster will be frozen until other nodes detect the offline state of the node. This time interval is defined by the `multimaster.heartbeat_recv_timeout` parameter.

To permanently drop the node from the cluster:

1. Run the `mtm.stop_node()` function with the `drop_slot` parameter set to `true`:

```
SELECT mtm.stop_node(3, true);
```

This disables replication slots for node 3 on all cluster nodes and stops replication to this node.

2. Adjust `multimaster.node_id` and `multimaster.conn_strings` settings in `postgresql.conf` on the remaining cluster nodes to reflect the new state of the cluster.

3. Edit the `pg_hba.conf` file on the remaining cluster nodes to disable replication to the removed node, if required.

If you would like to return the node to the cluster later, you will have to add it as a new node, as explained in [Section F.31.4.2](#).

F.31.4.4. Restoring a Cluster Node Manually

The `multimaster` extension can [automatically restore](#) a failed node if the WAL is available for the time when the node was disconnected from the cluster. However, if the data updates on the alive nodes exceed the allowed WAL size specified in the `multimaster.max_recovery_lag` variable, automatic recovery is impossible. In this case, you can manually restore the failed node.

Suppose `node2` got disconnected from your three-node cluster and needs to be manually restored. The typical workflow is as follows:

1. In `psql` connected to any alive node, create a new replication slot for the disconnected node with the following command:

```
SELECT mtm.recover_node(2);
```

where 2 is the ID of the disconnected node specified in the `multimaster.node_id` variable.

2. Connect to `node2` and clone all the data from one of the alive nodes:

```
pg_basebackup -D datadir -h node1 -x
```

`pg_basebackup` copies the entire data directory from `node1`, together with configuration settings.

3. On the restored node, update the `multimaster.node_id` setting to the value this node used to have before the failure.
4. Make sure replication is enabled between the restored node and the rest of the cluster.
5. Start Postgres Pro on the restored node:

```
pg_ctl -D datadir -l pg.log start
```

When the node gets synchronized up to the minimum recovery lag, all the cluster nodes get locked for write transactions until the restored node retrieves all the updates. When data recovery is complete, `multimaster` promotes the new node to the online state and includes it into the replication scheme.

See Also

[Failure Detection and Recovery](#)

F.31.5. Reference

F.31.5.1. GUC Variables

`multimaster.node_id`

Node ID — a unique natural number identifying the node of a multi-master cluster. You must start node numbering from 1. There must be no gaps in numbering. For example, for a cluster of five nodes, set node IDs to 1, 2, 3, 4, and 5.

`multimaster.conn_strings`

Connection strings for each node of a multi-master cluster, separated by commas. The `multimaster.conn_strings` parameter must be identical on all nodes. Each connection string must include the name of the database to replicate and the cluster node domain name. For example, `'dbname=mydb host=node1,dbname=mydb host=node2,dbname=mydb host=node3'`. Optionally, you can add other [connection parameters](#) to change the default connection settings. Connection strings must appear in the order of the node IDs specified in the `multimaster.node_id` variable. Connection string for the *i*-th node must be on the *i*-th position. If you specify a custom port in the `multimaster.arbiter_port`, you must provide this value in the `arbiter_port` parameter in the connection string for the corresponding node.

`multimaster.max_nodes`

The maximum number of nodes allowed in the cluster. If you plan to add new nodes to your cluster, the `multimaster.max_nodes` value should exceed the initial number of nodes. In this case, you can add new nodes without restarting Postgres Pro Enterprise until the specified number of nodes is reached. In most cases, three cluster nodes are enough to ensure high availability. Since the data on all cluster nodes is the same, you do not typically need more than five cluster nodes. The maximum possible number of nodes is limited to 64.

Default: the number of nodes specified in the `multimaster.conn_strings` variable

`multimaster.arbiter_port`

Port for the arbiter process to listen on. If you change the default value, you must specify this value in the `arbiter_port` parameter in the connection string for the corresponding node.

Default: 5433

`multimaster.heartbeat_send_timeout`

Time interval between heartbeat messages, in milliseconds. An arbiter process broadcasts heartbeat messages to all nodes to detect connection problems.

Default: 200

`multimaster.heartbeat_recv_timeout`

Timeout, in milliseconds. If no heartbeat message is received from the node within this timeframe, the node is excluded from the cluster.

Default: 1000

`multimaster.min_recovery_lag`

Minimal WAL lag between the node to be restored and the current cluster state, in kB. When this threshold is reached during node recovery, the cluster is locked for write transactions until the recovery is complete.

Default: 10KB

`multimaster.max_recovery_lag`

Maximal WAL lag size, in kB. When a node is disconnected from the cluster, other nodes copy WAL data for all new transactions into the replication slot of this node. Upon reaching the `multimaster.max_recovery_lag` value, the replication slot for the disconnected node is dropped to avoid overflow. At this point, automatic recovery of the node is no longer possible. In this case, you can restore the node manually by cloning the data from one of the alive nodes using `pg_basebackup` or a similar tool. If you set this variable to zero, replication slot will not be dropped.

Default: 1GB

`multimaster.ignore_tables_without_pk`

Boolean. This variable enables/disables replication of `INSERT` operations for tables without primary keys. By default, such replication is enabled. Setting this parameter to `on` disables replication of `INSERT` operations for these tables. Regardless of this setting, DDL operations on tables without primary keys are always replicated, while `UPDATE` and `DELETE` operations are not replicated because of the logical replication restrictions.

Default: `off`

`multimaster.cluster_name`

Name of the cluster. If you define this variable when setting up the cluster, `multimaster` checks that the cluster name is the same for all the cluster nodes.

`multimaster.break_connection`

Break connection with clients connected to the node if this node disconnects from the cluster. If this variable is set to `false`, the client stays connected to the node but receives an error that the node is in minority.

Default: `false`

`multimaster.major_node`

The node with this flag continues working even if there is no quorum. This may be required to break the symmetry in two-node clusters, or to quickly restore a single node in a broken cluster.

Important

This parameter should be used with caution to avoid split-brain problems:

- Do not use the *major_node* parameter on clusters with more than two nodes. If the major node gets isolated by a network failure while the majority of nodes are connected to each other, both the major node and the subset that has a quorum will continue working. Consider setting up a standalone referee instead.
- Never set more than one major node in the cluster.

`multimaster.referee_connstring`

Connection string to access the referee node. You must set this parameter on all cluster nodes if the referee is set up.

`multimaster.max_workers`

The maximum number of `walreceiver` workers on this server.

Important

This parameter should be used with caution. If the number of simultaneous transactions in the whole cluster is bigger than the provided value, it can lead to undetected deadlocks.

`multimaster.trans_spill_threshold`

The maximal size of transaction, in kB. When this threshold is reached, the transaction is written to the disk.

Default: 100MB

`multimaster.monotonic_sequences`

Defines the sequence generation mode for unique identifiers. This variable can take the following values:

- `false` (default) — ID generation on each node is started with this node number and is incremented by the number of nodes. For example, in a three-node cluster, 1, 4, and 7 IDs are allocated to the objects written onto the first node, while 2, 5, and 8 IDs are reserved for the second node. If you change the number of nodes in the cluster, the incrementation interval for new IDs is adjusted accordingly.
- `true` — the generated sequence increases monotonically cluster-wide. ID generation on each node is started with this node number and is incremented by the number of nodes, but the values are omitted if they are smaller than the already generated IDs on another node. For example, in a three-node cluster, if 1, 4 and 7 IDs are already allocated to the objects on the first node, 2 and 5 IDs will be omitted on the second node. In this case, the first ID on the second node is 8. Thus, the next generated ID is always higher than the previous one, regardless of the cluster node.

Default: `false`

`multimaster.remote_functions`

Provides a comma-separated list of function names that should be executed remotely on all multimaster nodes instead of replicating the result of their work.

F.31.5.2. Functions

`mtm.get_nodes_state()`

Shows the status of all nodes in the cluster. Returns a tuple of the following values:

- `id`, integer

Node ID.

- *enabled*, boolean

Shows whether the node is excluded from the cluster. The node can only be disabled if responses to heartbeats are not received within the `heartbeat_recv_timeout` time interval. When the node starts responding to heartbeats, `multimaster` can automatically restore the node and switch it back to the enabled state. Automatic recovery is only possible if the replication slot is still active. Otherwise, you can [restore the node manually](#).

- *connected*, boolean

Shows whether the node is connected to the WAL sender.

- *slot_active*, boolean

Shows whether the node has an active replication slot. For a disabled node, the slot remains active until the `max_recovery_lag` value is reached.

- *stopped*, boolean

Shows whether replication to this node was stopped by the `mtm.stop_node()` function. A stopped node acts as a disabled one, but cannot be automatically recovered. Call `mtm.recover_node()` to re-enable such a node.

- *catchUp*, boolean

During the node recovery, shows whether the data is recovered up to the `min_recovery_lag` value.

- *slotLag*, bigint

The size of WAL data that the replication slot holds for a disabled/stopped node. The slot is dropped when `slotLag` reaches the `max_recovery_lag` value.

- *avgTransDelay*, bigint

An average commit delay caused by this node, in microseconds.

- *lastStatusChange*, timestamp

Last time when the node changed its status (enabled/disabled).

- *oldestSnapshot*, bigint

The oldest global snapshot existing on this node.

- *SenderId*, integer

Process ID of the WAL sender.

- *SenderStartTime*, timestamp

WAL sender start time.

- *ReceiverPid*, integer

Process ID of the WAL receiver.

- *ReceiverStartTime*, timestamp

WAL receiver start time.

- *connStr*, text

Connection string to this node.

- *connectivityMask*, bigint

Bitmask representing connectivity to neighbor nodes. Each bit represents a connection to node.

- *nHeartbeats*, integer

The number of heartbeat responses received from this node.

`mtm.collect_cluster_info()`

Collects the data returned by the `mtm.get_cluster_state()` function from all available nodes. For this function to work, in addition to replication connections, `pg_hba.conf` must allow ordinary connections to the node with the specified connection string.

`mtm.get_cluster_state()`

Shows the status of the `multimaster` extension. Returns a tuple of the following values:

- *id*, integer

Node ID.

- *status*, text

Node status. Possible values are: Initialization, Offline, Connected, Online, Recovery, Recovered, InMinor, OutOfService.

- *disabledNodeMask*, bigint

Bitmask of disabled nodes.

- *disconnectedNodeMask*, bigint

Bitmask of disconnected nodes.

- *catchUpNodeMask*, bigint

Bitmask of nodes that completed the recovery.

- *liveNodes*, integer

Number of enabled nodes.

- *allNodes*, integer

Number of nodes in the cluster. The majority of alive nodes is calculated based on this parameter.

- *nActiveQueries*, integer

Number of queries being currently processed on this node.

- *nPendingQueries*, integer

Number of queries waiting for execution on this node.

- *queueSize*, bigint

Size of the pending query queue, in bytes.

- *transCount*, bigint

The total number of replicated transactions processed by this node.

- *timeShift*, bigint

Global snapshot shift caused by unsynchronized clocks on nodes, in microseconds.

- *recoverySlot*, integer

The node from which a failed node gets data updates during automatic recovery.

- *xidHashSize*, bigint

Size of xid2state hash.

- *gidHashSize*, bigint

Size of gid2state hash.

- *oldestXid*, bigint

The oldest transaction ID on this node.

- *configChanges*, integer

Number of state changes (enabled/disabled) since the last reboot.

- *stalledNodeMask*, bigint

Bitmask of nodes for which replication slots were dropped.

- *stoppedNodeMask*, bigint

Bitmask of nodes that were stopped by `mtm.stop_node()`.

- *lastStatusChange*, timestamp

Timestamp of the last state change.

`mtm.add_node(connstr text)`

Adds a new node to the cluster.

Arguments:

- *connstr* — connection string for the new node. For example, for the database `mydb`, user `myuser`, and the new node `node4`, the connection string is `"dbname=mydb user=myuser host=node4"`.

Type: text

`mtm.alter_sequences()`

Fixes unique identifiers on all cluster nodes. This may be required after restoring all nodes from a single base backup.

`mtm.stop_node(node integer, drop_slot bool default false)`

Excludes a node from the cluster.

Arguments:

- *node* — ID of the node to be dropped that you specified in the `multimaster.node_id` variable.

Type: integer

- *drop_slot* — Optional. Defines whether the replication slot should be dropped together with the node. Set this option to `true` if you do not plan to restore the node in the future.

Type: boolean

Default: false

```
mtm.recover_node(node integer)
```

Creates a replication slot for the node that was previously dropped together with its slot.

Arguments:

- *node* — ID of the node to be restored.

```
mtm.make_table_local('table_name' regclass)
```

Stops replication for the specified table.

Arguments:

- *table_name* — the table you would like to exclude from the replication scheme.

Type: `regclass`

```
mtm.copy_table(table_name regclass, node_id integer)
```

Copies the specified table to another node. You can use this function to restore the corrupted data on one or more nodes of the cluster. This function must be called on the node from which the table is copied.

Arguments:

- *table_name* — the table you would like to copy.

Type: `regclass`

- *node_id* — the node to copy the table to.

Type: `integer`

```
mtm.broadcast_table(table_name regclass)
```

Copies the specified table to all the alive nodes of the cluster. You can use this function to restore the corrupted data. This function must be called on the node from which the table is copied.

Arguments:

- *table_name* — the table you would like to copy.

Type: `regclass`

F.31.6. Compatibility

The `multimaster` extension currently passes almost all PostgreSQL regression tests, except for a few tests for edge cases related to working with temporary tables and updating `enum`, which are not always transactional in PostgreSQL. We are working right now on providing full compatibility with the standard PostgreSQL.

F.31.7. Authors

Postgres Professional, Moscow, Russia.

F.31.7.1. Credits

The replication mechanism is based on logical decoding and an earlier version of the `pglogical` extension provided for community by the 2ndQuadrant team.

The three-phase E3PC commit protocol is based on the following works:

- Idit Keidar, Danny Dolev. *Increasing the Resilience of Distributed and Replicated Database Systems*.
- Tim Kempster, Colin Stirling, Peter Thanisch. *A More Committed Quorum-Based Three Phase Commit Protocol*.

F.32. online_analyze

The `online_analyze` module provides a set of features that immediately update statistics after `INSERT`, `UPDATE`, `DELETE`, or `SELECT INTO` operations for the affected tables.

Note

This extension cannot be used together with autonomous transactions.

F.32.1. Module Loading

To use `online_analyze` module, load the shared library:

```
LOAD 'online_analyze';
```

F.32.2. Module Configuration

You can configure `online_analyze` using the following custom variables (default values are shown):

- `online_analyze.enable = on`

Enables `online_analyze`.

- `online_analyze.verbose = on`

Executes `ANALYZE VERBOSE`.

Note

Since `verbose` is a reserved SQL key word, this parameter has to be double-quoted when used in SQL queries. For example:

```
ALTER SYSTEM SET "online_analyze.verbose" = 'off';
```

- `online_analyze.scale_factor = 0.1`

Fraction of table size to start online analysis (similar to [autovacuum_analyze_scale_factor](#)).

- `online_analyze.threshold = 50`

Minimum number of row updates before starting online analysis (similar to [autovacuum_analyze_threshold](#)).

- `online_analyze.min_interval = 10000`

Minimum time interval between `ANALYZE` calls per table, in milliseconds.

- `online_analyze.table_type = "all"`

Type(s) of tables for online analysis. Possible values are: `all`, `persistent`, `temporary`, `none`.

- `online_analyze.exclude_tables = ""`

List of tables to exclude from online analysis.

- `online_analyze.include_tables = ""`

List of tables to include in online analysis (`online_analyze.include_tables` overrides `online_analyze.exclude_tables`).

- `online_analyze.local_tracking = off`

Enables per-backend tracking for temporary tables by `online_analyze`. When this variable is set to `off`, `online_analyze` uses the default system statistics for temporary tables.

- `online_analyze.lower_limit = 0`

Minimum number of rows in a table required to trigger `online_analyze`.

- `online_analyze.capacity_threshold = 100000`

Maximum number of temporary tables to store in local cache.

F.32.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

F.33. pageinspect

The `pageinspect` module provides functions that allow you to inspect the contents of database pages at a low level, which is useful for debugging purposes. All of these functions may be used only by superusers.

F.33.1. Functions

`get_raw_page(relname text, fork text, blkno int)` returns `bytea`

`get_raw_page` reads the specified block of the named relation and returns a copy as a `bytea` value. This allows a single time-consistent copy of the block to be obtained. `fork` should be 'main' for the main data fork, 'fsm' for the free space map, 'vm' for the visibility map, or 'init' for the initialization fork.

`get_raw_page(relname text, blkno int)` returns `bytea`

A shorthand version of `get_raw_page`, for reading from the main fork. Equivalent to `get_raw_page(relname, 'main', blkno)`

`page_header(page bytea)` returns `record`

`page_header` shows fields that are common to all Postgres Pro heap and index pages.

A page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM page_header(get_raw_page('pg_class', 0));
   lsn      | checksum | flags  | lower | upper | special | pagesize | version |
   xid_base | multi_base | prune_xid
-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+
0/24A1B50 |          | 1 | 1 | 232 | 368 | 8192 | 8192 | 4 |
0 | 0 | 0
```

The returned columns correspond to the fields in the `PageHeaderData` struct. See `src/include/storage/bufpage.h` for details.

`heap_page_items(page bytea)` returns `setof record`

`heap_page_items` shows all line pointers on a heap page. For those line pointers that are in use, tuple headers as well as tuple raw data are also shown. All tuples are shown, whether or not the tuples were visible to an MVCC snapshot at the time the raw page was copied.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_items(get_raw_page('pg_class', 0));
```

See `src/include/storage/itemid.h` and `src/include/access/htup_details.h` for explanations of the fields returned.

`tuple_data_split(rel_oid oid, t_data bytea, t_infomask integer, t_infomask2 integer, t_bits text [, do_detoast bool])` returns `bytea[]`

`tuple_data_split` splits tuple data into attributes in the same way as backend internals.

```
test=# SELECT tuple_data_split('pg_class'::regclass, t_data, t_infomask,
    t_infomask2, t_bits) FROM heap_page_items(get_raw_page('pg_class', 0));
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

If `do_detoast` is true, attribute that will be detoasted as needed. Default value is false.

`heap_page_item_attrs(page bytea, rel_oid regclass [, do_detoast bool])` returns set of record

`heap_page_item_attrs` is equivalent to `heap_page_items` except that it returns tuple raw data as an array of attributes that can optionally be detoasted by `do_detoast` which is false by default.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_item_attrs(get_raw_page('pg_class', 0),
    'pg_class'::regclass);
```

`bt_metap(relname text)` returns record

`bt_metap` returns information about a B-tree index's metapage. For example:

```
test=# SELECT * FROM bt_metap('pg_cast_oid_index');
-[ RECORD 1 ]-----
magic      | 340322
version    | 2
root       | 1
level      | 0
fastroot   | 1
fastlevel  | 0
```

`bt_page_stats(relname text, blkno int)` returns record

`bt_page_stats` returns summary information about single pages of B-tree indexes. For example:

```
test=# SELECT * FROM bt_page_stats('pg_cast_oid_index', 1);
-[ RECORD 1 ]+-----
blkno      | 1
type       | 1
live_items | 256
dead_items | 0
avg_item_size | 12
page_size  | 8192
free_size  | 4056
btpo_prev  | 0
btpo_next  | 0
btpo       | 0
btpo_flags | 3
```

`bt_page_items(relname text, blkno int)` returns set of record

`bt_page_items` returns detailed information about all of the items on a B-tree index page. For example:

```
test=# SELECT * FROM bt_page_items('pg_cast_oid_index', 1);
 itemoffset |  ctid   | itemlen | nulls | vars |      data
-----+-----+-----+-----+-----+-----
          1 | (0,1)   |      12 | f     | f    | 23 27 00 00
          2 | (0,2)   |      12 | f     | f    | 24 27 00 00
          3 | (0,3)   |      12 | f     | f    | 25 27 00 00
          4 | (0,4)   |      12 | f     | f    | 26 27 00 00
          5 | (0,5)   |      12 | f     | f    | 27 27 00 00
          6 | (0,6)   |      12 | f     | f    | 28 27 00 00
          7 | (0,7)   |      12 | f     | f    | 29 27 00 00
          8 | (0,8)   |      12 | f     | f    | 2a 27 00 00
```

In a B-tree leaf page, `ctid` points to a heap tuple. In an internal page, the block number part of `ctid` points to another page in the index itself, while the offset part (the second number) is ignored and is usually 1.

Note that the first item on any non-rightmost page (any page with a non-zero value in the `btpo_next` field) is the page's “high key”, meaning its `data` serves as an upper bound on all items appearing on the page, while its `ctid` field is meaningless. Also, on non-leaf pages, the first real data item (the first item that is not a high key) is a “minus infinity” item, with no actual value in its `data` field. Such an item does have a valid downlink in its `ctid` field, however.

`brin_page_type(page bytea)` returns text

`brin_page_type` returns the page type of the given BRIN index page, or throws an error if the page is not a valid BRIN page. For example:

```
test=# SELECT brin_page_type(get_raw_page('brinidx', 0));
 brin_page_type
-----
 meta
```

`brin_metapage_info(page bytea)` returns record

`brin_metapage_info` returns assorted information about a BRIN index metapage. For example:

```
test=# SELECT * FROM brin_metapage_info(get_raw_page('brinidx', 0));
 magic | version | pagesperpage | lastrevmappage
-----+-----+-----+-----
0xA8109CFA |      1 |           4 |           2
```

`brin_revmap_data(page bytea)` returns setof tid

`brin_revmap_data` returns the list of tuple identifiers in a BRIN index range map page. For example:

```
test=# SELECT * FROM brin_revmap_data(get_raw_page('brinidx', 2)) limit 5;
 pages
-----
(6,137)
(6,138)
(6,139)
(6,140)
(6,141)
```

`brin_page_items(page bytea, index oid)` returns setof record

`brin_page_items` returns the data stored in the BRIN data page. For example:

```
test=# SELECT * FROM brin_page_items(get_raw_page('brinidx', 5),
                                     'brinidx')
      ORDER BY blknum, attnum LIMIT 6;
 itemoffset | blknum | attnum | allnulls | hasnulls | placeholder | value
```

137		0		1		t	f f
137		0		2		f	f f {1 .. 88}
138		4		1		t	f f
138		4		2		f	f f {89 .. 176}
139		8		1		t	f f
139		8		2		f	f f {177 .. 264}

The returned columns correspond to the fields in the `BrinMemTuple` and `BrinValues` structs. See `src/include/access/brin_tuple.h` for details.

`gin_metapage_info(page bytea)` returns record

`gin_metapage_info` returns information about a GIN index metapage. For example:

```
test=# SELECT * FROM gin_metapage_info(get_raw_page('gin_index', 0));
-[ RECORD 1 ]-----+-----
pending_head      | 4294967295
pending_tail      | 4294967295
tail_free_size    | 0
n_pending_pages   | 0
n_pending_tuples  | 0
n_total_pages     | 7
n_entry_pages     | 6
n_data_pages      | 0
n_entries         | 693
version          | 2
```

`gin_page_opaque_info(page bytea)` returns record

`gin_page_opaque_info` returns information about a GIN index opaque area, like the page type. For example:

```
test=# SELECT * FROM gin_page_opaque_info(get_raw_page('gin_index', 2));
 rightlink | maxoff |          flags
-----+-----+-----
          5 |        0 | {data,leaf,compressed}
(1 row)
```

`gin_leafpage_items(page bytea)` returns setof record

`gin_leafpage_items` returns information about the data stored in a GIN leaf page. For example:

```
test=# SELECT first_tid, nbytes, tids[0:5] as some_tids
       FROM gin_leafpage_items(get_raw_page('gin_test_idx', 2));
 first_tid | nbytes |          some_tids
-----+-----+-----
(8,41)    |    244 | {"(8,41)","(8,43)","(8,44)","(8,45)","(8,46)"}
(10,45)   |    248 | {"(10,45)","(10,46)","(10,47)","(10,48)","(10,49)"}
(12,52)   |    248 | {"(12,52)","(12,53)","(12,54)","(12,55)","(12,56)"}
(14,59)   |    320 | {"(14,59)","(14,60)","(14,61)","(14,62)","(14,63)"}
(167,16)  |    376 | {"(167,16)","(167,17)","(167,18)","(167,19)","(167,20)"}
(170,30)  |    376 | {"(170,30)","(170,31)","(170,32)","(170,33)","(170,34)"}
(173,44)  |    197 | {"(173,44)","(173,45)","(173,46)","(173,47)","(173,48)"}
(7 rows)
```

`fsm_page_contents(page bytea)` returns text

`fsm_page_contents` shows the internal node structure of a FSM page. The output is a multiline string, with one line per node in the binary tree within the page. Only those nodes that are not zero are printed. The so-called "next" pointer, which points to the next slot to be returned from the page, is also printed.

F.34. passwordcheck

The `passwordcheck` module checks users' passwords whenever they are set with [CREATE ROLE](#) or [ALTER ROLE](#). If a password is considered too weak, it will be rejected and the command will terminate with an error.

To enable this module, add '`$libdir/passwordcheck`' to [shared_preload_libraries](#) in `postgresql.conf`, then restart the server.

Caution

To prevent unencrypted passwords from being sent across the network, written to the server log or otherwise stolen by a database administrator, Postgres Pro allows the user to supply pre-encrypted passwords. Many client programs make use of this functionality and encrypt the password before sending it to the server.

This limits the usefulness of the `passwordcheck` module, because in that case it can only try to guess the password. For this reason, `passwordcheck` is not recommended if your security requirements are high. It is more secure to use an external authentication method such as GSSAPI (see [Chapter 20](#)) than to rely on passwords within the database.

F.35. pg_buffercache

The `pg_buffercache` module provides a means for examining what's happening in the shared buffer cache in real time.

The module provides a C function `pg_buffercache_pages` that returns a set of records, plus a view `pg_buffercache` that wraps the function for convenient use.

By default public access is revoked from both of these, just in case there are security issues lurking.

F.35.1. The pg_buffercache View

The definitions of the columns exposed by the view are shown in [Table F.21](#).

Table F.21. pg_buffercache Columns

Name	Type	References	Description
<code>bufferid</code>	<code>integer</code>		ID, in the range 1.. <code>shared_buffers</code>
<code>relfilenode</code>	<code>oid</code>	<code>pg_class.relfilenode</code>	Filenode number of the relation
<code>reltablespace</code>	<code>oid</code>	<code>pg_tablespace.oid</code>	Tablespace OID of the relation
<code>reldatabase</code>	<code>oid</code>	<code>pg_database.oid</code>	Database OID of the relation
<code>relforknumber</code>	<code>smallint</code>		Fork number within the relation; see <code>include/common/relpath.h</code>
<code>relblocknumber</code>	<code>bigint</code>		Page number within the relation
<code>isdirty</code>	<code>boolean</code>		Is the page dirty?
<code>usagecount</code>	<code>smallint</code>		Clock-sweep access count

Name	Type	References	Description
pinning_backends	integer		Number of backends pinning this buffer

There is one row for each buffer in the shared cache. Unused buffers are shown with all fields null except `bufferid`. Shared system catalogs are shown as belonging to database zero.

Because the cache is shared by all the databases, there will normally be pages from relations not belonging to the current database. This means that there may not be matching join rows in `pg_class` for some rows, or that there could even be incorrect joins. If you are trying to join against `pg_class`, it's a good idea to restrict the join to rows having `reldatabase` equal to the current database's OID or zero.

When the `pg_buffercache` view is accessed, internal buffer manager locks are taken for long enough to copy all the buffer state data that the view will display. This ensures that the view produces a consistent set of results, while not blocking normal buffer activity longer than necessary. Nonetheless there could be some impact on database performance if this view is read often.

F.35.2. Sample Output

```
regression=# SELECT n.nspname, c.relname, count(*) AS buffers
              FROM pg_buffercache b JOIN pg_class c
              ON b.relfilenode = pg_relation_filenode(c.oid) AND
                 b.reldatabase IN (0, (SELECT oid FROM pg_database
                                     WHERE datname = current_database()))
              JOIN pg_namespace n ON n.oid = c.relnamespace
              GROUP BY n.nspname, c.relname
              ORDER BY 3 DESC
              LIMIT 10;
```

nspname	relname	buffers
public	delete_test_table	593
public	delete_test_table_pkey	494
pg_catalog	pg_attribute	472
public	quad_poly_tbl	353
public	tenk2	349
public	tenk1	349
public	gin_test_idx	306
pg_catalog	pg_largeobject	206
public	gin_test_tbl	188
public	spgist_text_tbl	182

Debugging advice: Tom Lane <tgl@sss.pgh.pa.us>

F.36. pgcrypto

The `pgcrypto` module provides cryptographic functions for Postgres Pro.

F.36.1. General Hashing Functions

F.36.1.1. `digest()`

`digest(data text, type text)` returns `bytea`
`digest(data bytea, type text)` returns `bytea`

Computes a binary hash of the given *data*. *type* is the algorithm to use. Standard algorithms are `md5`, `sha1`, `sha224`, `sha256`, `sha384` and `sha512`. If `pgcrypto` was built with OpenSSL, more algorithms are available, as detailed in [Table F.25](#).

If you want the digest as a hexadecimal string, use `encode()` on the result. For example:

```
CREATE OR REPLACE FUNCTION sha1(bytea) returns text AS $$  
    SELECT encode(digest($1, 'sha1'), 'hex')  
$$ LANGUAGE SQL STRICT IMMUTABLE;
```

F.36.1.2. `hmac()`

`hmac(data text, key text, type text)` returns `bytea`
`hmac(data bytea, key bytea, type text)` returns `bytea`

Calculates hashed MAC for *data* with key *key*. *type* is the same as in `digest()`.

This is similar to `digest()` but the hash can only be recalculated knowing the key. This prevents the scenario of someone altering data and also changing the hash to match.

If the key is larger than the hash block size it will first be hashed and the result will be used as key.

F.36.2. Password Hashing Functions

The functions `crypt()` and `gen_salt()` are specifically designed for hashing passwords. `crypt()` does the hashing and `gen_salt()` prepares algorithm parameters for it.

The algorithms in `crypt()` differ from the usual MD5 or SHA1 hashing algorithms in the following respects:

1. They are slow. As the amount of data is so small, this is the only way to make brute-forcing passwords hard.
2. They use a random value, called the *salt*, so that users having the same password will have different encrypted passwords. This is also an additional defense against reversing the algorithm.
3. They include the algorithm type in the result, so passwords hashed with different algorithms can co-exist.
4. Some of them are adaptive — that means when computers get faster, you can tune the algorithm to be slower, without introducing incompatibility with existing passwords.

[Table F.22](#) lists the algorithms supported by the `crypt()` function.

Table F.22. Supported Algorithms for `crypt()`

Algorithm	Max Password Length	Adaptive?	Salt Bits	Output Length	Description
bf	72	yes	128	60	Blowfish-based, variant 2a
md5	unlimited	no	48	34	MD5-based crypt
xdes	8	yes	24	20	Extended DES
des	8	no	12	13	Original UNIX crypt

F.36.2.1. `crypt()`

`crypt(password text, salt text)` returns `text`

Calculates a crypt(3)-style hash of *password*. When storing a new password, you need to use `gen_salt()` to generate a new *salt* value. To check a password, pass the stored hash value as *salt*, and test whether the result matches the stored value.

Example of setting a new password:

```
UPDATE ... SET pswhash = crypt('new password', gen_salt('md5'));
```

Example of authentication:

```
SELECT (pswhash = crypt('entered password', pswhash)) AS pswmatch FROM ... ;
```

This returns `true` if the entered password is correct.

F.36.2.2. `gen_salt()`

`gen_salt(type text [, iter_count integer])` returns text

Generates a new random salt string for use in `crypt()`. The salt string also tells `crypt()` which algorithm to use.

The *type* parameter specifies the hashing algorithm. The accepted types are: `des`, `xdes`, `md5` and `bf`.

The *iter_count* parameter lets the user specify the iteration count, for algorithms that have one. The higher the count, the more time it takes to hash the password and therefore the more time to break it. Although with too high a count the time to calculate a hash may be several years — which is somewhat impractical. If the *iter_count* parameter is omitted, the default iteration count is used. Allowed values for *iter_count* depend on the algorithm and are shown in [Table F.23](#).

Table F.23. Iteration Counts for `crypt()`

Algorithm	Default	Min	Max
xdes	725	1	16777215
bf	6	4	31

For `xdes` there is an additional limitation that the iteration count must be an odd number.

To pick an appropriate iteration count, consider that the original DES crypt was designed to have the speed of 4 hashes per second on the hardware of that time. Slower than 4 hashes per second would probably dampen usability. Faster than 100 hashes per second is probably too fast.

[Table F.24](#) gives an overview of the relative slowness of different hashing algorithms. The table shows how much time it would take to try all combinations of characters in an 8-character password, assuming that the password contains either only lower case letters, or upper- and lower-case letters and numbers. In the `crypt-bf` entries, the number after a slash is the *iter_count* parameter of `gen_salt`.

Table F.24. Hash Algorithm Speeds

Algorithm	Hashes/sec	For [a-z]	For [A-Za-z0-9]	Duration relative to md5 hash
crypt-bf/8	1792	4 years	3927 years	100k
crypt-bf/7	3648	2 years	1929 years	50k
crypt-bf/6	7168	1 year	982 years	25k
crypt-bf/5	13504	188 days	521 years	12.5k
crypt-md5	171584	15 days	41 years	1k
crypt-des	23221568	157.5 minutes	108 days	7
sha1	37774272	90 minutes	68 days	4

Algorithm	Hashes/sec	For [a-z]	For [A-Za-z0-9]	Duration relative to md5 hash
md5 (hash)	150085504	22.5 minutes	17 days	1

Notes:

- The machine used is an Intel Mobile Core i3.
- `crypt-des` and `crypt-md5` algorithm numbers are taken from John the Ripper v1.6.38 `-test` output.
- `md5 hash` numbers are from `mdcrack 1.2`.
- `sha1` numbers are from `lcrack-20031130-beta`.
- `crypt-bf` numbers are taken using a simple program that loops over 1000 8-character passwords. That way I can show the speed with different numbers of iterations. For reference: `john -test` shows 13506 loops/sec for `crypt-bf/5`. (The very small difference in results is in accordance with the fact that the `crypt-bf` implementation in `pgcrypto` is the same one used in John the Ripper.)

Note that “try all combinations” is not a realistic exercise. Usually password cracking is done with the help of dictionaries, which contain both regular words and various mutations of them. So, even somewhat word-like passwords could be cracked much faster than the above numbers suggest, while a 6-character non-word-like password may escape cracking. Or not.

F.36.3. PGP Encryption Functions

The functions here implement the encryption part of the OpenPGP (RFC 4880) standard. Supported are both symmetric-key and public-key encryption.

An encrypted PGP message consists of 2 parts, or *packets*:

- Packet containing a session key — either symmetric-key or public-key encrypted.
- Packet containing data encrypted with the session key.

When encrypting with a symmetric key (i.e., a password):

1. The given password is hashed using a String2Key (S2K) algorithm. This is rather similar to `crypt()` algorithms — purposefully slow and with random salt — but it produces a full-length binary key.
2. If a separate session key is requested, a new random key will be generated. Otherwise the S2K key will be used directly as the session key.
3. If the S2K key is to be used directly, then only S2K settings will be put into the session key packet. Otherwise the session key will be encrypted with the S2K key and put into the session key packet.

When encrypting with a public key:

1. A new random session key is generated.
2. It is encrypted using the public key and put into the session key packet.

In either case the data to be encrypted is processed as follows:

1. Optional data-manipulation: compression, conversion to UTF-8, and/or conversion of line-endings.
2. The data is prefixed with a block of random bytes. This is equivalent to using a random IV.
3. An SHA1 hash of the random prefix and data is appended.
4. All this is encrypted with the session key and placed in the data packet.

F.36.3.1. `pgp_sym_encrypt()`

```
pgp_sym_encrypt(data text, psw text [, options text ]) returns bytea
pgp_sym_encrypt_bytea(data bytea, psw text [, options text ]) returns bytea
```

Encrypt *data* with a symmetric PGP key *psw*. The *options* parameter can contain option settings, as described below.

F.36.3.2. `pgp_sym_decrypt()`

```
pgp_sym_decrypt(msg bytea, psw text [, options text ]) returns text
pgp_sym_decrypt_bytea(msg bytea, psw text [, options text ]) returns bytea
```

Decrypt a symmetric-key-encrypted PGP message.

Decrypting *bytea* data with `pgp_sym_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_sym_decrypt_bytea` is fine.

The *options* parameter can contain option settings, as described below.

F.36.3.3. `pgp_pub_encrypt()`

```
pgp_pub_encrypt(data text, key bytea [, options text ]) returns bytea
pgp_pub_encrypt_bytea(data bytea, key bytea [, options text ]) returns bytea
```

Encrypt *data* with a public PGP key *key*. Giving this function a secret key will produce an error.

The *options* parameter can contain option settings, as described below.

F.36.3.4. `pgp_pub_decrypt()`

```
pgp_pub_decrypt(msg bytea, key bytea [, psw text [, options text ]]) returns text
pgp_pub_decrypt_bytea(msg bytea, key bytea [, psw text [, options text ]]) returns
bytea
```

Decrypt a public-key-encrypted message. *key* must be the secret key corresponding to the public key that was used to encrypt. If the secret key is password-protected, you must give the password in *psw*. If there is no password, but you want to specify options, you need to give an empty password.

Decrypting *bytea* data with `pgp_pub_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_pub_decrypt_bytea` is fine.

The *options* parameter can contain option settings, as described below.

F.36.3.5. `pgp_key_id()`

```
pgp_key_id(bytea) returns text
```

`pgp_key_id` extracts the key ID of a PGP public or secret key. Or it gives the key ID that was used for encrypting the data, if given an encrypted message.

It can return 2 special key IDs:

- SYMKEY

The message is encrypted with a symmetric key.

- ANYKEY

The message is public-key encrypted, but the key ID has been removed. That means you will need to try all your secret keys on it to see which one decrypts it. `pgcrypto` itself does not produce such messages.

Note that different keys may have the same ID. This is rare but a normal event. The client application should then try to decrypt with each one, to see which fits — like handling `ANYKEY`.

F.36.3.6. `armor()`, `dearmor()`

```
armor(data bytea [, keys text[], values text[] ]) returns text
```

`dearmor(data text)` returns `bytea`

These functions wrap/unwrap binary data into PGP ASCII-armor format, which is basically Base64 with CRC and additional formatting.

If the *keys* and *values* arrays are specified, an *armor header* is added to the armored format for each key/value pair. Both arrays must be single-dimensional, and they must be of the same length. The keys and values cannot contain any non-ASCII characters.

F.36.3.7. `pgp_armor_headers`

`pgp_armor_headers(data text, key out text, value out text)` returns `setof record`

`pgp_armor_headers()` extracts the armor headers from *data*. The return value is a set of rows with two columns, key and value. If the keys or values contain any non-ASCII characters, they are treated as UTF-8.

F.36.3.8. Options for PGP Functions

Options are named to be similar to GnuPG. An option's value should be given after an equal sign; separate options from each other with commas. For example:

```
pgp_sym_encrypt(data, psw, 'compress-algo=1, cipher-algo=aes256')
```

All of the options except `convert-crlf` apply only to encrypt functions. Decrypt functions get the parameters from the PGP data.

The most interesting options are probably `compress-algo` and `unicode-mode`. The rest should have reasonable defaults.

F.36.3.8.1. `cipher-algo`

Which cipher algorithm to use.

Values: `bf`, `aes128`, `aes192`, `aes256` (OpenSSL-only: `3des`, `cast5`)

Default: `aes128`

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

F.36.3.8.2. `compress-algo`

Which compression algorithm to use. Only available if Postgres Pro was built with `zlib`.

Values:

0 - no compression

1 - ZIP compression

2 - ZLIB compression (= ZIP plus meta-data and block CRCs)

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

F.36.3.8.3. `compress-level`

How much to compress. Higher levels compress smaller but are slower. 0 disables compression.

Values: 0, 1-9

Default: 6

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

F.36.3.8.4. `convert-crlf`

Whether to convert `\n` into `\r\n` when encrypting and `\r\n` to `\n` when decrypting. RFC 4880 specifies that text data should be stored using `\r\n` line-feeds. Use this to get fully RFC-compliant behavior.

Values: 0, 1

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`, `pgp_sym_decrypt`, `pgp_pub_decrypt`

F.36.3.8.5. disable-mdc

Do not protect data with SHA-1. The only good reason to use this option is to achieve compatibility with ancient PGP products, predating the addition of SHA-1 protected packets to RFC 4880. Recent gnupg.org and pgp.com software supports it fine.

Values: 0, 1

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

F.36.3.8.6. sess-key

Use separate session key. Public-key encryption always uses a separate session key; this option is for symmetric-key encryption, which by default uses the S2K key directly.

Values: 0, 1

Default: 0

Applies to: `pgp_sym_encrypt`

F.36.3.8.7. s2k-mode

Which S2K algorithm to use.

Values:

0 - Without salt. Dangerous!

1 - With salt but with fixed iteration count.

3 - Variable iteration count.

Default: 3

Applies to: `pgp_sym_encrypt`

F.36.3.8.8. s2k-count

The number of iterations of the S2K algorithm to use. It must be a value between 1024 and 65011712, inclusive.

Default: A random value between 65536 and 253952

Applies to: `pgp_sym_encrypt`, only with `s2k-mode=3`

F.36.3.8.9. s2k-digest-algo

Which digest algorithm to use in S2K calculation.

Values: md5, sha1

Default: sha1

Applies to: `pgp_sym_encrypt`

F.36.3.8.10. s2k-cipher-algo

Which cipher to use for encrypting separate session key.

Values: bf, aes, aes128, aes192, aes256

Default: use cipher-algo

Applies to: `pgp_sym_encrypt`

F.36.3.8.11. unicode-mode

Whether to convert textual data from database internal encoding to UTF-8 and back. If your database already is UTF-8, no conversion will be done, but the message will be tagged as UTF-8. Without this option it will not be.

Values: 0, 1

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

F.36.3.9. Generating PGP Keys with GnuPG

To generate a new key:

```
gpg --gen-key
```

The preferred key type is “DSA and Elgamal”.

For RSA encryption you must create either DSA or RSA sign-only key as master and then add an RSA encryption subkey with `gpg --edit-key`.

To list keys:

```
gpg --list-secret-keys
```

To export a public key in ASCII-armor format:

```
gpg -a --export KEYID > public.key
```

To export a secret key in ASCII-armor format:

```
gpg -a --export-secret-keys KEYID > secret.key
```

You need to use `dearmor()` on these keys before giving them to the PGP functions. Or if you can handle binary data, you can drop `-a` from the command.

For more details see `man gpg`, *The GNU Privacy Handbook* and other documentation on <http://www.gnupg.org>.

F.36.3.10. Limitations of PGP Code

- No support for signing. That also means that it is not checked whether the encryption subkey belongs to the master key.
- No support for encryption key as master key. As such practice is generally discouraged, this should not be a problem.
- No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with `pgcrypto`, but create new ones, as the usage scenario is rather different.

F.36.4. Raw Encryption Functions

These functions only run a cipher over data; they don't have any advanced features of PGP encryption. Therefore they have some major problems:

1. They use user key directly as cipher key.
2. They don't provide any integrity checking, to see if the encrypted data was modified.
3. They expect that users manage all encryption parameters themselves, even IV.
4. They don't handle text.

So, with the introduction of PGP encryption, usage of raw encryption functions is discouraged.

```
encrypt(data bytea, key bytea, type text) returns bytea  
decrypt(data bytea, key bytea, type text) returns bytea
```

```
encrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea  
decrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea
```

Encrypt/decrypt data using the cipher method specified by *type*. The syntax of the *type* string is:

```
algorithm [ - mode ] [ /pad: padding ]
```

where *algorithm* is one of:

- bf — Blowfish

- `aes` — AES (Rijndael-128, -192 or -256)

and `mode` is one of:

- `cbc` — next block depends on previous (default)
- `ecb` — each block is encrypted separately (for testing only)

and `padding` is one of:

- `pkcs` — data may be any length (default)
- `none` — data must be multiple of cipher block size

So, for example, these are equivalent:

```
encrypt(data, 'fooz', 'bf')
encrypt(data, 'fooz', 'bf-cbc/pad:pkcs')
```

In `encrypt_iv` and `decrypt_iv`, the `iv` parameter is the initial value for the CBC mode; it is ignored for ECB. It is clipped or padded with zeroes if not exactly block size. It defaults to all zeroes in the functions without this parameter.

F.36.5. Random-Data Functions

`gen_random_bytes(count integer)` returns `bytea`

Returns `count` cryptographically strong random bytes. At most 1024 bytes can be extracted at a time. This is to avoid draining the randomness generator pool.

`gen_random_uuid()` returns `uuid`

Returns a version 4 (random) UUID.

F.36.6. Notes

F.36.6.1. Configuration

`pgcrypto` configures itself according to the findings of the main Postgres Pro `configure` script. The options that affect it are `--with-zlib` and `--with-openssl`.

When compiled with `zlib`, PGP encryption functions are able to compress data before encrypting.

When compiled with `OpenSSL`, there will be more algorithms available. Also public-key encryption functions will be faster as `OpenSSL` has more optimized `BIGNUM` functions.

Table F.25. Summary of Functionality with and without OpenSSL

Functionality	Built-in	With OpenSSL
MD5	yes	yes
SHA1	yes	yes
SHA224/256/384/512	yes	yes (Note 1)
Other digest algorithms	no	yes (Note 2)
Blowfish	yes	yes
AES	yes	yes (Note 3)
DES/3DES/CAST5	no	yes
Raw encryption	yes	yes
PGP Symmetric encryption	yes	yes
PGP Public-Key encryption	yes	yes

Notes:

1. SHA2 algorithms were added to OpenSSL in version 0.9.8. For older versions, `pgcrypto` will use built-in code.
2. Any digest algorithm OpenSSL supports is automatically picked up. This is not possible with ciphers, which need to be supported explicitly.
3. AES is included in OpenSSL since version 0.9.7. For older versions, `pgcrypto` will use built-in code.

F.36.6.2. NULL Handling

As is standard in SQL, all functions return NULL, if any of the arguments are NULL. This may create security risks on careless usage.

F.36.6.3. Security Limitations

All `pgcrypto` functions run inside the database server. That means that all the data and passwords move between `pgcrypto` and client applications in clear text. Thus you must:

1. Connect locally or use SSL connections.
2. Trust both system and database administrator.

If you cannot, then better do crypto inside client application.

The implementation does not resist *side-channel attacks*. For example, the time required for a `pgcrypto` decryption function to complete varies among ciphertexts of a given size.

SHA256/384/512	Aaron D. Gifford	OpenBSD sys/crypto
BIGNUM math	Michael J. Fromberger	dartmouth.edu/~sting/sw/imath

F.37. pg_freespacemap

The `pg_freespacemap` module provides a means for examining the free space map (FSM). It provides a function called `pg_freespace`, or two overloaded functions, to be precise. The functions show the value recorded in the free space map for a given page, or for all pages in the relation.

By default public access is revoked from the functions, just in case there are security issues lurking.

F.37.1. Functions

`pg_freespace(rel regclass IN, blkno bigint IN) returns int2`

Returns the amount of free space on the page of the relation, specified by `blkno`, according to the FSM.

`pg_freespace(rel regclass IN, blkno OUT bigint, avail OUT int2)`

Displays the amount of free space on each page of the relation, according to the FSM. A set of (`blkno bigint`, `avail int2`) tuples is returned, one tuple for each page in the relation.

The values stored in the free space map are not exact. They're rounded to precision of 1/256th of `BLCKSZ` (32 bytes with default `BLCKSZ`), and they're not kept fully up-to-date as tuples are inserted and updated.

For indexes, what is tracked is entirely-unused pages, rather than free space within pages. Therefore, the values are not meaningful, just whether a page is full or empty.

Note

The interface was changed in version 8.4, to reflect the new FSM implementation introduced in the same version.

F.37.2. Sample Output

```
postgres=# SELECT * FROM pg_freespace('foo');
```

```
blkno | avail
-----+-----
    0 |      0
    1 |      0
    2 |      0
    3 |     32
    4 |    704
    5 |    704
    6 |    704
    7 |   1216
    8 |    704
    9 |    704

```
postgres=# SELECT * FROM pg_freespace('foo', 7);
pg_freespace
-----
        1216
(1 row)
```

F.37.3. Author

Original version by Mark Kirkwood <markir@paradise.net.nz>. Rewritten in version 8.4 to suit new FSM implementation by Heikki Linnakangas <heikki@enterprisedb.com>

F.38. pg_hint_plan

F.38.1. Name

`pg_hint_plan` - controls execution plan with hinting phrases in comment of special form.

F.38.2. Synopsis

Postgres Pro Enterprise uses cost-based optimizer, which utilizes data statistics, not static rules. The planner (optimizer) estimates costs of each possible execution plans for a SQL statement then the execution plan with the lowest cost finally be executed. The planner does its best to select the best execution plan, but not perfect, since it doesn't count some properties of the data, for example, correlation between columns.

`pg_hint_plan` makes it possible to tweak execution plans using so-called “hints”, which are simple descriptions in the SQL comment of special form.

F.38.3. Description

F.38.3.1. Basic Usage

`pg_hint_plan` reads hinting phrases in a comment of special form given with the target SQL statement. The special form is beginning by the character sequence “/*+” and ends with “*/”. Hint phrases consist

of hint name and following parameters enclosed in parentheses and delimited by spaces. Each hinting phrases can be delimited by new lines for readability.

In the example below, hash join is selected as the joining method and scanning `pgbench_accounts` by sequential scan method.

```
postgres=# /*+
postgres*#      HashJoin(a b)
postgres*#      SeqScan(a)
postgres*#      */
postgres-# EXPLAIN SELECT *
postgres-#      FROM pgbench_branches b
postgres-#      JOIN pgbench_accounts a ON b.bid = a.bid
postgres-#      ORDER BY a.aid;

                                QUERY PLAN
-----
Sort  (cost=31465.84..31715.84 rows=100000 width=197)
  Sort Key: a.aid
    -> Hash Join  (cost=1.02..4016.02 rows=100000 width=197)
          Hash Cond: (a.bid = b.bid)
            -> Seq Scan on pgbench_accounts a  (cost=0.00..2640.00 rows=100000 width=97)
            -> Hash  (cost=1.01..1.01 rows=1 width=100)
                  -> Seq Scan on pgbench_branches b  (cost=0.00..1.01 rows=1 width=100)

(7 rows)

postgres=#
```

F.38.4. The hint table

The above section mentions that hints are described in a comment of a special form. This is inconvenient if queries cannot be edited. For such cases, hints can be placed in a special table called `hint_plan.hints`. The table consists of the following columns:

Column	Description
id	Unique number to identify a row for a hint. This column is filled automatically by sequence.
norm_query_string	A pattern that matches the query to be hinted. Constants in the query have to be replaced with ? as in the example below. Whitespace is significant in the pattern.
application_name	The value of <code>application_name</code> of sessions to apply the hint to. The hint in the example below applies to sessions connected from <code>psql</code> . An empty string means sessions with any <code>application_name</code> .
hint	Hint phrase. This must be a series of hints excluding surrounding comment marks.

The following example shows how to operate with the hint table.

```
postgres=# INSERT INTO hint_plan.hints(norm_query_string, application_name, hints)
postgres-#      VALUES (
postgres(#      'EXPLAIN (COSTS false) SELECT * FROM t1 WHERE t1.id = ?;',
postgres(#      'psql',
postgres(#      'SeqScan(t1) '
postgres(#      );
INSERT 0 1
```

```
postgres=# UPDATE hint_plan.hints
postgres=#     SET hints = 'IndexScan(t1)'
postgres=# WHERE id = 1;
UPDATE 1
postgres=# DELETE FROM hint_plan.hints
postgres=# WHERE id = 1;
DELETE 1
postgres=#
```

The hint table is owned by the creator user and has the default privileges at the time of creation, during `CREATE EXTENSION`. Table hints are prioritized than comment hints.

F.38.4.1. The types of hints

Hinting phrases are classified into six types based on the kind of object and how they can affect planning: scanning methods, join methods, joining order, row number correction, parallel query, and GUC setting. You will see the lists of hint phrases of each type in Hint list (See [Section F.38.10](#)).

F.38.4.1.1. Hints for scan methods

Scan method hints enforce specific scanning method on the target table. `pg_hint_plan` recognizes the target table by alias names, if any. In this kind of hint, they are “SeqScan”, “IndexScan”, and so on.

Scan hints are effective on ordinary tables, inheritance tables, `UNLOGGED` tables, temporary tables and system catalogs. External (foreign) tables, table functions, `VALUES` clause, CTEs, views and subqueries are not affected.

```
postgres=# /*+
postgres*#     SeqScan(t1)
postgres*#     IndexScan(t2 t2_pkey)
postgres*# */
postgres=# SELECT * FROM table1 t1 JOIN table table2 t2 ON (t1.key = t2.key);
```

F.38.4.1.2. Hints for join methods

Join method hints enforce the join methods of the joins involving the specified tables.

This can affect joins only on ordinary tables, inheritance tables, `UNLOGGED` tables, temporary tables, external (foreign) tables, system catalogs, table functions, `VALUES` command results, and CTEs. But joins on views and subqueries are not affected.

F.38.4.1.3. Hint for joining order

The “Leading” hint enforces the order of join on two or more tables. There are two ways of enforcing. One is enforcing specific order of joining but not restricting direction at each join level. Another enforces join direction additionally. For details, see [Section F.38.10](#).

```
postgres=# /*+
postgres*#     NestLoop(t1 t2)
postgres*#     MergeJoin(t1 t2 t3)
postgres*#     Leading(t1 t2 t3)
postgres*# */
postgres=# SELECT * FROM table1 t1
postgres=#     JOIN table table2 t2 ON (t1.key = t2.key)
postgres=#     JOIN table table3 t3 ON (t2.key = t3.key);
```

F.38.4.1.4. Hint for row number correction

The “Rows” hint corrects row number misestimation of joins that comes from restrictions of the planner.

```
postgres=# /*+ Rows(a b #10) */ SELECT... ; Sets rows of join result to 10
postgres=# /*+ Rows(a b +10) */ SELECT... ; Increments row number by 10
postgres=# /*+ Rows(a b -10) */ SELECT... ; Subtracts 10 from the row number.
```

```
postgres=# /*+ Rows(a b *10) */ SELECT... ; Makes the number 10 times larger.
```

F.38.4.1.5. Hint for parallel plan

The “Parallel” hint enforces parallel execution configuration on scans. The third parameter specifies the strength of enforcement. “soft” means that `pg_hint_plan` only changes `max_parallel_workers_per_gather` and leaves all others to the planner. “hard” changes other planner parameters so as to forcibly apply the number. This can affect ordinary tables, inheritance parents, unlogged tables and system catalog. External tables, table functions, `VALUES` clause, CTEs, views and subqueries are not affected. Internal tables of a view can be specified by its real name/alias as the target object. The following example shows that the query is enforced differently on each table.

```
postgres=# explain /*+ Parallel(c1 3 hard) Parallel(c2 5 hard) */
SELECT c2.a FROM c1 JOIN c2 ON (c1.a = c2.a);
QUERY PLAN
-----
Hash Join  (cost=2.86..11406.38 rows=101 width=4)
  Hash Cond: (c1.a = c2.a)
    -> Gather  (cost=0.00..7652.13 rows=1000101 width=4)
        Workers Planned: 3
        -> Parallel Seq Scan on c1  (cost=0.00..7652.13 rows=322613 width=4)
    -> Hash  (cost=1.59..1.59 rows=101 width=4)
        -> Gather  (cost=0.00..1.59 rows=101 width=4)
            Workers Planned: 5
            -> Parallel Seq Scan on c2  (cost=0.00..1.59 rows=59 width=4)

postgres=# EXPLAIN /*+ Parallel(t1 5 hard) */ SELECT sum(a) FROM t1;
QUERY PLAN
-----
Finalize Aggregate  (cost=693.02..693.03 rows=1 width=8)
  -> Gather  (cost=693.00..693.01 rows=5 width=8)
      Workers Planned: 5
      -> Partial Aggregate  (cost=693.00..693.01 rows=1 width=8)
          -> Parallel Seq Scan on t1  (cost=0.00..643.00 rows=20000 width=4)
```

F.38.4.1.6. GUC parameters temporarily setting

“Set” hint changes GUC parameters just while planning. GUC parameter shown in [Section 19.7.2](#) can have the expected effects on planning unless any other hint conflicts with the planner method configuration parameters. The last one among hints on the same GUC parameter makes effect. GUC parameters for `pg_hint_plan` are also settable by this hint but it won't work as you expect.

```
postgres=# /*+ Set(random_page_cost 2.0) */
postgres=# SELECT * FROM table1 t1 WHERE key = 'value';
...
```

F.38.4.2. GUC parameters for `pg_hint_plan`

GUC parameters described below affect the behavior of `pg_hint_plan`.

Table F.26. GUC Parameters

Parameter Name	Description	Default Value
<code>pg_hint_plan.enable_hint</code>	True enables <code>pg_hint_plan</code> .	on
<code>pg_hint_plan.enable_hint_table</code>	True enables hinting by table.	on
<code>pg_hint_plan.parse_messages</code>	Specifies the log level of hint parse error. Valid values are error, warning, notice, info, log, debug.	INFO

Parameter Name	Description	Default Value
pg_hint_plan.debug_print	Controls debug print and verbosity. Valid values are off, on, detailed, and verbose.	off
pg_hint_plan.message_level	Specifies message level of debug print. Valid values are error, warning, notice, info, log, debug.	INFO

F.38.5. Installation

Basically `pg_hint_plan` does not requires `CREATE EXTENSION`. Simply loading it by `LOAD` command will activate it and of course you can load it globally by setting `shared_preload_libraries` in `postgresql.conf`. Or you might be interested in `ALTER USER SET/ALTER DATABASE SET` for automatic loading for specific sessions.

```
postgres=# LOAD 'pg_hint_plan';
LOAD
postgres=#
```

Do `CREATE EXTENSION` and `SET pg_hint_plan.enable_hint_table TO on` if you are planning to use hint table.

F.38.6. Details in hinting

F.38.6.1. Syntax and placement

`pg_hint_plan` reads hints from only the first block comment and any characters except alphabets, digits, spaces, underscores, commas and parentheses stop parsing immediately. In the following example `HashJoin(a b)` and `SeqScan(a)` are parsed as hints, but `IndexScan(a)` and `MergeJoin(a b)` are not.

```
postgres=# /*+
postgres*#      HashJoin(a b)
postgres*#      SeqScan(a)
postgres*#    */
postgres-# /*+ IndexScan(a) */
postgres-# EXPLAIN SELECT /*+ MergeJoin(a b) */ *
postgres-#      FROM pgbench_branches b
postgres-#      JOIN pgbench_accounts a ON b.bid = a.bid
postgres-#      ORDER BY a.aid;
```

QUERY PLAN

```
-----
Sort  (cost=31465.84..31715.84 rows=100000 width=197)
@@ -237,17 +285,56 @@ postgres-#      ORDER BY a.aid;
(7 rows)
```

```
postgres=#
```

F.38.6.2. Using with PL/pgSQL

`pg_hint_plan` works for queries in PL/pgSQL scripts with some restrictions.

- Hints affect only the following kinds of queries:
 - Queries that return one row. (`SELECT`, `INSERT`, `UPDATE`, and `DELETE`)
 - Queries that return multiple rows. (`RETURN QUERY`)
 - Dynamic SQL statements. (`EXECUTE`)
 - Cursor open. (`OPEN`)

- Loop over result of a query (FOR)
- A hint comment have to be placed after the first word in a query as the following since preceding comments are not sent as a part of the query.

```
postgres=# CREATE FUNCTION hints_func(integer) RETURNS integer AS $$
postgres$# DECLARE
postgres$#     id integer;
postgres$#     cnt integer;
postgres$# BEGIN
postgres$#     SELECT /*+ NoIndexScan(a) */ aid
postgres$#         INTO id FROM pgbench_accounts a WHERE aid = $1;
postgres$#     SELECT /*+ SeqScan(a) */ count(*)
postgres$#         INTO cnt FROM pgbench_accounts a;
postgres$#     RETURN id + cnt;
postgres$# END;
postgres$# $$ LANGUAGE plpgsql;
```

F.38.6.3. Letter case in object names

Unlike the way PostgreSQL handles object names, `pg_hint_plan` compares bare object names in hints against the database internal object names in a case-sensitive way. Therefore, an object name `TBL` in a hint matches only “TBL” in database and does not match any unquoted names like `TBL`, `tbl`, or `Tbl`.

F.38.6.4. Escaping special characters in object names

The objects as the hint parameter should be enclosed in double quotes if they includes parentheses, double quotes, and white spaces. The escaping rule is the same as in PostgreSQL.

F.38.6.5. Distinction between multiple occurrences of a table

`pg_hint_plan` identifies the target object by using aliases if exists. This behavior is usable to point a specific occurrence among multiple occurrences of one table.

```
postgres=# /*+ HashJoin(t1 t1) */
postgres=# EXPLAIN SELECT * FROM s1.t1
postgres=# JOIN public.t1 ON (s1.t1.id=public.t1.id);
INFO:  hint syntax error at or near "HashJoin(t1 t1)"
DETAIL:  Relation name "t1" is ambiguous.
QUERY PLAN
-----
Merge Join  (cost=337.49..781.49 rows=28800 width=8)
  Merge Cond: (s1.t1.id = public.t1.id)
    -> Sort  (cost=168.75..174.75 rows=2400 width=4)
        Sort Key: s1.t1.id
        -> Seq Scan on t1  (cost=0.00..34.00 rows=2400 width=4)
    -> Sort  (cost=168.75..174.75 rows=2400 width=4)
        Sort Key: public.t1.id
        -> Seq Scan on t1  (cost=0.00..34.00 rows=2400 width=4)
(8 rows)
```

```
postgres=# /*+ HashJoin(pt st) */
postgres=# EXPLAIN SELECT * FROM s1.t1 st
postgres=# JOIN public.t1 pt ON (st.id=pt.id);
QUERY PLAN
-----
Hash Join   (cost=64.00..1112.00 rows=28800 width=8)
  Hash Cond: (st.id = pt.id)
    -> Seq Scan on t1 st  (cost=0.00..34.00 rows=2400 width=4)
    -> Hash  (cost=34.00..34.00 rows=2400 width=4)
```

```
-> Seq Scan on t1 pt (cost=0.00..34.00 rows=2400 width=4)
(5 rows)
```

F.38.6.6. Underlying tables of views or rules

Hints are not applicable on views itself, but they can affect the queries within if the object names match the object names in the expanded query on the view. Assigning aliases to the tables in a view enables them to be manipulated from outside of the view.

```
postgres=# CREATE VIEW v1 AS SELECT * FROM t2;
postgres=# EXPLAIN /*+ HashJoin(t1 v1) */
        SELECT * FROM t1 JOIN v1 ON (c1.a = v1.a);
        QUERY PLAN
-----
Hash Join (cost=3.27..18181.67 rows=101 width=8)
  Hash Cond: (t1.a = t2.a)
    -> Seq Scan on t1 (cost=0.00..14427.01 rows=1000101 width=4)
    -> Hash (cost=2.01..2.01 rows=101 width=4)
        -> Seq Scan on t2 (cost=0.00..2.01 rows=101 width=4)
```

F.38.6.7. Inheritance tables

Hints can point only the parent of inheritance tables and the hint affect all the inheritance. Hints simultaneously point directly to children are not in effect.

F.38.6.8. Hinting on multistatements

One multistatement can have exactly one hint comment and the hint affects all of the individual statements in the multistatement. Notice that the seemingly multistatement on the interactive interface of psql is internally a sequence of single statements so hints affect only the statement just following.

F.38.6.9. VALUES expressions

VALUES expressions in the FROM clause are named as “*VALUES*” internally so it is hintable if it is the only VALUES in a query. Two or more VALUES expressions in a query seems distinguishable looking its explain result. But in reality it is mere a cosmetic and they are not distinguishable.

```
postgres=# /*+ MergeJoin(*VALUES*_1 *VALUES*) */
        EXPLAIN SELECT * FROM (VALUES (1, 1), (2, 2)) v (a, b)
        JOIN (VALUES (1, 5), (2, 8), (3, 4)) w (a, c) ON v.a = w.a;
INFO:  pg_hint_plan: hint syntax error at or near "MergeJoin(*VALUES*_1 *VALUES*) "
DETAIL:  Relation name "*VALUES*" is ambiguous.
        QUERY PLAN
-----
Hash Join (cost=0.05..0.12 rows=2 width=16)
  Hash Cond: ("*VALUES*_1".column1 = "*VALUES*".column1)
    -> Values Scan on "*VALUES*_1" (cost=0.00..0.04 rows=3 width=8)
    -> Hash (cost=0.03..0.03 rows=2 width=8)
        -> Values Scan on "*VALUES*" (cost=0.00..0.03 rows=2 width=8)
```

F.38.7. Subqueries

Subqueries in the following context occasionally can be hinted using the name “ANY_subquery”.

```
IN (SELECT ... {LIMIT | OFFSET ...} ...)
= ANY (SELECT ... {LIMIT | OFFSET ...} ...)
= SOME (SELECT ... {LIMIT | OFFSET ...} ...)
```

For these syntaxes, planner internally assigns the name to the subquery when planning joins on tables including it, so join hints are applicable on such joins using the implicit name as follows:

```
postgres=# /*+HashJoin(a1 ANY_subquery)*/
```

```
postgres=# EXPLAIN SELECT *
postgres=#       FROM pgbench_accounts a1
postgres=#       WHERE aid IN (SELECT bid FROM pgbench_accounts a2 LIMIT 10);
               QUERY PLAN

-----
Hash Semi Join  (cost=0.49..2903.00 rows=1 width=97)
  Hash Cond: (a1.aid = a2.bid)
    -> Seq Scan on pgbench_accounts a1  (cost=0.00..2640.00 rows=100000 width=97)
    -> Hash  (cost=0.36..0.36 rows=10 width=4)
          -> Limit  (cost=0.00..0.26 rows=10 width=4)
                -> Seq Scan on pgbench_accounts a2  (cost=0.00..2640.00 rows=100000
width=4)
```

F.38.7.1. Using `IndexOnlyScan` hint

Index scan may be unexpectedly performed on another index when the index specified in `IndexOnlyScan` hint cannot perform index-only scan.

F.38.7.2. Behavior of `NoIndexScan`

`NoIndexScan` hint involves `NoIndexOnlyScan`.

F.38.7.3. Parallel hint and `UNION`

A `UNION` can run in parallel only when all underlying subqueries are parallel-safe. Conversely, enforcing parallel on any of the subqueries lets a parallel-executable `UNION` run in parallel. Meanwhile, a parallel hint with zero workers inhibits a scan from being executed in parallel.

F.38.7.4. Setting `pg_hint_plan` parameters by `Set` hints

`pg_hint_plan` parameters change the behavior of itself so some parameters do not work as expected.

- Hints to change `enable_hint`, `enable_hint_table` are ignored even though they are reported as “used hints” in debug logs.
- Setting `debug_print` and `message_level` works from midst of the processing of the target query.

F.38.8. Errors

`pg_hint_plan` stops parsing on any error and uses hints already parsed on the most cases. Followings are the typical errors.

F.38.8.1. Syntax errors

Any syntactical errors or wrong hint names are reported as an syntax error. These errors are reported in the server log with the message level which specified by `pg_hint_plan.message_level` if `pg_hint_plan.debug_print` is on or above.

F.38.8.2. Object misspecifications

Object misspecifications results silent ignorance of the hints. This kind of error is reported as “not used hints” in the server log by the same condition to syntax errors.

F.38.8.3. Redundant or conflicting hints

The last hint will be active when redundant hints or hints conflicting with each other. This kind of error is reported as “duplication hints” in the server log by the same condition to syntax errors.

F.38.8.4. Nested comments

Hint comment cannot include another block comment within. If `pg_hint_plan` finds it, differently from other errors, it stops parsing and abandons all hints already parsed. This kind of error is reported in the same manner as other errors.

F.38.9. Functional limitations

F.38.9.1. Influences of some of planner GUC parameters

The planner does not try to consider joining order for FROM clause entries more than `from_collapse_limit`. `pg_hint_plan` cannot affect joining order as expected for the case.

F.38.9.2. Hints trying to enforce inexecutable plans

Planner chooses any executable plans when the enforced plan cannot be executed.

- FULL OUTER JOIN to use nested loop
- To use indexes that does not have columns used in quals
- To do TID scans for queries without ctid conditions

F.38.9.3. Queries in ECPG

ECPG removes comments in queries written as embedded SQL so hints cannot be passed from those queries. The only exception is that EXECUTE command passes given string unmodified. Please consider hint tables for this case.

F.38.9.4. Work with `pg_stat_statements`

`pg_stat_statements` generates a query ID ignoring comments. As the result, the identical queries with different hints are summarized as the same query.

F.38.10. Available Hints

The available hints are listed below.

Table F.27. Hints list

Group	Format	Description
Scan method	<code>SeqScan(<i>table</i>)</code>	Forces sequential scan on the table.
	<code>TidScan(<i>table</i>)</code>	Forces TID scan on the table.
	<code>IndexScan(<i>table</i>[<i>index</i>...])</code>	Forces index scan on the table. Restricts to specified indexes if any.
	<code>IndexOnlyScan(<i>table</i>[<i>index</i>...])</code>	Forces index only scan on the table. Restricts to specified indexes if any. Index scan may be used if index only scan is not available. Available for PostgreSQL 9.2 and later.
	<code>BitmapScan(<i>table</i>[<i>index</i>...])</code>	Forces bitmap scan on the table. Restricts to specified indexes if any.
	<code>NoSeqScan(<i>table</i>)</code>	Forces not to do sequential scan on the table.
	<code>NoTidScan(<i>table</i>)</code>	Forces not to do TID scan on the table.
	<code>NoIndexScan(<i>table</i>)</code>	Forces not to do index scan and index only scan (For PostgreSQL 9.2 and later) on the table.
	<code>NoIndexOnlyScan(<i>table</i>)</code>	Forces not to do index only scan on the table. Available for PostgreSQL 9.2 and later.

Group	Format	Description
	NoBitmapScan(<i>table</i>)	Forces not to do bitmap scan on the table.
Join method	NestLoop(<i>table table[table...]</i>)	Forces nested loop for the joins with the specified tables.
	HashJoin(<i>table table[table...]</i>)	Forces hash join for the joins with the specified tables.
	MergeJoin(<i>table table[table...]</i>)	Forces merge join for the joins with the specified tables.
	NoNestLoop(<i>table table[table...]</i>)	Forces not to do nested loop for the joins with the specified tables.
	NoHashJoin(<i>table table[table...]</i>)	Forces not to do hash join for the joins with the specified tables.
	NoMergeJoin(<i>table table[table...]</i>)	Forces not to do merge join for the joins with the specified tables.
Join order	Leading(<i>table table[table...]</i>)	Forces join order as specified.
	Leading(< <i>join pair</i> >)	Forces join order and directions as specified. A join pair is a pair of tables and/or other join pairs enclosed in parentheses, which can make a nested structure.
Row number correction	Rows(<i>table table[table...]</i> <i>correction</i>)	Corrects row number of a result of the joins with the specified tables. The available correction methods are absolute (#< <i>n</i> >), addition (+< <i>n</i> >), subtraction (-< <i>n</i> >) and multiplication (*< <i>n</i> >). < <i>n</i> > should be a string that strtod() can read.
Parallel query configuration	Parallel(<i>table</i> <# of workers> [<i>soft hard</i>])	Enforce or inhibit parallel execution of the specified table. <# of workers> is the desired number of parallel workers, where zero means inhibiting parallel execution. If the third parameter is <i>soft</i> (default), it just changes <code>max_parallel_workers_per_gather</code> and leaves everything else to the planner. The <i>hard</i> value enforces the specified number of workers.
GUC	Set(<i>GUC-parameter value</i>)	Set the GUC parameter to the value while planner is running.

F.39. pg_pathman

The `pg_pathman` is a Postgres Pro extension that provides an optimized partitioning solution for large and distributed databases. Using `pg_pathman`, you can:

- Partition large databases without downtime.

- Speed up query execution for partitioned tables.
- Manage existing partitions and add new partitions on the fly.
- Add foreign tables as partitions.
- Join partitioned tables for read and write operations.

The extension is compatible with Postgres Pro 9.5 or higher.

F.39.1. Installation and Setup

The `pg_pathman` extension is included into the Postgres Pro. Once you have Postgres Pro installed, complete the following steps to enable `pg_pathman`:

1. Add `pg_pathman` to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'pg_pathman'
```

Important

`pg_pathman` may have conflicts with other extensions that use the same hook functions. For example, `pg_pathman` may interfere with the `pg_stat_statements` extension as they both use `ProcessUtility_hook`. To avoid such issues, `pg_pathman` must always be the last in the list of libraries: `shared_preload_libraries = 'pg_stat_statements, pg_pathman'`

2. Restart the Postgres Pro instance for the settings to take effect.
3. Create the `pg_pathman` extension as follows:

```
CREATE SCHEMA pathman;  
GRANT USAGE ON SCHEMA pathman TO PUBLIC;  
CREATE EXTENSION pg_pathman WITH SCHEMA pathman;
```

Important

To ensure that your calls to `pg_pathman`'s functions are always secure against `search_path`-based attacks (see [CREATE EXTENSION](#) for details), install it only into a clean schema where nobody except superusers has the `CREATE` privilege for database objects.

Once `pg_pathman` is enabled, you can start partitioning tables.

Note

During installation, `pg_pathman` creates a few RLS policies to restrict access to its own tables. Postgres Pro core, however, does not support dump/restore of databases where extensions issuing `CREATE POLICY` statements are installed. Therefore, when restoring a dump of a database where `pg_pathman` is installed, you will get error messages such as:

```
ERROR: policy "allow_select" for table "pathman_config" already exists
```

Ignore them since they do not affect whether the data being restored is complete.

Tip

You can also build `pg_pathman` from source code by executing the following command in the `pg_pathman` directory:

```
make install USE_PGXS=1
```

When this operation is complete, follow the steps described above to complete the setup.

In addition, do not forget to set the `PG_CONFIG` variable if you want to test `pg_pathman` on a custom build of Postgres Pro. For details, see [Building and Installing PostgreSQL Extension Modules](#).

You can toggle `pg_pathman` or its specific custom nodes on and off using GUC variables. For details, see [Section F.39.5.1](#).

If you want to permanently disable `pg_pathman` for a previously partitioned table, use the `disable_pathman_for()` function:

```
SELECT disable_pathman_for('range_rel');
```

All sections and data will remain unchanged and will be handled by the standard Postgres Pro inheritance mechanism.

F.39.1.1. Updating `pg_pathman`

If you already have a previous version of `pg_pathman` installed, complete the following steps to upgrade to a newer version:

1. Install Postgres Pro.
2. Restart your Postgres Pro cluster.
3. If you are running a previous major version of `pg_pathman` (the second digit in the version number is different), complete the update as follows:

```
ALTER EXTENSION pg_pathman UPDATE TO version;  
SET pg_pathman.enable = t;
```

where *version* is the `pg_pathman` major version number, such as 1.5.

You can check the current `pg_pathman` version by running the `pathman_version()` function.

F.39.2. Usage

[Choosing Partitioning Strategies](#)

[Running Non-Blocking Data Migration](#)

[Partitioning by a Single Expression](#)

[Partitioning by Composite Key](#)

[Running Multilevel Partitioning](#)

[Using Declarative Syntax](#)

[Managing Partitions](#)

As your database grows, indexing mechanisms may become inefficient and cause high latency as you run queries. To improve performance, ensure scalability, and optimize database administration processes you can use partitioning — splitting a large table into smaller pieces, with each row moved to a single partition according to the partitioning key.

Traditionally, Postgres Pro has supported partitioning via table inheritance, with each partition created as a child table with a CHECK constraint. In Postgres Pro 10, support for declarative partitioning was added, which also relies on inheritance. With these approaches, the query planner has to perform an exhaustive search and check constraints on each partition to build a query plan, which may slow

down queries for tables with a large number of partitions. The `pg_pathman` extension uses an optimized planning algorithms and partitioning functions based on the internal structure of the partitioned tables, which allows to achieve better performance results. For details on `pg_pathman` implementation specifics, see [Section F.39.4](#).

F.39.2.1. Choosing Partitioning Strategies

The `pg_pathman` extension supports the following partitioning strategies:

- Hash — maps rows to partitions using a generic hash function. Choose this strategy if most of your queries will be of the exact-match type.
- Range — maps rows to partitions based on partitioning key ranges assigned to each partition. Choose this strategy if your database contains numeric data that you are likely to query or manage by ranges. For example, you may want to query historical data by years, or review experiment results by specific numeric ranges. To achieve performance gains, `pg_pathman` uses the binary search algorithm.

By default, `pg_pathman` migrates all data from the parent table to the newly created partitions at once (*blocking partitioning*). This approach enables you to restructure the table in a single transaction, but may cause downtime if you have a lot of data. If it is critical to avoid downtime, you can use *concurrent partitioning*. In this case, `pg_pathman` writes all the updates to the newly created partitions, but keeps the original data in the parent table until you explicitly migrate it. This enables you to partition large databases without downtime, as you can choose convenient time for migration and copy data in small batches without blocking other transactions. For details on concurrent partitioning, see [Section F.39.2.2](#).

F.39.2.1.1. Setting up Hash Partitioning

To perform hash partitioning with `pg_pathman`, run the `create_hash_partitions()` function:

```
create_hash_partitions(parent_relid    REGCLASS,  
                      expression      TEXT,  
                      partitions_count INTEGER,  
                      partition_data   BOOLEAN DEFAULT TRUE,  
                      partition_names  TEXT[]  DEFAULT NULL,  
                      tablespaces     TEXT[]  DEFAULT NULL)
```

The `pg_pathman` module creates the specified number of partitions based on the hash function. Optionally, you can specify partition names and tablespaces by setting `partition_names` and `tablespaces` options, respectively.

You cannot add or remove partitions after the parent table is split. If required, you can replace the specified partition with another table:

```
replace_hash_partition(old_partition  REGCLASS,  
                      new_partition  REGCLASS,  
                      lock_parent    BOOL DEFAULT TRUE);
```

When set to `true`, `lock_parent` parameter will prevent any `INSERT/UPDATE/ALTER TABLE` queries to parent table.

If you omit the optional `partition_data` parameter or set it to `true`, all the data from the parent table gets migrated to partitions. The `pg_pathman` module blocks the table for other transactions until data migration completes. To avoid downtime, you can set the `partition_data` parameter to `false` and later use the `partition_table_concurrently()` function to migrate your data to partitions without blocking other queries. For details, see the [Section F.39.2.2](#).

F.39.2.1.2. Setting up Range Partitioning

The `pg_pathman` module provides the `create_range_partitions()` for range partitioning. This function creates partitions based on the specified interval and the initial partitioning key value. New partitions are created automatically when you insert data outside of the already covered range.

```
create_range_partitions(parent_relid REGCLASS,  
                        expression TEXT,  
                        start_value ANYELEMENT,  
                        p_interval ANYELEMENT | INTERVAL,  
                        p_count INTEGER DEFAULT NULL,  
                        partition_data BOOLEAN DEFAULT TRUE)
```

The `pg_pathman` module creates partitions based on the specified parameters. If you omit the optional `p_count` parameter, `pg_pathman` calculates the required number of partitions based on the specified start value and interval. If you insert new data outside of the existing partition range, `pg_pathman` creates new partitions automatically, keeping the specified interval. This approach ensures that all partitions are of the same size, which can improve query performance and facilitate database management.

Alternatively, you can specify an array defining the bounds of partitions to be created using the `bounds` parameter:

```
create_range_partitions(parent_relid REGCLASS,  
                        expression TEXT,  
                        bounds ANYARRAY,  
                        partition_names TEXT[] DEFAULT NULL,  
                        tablespaces TEXT[] DEFAULT NULL,  
                        partition_data BOOLEAN DEFAULT TRUE)
```

If required, you can also use [partition management functions](#) to add partitions manually. For example, if there is a gap between the created partitions, `pg_pathman` cannot fill it with a new partition in an automated mode.

By default, all the data from the parent table gets migrated to the specified number of partitions. The `pg_pathman` module blocks the table for other transactions until data migration completes. To avoid downtime, you can set the `partition_data` parameter to `false` and later use the `partition_table_concurrently()` function to migrate your data to partitions without blocking other queries. For details, see the [Section F.39.2.2](#).

F.39.2.2. Running Non-Blocking Data Migration

If it is critical to avoid downtime, you can perform concurrent partitioning by setting the `partition_data` parameter of the partitioning function to `false`. In this case, `pg_pathman` creates empty partitions, keeping all the original data in the parent table. At the same time, all the database updates are written to the newly created partitions. You can later migrate the original data to partitions without blocking other queries using the `partition_table_concurrently()` function:

```
partition_table_concurrently(relation REGCLASS,  
                             batch_size INTEGER DEFAULT 1000,  
                             sleep_time FLOAT8 DEFAULT 1.0)
```

where:

- `relation` is the parent table.
- `batch_size` is the number of rows to copy from the parent table to partitions at a time. You can set this parameter to any integer value from 1 to 10000.
- `sleep_time` is the time interval between migration attempts, in seconds.

The `pg_pathman` module starts a background worker to move the data from the parent table to partitions in small batches of the specified `batch_size`. If one or more rows in the batch are locked by other queries, `pg_pathman` waits for the specified `sleep_time` and tries again, up to 60 times. You can monitor the migration process in the `pathman_concurrent_part_tasks` view that shows the number of rows migrated so far:

```
[user]postgres: select * from pathman_concurrent_part_tasks ;  
userid | pid  | dbid  | relid | processed | status
```

```
-----+-----+-----+-----+-----+-----  
user   | 20012 | 12413 | test  |      334000 | working  
(1 row)
```

If you need to stop data migration, run the `stop_concurrent_part_task()` function at any time:

```
SELECT stop_concurrent_part_task(relation REGCLASS);
```

`pg_pathman` completes the migration of the current batch and terminates the migration process.

Tip

When `pg_pathman` migrates all the data from the parent table, you can exclude the parent table from the query plan. See the `set_enable_parent()` function description for details.

F.39.2.3. Partitioning by a Single Expression

For both range and hash partitioning strategies, `pg_pathman` supports partitioning by expression that returns a single scalar value. The partitioning expression can reference a table column, as well as calculate the partitioning key based on one or more column values.

Tip

If you would like to partition a table by a tuple, see [Section F.39.2.4](#).

To partition a table by expression, use `pg_pathman` [partitioning functions](#). The partitioning expression must satisfy the following conditions:

- Expression must reference at least one column of the partitioned table.
- All referenced columns must be marked as `NOT NULL`.
- Expression cannot reference system attributes, such as `oid`, `xmin`, `xmax`, etc.
- Expression cannot include subqueries.
- All functions used by expression must be marked as `IMMUTABLE`.

As the expression can return a value of virtually any type, make sure to convert it to the type you need for partitioning.

To access a partition, you must use the exact expression used for partitioning. Otherwise, `pg_pathman` cannot optimize the query. You can view the partitioning expression for each partitioned table in the `pathman_config` table.

F.39.2.3.1. Examples

Suppose you have the `test` table that stores some `jsonb` data:

```
CREATE TABLE test(col jsonb NOT NULL);  
INSERT INTO test  
SELECT format('{ "key": %s, "date": "%s", "value": "%s"}',  
             i, current_date, md5(i::text))::jsonb  
FROM generate_series(1, 10000 * 10) as g(i);
```

To partition this data by range of the `key` value, you need to extract this value from the `jsonb` object and convert it to a numeric type, such as `bigint`:

```
SELECT create_range_partitions('test', '(col->>'key')::bigint', 1, 10000, 10);
```

`pg_pathman` splits the parent table into ten partitions, with each partition storing 10000 rows:

```
SELECT * FROM pathman_partition_list;
```

parent	partition	parttype	expr	range_min	range_max
test	test_1	2	((col ->> 'key'::text))::bigint	1	10001
test	test_2	2	((col ->> 'key'::text))::bigint	10001	20001
test	test_3	2	((col ->> 'key'::text))::bigint	20001	30001
test	test_4	2	((col ->> 'key'::text))::bigint	30001	40001
test	test_5	2	((col ->> 'key'::text))::bigint	40001	50001
test	test_6	2	((col ->> 'key'::text))::bigint	50001	60001
test	test_7	2	((col ->> 'key'::text))::bigint	60001	70001
test	test_8	2	((col ->> 'key'::text))::bigint	70001	80001
test	test_9	2	((col ->> 'key'::text))::bigint	80001	90001
test	test_10	2	((col ->> 'key'::text))::bigint	90001	100001

(10 rows)

F.39.2.4. Partitioning by Composite Key

Using `pg_pathman`, you can also perform range partitioning by composite key. A composite key consists of two or more comma-separated values, which can be columns or expressions extracting the values from the table. The expressions defining the composite key must satisfy the conditions described in [Section F.39.2.3](#).

Although `pg_pathman` does not support automatic partition creation by composite key, you can add partitions using the `add_range_partition()` function. A typical workflow is as follows:

1. Enable automatic partition naming for your table by running the `create_naming_sequence()` function.
2. Create a composite partitioning key.
3. Register a table you are going to partition with `pg_pathman` using the `add_to_pathman_config()` function.
4. Add a partition based on the defined composite partitioning key using the `add_range_partition()` function.

F.39.2.4.1. Examples

Suppose you have the `test` table that stores some temporal data:

```
CREATE TABLE test (logdate date NOT NULL, comment text);
```

To partition this data by month and year, you have to create a composite key:

```
CREATE TYPE test_key AS (year float8, month float8);
```

To enable automatic partition naming, run the `create_naming_sequence()` function passing the table name as an argument:

```
SELECT create_naming_sequence('test');
```

Register the `test` table with `pg_pathman`, specifying the partitioning key you are going to use:

```
SELECT add_to_pathman_config('test',
                             '( extract(year from logdate),
                               extract(month from logdate) )::test_key',
                             NULL);
```

Create a partition that includes all the data in the range of ten years, starting from January of the current year:

```
SELECT add_range_partition('test',
                           (extract(year from current_date), 1)::test_key,
                           (extract(year from current_date + '10 years'::interval),
                             1)::test_key);
```

F.39.2.5. Running Multilevel Partitioning

`pg_pathman` supports multilevel partitioning for both hash and range partitioning strategies. You can use partitioning strategies in any combination: a hash- or range-partitioned table can be further partitioned by both hash or range.

To split an existing partition into several child ones, use the regular `pg_pathman` partitioning functions as explained in [Section F.39.2.1](#), passing the name of the partition to be split as the `parent_relid` parameter. You can check the exact partition names in the [pathman_partition_list](#) view.

When opting for the range-range partitioning combination, you can either choose a different partitioning expression, or use the same expression as for the parent table. In the latter case, if the selected range is larger than that of the parent partition, only those child partitions that intersect with the parent range will be in use. Other child partitions will remain empty unless their parent is merged with an adjacent partition that covers at least a part of their range.

F.39.2.5.1. Examples

Suppose you have the `journal` table with some logs, which is partitioned by month:

```
-- create an empty table
CREATE TABLE journal (
  id      SERIAL,
  dt      TIMESTAMP NOT NULL,
  level   INTEGER,
  msg     TEXT);

-- generate some log data into the table
INSERT INTO journal (dt, level, msg)
SELECT g, random() * 6, md5(g::text)
FROM generate_series('2015-01-01'::date, '2015-12-31'::date, '1 minute') as g;

-- partition the table by range
SELECT create_range_partitions('journal', 'dt', '2015-01-01'::date, '1
month'::interval);
```

If having smaller partitions makes more sense at some point, you can further split the partitions by hash or range. For example, to split the `journal_1` partition into subpartitions by day, run:

```
SELECT create_range_partitions('journal_1', 'dt', '2015-01-01'::date, '1
day'::interval);
```

Similarly, you can use hash partitioning to create child partitions. For example, split the `journal_2` partition into five partitions by hash using the `id` column as the partitioning key:

```
SELECT create_hash_partitions('journal_2', 'id', '5');
```

F.39.2.6. Using Declarative Syntax

Declarative syntax for partitioning enables you to define the partitioning strategy when creating a table, as well as partition existing tables and manage table partitions using SQL commands.

When running the `CREATE TABLE` command, you can use the `PARTITION BY` clause to split the resulting table into partitions by range or hash.

To create a table partitioned by range, specify the partition names, the range of values to include into each partition and, optionally, a tablespace. For example:

```
CREATE TABLE abc(id serial NOT NULL)
  PARTITION BY RANGE(id)
  (
    PARTITION abc_100 VALUES LESS THAN (100) TABLESPACE ts1,
```

```
    PARTITION abc_200 VALUES LESS THAN (200) TABLESPACE ts2
);
```

When creating a table partitioned by hash, you can either specify the number of partitions to create, or the exact partitions and tablespaces. For example, to create the `abc` table with three partitions, run:

```
CREATE TABLE abc(id serial NOT NULL)
    PARTITION BY HASH (id) PARTITIONS (3);
```

To define the exact partitions to create, use the following statement:

```
CREATE TABLE abc(id serial NOT NULL)
    PARTITION BY HASH (id)
(
    PARTITION abc_first TABLESPACE ts1,
    PARTITION abc_second TABLESPACE ts2
);
```

To partition an already created table, you can use the `ALTER TABLE` command with the `PARTITION BY` clause. For example, to split the `abc` table into three hash partitions, run:

```
ALTER TABLE abc PARTITION BY HASH (id) PARTITIONS (3);
```

When performing range partitioning of an already created table, you have to specify the lower bound of the first partition, which must not be greater than the smallest value in the partition key column, and provide the partitioning interval that defines the range of values to include into a single partition:

```
ALTER TABLE abc PARTITION BY RANGE (id) START FROM (0) INTERVAL (2000);
```

If the table to partition contains a lot of data and it is critical to avoid downtime, consider using the optional `CONCURRENTLY` clause. In this case, `pg_pathman` first creates empty partitions, and then migrates the data in batches of 1000 rows. This clause can be used for both hash and range partitioning. For example:

```
ALTER TABLE abc PARTITION BY RANGE (id) START FROM (0) INTERVAL (50000) CONCURRENTLY;
ALTER TABLE abc PARTITION BY HASH (id) PARTITIONS (3) CONCURRENTLY;
```

`pg_pathman` declarative syntax also supports multilevel partitioning. Once the table is partitioned, you can run the `ALTER TABLE` command with the `PARTITION BY` clause on the partition that you would like to split. Consider the following example with hash partitioning:

```
CREATE TABLE test(a int NOT NULL, b int NOT NULL)
    PARTITION BY by hash(a) PARTITIONS (8);

ALTER TABLE test_1
    PARTITION BY hash(b) PARTITIONS (10);
```

As a result, the `test` table is split into eight hash partitions, and its `test_1` partition is further split into ten partitions by another key.

The `ALTER TABLE` command can also be run with partition management clauses to add, remove, or modify partitions, as explained in [ALTER TABLE](#).

F.39.2.7. Managing Partitions

`pg_pathman` provides multiple functions for easy partition management. For details, see [Section F.39.5.3.4](#).

F.39.3. Examples

F.39.3.1. Common Tips

- You can add partition column containing the names of the underlying partitions using the system attribute called `tableoid`:

```
SELECT tableoid::regclass AS partition, * FROM partitioned_table;
```

- Though indices on a parent table are not particularly useful (since the parent table is supposed to be empty), they act as prototypes for indices on partitions. For each index on the parent table, `pg_pathman` creates a similar index on each partition.
- All running concurrent partitioning tasks can be listed using the `pathman_concurrent_part_tasks` view:

```
SELECT * FROM pathman_concurrent_part_tasks;
userid  | pid  | dbid  | relid | processed | status
-----+-----+-----+-----+-----+-----
user    | 7367 | 16384 | test  | 472000    | working
(1 row)
```

- The `pathman_partition_list` in conjunction with `drop_range_partition()` can be used to drop range partitions in a more flexible way compared to `DROP TABLE`:

```
SELECT drop_range_partition(partition, false) /* move data to parent */
FROM pathman_partition_list
WHERE parent = 'part_test'::regclass AND range_min::int < 500;
NOTICE:  1 rows copied from part_test_11
NOTICE:  100 rows copied from part_test_1
NOTICE:  100 rows copied from part_test_2
drop_range_partition
-----
dummy_test_11
dummy_test_1
dummy_test_2
(3 rows)
```

- You can turn foreign tables into partitions using the `attach_range_partition()` function. Rows that were meant to be inserted into the parent will be redirected to foreign partitions using `PartitionFilter`. By default, it is only allowed to insert rows into partitions provided by `postgres_fdw`. This setting is controlled by the `pg_pathman.insert_into_fdw` variable. You must have superuser rights to change this setting.

F.39.3.2. Hash Partitioning

Consider an example of hash partitioning. First create a table with an integer column:

```
CREATE TABLE items (
id          SERIAL PRIMARY KEY,
name        TEXT,
code        BIGINT);

INSERT INTO items (id, name, code)
SELECT g, md5(g::text), random() * 100000
FROM generate_series(1, 100000) as g;
```

Now run the `create_hash_partitions()` function with appropriate arguments:

```
SELECT create_hash_partitions('items', 'id', 100);
```

This will create new partitions and move the data from the parent table to partitions.

Here is an example of the query performing filtering by partitioning key:

```
SELECT * FROM items WHERE id = 1234;
 id  |                               name                               | code
-----+-----+-----+-----+-----+-----
1234 | 81dc9bdb52d04dc20036dbd8313ed055 | 1855
```

(1 row)

```
EXPLAIN SELECT * FROM items WHERE id = 1234;
QUERY PLAN
```

```
-----
Append  (cost=0.28..8.29 rows=0 width=0)
->  Index Scan using items_34_pkey on items_34  (cost=0.28..8.29 rows=0 width=0)
Index Cond: (id = 1234)
```

Notice that the Append node contains only one child scan, which corresponds to the WHERE clause.

Important

Pay attention to the fact that pg_pathman excludes the parent table from the query plan.

To access the parent table, use the ONLY modifier:

```
EXPLAIN SELECT * FROM ONLY items;
QUERY PLAN
```

```
-----
Seq Scan on items  (cost=0.00..0.00 rows=1 width=45)
```

F.39.3.3. Range Partitioning

Consider an example of range partitioning. Let's create a table containing some dummy logs:

```
CREATE TABLE journal (
id      SERIAL,
dt      TIMESTAMP NOT NULL,
level   INTEGER,
msg     TEXT);

-- similar index will also be created for each partition
CREATE INDEX ON journal(dt);

-- generate some data
INSERT INTO journal (dt, level, msg)
SELECT g, random() * 6, md5(g::text)
FROM generate_series('2015-01-01'::date, '2015-12-31'::date, '1 minute') as g;
```

Run the `create_range_partitions()` function to create partitions so that each partition would contain the data for one day:

```
SELECT create_range_partitions('journal', 'dt', '2015-01-01'::date, '1 day'::interval);
```

It will create 364 partitions and move the data from the parent table to partitions.

New partitions are appended automatically by insert trigger, but it can be done manually with the following functions:

```
-- add new partition with specified range
SELECT add_range_partition('journal', '2016-01-01'::date, '2016-01-07'::date);

-- append new partition with default range
SELECT append_range_partition('journal');
```

The first one creates a partition with specified range. The second one creates a partition with default interval and appends it to the partition list. It is also possible to attach an existing table as partition. For example, we may want to attach an archive table (or even foreign table from another server) for some outdated data:

```
CREATE FOREIGN TABLE journal_archive (
id      INTEGER NOT NULL,
dt      TIMESTAMP NOT NULL,
level   INTEGER,
msg     TEXT)
SERVER archive_server;

SELECT attach_range_partition('journal', 'journal_archive', '2014-01-01'::date,
'2015-01-01'::date);
```

Important

The attached table must have the same columns as the partitioned table, except for the dropped columns. The attached columns must have the same type, collation, and NOT NULL settings as the original columns.

To merge two adjacent partitions, use the `merge_range_partitions()` function:

```
SELECT merge_range_partitions('journal_archive', 'journal_1');
```

To split partition by value, use the `split_range_partition()` function:

```
SELECT split_range_partition('journal_366', '2016-01-03'::date);
```

To detach partition, use the `detach_range_partition()` function:

```
SELECT detach_range_partition('journal_archive');
```

Here is an example of the query performing filtering by partitioning key:

```
SELECT * FROM journal WHERE dt >= '2015-06-01' AND dt < '2015-06-03';
id      |          dt          | level |          msg
-----+-----+-----+-----
217441  | 2015-06-01 00:00:00 |     2 | 15053892d993ce19f580a128f87e3dbf
217442  | 2015-06-01 00:01:00 |     1 | 3a7c46f18a952d62ce5418ac2056010c
217443  | 2015-06-01 00:02:00 |     0 | 92c8de8f82faf0b139a3d99f2792311d
...
(2880 rows)

EXPLAIN SELECT * FROM journal WHERE dt >= '2015-06-01' AND dt < '2015-06-03';
QUERY PLAN
-----
Append  (cost=0.00..58.80 rows=0 width=0)
->  Seq Scan on journal_152  (cost=0.00..29.40 rows=0 width=0)
->  Seq Scan on journal_153  (cost=0.00..29.40 rows=0 width=0)
(3 rows)
```

F.39.4. Internals

`pg_pathman` stores partitioning configuration in the `pathman_config` table; each row contains a single entry for a partitioned table (relation name, partitioning column and its type). During the initialization stage the `pg_pathman` module caches some information about child partitions in the shared memory, which is used later for plan construction. Before a `SELECT` query is executed, `pg_pathman` traverses the condition tree in search of expressions like:

```
VARIABLE OP CONST
```

where `VARIABLE` is a partitioning key, `OP` is a comparison operator (supported operators are `=`, `<`, `<=`, `>`, `>=`), `CONST` is a scalar value. For example:

```
WHERE id = 150
```

Based on the partitioning type and condition's operator, `pg_pathman` searches for the corresponding partitions and builds the plan.

F.39.4.1. Custom Plan Nodes

`pg_pathman` provides a couple of *custom plan nodes* which aim to reduce execution time, namely:

- `RuntimeAppend` (overrides `Append` plan node)
- `RuntimeMergeAppend` (overrides `MergeAppend` plan node)
- `PartitionFilter` (drop-in replacement for `INSERT` triggers)
- `PartitionRouter` for cross-partition `UPDATE` queries instead of triggers

`PartitionFilter` acts as a *proxy node* for `INSERT`'s child scan, which means it can redirect output tuples to the corresponding partition:

```
EXPLAIN (COSTS OFF)
INSERT INTO partitioned_table
SELECT generate_series(1, 10), random();
      QUERY PLAN
```

```
-----
Insert on partitioned_table
-> Custom Scan (PartitionFilter)
    -> Subquery Scan on "*SELECT*"
        -> Result
(4 rows)
```

`PartitionRouter` is another proxy node used in conjunction with `PartitionFilter` to enable cross-partition `UPDATE` operations, for example, when you update any column of a partitioning key.

Important

The `PartitionRouter` node transforms cross-partition `UPDATE` commands into `DELETE + INSERT`. On Postgres Pro versions prior to 11, this operation is unsafe as `pg_pathman` cannot determine whether the updated row has been deleted or moved to another partition.

By default, `PartitionRouter` is disabled to avoid undesirable side effects. To enable this node, set the `pg_pathman.enable_partitionrouter` to on.

```
EXPLAIN (COSTS OFF)
UPDATE partitioned_table
SET value = value + 1 WHERE value = 2;
      QUERY PLAN
```

```
-----
Update on partitioned_table_0
-> Custom Scan (PartitionRouter)
    -> Custom Scan (PartitionFilter)
        -> Seq Scan on partitioned_table_0
            Filter: (value = 2)
(5 rows)
```

`RuntimeAppend` and `RuntimeMergeAppend` have much in common: they come in handy in a case when `WHERE` condition takes form of:

```
VARIABLE OP PARAM
```

This kind of expressions can no longer be optimized at planning time since the parameter's value is not known until the execution stage takes place. The problem can be solved by embedding the *WHERE condition analysis routine* into the original `Append`'s code, thus making it pick only required scans out of a whole bunch of planned partition scans. This effectively boils down to creation of a custom node capable of performing such a check.

There are at least several cases that demonstrate usefulness of these nodes:

```
/* create table we're going to partition */
CREATE TABLE partitioned_table(id INT NOT NULL, payload REAL);

/* insert some data */
INSERT INTO partitioned_table
SELECT generate_series(1, 1000), random();

/* perform partitioning */
SELECT create_hash_partitions('partitioned_table', 'id', 100);

/* create ordinary table */
CREATE TABLE some_table AS SELECT generate_series(1, 100) AS VAL;
```

- id = (select ... limit 1)

```
EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = (SELECT * FROM some_table LIMIT 1);
```

QUERY PLAN

```
-----
Custom Scan (RuntimeAppend) (actual time=0.030..0.033 rows=1 loops=1)
  InitPlan 1 (returns $0)
    -> Limit (actual time=0.011..0.011 rows=1 loops=1)
        -> Seq Scan on some_table (actual time=0.010..0.010 rows=1 loops=1)
    -> Seq Scan on partitioned_table_70 partitioned_table (actual time=0.004..0.006
rows=1 loops=1)
      Filter: (id = $0)
      Rows Removed by Filter: 9
Planning time: 1.131 ms
Execution time: 0.075 ms
(9 rows)
```

```
/* disable RuntimeAppend node */
SET pg_pathman.enable_runtimeappend = f;
```

```
EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = (SELECT * FROM some_table LIMIT 1);
```

QUERY PLAN

```
-----
Append (actual time=0.196..0.274 rows=1 loops=1)
  InitPlan 1 (returns $0)
    -> Limit (actual time=0.005..0.005 rows=1 loops=1)
        -> Seq Scan on some_table (actual time=0.003..0.003 rows=1 loops=1)
    -> Seq Scan on partitioned_table_0 (actual time=0.014..0.014 rows=0 loops=1)
      Filter: (id = $0)
      Rows Removed by Filter: 6
    -> Seq Scan on partitioned_table_1 (actual time=0.003..0.003 rows=0 loops=1)
      Filter: (id = $0)
      Rows Removed by Filter: 5
      ... /* more plans follow */
Planning time: 1.140 ms
Execution time: 0.855 ms
(306 rows)
```

- id = ANY (select ...)

```
EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = any (SELECT * FROM some_table limit 4);
```

QUERY PLAN

```
-----
Nested Loop (actual time=0.025..0.060 rows=4 loops=1)
  -> Limit (actual time=0.009..0.011 rows=4 loops=1)
        -> Seq Scan on some_table (actual time=0.008..0.010 rows=4 loops=1)
  -> Custom Scan (RuntimeAppend) (actual time=0.002..0.004 rows=1 loops=4)
        -> Seq Scan on partitioned_table_70 partitioned_table (actual
time=0.001..0.001 rows=10 loops=1)
        -> Seq Scan on partitioned_table_26 partitioned_table (actual
time=0.002..0.003 rows=9 loops=1)
        -> Seq Scan on partitioned_table_27 partitioned_table (actual
time=0.001..0.002 rows=20 loops=1)
        -> Seq Scan on partitioned_table_63 partitioned_table (actual
time=0.001..0.002 rows=9 loops=1)
Planning time: 0.771 ms
Execution time: 0.101 ms
(10 rows)
```

```
/* disable RuntimeAppend node */
```

```
SET pg_pathman.enable_runtimeappend = f;
```

```
EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = any (SELECT * FROM some_table limit 4);
```

QUERY PLAN

```
-----
Nested Loop Semi Join (actual time=0.531..1.526 rows=4 loops=1)
  Join Filter: (partitioned_table.id = some_table.val)
  Rows Removed by Join Filter: 3990
  -> Append (actual time=0.190..0.470 rows=1000 loops=1)
        -> Seq Scan on partitioned_table (actual time=0.187..0.187 rows=0 loops=1)
        -> Seq Scan on partitioned_table_0 (actual time=0.002..0.004 rows=6
loops=1)
        -> Seq Scan on partitioned_table_1 (actual time=0.001..0.001 rows=5
loops=1)
        -> Seq Scan on partitioned_table_2 (actual time=0.002..0.004 rows=14
loops=1)
... /* 96 scans follow */
  -> Materialize (actual time=0.000..0.000 rows=4 loops=1000)
        -> Limit (actual time=0.005..0.006 rows=4 loops=1)
              -> Seq Scan on some_table (actual time=0.003..0.004 rows=4 loops=1)
Planning time: 2.169 ms
Execution time: 2.059 ms
(110 rows)
```

- NestLoop **involving a partitioned table**, which is omitted since it's occasionally shown above.

To learn more about custom nodes, see Alexander Korotkov's [blog](#).

F.39.5. Reference

F.39.5.1. GUC Variables

There are several user-accessible [GUC](#) variables designed to toggle `pg_pathman` or its specific custom nodes on and off.

- `pg_pathman.enable` — enable/disable the `pg_pathman` module.

Default: on

- `pg_pathman.enable_runtimeappend` — toggle the `RuntimeAppend` custom node on/off.

Default: on

- `pg_pathman.enable_runtime_merge_append` — toggle the `RuntimeMergeAppend` custom node on/off.

Default: on

- `pg_pathman.enable_partitionfilter` — toggle the `PartitionFilter` custom node on/off to enable/disable cross-partition INSERT operations.

Default: on

- `pg_pathman.enable_partitionrouter` — toggle the `PartitionRouter` custom node on/off to enable/disable cross-partition UPDATE operations.

Default: off

- `pg_pathman.enable_auto_partition` — toggle automatic partition creation on/off (per session).

Default: on

- `pg_pathman.enable_bounds_cache` — toggle bounds cache on/off.

Default: on

- `pg_pathman.insert_into_fdw` — allow INSERT operations into various foreign-data wrappers. Possible values: `disabled`, `postgres`, and `any_fdw`.

Default: `postgres`

- `pg_pathman.override_copy` — toggle COPY statement hooking on/off.

Default: on

F.39.5.2. Views and Tables

F.39.5.2.1. `pathman_config`

This table stores the list of partitioned tables. This is the main configuration storage.

```
CREATE TABLE IF NOT EXISTS pathman_config (
    partrel          REGCLASS NOT NULL PRIMARY KEY,
    attname          TEXT NOT NULL,
    parttype         INTEGER NOT NULL,
    range_interval   TEXT);
```

F.39.5.2.2. `pathman_config_params`

This table stores optional parameters that override standard `pg_pathman` behavior.

```
CREATE TABLE IF NOT EXISTS pathman_config_params (
    partrel          REGCLASS NOT NULL PRIMARY KEY,
    enable_parent    BOOLEAN NOT NULL DEFAULT TRUE,
    auto             BOOLEAN NOT NULL DEFAULT TRUE,
    init_callback    REGPROCEDURE NOT NULL DEFAULT 0,
    spawn_using_bgw  BOOLEAN NOT NULL DEFAULT FALSE);
```

F.39.5.2.3. `pathman_concurrent_part_tasks`

This view lists all currently running concurrent partitioning tasks.

```
-- helper SRF function
CREATE OR REPLACE FUNCTION show_concurrent_part_tasks()
RETURNS TABLE (
    userid          REGROLE,
    pid             INT,
    dbid            OID,
    relid           REGCLASS,
```

```
    processed INT,
    status    TEXT)
AS 'pg_pathman', 'show_concurrent_part_tasks_internal'
LANGUAGE C STRICT;
```

```
CREATE OR REPLACE VIEW pathman_concurrent_part_tasks
AS SELECT * FROM show_concurrent_part_tasks();
```

F.39.5.2.4. pathman_partition_list

This view lists all existing partitions, as well as their parents and range boundaries (NULL for hash partitions).

```
-- helper SRF function
CREATE OR REPLACE FUNCTION show_partition_list()
RETURNS TABLE (
    parent      REGCLASS,
    partition   REGCLASS,
    parttype    INT4,
    expr        TEXT,
    range_min   TEXT,
    range_max   TEXT)
AS 'pg_pathman', 'show_partition_list_internal'
LANGUAGE C STRICT;
```

```
CREATE OR REPLACE VIEW pathman_partition_list
AS SELECT * FROM show_partition_list();
```

F.39.5.3. Functions

F.39.5.3.1. Partitioning Functions

```
create_hash_partitions(parent_relid      REGCLASS,
                       expression        TEXT,
                       partitions_count  INTEGER,
                       partition_data    BOOLEAN DEFAULT TRUE,
                       partition_names   TEXT[]  DEFAULT NULL,
                       tablespaces       TEXT[]  DEFAULT NULL)
```

Performs hash partitioning for relation by integer key expression. The `partitions_count` parameter specifies the number of partitions to create; it cannot be changed afterwards. If `partition_data` is true, all the data will be automatically migrated from the parent table to partitions. Note that data migration may take a while to finish and the table will be locked until transaction commits. See `partition_table_concurrently()` for a lock-free way to migrate data. Partition creation callback is invoked for each partition if set beforehand (see `set_init_callback()`).

```
create_range_partitions(relation         REGCLASS,
                       expression        TEXT,
                       start_value       ANYELEMENT,
                       p_interval        ANYELEMENT,
                       p_count           INTEGER DEFAULT NULL,
                       partition_data    BOOLEAN DEFAULT TRUE)
```

```
create_range_partitions(relation         REGCLASS,
                       expression        TEXT,
                       start_value       ANYELEMENT,
                       p_interval        INTERVAL,
                       p_count           INTEGER DEFAULT NULL,
                       partition_data    BOOLEAN DEFAULT TRUE)
```

```
create_range_partitions(relation      REGCLASS,  
                       expression    TEXT,  
                       bounds        ANYARRAY,  
                       partition_names TEXT[] DEFAULT NULL,  
                       tablespaces   TEXT[] DEFAULT NULL,  
                       partition_data BOOLEAN DEFAULT TRUE)
```

Performs range partitioning for `relation` by partitioning key defined by `expression`. The `start_value` argument specifies the initial value, `p_interval` sets the default range for automatically created partitions or partitions created with `append_range_partition()` or `prepend_range_partition()`. If `p_interval` is set to `NULL`, automatic partition creation is disabled. `p_count` is the number of premade partitions. If `p_count` is not set, than `pg_pathman` tries to determine the number of partitions based on the `expression` value. The `bounds` array defines the bounds for partitions to be created. You can build this array using the `generate_range_bounds()` function. Partition creation callback is invoked for each partition if set beforehand.

F.39.5.3.2. Data Migration Functions

```
partition_table_concurrently(relation REGCLASS,  
                             batch_size INTEGER DEFAULT 1000,  
                             sleep_time FLOAT8 DEFAULT 1.0)
```

Starts a background worker to move data from parent table to partitions. The worker utilizes short transactions to copy small batches of data (up to 10K rows per transaction) and thus doesn't significantly interfere with user's activity.

```
stop_concurrent_part_task(relation REGCLASS)
```

Stops a background worker performing a concurrent partitioning task. Note: worker will exit after it finishes relocating a current batch.

F.39.5.3.3. Triggers

Triggers are no longer required for `INSERT` and cross-partition `UPDATE` operations. However, user-supplied triggers are supported:

- Each inserted row results in execution of `BEFORE/AFTER INSERT` trigger functions of a corresponding partition.
- Each updated row results in execution of `BEFORE/AFTER UPDATE` trigger functions of a corresponding partition.
- Each moved row (cross-partition update) results in execution of `BEFORE UPDATE + BEFORE/AFTER DELETE + BEFORE/AFTER INSERT` trigger functions of corresponding partitions.

F.39.5.3.4. Partition Management Functions

```
replace_hash_partition(old_partition  REGCLASS,  
                       new_partition  REGCLASS,  
                       lock_parent    BOOLEAN DEFAULT TRUE)
```

Replaces the specified partition of hash-partitioned table with another table. When set to `true`, the `lock_parent` parameter prevents any `INSERT/UPDATE/ALTER TABLE` queries to the parent table.

```
split_range_partition(partition_relid REGCLASS,  
                      split_value     ANYELEMENT,  
                      partition_name  TEXT DEFAULT NULL,  
                      tablespace      TEXT DEFAULT NULL)
```

Split range partition in two by value, with the specified value included into the second partition. Partition creation callback is invoked for a new partition if available.

```
merge_range_partitions(variadic partitions REGCLASS[])
```

Merge several adjacent range partitions. Partitions are automatically ordered by increasing bounds. All the data will be accumulated in the first partition, while other merged partitions are removed. If the remaining partition has any child partitions, new child partitions for the merged data will be created as required using the same partitioning expression.

```
append_range_partition(parent_relid REGCLASS,  
                      partition_name TEXT DEFAULT NULL,  
                      tablespace TEXT DEFAULT NULL)
```

Append new range partition with `pathman_config.range_interval` as interval.

```
prepend_range_partition(parent_relid REGCLASS,  
                      partition_name TEXT DEFAULT NULL,  
                      tablespace TEXT DEFAULT NULL)
```

Prepend new range partition with `pathman_config.range_interval` as interval.

```
add_range_partition(parent_relid REGCLASS,  
                  start_value ANYELEMENT,  
                  end_value ANYELEMENT,  
                  partition_name TEXT DEFAULT NULL,  
                  tablespace TEXT DEFAULT NULL)
```

Create a new range partition for relation with the specified range bounds. If the `start_value` or the `end_value` is NULL, the corresponding range bound will be infinite.

```
drop_range_partition(partition_relid TEXT, delete_data BOOLEAN DEFAULT TRUE)
```

Drop range partition and all of its data if `delete_data` is true.

```
attach_range_partition(parent_relid REGCLASS,  
                    partition_relid REGCLASS,  
                    start_value ANYELEMENT,  
                    end_value ANYELEMENT)
```

Attach partition to the existing range-partitioned relation. The attached table must have exactly the same structure as the parent table, including the dropped columns. Partition creation callback is invoked if set (see [Section F.39.5.2.2](#)).

```
detach_range_partition(partition_relid REGCLASS)
```

Detach partition from the existing range-partitioned relation.

```
disable_pathman_for(parent_relid REGCLASS)
```

Permanently disable `pg_pathman` partitioning mechanism for the specified parent table and remove the insert trigger if it exists. All partitions and data remain unchanged.

```
drop_partitions(parent_relid REGCLASS,  
               delete_data BOOLEAN DEFAULT FALSE)
```

Drop partitions of the parent table (both foreign and local relations). If `delete_data` is false, the data is copied to the parent table first. Default is false.

F.39.5.3.5. Additional Functions

```
pathman_version()
```

Returns the `pg_pathman` version number.

```
set_interval(relation REGCLASS, value ANYELEMENT)
```

Update range-partitioned table interval. Note that interval must not be negative and it must not be trivial, i.e. its value should be greater than zero for numeric types, at least 1 microsecond for `timestamp` and at least 1 day for `date`.

```
set_enable_parent(relation REGCLASS, value BOOLEAN)
```

Include/exclude parent table into/from query plan. In original Postgres Pro planner parent table is always included into query plan even if it's empty, which can lead to additional overhead. You can use `disable_parent()` if you are never going to use parent table as a storage. Default value depends on the `partition_data` parameter specified during initial partitioning with the `create_range_partitions()` function. If the `partition_data` parameter was `true`, then all data have already been migrated to partitions and the parent table is disabled. Otherwise, it is enabled.

```
set_auto(relation REGCLASS, value BOOLEAN)
```

Enable/disable auto partition propagation (only for range partitioning). It is enabled by default.

```
set_init_callback(relation REGCLASS, callback REGPROCEDURE DEFAULT 0)
```

Set partition creation callback to be invoked for each attached or created partition (both hash and range). If callback is marked with `SECURITY INVOKER`, it is executed with the privileges of the user who produced a statement that has led to creation of a new partition. For example:

```
INSERT INTO partitioned_table VALUES (-5)
```

The callback must have the following signature: `part_init_callback(args JSONB) RETURNS VOID`. Parameter `arg` consists of several fields whose presence depends on partitioning type:

```
/* Range-partitioned table abc (child abc_4) */
```

```
{
  "parent":      "abc",
  "parttype":    "2",
  "partition":   "abc_4",
  "range_max":   "401",
  "range_min":   "301"
}
```

```
/* Hash-partitioned table abc (child abc_0) */
```

```
{
  "parent":      "abc",
  "parttype":    "1",
  "partition":   "abc_0"
}
```

```
set_spawn_using_bgw(relation REGCLASS, value BOOLEAN)
```

When inserting new data beyond the partitioning range, use `SpawnPartitionsWorker` to create new partitions in a separate transaction.

```
create_naming_sequence(parent_relid REGCLASS)
```

Enable automatic partition naming for the specified `relation` table. You must run this function when partitioning this table by composite key.

```
add_to_pathman_config(parent_relid    REGCLASS,
                      expression      TEXT,
                      range_interval   TEXT)
add_to_pathman_config(parent_relid    REGCLASS,
                      expression      TEXT)
```

Register the specified `relation` table with `pg_pathman` to enable partitioning by the provided expression. For range partitioning, the `range_interval` argument is mandatory. You can set it to `NULL` if you are going to add partition manually.

```
generate_range_bounds(p_start    ANYELEMENT,  
                      p_interval  INTERVAL,  
                      p_count     INTEGER)
```

```
generate_range_bounds(p_start    ANYELEMENT,  
                      p_interval  ANYELEMENT,  
                      p_count     INTEGER)
```

Build the `bounds` array that defines the bounds for partitions to be created. You can pass this array as an argument to the `create_range_partitions()` function.

F.40. pg_prewarm

The `pg_prewarm` module provides a convenient way to load relation data into either the operating system buffer cache or the Postgres Pro buffer cache.

F.40.1. Functions

```
pg_prewarm(regclass, mode text default 'buffer', fork text default 'main',  
           first_block int8 default null,  
           last_block int8 default null) RETURNS int8
```

The first argument is the relation to be prewarmed. The second argument is the prewarming method to be used, as further discussed below; the third is the relation fork to be prewarmed, usually `main`. The fourth argument is the first block number to prewarm (`NULL` is accepted as a synonym for zero). The fifth argument is the last block number to prewarm (`NULL` means prewarm through the last block in the relation). The return value is the number of blocks prewarmed.

There are three available prewarming methods. `prefetch` issues asynchronous prefetch requests to the operating system, if this is supported, or throws an error otherwise. `read` reads the requested range of blocks; unlike `prefetch`, this is synchronous and supported on all platforms and builds, but may be slower. `buffer` reads the requested range of blocks into the database buffer cache.

Note that with any of these methods, attempting to prewarm more blocks than can be cached — by the OS when using `prefetch` or `read`, or by Postgres Pro when using `buffer` — will likely result in lower-numbered blocks being evicted as higher numbered blocks are read in. Prewarmed data also enjoys no special protection from cache evictions, so it is possible that other system activity may evict the newly prewarmed blocks shortly after they are read; conversely, prewarming may also evict other data from cache. For these reasons, prewarming is typically most useful at startup, when caches are largely empty.

Robert Haas <rhaas@postgresql.org>

F.41. pgpro_scheduler

`pgpro_scheduler` is a built-in Postgres Pro Enterprise extension for scheduling, monitoring, and managing job execution within the Postgres Pro Enterprise database. With `pgpro_scheduler`, you can:

- Set advanced schedules using `jsonb` objects or `crontab` strings.
- Dynamically calculate the next execution time for repeated jobs.
- Execute SQL commands of the job in a single transaction or in sequential transactions, if required.
- Submit jobs for immediate or delayed one-time execution in parallel with the scheduled jobs.

Unlike external scheduling daemons, `pgpro_scheduler` offers the following benefits:

- Any user can schedule jobs independently.
- Job scheduling can be managed on the fly without restarting the database.
- Scheduling is very lightweight since `pgpro_scheduler` uses background workers to schedule, monitor, and manage job execution. At the same time, `pgpro_scheduler` does not require any client connections for scheduling.
- For enhanced stability, each database has its own supervisor scheduler, with each scheduled job executed by a separate background worker.

Note

`pgpro_scheduler` waits in the suspended state on a standby server to be started when the standby is promoted to a master server.

F.41.1. Installation and Setup

The `pgpro_scheduler` extension is included into Postgres Pro Enterprise. Once you have Postgres Pro Enterprise installed, complete the following steps to enable `pgpro_scheduler`:

1. Add `pgpro_scheduler` to the `shared_preload_libraries` parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'pgpro_scheduler'
```

2. Create the `pgpro_scheduler` extension using the following query:

```
CREATE EXTENSION pgpro_scheduler;
```

Make sure to create the `pgpro_scheduler` extension for each database you are planning to use.

Once you complete the installation and setup, configure `pgpro_scheduler` for your database.

F.41.2. Configuration

You must have superuser rights to configure `pgpro_scheduler`.

To configure `pgpro_scheduler`, modify the following settings in the `postgresql.conf` file:

1. Specify the names of the databases for which you need to schedule jobs, in the comma-separated format:

```
schedule.database = 'database1,database2'
```

You can omit this step when using `pgpro_scheduler` on a cluster configured with `multimaster`.

2. To control the workload in your system, set the maximum number of background workers that can run simultaneously on each database:

```
schedule.max_workers = 5
```

3. Optionally, set the number of background workers available for one-time job execution:

```
schedule.max_parallel_workers = 3
```

By default, two background workers for one-time jobs are available. These workers are not included into the `schedule.max_workers` number. Thus, one-time jobs can run in parallel with the scheduled jobs even if all the `schedule.max_workers` workers are busy.

4. Run `pg_reload_conf()` for the changes to take effect:

```
SELECT pg_reload_conf();
```

Important

When setting the `schedule.max_workers` variable, make sure to leave enough workers for the rest of the system as other subsystems may also use background workers. The `schedule.max_workers` value cannot exceed the total number of workers enabled by the `max_worker_processes` PostgreSQL Pro variable.

The `pgpro_scheduler` extension starts a separate background worker for the system, each database, and each executed job. For example, if you work with two databases and set the maximum number of workers and parallel workers to 5 and 3, respectively, `pgpro_scheduler` can use up to 19 workers at peak times: one worker is supervising the system, two workers are monitoring the two databases, and each database uses five workers for job scheduling and three workers for running one-time jobs. If all background workers are busy, the jobs will wait for the next available worker. Scheduled and one-time jobs have separate job queues.

If required, you can later change the number of workers. The running jobs will not be affected.

You can also dynamically configure `pgpro_scheduler` from the command line. In this case, you can set different number of workers for different databases:

```
ALTER SYSTEM SET schedule.database = 'database1,database2';
ALTER DATABASE database1 SET schedule.max_workers = 5;
ALTER DATABASE database2 SET schedule.max_workers = 3;
ALTER SYSTEM SET schedule.max_parallel_workers = 3;
SELECT pg_reload_conf();
```

Once `pgpro_scheduler` is configured, enable it on your system, as follows:

```
SELECT schedule.enable();
```

If this function returns `true`, `pgpro_scheduler` is ready to use, and you can start scheduling jobs as explained in [Section F.41.3.1](#) and [Section F.41.3.2](#).

Note

If you restart the server, `pgpro_scheduler` is not automatically restarted by default. To change this behavior, you can set the `schedule.auto_enabled` parameter to `on`.

F.41.3. Usage

F.41.3.1. Creating Scheduled Jobs

To create and schedule a job, run the `create_job()` function that takes scheduling options as a `jsonb` object:

```
schedule.create_job(options jsonb)
```

In the `jsonb` object, you must specify one or more SQL commands in the `commands` key, and set the job schedule with at least one of the following keys:

- `dates` — a single date or an array of dates, in the `timestamp with time zone` format
- `cron` — a string, in the `crontab` format. A traditional five-field `crontab` format is used. The first field stands for minute, the second — for hour, the third — for day of the month, the fourth — for

month, and the fifth — for day of the week. A six-field `crontab` format can be used alongside the traditional five-field format. In this case the first field stands for second. When you use the six-field format and do not want to specify a second you have to put 0 in the first field.

Alternatively, the following keywords can be used instead of a `crontab` string to specify when the job will be started:

- `@every_second` — each second
- `@hourly` — at the beginning of each hour
- `@daily` — at the beginning of each day
- `@midnight` — at the beginning of each day
- `@weekly` — at the beginning of each week
- `@monthly` — at the beginning of each month
- `@yearly` — at the beginning of each year
- `@annually` — at the beginning of each year
- `rule` — a `jsonb` object that includes one or more of the following keys:
 - `seconds` — seconds; an array of integers in range [0, 59]
 - `minutes` — minutes; an array of integers in range [0, 59]
 - `hours` — hours; an array of integers in range [0, 23]
 - `days` — days of the month; an array of integers in range [1, 31]
 - `months` — months; an array of integers in range [1, 12]
 - `wdays` — days of the week; an array of integers in range [0, 6], where 0 is Sunday.
 - `onstart` — integer value 0 or 1. If `onstart` is set to 1, the job is executed only once when `pgpro_scheduler` is started.

You can combine `dates`, `cron`, and `rule` scheduling keys for advanced use cases.

As a result, `pgpro_scheduler` creates an active job with the specified schedule and returns the job ID.

Tip

For simple job schedules, you can use the following shortcut syntax:

```
schedule.create_job(cron, commands)
schedule.create_job(dates, commands)
```

For details, see [schedule.create_job\(\)](#) function description.

If required, you can later modify one or more scheduling options with the `set_job_attribute()` or `set_job_attributes()` functions, respectively.

If all background workers are busy at the specified time, the job waits for the next available worker. By default, the job can wait forever. You can limit the maximum wait time by setting the `last_start_available` key, in the [time interval](#) format. If the timeout is reached, `pgpro_scheduler` cancels the job execution.

Examples:

To run the job every day at 3pm, and, additionally, on December 31, 2017 at 7pm , and on April 4, 2020 at 1pm:

```
SELECT schedule.create_job('{ "commands": "SELECT 15", "cron": "0 15 * * *", "dates":  
[ "2017-12-31 19:00", "2020-04-04 13:00" ]}');
```

To limit the wait time for job execution to 30 seconds after the scheduled time:

```
SELECT schedule.create_job('{ "commands": "SELECT pg_sleep(100)", "cron": "15 */2 * *  
*", "last_start_available": "30 seconds" }');
```

F.41.3.1.1. Specifying the Time Window for Job Execution

In addition to the general schedule, you can specify the timeframe during which the scheduled job can be executed. To ensure that `pgpro_scheduler` only executes the job within the specified time window, define the `start_date` and `end_date` keys, in the timestamp with time zone format. You can set one of these keys only to limit the start or the end time, respectively. If you define a time window for the job, `pgpro_scheduler` will only schedule this job within this time window. If the started job is incomplete when the specified time window ends, `pgpro_scheduler` completes the job and then excludes the job from further scheduling.

Examples:

To start scheduling the job only after 11am on May 1, 2017:

```
SELECT schedule.create_job('{ "commands": "SELECT now()", "cron": "2 17 * * *",  
"start_date": "2017-05-01 11:00" }');
```

To schedule the job in the timeframe from 11am on May 1 to 3pm on June 4, 2017:

```
SELECT schedule.create_job('{ "commands": "SELECT now()", "cron": "2 17 * * *",  
"start_date": "2017-05-01 11:00", "end_date": "2017-06-04 15:00" }');
```

F.41.3.1.2. Running SQL Commands in Separate Transactions

The `commands` key can have values of text and array types. If you specify several SQL commands as text separated by semicolons, the whole job is executed in a single transaction. If it is critical to perform each SQL command in a separate transaction, pass the SQL commands as an array. You can modify this behavior by setting the `use_same_transaction` key to `true`. In this case, SQL commands in the array are executed in a single transaction.

Examples:

To run the whole job in a single transaction:

```
SELECT schedule.create_job('{ "commands": "SELECT 1; SELECT 2; SELECT 3;", "cron": "23  
23 */2 * *" }');
```

To run commands in separate transactions:

```
SELECT schedule.create_job('{ "commands": [ "SELECT 1", "SELECT 2", "SELECT 3" ],  
"cron": "23 23 */2 * *" }');
```

To run the whole job in a single transaction when passing the commands as an array:

```
SELECT schedule.create_job('{ "commands": [ "SELECT 1", "SELECT 2", "SELECT 3" ],  
"cron": "23 23 */2 * *", "use_same_transaction": true }');
```

F.41.3.1.3. Calculating the Next Start Time of the Scheduled Job

For repeated jobs, the next start time can be computed by an SQL statement specified in the `next_time_statement` key. In this case, the first job starts on schedule, while all the successive job runs occur at the computed times.

After the job run completes, `pgpro_scheduler` executes the SQL statement in the `next_time_statement` key to calculate the next start time and returns the result, in the timestamp with time zone type. If the return value is of a different type or an error occurs, `pgpro_scheduler` marks the job as broken and cancels any further execution. This process is repeated for each successive job run.

Tip

When the job run completes, `pgpro_scheduler` sets the transaction state in the `schedule.transaction_state` variable, in the text format. You can use this variable in your `next_time_statement` to dynamically calculate the next start time depending on the transaction state. At the time of the `next_time_statement` execution, the `schedule.transaction_state` variable must contain either success or failure state values for the main transaction. Other values may indicate an internal `pgpro_scheduler` error.

Examples:

To run the job first at 10:45, and then in a day after the job completes:

```
SELECT schedule.create_job('{ "commands": "SELECT random()", "cron": "45 10 * * *",
"next_time_statement": "SELECT now() + ''1 day''::interval" }');
```

F.41.3.1.4. Setting Additional Conditions for Job Execution

The `pgpro_scheduler` extension enables you to define additional conditions for task execution:

- Set time limits for job execution with the `max_run_time` key. If the execution time is exceeded, `pgpro_scheduler` cancels the job.
- Define the maximum time a scheduled job can wait for execution using the `last_start_available` key. If the timeout is reached, `pgpro_scheduler` cancels the job.
- Schedule a job on behalf of another user with the `run_as` key. You must have superuser rights to use this key.
- Define an SQL command to execute if the main command fails using the `onrollback` key.

Examples:

To limit job execution to 5 seconds:

```
SELECT schedule.create_job('{ "commands": "SELECT pg_sleep(10)", "cron": "15 */10 * *
* ", "max_run_time": "5 seconds" }');
```

To limit the wait time for job execution to 30 seconds after the scheduled time:

```
SELECT schedule.create_job('{ "commands": "SELECT pg_sleep(100)", "cron": "15 */2 * *
* ", "last_start_available": "30 seconds" }');
```

To start the job on behalf of the `robot` user:

```
SELECT schedule.create_job('{ "commands": "SELECT session_user", "cron": "5 */5 * * *",
"run_as": "robot" }');
```

To define a fallback SQL command in case the main command fails:

```
SELECT schedule.create_job('{ "commands": "SELECT ''zzz''", "cron": "55 */12 * * *",
"onrollback": "SELECT ''Cannot select zzz''" }');
```

F.41.3.2. Submitting One-Time Jobs

You can submit jobs for one-time execution using the `schedule.submit_job()` function. Such jobs use a separate pool of background workers defined by the `schedule.max_parallel_workers` variable, and can run in parallel with the scheduled jobs. By default, two one-time jobs can run concurrently. If you submit more jobs, they will wait in the queue for the next available background worker.

To execute a one-time job immediately, pass SQL commands in the `query` argument. For example:

```
schedule.submit_job(query := 'select 1');
```

Instead of passing SQL query parameters directly, you can define numbered placeholders in the *query* argument, such as \$1 and \$2, and pass an array of parameters in the *params* argument, with each array element corresponding to a placeholder. For brevity, you can omit the *query* and *params* names:

```
schedule.submit_job(query := 'select $1, $2', params := '{"text 1", "text 2"}')
```

To start a one-time job at the specified time, use the *run_after* argument:

```
schedule.submit_job('select ''flowers'', run_after := '2017-03-08 08:00:01');
```

Alternatively, you can delay the job start until the specified jobs are complete using the *depends_on* argument. For example, to run a job after completing the jobs with 23, 15, and 334 IDs, run:

```
schedule.submit_job('select ''well done'', depends_on := '{23, 15, 334}')
```

If required, you can repeat the job execution by passing the `schedule.resubmit()` function as part of the *query* argument. For example:

```
schedule.submit_job('select 1, schedule.resubmit(run_after := ''5'')');
```

The *run_after* argument specifies the time interval before the job is restarted, in seconds. By default, the interval is 1 second.

The resubmitted job cannot be executed more than the number of times set in the *resubmit_limit* argument. If this limit is reached, the job receives the *done* status, with the corresponding error message.

If you want to cancel a resubmitted job, run:

```
schedule.cancel_job(job_id bigint);
```

To monitor one-time jobs, use the [job_status](#) and [all_job_status](#) `pgpro_scheduler` views.

For details on all the functions available for managing one-time jobs, see [Section F.41.4.6.3](#).

F.41.3.3. Changing and Removing Scheduled Jobs

When you create a new job with the `create_job()` function, the job becomes active and waits for execution based on the specified schedule. Using the job ID returned by the `create_job()` function, you can change the scheduling settings or remove the job from the schedule. To change the specified schedule for the jobs, use `set_job_attribute()` or `set_job_attributes()` functions:

- To modify a single property of the job, run the `set_job_attribute()` function with the job ID, the property name to change, and the new value for this property.
- To modify more than one property of the job, run the `set_job_attributes()` function instead. In this case, you can specify all the job properties at once in a `jsonb` object. For details on all the keys available for job scheduling, see the `create_job()` function description.

To temporarily exclude the job from scheduling, run the `deactivate_job()` function:

```
schedule.deactivate_job(job_id integer)
```

You can re-activate the job later by running the `activate_job()` function:

```
schedule.activate_job(job_id integer)
```

To permanently remove the job from the schedule, run the `drop_job()` function:

```
schedule.drop_job(job_id integer)
```

F.41.3.4. Monitoring Scheduled Jobs

You must have superuser rights to monitor job execution for the whole system. Otherwise, you can only monitor the jobs that you own. To monitor scheduled jobs, `pgpro_scheduler` provides multiple functions that return `cron_rec` or `cron_job` records:

- `get_job()` — retrieves information about the job.

- `get_owned_cron()` — retrieves the list of jobs owned by user.
- `get_cron()` — retrieves the list of jobs executed by user.
- `get_active_jobs()` — returns the list of jobs executed at the moment of the function call.
- `get_log()` — returns the list of all completed jobs.
- `get_user_log()` — returns list of the completed jobs executed by the specified user.
- `clean_log()` — deletes all records with information about completed jobs.

To learn more about each function, see [Section F.41.4.6](#).

F.41.3.5. Auditing Job Scheduling

`pgpro_scheduler` enables you to audit job scheduling to rule out human error if you observe unexpected changes in scheduled job execution.

By default, `pgpro_scheduler` does not store information on schedule changes. To enable this feature, set the [`schedule.enable\_history`](#) parameter to `true`. Once this parameter is enabled, `pgpro_scheduler` stores schedule modifications in the `schedule.cron_history` table, and logs all deleted jobs in the `schedule.cron_deleted` table. Logged history is never deleted from these tables, so a superuser can review schedule changes introduced by all users at any time.

For details on logged information, see [Section F.41.4.5](#).

F.41.3.6. Scheduling Jobs on a Multi-Master Cluster

Using `pgpro_scheduler`, you can manage scheduled and one-time jobs on a cluster configured with [Section F.31](#). `pgpro_scheduler` can only manage jobs on the node on which it is installed. Thus, you must install and enable `pgpro_scheduler` on all nodes on which you would like to schedule jobs. `pgpro_scheduler` instances will manage jobs on different nodes independently, but the executed jobs will be replicated to other nodes.

Even if you are planning to schedule jobs on a single node only, it is recommended to enable `pgpro_scheduler` on several nodes. In this case, if a node with scheduled jobs fails, another `pgpro_scheduler` instance picks up these jobs. If `pgpro_scheduler` is running on more than one node, the node with the smallest node ID is selected. The naming pattern of node IDs is defined by the [`schedule.nodename`](#) GUC variable.

F.41.4. Reference

F.41.4.1. GUC Variables

`schedule.enabled` (boolean)

Deprecated. Specifies whether `pgpro_scheduler` is enabled on your system.

Default: `false`.

For `pgpro_scheduler` 2.5 or higher, you can set the [`schedule.auto\_enabled`](#) parameter to control whether `pgpro_scheduler` is enabled at the server start, or use `schedule.enable()`/`schedule.disable()` functions to enable/disable `pgpro_scheduler` on demand. To check if `pgpro_scheduler` is currently running, use the `schedule.is_enabled()` function.

`schedule.auto_enabled` (boolean)

Specifies whether to enable `pgpro_scheduler` at the server start.

Default: `false`.

`schedule.database` (text)

Specifies the databases for which `pgpro_scheduler` is enabled. Database names must be separated by commas.

If `pgpro_scheduler` is running on a cluster configured with `multimaster`, the database name is derived from the `multimaster.conn_strings` variable.

Default: empty string.

`schedule.database_to_connect` (text)

The database to which `pgpro_scheduler` gets connected to receive Postgres Pro Enterprise cluster metadata. The specified database cannot be dropped while `pgpro_scheduler` is running. You can change this parameter only when restarting the server.

Default: `postgres`.

`schedule.schema` (text)

Deprecated. Specifies the name of a schema where the scheduler stores its tables and functions. If you need to change the default schema, use `ALTER EXTENSION`.

Default: `schedule`.

`schedule.nodename` (text)

Specifies the name of the cluster node on which `pgpro_scheduler` is running. Do not change or use this variable if you run a single-server cluster configuration.

On a cluster configured with `multimaster`, the node name is derived from the `multimaster.node_id` variable. For example, if `multimaster.node_id = 3`, the `schedule.nodename` variable is set to `mtm-node-3`. However, if you explicitly set the `schedule.nodename` variable by editing the `postgresql.conf` file or running the `ALTER` command, `pgpro_scheduler` will use the provided value, ignoring the `multimaster.node_id` variable.

Default: `master`.

`schedule.max_workers` (integer)

Specifies the maximum number of simultaneously running scheduled jobs in one database.

Default: 2.

`schedule.max_parallel_workers` (integer)

Specifies the maximum number of parallel threads that can be used for executing one-time jobs.

Default: 2.

`schedule.transaction_state` (text)

An internal variable containing the state of the executed job. `pgpro_scheduler` uses this variable when calculating the next job start time. Possible values are:

- `success` — transaction has finished successfully.
- `failure` — transaction has failed to finish.
- `running` — transaction is in progress.
- `undefined` — transaction has not started yet.

At the time of the `next_time_statement` execution, the `schedule.transaction_state` variable must contain either `success` or `failure` state values. Other values may indicate an internal `pgpro_scheduler` error.

`schedule.enable_history` (boolean)

Log all schedule changes, including the name of the user who initiated the change and the time when this change occurred. If a new job is added, or the schedule of an existing job is modified, this information is stored in the `schedule.cron__history` table. If a job is deleted, this information

is stored in the `schedule.cron__deleted` table. If you later disable the `schedule.enable_history` parameter, the history of the already recorded changes is preserved.

Default: `false`

F.41.4.2. SQL Schema

To store its internal tables and functions, `pgpro_scheduler` uses the `schedule` SQL schema. Direct access to tables is not recommended and should not be attempted. To manage job scheduling, use the functions defined by the `pgpro_scheduler` extension.

F.41.4.3. SQL Types

`pgpro_scheduler` defines the following types that are used by some of the `pgpro_scheduler` functions.

F.41.4.3.1. `cron_rec`

This type contains information about the scheduled job.

```
CREATE TYPE schedule.cron_rec AS(
    id integer,           -- job ID
    node text,            -- name of the node
                        -- on which to execute the job
    name text,            -- job name
    comments text,        -- comments about the job
    rule jsonb,           -- scheduling rules
    commands text[],      -- SQL commands to be executed
    run_as text,          -- username of the job executor
    owner text,           -- username of the job owner
    start_date timestamptz, -- lower bound of the execution window;
                        -- NULL if unbound
    end_date timestamptz,  -- upper bound of the execution window;
                        -- NULL if unbound
    use_same_transaction boolean, -- true if an array of SQL
                        -- commands will be executed
                        -- in a single transaction
    last_start_available interval, -- maximum wait time for
                        -- the scheduled job if all
                        -- allowed workers are busy
    max_run_time interval, -- maximum execution time
    onrollback text,       -- SQL statement to execute
                        -- if the main transaction fails
    max_instances int,     -- maximum number of simultaneously
                        -- running job instances
    next_time_statement text, -- SQL statement to calculate
                        -- the next start time
    active boolean,        -- true if job is scheduled
                        -- successfully
    broken boolean         -- true if job has errors in
                        -- configuration that prevented
                        -- its further execution
);
```

F.41.4.3.2. `cron_job`

This type contains information about a particular job execution.

```
CREATE TYPE schedule.cron_job AS(
    cron integer,         -- job id
    node text,            -- name of the node
                        -- on which to execute the job
    scheduled_at timestamptz, -- scheduled execution time
```

```
name text,           -- job name
comments text,       -- comments about the job
commands text[],     -- SQL statement to be executed
run_as text,         -- username of the job executor
owner text,          -- username of the job owner
use_same_transaction boolean, -- true if an array of SQL
                        -- commands will be executed
                        -- in a single transaction
started timestampz,  -- timestamp of the job execution start
last_start_available timestamp, -- maximum wait time for
                        -- the scheduled job if all
                        -- allowed workers are busy
finished timestampz, -- timestamp of the job
                        -- execution finish
max_run_time interval, -- maximum execution time
onrollback text,     -- SQL statement to execute if the main
                        -- transaction fails
next_time_statement text, -- SQL statement to calculate
                        -- the next start time
max_instances int,   -- the number of simultaneously
                        -- running job instances
status job_status_t, -- status of the task:
                        -- working, done, or error
message text         -- error message
);
```

F.41.4.3.3. `job_status_t`

Enumerated type. Can take the following values:

- `working` — the job is being executed.
- `done` — job execution is complete.
- `error` — job execution has failed.

F.41.4.3.4. `job_at_status_t`

Enumerated type. Can take the following values:

- `submitted` — the job is submitted into the queue, but the execution has not started yet.
- `processing` — the job is being executed.
- `done` — job execution is complete.

F.41.4.4. Views

`pgpro_scheduler` provides several views for monitoring execution status of one-time jobs.

F.41.4.4.1. `job_status` View

Shows the status of one-time jobs belonging to the current user.

Table F.28. `job_status` View

Column Name	Column Type	Description
<code>id</code>	<code>bigint</code>	Job ID.
<code>node</code>	<code>text</code>	Name of the node on which the job is being executed.
<code>name</code>	<code>text</code>	Name of the job.
<code>comments</code>	<code>text</code>	Comments about the job.

Column Name	Column Type	Description
run_after	timestamp with time zone	Timestamp after which the job execution must start.
query	text	SQL commands executed by the job.
params	text[]	An array of parameters for the SQL query.
depends_on	bigint[]	An array of job IDs on which the job execution depends.
run_as	text	User or role with whose rights the job will be executed.
attempt	bigint	The number of execution attempts.
resubmit_limit	bigint	The maximum number of allowed job resubmissions.
max_wait_interval	interval	The maximum time interval to postpone the job execution if all background workers are busy at the scheduled moment.
max_duration	interval	Time interval during which the job can be executed.
submit_time	timestamp with time zone	Time when the job was submitted to the execution queue.
canceled	boolean	Specifies whether the job was canceled by user.
start_time	timestamp with time zone	Job execution start time.
is_success	boolean	- true — job execution completed successfully. - false — job execution completed with errors.
error	text	Error message.
done_time	timestamp with time zone	Time when the job execution completed.
status	job_at_status_t	Job status. See the Section F.41.4.3.4 for details.

F.41.4.4.2. all_job_status View

Shows the status of all one-time jobs. You must have superuser rights to access this view.

Table F.29. all_job_status View

Column Name	Column Type	Description
id	bigint	Job ID.
node	text	Name of the node on which the job is being executed.
name	text	Name of the job.
comments	text	Comments about the job.
run_after	timestamp with time zone	Timestamp after which the job execution must start.

Column Name	Column Type	Description
query	text	SQL commands executed by the job.
params	text[]	An array of parameters for the SQL query.
depends_on	bigint[]	An array of job IDs on which the job execution depends.
run_as	text	User or role with whose rights the job will be executed.
owner	text	The user who created the job.
attempt	bigint	The number of execution attempts.
resubmit_limit	bigint	The maximum number of allowed job resubmissions.
max_wait_interval	interval	The maximum time interval to postpone the job execution for if all background workers are busy at the scheduled moment.
max_duration	interval	Time interval during which the job can be executed.
submit_time	timestamp with time zone	Time when the job was submitted to the execution queue.
canceled	boolean	Specifies whether the job was canceled by user.
start_time	timestamp with time zone	Job execution start time.
is_success	boolean	• <code>true</code> — job execution completed successfully. • <code>false</code> — job execution completed with errors.
error	text	Error message.
done_time	timestamp with time zone	Time when the job execution completed.
status	job_at_status_t	Job status. See the Section F.41.4.3.4 for details.

F.41.4.5. Audit Tables

The following tables store all schedule changes if the `schedule.enable_history` parameter is set to `true`. If you later disable the `schedule.enable_history` parameter, the history of the already recorded changes is preserved.

F.41.4.5.1. `schedule.cron_history` Table

Registers job scheduling changes. Whenever a new job is scheduled, or the schedule for an existing job is changed, a new row is inserted into this table to record the following information:

- All details about the scheduled job, as defined by the `cron_rec` data type. For details on the `cron_rec` type, see [Section F.41.4.3](#).
- `submitter` — name of the user who updated the schedule.
- `version_id` — a unique ID for each registered change in the schedule.
- `submit_time` — time when the schedule was updated.

F.41.4.5.2. `schedule.cron__deleted` Table

Registers all jobs that were removed from the schedule:

- `cron` — ID of the deleted job.
- `submitter` — name of the user who deleted the job.
- `submit_time` — time when the job was deleted.

F.41.4.6. Functions

`pgpro_scheduler` provides two separate sets of functions for managing scheduled and one-time jobs, as well as several common functions that can toggle `pgpro_scheduler` on and off for your database and show the current status of the extension:

- [Section F.41.4.6.1](#)
- [Section F.41.4.6.2](#)
- [Section F.41.4.6.3](#)

Important

With each job, you can only use the function specifically tailored for this job type.

F.41.4.6.1. Common Functions

These functions facilitate `pgpro_scheduler` management.

`schedule.enable()`

Enables `pgpro_scheduler` for the current Postgres Pro Enterprise instance.

Return values:

- `true` if `pgpro_scheduler` is enabled and ready to use.
- `false` if the command has failed.

`schedule.is_enabled()`

Checks whether `pgpro_scheduler` is enabled.

Return values:

- `true` if `pgpro_scheduler` is enabled and ready to use.
- `false` if `pgpro_scheduler` is not currently running.

`schedule.disable()`

Disables `pgpro_scheduler` for the current Postgres Pro Enterprise instance.

Return values:

- `true` if `pgpro_scheduler` is disabled.
- `false` if the command has failed.

`schedule.start()`

Launches `pgpro_scheduler` for the currently connected database.

Return values:

- `true` — `pgpro_scheduler` started successfully.
- `false` — if the command has failed, or `pgpro_scheduler` is already started.

```
schedule.stop()
```

Stops `pgpro_scheduler` for the currently connected database.

Return values:

- `true` — `pgpro_scheduler` is stopped.
- `false` — if the command has failed, or `pgpro_scheduler` is not running.

```
schedule.status()
```

Returns the status of `pgpro_scheduler` background workers:

- `pid` — process ID of the background worker. If the process ID is `NULL`, the background worker is not running.
- `database` — name of the database to which the background worker is connected.
- `type` — type of the background worker:
 - `supervisor` — distributes the scheduled jobs between the databases.
 - `database manager` distributes the scheduled jobs within the database.
 - `cron job executor` executes a scheduled job.
 - `at job executor` executes a one-time job.

```
schedule.version()
```

Returns `pgpro_scheduler` version.

F.41.4.6.2. Functions for Managing Scheduled Jobs

```
schedule.create_job(options jsonb)
```

Creates an active job and returns the job ID.

Alternative Syntax:

```
schedule.create_job(cron text, commands text [, node text])
schedule.create_job(cron text, commands text[] [, node text])
schedule.create_job(dates timestamp with time zone, commands text [, node text])
schedule.create_job(dates timestamp with time zone, commands text[] [, node text])
schedule.create_job(dates timestamp with time zone[], commands text [, node text])
schedule.create_job(dates timestamp with time zone[], commands text[] [, node text])
```

Arguments:

- `options` — a `jsonb` object defining all the job properties. You do not need to define other parameters if the `data` is set. All the available `jsonb` keys are listed in [Table F.30](#).

Type: `jsonb`

- `cron` — a crontab-like string defining the job schedule.

Type: `text`

- `dates` — the exact date or an array of dates for job execution.

Type: `timestamp with time zone, timestamp with time zone[]`

- `commands` — SQL statement to execute. You can pass one or more SQL commands separated by semicolons, or an array of SQL commands. When passed as an array, SQL commands are executed in separate transactions.

Type: `text, text[]`

- `node` — the name of the node on which the scheduled jobs run. Optional. You may need to specify this argument if you are scheduling jobs on a multi-master cluster.

Type: `text`

Return values:

- ID of the created job.

Table F.30. jsonb Keys for Job Scheduling

Key	Type	Description
cron	text	A crontab-like string defining the job schedule. A traditional five-field or nonstandard six-field (seconds in the first field) crontab format may be used. You can combine <code>cron</code> with <code>rule</code> and <code>dates</code> keys, but at least one of them is mandatory. Alternatively, the following keywords can be used instead of a crontab string to specify when the job will be started: • <code>@every_second</code> — each second • <code>@hourly</code> — at the beginning of each hour • <code>@daily</code> — at the beginning of each day • <code>@midnight</code> — at the beginning of each day • <code>@weekly</code> — at the beginning of each week • <code>@monthly</code> — at the beginning of each month • <code>@yearly</code> — at the beginning of each year • <code>@annually</code> — at the beginning of each year
dates	timestamp with time zone, timestamp with time zone[]	The exact date or an array of dates when the scheduled job will be executed. You can combine <code>dates</code> with <code>rule</code> and <code>cron</code> keys, but at least one of them is mandatory.
rule	jsonb	A jsonb object defining the job schedule. Mandatory, if both <code>cron</code> and <code>dates</code> keys are undefined. The <code>rule</code> object includes one or more of the following keys: • <code>seconds</code> — seconds; an array of integers in range [0, 59] • <code>minutes</code> — minutes; an array of integers in range [0, 59]

Key	Type	Description
		<code>hours</code> — hours; an array of integers in range [0, 23] <code>days</code> — days of the month; an array of integers in range [1, 31] <code>months</code> — months; an array of integers in range [1, 12] <code>wdays</code> — days of the week; an array of integers in range [0, 6], where 0 is Sunday. <code>onstart</code> — integer value 0 or 1. If <code>onstart</code> is set to 1, the job is executed only once when <code>pgpro_scheduler</code> is started.
<code>commands</code>	<code>text, text []</code>	SQL statements to execute. You can pass one or more SQL statements separated by semicolons, or an array of SQL statements. When passed as an array, SQL statements are executed in separate transactions by default. You can change this behavior by setting the <code>use_same_transaction</code> key.
<code>name</code>	<code>text</code>	Optional. Job name.
<code>node</code>	<code>text</code>	Optional. The name of the node on which the scheduled jobs run. You may need to specify this argument if you are scheduling jobs on a multi-master cluster.
<code>comments</code>	<code>text</code>	Optional. Comments about the scheduled job.
<code>run_as</code>	<code>text</code>	Optional. The user to execute command(s).
<code>start_date</code>	<code>timestamp with time zone</code>	Optional. The start of the timeframe when the scheduled job can be executed. This key can be <code>NULL</code> .
<code>end_date</code>	<code>timestamp with time zone</code>	Optional. The end of the timeframe when the scheduled job can be executed. This key can be <code>NULL</code> .
<code>use_same_transaction</code>	<code>boolean</code>	Optional. If set to <code>true</code> , forces an array of SQL statements to be executed in a single transaction. Default: <code>false</code>
<code>last_start_available</code>	<code>interval</code>	Optional. The maximum time interval to postpone the

Key	Type	Description
		job execution for if all background workers are busy at the scheduled moment. For example, if this key is set to '00:02:34', the job will wait for 2 minutes 34 seconds. If this key is <code>NULL</code> or not set, the job can wait forever. Default: <code>NULL</code> .
<code>max_instances</code>	<code>integer</code>	Optional. The maximum number of job instances that can be executed simultaneously. Default: 1.
<code>max_run_time</code>	<code>interval</code>	Optional. The maximum time interval during which the scheduled job can be executed. If this key is <code>NULL</code> or not set, there are no time limits. Default: <code>NULL</code> .
<code>onrollback</code>	<code>text</code>	Optional. SQL statement to be executed if the main transaction fails.
<code>next_time_statement</code>	<code>text</code>	Optional. SQL statement to calculate the start time for the next job execution. For details, see Section F.41.3.1.3 .

```
schedule.set_job_attributes(job_id integer, data jsonb)
```

Updates properties of the existing job.

Arguments:

- `job_id` — identifier of the existing job.
- `data` — a `jsonb` object with properties to be edited. For the list of keys and their structure, see [Table F.30](#).

Return values:

- `true` — job properties were updated successfully.
- `false` — job properties were not updated.

To update the job properties, you must be the owner of the job or have superuser rights.

```
schedule.set_job_attribute(job_id integer, name text, value text || anyarray)
```

Updates a property of the existing job.

Arguments:

- `job_id` — identifier of the existing job.
- `name` — property name.
- `value` — property value.

See [Table F.30](#) for the list of job properties you can update. Some values are of array types. They should be passed as an array. If a value of a wrong type is passed, an exception is raised.

Return values:

- *true* — job property was updated successfully.
- *false* — job property was not updated.

To update the job properties, you must be the owner of the job or have superuser rights.

```
schedule.deactivate_job(job_id integer)
```

Deactivates the job and suspends its further scheduling and execution.

Arguments:

- *job_id* — identifier of the existing job.

Return values:

- *true* — the job is deactivated successfully.
- *false* — job deactivation failed.

```
schedule.activate_job(job_id integer)
```

Activates a job and starts its scheduling and execution.

Arguments:

- *job_id* — identifier of the existing job.

Return values:

- *true* — the job was activated successfully.
- *false* — job activation failed.

```
schedule.drop_job(job_id integer)
```

Deletes a job.

Arguments:

- *job_id* — identifier of the existing job.

Return values:

- *true* — the job was deleted successfully.
- *false* — job was not deleted.

```
schedule.get_job(job_id integer)
```

Returns information about the specified job.

Arguments:

- *job_id* — identifier of the existing job.

Return values:

- An object of type `cron_rec`.

For details on the `cron_rec` type, see [Section F.41.4.3](#).

```
schedule.get_owned_cron(username text)
```

Retrieves the list of jobs owned by the specified user.

Arguments:

- *username* — username, optional.

Return values:

- A set of records of type `cron_rec`. These records contain information about all jobs owned by the specified user. If the *username* is omitted, the session username is used. You must have superuser rights to retrieve jobs owned by another user.

For details on the `cron_rec` type, see [Section F.41.4.3](#).

```
schedule.get_cron(username text)
```

Retrieves the list of jobs executed by the specified user.

Arguments:

- *username* — username, optional.

Return values:

- A set of records of type `cron_rec`. These records contain information about all jobs executed by the specified user. If *username* is omitted, the session username is used. You must have superuser rights to retrieve jobs executed by another user.

For details on the `cron_rec` type, see [Section F.41.4.3](#).

```
schedule.get_active_jobs(username text)
```

Returns the list of jobs currently being executed by the specified user.

Arguments:

- *username* — username, optional.

If *username* is omitted, the session username is used. You must have superuser rights to retrieve jobs executed by another user.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see [Section F.41.4.3](#).

```
schedule.get_active_jobs()
```

Returns the list of jobs being currently executed. You must have superuser rights to call this function.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see [Section F.41.4.3](#).

```
schedule.get_log()
```

Returns the list of all completed jobs. You must have superuser rights to call this function.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see [Section F.41.4.3](#).

```
schedule.get_user_log(username text)
```

Returns the list of completed jobs executed by the specified user.

Arguments:

- *username* — username, optional.

If *username* is omitted, the session username is used. You must have superuser rights to retrieve the list of jobs executed by another user.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see [Section F.41.4.3](#).

```
schedule.clean_log()
```

Deletes all records with information about the completed jobs. You must have superuser rights to call this function.

Return values:

- The number of records deleted.

```
schedule.nodename()
```

Returns the current node name.

F.41.4.6.3. Functions for Managing One-Time Jobs

```
schedule.submit_job(query text [options...])
```

Submits a job for immediate or delayed one-time execution. By default, the job is scheduled for immediate execution and can run in parallel with other scheduled jobs. To submit a job with a delayed start, you can set the execution start time using the *run_after* argument, or pass an array of job IDs in the *depends_on* argument to schedule job execution right after these jobs are complete.

Arguments:

- *query* — SQL commands to execute.

Type: text

- *params* — an array of parameters for the SQL query that can substitute numbered placeholders in the *query* argument, such as \$1, \$2, etc. Default: NULL

Type: text[]

- *run_after* — a timestamp after which the job execution starts. If this argument is set to NULL, the job is scheduled for immediate execution. You can also use the *depends_on* argument to delay the job start. Default: NULL

Type: timestamp with time zone

- *node* — the name of the node on which to execute the job. Default: NULL

Type: text

- *max_duration* — the maximum time interval during which the job can be executed. If this time is exceeded, the job is forced to stop. If this argument is NULL or not set, there are no time limits. Default: NULL

Type: interval

- *max_wait_interval* — the maximum time interval to postpone the job execution for if all background workers are busy at the scheduled moment. For example, if this key is set to '00:02:34', the job will wait for 2 minutes 34 seconds. If this key is `NULL` or not set, the job can wait forever. Default: `NULL`

Type: interval

- *run_as* — user or role with whose rights the job will be executed. If *run_as* is set to `NULL`, the job is executed on behalf of the current user. You must have superuser rights to set this argument. Default: `NULL`

Type: text

- *depends_on* — an array of job IDs. The created job starts immediately after the specified jobs complete the execution. This argument is an alternative to *run_after*. Default: `NULL`

Type: bigint[]

- *name* — name of the job. Default: `NULL`

Type: text

- *comments* — comments about the job.

Type: text

- *resubmit_limit* — maximum number of times the job can be resubmitted for execution. See the `schedule.resubmit()` function for details. Default: 100

Type: bigint

Return values:

- ID of the created job.

Type: bigint

`schedule.get_self_id()`

Returns the ID of the job, in the context of which it was called. The returned ID is of the `bigint` type. This function must be called inside the *query* of the `schedule.submit_job()` function. Otherwise, an exception is raised.

Return values:

- Job ID.

`schedule.cancel_job(job_id bigint)`

Cancels all subsequent runs of the specified job. If the job is currently being executed, it will not be interrupted, but cannot be resubmitted. You must have superuser rights or be the owner of the job to call this function.

Arguments:

- *job_id* — identifier of the job to cancel.

Return values:

- `true` if the operation completed successfully.
- `false` if the operation failed.

`schedule.resubmit(run_after interval default NULL)`

Sets the start time for the next execution of the job, without interrupting the current job run. This function must be called inside the *query* argument of the `schedule.submit_job()` function.

Otherwise, an exception is raised. If this function is called several times within a single job execution, only the last function call is taken into account.

Arguments:

- *run_after* — time interval after which the job will be resubmitted for execution. Default: 1 second

Type: `interval`

Return values:

- The number of seconds after which the job will be resubmitted for execution.

F.41.5. Authors

Postgres Professional, Moscow, Russia

F.42. `pg_query_state`

The `pg_query_state` module provides facility to know the current state of query execution on working backend.

F.42.1. Overview

Each non-utility query statement (SELECT/INSERT/UPDATE/DELETE) after optimization/planning stage is translated into plan tree, which is kind of imperative representation of declarative SQL query. EXPLAIN ANALYZE request allows to demonstrate execution statistics gathered from each node of plan tree (full time of execution, number of rows emitted to upper nodes, etc). But this statistics is collected after execution of query. This module allows to show actual statistics of query running on external backend. At that, format of resulting output is almost identical to ordinal EXPLAIN ANALYZE. Thus users are able to track of query execution in progress. In fact, this module is able to explore external backend and determine its actual state. Particularly it's helpful when backend executes a heavy query or gets stuck.

F.42.2. Use cases

Using this module there can help in the following things:

- detect a long query (along with other monitoring tools);
- supervise query execution.

F.42.3. Installation

To install `pg_query_state` run in `psql`:

```
CREATE EXTENSION pg_query_state;
```

Then modify `shared_preload_libraries` parameter in `postgres.conf` as following:

```
shared_preload_libraries = 'pg_query_state'
```

It will require to restart the Postgres Pro instance.

F.42.4. Function `pg_query_state`

```
pg_query_state(integer pid,  
               verbose boolean DEFAULT FALSE,  
               costs  boolean DEFAULT FALSE,  
               timing  boolean DEFAULT FALSE,  
               buffers boolean DEFAULT FALSE,
```

```
triggers boolean DEFAULT FALSE,  
format text DEFAULT 'text')  
returns TABLE (pid integer,  
                frame_number integer,  
                query_text text,  
                plan text,  
                leader_pid integer)
```

Extract current query state from backend with specified `pid`. Since parallel query can spawn multiple workers and function call causes nested subqueries so that state of execution may be viewed as stack of running queries, return value of `pg_query_state` has type `TABLE (pid integer, frame_number integer, query_text text, plan text, leader_pid integer)`. It represents tree structure consisting of leader process and its spawned workers identified by `pid`. Each worker refers to leader through `leader_pid` column. For leader process the value of this column is `null`. The state of each process is represented as stack of function calls. Each frame of that stack is specified as correspondence between `frame_number` starting from zero, `query_text` and `plan` with online statistics columns.

Thus, user can see the states of main query and queries generated from function calls for leader process and all workers spawned from it.

In process of execution some nodes of plan tree can take loops of full execution. Therefore statistics for each node consists of two parts: average statistics for previous loops just like in `EXPLAIN ANALYZE` output and statistics for current loop if node have not finished.

Optional arguments:

- `verbose` - use `EXPLAIN VERBOSE` for plan printing;
- `costs` - costs for each node;
- `timing` - print timing data for each node, if collecting of timing statistics is turned off on called side resulting output will contain `WARNING` message `timing statistics disabled`;
- `buffers` - print buffers usage, if collecting of buffers statistics is turned off on called side resulting output will contain `WARNING` message `buffers statistics disabled`;
- `triggers` - include triggers statistics in result plan trees;
- `format` - `EXPLAIN` format to be used for plans printing, possible values: `text`, `xml`, `json`, `yaml`.

If callable backend is not executing any query the function prints `INFO` message about backend's state taken from `pg_stat_activity` view if it exists there.

Calling role have to be superuser or member of the role whose backend is being called. Otherwise function prints `ERROR` message `permission denied`.

F.42.5. Configuration settings

There are several user-accessible GUC variables designed to toggle the whole module and the collecting of specific statistic parameters while query is running:

- `pg_query_state.enable` - disable (or enable) `pg_query_state` completely, default value is `true`
- `pg_query_state.enable_timing` - collect timing data for each node, default value is `false`
- `pg_query_state.enable_buffers` - collect buffers usage, default value is `false`

These parameters are set on called side before running any queries whose states are attempted to extract. `WARNING`: if `pg_query_state.enable_timing` is turned off the calling side cannot get time statistics, similarly for `pg_query_state.enable_buffers` parameter.

F.42.6. Examples

Set maximum number of parallel workers on `gather` node equals 2:

```
postgres=# set max_parallel_workers_per_gather = 2;
```

Assume one backend with pid = 49265 performs a simple query:

```
postgres=# select pg_backend_pid();
pg_backend_pid
-----
      49265
(1 row)
postgres=# select count(*) from foo join bar on foo.c1=bar.c1;
```

Other backend can extract intermediate state of execution that query:

```
postgres=# \x
postgres=# select * from pg_query_state(49265);
-[ RECORD
  1 ]+-----
pid          | 49265
frame_number | 0
query_text   | select count(*) from foo join bar on foo.c1=bar.c1;
plan         | Finalize Aggregate (Current loop: actual rows=0, loop number=1)
              |
              |      -> Gather (Current loop: actual rows=0, loop number=1)
              |
              |      Workers Planned: 2
              |
              |      Workers Launched: 2
              |
              |      -> Partial Aggregate (Current loop: actual rows=0, loop
number=1)
              |
              |      -> Nested Loop (Current loop: actual rows=12, loop
number=1)
              |
              |      Join Filter: (foo.c1 = bar.c1)
              |
              |      Rows Removed by Join Filter: 5673232
              |
              |      -> Parallel Seq Scan on foo (Current loop: actual
rows=12, loop number=1)
              |
              |      -> Seq Scan on bar (actual rows=500000 loops=11)
              |      (Current loop: actual rows=173244, loop number=12)
leader_pid   | (null)
-[ RECORD
  2 ]+-----
pid          | 49324
frame_number | 0
query_text   | <parallel query>
plan         | Partial Aggregate (Current loop: actual rows=0, loop number=1)
              |
              |      -> Nested Loop (Current loop: actual rows=10, loop number=1)
              |
              |      Join Filter: (foo.c1 = bar.c1)
              |
              |      Rows Removed by Join Filter: 4896779
              |
              |      -> Parallel Seq Scan on foo (Current loop: actual rows=10, loop
number=1)
              |
              |      -> Seq Scan on bar (actual rows=500000 loops=9) (Current loop:
actual rows=396789, loop number=10)
leader_pid   | 49265
```

In example above working backend spawns two parallel workers with pids 49324 and 49323. Their `leader_pid` column's values clarify that these workers belong to the main backend. `Seq Scan` node has statistics on passed loops (average number of rows delivered to `Nested Loop` and number of passed loops are shown) and statistics on current loop. Other nodes has statistics only for current loop as this loop is first (loop number = 1).

```
postgres=# select n_join_foo_bar();
```

```
postgres=# select * from pg_query_state(49265);
```

2240

```

|                                     -> Materialize (actual rows=1000000 loops=51) (Current
loop: actual rows=636355, loop number=52)+
|                                     -> Seq Scan on foo (Current loop: actual
rows=1000000, loop number=1)
leader_pid | (null)

```

First row corresponds to function call, second - to query which is in the body of that function.

We can get result plans in different format (e.g. json):

```

postgres=# select * from pg_query_state(pid := 49265, format := 'json');
-[ RECORD 1 ]+-----+
pid          | 49265
frame_number | 0
query_text   | select * from n_join_foo_bar();
plan         | {
|   "Plan": {
|     "Node Type": "Function Scan",
|     "Parallel Aware": false,
|     "Function Name": "n_join_foo_bar",
|     "Alias": "n_join_foo_bar",
|     "Current loop": {
|       "Actual Loop Number": 1,
|       "Actual Rows": 0
|     }
|   }
| }
leader_pid   | (null)
-[ RECORD 2 ]+-----+
pid          | 49265
frame_number | 1
query_text   | SELECT (select count(*) from foo join bar on foo.c1=bar.c1)
plan         | {
|   "Plan": {
|     "Node Type": "Result",
|     "Parallel Aware": false,
|     "Current loop": {
|       "Actual Loop Number": 1,
|       "Actual Rows": 0
|     },
|     "Plans": [
|       {
|         "Node Type": "Aggregate",
|         "Strategy": "Plain",
|         "Partial Mode": "Simple",
|         "Parent Relationship": "InitPlan",
|         "Subplan Name": "InitPlan 1 (returns $0)",
|         "Parallel Aware": false,
|         "Current loop": {
|           "Actual Loop Number": 1,
|           "Actual Rows": 0
|         },
|       },
|       "Plans": [
|         {
|           "Node Type": "Nested Loop",
|           "Parent Relationship": "Outer",
|           "Parallel Aware": false,
|           "Join Type": "Inner",

```

```
leader_pid | (null)
```

F.43. pgrowlocks

The `pgrowlocks` module provides a function to show row locking information for a specified table.

F.43.1. Overview

`pgrowlocks(text)` returns setof record

The parameter is the name of a table. The result is a set of records, with one row for each locked row within the table. The output columns are shown in [Table F.31](#).

Table F.31. pgrowlocks Output Columns

Name	Type	Description
locked_row	tid	Tuple ID (TID) of locked row
locker	xid	Transaction ID of locker, or multixact ID if multitransaction
multi	boolean	True if locker is a multitransaction
xids	xid[]	Transaction IDs of lockers (more than one if multitransaction)
modes	text[]	Lock mode of lockers (more than one if multitransaction), an array of Key Share, Share, For No Key Update, No Key Update, For Update, Update.
pids	integer[]	Process IDs of locking backends (more than one if multitransaction)

`pgrowlocks` takes `AccessShareLock` for the target table and reads each row one by one to collect the row locking information. This is not very speedy for a large table. Note that:

1. If the table as a whole is exclusive-locked by someone else, `pgrowlocks` will be blocked.
2. `pgrowlocks` is not guaranteed to produce a self-consistent snapshot. It is possible that a new row lock is taken, or an old lock is freed, during its execution.

`pgrowlocks` does not show the contents of locked rows. If you want to take a look at the row contents at the same time, you could do something like this:

```
SELECT * FROM accounts AS a, pgrowlocks('accounts') AS p
WHERE p.locked_row = a.ctid;
```

Be aware however that such a query will be very inefficient.

F.43.2. Sample Output

```
=# SELECT * FROM pgrowlocks('t1');
locked_row | locker | multi | xids | modes | pids
-----+-----+-----+-----+-----+-----
(0,1)      | 609   | f     | {609} | {"For Share"} | {3161}
(0,2)      | 609   | f     | {609} | {"For Share"} | {3161}
(0,3)      | 607   | f     | {607} | {"For Update"} | {3107}
(0,4)      | 607   | f     | {607} | {"For Update"} | {3107}
(4 rows)
```

F.43.3. Author

Tatsuo Ishii

F.44. pg_stat_statements

The `pg_stat_statements` module provides a means for tracking execution statistics of all SQL statements executed by a server.

The module must be loaded by adding `pg_stat_statements` to `shared_preload_libraries` in `postgresql.conf`, because it requires additional shared memory. This means that a server restart is needed to add or remove the module.

When `pg_stat_statements` is loaded, it tracks statistics across all databases of the server. To access and manipulate these statistics, the module provides a view, `pg_stat_statements`, and the utility functions `pg_stat_statements_reset` and `pg_stat_statements`. These are not available globally but can be enabled for a specific database with `CREATE EXTENSION pg_stat_statements`.

F.44.1. The `pg_stat_statements` View

The statistics gathered by the module are made available via a view named `pg_stat_statements`. This view contains one row for each distinct database ID, user ID and query ID (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in [Table F.32](#).

Table F.32. `pg_stat_statements` Columns

Name	Type	References	Description
<code>userid</code>	<code>oid</code>	<code>pg_authid .oid</code>	OID of user who executed the statement
<code>dbid</code>	<code>oid</code>	<code>pg_database .oid</code>	OID of database in which the statement was executed
<code>queryid</code>	<code>bigint</code>		Internal hash code, computed from the statement's parse tree
<code>query</code>	<code>text</code>		Text of a representative statement
<code>calls</code>	<code>bigint</code>		Number of times executed
<code>total_time</code>	<code>double precision</code>		Total time spent in the statement, in milliseconds
<code>min_time</code>	<code>double precision</code>		Minimum time spent in the statement, in milliseconds
<code>max_time</code>	<code>double precision</code>		Maximum time spent in the statement, in milliseconds
<code>mean_time</code>	<code>double precision</code>		Mean time spent in the statement, in milliseconds
<code>stddev_time</code>	<code>double precision</code>		Population standard deviation of time spent in the statement, in milliseconds
<code>rows</code>	<code>bigint</code>		Total number of rows retrieved or affected by the statement
<code>shared_blks_hit</code>	<code>bigint</code>		Total number of shared block cache hits by the statement

Name	Type	References	Description
shared_blks_read	bigint		Total number of shared blocks read by the statement
shared_blks_dirtied	bigint		Total number of shared blocks dirtied by the statement
shared_blks_written	bigint		Total number of shared blocks written by the statement
local_blks_hit	bigint		Total number of local block cache hits by the statement
local_blks_read	bigint		Total number of local blocks read by the statement
local_blks_dirtied	bigint		Total number of local blocks dirtied by the statement
local_blks_written	bigint		Total number of local blocks written by the statement
temp_blks_read	bigint		Total number of temp blocks read by the statement
temp_blks_written	bigint		Total number of temp blocks written by the statement
blk_read_time	double precision		Total time the statement spent reading blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
blk_write_time	double precision		Total time the statement spent writing blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)

For security reasons, non-superusers are not allowed to see the SQL text or `queryid` of queries executed by other users. They can see the statistics, however, if the view has been installed in their database.

Plannable queries (that is, `SELECT`, `INSERT`, `UPDATE`, and `DELETE`) are combined into a single `pg_stat_statements` entry whenever they have identical query structures according to an internal hash calculation. Typically, two queries will be considered the same for this purpose if they are semantically equivalent except for the values of literal constants appearing in the query. Utility commands (that is, all other commands) are compared strictly on the basis of their textual query strings, however.

When a constant's value has been ignored for purposes of matching the query to other queries, the constant is replaced by `?` in the `pg_stat_statements` display. The rest of the query text is that of the first query that had the particular `queryid` hash value associated with the `pg_stat_statements` entry.

In some cases, queries with visibly different texts might get merged into a single `pg_stat_statements` entry. Normally this will happen only for semantically equivalent queries, but there is a small chance of

hash collisions causing unrelated queries to be merged into one entry. (This cannot happen for queries belonging to different users or databases, however.)

Since the `queryid` hash value is computed on the post-parse-analysis representation of the queries, the opposite is also possible: queries with identical texts might appear as separate entries, if they have different meanings as a result of factors such as different `search_path` settings.

Consumers of `pg_stat_statements` may wish to use `queryid` (perhaps in combination with `dbid` and `userid`) as a more stable and reliable identifier for each entry than its query text. However, it is important to understand that there are only limited guarantees around the stability of the `queryid` hash value. Since the identifier is derived from the post-parse-analysis tree, its value is a function of, among other things, the internal object identifiers appearing in this representation. This has some counterintuitive implications. For example, `pg_stat_statements` will consider two apparently-identical queries to be distinct, if they reference a table that was dropped and recreated between the executions of the two queries. The hashing process is also sensitive to differences in machine architecture and other facets of the platform. Furthermore, it is not safe to assume that `queryid` will be stable across major versions of Postgres Pro.

As a rule of thumb, `queryid` values can be assumed to be stable and comparable only so long as the underlying server version and catalog metadata details stay exactly the same. Two servers participating in replication based on physical WAL replay can be expected to have identical `queryid` values for the same query. However, logical replication schemes do not promise to keep replicas identical in all relevant details, so `queryid` will not be a useful identifier for accumulating costs across a set of logical replicas. If in doubt, direct testing is recommended.

The representative query texts are kept in an external disk file, and do not consume shared memory. Therefore, even very lengthy query texts can be stored successfully. However, if many long query texts are accumulated, the external file might grow unmanageably large. As a recovery method if that happens, `pg_stat_statements` may choose to discard the query texts, whereupon all existing entries in the `pg_stat_statements` view will show null `query` fields, though the statistics associated with each `queryid` are preserved. If this happens, consider reducing `pg_stat_statements.max` to prevent recurrences.

F.44.2. Functions

`pg_stat_statements_reset()` returns void

`pg_stat_statements_reset` discards all statistics gathered so far by `pg_stat_statements`. By default, this function can only be executed by superusers.

`pg_stat_statements(showtext boolean)` returns setof record

The `pg_stat_statements` view is defined in terms of a function also named `pg_stat_statements`. It is possible for clients to call the `pg_stat_statements` function directly, and by specifying `showtext := false` have query text be omitted (that is, the `OUT` argument that corresponds to the view's `query` column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all `pg_stat_statements` itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the `pg_stat_statements` data.

F.44.3. Configuration Parameters

`pg_stat_statements.max` (integer)

`pg_stat_statements.max` is the maximum number of statements tracked by the module (i.e., the maximum number of rows in the `pg_stat_statements` view). If more distinct statements than that are observed, information about the least-executed statements is discarded. The default value is 5000. This parameter can only be set at server start.

`pg_stat_statements.track` (enum)

`pg_stat_statements.track` controls which statements are counted by the module. Specify `top` to track top-level statements (those issued directly by clients), `all` to also track nested statements

(such as statements invoked within functions), or `none` to disable statement statistics collection. The default value is `top`. Only superusers can change this setting.

`pg_stat_statements.track_utility` (boolean)

`pg_stat_statements.track_utility` controls whether utility commands are tracked by the module. Utility commands are all those other than `SELECT`, `INSERT`, `UPDATE` and `DELETE`. The default value is `on`. Only superusers can change this setting.

`pg_stat_statements.save` (boolean)

`pg_stat_statements.save` specifies whether to save statement statistics across server shutdowns. If it is `off` then statistics are not saved at shutdown nor reloaded at server start. The default value is `on`. This parameter can only be set in the `postgresql.conf` file or on the server command line.

The module requires additional shared memory proportional to `pg_stat_statements.max`. Note that this memory is consumed whenever the module is loaded, even if `pg_stat_statements.track` is set to `none`.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'pg_stat_statements'

pg_stat_statements.max = 10000
pg_stat_statements.track = all
```

F.44.4. Sample Output

```
bench=# SELECT pg_stat_statements_reset();

$ pgbench -i bench
$ pgbench -c10 -t300 bench

bench=# \x
bench=# SELECT query, calls, total_time, rows, 100.0 * shared_blks_hit /
           nullif(shared_blks_hit + shared_blks_read, 0) AS hit_percent
           FROM pg_stat_statements ORDER BY total_time DESC LIMIT 5;
-[ RECORD 1 ]-----

F.44.5. Authors

Takahiro Itagaki <itagaki.takahiro@oss.ntt.co.jp>. Query normalization added by Peter Geoghegan <peter@2ndquadrant.com>.

F.45. pgstattuple

The `pgstattuple` module provides various functions to obtain tuple-level statistics.

F.45.1. Functions

`pgstattuple(regclass)` returns record

`pgstattuple` returns a relation's physical length, percentage of “dead” tuples, and other info. This may help users to determine whether vacuum is necessary or not. The argument is the target relation's name (optionally schema-qualified) or OID. For example:

```

test=> SELECT * FROM pgstattuple('pg_catalog.pg_proc');
-[ RECORD 1 ]-----+-----
table_len          | 458752
tuple_count        | 1470
tuple_len          | 438896
tuple_percent      | 95.67
dead_tuple_count   | 11
dead_tuple_len     | 3157
dead_tuple_percent | 0.69
free_space         | 8932
free_percent       | 1.95

```

The output columns are described in [Table F.33](#).

Table F.33. `pgstattuple` Output Columns

Column	Type	Description
<code>table_len</code>	<code>bigint</code>	Physical relation length in bytes
<code>tuple_count</code>	<code>bigint</code>	Number of live tuples
<code>tuple_len</code>	<code>bigint</code>	Total length of live tuples in bytes
<code>tuple_percent</code>	<code>float8</code>	Percentage of live tuples
<code>dead_tuple_count</code>	<code>bigint</code>	Number of dead tuples
<code>dead_tuple_len</code>	<code>bigint</code>	Total length of dead tuples in bytes
<code>dead_tuple_percent</code>	<code>float8</code>	Percentage of dead tuples
<code>free_space</code>	<code>bigint</code>	Total free space in bytes
<code>free_percent</code>	<code>float8</code>	Percentage of free space

Note

The `table_len` will always be greater than the sum of the `tuple_len`, `dead_tuple_len` and `free_space`. The difference is accounted for by fixed page overhead, the per-page table of pointers to tuples, and padding to ensure that tuples are correctly aligned.

`pgstattuple` acquires only a read lock on the relation. So the results do not reflect an instantaneous snapshot; concurrent updates will affect them.

`pgstattuple` judges a tuple is “dead” if `HeapTupleSatisfiesDirty` returns false.

`pgstattuple(text)` returns record

This is the same as `pgstattuple(regclass)`, except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatindex(regclass)` returns record

`pgstatindex` returns a record showing information about a B-tree index. For example:

```
test=> SELECT * FROM pgstatindex('pg_cast_oid_index');
-[ RECORD 1 ]-----+-----
version           | 2
tree_level        | 0
index_size        | 16384
root_block_no     | 1
internal_pages    | 0
leaf_pages        | 1
empty_pages       | 0
deleted_pages     | 0
avg_leaf_density  | 54.27
leaf_fragmentation | 0
```

The output columns are:

Column	Type	Description
<code>version</code>	integer	B-tree version number
<code>tree_level</code>	integer	Tree level of the root page
<code>index_size</code>	bigint	Total index size in bytes
<code>root_block_no</code>	bigint	Location of root page (zero if none)
<code>internal_pages</code>	bigint	Number of “internal” (upper-level) pages
<code>leaf_pages</code>	bigint	Number of leaf pages
<code>empty_pages</code>	bigint	Number of empty pages
<code>deleted_pages</code>	bigint	Number of deleted pages
<code>avg_leaf_density</code>	float8	Average density of leaf pages
<code>leaf_fragmentation</code>	float8	Leaf page fragmentation

The reported `index_size` will normally correspond to one more page than is accounted for by `internal_pages` + `leaf_pages` + `empty_pages` + `deleted_pages`, because it also includes the index's metapage.

As with `pgstattuple`, the results are accumulated page-by-page, and should not be expected to represent an instantaneous snapshot of the whole index.

`pgstatindex(text)` returns record

This is the same as `pgstatindex(regclass)`, except that the target index is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatginindex(regclass)` returns record

`pgstatginindex` returns a record showing information about a GIN index. For example:

```
test=> SELECT * FROM pgstatginindex('test_gin_index');
-[ RECORD 1 ]--+-
version          | 1
pending_pages    | 0
pending_tuples   | 0
```

The output columns are:

Column	Type	Description
version	integer	GIN version number
pending_pages	integer	Number of pages in the pending list
pending_tuples	bigint	Number of tuples in the pending list

`pg_relpages(regclass)` returns bigint

`pg_relpages` returns the number of pages in the relation.

`pg_relpages(text)` returns bigint

This is the same as `pg_relpages(regclass)`, except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstattuple_approx(regclass)` returns record

`pgstattuple_approx` is a faster alternative to `pgstattuple` that returns approximate results. The argument is the target relation's name or OID. For example:

```
test=> SELECT * FROM pgstattuple_approx('pg_catalog.pg_proc'::regclass);
-[ RECORD 1 ]-----+-----
table_len          | 573440
scanned_percent     | 2
approx_tuple_count  | 2740
approx_tuple_len    | 561210
approx_tuple_percent | 97.87
dead_tuple_count    | 0
dead_tuple_len      | 0
dead_tuple_percent  | 0
approx_free_space   | 11996
approx_free_percent  | 2.09
```

The output columns are described in [Table F.34](#).

Whereas `pgstattuple` always performs a full-table scan and returns an exact count of live and dead tuples (and their sizes) and free space, `pgstattuple_approx` tries to avoid the full-table scan and returns exact dead tuple statistics along with an approximation of the number and size of live tuples and free space.

It does this by skipping pages that have only visible tuples according to the visibility map (if a page has the corresponding VM bit set, then it is assumed to contain no dead tuples). For such pages, it derives the free space value from the free space map, and assumes that the rest of the space on the page is taken up by live tuples.

For pages that cannot be skipped, it scans each tuple, recording its presence and size in the appropriate counters, and adding up the free space on the page. At the end, it estimates the total number of live tuples based on the number of pages and tuples scanned (in the same way that VACUUM estimates `pg_class.reltuples`).

Table F.34. `pgstattuple_approx` Output Columns

Column	Type	Description
<code>table_len</code>	<code>bigint</code>	Physical relation length in bytes (exact)
<code>scanned_percent</code>	<code>float8</code>	Percentage of table scanned
<code>approx_tuple_count</code>	<code>bigint</code>	Number of live tuples (estimated)
<code>approx_tuple_len</code>	<code>bigint</code>	Total length of live tuples in bytes (estimated)
<code>approx_tuple_percent</code>	<code>float8</code>	Percentage of live tuples
<code>dead_tuple_count</code>	<code>bigint</code>	Number of dead tuples (exact)
<code>dead_tuple_len</code>	<code>bigint</code>	Total length of dead tuples in bytes (exact)
<code>dead_tuple_percent</code>	<code>float8</code>	Percentage of dead tuples
<code>approx_free_space</code>	<code>bigint</code>	Total free space in bytes (estimated)
<code>approx_free_percent</code>	<code>float8</code>	Percentage of free space

In the above output, the free space figures may not match the `pgstattuple` output exactly, because the free space map gives us an exact figure, but is not guaranteed to be accurate to the byte.

F.45.2. Authors

Tatsuo Ishii, Satoshi Nagayasu and Abhijit Menon-Sen

F.46. `pg_transfer`

The `pg_transfer` extension enables quick transfer of tables between Postgres Pro Enterprise instances.

It may sometimes be required to load large volumes of data into a database, for example, when consolidating data from regional servers into a central one. If your data needs to be uploaded to a server under heavy load, you can use a temporary database on another server to accumulate the data and then transfer it all at once when the main server load is minimal.

If you use `pg_dump` and `pg_restore` applications to transfer data, the load on the receiving server is usually higher than that on the sending server. Since the data is loaded using `INSERT` or `COPY` commands, it creates a significant impact on the disk subsystem. Besides, you will have to re-build indexes in the target database once all the data is loaded, which will also contribute to the server load.

To achieve a much higher load speed for read-only data, you can use the `pg_transfer` extension while doing dump/restore, which allows to copy data files directly, without using `COPY/INSERT` commands. `pg_transfer` also provides auxiliary functions for `pg_dump` and `pg_restore` to transfer tables together with pre-built indexes and collected statistics, so you can avoid extra load on the target server incurred by statistics re-collection.

Note

Postgres Pro Enterprise configuration and the architectures of source and target servers must provide binary-compatible file formats. When restoring data, `pg_transfer` checks that source and target servers have the same alignment, page and segment sizes, etc.

F.46.1. Installation

`pg_transfer` is included into Postgres Pro Enterprise. To enable `pg_transfer`, create its extension in your database using the following SQL command:

```
CREATE EXTENSION pg_transfer;
```

You must create `pg_transfer` extension in both source and target databases.

F.46.2. Usage

To transfer data using the `pg_transfer` module, do the following:

1. Prepare source and target systems for data transfer

Before the actual data transfer, you first need to transfer data schema to the target server:

1. In the source database, mark the table to be transferred as read-only:

```
ALTER TABLE table_name SET CONSTANT;
```

2. Run the `VACUUM (ANALYZE)` command to remove dead tuples and refresh statistics:

```
VACUUM (ANALYZE) table_name;
```

3. Take a logical dump of the data schema on the source server and restore it on the target server:

```
pg_dump -Fc -t table_name --schema-only -f transfer_dir/archive.out old_database  
pg_restore -d new_database --schema-only transfer_dir/archive.out
```

2. Prepare TOAST identifiers for the transfer

This step is only required if the tables to be transferred have toasted values.

1. Determine TOAST identifiers (`reltoastid`) in the new database:

```
psql new_database -c "SELECT reltoastrelid FROM pg_class WHERE  
relname='table_name';"
```

2. Using the received `reltoastid` identifiers, prepare the table for the transfer and force data flush to disk:

```
psql -d old_database -c "SELECT  
pg_transfer_freeze('table_name::regclass::oid, reltoastrelid::oid);"
```

3. Transfer the data to the target system

1. Copy the data into a separate directory using `pg_dump` utility:

```
pg_dump -Fc -t table_name --transfer-dir transfer_dir/ -f transfer_dir/  
archive.out old_database
```

2. Restore the data in the target database:

```
pg_restore -d new_database --data-only --transfer-dir transfer_dir/ --copy-mode=  
transfer transfer_dir/archive.out
```

When source and target databases are located in the same file system, the `--copy-mode=transfer` option must be specified at least once (for either `pg_dump` or `pg_restore` command) to

get an independent copy of data. When restoring data on the primary server, `--generate-wal` option must be specified for `pg_restore` for changes to be replicated to a standby server.

F.46.3. Compatibility

The `pg_transfer` extension is only supported on Linux systems.

F.46.4. Authors

Postgres Professional, Moscow, Russia

F.47. `pg_trgm`

The `pg_trgm` module provides functions and operators for determining the similarity of alphanumeric text based on trigram matching, as well as index operator classes that support fast searching for similar strings.

F.47.1. Trigram (or Trigraph) Concepts

A trigram is a group of three consecutive characters taken from a string. We can measure the similarity of two strings by counting the number of trigrams they share. This simple idea turns out to be very effective for measuring the similarity of words in many natural languages.

Note

`pg_trgm` ignores non-word characters (non-alphanumerics) when extracting trigrams from a string. Each word is considered to have two spaces prefixed and one space suffixed when determining the set of trigrams contained in the string. For example, the set of trigrams in the string `"cat"` is `" c"`, `" ca"`, `"cat"`, and `"at "`. The set of trigrams in the string `"foo|bar"` is `" f"`, `" fo"`, `"foo"`, `"oo "`, `" b"`, `" ba"`, `"bar"`, and `"ar "`.

F.47.2. Functions and Operators

The functions provided by the `pg_trgm` module are shown in [Table F.35](#), the operators in [Table F.36](#).

Table F.35. `pg_trgm` Functions

Function	Returns	Description
<code>similarity(text, text)</code>	<code>real</code>	Returns a number that indicates how similar the two arguments are. The range of the result is zero (indicating that the two strings are completely dissimilar) to one (indicating that the two strings are identical).
<code>show_trgm(text)</code>	<code>text[]</code>	Returns an array of all the trigrams in the given string. (In practice this is seldom useful except for debugging.)
<code>word_similarity(text, text)</code>	<code>real</code>	Returns a number that indicates the greatest similarity between the set of trigrams in the first string and any continuous extent of an ordered set of trigrams in the second string. For details, see the explanation below.

Function	Returns	Description
<code>show_limit()</code>	real	Returns the current similarity threshold used by the % operator. This sets the minimum similarity between two words for them to be considered similar enough to be misspellings of each other, for example (<i>deprecated</i>).
<code>set_limit(real)</code>	real	Sets the current similarity threshold that is used by the % operator. The threshold must be between 0 and 1 (default is 0.3). Returns the same value passed in (<i>deprecated</i>).

Consider the following example:

```
# SELECT word_similarity('word', 'two words');
word_similarity
-----
              0.8
(1 row)
```

In the first string, the set of trigrams is {" w", " wo", "ord", "wor", "rd "}. In the second string, the ordered set of trigrams is {" t", " tw", "two", "wo ", " w", " wo", "wor", "ord", "rds", "ds "}. The most similar extent of an ordered set of trigrams in the second string is {" w", " wo", "wor", "ord"}, and the similarity is 0.8.

This function returns a value that can be approximately understood as the greatest similarity between the first string and any substring of the second string. However, this function does not add padding to the boundaries of the extent. Thus, the number of additional characters present in the second string is not considered, except for the mismatched word boundaries.

Table F.36. pg_trgm Operators

Operator	Returns	Description
<code>text % text</code>	boolean	Returns true if its arguments have a similarity that is greater than the current similarity threshold set by <code>pg_trgm.similarity_threshold</code> .
<code>text <% text</code>	boolean	Returns true if the similarity between the trigram set in the first argument and a continuous extent of an ordered trigram set in the second argument is greater than the current word similarity threshold set by <code>pg_trgm.word_similarity_threshold</code> parameter.
<code>text %> text</code>	boolean	Commutator of the <% operator.
<code>text <-> text</code>	real	Returns the “distance” between the arguments, that is one minus the <code>similarity()</code> value.
<code>text <<-> text</code>	real	Returns the “distance” between the arguments, that is one minus the <code>word_similarity()</code> value.

Operator	Returns	Description
text <-> text	real	Commutator of the <-> operator.

F.47.3. GUC Parameters

`pg_trgm.similarity_threshold` (real)

Sets the current similarity threshold that is used by the % operator. The threshold must be between 0 and 1 (default is 0.3).

`pg_trgm.word_similarity_threshold` (real)

Sets the current word similarity threshold that is used by the <% and %> operators. The threshold must be between 0 and 1 (default is 0.6).

F.47.4. Index Support

The `pg_trgm` module provides GiST and GIN index operator classes that allow you to create an index over a text column for the purpose of very fast similarity searches. These index types support the above-described similarity operators, and additionally support trigram-based index searches for `LIKE`, `ILIKE`, `~` and `~*` queries. (These indexes do not support equality nor simple comparison operators, so you may need a regular B-tree index too.)

Example:

```
CREATE TABLE test_trgm (t text);
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops);
```

or

```
CREATE INDEX trgm_idx ON test_trgm USING GIN (t gin_trgm_ops);
```

At this point, you will have an index on the `t` column that you can use for similarity searching. A typical query is

```
SELECT t, similarity(t, 'word') AS sml
FROM test_trgm
WHERE t % 'word'
ORDER BY sml DESC, t;
```

This will return all values in the text column that are sufficiently similar to `word`, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

A variant of the above query is

```
SELECT t, t <-> 'word' AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes. It will usually beat the first formulation when only a small number of the closest matches is wanted.

Also you can use an index on the `t` column for word similarity. For example:

```
SELECT t, word_similarity('word', t) AS sml
FROM test_trgm
WHERE 'word' <% t
ORDER BY sml DESC, t;
```

This will return all values in the text column for which there is a continuous extent in the corresponding ordered trigram set that is sufficiently similar to the trigram set of `word`, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

A variant of the above query is

```
SELECT t, 'word' <<-> t AS dist
```

```
FROM test_trgm
ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes.

Beginning in PostgreSQL 9.1, these index types also support index searches for `LIKE` and `ILIKE`, for example

```
SELECT * FROM test_trgm WHERE t LIKE '%foo%bar';
```

The index search works by extracting trigrams from the search string and then looking these up in the index. The more trigrams in the search string, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

Beginning in PostgreSQL 9.3, these index types also support index searches for regular-expression matches (`~` and `~*` operators), for example

```
SELECT * FROM test_trgm WHERE t ~ '(foo|bar)';
```

The index search works by extracting trigrams from the regular expression and then looking these up in the index. The more trigrams that can be extracted from the regular expression, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

For both `LIKE` and regular-expression searches, keep in mind that a pattern with no extractable trigrams will degenerate to a full-index scan.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

F.47.5. Text Search Integration

Trigram matching is a very useful tool when used in conjunction with a full text index. In particular it can help to recognize misspelled input words that will not be matched directly by the full text search mechanism.

The first step is to generate an auxiliary table containing all the unique words in the documents:

```
CREATE TABLE words AS SELECT word FROM
    ts_stat('SELECT to_tsvector(''simple'', bodytext) FROM documents');
```

where `documents` is a table that has a text field `bodytext` that we wish to search. The reason for using the `simple` configuration with the `to_tsvector` function, instead of using a language-specific configuration, is that we want a list of the original (unstemmed) words.

Next, create a trigram index on the word column:

```
CREATE INDEX words_idx ON words USING GIN (word gin_trgm_ops);
```

Now, a `SELECT` query similar to the previous example can be used to suggest spellings for misspelled words in user search terms. A useful extra test is to require that the selected words are also of similar length to the misspelled word.

Note

Since the `words` table has been generated as a separate, static table, it will need to be periodically regenerated so that it remains reasonably up-to-date with the document collection. Keeping it exactly current is usually unnecessary.

F.48. pg_tsparser

`pg_tsparser` is a Postgres Pro extension for text search. This extension modifies the default text parsing strategy for words that include:

- underscores
- numbers and letters separated by the hyphen character

In addition to separate word parts returned by default, `pg_tsparser` also returns the whole word.

F.48.1. Installation and Setup

`pg_tsparser` is included into the Postgres Pro distribution. To enable `pg_tsparser`, once Postgres Pro is installed, create the `pg_tsparser` extension for each database you are planning to use:

```
CREATE EXTENSION pg_tsparser;
```

Once `pg_tsparser` is enabled, you can create your own text search configuration. In addition to `pg_tsparser`, you can use any available dictionary.

For example, you can create `english_ts` configuration for the English language, as follows:

```
CREATE TEXT SEARCH CONFIGURATION english_ts (  
    PARSER = tsparser  
);
```

```
COMMENT ON TEXT SEARCH CONFIGURATION english_ts IS 'text search configuration for  
english language';
```

```
ALTER TEXT SEARCH CONFIGURATION english_ts  
    ADD MAPPING FOR email, file, float, host, hword_numpart, int,  
    numhword, numword, sfloat, uint, url, url_path, version  
    WITH simple;
```

```
ALTER TEXT SEARCH CONFIGURATION english_ts  
    ADD MAPPING FOR asciiword, asciihword, hword_asciipart,  
    word, hword, hword_part  
    WITH english_stem;
```

F.48.2. Examples

The following examples illustrate the difference in search results returned by `pg_tsparser` and the default parser:

```
SELECT to_tsvector('english', 'pg_trgm') as def_parser,  
       to_tsvector('english_ts', 'pg_trgm') as new_parser;  
def_parser | new_parser  
-----+-----  
'pg':1 'trgm':2 | 'pg':2 'pg_trgm':1 'trgm':3  
(1 row)
```

```
SELECT to_tsvector('english', '123-abc') as def_parser,
       to_tsvector('english_ts', '123-abc') as new_parser;
 def_parser      |      new_parser
-----+-----
 '123':1 'abc':2 | '123':2 '123-abc':1 'abc':3
(1 row)
```

```
SELECT to_tsvector('english', 'rel-3.2-A') as def_parser,
       to_tsvector('english_ts', 'rel-3.2-A') as new_parser;
 def_parser      |      new_parser
-----+-----
 '-3.2':2 'rel':1 | '3.2':3 'rel':2 'rel-3.2-a':1
(1 row)
```

See Also[CREATE TEXT SEARCH CONFIGURATION](#)[ALTER TEXT SEARCH CONFIGURATION](#)**F.48.3. Authors**

Postgres Professional, Moscow, Russia

F.49. pg_variables

The `pg_variables` module provides functions for working with variables of various types. The created variables are only available in the current user session.

Note

This extension cannot be used together with autonomous transactions.

F.49.1. Installation

The `pg_variables` extension is included into Postgres Pro. Once you have Postgres Pro installed, you must execute the [CREATE EXTENSION](#) command to enable `pg_variables`, as follows:

```
CREATE EXTENSION pg_variables;
```

F.49.2. Usage

The `pg_variables` module provides several functions for creating, reading, and managing variables of scalar, record, and array types. See the following sections for function descriptions and syntax:

- [Section F.49.3.1](#) describes functions for scalar variables.
- [Section F.49.3.2](#) describes functions for record variables.
- [Section F.49.3.3](#) describes functions for array variables.
- [Section F.49.3.4](#) lists functions you can use to manage all variables in your current session.

For detailed usage examples, see [Section F.49.4](#).

F.49.2.1. Using Transactional Variables

By default, the created variables are non-transactional. Once successfully set, a variable exists for the whole session, regardless of rollbacks, if any. For example:

```
SELECT pgv_set('vars', 'int1', 101);
BEGIN;
SELECT pgv_set('vars', 'int2', 102);
```

```
ROLLBACK;
```

```
SELECT * FROM pgv_list() order by package, name;
 package | name | is_transactional
-----+-----+-----
 vars    | int1 | f
 vars    | int2 | f
```

If you would like to use variables that support transactions and savepoints, pass the optional `is_transactional` flag as the last parameter when creating this variable:

```
BEGIN;
SELECT pgv_set('vars', 'trans_int', 101, true);
SAVEPOINT sp1;
SELECT pgv_set('vars', 'trans_int', 102, true);
ROLLBACK TO sp1;
COMMIT;
SELECT pgv_get('vars', 'trans_int', NULL::int);
 pgv_get
-----
      101
```

You must use the `is_transactional` flag every time you change the value of a transactional variable using `pgv_set()` or `pgv_insert()` functions. Otherwise, an error occurs. Other functions do not require this flag.

```
SELECT pgv_insert('pack', 'var_record', row(123::int, 'text'::text), true);

SELECT pgv_insert('pack', 'var_record', row(456::int, 'another text'::text));
ERROR:  variable "var_record" already created as TRANSACTIONAL

SELECT pgv_delete('pack', 'var_record', 123::int);
```

If the `pgv_free()` or `pgv_remove()` function calls are rolled back, the affected transactional variables will be restored, unlike non-transactional variables, which are removed permanently. For example:

```
SELECT pgv_set('pack', 'var_reg', 123);
SELECT pgv_set('pack', 'var_trans', 456, true);
BEGIN;
SELECT pgv_free();
ROLLBACK;
SELECT * FROM pgv_list();
 package | name | is_transactional
-----+-----+-----
 pack    | var_trans | t
```

F.49.3. Functions

F.49.3.1. Scalar Variables

The following functions support scalar variables:

Function	Returns
<code>pgv_set(package text, name text, value anynonarray, is_transactional bool default false)</code>	void
<code>pgv_get(package text, name text, var_type anynonarray, strict bool default true)</code>	anynonarray

To use the `pgv_get()` function, you must first create a package and a variable using the `pgv_set()` function. If the specified package or variable does not exist, an error occurs:

```
SELECT pgv_get('vars', 'int1', NULL::int);
ERROR:  unrecognized package "vars"
```

```
SELECT pgv_get('vars', 'int1', NULL::int);
ERROR:  unrecognized variable "int1"
```

`pgv_get()` function checks the variable type. If the specified type does not match the type of the variable, an error is raised:

```
SELECT pgv_get('vars', 'int1', NULL::text);
ERROR:  variable "int1" requires "integer" value
```

F.49.3.2. Records

The following functions support collections of record variables:

Function	Returns	Description
<code>pgv_insert(package text, name text, r record, is_transactional bool default false)</code>	void	Inserts a record into a variable collection for the specified package. If the package or variable does not exist, it is created automatically. The first column of <code>r</code> is the primary key. If a record with the same primary key already exists or this variable collection has another structure, an error is raised.
<code>pgv_update(package text, name text, r record)</code>	boolean	Updates a record with the corresponding primary key (the first column of <code>r</code> is the primary key). Returns <code>true</code> if the record was found. If this variable collection has another structure, an error is raised.
<code>pgv_delete(package text, name text, value anynonarray)</code>	boolean	Deletes a record with the corresponding primary key (the first column of <code>r</code> is the primary key). Returns <code>true</code> if the record was found.
<code>pgv_select(package text, name text)</code>	set of records	Returns the variable collection records.
<code>pgv_select(package text, name text, value anynonarray)</code>	record	Returns the record with the corresponding primary key (the first column of <code>r</code> is a primary key).
<code>pgv_select(package text, name text, value anyarray)</code>	set of records	Returns the variable collection records with the corresponding primary keys (the first column of <code>r</code> is a primary key).

To use `pgv_update()`, `pgv_delete()` and `pgv_select()` functions, you must first create a package and a variable using the `pgv_insert()` function. The variable type and the record type must be the same; otherwise, an error occurs.

F.49.3.3. Arrays

The following functions support array variables:

Function	Returns
<code>pgv_set(package text, name text, value anyarray, is_transactional bool default false)</code>	void
<code>pgv_get(package text, name text, var_type anyarray, strict bool default true)</code>	anyarray

Usage instructions for these functions are the same as those provided in [Section F.49.3.1](#) for scalar variables.

F.49.3.4. Miscellaneous Functions

Function	Returns	Description
<code>pgv_exists(package text, name text)</code>	bool	Returns true if the specified package and variable exist.
<code>pgv_exists(package text)</code>	bool	Returns true if the specified package exists.
<code>pgv_remove(package text, name text)</code>	void	Removes the variable with the specified name. The specified package and variable must exist; otherwise, an error is raised.
<code>pgv_remove(package text)</code>	void	Removes the specified package and all the corresponding variables. The specified package must exist; otherwise, an error is raised.
<code>pgv_free()</code>	void	Removes all packages and variables.
<code>pgv_list()</code>	<code>table(package text, name text, is_transactional bool)</code>	Displays all the available variables and the corresponding packages, as well as whether each variable is transactional.
<code>pgv_stats()</code>	<code>table(package text, allocated_memory bigint)</code>	Returns the list of assigned packages and the amount of memory used by variables, in bytes. If you are using transactional variables, this list also includes all deleted packages that still may be restored by a <code>ROLLBACK</code> . This function only supports Postgres Pro 9.6 or higher.

F.49.3.5. Deprecated Functions

F.49.3.5.1. Integer Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_int(package text, name text, value int, is_transactional bool default false)</code>	void

Function	Returns
<code>pgv_get_int(package text, name text, strict bool default true)</code>	int

F.49.3.5.2. Text Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_text(package text, name text, value text, is_transactional bool default false)</code>	void
<code>pgv_get_text(package text, name text, strict bool default true)</code>	text

F.49.3.5.3. Numeric Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_numeric(package text, name text, value numeric, is_transactional bool default false)</code>	void
<code>pgv_get_numeric(package text, name text, strict bool default true)</code>	numeric

F.49.3.5.4. Timestamp Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_timestamp(package text, name text, value timestamp, is_transactional bool default false)</code>	void
<code>pgv_get_timestamp(package text, name text, strict bool default true)</code>	timestamp

F.49.3.5.5. Timestamp with timezone Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_timestamptz(package text, name text, value timestamptz, is_ transactional bool default false)</code>	void
<code>pgv_get_timestamptz(package text, name text, strict bool default true)</code>	timestamptz

F.49.3.5.6. Date Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_date(package text, name text, value date, is_transactional bool default false)</code>	void

Function	Returns
<code>pgv_get_date(package text, name text, strict bool default true)</code>	date

F.49.3.5.7. Jsonb Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_jsonb(package text, name text, value jsonb, is_transactional bool default false)</code>	void
<code>pgv_get_jsonb(package text, name text, strict bool default true)</code>	jsonb

F.49.4. Examples

Define scalar variables using the `pgv_set()` function, and then return their values using the `pgv_get()` function:

```
SELECT pgv_set('vars', 'int1', 101);
SELECT pgv_set('vars', 'int2', 102);
SELECT pgv_set('vars', 'text1', 'text variable'::text);
```

```
SELECT pgv_get('vars', 'int1', NULL::int);
pgv_get
-----
      101
```

```
SELECT pgv_get('vars', 'int2', NULL::int);
pgv_get
-----
      102
```

```
SELECT pgv_get('vars', 'text1', NULL::text);
pgv_get
-----
text variable
```

Let's assume we have the `tab` table and examine several examples of using record variables:

```
CREATE TABLE tab (id int, t varchar);
INSERT INTO tab VALUES (0, 'str00'), (1, 'str11');
```

You can use the following functions to work with record variables:

```
SELECT pgv_insert('vars', 'r1', tab) FROM tab;
```

```
SELECT pgv_select('vars', 'r1');
pgv_select
-----
(1,str11)
(0,str00)
```

```
SELECT pgv_select('vars', 'r1', 1);
pgv_select
-----
(1,str11)
```

```

SELECT pgv_select('vars', 'r1', 0);
pgv_select
-----
(0,str00)

SELECT pgv_select('vars', 'r1', ARRAY[1, 0]);
pgv_select
-----
(1,str11)
(0,str00)

SELECT pgv_delete('vars', 'r1', 1);

SELECT pgv_select('vars', 'r1');
pgv_select
-----
(0,str00)

```

Consider the behavior of a transactional variable `var_text` when changed before and after savepoints:

```

SELECT pgv_set('pack', 'var_text', 'before transaction block'::text, true);
BEGIN;
SELECT pgv_set('pack', 'var_text', 'before savepoint'::text, true);
SAVEPOINT sp1;
SELECT pgv_set('pack', 'var_text', 'savepoint sp1'::text, true);
SAVEPOINT sp2;
SELECT pgv_set('pack', 'var_text', 'savepoint sp2'::text, true);
RELEASE sp2;
SELECT pgv_get('pack', 'var_text', NULL::text);
pgv_get
-----
savepoint sp2

ROLLBACK TO sp1;
SELECT pgv_get('pack', 'var_text', NULL::text);
pgv_get
-----
before savepoint

ROLLBACK;
SELECT pgv_get('pack', 'var_text', NULL::text);
pgv_get
-----
before transaction block

```

If you create a variable after `BEGIN` or `SAVEPOINT` statements and then rollback to the previous state, the transactional variable is removed:

```

BEGIN;
SAVEPOINT sp1;
SAVEPOINT sp2;
SELECT pgv_set('pack', 'var_int', 122, true);
RELEASE SAVEPOINT sp2;
SELECT pgv_get('pack', 'var_int', NULL::int);
pgv_get
-----
122

ROLLBACK TO sp1;

```

```
SELECT pgv_get('pack','var_int', NULL::int);
ERROR:  unrecognized variable "var_int"
COMMIT;
```

List the available packages and variables:

```
SELECT * FROM pgv_list() ORDER BY package, name;
 package |   name   | is_transactional
-----+-----+-----
 pack    | var_text | t
 vars    | int1     | f
 vars    | int2     | f
 vars    | r1       | f
 vars    | text1    | f
```

Get the amount of memory used by variables, in bytes:

```
SELECT * FROM pgv_stats() ORDER BY package;
 package | allocated_memory
-----+-----
 pack    |          16384
 vars    |          32768
```

Delete the specified variables or packages:

```
SELECT pgv_remove('vars', 'int1');
SELECT pgv_remove('vars');
```

Delete all packages and variables:

```
SELECT pgv_free();
```

F.49.5. Authors

Postgres Professional, Moscow, Russia

F.50. pg_visibility

The `pg_visibility` module provides a means for examining the visibility map (VM) and page-level visibility information of a table. It also provides functions to check the integrity of a visibility map and to force it to be rebuilt.

Three different bits are used to store information about page-level visibility. The all-visible bit in the visibility map indicates that every tuple in the corresponding page of the relation is visible to every current and future transaction. The all-frozen bit in the visibility map indicates that every tuple in the page is frozen; that is, no future vacuum will need to modify the page until such time as a tuple is inserted, updated, deleted, or locked on that page. The page header's `PD_ALL_VISIBLE` bit has the same meaning as the all-visible bit in the visibility map, but is stored within the data page itself rather than in a separate data structure. These two bits will normally agree, but the page's all-visible bit can sometimes be set while the visibility map bit is clear after a crash recovery. The reported values can also disagree because of a change that occurs after `pg_visibility` examines the visibility map and before it examines the data page. Any event that causes data corruption can also cause these bits to disagree.

Functions that display information about `PD_ALL_VISIBLE` bits are much more costly than those that only consult the visibility map, because they must read the relation's data blocks rather than only the (much smaller) visibility map. Functions that check the relation's data blocks are similarly expensive.

F.50.1. Functions

```
pg_visibility_map(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen
OUT boolean) returns record
```

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation.

`pg_visibility(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean)` returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation, plus the `PD_ALL_VISIBLE` bit of that block.

`pg_visibility_map(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean)` returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation.

`pg_visibility(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean)` returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation, plus the `PD_ALL_VISIBLE` bit of each block.

`pg_visibility_map_summary(relation regclass, all_visible OUT bigint, all_frozen OUT bigint)` returns record

Returns the number of all-visible pages and the number of all-frozen pages in the relation according to the visibility map.

`pg_check_frozen(relation regclass, t_ctid OUT tid)` returns setof tid

Returns the TIDs of non-frozen tuples stored in pages marked all-frozen in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

`pg_check_visible(relation regclass, t_ctid OUT tid)` returns setof tid

Returns the TIDs of non-all-visible tuples stored in pages marked all-visible in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

`pg_truncate_visibility_map(relation regclass)` returns void

Truncates the visibility map for the given relation. This function is useful if you believe that the visibility map for the relation is corrupt and wish to force rebuilding it. The first `VACUUM` executed on the given relation after this function is executed will scan every page in the relation and rebuild the visibility map. (Until that is done, queries will treat the visibility map as containing all zeroes.)

By default, these functions are executable only by superusers.

F.51. `pg_wait_sampling`

`pg_wait_sampling` is a Postgres Pro Enterprise extension for collecting sampling-based statistics on wait events.

Starting from the 9.6 version, Postgres Pro Enterprise provides information about the current wait events for particular processes. However, to get descriptive statistics of the server activity, you have to sample wait events multiple times. The `pg_wait_sampling` extension automates wait events sampling by launching a special background worker. With `pg_wait_sampling` enabled, you can get the following sampling-based data:

- *Waits history* — the list of wait events for recent processes, with timestamps.
- *Waits profile* — the number of wait event samples for all processes over time, per wait event type.
- Current wait events for all processes, including background workers.

Using `pg_wait_sampling`, you can troubleshoot dependencies for queries that take longer than expected. You can see what a particular process is waiting for at each moment of time, and analyze wait events statistics. For the list of possible wait events, see [Table 28.4](#).

See Also

[Viewing Statistics on Wait Events](#)

[Reference](#)

F.51.1. Installation

The `pg_wait_sampling` extension is included into Postgres Pro Enterprise and requires no special prerequisites.

To enable `pg_wait_sampling`, do the following:

1. Add `pg_wait_sampling` to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'pg_wait_sampling'
```

2. Create the `pg_wait_sampling` extension using the following query:

```
CREATE EXTENSION pg_wait_sampling;
```

3. Restart the server. Since `pg_wait_sampling` requires additional shared memory and launches a background worker, you must restart the server after adding or removing `pg_wait_sampling`.

Once the extension is created, `pg_wait_sampling` starts collecting statistics on wait events for each process. Optionally, you can change the sampling frequency and configure statistics collection modes using [GUC variables](#).

If you want to stop collecting statistics, drop the `pg_wait_sampling` extension, remove the `pg_wait_sampling` from the `shared_preload_libraries` variable, and restart the server again.

F.51.2. Usage

F.51.2.1. Viewing Statistics on Wait Events

When `pg_wait_sampling` is enabled, wait events are sampled each 10ms by default. You can access the collected statistics through a set of functions and views. If some of your queries appear stalled or take longer than expected, you can review all the current wait events in the `pg_wait_sampling_current` view:

```
SELECT * FROM pg_wait_sampling_current;
```

The returned statistics covers all the active processes, including background workers. To filter the view for a single process, run `pg_wait_sampling_get_current()` function specifying the process ID:

```
SELECT * FROM pg_wait_sampling_get_current(pid);
```

To better understand the dynamics of the recent wait events, you can access the `pg_wait_sampling_history` view that provides the wait events history for the latest processes:

```
SELECT * FROM pg_wait_sampling_history;
```

The returned view displays wait samples per process, with event timestamps. Waits history is implemented as an in-memory ring buffer. By default, the history size is limited to 5000 samples. To save history for a longer period of time, you can modify the `pg_wait_sampling.history_size` variable, or connect a client application to periodically read waits history and dump it to a local storage.

To monitor wait events in your database over time, use the `pg_wait_sampling_profile` view:

```
SELECT * FROM pg_wait_sampling_profile;
```

Waits profile is stored as an in-memory hash table that accumulates samples per each process and each wait event. You can reset waits profile by calling the `pg_wait_sampling_reset_profile()` function. If you connect a client to your database that periodically dumps the wait events data and resets the profile, you can save and compare statistics of wait events intensity over time.

Important

Since wait sampling statistics is stored in RAM, make sure to reset the waits profile from time to time to avoid memory overflow.

If you are not interested in the distribution of wait events between processes, you can set the `pg_wait_sampling.profile_pid` variable to `false`. In this case, the `pid` value for each process is set to zero, and wait samples for all the processes are stored together.

F.51.3. Reference

F.51.3.1. GUC Variables

The `pg_wait_sampling` extension is configured with GUC variables. You must have superuser rights to change GUC variables. Since these variables are placed into shared memory, you can change them from any backend that affects the `pg_wait_sampling` background worker runtime.

`pg_wait_sampling.history_size (int4)`

Size of in-memory ring buffer for history sampling, in the number of samples.

Default: 5000

`pg_wait_sampling.history_period (int4)`

Time interval for history sampling, in milliseconds.

Default: 10

`pg_wait_sampling.profile_period (int4)`

Time interval for waits profile sampling, in milliseconds.

Default: 10

`pg_wait_sampling.profile_pid (int4)`

Sampling mode for waits profile. If set to `true`, waits profile is collected per process. If you set `pg_wait_sampling.profile_pid` to `false`, waits profile is collected for all processes together. In this case, the `pid` value for each process is set to zero, and the corresponding row contains wait samples for all the processes.

Default: `true`

F.51.3.2. `pg_wait_sampling` Views

F.51.3.2.1. `pg_wait_sampling_current` View

The `pg_wait_sampling_current` view provides the information about the current wait events for all processes, including background workers.

Table F.37. `pg_wait_sampling_current` View

Column Name	Column Type	Description
<code>pid</code>	<code>int4</code>	Process ID

Column Name	Column Type	Description
event_type	text	Name of wait event type
event	text	Name of wait event

F.51.3.2.2. `pg_wait_sampling_history` View

The `pg_wait_sampling_history` view provides the history of wait events. This data is stored as an in-memory ring buffer.

Table F.38. `pg_wait_sampling_history` View

Column Name	Column Type	Description
pid	int4	Process ID
ts	timestampz	Sample timestamp
event_type	text	Name of wait event type
event	text	Name of wait event

F.51.3.2.3. `pg_wait_sampling_profile` View

The `pg_wait_sampling_profile` view provides the profile of wait events. This data is stored as an in-memory hash table.

Table F.39. `pg_wait_sampling_profile` View

Column Name	Column Type	Description
pid	int4	Process ID
event_type	text	Name of wait event type
event	text	Name of wait event
count	text	Number of samples

F.51.3.3. Functions

`pg_wait_sampling_get_current(pid int4)`

Returns the `pg_wait_sampling_current` view with the list of current wait events. If you set the `pid` argument, the view is filtered for the process with this `pid`.

Arguments:

- `pid` — Optional. The process ID for which to display the current wait events.

`pg_wait_sampling_reset_profile()`

Resets the waits profile and clears the memory.

Alexander Korotkov

F.52. plantuner

The `plantuner` module provides hints for the planner that can disable or enable indexes for query execution.

F.52.1. Motivation

In some cases, it may be required to control the planner by providing hints that make the optimizer ignore some parts of its algorithm. There are many situations when a developer may want to temporarily disable specific index(es), without dropping them, or to instruct the planner to use a specific index.

This version of `plantuner` provides a possibility to hide the specified indexes from Postgres Pro planner, so it will not use them. For some workloads, Postgres Pro could be too pessimistic about newly created tables and assume that there are much more rows in a table than it actually has. If the `plantuner.fix_empty_table` GUC variable is set to `true`, `plantuner` sets to zero the number of pages/tuples of the table that has no blocks in a file.

F.52.2. GUC Variables

`plantuner.disable_index` — list of indexes invisible to planner.

`plantuner.enable_index` — list of indexes visible to planner even if they are hidden by `plantuner.disable_index`.

F.52.3. Example

To enable the module, you can either load `plantuner` shared library in a `psql` session or specify `shared_preload_libraries` option in `postgresql.conf`.

```
=# LOAD 'plantuner';
=# create table test(id int);
=# create index id_idx on test(id);
=# create index id_idx2 on test(id);
=# \d test
      Table "public.test"
  Column | Type      | Modifiers
-----+-----+-----
 id      | integer   |
Indexes:
    "id_idx" btree (id)
    "id_idx2" btree (id)
=# explain select id from test where id=1;
               QUERY PLAN
-----
Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
    -> Bitmap Index Scan on id_idx2  (cost=0.00..4.34 rows=12 width=0)
        Index Cond: (id = 1)
(4 rows)
=# set enable_seqscan=off;
=# set plantuner.disable_index='id_idx2';
=# explain select id from test where id=1;
               QUERY PLAN
-----
Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
    -> Bitmap Index Scan on id_idx  (cost=0.00..4.34 rows=12 width=0)
        Index Cond: (id = 1)
(4 rows)
=# set plantuner.disable_index='id_idx2,id_idx';
=# explain select id from test where id=1;
               QUERY PLAN
-----
Seq Scan on test  (cost=10000000000.00..10000000040.00 rows=12 width=4)
  Filter: (id = 1)
(2 rows)
=# set plantuner.enable_index='id_idx';
=# explain select id from test where id=1;
               QUERY PLAN
-----
```

```
Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
    -> Bitmap Index Scan on id_idx  (cost=0.00..4.34 rows=12 width=0)
        Index Cond: (id = 1)
(4 rows)
```

The work sponsored by Nomao project (<http://www.nomao.com>).

F.53. postgres_fdw

The `postgres_fdw` module provides the foreign-data wrapper `postgres_fdw`, which can be used to access data stored in external Postgres Pro servers.

The functionality provided by this module overlaps substantially with the functionality of the older [dblink](#) module. But `postgres_fdw` provides more transparent and standards-compliant syntax for accessing remote tables, and can give better performance in many cases.

To prepare for remote access using `postgres_fdw`:

1. Install the `postgres_fdw` extension using [CREATE EXTENSION](#).
2. Create a foreign server object, using [CREATE SERVER](#), to represent each remote database you want to connect to. Specify connection information, except `user` and `password`, as options of the server object.
3. Create a user mapping, using [CREATE USER MAPPING](#), for each database user you want to allow to access each foreign server. Specify the remote user name and password to use as `user` and `password` options of the user mapping.
4. Create a foreign table, using [CREATE FOREIGN TABLE](#) or [IMPORT FOREIGN SCHEMA](#), for each remote table you want to access. The columns of the foreign table must match the referenced remote table. You can, however, use table and/or column names different from the remote table's, if you specify the correct remote names as options of the foreign table object.

Now you need only `SELECT` from a foreign table to access the data stored in its underlying remote table. You can also modify the remote table using `INSERT`, `UPDATE`, or `DELETE`. (Of course, the remote user you have specified in your user mapping must have privileges to do these things.)

Note that `postgres_fdw` currently lacks support for `INSERT` statements with an `ON CONFLICT DO UPDATE` clause. However, the `ON CONFLICT DO NOTHING` clause is supported, provided a unique index inference specification is omitted.

It is generally recommended that the columns of a foreign table be declared with exactly the same data types, and collations if applicable, as the referenced columns of the remote table. Although `postgres_fdw` is currently rather forgiving about performing data type conversions at need, surprising semantic anomalies may arise when types or collations do not match, due to the remote server interpreting `WHERE` clauses slightly differently from the local server.

Note that a foreign table can be declared with fewer columns, or with a different column order, than its underlying remote table has. Matching of columns to the remote table is by name, not position.

F.53.1. FDW Options of postgres_fdw

F.53.1.1. Connection Options

A foreign server using the `postgres_fdw` foreign data wrapper can have the same options that `libpq` accepts in connection strings, as described in [Section 32.1.2](#), except that these options are not allowed:

- `user` and `password` (specify these in a user mapping, instead)
- `client_encoding` (this is automatically set from the local server encoding)

- `fallback_application_name` (always set to `postgres_fdw`)

Only superusers may connect to foreign servers without password authentication, so always specify the `password` option for user mappings belonging to non-superusers.

F.53.1.2. Object Name Options

These options can be used to control the names used in SQL statements sent to the remote Postgres Pro server. These options are needed when a foreign table is created with names different from the underlying remote table's names.

`schema_name`

This option, which can be specified for a foreign table, gives the schema name to use for the foreign table on the remote server. If this option is omitted, the name of the foreign table's schema is used.

`table_name`

This option, which can be specified for a foreign table, gives the table name to use for the foreign table on the remote server. If this option is omitted, the foreign table's name is used.

`column_name`

This option, which can be specified for a column of a foreign table, gives the column name to use for the column on the remote server. If this option is omitted, the column's name is used.

F.53.1.3. Cost Estimation Options

`postgres_fdw` retrieves remote data by executing queries against remote servers, so ideally the estimated cost of scanning a foreign table should be whatever it costs to be done on the remote server, plus some overhead for communication. The most reliable way to get such an estimate is to ask the remote server and then add something for overhead — but for simple queries, it may not be worth the cost of an additional remote query to get a cost estimate. So `postgres_fdw` provides the following options to control how cost estimation is done:

`use_remote_estimate`

This option, which can be specified for a foreign table or a foreign server, controls whether `postgres_fdw` issues remote `EXPLAIN` commands to obtain cost estimates. A setting for a foreign table overrides any setting for its server, but only for that table. The default is `false`.

`fdw_startup_cost`

This option, which can be specified for a foreign server, is a numeric value that is added to the estimated startup cost of any foreign-table scan on that server. This represents the additional overhead of establishing a connection, parsing and planning the query on the remote side, etc. The default value is `100`.

`fdw_tuple_cost`

This option, which can be specified for a foreign server, is a numeric value that is used as extra cost per-tuple for foreign-table scans on that server. This represents the additional overhead of data transfer between servers. You might increase or decrease this number to reflect higher or lower network delay to the remote server. The default value is `0.01`.

When `use_remote_estimate` is `true`, `postgres_fdw` obtains row count and cost estimates from the remote server and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. When `use_remote_estimate` is `false`, `postgres_fdw` performs local row count and cost estimation and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. This local estimation is unlikely to be very accurate unless local copies of the remote table's statistics are available. Running [ANALYZE](#) on the foreign table is the way to update the local statistics; this will perform a scan of the remote table and then calculate and store statistics just as though the table were local. Keeping local statistics can be a useful way to reduce per-query planning overhead for a remote table — but if the remote table is frequently updated, the local statistics will soon be obsolete.

F.53.1.4. Remote Execution Options

By default, only `WHERE` clauses using built-in operators and functions will be considered for execution on the remote server. Clauses involving non-built-in functions are checked locally after rows are fetched. If such functions are available on the remote server and can be relied on to produce the same results as they do locally, performance can be improved by sending such `WHERE` clauses for remote execution. This behavior can be controlled using the following option:

`extensions`

This option is a comma-separated list of names of Postgres Pro extensions that are installed, in compatible versions, on both the local and remote servers. Functions and operators that are immutable and belong to a listed extension will be considered shippable to the remote server. This option can only be specified for foreign servers, not per-table.

When using the `extensions` option, *it is the user's responsibility* that the listed extensions exist and behave identically on both the local and remote servers. Otherwise, remote queries may fail or behave unexpectedly.

`fetch_size`

This option specifies the number of rows `postgres_fdw` should get in each fetch operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is `100`.

F.53.1.5. Updatability Options

By default all foreign tables using `postgres_fdw` are assumed to be updatable. This may be overridden using the following option:

`updatable`

This option controls whether `postgres_fdw` allows foreign tables to be modified using `INSERT`, `UPDATE` and `DELETE` commands. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`.

Of course, if the remote table is not in fact updatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server. Note however that the `information_schema` views will report a `postgres_fdw` foreign table to be updatable (or not) according to the setting of this option, without any check of the remote server.

F.53.1.6. Importing Options

`postgres_fdw` is able to import foreign table definitions using `IMPORT FOREIGN SCHEMA`. This command creates foreign table definitions on the local server that match tables or views present on the remote server. If the remote tables to be imported have columns of user-defined data types, the local server must have compatible types of the same names.

Importing behavior can be customized with the following options (given in the `IMPORT FOREIGN SCHEMA` command):

`import_collate`

This option controls whether column `COLLATE` options are included in the definitions of foreign tables imported from a foreign server. The default is `true`. You might need to turn this off if the remote server has a different set of collation names than the local server does, which is likely to be the case if it's running on a different operating system.

`import_default`

This option controls whether column `DEFAULT` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `false`. If you enable this option, be wary of defaults that might get computed differently on the local server than they would be on the remote

server; `nextval()` is a common source of problems. The `IMPORT` will fail altogether if an imported default expression uses a function or operator that does not exist locally.

`import_not_null`

This option controls whether column `NOT NULL` constraints are included in the definitions of foreign tables imported from a foreign server. The default is `true`.

Note that constraints other than `NOT NULL` will never be imported from the remote tables. Although Postgres Pro does support `CHECK` constraints on foreign tables, there is no provision for importing them automatically, because of the risk that a constraint expression could evaluate differently on the local and remote servers. Any such inconsistency in the behavior of a `CHECK` constraint could lead to hard-to-detect errors in query optimization. So if you wish to import `CHECK` constraints, you must do so manually, and you should verify the semantics of each one carefully. For more detail about the treatment of `CHECK` constraints on foreign tables, see [CREATE FOREIGN TABLE](#).

F.53.2. Connection Management

`postgres_fdw` establishes a connection to a foreign server during the first query that uses a foreign table associated with the foreign server. This connection is kept and re-used for subsequent queries in the same session. However, if multiple user identities (user mappings) are used to access the foreign server, a connection is established for each user mapping.

F.53.3. Transaction Management

During a query that references any remote tables on a foreign server, `postgres_fdw` opens a transaction on the remote server if one is not already open corresponding to the current local transaction. The remote transaction is committed or aborted when the local transaction commits or aborts. Savepoints are similarly managed by creating corresponding remote savepoints.

The remote transaction uses `SERIALIZABLE` isolation level when the local transaction has `SERIALIZABLE` isolation level; otherwise it uses `REPEATABLE READ` isolation level. This choice ensures that if a query performs multiple table scans on the remote server, it will get snapshot-consistent results for all the scans. A consequence is that successive queries within a single transaction will see the same data from the remote server, even if concurrent updates are occurring on the remote server due to other activities. That behavior would be expected anyway if the local transaction uses `SERIALIZABLE` or `REPEATABLE READ` isolation level, but it might be surprising for a `READ COMMITTED` local transaction. A future Postgres Pro release might modify these rules.

Note that it is currently not supported by `postgres_fdw` to prepare the remote transaction for two-phase commit.

F.53.4. Remote Query Optimization

`postgres_fdw` attempts to optimize remote queries to reduce the amount of data transferred from foreign servers. This is done by sending query `WHERE` clauses to the remote server for execution, and by not retrieving table columns that are not needed for the current query. To reduce the risk of misexecution of queries, `WHERE` clauses are not sent to the remote server unless they use only data types, operators, and functions that are built-in or belong to an extension that's listed in the foreign server's `extensions` option. Operators and functions in such clauses must be `IMMUTABLE` as well. For an `UPDATE` or `DELETE` query, `postgres_fdw` attempts to optimize the query execution by sending the whole query to the remote server if there are no query `WHERE` clauses that cannot be sent to the remote server, no local joins for the query, no row-level local `BEFORE` or `AFTER` triggers on the target table, and no `CHECK OPTION` constraints from parent views. In `UPDATE`, expressions to assign to target columns must use only built-in data types, `IMMUTABLE` operators, or `IMMUTABLE` functions, to reduce the risk of misexecution of the query.

When `postgres_fdw` encounters a join between foreign tables on the same foreign server, it sends the entire join to the foreign server, unless for some reason it believes that it will be more efficient to fetch rows from each table individually, or unless the table references involved are subject to different user

mappings. While sending the `JOIN` clauses, it takes the same precautions as mentioned above for the `WHERE` clauses.

The query that is actually sent to the remote server for execution can be examined using `EXPLAIN VERBOSE`.

F.53.5. Remote Query Execution Environment

In the remote sessions opened by `postgres_fdw`, the `search_path` parameter is set to just `pg_catalog`, so that only built-in objects are visible without schema qualification. This is not an issue for queries generated by `postgres_fdw` itself, because it always supplies such qualification. However, this can pose a hazard for functions that are executed on the remote server via triggers or rules on remote tables. For example, if a remote table is actually a view, any functions used in that view will be executed with the restricted search path. It is recommended to schema-qualify all names in such functions, or else attach `SET search_path` options (see [CREATE FUNCTION](#)) to such functions to establish their expected search path environment.

`postgres_fdw` likewise establishes remote session settings for the parameters [TimeZone](#), [DateStyle](#), [IntervalStyle](#), and [extra_float_digits](#). These are less likely to be problematic than `search_path`, but can be handled with function `SET` options if the need arises.

It is *not* recommended that you override this behavior by changing the session-level settings of these parameters; that is likely to cause `postgres_fdw` to malfunction.

F.53.6. Cross-Version Compatibility

`postgres_fdw` can be used with remote servers dating back to PostgreSQL 8.3. Read-only capability is available back to 8.1. A limitation however is that `postgres_fdw` generally assumes that immutable built-in functions and operators are safe to send to the remote server for execution, if they appear in a `WHERE` clause for a foreign table. Thus, a built-in function that was added since the remote server's release might be sent to it for execution, resulting in “function does not exist” or a similar error. This type of failure can be worked around by rewriting the query, for example by embedding the foreign table reference in a sub-`SELECT` with `OFFSET 0` as an optimization fence, and placing the problematic function or operator outside the sub-`SELECT`.

F.53.7. Examples

Here is an example of creating a foreign table with `postgres_fdw`. First install the extension:

```
CREATE EXTENSION postgres_fdw;
```

Then create a foreign server using [CREATE SERVER](#). In this example we wish to connect to a Postgres Pro server on host `192.83.123.89` listening on port `5432`. The database to which the connection is made is named `foreign_db` on the remote server:

```
CREATE SERVER foreign_server
    FOREIGN DATA WRAPPER postgres_fdw
    OPTIONS (host '192.83.123.89', port '5432', dbname 'foreign_db');
```

A user mapping, defined with [CREATE USER MAPPING](#), is needed as well to identify the role that will be used on the remote server:

```
CREATE USER MAPPING FOR local_user
    SERVER foreign_server
    OPTIONS (user 'foreign_user', password 'password');
```

Now it is possible to create a foreign table with [CREATE FOREIGN TABLE](#). In this example we wish to access the table named `some_schema.some_table` on the remote server. The local name for it will be `foreign_table`:

```
CREATE FOREIGN TABLE foreign_table (
    id integer NOT NULL,
```

```
data text
)

SERVER foreign_server
OPTIONS (schema_name 'some_schema', table_name 'some_table');
```

It's essential that the data types and other properties of the columns declared in `CREATE FOREIGN TABLE` match the actual remote table. Column names must match as well, unless you attach `column_name` options to the individual columns to show how they are named in the remote table. In many cases, use of [IMPORT FOREIGN SCHEMA](#) is preferable to constructing foreign table definitions manually.

Shigeru Hanada <shigeru.hanada@gmail.com>

F.54. referee

`referee` is a Postgres Pro Enterprise extension for managing quorum settings in clusters with an even number of nodes configured with [multimaster](#). Installed on a separate system, the `referee` extension provides a voting node to assign the quorum status to a subset of nodes if only half of the cluster nodes remain connected to each other.

If a multi-master cluster is split into equal parts, or half of the cluster nodes fail, each subset of nodes that equals half of the cluster tries to access the referee. The first subset that gets connected to the referee wins the voting and continues working, while all the other nodes are excluded from the cluster to avoid split-brain problems.

The referee node does not store any cluster data, so it is very lightweight and can be located on systems with limited resources. For details on how to set up and use a referee node with `multimaster`, see [Section F.31.3.3.1](#).

F.55. rum

F.55.1. Introduction

The **rum** module provides access method to work with the `RUM` indexes. It is based on the `GIN` access methods code.

`GIN` index allows to perform fast full-text search using `tsvector` and `tsquery` types. However, full-text search with `GIN` index has the following drawbacks:

- Slow ranking. Ranking requires positional information, but `GIN` index does not store positions of lexemes. So after the index scan we need an additional heap scan to retrieve lexeme positions.
- Slow phrase search. This problem is related to the previous one as phrase search also needs positional information.
- Slow ordering by timestamp. `GIN` index cannot store any additional information together with lexemes, so it is necessary to perform a heap scan.

`RUM` solves these issues by storing additional information in posting tree. In particular, it stores positional information of lexemes or timestamps.

The drawback of `RUM` is that it has slower build and insert time as compared to `GIN` because `RUM` stores additional information together with keys and uses generic WAL records.

F.55.2. Installation

`rum` is a Postgres Pro Enterprise extension and it has no special prerequisites.

Install extension as follows:

```
$ psql dbname -c "CREATE EXTENSION rum"
```

F.55.3. Common Operators

The operators provided by the `rum` module are shown in [Table F.40](#):

Table F.40. `rum` Operators

Operator	Returns	Description
<code>tsvector <=> tsquery</code>	<code>float4</code>	Returns distance between <code>tsvector</code> and <code>tsquery</code> values.
<code>timestamp <=> timestamp</code>	<code>float8</code>	Returns distance between two <code>timestamp</code> values.
<code>timestamp <= timestamp</code>	<code>float8</code>	Returns distance only for ascending <code>timestamp</code> values.
<code>timestamp => timestamp</code>	<code>float8</code>	Returns distance only for descending <code>timestamp</code> values.

F.55.4. Operator Classes

The `rum` extension provides the following operator classes:

`rum_tsvector_ops`

Stores `tsvector` lexemes with positional information. Supports ordering by `<=>` operator and prefix search.

`rum_tsvector_hash_ops`

Stores hash of `tsvector` lexemes with positional information. Supports ordering by `<=>` operator, but does not support prefix search.

`rum_tsvector_addon_ops`

Stores `tsvector` lexemes with additional data of any type supported by `RUM`.

`rum_tsvector_hash_addon_ops`

Stores `tsvector` lexemes with additional data of any type supported by `RUM`. Does not support prefix search.

`rum_tsquery_ops`

Stores branches of query tree in additional information.

`rum_anyarray_ops`

Stores `anyarray` elements with length of the array. Supports ordering by `<=>` operator.

Indexable operators: `&&` `@>` `<@` `=` `%`

`rum_anyarray_addon_ops`

Stores `anyarray` elements with additional data of any type supported by `RUM`.

`rum_type_ops`

Stores lexemes of the corresponding type with positional information. The `type` placeholder in the class name must be substituted by one of the following type names: `int2`, `int4`, `int8`, `float4`, `float8`,

money, oid, timestamp, timestampz, time, timetz, date, interval, macaddr, inet, cidr, text, varchar, char, bytea, bit, varbit, numeric.

`rum_type_ops` supports ordering by `<=>`, `<=|`, and `|=>` operators. This operator class can be used together with `rum_tsvector_addon_ops`, `rum_tsvector_hash_addon_ops`, and `rum_anyarray_addon_ops` operator classes.

Supported indexable operators depend on the data type:

- `<` `<=` `=` `>=` `>` `<=>` `<=|` `|=>` are supported for `int2`, `int4`, `int8`, `float4`, `float8`, `money`, `oid`, `timestamp`, `timestampz`.
- `<` `<=` `=` `>=` `>` are supported for `time`, `timetz`, `date`, `interval`, `macaddr`, `inet`, `cidr`, `text`, `varchar`, `char`, `bytea`, `bit`, `varbit`, `numeric`.

Note

The following operator classes are now deprecated: `rum_tsvector_timestamp_ops`, `rum_tsvector_timestampz_ops`, `rum_tsvector_hash_timestamp_ops`, `rum_tsvector_hash_timestampz_ops`.

F.55.5. Examples

F.55.5.1. `rum_tsvector_ops` Example

Let's assume we have the following table:

```
CREATE TABLE test_rum(t text, a tsvector);

CREATE TRIGGER tsvectorupdate
BEFORE UPDATE OR INSERT ON test_rum
FOR EACH ROW EXECUTE PROCEDURE tsvector_update_trigger('a', 'pg_catalog.english', 't');

INSERT INTO test_rum(t) VALUES ('The situation is most beautiful');
INSERT INTO test_rum(t) VALUES ('It is a beautiful');
INSERT INTO test_rum(t) VALUES ('It looks like a beautiful place');
```

Then we can create a new index:

```
CREATE INDEX rumidx ON test_rum USING rum (a rum_tsvector_ops);
```

And we can execute the following queries:

```
SELECT t, a <=> to_tsquery('english', 'beautiful | place') AS rank
FROM test_rum
WHERE a @@ to_tsquery('english', 'beautiful | place')
ORDER BY a <=> to_tsquery('english', 'beautiful | place');
      t              | rank
-----+-----
The situation is most beautiful | 0.0303964
It is a beautiful              | 0.0303964
It looks like a beautiful place | 0.0607927
(3 rows)
```

```
SELECT t, a <=> to_tsquery('english', 'place | situation') AS rank
FROM test_rum
WHERE a @@ to_tsquery('english', 'place | situation')
ORDER BY a <=> to_tsquery('english', 'place | situation');
      t              | rank
-----+-----
```

```
The situation is most beautiful | 0.0303964
It looks like a beautiful place | 0.0303964
(2 rows)
```

F.55.5.2. rum_tsvector_addon_ops Example

Let's assume we have the following table:

```
CREATE TABLE tsts (id int, t tsvector, d timestamp);

\copy tsts from 'rum/data/tsts.data'

CREATE INDEX tsts_idx ON tsts USING rum (t rum_tsvector_addon_ops, d)
  WITH (attach = 'd', to = 't');
```

Now we can execute the following queries:

```
EXPLAIN (costs off)
  SELECT id, d, d <=> '2016-05-16 14:21:25' FROM tsts WHERE t @@ 'wr&qh' ORDER BY d
  <=> '2016-05-16 14:21:25' LIMIT 5;
                                QUERY PLAN
```

```
-----
Limit
->  Index Scan using tsts_idx on tsts
      Index Cond: (t @@ '''wr'' & ''qh''::tsquery)
      Order By: (d <=> 'Mon May 16 14:21:25 2016'::timestamp without time zone)
(4 rows)
```

```
SELECT id, d, d <=> '2016-05-16 14:21:25' FROM tsts WHERE t @@ 'wr&qh' ORDER BY d <=>
'2016-05-16 14:21:25' LIMIT 5;
 id |          d          | ?column?
-----+-----+-----
355 | Mon May 16 14:21:22.326724 2016 | 2.673276
354 | Mon May 16 13:21:22.326724 2016 | 3602.673276
371 | Tue May 17 06:21:22.326724 2016 | 57597.326724
406 | Wed May 18 17:21:22.326724 2016 | 183597.326724
415 | Thu May 19 02:21:22.326724 2016 | 215997.326724
(5 rows)
```

F.55.5.3. rum_tsquery_ops Example

Suppose we have the table:

```
CREATE TABLE query (q tsquery, tag text);

INSERT INTO query VALUES ('supernova & star', 'sn'),
  ('black', 'color'),
  ('big & bang & black & hole', 'bang'),
  ('spiral & galaxy', 'shape'),
  ('black & hole', 'color');

CREATE INDEX query_idx ON query USING rum(q);
```

We can execute the following fast query:

```
SELECT * FROM query
  WHERE to_tsvector('black holes never exists before we think about them') @@ q;
      q          | tag
-----+-----
'black'          | color
'black' & 'hole' | color
(2 rows)
```

F.55.5.4. rum_anyarray_ops Example

Let's assume we have the following table:

```
CREATE TABLE test_array (i int2[]);

INSERT INTO test_array VALUES ('{}'), ('{0}'), ('{1,2,3,4}'), ('{1,2,3}'), ('{1,2}'),
    ('{1}');

CREATE INDEX idx_array ON test_array USING rum (i rum_anyarray_ops);
```

Now we can execute the following query using index scan:

```
SET enable_seqscan TO off;

EXPLAIN (COSTS OFF) SELECT * FROM test_array WHERE i && '{1}' ORDER BY i <=> '{1}' ASC;
      QUERY PLAN
-----
Index Scan using idx_array on test_array
  Index Cond: (i && '{1}'::smallint[])
  Order By: (i <=> '{1}'::smallint[])
(3 rows)

SELECT * FROM test_array WHERE i && '{1}' ORDER BY i <=> '{1}' ASC;
      i
-----
 {1}
 {1,2}
 {1,2,3}
 {1,2,3,4}
(4 rows)
```

F.56. seg

This module implements a data type `seg` for representing line segments, or floating point intervals. `seg` can represent uncertainty in the interval endpoints, making it especially useful for representing laboratory measurements.

F.56.1. Rationale

The geometry of measurements is usually more complex than that of a point in a numeric continuum. A measurement is usually a segment of that continuum with somewhat fuzzy limits. The measurements come out as intervals because of uncertainty and randomness, as well as because the value being measured may naturally be an interval indicating some condition, such as the temperature range of stability of a protein.

Using just common sense, it appears more convenient to store such data as intervals, rather than pairs of numbers. In practice, it even turns out more efficient in most applications.

Further along the line of common sense, the fuzziness of the limits suggests that the use of traditional numeric data types leads to a certain loss of information. Consider this: your instrument reads 6.50, and you input this reading into the database. What do you get when you fetch it? Watch:

```
test=> select 6.50 :: float8 as "pH";
```

```
pH
---
6.5
(1 row)
```

In the world of measurements, 6.50 is not the same as 6.5. It may sometimes be critically different. The experimenters usually write down (and publish) the digits they trust. 6.50 is actually a fuzzy interval contained within a bigger and even fuzzier interval, 6.5, with their center points being (probably) the only common feature they share. We definitely do not want such different data items to appear the same.

Conclusion? It is nice to have a special data type that can record the limits of an interval with arbitrarily variable precision. Variable in the sense that each data element records its own precision.

Check this out:

```
test=> select '6.25 .. 6.50'::seg as "pH";
           pH
-----
6.25 .. 6.50
(1 row)
```

F.56.2. Syntax

The external representation of an interval is formed using one or two floating-point numbers joined by the range operator (`..` or `...`). Alternatively, it can be specified as a center point plus or minus a deviation. Optional certainty indicators (`<`, `>` or `~`) can be stored as well. (Certainty indicators are ignored by all the built-in operators, however.) [Table F.41](#) gives an overview of allowed representations; [Table F.42](#) shows some examples.

In [Table F.41](#), *x*, *y*, and *delta* denote floating-point numbers. *x* and *y*, but not *delta*, can be preceded by a certainty indicator.

Table F.41. `seg` External Representations

<i>x</i>	Single value (zero-length interval)
<i>x</i> .. <i>y</i>	Interval from <i>x</i> to <i>y</i>
<i>x</i> (+-) <i>delta</i>	Interval from <i>x</i> - <i>delta</i> to <i>x</i> + <i>delta</i>
<i>x</i> ..	Open interval with lower bound <i>x</i>
.. <i>x</i>	Open interval with upper bound <i>x</i>

Table F.42. Examples of Valid `seg` Input

5.0	Creates a zero-length segment (a point, if you will)
~5.0	Creates a zero-length segment and records ~ in the data. ~ is ignored by <code>seg</code> operations, but is preserved as a comment.
<5.0	Creates a point at 5.0. < is ignored but is preserved as a comment.
>5.0	Creates a point at 5.0. > is ignored but is preserved as a comment.
5 (+-) 0.3	Creates an interval 4.7 .. 5.3. Note that the (+-) notation isn't preserved.
50 ..	Everything that is greater than or equal to 50
.. 0	Everything that is less than or equal to 0
1.5e-2 .. 2E-2	Creates an interval 0.015 .. 0.02

1 ... 2	The same as 1...2, or 1 .. 2, or 1..2 (spaces around the range operator are ignored)

Because the ... operator is widely used in data sources, it is allowed as an alternative spelling of the .. operator. Unfortunately, this creates a parsing ambiguity: it is not clear whether the upper bound in 0...23 is meant to be 23 or 0.23. This is resolved by requiring at least one digit before the decimal point in all numbers in `seg` input.

As a sanity check, `seg` rejects intervals with the lower bound greater than the upper, for example 5 .. 2.

F.56.3. Precision

`seg` values are stored internally as pairs of 32-bit floating point numbers. This means that numbers with more than 7 significant digits will be truncated.

Numbers with 7 or fewer significant digits retain their original precision. That is, if your query returns 0.00, you will be sure that the trailing zeroes are not the artifacts of formatting: they reflect the precision of the original data. The number of leading zeroes does not affect precision: the value 0.0067 is considered to have just 2 significant digits.

F.56.4. Usage

The `seg` module includes a GiST index operator class for `seg` values. The operators supported by the GiST operator class are shown in [Table F.43](#).

Table F.43. Seg GiST Operators

Operator	Description
<code>[a, b] << [c, d]</code>	<code>[a, b]</code> is entirely to the left of <code>[c, d]</code> . That is, <code>[a, b] << [c, d]</code> is true if <code>b < c</code> and false otherwise.
<code>[a, b] >> [c, d]</code>	<code>[a, b]</code> is entirely to the right of <code>[c, d]</code> . That is, <code>[a, b] >> [c, d]</code> is true if <code>a > d</code> and false otherwise.
<code>[a, b] &< [c, d]</code>	Overlaps or is left of — This might be better read as “does not extend to right of”. It is true when <code>b <= d</code> .
<code>[a, b] &> [c, d]</code>	Overlaps or is right of — This might be better read as “does not extend to left of”. It is true when <code>a >= c</code> .
<code>[a, b] = [c, d]</code>	Same as — The segments <code>[a, b]</code> and <code>[c, d]</code> are identical, that is, <code>a = c</code> and <code>b = d</code> .
<code>[a, b] && [c, d]</code>	The segments <code>[a, b]</code> and <code>[c, d]</code> overlap.
<code>[a, b] @> [c, d]</code>	The segment <code>[a, b]</code> contains the segment <code>[c, d]</code> , that is, <code>a <= c</code> and <code>b >= d</code> .
<code>[a, b] <@ [c, d]</code>	The segment <code>[a, b]</code> is contained in <code>[c, d]</code> , that is, <code>a >= c</code> and <code>b <= d</code> .

(Before PostgreSQL 8.2, the containment operators `@>` and `<@` were respectively called `@` and `~`. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!)

The standard B-tree operators are also provided, for example

Operator	Description
<code>[a, b] < [c, d]</code>	Less than
<code>[a, b] > [c, d]</code>	Greater than

These operators do not make a lot of sense for any practical purpose but sorting. These operators first compare (a) to (c), and if these are equal, compare (b) to (d). That results in reasonably good sorting in most cases, which is useful if you want to use ORDER BY with this type.

F.56.5. Notes

For examples of usage, see the regression test `sql/seg.sql`.

The mechanism that converts (+-) to regular ranges isn't completely accurate in determining the number of significant digits for the boundaries. For example, it adds an extra digit to the lower boundary if the resulting interval includes a power of ten:

```
postgres=> select '10(+-)1'::seg as seg;
      seg
-----
9.0 .. 11          -- should be: 9 .. 11
```

The performance of an R-tree index can largely depend on the initial order of input values. It may be very helpful to sort the input table on the `seg` column; see the script `sort-segments.pl` for an example.

F.56.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (<https://dsf.berkeley.edu/jmh/>) for elucidating the gist of the GiST (<http://gist.cs.berkeley.edu/>). I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

F.57. shared_ispell

The `shared_ispell` module provides a shared ispell dictionary, i.e. a dictionary that's stored in shared segment. The traditional ispell implementation means that each session initializes and stores the dictionary on it's own, which means a lot of CPU/RAM is wasted.

This extension allocates an area in shared segment (you have to choose the size in advance) and then loads the dictionary into it when it's used for the first time.

F.57.1. Functions

The functions provided by the `shared_ispell` module are shown in [Table F.44](#).

Table F.44. shared_ispell Functions

Function	Returns	Description
<code>shared_ispell_reset()</code>	void	Resets the dictionaries (e.g. so that you can reload the updated files from disk). The sessions that already use the dictionaries will be forced to reinitialize them.
<code>shared_ispell_mem_used()</code>	int	Returns a value of used memory of the shared segment by loaded shared dictionaries in bytes.
<code>shared_ispell_mem_available()</code>	int	Returns a value of available memory of the shared segment.
<code>shared_ispell_dicts()</code>	setof(dict_name varchar, affix_name varchar, words	Returns a list of dictionaries loaded in the shared segment.

Function	Returns	Description
	int, affixes int, bytes int)	
shared_ispell_stoplists()	setof(stop_name varchar, words int, bytes int)	Returns a list of stopwords loaded in the shared segment.

F.57.2. GUC Parameters

`shared_ispell.max_size (int)`

Defines the maximum size of the shared segment. This is a hard limit, the shared segment is not extensible and you need to set it so that all the dictionaries fit into it and not much memory is wasted.

F.57.3. Using the dictionary

The module needs to allocate space in the shared memory segment. So add this to the config file (or update the current values):

```
# libraries to load
shared_preload_libraries = 'shared_ispell'
```

```
# config of the shared memory
shared_ispell.max_size = 32MB
```

To find out how much memory you actually need, use a large value (e.g. 200MB) and load all the dictionaries you want to use. Then use the `shared_ispell_mem_used()` function to find out how much memory was actually used (and set the `shared_ispell.max_size` GUC variable accordingly).

Don't set it exactly to that value, leave there some free space, so that you can reload the dictionaries without changing the GUC `max_size` limit (which requires a restart of the DB). Something like 512kB should be just fine.

The extension defines a `shared_ispell` template that you may use to define custom dictionaries. E.g. you may do this:

```
CREATE TEXT SEARCH DICTIONARY english_shared (
    TEMPLATE = shared_ispell,
    DictFile = en_us,
    AffFile = en_us,
    StopWords = english
);

CREATE TEXT SEARCH CONFIGURATION public.english_shared
( COPY = pg_catalog.simple );

ALTER TEXT SEARCH CONFIGURATION english_shared
ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
                word, hword, hword_part
WITH english_shared, english_stem;
```

We can test created configuration:

```
SELECT * FROM ts_debug('english_shared', 'abilities');
 alias | description | token | dictionaries | dictionary
-----+-----
| lexemes
-----+-----
asciiword | Word, all ASCII | abilities | {english_shared,english_stem} |
english_shared | {ability}
(1 row)
```

Or you can update your own text search configuration. For example, you have the `public.english` dictionary. You can update it to use the `shared_ispell` template:

```
ALTER TEXT SEARCH CONFIGURATION public.english
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
                        word, hword, hword_part
    WITH english_shared, english_stem;
```

Tomas Vondra <tomas.vondra@2ndquadrant.com>, Prague, Czech Republic

F.58. sr_plan

Important

`sr_plan` is incompatible with extensions that use `post_parse_analyze_hook`, such as `pg_stat_statements`. Do not use `sr_plan` together with such extensions.

F.58.1. Rationale

`sr_plan` is an extension which allows to save query execution plans and use these plans for all repetitions of same query, instead of optimizing identical query again and again.

`sr_plan` looks like Oracle Outline system. It can be used to lock the execution plan. It is necessary if you do not trust the planner or able to form a better plan.

Typically, DBA would play with queries interactively, and save their plans and then enable use of saved plans for the queries, where predictable response time is essential.

Then application which uses these queries would use saved plans.

F.58.2. Installation

In your db:

```
CREATE EXTENSION sr_plan;
```

and modify your `postgresql.conf`:

```
shared_preload_libraries = 'sr_plan'
```

It is essential that library is preloaded during server startup, because use of saved plans is enabled on per-database basis and doesn't require any per-connection actions.

F.58.3. Usage

If you want to save the query plan is necessary to set the variable:

```
set sr_plan.write_mode = true;
```

Now plans for all subsequent queries will be stored in the table `sr_plans`, until this variable is set to false. Don't forget that all queries will be stored including duplicates. Making an example query:

```
select query_hash from sr_plans where query_hash=10;
```

Disable saving the query:

```
set sr_plan.write_mode = false;
```

Now verify that your query is saved:

```
select query_hash, enable, valid, query, explain_jsonb_plan(plan) from sr_plans;
```

query_hash	enable	valid	query	explain_jsonb_plan
1783086253	f	t	select query_hash from sr_plans where query_hash=10;	<pre> Bitmap Heap Scan on sr_plans Recheck Cond: (query_hash = 10) -> Bitmap Index Scan on sr_plans_query_hash_idx Index Cond: (query_hash = 10) </pre>

Note use of `explain_jsonb_plan` function, that allows you to visualize execution plan in the similar way as `EXPLAIN` command does.

In the database plans are stored as jsonb. By default, all the newly saved plans are disabled, you need enable it manually:

To enable use of the saved plan

```
update sr_plans set enable=true where query_hash=1783086253;
```

(1783086253 for example only) After that, the plan for the query will be taken from the `sr_plans` table.

In addition sr plan allows you to save a parameterized query plan. In this case, we have some constants in the query that, as we know, do not affect plan.

During plan saving mode we can mark these constants as query parameters using a special function `_p` (anyelement). For example:

```
=>create table test_table (a numeric, b text);
CREATE TABLE
=>insert into test_table values (1,'1'), (2,'2'), (3,'3');
INSERT 0 3
=> set sr_plan.write_mode = true;
SET
=> select a,b from test_table where a = _p(1);
 a | b
---+---
 1 | 1
(1 row)

=> set sr_plan.write_mode = false;
SET
```

Now plan for query from our table is saved with parameter. So, if we enable saved plan in this table, this plan would be used for query with any value for a, as long as this value is wrapped with `_p()` function.

```
=>update sr_plans set enable = true where query=
'select a,b from test_table where a = _p(1)';
UPDATE 1
-- These queries would use saved plan

=>select a,b from test_table where a = _p(2);
```

```
a | b
---+---
2 | 2
(1 row)
```

```
=>select a,b from test_table where a = _p(3);
```

```
a | b
---+---
3 | 3
(1 row)
```

```
-- This query wouldn't use saved plan, because constant is not wrapped
-- with _p()
```

```
=>select a,b from test_table where a = 1;
```

```
a | b
---+---
1 | 1
(1 row)
```

F.59. sslinfo

The `sslinfo` module provides information about the SSL certificate that the current client provided when connecting to Postgres Pro. The module is useless (most functions will return NULL) if the current connection does not use SSL.

This extension won't build at all unless the installation was configured with `--with-openssl`.

F.59.1. Functions Provided

`ssl_is_used()` returns boolean

Returns TRUE if current connection to server uses SSL, and FALSE otherwise.

`ssl_version()` returns text

Returns the name of the protocol used for the SSL connection (e.g., SSLv2, SSLv3, or TLSv1).

`ssl_cipher()` returns text

Returns the name of the cipher used for the SSL connection (e.g., DHE-RSA-AES256-SHA).

`ssl_client_cert_present()` returns boolean

Returns TRUE if current client has presented a valid SSL client certificate to the server, and FALSE otherwise. (The server might or might not be configured to require a client certificate.)

`ssl_client_serial()` returns numeric

Returns serial number of current client certificate. The combination of certificate serial number and certificate issuer is guaranteed to uniquely identify a certificate (but not its owner — the owner ought to regularly change their keys, and get new certificates from the issuer).

So, if you run your own CA and allow only certificates from this CA to be accepted by the server, the serial number is the most reliable (albeit not very mnemonic) means to identify a user.

`ssl_client_dn()` returns text

Returns the full subject of the current client certificate, converting character data into the current database encoding. It is assumed that if you use non-ASCII characters in the certificate names, your database is able to represent these characters, too. If your database uses the `SQL_ASCII` encoding, non-ASCII characters in the name will be represented as UTF-8 sequences.

The result looks like `/CN=Somebody /C=Some country/O=Some organization`.

`ssl_issuer_dn()` returns text

Returns the full issuer name of the current client certificate, converting character data into the current database encoding. Encoding conversions are handled the same as for `ssl_client_dn`.

The combination of the return value of this function with the certificate serial number uniquely identifies the certificate.

This function is really useful only if you have more than one trusted CA certificate in your server's `root.crt` file, or if this CA has issued some intermediate certificate authority certificates.

`ssl_client_dn_field(fieldname text)` returns text

This function returns the value of the specified field in the certificate subject, or NULL if the field is not present. Field names are string constants that are converted into ASN1 object identifiers using the OpenSSL object database. The following values are acceptable:

```
commonName (alias CN)
surname (alias SN)
name
givenName (alias GN)
countryName (alias C)
localityName (alias L)
stateOrProvinceName (alias ST)
organizationName (alias O)
organizationalUnitName (alias OU)
title
description
initials
postalCode
streetAddress
generationQualifier
description
dnQualifier
x500UniqueIdentifier
pseudonym
role
emailAddress
```

All of these fields are optional, except `commonName`. It depends entirely on your CA's policy which of them would be included and which wouldn't. The meaning of these fields, however, is strictly defined by the X.500 and X.509 standards, so you cannot just assign arbitrary meaning to them.

`ssl_issuer_field(fieldname text)` returns text

Same as `ssl_client_dn_field`, but for the certificate issuer rather than the certificate subject.

`ssl_extension_info()` returns setof record

Provide information about extensions of client certificate: extension name, extension value, and if it is a critical extension.

F.60. tablefunc

The `tablefunc` module includes various functions that return tables (that is, multiple rows). These functions are useful both in their own right and as examples of how to write C functions that return multiple rows.

F.60.1. Functions Provided

Table F.45 shows the functions provided by the `tablefunc` module.

Table F.45. tablefunc Functions

Function	Returns	Description
<code>normal_rand(int numvals, float8 mean, float8 stddev)</code>	setof float8	Produces a set of normally distributed random values
<code>crosstab(text sql)</code>	setof record	Produces a “pivot table” containing row names plus <i>N</i> value columns, where <i>N</i> is determined by the row type specified in the calling query
<code>crosstabN(text sql)</code>	setof table_crosstab_ <i>N</i>	Produces a “pivot table” containing row names plus <i>N</i> value columns. <code>crosstab2</code> , <code>crosstab3</code> , and <code>crosstab4</code> are predefined, but you can create additional <code>crosstabN</code> functions as described below
<code>crosstab(text source_sql, text category_sql)</code>	setof record	Produces a “pivot table” with the value columns specified by a second query
<code>crosstab(text sql, int N)</code>	setof record	Obsolete version of <code>crosstab(text)</code> . The parameter <i>N</i> is now ignored, since the number of value columns is always determined by the calling query
<code>connectby(text relname, text keyid_fld, text parent_keyid_fld [, text orderby_fld], text start_with, int max_depth [, text branch_delim])</code>	setof record	Produces a representation of a hierarchical tree structure

F.60.1.1. normal_rand

`normal_rand(int numvals, float8 mean, float8 stddev)` returns setof float8

`normal_rand` produces a set of normally distributed random values (Gaussian distribution).

numvals is the number of values to be returned from the function. *mean* is the mean of the normal distribution of values and *stddev* is the standard deviation of the normal distribution of values.

For example, this call requests 1000 values with a mean of 5 and a standard deviation of 3:

```
test=# SELECT * FROM normal_rand(1000, 5, 3);
      normal_rand
-----
```

```
1.56556322244898
9.10040991424657
5.36957140345079
-0.369151492880995
0.283600703686639
.
.
.
4.82992125404908
9.71308014517282
2.49639286969028
(1000 rows)
```

F.60.1.2. `crosstab(text)`

```
crosstab(text sql)
crosstab(text sql, int N)
```

The `crosstab` function is used to produce “pivot” displays, wherein data is listed across the page rather than down. For example, we might have data like

```
row1    val11
row1    val12
row1    val13
...
row2    val21
row2    val22
row2    val23
...
```

which we wish to display like

```
row1    val11    val12    val13    ...
row2    val21    val22    val23    ...
...
```

The `crosstab` function takes a text parameter that is a SQL query producing raw data formatted in the first way, and produces a table formatted in the second way.

The `sql` parameter is a SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. `N` is an obsolete parameter, ignored if supplied (formerly this had to match the number of output value columns, but now that is determined by the calling query).

For example, the provided query might produce a set something like:

row_name	cat	value
row1	cat1	val1
row1	cat2	val2
row1	cat3	val3
row1	cat4	val4
row2	cat1	val5
row2	cat2	val6
row2	cat3	val7
row2	cat4	val8

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...') AS ct(row_name text, category_1 text, category_2 text);
```

This example produces a set something like:

```

      <== value  columns  ==>
row_name  category_1  category_2
-----+-----+-----
row1      val1       val2
row2      val5       val6

```

The `FROM` clause must define the output as one `row_name` column (of the same data type as the first result column of the SQL query) followed by `N value` columns (all of the same data type as the third result column of the SQL query). You can set up as many output value columns as you wish. The names of the output columns are up to you.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. It fills the output value columns, left to right, with the value fields from these rows. If there are fewer rows in a group than there are output value columns, the extra output columns are filled with nulls; if there are more rows, the extra input rows are skipped.

In practice the SQL query should always specify `ORDER BY 1,2` to ensure that the input rows are properly ordered, that is, values with the same `row_name` are brought together and correctly ordered within the row. Notice that `crosstab` itself does not pay any attention to the second column of the query result; it's just there to be ordered by, to control the order in which the third-column values appear across the page.

Here is a complete example:

```

CREATE TABLE ct(id SERIAL, rowid TEXT, attribute TEXT, value TEXT);
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att1','val1');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att2','val2');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att3','val3');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att4','val4');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att1','val5');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att2','val6');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att3','val7');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att4','val8');

SELECT *
FROM crosstab(
  'select rowid, attribute, value
   from ct
   where attribute = ''att2'' or attribute = ''att3''
   order by 1,2')
AS ct(row_name text, category_1 text, category_2 text, category_3 text);

 row_name | category_1 | category_2 | category_3
-----+-----+-----+-----
test1    | val2      | val3      |
test2    | val6      | val7      |
(2 rows)

```

You can avoid always having to write out a `FROM` clause to define the output columns, by setting up a custom `crosstab` function that has the desired output row type wired into its definition. This is described in the next section. Another possibility is to embed the required `FROM` clause in a view definition.

Note

See also the `\crosstabview` command in `psql`, which provides functionality similar to `crosstab()`.

F.60.1.3. `crosstabN(text)`

```
crosstabN(text sql)
```

The `crosstabN` functions are examples of how to set up custom wrappers for the general `crosstab` function, so that you need not write out column names and types in the calling `SELECT` query. The `tablefunc` module includes `crosstab2`, `crosstab3`, and `crosstab4`, whose output row types are defined as

```
CREATE TYPE tablefunc_crosstab_N AS (  
    row_name TEXT,  
    category_1 TEXT,  
    category_2 TEXT,  
    .  
    .  
    .  
    category_N TEXT  
);
```

Thus, these functions can be used directly when the input query produces `row_name` and `value` columns of type `text`, and you want 2, 3, or 4 output values columns. In all other ways they behave exactly as described above for the general `crosstab` function.

For instance, the example given in the previous section would also work as

```
SELECT *  
FROM crosstab3(  
    'select rowid, attribute, value  
    from ct  
    where attribute = ''att2'' or attribute = ''att3''  
    order by 1,2');
```

These functions are provided mostly for illustration purposes. You can create your own return types and functions based on the underlying `crosstab()` function. There are two ways to do it:

- Create a composite type describing the desired output columns, similar to the examples in `contrib/tablefunc/tablefunc--1.0.sql`. Then define a unique function name accepting one `text` parameter and returning `setof your_type_name`, but linking to the same underlying `crosstab C` function. For example, if your source data produces row names that are `text`, and values that are `float8`, and you want 5 value columns:

```
CREATE TYPE my_crosstab_float8_5_cols AS (  
    my_row_name text,  
    my_category_1 float8,  
    my_category_2 float8,  
    my_category_3 float8,  
    my_category_4 float8,  
    my_category_5 float8  
);  
  
CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(text)  
    RETURNS setof my_crosstab_float8_5_cols  
    AS '$libdir/tablefunc', 'crosstab' LANGUAGE C STABLE STRICT;
```

- Use `OUT` parameters to define the return type implicitly. The same example could also be done this way:

```
CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(  
    IN text,  
    OUT my_row_name text,  
    OUT my_category_1 float8,  
    OUT my_category_2 float8,  
    OUT my_category_3 float8,  
    OUT my_category_4 float8,  
    OUT my_category_5 float8)
```

```
RETURNS setof record
AS '$libdir/tablefunc', 'crosstab' LANGUAGE C STABLE STRICT;
```

F.60.1.4. `crosstab(text, text)`

```
crosstab(text source_sql, text category_sql)
```

The main limitation of the single-parameter form of `crosstab` is that it treats all values in a group alike, inserting each value into the first available column. If you want the value columns to correspond to specific categories of data, and some groups might not have data for some of the categories, that doesn't work well. The two-parameter form of `crosstab` handles this case by providing an explicit list of the categories corresponding to the output columns.

source_sql is a SQL statement that produces the source set of data. This statement must return one *row_name* column, one *category* column, and one *value* column. It may also have one or more “extra” columns. The *row_name* column must be first. The *category* and *value* columns must be the last two columns, in that order. Any columns between *row_name* and *category* are treated as “extra”. The “extra” columns are expected to be the same for all rows with the same *row_name* value.

For example, *source_sql* might produce a set something like:

```
SELECT row_name, extra_col, cat, value FROM foo ORDER BY 1;
```

row_name	extra_col	cat	value
row1	extra1	cat1	val1
row1	extra1	cat2	val2
row1	extra1	cat4	val4
row2	extra2	cat1	val5
row2	extra2	cat2	val6
row2	extra2	cat3	val7
row2	extra2	cat4	val8

category_sql is a SQL statement that produces the set of categories. This statement must return only one column. It must produce at least one row, or an error will be generated. Also, it must not produce duplicate values, or an error will be generated. *category_sql* might be something like:

```
SELECT DISTINCT cat FROM foo ORDER BY 1;
cat
-----
cat1
cat2
cat3
cat4
```

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...', '...')
AS ct(row_name text, extra text, cat1 text, cat2 text, cat3 text, cat4 text);
```

This will produce a result something like:

		<== value columns ==>			
row_name	extra	cat1	cat2	cat3	cat4
row1	extra1	val1	val2		val4
row2	extra2	val5	val6	val7	val8

The `FROM` clause must define the proper number of output columns of the proper data types. If there are *N* columns in the *source_sql* query's result, the first *N-2* of them must match up with the first *N-2* output

columns. The remaining output columns must have the type of the last column of the *source_sql* query's result, and there must be exactly as many of them as there are rows in the *category_sql* query's result.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. The output `row_name` column, plus any “extra” columns, are copied from the first row of the group. The output value columns are filled with the value fields from rows having matching category values. If a row's category does not match any output of the *category_sql* query, its value is ignored. Output columns whose matching category is not present in any input row of the group are filled with nulls.

In practice the *source_sql* query should always specify `ORDER BY 1` to ensure that values with the same `row_name` are brought together. However, ordering of the categories within a group is not important. Also, it is essential to be sure that the order of the *category_sql* query's output matches the specified output column order.

Here are two complete examples:

```
create table sales(year int, month int, qty int);
insert into sales values(2007, 1, 1000);
insert into sales values(2007, 2, 1500);
insert into sales values(2007, 7, 500);
insert into sales values(2007, 11, 1500);
insert into sales values(2007, 12, 2000);
insert into sales values(2008, 1, 1000);
```

```
select * from crosstab(
  'select year, month, qty from sales order by 1',
  'select m from generate_series(1,12) m'
) as (
  year int,
  "Jan" int,
  "Feb" int,
  "Mar" int,
  "Apr" int,
  "May" int,
  "Jun" int,
  "Jul" int,
  "Aug" int,
  "Sep" int,
  "Oct" int,
  "Nov" int,
  "Dec" int
);
```

year	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
2007	1000	1500					500				1500	2000
2008	1000											

(2 rows)

```
CREATE TABLE cth(rowid text, rowdt timestamp, attribute text, val text);
INSERT INTO cth VALUES('test1','01 March 2003','temperature','42');
INSERT INTO cth VALUES('test1','01 March 2003','test_result','PASS');
INSERT INTO cth VALUES('test1','01 March 2003','volts','2.6987');
INSERT INTO cth VALUES('test2','02 March 2003','temperature','53');
INSERT INTO cth VALUES('test2','02 March 2003','test_result','FAIL');
INSERT INTO cth VALUES('test2','02 March 2003','test_startdate','01 March 2003');
INSERT INTO cth VALUES('test2','02 March 2003','volts','3.1234');
```

```
SELECT * FROM crosstab
```

```

(
  'SELECT rowid, rowdt, attribute, val FROM cth ORDER BY 1',
  'SELECT DISTINCT attribute FROM cth ORDER BY 1'
)
AS
(
  rowid text,
  rowdt timestamp,
  temperature int4,
  test_result text,
  test_startdate timestamp,
  volts float8
);
 rowid |          rowdt          | temperature | test_result |          test_startdate
| volts
-----+-----+-----+-----+-----
test1 | Sat Mar 01 00:00:00 2003 |          42 | PASS      |
| 2.6987
test2 | Sun Mar 02 00:00:00 2003 |          53 | FAIL      | Sat Mar 01 00:00:00
2003 | 3.1234
(2 rows)

```

You can create predefined functions to avoid having to write out the result column names and types in each query. See the examples in the previous section. The underlying C function for this form of `crosstab` is named `crosstab_hash`.

F.60.1.5. `connectby`

```

connectby(text relname, text keyid_fld, text parent_keyid_fld
          [, text orderby_fld ], text start_with, int max_depth
          [, text branch_delim ])

```

The `connectby` function produces a display of hierarchical data that is stored in a table. The table must have a key field that uniquely identifies rows, and a parent-key field that references the parent (if any) of each row. `connectby` can display the sub-tree descending from any row.

Table F.46 explains the parameters.

Table F.46. `connectby` Parameters

Parameter	Description
<i>relname</i>	Name of the source relation
<i>keyid_fld</i>	Name of the key field
<i>parent_keyid_fld</i>	Name of the parent-key field
<i>orderby_fld</i>	Name of the field to order siblings by (optional)
<i>start_with</i>	Key value of the row to start at
<i>max_depth</i>	Maximum depth to descend to, or zero for unlimited depth
<i>branch_delim</i>	String to separate keys with in branch output (optional)

The key and parent-key fields can be any data type, but they must be the same type. Note that the *start_with* value must be entered as a text string, regardless of the type of the key field.

The `connectby` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0,
 '~')
  AS t(keyid text, parent_keyid text, level int, branch text, pos int);
```

The first two output columns are used for the current row's key and its parent row's key; they must match the type of the table's key field. The third output column is the depth in the tree and must be of type `integer`. If a `branch_delim` parameter was given, the next output column is the branch display and must be of type `text`. Finally, if an `orderby_fld` parameter was given, the last output column is a serial number, and must be of type `integer`.

The “branch” output column shows the path of keys taken to reach the current row. The keys are separated by the specified `branch_delim` string. If no branch display is wanted, omit both the `branch_delim` parameter and the branch column in the output column list.

If the ordering of siblings of the same parent is important, include the `orderby_fld` parameter to specify which field to order siblings by. This field can be of any sortable data type. The output column list must include a final integer serial-number column, if and only if `orderby_fld` is specified.

The parameters representing table and field names are copied as-is into the SQL queries that `connectby` generates internally. Therefore, include double quotes if the names are mixed-case or contain special characters. You may also need to schema-qualify the table name.

In large tables, performance will be poor unless there is an index on the parent-key field.

It is important that the `branch_delim` string not appear in any key values, else `connectby` may incorrectly report an infinite-recursion error. Note that if `branch_delim` is not provided, a default value of `~` is used for recursion detection purposes.

Here is an example:

```
CREATE TABLE connectby_tree(keyid text, parent_keyid text, pos int);
```

```
INSERT INTO connectby_tree VALUES('row1',NULL, 0);
INSERT INTO connectby_tree VALUES('row2','row1', 0);
INSERT INTO connectby_tree VALUES('row3','row1', 0);
INSERT INTO connectby_tree VALUES('row4','row2', 1);
INSERT INTO connectby_tree VALUES('row5','row2', 0);
INSERT INTO connectby_tree VALUES('row6','row4', 0);
INSERT INTO connectby_tree VALUES('row7','row3', 0);
INSERT INTO connectby_tree VALUES('row8','row6', 0);
INSERT INTO connectby_tree VALUES('row9','row5', 0);
```

```
-- with branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0, '~')
  AS t(keyid text, parent_keyid text, level int, branch text);
keyid | parent_keyid | level |      branch
-----+-----+-----+-----
row2  |              |      0 | row2
row4  | row2         |      1 | row2~row4
row6  | row4         |      2 | row2~row4~row6
row8  | row6         |      3 | row2~row4~row6~row8
row5  | row2         |      1 | row2~row5
row9  | row5         |      2 | row2~row5~row9
(6 rows)
```

```
-- without branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0)
  AS t(keyid text, parent_keyid text, level int);
keyid | parent_keyid | level
-----+-----+-----
```

```

row2 |      |      0
row4 | row2 |      1
row6 | row4 |      2
row8 | row6 |      3
row5 | row2 |      1
row9 | row5 |      2
(6 rows)

```

```

-- with branch, with orderby_fld (notice that row5 comes before row4)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0,
 '~')
AS t(keyid text, parent_keyid text, level int, branch text, pos int);
keyid | parent_keyid | level |      branch      | pos
-----+-----+-----+-----+-----
row2  |              |      0 | row2              | 1
row5  | row2         |      1 | row2~row5         | 2
row9  | row5         |      2 | row2~row5~row9    | 3
row4  | row2         |      1 | row2~row4         | 4
row6  | row4         |      2 | row2~row4~row6    | 5
row8  | row6         |      3 | row2~row4~row6~row8 | 6
(6 rows)

```

```

-- without branch, with orderby_fld (notice that row5 comes before row4)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0)
AS t(keyid text, parent_keyid text, level int, pos int);
keyid | parent_keyid | level | pos
-----+-----+-----+-----
row2  |              |      0 | 1
row5  | row2         |      1 | 2
row9  | row5         |      2 | 3
row4  | row2         |      1 | 4
row6  | row4         |      2 | 5
row8  | row6         |      3 | 6
(6 rows)

```

F.60.2. Author

Joe Conway

F.61. tcn

The `tcn` module provides a trigger function that notifies listeners of changes to any table on which it is attached. It must be used as an `AFTER` trigger `FOR EACH ROW`.

Only one parameter may be supplied to the function in a `CREATE TRIGGER` statement, and that is optional. If supplied it will be used for the channel name for the notifications. If omitted `tcn` will be used for the channel name.

The payload of the notifications consists of the table name, a letter to indicate which type of operation was performed, and column name/value pairs for primary key columns. Each part is separated from the next by a comma. For ease of parsing using regular expressions, table and column names are always wrapped in double quotes, and data values are always wrapped in single quotes. Embedded quotes are doubled.

A brief example of using the extension follows.

```

test=# create table tcndata
test=# (
test(#   a int not null,
test(#   b date not null,

```

```
test(#      c text,
test(#      primary key (a, b)
test(#      );
CREATE TABLE
test=# create trigger tcndata_tcn_trigger
test=#      after insert or update or delete on tcndata
test=#      for each row execute procedure triggered_change_notification();
CREATE TRIGGER
test=# listen tcn;
LISTEN
test=# insert into tcndata values (1, date '2012-12-22', 'one'),
test=#                                     (1, date '2012-12-23', 'another'),
test=#                                     (2, date '2012-12-23', 'two');
INSERT 0 3
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='1',"b"='2012-12-22'"
received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='1',"b"='2012-12-23'"
received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='2',"b"='2012-12-23'"
received from server process with PID 22770.
test=# update tcndata set c = 'uno' where a = 1;
UPDATE 2
Asynchronous notification "tcn" with payload ""tcndata",U,"a"='1',"b"='2012-12-22'"
received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",U,"a"='1',"b"='2012-12-23'"
received from server process with PID 22770.
test=# delete from tcndata where a = 1 and b = date '2012-12-22';
DELETE 1
Asynchronous notification "tcn" with payload ""tcndata",D,"a"='1',"b"='2012-12-22'"
received from server process with PID 22770.
```

F.62. test_decoding

`test_decoding` is an example of a logical decoding output plugin. It doesn't do anything especially useful, but can serve as a starting point for developing your own output plugin.

`test_decoding` receives WAL through the logical decoding mechanism and decodes it into text representations of the operations performed.

Typical output from this plugin, used over the SQL logical decoding interface, might be:

```
postgres=# SELECT * FROM pg_logical_slot_get_changes('test_slot', NULL, NULL, 'include-
xids', '0');
 location | xid | data
-----+-----+-----
 0/16D30F8 | 691 | BEGIN
 0/16D32A0 | 691 | table public.data: INSERT: id[int4]:2 data[text]:'arg'
 0/16D32A0 | 691 | table public.data: INSERT: id[int4]:3 data[text]:'demo'
 0/16D32A0 | 691 | COMMIT
 0/16D32D8 | 692 | BEGIN
 0/16D3398 | 692 | table public.data: DELETE: id[int4]:2
 0/16D3398 | 692 | table public.data: DELETE: id[int4]:3
 0/16D3398 | 692 | COMMIT
(8 rows)
```

F.63. tsearch2

The `tsearch2` module provides backwards-compatible text search functionality for applications that used `tsearch2` before text searching was integrated into core PostgreSQL in release 8.3.

F.63.1. Portability Issues

Although the built-in text search features were based on `tsearch2` and are largely similar to it, there are numerous small differences that will create portability issues for existing applications:

- Some functions' names were changed, for example `rank` to `ts_rank`. The replacement `tsearch2` module provides aliases having the old names.
- The built-in text search data types and functions all exist within the system schema `pg_catalog`. In an installation using `tsearch2`, these objects would usually have been in the `public` schema, though some users chose to place them in a separate schema of their own. Explicitly schema-qualified references to the objects will therefore fail in either case. The replacement `tsearch2` module provides alias objects that are stored in `public` (or another schema if necessary) so that such references will still work.
- There is no concept of a “current parser” or “current dictionary” in the built-in text search features, only of a current search configuration (set by the `default_text_search_config` parameter). While the current parser and current dictionary were used only by functions intended for debugging, this might still pose a porting obstacle in some cases. The replacement `tsearch2` module emulates these additional state variables and provides backwards-compatible functions for setting and retrieving them.

There are some issues that are not addressed by the replacement `tsearch2` module, and will therefore require application code changes in any case:

- The old `tsearch2` trigger function allowed items in its argument list to be names of functions to be invoked on the text data before it was converted to `tsvector` format. This was removed as being a security hole, since it was not possible to guarantee that the function invoked was the one intended. The recommended approach if the data must be massaged before being indexed is to write a custom trigger that does the work for itself.
- Text search configuration information has been moved into core system catalogs that are noticeably different from the tables used by `tsearch2`. Any applications that examined or modified those tables will need adjustment.
- If an application used any custom text search configurations, those will need to be set up in the core catalogs using the new text search configuration SQL commands. The replacement `tsearch2` module offers a little bit of support for this by making it possible to load an old set of `tsearch2` configuration tables into PostgreSQL 8.3. (Without the module, it is not possible to load the configuration data because values in the `regprocedure` columns cannot be resolved to functions.) While those configuration tables won't actually *do* anything, at least their contents will be available to be consulted while setting up an equivalent custom configuration in 8.3.
- The old `reset_tsearch()` and `get_covers()` functions are not supported.
- The replacement `tsearch2` module does not define any alias operators, relying entirely on the built-in ones. This would only pose an issue if an application used explicitly schema-qualified operator names, which is very uncommon.

F.63.2. Converting a pre-8.3 Installation

The recommended way to update a pre-8.3 installation that uses `tsearch2` is:

1. Make a dump from the old installation in the usual way, but be sure not to use `-c` (`--clean`) option of `pg_dump` or `pg_dumpall`.
2. In the new installation, create empty database(s) and install the replacement `tsearch2` module into each database that will use text search. This must be done *before* loading the dump data! If your old installation had the `tsearch2` objects in a schema other than `public`, be sure to adjust the `CREATE EXTENSION` command so that the replacement objects are created in that same schema.
3. Load the dump data. There will be quite a few errors reported due to failure to recreate the original `tsearch2` objects. These errors can be ignored, but this means you cannot restore the dump in a single transaction (eg, you cannot use `pg_restore`'s `-1` switch).

4. Examine the contents of the restored `tsearch2` configuration tables (`pg_ts_cfg` and so on), and create equivalent built-in text search configurations as needed. You may drop the old configuration tables once you've extracted all the useful information from them.
5. Test your application.

At a later time you may wish to rename application references to the alias text search objects, so that you can eventually uninstall the replacement `tsearch2` module.

F.63.3. References

Tsearch2 Development Site <http://www.sai.msu.su/~megera/postgres/gist/tsearch/V2/>

F.64. `tsm_system_rows`

The `tsm_system_rows` module provides the table sampling method `SYSTEM_ROWS`, which can be used in the `TABLESAMPLE` clause of a `SELECT` command.

This table sampling method accepts a single integer argument that is the maximum number of rows to read. The resulting sample will always contain exactly that many rows, unless the table does not contain enough rows, in which case the whole table is selected.

Like the built-in `SYSTEM` sampling method, `SYSTEM_ROWS` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are requested.

`SYSTEM_ROWS` does not support the `REPEATABLE` clause.

F.64.1. Examples

Here is an example of selecting a sample of a table with `SYSTEM_ROWS`. First install the extension:

```
CREATE EXTENSION tsm_system_rows;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_ROWS(100);
```

This command will return a sample of 100 rows from the table `my_table` (unless the table does not have 100 visible rows, in which case all its rows are returned).

F.65. `tsm_system_time`

The `tsm_system_time` module provides the table sampling method `SYSTEM_TIME`, which can be used in the `TABLESAMPLE` clause of a `SELECT` command.

This table sampling method accepts a single floating-point argument that is the maximum number of milliseconds to spend reading the table. This gives you direct control over how long the query takes, at the price that the size of the sample becomes hard to predict. The resulting sample will contain as many rows as could be read in the specified time, unless the whole table has been read first.

Like the built-in `SYSTEM` sampling method, `SYSTEM_TIME` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are selected.

`SYSTEM_TIME` does not support the `REPEATABLE` clause.

F.65.1. Examples

Here is an example of selecting a sample of a table with `SYSTEM_TIME`. First install the extension:

```
CREATE EXTENSION tsm_system_time;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_TIME(1000);
```

This command will return as large a sample of `my_table` as it can read in 1 second (1000 milliseconds). Of course, if the whole table can be read in under 1 second, all its rows will be returned.

F.66. unaccent

`unaccent` is a text search dictionary that removes accents (diacritic signs) from lexemes. It's a filtering dictionary, which means its output is always passed to the next dictionary (if any), unlike the normal behavior of dictionaries. This allows accent-insensitive processing for full text search.

The current implementation of `unaccent` cannot be used as a normalizing dictionary for the `thesaurus` dictionary.

F.66.1. Configuration

An `unaccent` dictionary accepts the following options:

- `RULES` is the base name of the file containing the list of translation rules. This file must be stored in `$SHAREDIR/tsearch_data/` (where `$SHAREDIR` means the Postgres Pro installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `RULES` parameter).

The rules file has the following format:

- Each line represents one translation rule, consisting of a character with accent followed by a character without accent. The first is translated into the second. For example,

À	A
Á	A
Â	A
Ã	A
Ä	A
Å	A
Æ	AE

The two characters must be separated by whitespace, and any leading or trailing whitespace on a line is ignored.

- Alternatively, if only one character is given on a line, instances of that character are deleted; this is useful in languages where accents are represented by separate characters.
- Actually, each “character” can be any string not containing whitespace, so `unaccent` dictionaries could be used for other sorts of substring substitutions besides diacritic removal.
- As with other Postgres Pro text search configuration files, the rules file must be stored in UTF-8 encoding. The data is automatically translated into the current database's encoding when loaded. Any lines containing untranslatable characters are silently ignored, so that rules files can contain rules that are not applicable in the current encoding.

A more complete example, which is directly useful for most European languages, can be found in `unaccent.rules`, which is installed in `$SHAREDIR/tsearch_data/` when the `unaccent` module is installed. This rules file translates characters with accents to the same characters without accents, and it also expands ligatures into the equivalent series of simple characters (for example, `Æ` to `AE`).

F.66.2. Usage

Installing the `unaccent` extension creates a text search template `unaccent` and a dictionary `unaccent` based on it. The `unaccent` dictionary has the default parameter setting `RULES='unaccent'`, which makes it immediately usable with the standard `unaccent.rules` file. If you wish, you can alter the parameter, for example

```
mydb=# ALTER TEXT SEARCH DICTIONARY unaccent (RULES='my_rules');
```

or create new dictionaries based on the template.

To test the dictionary, you can try:

```
mydb=# select ts_lexize('unaccent','Hôtel');
 ts_lexize
-----
 {Hotel}
(1 row)
```

Here is an example showing how to insert the `unaccent` dictionary into a text search configuration:

```
mydb=# CREATE TEXT SEARCH CONFIGURATION fr ( COPY = french );
mydb=# ALTER TEXT SEARCH CONFIGURATION fr
        ALTER MAPPING FOR hword, hword_part, word
        WITH unaccent, french_stem;
mydb=# select to_tsvector('fr','Hôtels de la Mer');
 to_tsvector
-----
 'hotel':1 'mer':4
(1 row)

mydb=# select to_tsvector('fr','Hôtel de la Mer') @@ to_tsquery('fr','Hotels');
 ?column?
-----
 t
(1 row)

mydb=# select ts_headline('fr','Hôtel de la Mer',to_tsquery('fr','Hotels'));
 ts_headline
-----
 <b>Hôtel</b> de la Mer
(1 row)
```

F.66.3. Functions

The `unaccent()` function removes accents (diacritic signs) from a given string. Basically, it's a wrapper around `unaccent`-type dictionaries, but it can be used outside normal text search contexts.

`unaccent([dictionary regdictionary, ] string text)` returns text

If the *dictionary* argument is omitted, the text search dictionary named `unaccent` and appearing in the same schema as the `unaccent()` function itself is used.

For example:

```
SELECT unaccent('unaccent', 'Hôtel');
SELECT unaccent('Hôtel');
```

F.67. uuid-oss

The `uuid-oss` module provides functions to generate universally unique identifiers (UUIDs) using one of several standard algorithms. There are also functions to produce certain special UUID constants.

F.67.1. uuid-oss Functions

[Table F.47](#) shows the functions available to generate UUIDs. The relevant standards ITU-T Rec. X.667, ISO/IEC 9834-8:2005, and RFC 4122 specify four algorithms for generating UUIDs, identified by the

version numbers 1, 3, 4, and 5. (There is no version 2 algorithm.) Each of these algorithms could be suitable for a different set of applications.

Table F.47. Functions for UUID Generation

Function	Description
<code>uuid_generate_v1()</code>	This function generates a version 1 UUID. This involves the MAC address of the computer and a time stamp. Note that UUIDs of this kind reveal the identity of the computer that created the identifier and the time at which it did so, which might make it unsuitable for certain security-sensitive applications.
<code>uuid_generate_v1mc()</code>	This function generates a version 1 UUID but uses a random multicast MAC address instead of the real MAC address of the computer.
<code>uuid_generate_v3(namespace uuid, name text)</code>	This function generates a version 3 UUID in the given namespace using the specified input name. The namespace should be one of the special constants produced by the <code>uuid_ns_*</code>() functions shown in Table F.48. (It could be any UUID in theory.) The name is an identifier in the selected namespace. For example: <pre>SELECT uuid_generate_v3(uuid_ns_url(), 'http://www.postgresql.org');</pre> The name parameter will be MD5-hashed, so the cleartext cannot be derived from the generated UUID. The generation of UUIDs by this method has no random or environment-dependent element and is therefore reproducible.
<code>uuid_generate_v4()</code>	This function generates a version 4 UUID, which is derived entirely from random numbers.
<code>uuid_generate_v5(namespace uuid, name text)</code>	This function generates a version 5 UUID, which works like a version 3 UUID except that SHA-1 is used as a hashing method. Version 5 should be preferred over version 3 because SHA-1 is thought to be more secure than MD5.

Table F.48. Functions Returning UUID Constants

<code>uuid_nil()</code>	A “nil” UUID constant, which does not occur as a real UUID.
<code>uuid_ns_dns()</code>	Constant designating the DNS namespace for UUIDs.
<code>uuid_ns_url()</code>	Constant designating the URL namespace for UUIDs.
<code>uuid_ns_oid()</code>	Constant designating the ISO object identifier (OID) namespace for UUIDs. (This pertains to ASN.1 OIDs, which are unrelated to the OIDs used in Postgres Pro.)
<code>uuid_ns_x500()</code>	Constant designating the X.500 distinguished name (DN) namespace for UUIDs.

F.67.2. Building uuid-oss

Historically this module depended on the OSSP UUID library, which accounts for the module's name. While the OSSP UUID library can still be found at <http://www.ossdp.org/pkg/lib/uuid/>, it is not well maintained, and is becoming increasingly difficult to port to newer platforms. `uuid-oss` can now be built without the OSSP library on some platforms. On FreeBSD, NetBSD, and some other BSD-derived platforms, suitable UUID creation functions are included in the core `libc` library. On Linux, OS X, and some other platforms, suitable functions are provided in the `libuuid` library, which originally came from the `e2fsprogs` project (though on modern Linux it is considered part of `util-linux-ng`). When invoking `configure`, specify `--with-uuid=bsd` to use the BSD functions, or `--with-uuid=e2fs` to use `e2fsprogs`' `libuuid`, or `--with-uuid=oss` to use the OSSP UUID library. More than one of these libraries might be available on a particular machine, so `configure` does not automatically choose one.

Note

If you only need randomly-generated (version 4) UUIDs, consider using the `gen_random_uuid()` function from the [pgcrypto](#) module instead.

F.67.3. Author

Peter Eisentraut <peter_e@gmx.net>

F.68. xml2

The `xml2` module provides XPath querying and XSLT functionality.

F.68.1. Deprecation Notice

From PostgreSQL 8.3 on, there is XML-related functionality based on the SQL/XML standard in the core server. That functionality covers XML syntax checking and XPath queries, which is what this module does, and more, but the API is not at all compatible. It is planned that this module will be removed in a future version of Postgres Pro in favor of the newer standard API, so you are encouraged to try converting your applications. If you find that some of the functionality of this module is not available in an adequate form with the newer API, please explain your issue to <pgsql-hackers@lists.postgresql.org> so that the deficiency can be addressed.

F.68.2. Description of Functions

[Table F.49](#) shows the functions provided by this module. These functions provide straightforward XML parsing and XPath queries. All arguments are of type `text`, so for brevity that is not shown.

Table F.49. Functions

Function	Returns	Description
<code>xml_is_well_formed(document)</code>	<code>bool</code>	This parses the document text in its parameter and returns true if the document is well-formed XML. (Note: before PostgreSQL 8.2, this function was called <code>xml_valid()</code> . That is the wrong name since validity and well-formedness have different meanings in XML. The old name is still available, but is deprecated.)
<code>xpath_string(document, query)</code>	<code>text</code>	These functions evaluate the XPath query on the supplied

Function	Returns	Description
<code>xpath_number (document, query)</code>	float4	document, and cast the result to the specified type.
<code>xpath_bool (document, query)</code>	bool	
<code>xpath_nodeSet (document, query, toptag, itemtag)</code>	text	This evaluates query on document and wraps the result in XML tags. If the result is multivalued, the output will look like: <pre><toptag> <itemtag>Value 1 which could be an XML fragment</ itemtag> <itemtag>Value 2....</ itemtag> </toptag></pre> If either <code>toptag</code> or <code>itemtag</code> is an empty string, the relevant tag is omitted.
<code>xpath_nodeSet (document, query)</code>	text	Like <code>xpath_nodeSet (document, query, toptag, itemtag)</code> but result omits both tags.
<code>xpath_nodeSet (document, query, itemtag)</code>	text	Like <code>xpath_nodeSet (document, query, toptag, itemtag)</code> but result omits <code>toptag</code> .
<code>xpath_list (document, query, separator)</code>	text	This function returns multiple values separated by the specified separator, for example Value 1, Value 2, Value 3 if separator is , .
<code>xpath_list (document, query)</code>	text	This is a wrapper for the above function that uses , as the separator.

F.68.3. xpath_table

`xpath_table(text key, text document, text relation, text xpaths, text criteria)` returns setof record

`xpath_table` is a table function that evaluates a set of XPath queries on each of a set of documents and returns the results as a table. The primary key field from the original document table is returned as the first column of the result so that the result set can readily be used in joins. The parameters are described in [Table F.50](#).

Table F.50. xpath_table Parameters

Parameter	Description
<i>key</i>	the name of the “key” field — this is just a field to be used as the first column of the output table, i.e., it identifies the record from which each output row came (see note below about multiple values)
<i>document</i>	the name of the field containing the XML document

Parameter	Description
<i>relation</i>	the name of the table or view containing the documents
<i>xpaths</i>	one or more XPath expressions, separated by
<i>criteria</i>	the contents of the WHERE clause. This cannot be omitted, so use <code>true</code> or <code>1=1</code> if you want to process all the rows in the relation

These parameters (except the XPath strings) are just substituted into a plain SQL SELECT statement, so you have some flexibility — the statement is

```
SELECT <key>, <document> FROM <relation> WHERE <criteria>
```

so those parameters can be *anything* valid in those particular locations. The result from this SELECT needs to return exactly two columns (which it will unless you try to list multiple fields for key or document). Beware that this simplistic approach requires that you validate any user-supplied values to avoid SQL injection attacks.

The function has to be used in a FROM expression, with an AS clause to specify the output columns; for example

```
SELECT * FROM
xpath_table('article_id',
            'article_xml',
            'articles',
            '/article/author|/article/pages|/article/title',
            'date_entered > ''2003-01-01'' ')
AS t(article_id integer, author text, page_count integer, title text);
```

The AS clause defines the names and types of the columns in the output table. The first is the “key” field and the rest correspond to the XPath queries. If there are more XPath queries than result columns, the extra queries will be ignored. If there are more result columns than XPath queries, the extra columns will be NULL.

Notice that this example defines the `page_count` result column as an integer. The function deals internally with string representations, so when you say you want an integer in the output, it will take the string representation of the XPath result and use Postgres Pro input functions to transform it into an integer (or whatever type the AS clause requests). An error will result if it can't do this — for example if the result is empty — so you may wish to just stick to `text` as the column type if you think your data has any problems.

The calling SELECT statement doesn't necessarily have to be just `SELECT *` — it can reference the output columns by name or join them to other tables. The function produces a virtual table with which you can perform any operation you wish (e.g., aggregation, joining, sorting etc). So we could also have:

```
SELECT t.title, p.fullname, p.email
FROM xpath_table('article_id', 'article_xml', 'articles',
                '/article/title|/article/author/@id',
                'xpath_string(article_xml, '/article/@date') > ''2003-03-20'' ')
    AS t(article_id integer, title text, author_id integer),
    tblPeopleInfo AS p
WHERE t.author_id = p.person_id;
```

as a more complicated example. Of course, you could wrap all of this in a view for convenience.

F.68.3.1. Multivalued Results

The `xpath_table` function assumes that the results of each XPath query might be multivalued, so the number of rows returned by the function may not be the same as the number of input documents. The

first row returned contains the first result from each query, the second row the second result from each query. If one of the queries has fewer values than the others, null values will be returned instead.

In some cases, a user will know that a given XPath query will return only a single result (perhaps a unique document identifier) — if used alongside an XPath query returning multiple results, the single-valued result will appear only on the first row of the result. The solution to this is to use the key field as part of a join against a simpler XPath query. As an example:

```
CREATE TABLE test (
  id int PRIMARY KEY,
  xml text
);

INSERT INTO test VALUES (1, '<doc num="C1">
<line num="L1"><a>1</a><b>2</b><c>3</c></line>
<line num="L2"><a>11</a><b>22</b><c>33</c></line>
</doc>');

INSERT INTO test VALUES (2, '<doc num="C2">
<line num="L1"><a>111</a><b>222</b><c>333</c></line>
<line num="L2"><a>111</a><b>222</b><c>333</c></line>
</doc>');

SELECT * FROM
  xpath_table('id','xml','test',
    '/doc/@num|/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
    'true')
  AS t(id int, doc_num varchar(10), line_num varchar(10), val1 int, val2 int, val3 int)
WHERE id = 1 ORDER BY doc_num, line_num
```

id	doc_num	line_num	val1	val2	val3
1	C1	L1	1	2	3
1		L2	11	22	33

To get doc_num on every line, the solution is to use two invocations of `xpath_table` and join the results:

```
SELECT t.*,i.doc_num FROM
  xpath_table('id', 'xml', 'test',
    '/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
    'true')
  AS t(id int, line_num varchar(10), val1 int, val2 int, val3 int),
  xpath_table('id', 'xml', 'test', '/doc/@num', 'true')
  AS i(id int, doc_num varchar(10))
WHERE i.id=t.id AND i.id=1
ORDER BY doc_num, line_num;
```

id	line_num	val1	val2	val3	doc_num
1	L1	1	2	3	C1
1	L2	11	22	33	C1

(2 rows)

F.68.4. XSLT Functions

The following functions are available if `libxslt` is installed:

F.68.4.1. xslt_process

`xslt_process(text document, text stylesheet, text paramlist)` returns text

This function applies the XSL stylesheet to the document and returns the transformed result. The `paramlist` is a list of parameter assignments to be used in the transformation, specified in the form `a=1,b=2`. Note that the parameter parsing is very simple-minded: parameter values cannot contain commas!

There is also a two-parameter version of `xslt_process` which does not pass any parameters to the transformation.

F.68.5. Author

John Gray <jgray@azuli.co.uk>

Development of this module was sponsored by Torchbox Ltd. (www.torchbox.com). It has the same BSD license as Postgres Pro.

Appendix G. Additional Supplied Programs

This appendix and the previous one contain information regarding additional modules available in the Postgres Pro Enterprise distribution. See [Appendix F](#) for more information about the server extensions and plug-ins.

This appendix covers the utility programs. Once installed, they are found in the `bin` directory of the Postgres Pro Enterprise installation and can be used like any other program.

G.1. Client Applications

This section covers Postgres Pro Enterprise client applications. They can be run from anywhere, independent of where the database server resides. See also [Postgres Pro Client Applications](#) for information about client applications are that part of the core Postgres Pro Enterprise distribution.

oid2name

oid2name — resolve OIDs and file nodes in a Postgres Pro data directory

Synopsis

```
oid2name [option...]
```

Description

oid2name is a utility program that helps administrators to examine the file structure used by Postgres Pro. To make use of it, you need to be familiar with the database file structure, which is described in [Chapter 63](#).

Note

The name “oid2name” is historical, and is actually rather misleading, since most of the time when you use it, you will really be concerned with tables' filenode numbers (which are the file names visible in the database directories). Be sure you understand the difference between table OIDs and table filenodes!

oid2name connects to a target database and extracts OID, filenode, and/or table name information. You can also have it show database OIDs or tablespace OIDs.

Options

oid2name accepts the following command-line arguments:

`-f filenode`

show info for table with filenode *filenode*

`-i`

include indexes and sequences in the listing

`-o oid`

show info for table with OID *oid*

`-q`

omit headers (useful for scripting)

`-s`

show tablespace OIDs

`-S`

include system objects (those in `information_schema`, `pg_toast` and `pg_catalog` schemas)

`-t tablename_pattern`

show info for table(s) matching *tablename_pattern*

`-V`

`--version`

Print the oid2name version and exit.

`-x`

display more information about each object shown: tablespace name, schema name, and OID

-?
--help

Show help about oid2name command line arguments, and exit.

oid2name also accepts the following command-line arguments for connection parameters:

-d *database*

database to connect to

-H *host*

database server's host

-p *port*

database server's port

-U *username*

user name to connect as

-P *password*

password (deprecated — putting this on the command line is a security hazard)

To display specific tables, select which tables to show by using -o, -f and/or -t. -o takes an OID, -f takes a filenode, and -t takes a table name (actually, it's a LIKE pattern, so you can use things like foo%). You can use as many of these options as you like, and the listing will include all objects matched by any of the options. But note that these options can only show objects in the database given by -d.

If you don't give any of -o, -f or -t, but do give -d, it will list all tables in the database named by -d. In this mode, the -s and -i options control what gets listed.

If you don't give -d either, it will show a listing of database OIDs. Alternatively you can give -s to get a tablespace listing.

Notes

oid2name requires a running database server with non-corrupt system catalogs. It is therefore of only limited use for recovering from catastrophic database corruption situations.

Examples

```
$ # what's in this database server, anyway?
```

```
$ oid2name
```

```
All databases:
```

Oid	Database Name	Tablespace
17228	alvherre	pg_default
17255	regression	pg_default
17227	template0	pg_default
1	template1	pg_default

```
$ oid2name -s
```

```
All tablespaces:
```

Oid	Tablespace Name
1663	pg_default
1664	pg_global
155151	fastdisk
155152	bigdisk

```
$ # OK, let's look into database alvherre
```

```
$ cd $PGDATA/base/17228
```

```
$ # get top 10 db objects in the default tablespace, ordered by size
$ ls -lS * | head -10
```

```
-rw----- 1 alvherre alvherre 136536064 sep 14 09:51 155173
-rw----- 1 alvherre alvherre 17965056 sep 14 09:51 1155291

Description

pg_probackup is a utility to manage backup and recovery of Postgres Pro database clusters. It is designed to perform periodic backups of the Postgres Pro instance that enable you to restore the server in case of a failure. pg_probackup supports Postgres Pro 9.5 or higher.

- [Overview](#)
- [Installation and Setup](#)
- [Command-Line Reference](#)
- [Usage](#)

Overview

As compared to other backup solutions, pg_probackup offers the following benefits that can help you implement different backup strategies and deal with large amounts of data:

- Incremental backup: with three different incremental modes, you can plan the backup strategy in accordance with your data flow. Incremental backups allow you to save disk space and speed up backup as compared to taking full backups. It is also faster to restore the cluster by applying incremental backups than by replaying WAL files.
- Incremental restore: speed up restore from backup by reusing valid unchanged pages available in PGDATA.
- Validation: automatic data consistency checks and on-demand backup validation without actual data recovery.
- Verification: on-demand verification of Postgres Pro instance with the `checkdb` command.
- Retention: managing WAL archive and backups in accordance with retention policy. You can configure retention policy based on recovery time or the number of backups to keep, as well as specify time to live (TTL) for a particular backup. Expired backups can be merged or deleted.
- Parallelization: running `backup`, `restore`, `merge`, `delete`, `validate`, and `checkdb` processes on multiple parallel threads.
- Compression: storing backup data in a compressed state to save disk space.
- Deduplication: saving disk space by excluding non-data files (such as `_vm` or `_fsm`) from incremental backups if these files have not changed since they were copied into one of the previous backups in this incremental chain.
- Remote operations: backing up Postgres Pro instance located on a remote system or restoring a backup remotely.
- Backup from standby: avoiding extra load on master by taking backups from a standby server.
- External directories: backing up files and directories located outside of the Postgres Pro data directory (PGDATA), such as scripts, configuration files, logs, or SQL dump files.
- Backup catalog: getting the list of backups and the corresponding meta information in plain text or JSON formats.
- Archive catalog: getting the list of all WAL timelines and the corresponding meta information in plain text or JSON formats.
- Partial restore: restoring only the specified databases.

To manage backup data, `pg_probackup` creates a *backup catalog*. This is a directory that stores all backup files with additional meta information, as well as WAL archives required for point-in-time recovery. You can store backups for different instances in separate subdirectories of a single backup catalog.

Using `pg_probackup`, you can take full or incremental [backups](#):

- FULL backups contain all the data files required to restore the database cluster.
- Incremental backups operate at the page level, only storing the data that has changed since the previous backup. It allows you to save disk space and speed up the backup process as compared to taking full backups. It is also faster to restore the cluster by applying incremental backups than by replaying WAL files. `pg_probackup` supports the following modes of incremental backups:
 - DELTA backup. In this mode, `pg_probackup` reads all data files in the data directory and copies only those pages that have changed since the previous backup. This mode can impose read-only I/O pressure equal to a full backup.
 - PAGE backup. In this mode, `pg_probackup` scans all WAL files in the archive from the moment the previous full or incremental backup was taken. Newly created backups contain only the pages that were mentioned in WAL records. This requires all the WAL files since the previous backup to be present in the WAL archive. If the size of these files is comparable to the total size of the database cluster files, speedup is smaller, but the backup still takes less space. You have to configure WAL archiving as explained in [Setting up continuous WAL archiving](#) to make PAGE backups.
 - PTRACK backup. In this mode, Postgres Pro tracks page changes on the fly. Continuous archiving is not necessary for it to operate. Each time a relation page is updated, this page is marked in a special PTRACK bitmap. Tracking implies some minor overhead on the database server operation, but speeds up incremental backups significantly.

`pg_probackup` can take only physical online backups, and online backups require WAL for consistent recovery. So regardless of the chosen backup mode (FULL, PAGE or DELTA), any backup taken with `pg_probackup` must use one of the following *WAL delivery modes*:

- **ARCHIVE**. Such backups rely on [continuous archiving](#) to ensure consistent recovery. This is the default WAL delivery mode.
- **STREAM**. Such backups include all the files required to restore the cluster to a consistent state at the time the backup was taken. Regardless of [continuous archiving](#) having been set up or not, the WAL segments required for consistent recovery are streamed via replication protocol during backup and included into the backup files. That's why such backups are called *autonomous*, or *standalone*.

Limitations

`pg_probackup` currently has the following limitations:

- `pg_probackup` only supports Postgres Pro 9.5 and higher.
- The remote mode is not supported on Windows systems.
- On Unix systems, for Postgres Pro 10 or lower, a backup can be made only by the same OS user that has started the Postgres Pro server. For example, if Postgres Pro server is started by user `postgres`, the `backup` command must also be run by user `postgres`. To satisfy this requirement when taking backups in the [remote mode](#) using SSH, you must set `--remote-user` option to `postgres`.
- For PostgreSQL 9.5, functions `pg_create_restore_point(text)` and `pg_switch_xlog()` can be executed only if the backup role is a superuser, so backup of a cluster with low amount of WAL traffic by a non-superuser role can take longer than the backup of the same cluster by a superuser role.
- The Postgres Pro server from which the backup was taken and the restored server must be compatible by the [block_size](#) and [wal_block_size](#) parameters and have the same major release number. Depending on cluster configuration, Postgres Pro itself may apply additional restrictions, such as CPU architecture or `libc/libicu` versions.

Installation and Setup

Once you have `pg_probackup` installed, complete the following setup:

- Initialize the backup catalog.
- Add a new backup instance to the backup catalog.
- Configure the database cluster to enable `pg_probackup` backups.
- Optionally, configure SSH for running `pg_probackup` operations in the remote mode.

Initializing the Backup Catalog

`pg_probackup` stores all WAL and backup files in the corresponding subdirectories of the backup catalog.

To initialize the backup catalog, run the following command:

```
pg_probackup init -B backup_dir
```

where `backup_dir` is the path to the backup catalog. If the `backup_dir` already exists, it must be empty. Otherwise, `pg_probackup` returns an error.

The user launching `pg_probackup` must have full access to the `backup_dir` directory.

`pg_probackup` creates the `backup_dir` backup catalog, with the following subdirectories:

- `wal/` — directory for WAL files.
- `backups/` — directory for backup files.

Once the backup catalog is initialized, you can add a new backup instance.

Adding a New Backup Instance

`pg_probackup` can store backups for multiple database clusters in a single backup catalog. To set up the required subdirectories, you must add a backup instance to the backup catalog for each database cluster you are going to back up.

To add a new backup instance, run the following command:

```
pg_probackup add-instance -B backup_dir -D data_dir --instance instance_name
[remote_options]
```

where:

- *data_dir* is the data directory of the cluster you are going to back up. To set up and use `pg_probackup`, write access to this directory is required.
- *instance_name* is the name of the subdirectories that will store WAL and backup files for this cluster.
- [remote_options](#) are optional parameters that need to be specified only if *data_dir* is located on a remote system.

`pg_probackup` creates the *instance_name* subdirectories under the `backups/` and `wal/` directories of the backup catalog. The `backups/instance_name` directory contains the `pg_probackup.conf` configuration file that controls `pg_probackup` settings for this backup instance. If you run this command with the [remote_options](#), the specified parameters will be added to `pg_probackup.conf`.

For details on how to fine-tune `pg_probackup` configuration, see [the section called “Configuring pg_probackup”](#).

The user launching `pg_probackup` must have full access to *backup_dir* directory and at least read-only access to *data_dir* directory. If you specify the path to the backup catalog in the `BACKUP_PATH` environment variable, you can omit the corresponding option when running `pg_probackup` commands.

Configuring the Database Cluster

Although `pg_probackup` can be used by a superuser, it is recommended to create a separate role with the minimum permissions required for the chosen backup strategy. In these configuration instructions, the `backup` role is used as an example.

To perform a [backup](#), the following permissions for role `backup` are required only in the database **used for connection** to the Postgres Pro server:

For PostgreSQL 9.5:

```
BEGIN;
CREATE ROLE backup WITH LOGIN;
GRANT USAGE ON SCHEMA pg_catalog TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_start_backup(text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_stop_backup() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_xlog() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;
COMMIT;
```

For Postgres Pro 9.6:

```
BEGIN;
CREATE ROLE backup WITH LOGIN;
GRANT USAGE ON SCHEMA pg_catalog TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_start_backup(text, boolean, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_stop_backup(boolean) TO backup;
```

```
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_xlog() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_last_xlog_replay_location() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_control_checkpoint() TO backup;
COMMIT;
```

For Postgres Pro 10 or higher:

```
BEGIN;
CREATE ROLE backup WITH LOGIN;
GRANT USAGE ON SCHEMA pg_catalog TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_start_backup(text, boolean, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_stop_backup(boolean, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_wal() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_last_wal_replay_lsn() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_control_checkpoint() TO backup;
COMMIT;
```

In the [pg_hba.conf](#) file, allow connection to the database cluster on behalf of the backup role.

Since pg_probackup needs to read cluster files directly, pg_probackup must be started by (or connected to, if used in the remote mode) the OS user that has read access to all files and directories inside the data directory (PGDATA) you are going to back up.

Depending on whether you plan to take [standalone](#) or [archive](#) backups, Postgres Pro cluster configuration will differ, as specified in the sections below. To back up the database cluster from a standby server, run pg_probackup in the remote mode, or create PTRACK backups, additional setup is required.

For details, see the sections [Setting up STREAM Backups](#), [Setting up continuous WAL archiving](#), [Setting up Backup from Standby](#), [Configuring the Remote Mode](#), [Setting up Partial Restore](#), and [Setting up PTRACK Backups](#).

Setting up STREAM Backups

To set up the cluster for [STREAM](#) backups, complete the following steps:

- Grant the `REPLICATION` privilege to the backup role:

```
ALTER ROLE backup WITH REPLICATION;
```

- In the [pg_hba.conf](#) file, allow replication on behalf of the backup role.
- Make sure the parameter [max_wal_senders](#) is set high enough to leave at least one session available for the backup process.
- Set the parameter [wal_level](#) to be higher than `minimal`.

If you are planning to take PAGE backups in the STREAM mode or perform PITR with STREAM backups, you still have to configure WAL archiving, as explained in the section [Setting up continuous WAL archiving](#).

Once these steps are complete, you can start taking FULL, PAGE, DELTA, and PTRACK backups in the [STREAM](#) WAL mode.

Note

If you are planning to rely on [pgpass](#) for authentication when running backup in STREAM mode, then `.pgpass` must contain credentials for `replication` database, used to establish connection via replication protocol. Example: `pghost:5432:replication:backup_user:my_strong_password`

Setting up Continuous WAL Archiving

Making backups in PAGE backup mode, performing [PITR](#), making backups with [ARCHIVE](#) WAL delivery mode and running incremental backup after timeline switch require [continuous WAL archiving](#) to be enabled. To set up continuous archiving in the cluster, complete the following steps:

- Make sure the [wal_level](#) parameter is higher than `minimal`.
- If you are configuring archiving on master, [archive_mode](#) must be set to `on` or `always`. To perform archiving on standby, set this parameter to `always`.
- Set the [archive_command](#) parameter, as follows:

```
archive_command = 'install_dir/pg_probackup archive-push -B backup_dir --
instance instance_name --wal-file-name=%f [remote_options]'
```

where `install_dir` is the installation directory of the `pg_probackup` version you are going to use, `backup_dir` and `instance_name` refer to the already initialized backup catalog instance for this database cluster, and [remote_options](#) only need to be specified to archive WAL on a remote host. For details about all possible `archive-push` parameters, see the section [archive-push](#).

Once these steps are complete, you can start making backups in the [ARCHIVE](#) WAL mode, backups in the PAGE backup mode, as well as perform [PITR](#).

You can view the current state of the WAL archive using the [show](#) command. For details, see [the section called “Viewing WAL Archive Information”](#).

If you are planning to make PAGE backups and/or backups with [ARCHIVE](#) WAL mode from a standby server that generates a small amount of WAL traffic, without long waiting for WAL segment to fill up, consider setting the [archive_timeout](#) Postgres Pro parameter **on master**. The value of this parameter should be slightly lower than the `--archive-timeout` setting (5 minutes by default), so that there is enough time for the rotated segment to be streamed to standby and sent to WAL archive before the backup is aborted because of `--archive-timeout`.

Note

Instead of using the [archive-push](#) command provided by `pg_probackup`, you can use any other tool to set up continuous archiving as long as it delivers WAL segments into `backup_dir/wal/instance_name` directory. If compression is used, it should be `gzip`, and `.gz` suffix in filename is mandatory.

Note

Instead of configuring continuous archiving by setting the `archive_mode` and `archive_command` parameters, you can opt for using the [pg_receivexlog](#) utility. In this case, `pg_receivexlog -D directory` option should point to `backup_dir/wal/instance_name` directory. `pg_probackup` supports WAL compression that can be done by `pg_receivexlog`. “Zero Data Loss” archive strategy can be achieved only by using `pg_receivexlog`.

Setting up Backup from Standby

For Postgres Pro 9.6 or higher, `pg_probackup` can take backups from a standby server. This requires the following additional setup:

- On the standby server, set the `hot_standby` parameter to `on`.
- On the master server, set the `full_page_writes` parameter to `on`.
- To perform standalone backups on standby, complete all steps in section [Setting up STREAM Backups](#).
- To perform archive backups on standby, complete all steps in section [Setting up continuous WAL archiving](#).

Once these steps are complete, you can start taking FULL, PAGE, DELTA, or PTRACK backups with appropriate WAL delivery mode: ARCHIVE or STREAM, from the standby server.

Backup from the standby server has the following limitations:

- If the standby is promoted to the master during backup, the backup fails.
- All WAL records required for the backup must contain sufficient full-page writes. This requires you to enable `full_page_writes` on the master, and not to use tools like `pg_compresslog` as [archive_command](#) to remove full-page writes from WAL files.

Setting up Cluster Verification

Logical verification of a database cluster requires the following additional setup. Role `backup` is used as an example:

- Install the [amcheck](#) or [amcheck_next](#) extension **in every database** of the cluster:

```
CREATE EXTENSION amcheck;
```

- Grant the following permissions to the `backup` role **in every database** of the cluster:

```
GRANT SELECT ON TABLE pg_catalog.pg_am TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_class TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_database TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_namespace TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_extension TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass) TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass, bool) TO backup;
```

Setting up Partial Restore

If you are planning to use partial restore, complete the following additional step:

- Grant the read-only access to `pg_catalog.pg_database` to the `backup` role only in the database **used for connection** to Postgres Pro server:

```
GRANT SELECT ON TABLE pg_catalog.pg_database TO backup;
```

Configuring the Remote Mode

`pg_probackup` supports the remote mode that allows to perform backup, restore and WAL archiving operations remotely. In this mode, the backup catalog is stored on a local system, while Postgres Pro instance to backup and/or to restore is located on a remote system. Currently the only supported remote protocol is SSH.

Set up SSH

If you are going to use `pg_probackup` in remote mode via SSH, complete the following steps:

- Install `pg_probackup` on both systems: `backup_host` and `db_host`.
- For communication between the hosts set up the passwordless SSH connection between `backup` user on `backup_host` and `postgres` user on `db_host`:

```
[backup@backup_host] ssh-copy-id postgres@db_host
```

- If you are going to rely on [continuous WAL archiving](#), set up passwordless SSH connection between `postgres` user on `db_host` and `backup` user on `backup_host`:

```
[postgres@db_host] ssh-copy-id backup@backup_host
```

where:

- `backup_host` is the system with *backup catalog*.
- `db_host` is the system with Postgres Pro cluster.
- `backup` is the OS user on `backup_host` used to run `pg_probackup`.
- `postgres` is the OS user on `db_host` used to start the Postgres Pro cluster.

`pg_probackup` in the remote mode via SSH works as follows:

- Only the following commands can be launched in the remote mode: [add-instance](#), [backup](#), [restore](#), [archive-push](#), [archive-get](#).
- Operating in remote mode requires `pg_probackup` binary to be installed on both local and remote systems. The versions of local and remote binary must be the same.
- When started in the remote mode, the main `pg_probackup` process on the local system connects to the remote system via SSH and launches one or more agent processes on the remote system, which are called *remote agents*. The number of remote agents is equal to the `-j/--threads` setting.
- The main `pg_probackup` process uses remote agents to access remote files and transfer data between local and remote systems.
- Remote agents try to minimize the network traffic and the number of round-trips between hosts.
- The main process is usually started on `backup_host` and connects to `db_host`, but in case of `archive-push` and `archive-get` commands the main process is started on `db_host` and connects to `backup_host`.
- Once data transfer is complete, remote agents are terminated and SSH connections are closed.
- If an error condition is encountered by a remote agent, then all agents are terminated and error details are reported by the main `pg_probackup` process, which exits with an error.
- Compression is always done on `db_host`, while decompression is always done on `backup_host`.

Note

You can impose [additional restrictions](#) on SSH settings to protect the system in the event of account compromise.

Setting up PTRACK Backups

Note

PTRACK versions lower than 2.0 are deprecated. Postgres Pro Standard and Postgres Pro Enterprise versions starting with 11.9.1 contain PTRACK 2.0. Upgrade your server to avoid issues in backups that you will take in future and be sure to take fresh backups of your clusters with the upgraded PTRACK since the backups taken with PTRACK 1.x might be corrupt.

If you are going to use PTRACK backups, complete the following additional steps. The role that will perform PTRACK backups (the `backup` role in the examples below) must have access to all the databases of the cluster.

For Postgres Pro 11 or higher:

1. Create PTRACK extension:

```
CREATE EXTENSION ptrack;
```

2. To enable tracking page updates, set `ptrack.map_size` parameter to a positive integer and restart the server.

For optimal performance, it is recommended to set `ptrack.map_size` to $N / 1024$, where N is the size of the Postgres Pro cluster, in MB. If you set this parameter to a lower value, PTRACK is more likely to map several blocks together, which leads to false-positive results when tracking changed blocks and increases the incremental backup size as unchanged blocks can also be copied into the incremental backup. Setting `ptrack.map_size` to a higher value does not affect PTRACK operation. The maximum allowed value is 1024.

Note

If you change the `ptrack.map_size` parameter value, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. Thus, you have to retake a full backup before taking incremental PTRACK backups after changing `ptrack.map_size`.

For older Postgres Pro versions, PTRACK required taking backups in the exclusive mode to provide exclusive access to bitmaps with changed blocks. To set up PTRACK backups for Postgres Pro 10 or lower, do the following:

1. Set the `ptrack_enable` parameter to `on`.
2. Grant the right to execute PTRACK functions to the `backup` role **in every database** of the cluster:

```
GRANT EXECUTE ON FUNCTION pg_catalog.pg_ptrack_clear() TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_ptrack_get_and_clear(oid, oid) TO backup;
```

Usage

Creating a Backup

To create a backup, run the following command:

```
pg_probackup backup -B backup_dir --instance instance_name -b backup_mode
```

Where `backup_mode` can take one of the following values:

- **FULL** — creates a full backup that contains all the data files of the cluster to be restored.
- **DELTA** — reads all data files in the data directory and creates an incremental backup for pages that have changed since the previous backup.
- **PAGE** — creates an incremental backup based on the WAL files that have been generated since the previous full or incremental backup was taken. Only changed blocks are read from data files.
- **PTRACK** — creates an incremental backup tracking page changes on the fly.

When restoring a cluster from an incremental backup, `pg_probackup` relies on the parent full backup and all the incremental backups between them, which is called “the backup chain”. You must create at least one full backup before taking incremental ones.

ARCHIVE Mode

ARCHIVE is the default WAL delivery mode.

For example, to make a FULL backup in ARCHIVE mode, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL
```

ARCHIVE backups rely on [continuous archiving](#) to get WAL segments required to restore the cluster to a consistent state at the time the backup was taken.

When a backup is taken, `pg_probackup` ensures that WAL files containing WAL records between `Start LSN` and `Stop LSN` actually exist in `backup_dir/wal/instance_name` directory. `pg_probackup` also ensures that WAL records between `Start LSN` and `Stop LSN` can be parsed. This precaution eliminates the risk of silent WAL corruption.

STREAM Mode

STREAM is the optional WAL delivery mode.

For example, to make a FULL backup in the STREAM mode, add the `--stream` flag to the command from the previous example:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --stream --temp-slot
```

The optional `--temp-slot` flag ensures that the required segments remain available if the WAL is rotated before the backup is complete.

Unlike backups in ARCHIVE mode, STREAM backups include all the WAL segments required to restore the cluster to a consistent state at the time the backup was taken.

During [backup](#) `pg_probackup` streams WAL files containing WAL records between `Start LSN` and `Stop LSN` to `backup_dir/backups/instance_name/backup_id/database/pg_wal` directory. To eliminate the risk of silent WAL corruption, `pg_probackup` also checks that WAL records between `Start LSN` and `Stop LSN` can be parsed.

Even if you are using [continuous archiving](#), STREAM backups can still be useful in the following cases:

- STREAM backups can be restored on the server that has no file access to WAL archive.
- STREAM backups enable you to restore the cluster state at the point in time for which WAL files in archive are no longer available.
- Backup in STREAM mode can be taken from a standby of a server that generates small amount of WAL traffic, without long waiting for WAL segment to fill up.

Page Validation

If [data checksums](#) are enabled in the database cluster, `pg_probackup` uses this information to check correctness of data files during backup. While reading each page, `pg_probackup` checks whether the calculated checksum coincides with the checksum stored in the page header. This guarantees that the Postgres Pro instance and the backup itself have no corrupt pages. Note that `pg_probackup` reads database files directly from the filesystem, so under heavy write load during backup it can show false-positive checksum mismatches because of partial writes. If a page checksum mismatch occurs, the page is re-read and checksum comparison is repeated.

A page is considered corrupt if checksum comparison has failed more than 100 times. In this case, the backup is aborted.

Even if data checksums are not enabled, `pg_probackup` always performs sanity checks for page headers.

External Directories

To back up a directory located outside of the data directory, use the optional `--external-dirs` parameter that specifies the path to this directory. If you would like to add more than one external directory, you can provide several paths separated by colons on Linux systems or semicolons on Windows systems.

For example, to include `/etc/dir1` and `/etc/dir2` directories into the full backup of your `instance_name` instance that will be stored under the `backup_dir` directory on Linux, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --external-dirs=/etc/dir1:/etc/dir2
```

Similarly, to include `C:\dir1` and `C:\dir2` directories into the full backup on Windows, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --external-dirs=C:\dir1;C:\dir2
```

`pg_probackup` recursively copies the contents of each external directory into a separate subdirectory in the backup catalog. Since external directories included into different backups do not have to be the same, when you are restoring the cluster from an incremental backup, only those directories that belong to this particular backup will be restored. Any external directories stored in the previous backups will be ignored.

To include the same directories into each backup of your instance, you can specify them in the `pg_probackup.conf` configuration file using the [set-config](#) command with the `--external-dirs` option.

Performing Cluster Verification

To verify that Postgres Pro database cluster is not corrupt, run the following command:

```
pg_probackup checkdb [-B backup_dir [--instance instance_name]] [-D data_dir] [connection_options]
```

This command performs physical verification of all data files located in the specified data directory by running page header sanity checks, as well as block-level checksum verification if checksums are enabled. If a corrupt page is detected, `checkdb` continues cluster verification until all pages in the cluster are validated.

By default, similar [page validation](#) is performed automatically while a backup is taken by `pg_probackup`. The `checkdb` command enables you to perform such page validation on demand, without taking any backup copies, even if the cluster is not backed up using `pg_probackup` at all.

To perform cluster verification, `pg_probackup` needs to connect to the cluster to be verified. In general, it is enough to specify the backup instance of this cluster for `pg_probackup` to determine the required connection options. However, if `-B` and `--instance` options are omitted, you have to provide [connection options](#) and `data_dir` via environment variables or command-line options.

Physical verification cannot detect logical inconsistencies, missing or nullified blocks and entire files, or similar anomalies. Extensions [amcheck](#) and [amcheck_next](#) provide a partial solution to these problems.

If you would like, in addition to physical verification, to verify all indexes in all databases using these extensions, you can specify the `--amcheck` flag when running the `checkdb` command:

```
pg_probackup checkdb -D data_dir --amcheck [connection_options]
```

You can skip physical verification by specifying the `--skip-block-validation` flag. In this case, you can omit `backup_dir` and `data_dir` options, only [connection options](#) are mandatory:

```
pg_probackup checkdb --amcheck --skip-block-validation [connection_options]
```

Logical verification can be done more thoroughly with the `--heapallindexed` flag by checking that all heap tuples that should be indexed are actually indexed, but at the higher cost of CPU, memory, and I/O consumption.

Validating a Backup

`pg_probackup` calculates checksums for each file in a backup during the backup process. The process of checking checksums of backup data files is called *the backup validation*. By default, validation is run immediately after the backup is taken and right before the restore, to detect possible backup corruption.

If you would like to skip backup validation, you can specify the `--no-validate` flag when running [backup](#) and [restore](#) commands.

To ensure that all the required backup files are present and can be used to restore the database cluster, you can run the [validate](#) command with the exact [recovery target options](#) you are going to use for recovery.

For example, to check that you can restore the database cluster from a backup copy up to transaction ID 4242, run this command:

```
pg_probackup validate -B backup_dir --instance instance_name --recovery-target-xid=4242
```

If validation completes successfully, `pg_probackup` displays the corresponding message. If validation fails, you will receive an error message with the exact time, transaction ID, and LSN up to which the recovery is possible.

If you specify *backup_id* via `-i/--backup-id` option, then only the backup copy with specified backup ID will be validated. If *backup_id* is specified with [recovery target options](#), the `validate` command will check whether it is possible to restore the specified backup to the specified recovery target.

For example, to check that you can restore the database cluster from a backup copy with the `PT8XFX` backup ID up to the specified timestamp, run this command:

```
pg_probackup validate -B backup_dir --instance instance_name -i PT8XFX --recovery-target-time='2017-05-18 14:18:11+03'
```

If you specify the *backup_id* of an incremental backup, all its parents starting from FULL backup will be validated.

If you omit all the parameters, all backups are validated.

Restoring a Cluster

To restore the database cluster from a backup, run the [restore](#) command with at least the following options:

```
pg_probackup restore -B backup_dir --instance instance_name -i backup_id
```

where:

- *backup_dir* is the backup catalog that stores all backup files and meta information.
- *instance_name* is the backup instance for the cluster to be restored.
- *backup_id* specifies the backup to restore the cluster from. If you omit this option, `pg_probackup` uses the latest valid backup available for the specified instance. If you specify an incremental backup to restore, `pg_probackup` automatically restores the underlying full backup and then sequentially applies all the necessary increments.

Once the `restore` command is complete, start the database service.

If you restore [ARCHIVE](#) backups, perform [PITR](#), or specify the `--restore-as-replica` flag with the `restore` command to set up a standby server, `pg_probackup` creates a recovery configuration file once all data files are copied into the target directory. This file includes the minimal settings required for recovery, except for the password in the [primary_conninfo](#) parameter; you have to add the password manually or use the `--primary-conninfo` option, if required. For Postgres Pro 11 or lower, recovery settings are written into the `recovery.conf` file. Starting from Postgres Pro 12, `pg_probackup` writes these settings into the `probackup_recovery.conf` file and then includes it into `postgresql.auto.conf`.

If you are restoring a `STREAM` backup, the restore is complete at once, with the cluster returned to a self-consistent state at the point when the backup was taken. For `ARCHIVE` backups, Postgres Pro replays all available archived WAL segments, so the cluster is restored to the latest state possible within the current timeline. You can change this behavior by using the [recovery target options](#) with the `restore` command, as explained in [the section called “Performing Point-in-Time \(PITR\) Recovery”](#).

If the cluster to restore contains tablespaces, `pg_probackup` restores them to their original location by default. To restore tablespaces to a different location, use the `--tablespace-mapping/-T` option. Otherwise, restoring the cluster on the same host will fail if tablespaces are in use, because the backup would have to be written to the same directories.

When using the `--tablespace-mapping/-T` option, you must provide absolute paths to the old and new tablespace directories. If a path happens to contain an equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces. For example:

```
pg_probackup restore -B backup_dir --instance instance_name -D data_dir -j 4 -
i backup_id -T tablespace1_dir=tablespace1_newdir -T tablespace2_dir=tablespace2_newdir
```

To restore the cluster on a remote host, follow the instructions in [the section called “Using pg_probackup in the Remote Mode”](#).

Note

By default, the `restore` command validates the specified backup before restoring the cluster. If you run regular backup validations and would like to save time when restoring the cluster, you can specify the `--no-validate` flag to skip validation and speed up the recovery.

Incremental Restore

The speed of restore from backup can be significantly improved by replacing only invalid and changed pages in already existing PostgreSQL data directory using [incremental restore options](#) with the `restore` command.

To restore the database cluster from a backup in incremental mode, run the `restore` command with the following options:

```
pg_probackup restore -B backup_dir --instance instance_name -D data_dir -
I incremental_mode
```

Where `incremental_mode` can take one of the following values:

- **CHECKSUM** — read all data files in the data directory, validate header and checksum in every page and replace only invalid pages and those with checksum and LSN not matching with corresponding page in backup. This is the simplest, the most fool-proof incremental mode. Recommended to use by default.
- **LSN** — read the `pg_control` in the data directory to obtain redo LSN and redo TLI, which allows to determine a point in history(shiftpoint), where data directory state shifted from target backup chain history. If shiftpoint is not within reach of backup chain history, then restore is aborted. If shiftpoint is within reach of backup chain history, then read all data files in the data directory, validate header and checksum in every page and replace only invalid pages and those with LSN greater than shiftpoint. This mode offers a greater speed up compared to CHECKSUM, but rely on two conditions to be met. First, [data_checksums](#) parameter must be enabled in data directory (to avoid corruption due to hint bits). This condition will be checked at the start of incremental restore and the operation will be aborted if checksums are disabled. Second, the `pg_control` file must be synched with state of data directory. This condition cannot be checked at the start of restore, so it is a user responsibility to ensure that `pg_control` contain valid information. Therefore it is not recommended to use LSN mode in any situation, where `pg_control` cannot be trusted or has been tampered with: after `pg_resetxlog` execution, after restore from backup without recovery been run, etc.
- **NONE** — regular restore without any incremental optimizations.

Regardless of chosen incremental mode, `pg_probackup` will check, that postmaster in given destination directory is not running and `system-identifier` is the same as in the backup.

Suppose you want to return an old master as replica after switchover using incremental restore in LSN mode:

```
=====
Instance  Version  ID      Recovery Time      Mode  WAL Mode  TLI      Time
Data      WAL    Zratio  Start LSN      Stop LSN      Status
```

```

```

Note

Incremental restore is possible only for backups with `program_version` equal or greater than 2.4.0.

Partial Restore

If you have enabled [partial restore](#) before taking backups, you can restore only some of the databases using [partial restore options](#) with the [restore](#) commands.

To restore the specified databases only, run the [restore](#) command with the following options:

```
pg_probackup restore -B backup_dir --instance instance_name --db-include=database_name
```

The `--db-include` option can be specified multiple times. For example, to restore only databases `db1` and `db2`, run the following command:

```
pg_probackup restore -B backup_dir --instance instance_name --db-include=db1 --db-include=db2
```

To exclude one or more databases from restore, use the `--db-exclude` option:

```
pg_probackup restore -B backup_dir --instance instance_name --db-exclude=database_name
```

The `--db-exclude` option can be specified multiple times. For example, to exclude the databases `db1` and `db2` from restore, run the following command:

```
pg_probackup restore -B backup_dir --instance instance_name --db-exclude=db1 --db-exclude=db2
```

Partial restore relies on lax behavior of Postgres Pro recovery process toward truncated files. For recovery to work properly, files of excluded databases are restored as files of zero size. After the

Postgres Pro cluster is successfully started, you must drop the excluded databases using `DROP DATABASE` command.

To decouple a single cluster containing multiple databases into separate clusters with minimal downtime, you can do partial restore of the cluster as a standby using the `--restore-as-replica` option for specific databases.

Note

The `template0` and `template1` databases are always restored.

Note

Due to recovery specifics of PostgreSQL versions earlier than 12, it is advisable that you set the `hot_standby` parameter to `off` when running partial restore of a PostgreSQL cluster of version earlier than 12. Otherwise the recovery may fail.

Performing Point-in-Time (PITR) Recovery

If you have enabled [continuous WAL archiving](#) before taking backups, you can restore the cluster to its state at an arbitrary point in time (recovery target) using [recovery target options](#) with the `restore` command.

You can use both STREAM and ARCHIVE backups for point in time recovery as long as the WAL archive is available at least starting from the time the backup was taken. If `-i/--backup-id` option is omitted, `pg_probackup` automatically chooses the backup that is the closest to the specified recovery target and starts the restore process, otherwise `pg_probackup` will try to restore the specified backup to the specified recovery target.

- To restore the cluster state at the exact time, specify the `--recovery-target-time` option, in the timestamp format. For example:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target-time='2017-05-18 14:18:11+03'
```

- To restore the cluster state up to a specific transaction ID, use the `--recovery-target-xid` option:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target-xid=687
```

- To restore the cluster state up to the specific LSN, use `--recovery-target-lsn` option:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target-lsn=16/B374D848
```

- To restore the cluster state up to the specific named restore point, use `--recovery-target-name` option:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target-name='before_app_upgrade'
```

- To restore the backup to the latest state available in the WAL archive, use `--recovery-target` option with `latest` value:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target='latest'
```

- To restore the cluster to the earliest point of consistency, use `--recovery-target` option with the `immediate` value:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-  
target='immediate'
```

Using pg_probackup in the Remote Mode

pg_probackup supports the remote mode that allows to perform backup and restore operations remotely via SSH. In this mode, the backup catalog is stored on a local system, while Postgres Pro instance to be backed up is located on a remote system. You must have pg_probackup installed on both systems.

Note

pg_probackup relies on passwordless SSH connection for communication between the hosts.

The typical workflow is as follows:

- On your backup host, configure pg_probackup as explained in the section [Installation and Setup](#). For the [add-instance](#) and [set-config](#) commands, make sure to specify [remote options](#) that point to the database host with the Postgres Pro instance.
- If you would like to take remote backups in [PAGE](#) mode, or rely on [ARCHIVE](#) WAL delivery mode, or use [PITR](#), configure continuous WAL archiving from the database host to the backup host as explained in the section [Setting up continuous WAL archiving](#). For the [archive-push](#) and [archive-get](#) commands, you must specify the [remote options](#) that point to the backup host with the backup catalog.
- Run [backup](#) or [restore](#) commands with [remote options on the backup host](#). pg_probackup connects to the remote system via SSH and creates a backup locally or restores the previously taken backup on the remote system, respectively.

For example, to create an archive full backup of a Postgres Pro cluster located on a remote system with host address 192.168.0.2 on behalf of the postgres user via SSH connection through port 2302, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --remote-  
user=postgres --remote-host=192.168.0.2 --remote-port=2302
```

To restore the latest available backup on a remote system with host address 192.168.0.2 on behalf of the postgres user via SSH connection through port 2302, run:

```
pg_probackup restore -B backup_dir --instance instance_name --remote-user=postgres --  
remote-host=192.168.0.2 --remote-port=2302
```

Restoring an ARCHIVE backup or performing PITR in the remote mode require additional information: destination address, port and username for establishing an SSH connection **from** the host with database **to** the host with the backup catalog. This information will be used by the `restore_command` to copy WAL segments from the archive to the Postgres Pro `pg_wal` directory.

To solve this problem, you can use [Remote WAL Archive Options](#).

For example, to restore latest backup on remote system using remote mode through SSH connection to user postgres on host with address 192.168.0.2 via port 2302 and user backup on backup catalog host with address 192.168.0.3 via port 2303, run:

```
pg_probackup restore -B backup_dir --instance instance_name --remote-user=postgres  
--remote-host=192.168.0.2 --remote-port=2302 --archive-host=192.168.0.3 --archive-  
port=2303 --archive-user=backup
```

Provided arguments will be used to construct the `restore_command`:

```
restore_command = 'install_dir/pg_probackup archive-get -B backup_dir --  
instance instance_name --wal-file-path=%p --wal-file-name=%f --remote-host=192.168.0.3  
--remote-port=2303 --remote-user=backup'
```

Alternatively, you can use the `--restore-command` option to provide the entire `restore_command`:

```
pg_probackup restore -B backup_dir --instance instance_name --remote-user=postgres --
remote-host=192.168.0.2 --remote-port=2302 --restore-command='install_dir/pg_probackup
archive-get -B backup_dir --instance instance_name --wal-file-path=%p --wal-file-name=
%f --remote-host=192.168.0.3 --remote-port=2303 --remote-user=backup'
```

Note

The remote mode is currently unavailable for Windows systems.

Running pg_probackup on Parallel Threads

`backup`, `restore`, `merge`, `delete`, `checkdb` and `validate` processes can be executed on several parallel threads. This can significantly speed up `pg_probackup` operation given enough resources (CPU cores, disk, and network bandwidth).

Parallel execution is controlled by the `-j/--threads` command-line option. For example, to create a backup using four parallel threads, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL -j 4
```

Note

Parallel restore applies only to copying data from the backup catalog to the data directory of the cluster. When Postgres Pro server is started, WAL records need to be replayed, and this cannot be done in parallel.

Configuring pg_probackup

Once the backup catalog is initialized and a new backup instance is added, you can use the `pg_probackup.conf` configuration file located in the `backup_dir/backups/instance_name` directory to fine-tune `pg_probackup` configuration.

For example, `backup` and `checkdb` commands use a regular Postgres Pro connection. To avoid specifying `connection options` each time on the command line, you can set them in the `pg_probackup.conf` configuration file using the `set-config` command.

Note

It is **not recommended** to edit `pg_probackup.conf` manually.

Initially, `pg_probackup.conf` contains the following settings:

- `PGDATA` — the path to the data directory of the cluster to back up.
- `system-identifier` — the unique identifier of the Postgres Pro instance.

Additionally, you can define `remote`, `retention`, `logging`, and `compression` settings using the `set-config` command:

```
pg_probackup set-config -B backup_dir --instance instance_name
[--external-dirs=external_directory_path] [remote_options] [connection_options]
[retention_options] [logging_options]
```

To view the current settings, run the following command:

```
pg_probackup show-config -B backup_dir --instance instance_name
```

You can override the settings defined in `pg_probackup.conf` when running `pg_probackup` [commands](#) via the corresponding environment variables and/or command line options.

Specifying Connection Settings

If you define connection settings in the `pg_probackup.conf` configuration file, you can omit connection options in all the subsequent `pg_probackup` commands. However, if the corresponding environment variables are set, they get higher priority. The options provided on the command line overwrite both environment variables and configuration file settings.

If nothing is given, the default values are taken. By default `pg_probackup` tries to use local connection via Unix domain socket (`localhost` on Windows) and tries to get the database name and the user name from the `PGUSER` environment variable or the current OS user name.

Managing the Backup Catalog

With `pg_probackup`, you can manage backups from the command line:

- [View backup information](#)
- [View WAL Archive Information](#)
- [Validate backups](#)
- [Merge backups](#)
- [Delete backups](#)

Viewing Backup Information

To view the list of existing backups for every instance, run the command:

```
pg_probackup show -B backup_dir
```

`pg_probackup` displays the list of all the available backups. For example:

```
BACKUP INSTANCE 'node'
```

=====										
Instance	Version	ID	Recovery time			Mode	WAL Mode	TLI	Time	Data
WAL	Zratio	Start LSN	Stop LSN	Status

16MB	1.00	0/F000028	0/F000198	OK						

For each backup, the following information is provided:

- Instance — the instance name.
- Version — Postgres Pro major version.
- ID — the backup identifier.
- Recovery time — the earliest moment for which you can restore the state of the database cluster.
- Mode — the method used to take this backup. Possible values: FULL, PAGE, DELTA, PTRACK.
- WAL Mode — WAL delivery mode. Possible values: STREAM and ARCHIVE.
- TLI — timeline identifiers of the current backup and its parent.

- **Time** — the time it took to perform the backup.
- **Data** — the size of the data files in this backup. This value does not include the size of WAL files. For **STREAM** backups, the total size of the backup can be calculated as **Data** + **WAL**.
- **WAL** — the uncompressed size of WAL files that need to be applied during recovery for the backup to reach a consistent state.
- **Zratio** — compression ratio calculated as “uncompressed-bytes” / “data-bytes”.
- **Start LSN** — WAL log sequence number corresponding to the start of the backup process. REDO point for Postgres Pro recovery process to start from.
- **Stop LSN** — WAL log sequence number corresponding to the end of the backup process. Consistency point for Postgres Pro recovery process.
- **Status** — backup status. Possible values:
 - **OK** — the backup is complete and valid.
 - **DONE** — the backup is complete, but was not validated.
 - **RUNNING** — the backup is in progress.
 - **MERGING** — the backup is being merged.
 - **MERGED** — the backup data files were successfully merged, but its metadata is in the process of being updated. Only full backups can have this status.
 - **DELETING** — the backup files are being deleted.
 - **CORRUPT** — some of the backup files are corrupt.
 - **ERROR** — the backup was aborted because of an unexpected error.
 - **ORPHAN** — the backup is invalid because one of its parent backups is corrupt or missing.

You can restore the cluster from the backup only if the backup status is **OK** or **DONE**.

To get more detailed information about the backup, run the `show` command with the backup ID:

```
pg_probackup show -B backup_dir --instance instance_name -i backup_id
```

The sample output is as follows:

```
#Configuration
backup-mode = FULL
stream = false
compress-alg = zlib
compress-level = 1
from-replica = false

#Compatibility
block-size = 8192
wal-block-size = 8192
checksum-version = 1
program-version = 2.1.3
server-version = 10

#Result backup info
timelineid = 1
start-lsn = 0/04000028
stop-lsn = 0/040000f8
start-time = '2017-05-16 12:57:29'
end-time = '2017-05-16 12:57:31'
recovery-xid = 597
recovery-time = '2017-05-16 12:57:31'
expire-time = '2020-05-16 12:57:31'
data-bytes = 22288792
wal-bytes = 16777216
```

```
uncompressed-bytes = 39961833
pgdata-bytes = 39859393
status = OK
parent-backup-id = 'PT8XFX'
primary_conninfo = 'user=backup passfile=/var/lib/pgsql/.pgpass port=5432
sslmode=disable sslcompression=1 target_session_attrs=any'
```

Detailed output has additional attributes:

- `compress-alg` — compression algorithm used during backup. Possible values: `zlib`, `pglz`, `none`.
- `compress-level` — compression level used during backup.
- `from-replica` — was this backup taken on standby? Possible values: `1`, `0`.
- `block-size` — the [block_size](#) setting of Postgres Pro cluster at the backup start.
- `checksum-version` — are [data_checksums](#) enabled in the backed up Postgres Pro cluster? Possible values: `1`, `0`.
- `program-version` — full version of `pg_probackup` binary used to create the backup.
- `start-time` — the backup start time.
- `end-time` — the backup end time.
- `expire-time` — the point in time when a pinned backup can be removed in accordance with retention policy. This attribute is only available for pinned backups.
- `uncompressed-bytes` — the size of data files before adding page headers and applying compression. You can evaluate the effectiveness of compression by comparing `uncompressed-bytes` to `data-bytes` if compression is used.
- `pgdata-bytes` — the size of Postgres Pro cluster data files at the time of backup. You can evaluate the effectiveness of an incremental backup by comparing `pgdata-bytes` to `uncompressed-bytes`.
- `recovery-xid` — transaction ID at the backup end time.
- `parent-backup-id` — ID of the parent backup. Available only for incremental backups.
- `primary_conninfo` — libpq connection parameters used to connect to the Postgres Pro cluster to take this backup. The password is not included.
- `note` — text note attached to backup.
- `content-crc` — CRC32 checksum of `backup_content.control` file. It is used to detect corruption of backup meta-information.

You can also get the detailed information about the backup in the JSON format:

```
pg_probackup show -B backup_dir --instance instance_name --format=json -i backup_id
```

The sample output is as follows:

```
[
  {
    "instance": "node",
    "backups": [
      {
        "id": "PT91HZ",
        "parent-backup-id": "PT8XFX",

    }
}
]
}
]

```

Viewing WAL Archive Information

To view the information about WAL archive for every instance, run the command:

```
pg_probackup show -B backup_dir [--instance instance_name] --archive
```

pg_probackup displays the list of all the available WAL files grouped by timelines. For example:

```
ARCHIVE INSTANCE 'node'
```

TLI	Parent TLI	Switchpoint	Min Segno	Max Segno	N
segments	Size	Zratio	N backups	Status	
5	1	0/B0000000	00000005000000000000000000000000B	00000005000000000000000000000000C	2
	685kB	48.00 0	OK		
4	3	0/18000000	00000004000000000000000000000018	0000000400000000000000000000001A	3
	648kB	77.00 0	OK		
3	2	0/15000000	00000003000000000000000000000015	00000003000000000000000000000017	3
	648kB	77.00 0	OK		
2	1	0/B000108	0000000200000000000000000000000B	00000002000000000000000000000015	5
	892kB	94.00 1	DEGRADED		
1	0	0/0	00000001000000000000000000000001	0000000100000000000000000000000A	10
	8774kB	19.00 1	OK		

For each timeline, the following information is provided:

- **TLI** — timeline identifier.
- **Parent TLI** — identifier of the timeline from which this timeline branched off.
- **Switchpoint** — LSN of the moment when the timeline branched off from its parent timeline.
- **Min Segno** — the first WAL segment belonging to the timeline.
- **Max Segno** — the last WAL segment belonging to the timeline.
- **N segments** — number of WAL segments belonging to the timeline.
- **Size** — the size that files take on disk.
- **Zratio** — compression ratio calculated as $N \text{ segments} * wal\_segment\_size * wal\_block\_size / \text{Size}$.
- **N backups** — number of backups belonging to the timeline. To get the details about backups, use the JSON format.
- **Status** — status of the WAL archive for this timeline. Possible values:
 - **OK** — all WAL segments between **Min Segno** and **Max Segno** are present.
 - **DEGRADED** — some WAL segments between **Min Segno** and **Max Segno** are missing. To find out which files are lost, view this report in the JSON format.

To get more detailed information about the WAL archive in the JSON format, run the command:

```
pg_probackup show -B backup_dir [--instance instance_name] --archive --format=json
```

The sample output is as follows:

```
[
  {
    "instance": "replica",

- ## Configuring Retention Policy

2338

Removing Redundant Backups

By default, all backup copies created with `pg_probackup` are stored in the specified backup catalog. To save disk space, you can configure retention policy to remove redundant backup copies.

To configure retention policy, set one or more of the following variables in the `pg_probackup.conf` file via [set-config](#):

```
--retention-redundancy=redundancy
```

Specifies **the number of full backup copies** to keep in the backup catalog.

```
--retention-window=window
```

Defines the earliest point in time for which `pg_probackup` can complete the recovery. This option is set in **the number of days** from the current moment. For example, if `retention-window=7`, `pg_probackup` must keep at least one backup copy that is older than seven days, with all the corresponding WAL files, and all the backups that follow.

If both `--retention-redundancy` and `--retention-window` options are set, both these conditions have to be taken into account when purging the backup catalog. For example, if you set `--retention-redundancy=2` and `--retention-window=7`, `pg_probackup` has to keep two full backup copies, as well as all the backups required to ensure recoverability for the last seven days:

```
pg_probackup set-config -B backup_dir --instance instance_name --retention-redundancy=2
--retention-window=7
```

To clean up the backup catalog in accordance with retention policy, you have to run the [delete](#) command with [retention flags](#), as shown below, or use the [backup](#) command with these flags to process the outdated backup copies right when the new backup is created.

For example, to remove all backup copies that no longer satisfy the defined retention policy, run the following command with the `--delete-expired` flag:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired
```

If you would like to also remove the WAL files that are no longer required for any of the backups, you should also specify the `--delete-wal` flag:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired --delete-wal
```

You can also set or override the current retention policy by specifying `--retention-redundancy` and `--retention-window` options directly when running `delete` or `backup` commands:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired --
retention-window=7 --retention-redundancy=2
```

Since incremental backups require that their parent full backup and all the preceding incremental backups are available, if any of such backups expire, they still cannot be removed while at least one incremental backup in this chain satisfies the retention policy. To avoid keeping expired backups that are still required to restore an active incremental one, you can merge them with this backup using the `--merge-expired` flag when running [backup](#) or [delete](#) commands.

Suppose you have backed up the `node` instance in the `backup_dir` directory, with the `--retention-window` option set to 7, and you have the following backups available on April 10, 2019:

```
BACKUP INSTANCE 'node'
```

```
=====
Instance  Version  ID          Recovery time          Mode  WAL    TLI  Time   Data
WAL  Zratio  Start LSN   Stop LSN    Status
=====
node      10      P7XDHR     2019-04-10 05:27:15+03  FULL  STREAM 1/0   11s   200MB
16MB     1.0    0/18000059 0/18000197  OK
```

Additional Supplied Programs

```

node      10      P7XDQV  2019-04-08 05:32:59+03  PAGE  STREAM  1/0   11s   19MB
16MB     1.0    0/15000060  0/15000198  OK
node      10      P7XDJA  2019-04-03 05:28:36+03  DELTA  STREAM  1/0   21s   32MB
16MB     1.0    0/13000028  0/13000198  OK
-----retention
window-----
node      10      P7XDHU  2019-04-02 05:27:59+03  PAGE  STREAM  1/0   31s   33MB
16MB     1.0    0/11000028  0/110001D0  OK
node      10      P7XDHB  2019-04-01 05:27:15+03  FULL  STREAM  1/0   11s   200MB
16MB     1.0    0/F0000028  0/F000198   OK
node      10      P7XDFT  2019-03-29 05:26:25+03  FULL  STREAM  1/0   11s   200MB
16MB     1.0    0/D0000028  0/D000198   OK

```

Even though P7XDHB and P7XDHU backups are outside the retention window, they cannot be removed as it invalidates the succeeding incremental backups P7XDJA and P7XDQV that are still required, so, if you run the [delete](#) command with the `--delete-expired` flag, only the P7XDFT full backup will be removed.

With the `--merge-expired` option, the P7XDJA backup is merged with the underlying P7XDHU and P7XDHB backups and becomes a full one, so there is no need to keep these expired backups anymore:

```
pg_probackup delete -B backup_dir --instance node --delete-expired --merge-expired
pg_probackup show -B backup_dir
```

```
BACKUP INSTANCE 'node'
```

```

=====
Instance  Version  ID      Recovery time      Mode  WAL      TLI  Time  Data
WAL  Zratio  Start LSN    Stop LSN    Status
=====
node      10      P7XDHR  2019-04-10 05:27:15+03  FULL  STREAM  1/0   11s   200MB
16MB     1.0    0/18000059  0/18000197  OK
node      10      P7XDQV  2019-04-08 05:32:59+03  PAGE  STREAM  1/0   11s   19MB
16MB     1.0    0/15000060  0/15000198  OK
node      10      P7XDJA  2019-04-03 05:28:36+03  FULL  STREAM  1/0   21s   32MB
16MB     1.0    0/13000028  0/13000198  OK

```

The Time field for the merged backup displays the time required for the merge.

Pinning Backups

If you need to keep certain backups longer than the established retention policy allows, you can pin them for arbitrary time. For example:

```
pg_probackup set-backup -B backup_dir --instance instance_name -i backup_id --ttl=30d
```

This command sets the expiration time of the specified backup to 30 days starting from the time indicated in its `recovery-time` attribute.

You can also explicitly set the expiration time for a backup using the `--expire-time` option. For example:

```
pg_probackup set-backup -B backup_dir --instance instance_name -i backup_id --expire-time='2020-01-01 00:00:00+03'
```

Alternatively, you can use the `--ttl` and `--expire-time` options with the [backup](#) command to pin the newly created backup:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --ttl=30d
pg_probackup backup -B backup_dir --instance instance_name -b FULL --expire-time='2020-01-01 00:00:00+03'
```

To check if the backup is pinned, run the [show](#) command:

```
pg_probackup show -B backup_dir --instance instance_name -i backup_id
```

If the backup is pinned, it has the `expire-time` attribute that displays its expiration time:

```
...
recovery-time = '2017-05-16 12:57:31'
expire-time = '2020-01-01 00:00:00+03'
data-bytes = 22288792
...
```

You can unpin the backup by setting the `--ttl` option to zero:

```
pg_probackup set-backup -B backup_dir --instance instance_name -i backup_id --ttl=0
```

Note

A pinned incremental backup implicitly pins all its parent backups. If you unpin such a backup later, its implicitly pinned parents will also be automatically unpinned.

Configuring WAL Archive Retention Policy

When [continuous WAL archiving](#) is enabled, archived WAL segments can take a lot of disk space. Even if you delete old backup copies from time to time, the `--delete-wal` flag can purge only those WAL segments that do not apply to any of the remaining backups in the backup catalog. However, if point-in-time recovery is critical only for the most recent backups, you can configure WAL archive retention policy to keep WAL archive of limited depth and win back some more disk space.

To configure WAL archive retention policy, you have to run the [set-config](#) command with the `--wal-depth` option that specifies the number of backups that can be used for PITR. This setting applies to all the timelines, so you should be able to perform PITR for the same number of backups on each timeline, if available. [Pinned backups](#) are not included into this count: if one of the latest backups is pinned, `pg_probackup` ensures that PITR is possible for one extra backup.

To remove WAL segments that do not satisfy the defined WAL archive retention policy, you simply have to run the [delete](#) or [backup](#) command with the `--delete-wal` flag. For archive backups, WAL segments between `Start LSN` and `Stop LSN` are always kept intact, so such backups remain valid regardless of the `--wal-depth` setting and can still be restored, if required.

You can also use the `--wal-depth` option with the [delete](#) and [backup](#) commands to override the previously defined WAL archive retention policy and purge old WAL segments on the fly.

Suppose you have backed up the `node` instance in the `backup_dir` directory and configured [continuous WAL archiving](#):

```
pg_probackup show -B backup_dir --instance node
```

```
BACKUP INSTANCE 'node'
```

Instance	Version	ID	Recovery Time	Mode	WAL Mode	TLI	Time	Data
WAL	Zratio	Start LSN	Stop LSN	Status				
node	11	PZ9442	2019-10-12 10:43:21+03	DELTA	STREAM	1/0	10s	121kB
16MB	1.00	0/46000028	0/46000160	OK				
node	11	PZ943L	2019-10-12 10:43:04+03	FULL	STREAM	1/0	10s	180MB
32MB	1.00	0/44000028	0/44000160	OK				
node	11	PZ7YR5	2019-10-11 19:49:56+03	DELTA	STREAM	1/1	10s	112kB
32MB	1.00	0/41000028	0/41000160	OK				
node	11	PZ7YMP	2019-10-11 19:47:16+03	DELTA	STREAM	1/1	10s	376kB
32MB	1.00	0/3E000028	0/3F0000B8	OK				
node	11	PZ7YK2	2019-10-11 19:45:45+03	FULL	STREAM	1/0	11s	180MB
16MB	1.00	0/3C000028	0/3C000198	OK				
node	11	PZ7YFO	2019-10-11 19:43:04+03	FULL	STREAM	1/0	10s	30MB
16MB	1.00	0/20000028	0/200ADD8	OK				

You can check the state of the WAL archive by running the [show](#) command with the `--archive` flag:

```
pg_probackup show -B backup_dir --instance node --archive
```

```
ARCHIVE INSTANCE 'node'
```

TLI segments	Parent	TLI Size	Switchpoint Zratio	Min N backups	Segno Status	Max Segno	N
1	0	36MB	0/0 31.00 6	00000001000000000000000001	OK	00000001000000000000000047	71

WAL purge without `--wal-depth` cannot achieve much, only one segment is removed:

```
pg_probackup delete -B backup_dir --instance node --delete-wal
```

```
ARCHIVE INSTANCE 'node'
```

TLI segments	Parent	TLI Size	Switchpoint Zratio	Min N backups	Segno Status	Max Segno	N
1	0	34MB	0/0 32.00 6	00000001000000000000000002	OK	00000001000000000000000047	70

If you would like, for example, to keep only those WAL segments that can be applied to the latest valid backup, set the `--wal-depth` option to 1:

```
pg_probackup delete -B backup_dir --instance node --delete-wal --wal-depth=1
```

```
ARCHIVE INSTANCE 'node'
```

TLI segments	Parent	TLI Size	Switchpoint Zratio	Min N backups	Segno Status	Max Segno	N
1	0	143kB	0/0 228.00 6	00000001000000000000000046	OK	00000001000000000000000047	2

Alternatively, you can use the `--wal-depth` option with the [backup](#) command:

```
pg_probackup backup -B backup_dir --instance node -b DELTA --wal-depth=1 --delete-wal
```

```
ARCHIVE INSTANCE 'node'
```

TLI segments	Parent	TLI Size	Switchpoint Zratio	Min N backups	Segno Status	Max Segno	N
1	0	72kB	0/0 228.00 7	00000001000000000000000048	OK	00000001000000000000000049	1

Merging Backups

As you take more and more incremental backups, the total size of the backup catalog can substantially grow. To save disk space, you can merge incremental backups to their parent full backup by running the `merge` command, specifying the backup ID of the most recent incremental backup you would like to merge:

```
pg_probackup merge -B backup_dir --instance instance_name -i backup_id
```

This command merges backups that belong to a common incremental backup chain. If you specify a full backup, it will be merged with its first incremental backup. If you specify an incremental backup, it will be merged to its parent full backup, together with all incremental backups between them. Once the merge is complete, the full backup takes in all the merged data, and the incremental backups are removed as redundant. Thus, the merge operation is virtually equivalent to retaking a full backup and

removing all the outdated backups, but it allows to save much time, especially for large data volumes, as well as I/O and network traffic if you are using `pg_probackup` in the [remote](#) mode.

Before the merge, `pg_probackup` validates all the affected backups to ensure that they are valid. You can check the current backup status by running the [show](#) command with the backup ID:

```
pg_probackup show -B backup_dir --instance instance_name -i backup_id
```

If the merge is still in progress, the backup status is displayed as `MERGING`. For full backups, it can also be shown as `MERGED` while the metadata is being updated at the final stage of the merge. The merge is idempotent, so you can restart the merge if it was interrupted.

Deleting Backups

To delete a backup that is no longer required, run the following command:

```
pg_probackup delete -B backup_dir --instance instance_name -i backup_id
```

This command will delete the backup with the specified `backup_id`, together with all the incremental backups that descend from `backup_id`, if any. This way you can delete some recent incremental backups, retaining the underlying full backup and some of the incremental backups that follow it.

To delete obsolete WAL files that are not necessary to restore any of the remaining backups, use the `--delete-wal` flag:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-wal
```

To delete backups that are expired according to the current retention policy, use the `--delete-expired` flag:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired
```

Expired backups cannot be removed while at least one incremental backup that satisfies the retention policy is based on them. If you would like to minimize the number of backups still required to keep incremental backups valid, specify the `--merge-expired` flag when running this command:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired --merge-expired
```

In this case, `pg_probackup` searches for the oldest incremental backup that satisfies the retention policy and merges this backup with the underlying full and incremental backups that have already expired, thus making it a full backup. Once the merge is complete, the remaining expired backups are deleted.

Before merging or deleting backups, you can run the `delete` command with the `--dry-run` flag, which displays the status of all the available backups according to the current retention policy, without performing any irreversible actions.

To delete all backups with specific status, use the `--status`:

```
pg_probackup delete -B backup_dir --instance instance_name --status=ERROR
```

Deleting backups by status ignores established retention policies.

Command-Line Reference

Commands

This section describes `pg_probackup` commands. Optional parameters are enclosed in square brackets. For detailed parameter descriptions, see the section [Options](#).

version

```
pg_probackup version
```

Prints `pg_probackup` version.

help

```
pg_probackup help [command]
```

Displays the synopsis of `pg_probackup` commands. If one of the `pg_probackup` commands is specified, shows detailed information about the options that can be used with this command.

init

```
pg_probackup init -B backup_dir [--help]
```

Initializes the backup catalog in `backup_dir` that will store backup copies, WAL archive, and meta information for the backed up database clusters. If the specified `backup_dir` already exists, it must be empty. Otherwise, `pg_probackup` displays a corresponding error message.

For details, see the section [Initializing the Backup Catalog](#).

add-instance

```
pg_probackup add-instance -B backup_dir -D data_dir --instance instance_name [--help]
```

Initializes a new backup instance inside the backup catalog `backup_dir` and generates the `pg_probackup.conf` configuration file that controls `pg_probackup` settings for the cluster with the specified `data_dir` data directory.

For details, see the section [Adding a New Backup Instance](#).

del-instance

```
pg_probackup del-instance -B backup_dir --instance instance_name [--help]
```

Deletes all backups and WAL files associated with the specified instance.

set-config

```
pg_probackup set-config -B backup_dir --instance instance_name
[--help] [--pgdata=pgdata-path]
[--retention-redundancy=redundancy] [--retention-window=window] [--wal-depth=wal_depth]
[--compress-algorithm=compression_algorithm] [--compress-level=compression_level]
[-d dbname] [-h host] [-p port] [-U username]
[--archive-timeout=timeout] [--external-dirs=external_directory_path]
[--restore-command=cmdline]
[remote_options] [remote_wal_archive_options] [logging_options]
```

Adds the specified connection, compression, retention, logging, and external directory settings into the `pg_probackup.conf` configuration file, or modifies the previously defined values.

For all available settings, see the [Options](#) section.

It is **not recommended** to edit `pg_probackup.conf` manually.

set-backup

```
pg_probackup set-backup -B backup_dir --instance instance_name -i backup_id
{--ttl=ttl | --expire-time=time}
[--note=backup_note] [--help]
```

Sets the provided backup-specific settings into the `backup.control` configuration file, or modifies the previously defined values.

```
--note=backup_note
```

Sets the text note for backup copy. If `backup_note` contain newline characters, then only substring before first newline character will be saved. Max size of text note is 1 KB. The `'none'` value removes current note.

For all available pinning settings, see the section [Pinning Options](#).

show-config

```
pg_probackup show-config -B backup_dir --instance instance_name [--format=plain|json]
```

Displays the contents of the `pg_probackup.conf` configuration file located in the `backup_dir/backups/instance_name` directory. You can specify the `--format=json` option to get the result in the JSON format. By default, configuration settings are shown as plain text.

To edit `pg_probackup.conf`, use the [set-config](#) command.

show

```
pg_probackup show -B backup_dir
[--help] [--instance instance_name [-i backup_id | --archive]] [--format=plain|json]
```

Shows the contents of the backup catalog. If *instance_name* and *backup_id* are specified, shows detailed information about this backup. If the `--archive` option is specified, shows the contents of WAL archive of the backup catalog.

By default, the contents of the backup catalog is shown as plain text. You can specify the `--format=json` option to get the result in the JSON format.

For details on usage, see the sections [Managing the Backup Catalog](#) and [Viewing WAL Archive Information](#).

backup

```
pg_probackup backup -B backup_dir -b backup_mode --instance instance_name
[--help] [-j num_threads] [--progress]
[-C] [--stream [-S slot_name] [--temp-slot]] [--backup-pg-log]
[--no-validate] [--skip-block-validation]
[-w --no-password] [-W --password]
[--archive-timeout=timeout] [--external-dirs=external_directory_path]
[--no-sync] [--note=backup_note]
[connection_options] [compression_options] [remote_options]
[retention_options] [pinning_options] [logging_options]
```

Creates a backup copy of the Postgres Pro instance.

`-b mode`

`--backup-mode=mode`

Specifies the backup mode to use. Possible values are:

- **FULL** — creates a full backup that contains all the data files of the cluster to be restored.
- **DELTA** — reads all data files in the data directory and creates an incremental backup for pages that have changed since the previous backup.
- **PAGE** — creates an incremental PAGE backup based on the WAL files that have changed since the previous full or incremental backup was taken.
- **PTRACK** — creates an incremental PTRACK backup tracking page changes on the fly.

`-C`

`--smooth-checkpoint`

Spreads out the checkpoint over a period of time. By default, `pg_probackup` tries to complete the checkpoint as soon as possible.

`--stream`

Makes a **STREAM** backup, which includes all the necessary WAL files by streaming them from the database server via replication protocol.

`--temp-slot`

Creates a temporary physical replication slot for streaming WAL from the backed up Postgres Pro instance. It ensures that all the required WAL segments remain available if WAL is rotated while the

backup is in progress. This flag can only be used together with the `--stream` flag. The default slot name is `pg_probackup_slot`, which can be changed using the `--slot/-S` option.

`-S slot_name`
`--slot=slot_name`

Specifies the replication slot for WAL streaming. This option can only be used together with the `--stream` flag.

`--backup-pg-log`

Includes the log directory into the backup. This directory usually contains log messages. By default, log directory is excluded.

`-E external_directory_path`
`--external-dirs=external_directory_path`

Includes the specified directory into the backup by recursively copying its contents into a separate subdirectory in the backup catalog. This option is useful to back up scripts, SQL dump files, and configuration files located outside of the data directory. If you would like to back up several external directories, separate their paths by a colon on Unix and a semicolon on Windows.

`--archive-timeout=wait_time`

Sets the timeout for WAL segment archiving and streaming, in seconds. By default, `pg_probackup` waits 300 seconds.

`--skip-block-validation`

Disables block-level checksum verification to speed up the backup process.

`--no-validate`

Skips automatic validation after the backup is taken. You can use this flag if you validate backups regularly and would like to save time when running backup operations.

`--no-sync`

Do not sync backed up files to disk. You can use this flag to speed up the backup process. Using this flag can result in data corruption in case of operating system or hardware crash. If you use this option, it is recommended to run the [validate](#) command once the backup is complete to detect possible issues.

`--note=backup_note`

Sets the text note for backup copy. If `backup_note` contain newline characters, then only substring before first newline character will be saved. Max size of text note is 1 KB. The `'none'` value removes current note.

Additionally, [connection options](#), [retention options](#), [pinning options](#), [remote mode options](#), [compression options](#), [logging options](#), and [common options](#) can be used.

For details on usage, see the section [Creating a Backup](#).

restore

```
pg_probackup restore -B backup_dir --instance instance_name
[--help] [-D data_dir] [-i backup_id]
[-j num_threads] [--progress]
[-T OLDDIR=NEWDIR] [--external-mapping=OLDDIR=NEWDIR] [--skip-external-dirs]
[-R | --restore-as-replica] [--no-validate] [--skip-block-validation]
[--force] [--no-sync]
[--restore-command=cmdline]
[--primary-conninfo=primary_conninfo]
[-S | --primary-slot-name=slot_name]
```

```
[recovery_target_options] [logging_options] [remote_options]
[partial_restore_options] [remote_wal_archive_options]
```

Restores the Postgres Pro instance from a backup copy located in the *backup_dir* backup catalog. If you specify a [recovery target option](#), `pg_probackup` finds the closest backup and restores it to the specified recovery target. If neither the backup ID nor recovery target options are provided, `pg_probackup` uses the most recent backup to perform the recovery.

```
-R
--restore-as-replica
```

Creates a minimal recovery configuration file to facilitate setting up a standby server. If the replication connection requires a password, you must specify the password manually in the [primary_conninfo](#) parameter as it is not included. For Postgres Pro 11 or lower, recovery settings are written into the `recovery.conf` file. Starting from Postgres Pro 12, `pg_probackup` writes these settings into the `probackup_recovery.conf` file in the data directory, and then includes them into the `postgresql.auto.conf` when the cluster is started.

```
--primary-conninfo=primary_conninfo
```

Sets the [primary_conninfo](#) parameter to the specified value. This option will be ignored unless the `-R` flag is specified.

Example: `--primary-conninfo='host=192.168.1.50 port=5432 user=foo password=foopass'`

```
-S
--primary-slot-name=slot_name
```

Sets the [primary_slot_name](#) parameter to the specified value. This option will be ignored unless the `-R` flag is specified.

```
-T OLDDIR=NEWDIR
--tablespace-mapping=OLDDIR=NEWDIR
```

Relocates the tablespace from the *OLDDIR* to the *NEWDIR* directory at the time of recovery. Both *OLDDIR* and *NEWDIR* must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces.

```
--external-mapping=OLDDIR=NEWDIR
```

Relocates an external directory included into the backup from the *OLDDIR* to the *NEWDIR* directory at the time of recovery. Both *OLDDIR* and *NEWDIR* must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple directories.

```
--skip-external-dirs
```

Skip external directories included into the backup with the `--external-dirs` option. The contents of these directories will not be restored.

```
--skip-block-validation
```

Disables block-level checksum verification to speed up validation. During automatic validation before the restore only file-level checksums will be verified.

```
--no-validate
```

Skips backup validation. You can use this flag if you validate backups regularly and would like to save time when running restore operations.

```
--restore-command=cmdline
```

Sets the [restore_command](#) parameter to the specified command. For example: `--restore-command='cp /mnt/server/archivedir/%f "%p"'`

`--force`

Allows to ignore an invalid status of the backup. You can use this flag if you need to restore the Postgres Pro cluster from a corrupt or an invalid backup. Use with caution. If `PGDATA` contains a non-empty directory with system ID different from that of the backup being restored, [incremental restore](#) with this flag overwrites the directory contents (while an error occurs without the flag). If tablespaces are remapped through the `--tablespace-mapping` option into non-empty directories, the contents of such directories will be deleted.

`--no-sync`

Do not sync restored files to disk. You can use this flag to speed up restore process. Using this flag can result in data corruption in case of operating system or hardware crash. If it happens, you have to run the [restore](#) command again.

Additionally, [recovery target options](#), [remote mode options](#), [remote WAL archive options](#), [logging options](#), [partial restore options](#), and [common options](#) can be used.

For details on usage, see the section [Restoring a Cluster](#).

checkdb

```
pg_probackup checkdb
[-B backup_dir] [--instance instance_name] [-D data_dir]
[--help] [-j num_threads] [--progress]
[--skip-block-validation] [--amcheck] [--heapallindexed]
[connection_options] [logging_options]
```

Verifies the Postgres Pro database cluster correctness by detecting physical and logical corruption.

`--amcheck`

Performs logical verification of indexes for the specified Postgres Pro instance if no corruption was found while checking data files. You must have the `amcheck` extension or the `amcheck_next` extension installed in the database to check its indexes. For databases without `amcheck`, index verification will be skipped.

`--skip-block-validation`

Skip validation of data files. You can use this flag only together with the `--amcheck` flag, so that only logical verification of indexes is performed.

`--heapallindexed`

Checks that all heap tuples that should be indexed are actually indexed. You can use this flag only together with the `--amcheck` flag.

This check is only possible if you are using the `amcheck` extension of version 2.0 or higher, or the `amcheck_next` extension of any version.

Additionally, [connection options](#) and [logging options](#) can be used.

For details on usage, see the section [Verifying a Cluster](#).

validate

```
pg_probackup validate -B backup_dir
[--help] [--instance instance_name] [-i backup_id]
[-j num_threads] [--progress]
[--skip-block-validation]
[recovery_target_options] [logging_options]
```

Verifies that all the files required to restore the cluster are present and are not corrupt. If `instance_name` is not specified, `pg_probackup` validates all backups available in the backup catalog. If you specify the `instance_name` without any additional options, `pg_probackup` validates all the backups available for this

backup instance. If you specify the *instance_name* with a [recovery target option](#) and/or a *backup_id*, `pg_probackup` checks whether it is possible to restore the cluster using these options.

For details, see the section [Validating a Backup](#).

merge

```
pg_probackup merge -B backup_dir --instance instance_name -i backup_id
[--help] [-j num_threads] [--progress]
[logging_options]
```

Merges backups that belong to a common incremental backup chain. If you specify a full backup, it will be merged with its first incremental backup. If you specify an incremental backup, it will be merged to its parent full backup, together with all incremental backups between them. Once the merge is complete, the full backup takes in all the merged data, and the incremental backups are removed as redundant.

For details, see the section [Merging Backups](#).

delete

```
pg_probackup delete -B backup_dir --instance instance_name
[--help] [-j num_threads] [--progress]
[--retention-redundancy=redundancy] [--retention-window=window] [--wal-depth=wal_depth]
[--delete-wal]
{-i backup_id | --delete-expired [--merge-expired] | --merge-expired | --
status=backup_status}
[--dry-run] [logging_options]
```

Deletes backup with specified *backup_id* or launches the retention purge of backups and archived WAL that do not satisfy the current retention policies.

For details, see the sections [Deleting Backups](#), [Retention Options](#) and [Configuring Retention Policy](#).

archive-push

```
pg_probackup archive-push -B backup_dir --instance instance_name
--wal-file-name=wal_file_name [--wal-file-path=wal_file_path]
[--help] [--no-sync] [--compress] [--no-ready-rename] [--overwrite]
[-j num_threads] [--batch-size=batch_size]
[--archive-timeout=timeout]
[--compress-algorithm=compression_algorithm]
[--compress-level=compression_level]
[remote_options] [logging_options]
```

Copies WAL files into the corresponding subdirectory of the backup catalog and validates the backup instance by *instance_name* and system-identifier. If parameters of the backup instance and the cluster do not match, this command fails with the following error message: `Refuse to push WAL segment segment_name into archive. Instance parameters mismatch.`

If the files to be copied already exists in the backup catalog, `pg_probackup` computes and compares their checksums. If the checksums match, `archive-push` skips the corresponding file and returns a successful execution code. Otherwise, `archive-push` fails with an error. If you would like to replace WAL files in the case of checksum mismatch, run the `archive-push` command with the `--overwrite` flag.

Each file is copied to a temporary file with the `.part` suffix. If the temporary file already exists, `pg_probackup` will wait `archive_timeout` seconds before discarding it. After the copy is done, atomic rename is performed. This algorithm ensures that a failed `archive-push` will not stall continuous archiving and that concurrent archiving from multiple sources into a single WAL archive has no risk of archive corruption.

To speed up archiving, you can specify the `--batch-size` option to copy WAL segments in batches of the specified size. If `--batch-size` option is used, then you can also specify the `-j` option to copy the batch of WAL segments on multiple threads.

WAL segments copied to the archive are synced to disk unless the `--no-sync` flag is used.

You can use `archive-push` in the [archive_command](#) Postgres Pro parameter to set up [continuous WAL archiving](#).

For details, see sections [Archiving Options](#) and [Compression Options](#).

archive-get

```
pg_probackup archive-get -B backup_dir --instance instance_name --wal-file-  
path=wal_file_path --wal-file-name=wal_file_name  
[-j num_threads] [--batch-size=batch_size]  
[--prefetch-dir=prefetch_dir_path] [--no-validate-wal]  
[--help] [remote_options] [logging_options]
```

Copies WAL files from the corresponding subdirectory of the backup catalog to the cluster's write-ahead log location. This command is automatically set by `pg_probackup` as part of the `restore_command` when restoring backups using a WAL archive. You do not need to set it manually.

To speed up recovery, you can specify the `--batch-size` option to copy WAL segments in batches of the specified size. If `--batch-size` option is used, then you can also specify the `-j` option to copy the batch of WAL segments on multiple threads.

For details, see section [Archiving Options](#).

Options

This section describes command-line options for `pg_probackup` commands. If the option value can be derived from an environment variable, this variable is specified below the command-line option, in the uppercase. Some values can be taken from the `pg_probackup.conf` configuration file located in the backup catalog.

For details, see [the section called “Configuring pg_probackup”](#).

If an option is specified using more than one method, command-line input has the highest priority, while the `pg_probackup.conf` settings have the lowest priority.

Common Options

The list of general options.

```
-B directory  
--backup-path=directory  
BACKUP_PATH
```

Specifies the absolute path to the backup catalog. Backup catalog is a directory where all backup files and meta information are stored. Since this option is required for most of the `pg_probackup` commands, you are recommended to specify it once in the `BACKUP_PATH` environment variable. In this case, you do not need to use this option each time on the command line.

```
-D directory  
--pgdata=directory  
PGDATA
```

Specifies the absolute path to the data directory of the database cluster. This option is mandatory only for the [add-instance](#) command. Other commands can take its value from the `PGDATA` environment variable, or from the `pg_probackup.conf` configuration file.

```
-i backup_id  
--backup-id=backup_id
```

Specifies the unique identifier of the backup.

`-j num_threads`

`--threads=num_threads`

Sets the number of parallel threads for backup, restore, merge, validate, checkdb, and archive-push processes.

`--progress`

Shows the progress of operations.

`--help`

Shows detailed information about the options that can be used with this command.

Recovery Target Options

If [continuous WAL archiving](#) is configured, you can use one of these options together with [restore](#) or [validate](#) commands to specify the moment up to which the database cluster must be restored or validated.

`--recovery-target=immediate|latest`

Defines when to stop the recovery:

- The `immediate` value stops the recovery after reaching the consistent state of the specified backup, or the latest available backup if the `-i/--backup-id` option is omitted. This is the default behavior for STREAM backups.
- The `latest` value continues the recovery until all WAL segments available in the archive are applied. This is the default behavior for ARCHIVE backups.

`--recovery-target-timeline=timeline`

Specifies a particular timeline to be used for recovery. By default, the timeline of the specified backup is used.

`--recovery-target-lsn=lsn`

Specifies the LSN of the write-ahead log location up to which recovery will proceed. Can be used only when restoring a database cluster of major version 10 or higher.

`--recovery-target-name=recovery_target_name`

Specifies a named savepoint up to which to restore the cluster.

`--recovery-target-time=time`

Specifies the timestamp up to which recovery will proceed. If the time zone offset is not specified, the local time zone is used.

Example: `--recovery-target-time='2020-01-01 00:00:00+03'`

`--recovery-target-xid=xid`

Specifies the transaction ID up to which recovery will proceed.

`--recovery-target-inclusive=boolean`

Specifies whether to stop just after the specified recovery target (`true`), or just before the recovery target (`false`). This option can only be used together with `--recovery-target-name`, `--recovery-target-time`, `--recovery-target-lsn` or `--recovery-target-xid` options. The default depends on the [recovery_target_inclusive](#) parameter.

`--recovery-target-action=pause|promote|shutdown`

Specifies [recovery_target_action](#) the server should take when the recovery target is reached.

Default: `pause`

Retention Options

You can use these options together with [backup](#) and [delete](#) commands.

For details on configuring retention policy, see the section [Configuring Retention Policy](#).

`--retention-redundancy=redundancy`

Specifies the number of full backup copies to keep in the data directory. Must be a non-negative integer. The zero value disables this setting.

Default: 0

`--retention-window=window`

Number of days of recoverability. Must be a non-negative integer. The zero value disables this setting.

Default: 0

`--wal-depth=wal_depth`

Number of latest valid backups on every timeline that must retain the ability to perform PITR. Must be a non-negative integer. The zero value disables this setting.

Default: 0

`--delete-wal`

Deletes WAL files that are no longer required to restore the cluster from any of the existing backups.

`--delete-expired`

Deletes backups that do not conform to the retention policy defined in the `pg_probackup.conf` configuration file.

`--merge-expired`

Merges the oldest incremental backup that satisfies the requirements of retention policy with its parent backups that have already expired.

`--dry-run`

Displays the current status of all the available backups, without deleting or merging expired backups, if any.

Pinning Options

You can use these options together with [backup](#) and [set-backup](#) commands.

For details on backup pinning, see the section [Backup Pinning](#).

`--ttl=ttl`

Specifies the amount of time the backup should be pinned. Must be a non-negative integer. The zero value unpins the already pinned backup. Supported units: ms, s, min, h, d (s by default).

Example: `--ttl=30d`

`--expire-time=time`

Specifies the timestamp up to which the backup will stay pinned. Must be an ISO-8601 complaint timestamp. If the time zone offset is not specified, the local time zone is used.

Example: `--expire-time='2020-01-01 00:00:00+03'`

Logging Options

You can use these options with any command.

`--log-level-console=log_level`

Controls which message levels are sent to the console log. Valid values are `verbose`, `log`, `info`, `warning`, `error` and `off`. Each level includes all the levels that follow it. The later the level, the fewer messages are sent. The `off` level disables console logging.

Default: `info`

Note

All console log messages are going to `stderr`, so the output of `show` and `show-config` commands does not mingle with log messages.

`--log-level-file=log_level`

Controls which message levels are sent to a log file. Valid values are `verbose`, `log`, `info`, `warning`, `error`, and `off`. Each level includes all the levels that follow it. The later the level, the fewer messages are sent. The `off` level disables file logging.

Default: `off`

`--log-filename=log_filename`

Defines the filenames of the created log files. The filenames are treated as a `strftime` pattern, so you can use %-escapes to specify time-varying filenames.

Default: `pg_probackup.log`

For example, if you specify the `pg_probackup-%u.log` pattern, `pg_probackup` generates a separate log file for each day of the week, with `%u` replaced by the corresponding decimal number: `pg_probackup-1.log` for Monday, `pg_probackup-2.log` for Tuesday, and so on.

This option takes effect if file logging is enabled by the `--log-level-file` option.

`--error-log-filename=error_log_filename`

Defines the filenames of log files for error messages only. The filenames are treated as a `strftime` pattern, so you can use %-escapes to specify time-varying filenames.

Default: `none`

For example, if you specify the `error-pg_probackup-%u.log` pattern, `pg_probackup` generates a separate log file for each day of the week, with `%u` replaced by the corresponding decimal number: `error-pg_probackup-1.log` for Monday, `error-pg_probackup-2.log` for Tuesday, and so on.

This option is useful for troubleshooting and monitoring.

`--log-directory=log_directory`

Defines the directory in which log files will be created. You must specify the absolute path. This directory is created lazily, when the first log message is written.

Default: `$BACKUP_PATH/log/`

`--log-rotation-size=log_rotation_size`

Maximum size of an individual log file. If this value is reached, the log file is rotated once a `pg_probackup` command is launched, except `help` and `version` commands. The zero value disables size-based rotation. Supported units: `KB`, `MB`, `GB`, `TB` (`KB` by default).

Default: `0`

`--log-rotation-age=log_rotation_age`

Maximum lifetime of an individual log file. If this value is reached, the log file is rotated once a `pg_probackup` command is launched, except `help` and `version` commands. The time of the last log file creation is stored in `$BACKUP_PATH/log/log_rotation`. The zero value disables time-based rotation. Supported units: ms, s, min, h, d (min by default).

Default: 0

Connection Options

You can use these options together with [backup](#) and [checkdb](#) commands.

All [libpq environment variables](#) are supported.

`-d dbname`

`--pgdatabase=dbname`

`PGDATABASE`

Specifies the name of the database to connect to. The connection is used only for managing backup process, so you can connect to any existing database. If this option is not provided on the command line, `PGDATABASE` environment variable, or the `pg_probackup.conf` configuration file, `pg_probackup` tries to take this value from the `PGUSER` environment variable, or from the current user name if `PGUSER` variable is not set.

`-h host`

`--pghost=host`

`PGHOST`

Specifies the host name of the system on which the server is running. If the value begins with a slash, it is used as a directory for the Unix domain socket.

Default: localhost

`-p port`

`--pgport=port`

`PGPORT`

Specifies the TCP port or the local Unix domain socket file extension on which the server is listening for connections.

Default: 5432

`-U username`

`--pguser=username`

`PGUSER`

User name to connect as.

`-w`

`--no-password`

Disables a password prompt. If the server requires password authentication and a password is not available by other means such as a [.pgpass](#) file or `PGPASSWORD` environment variable, the connection attempt will fail. This flag can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`

`--password`

Forces a password prompt. (Deprecated)

Compression Options

You can use these options together with [backup](#) and [archive-push](#) commands.

`--compress-algorithm=compression_algorithm`

Defines the algorithm to use for compressing data files. Possible values are `zlib`, `pglz`, and `none`. If set to `zlib` or `pglz`, this option enables compression. By default, compression is disabled. For the [archive-push](#) command, the `pglz` compression algorithm is not supported.

Default: `none`

`--compress-level=compression_level`

Defines compression level (0 through 9, 0 being no compression and 9 being best compression). This option can be used together with the `--compress-algorithm` option.

Default: `1`

`--compress`

Alias for `--compress-algorithm=zlib` and `--compress-level=1`.

Archiving Options

These options can be used with the [archive-push](#) command in the [archive_command](#) setting and the [archive-get](#) command in the [restore_command](#) setting.

Additionally, [remote mode options](#) and [logging options](#) can be used.

`--wal-file-path=wal_file_path`

Provides the path to the WAL file in *archive_command* and *restore_command*. Use the `%p` variable as the value for this option for correct processing.

`--wal-file-name=wal_file_name`

Provides the name of the WAL file in *archive_command* and *restore_command*. Use the `%f` variable as the value for this option for correct processing.

`--overwrite`

Overwrites archived WAL file. Use this flag together with the [archive-push](#) command if the specified subdirectory of the backup catalog already contains this WAL file and it needs to be replaced with its newer copy. Otherwise, `archive-push` reports that a WAL segment already exists, and aborts the operation. If the file to replace has not changed, `archive-push` skips this file regardless of the `--overwrite` flag.

`--batch-size=batch_size`

Sets the maximum number of files that can be copied into the archive by a single `archive-push` process, or from the archive by a single `archive-get` process.

`--archive-timeout=wait_time`

Sets the timeout for considering existing `.part` files to be stale. By default, `pg_probackup` waits 300 seconds. This option can be used only with [archive-push](#) command.

`--no-ready-rename`

Do not rename status files in the `archive_status` directory. This option should be used only if *archive_command* contains multiple commands. This option can be used only with [archive-push](#) command.

`--no-sync`

Do not sync copied WAL files to disk. You can use this flag to speed up archiving process. Using this flag can result in WAL archive corruption in case of operating system or hardware crash. This option can be used only with [archive-push](#) command.

`--prefetch-dir=path`

Directory used to store prefetched WAL segments if `--batch-size` option is used. Directory must be located on the same filesystem and on the same mountpoint the `PGDATA/pg_wal` is located. By default files are stored in `PGDATA/pg_wal/pbk_prefetch` directory. This option can be used only with [archive-get](#) command.

`--no-validate-wal`

Do not validate prefetched WAL file before using it. Use this option if you want to increase the speed of recovery. This option can be used only with [archive-get](#) command.

Remote Mode Options

This section describes the options related to running `pg_probackup` operations remotely via SSH. These options can be used with [add-instance](#), [set-config](#), [backup](#), [restore](#), [archive-push](#), and [archive-get](#) commands.

For details on configuring and using the remote mode, see [the section called “Configuring the Remote Mode”](#) and [the section called “Using pg_probackup in the Remote Mode”](#).

`--remote-proto=proto`

Specifies the protocol to use for remote operations. Currently only the SSH protocol is supported. Possible values are:

- `ssh` enables the remote mode via SSH. This is the default value.
- `none` explicitly disables the remote mode.

You can omit this option if the `--remote-host` option is specified.

`--remote-host=destination`

Specifies the remote host IP address or hostname to connect to.

`--remote-port=port`

Specifies the remote host port to connect to.

Default: 22

`--remote-user=username`

Specifies remote host user for SSH connection. If you omit this option, the current user initiating the SSH connection is used.

`--remote-path=path`

Specifies `pg_probackup` installation directory on the remote system.

`--ssh-options=ssh_options`

Provides a string of SSH command-line options. For example, the following options can be used to set `keep-alive` for SSH connections opened by `pg_probackup`: `--ssh-options='-o ServerAliveCountMax=5 -o ServerAliveInterval=60'`. For the full list of possible options, see [ssh_config manual page](#).

Remote WAL Archive Options

This section describes the options used to provide the arguments for [remote mode options](#) in [archive-get](#) used in the [restore_command](#) command when restoring ARCHIVE backups or performing PITR.

`--archive-host=destination`

Provides the argument for the `--remote-host` option in the `archive-get` command.

`--archive-port=port`

Provides the argument for the `--remote-port` option in the `archive-get` command.

Default: 22

`--archive-user=username`

Provides the argument for the `--remote-user` option in the `archive-get` command. If you omit this option, the user that has started the Postgres Pro cluster is used.

Default: Postgres Pro user

Incremental Restore Options

This section describes the options for incremental cluster restore. These options can be used with the `restore` command.

`-I incremental_mode`

`--incremental-mode=incremental_mode`

Specifies the incremental mode to be used. Possible values are:

- `CHECKSUM` — replace only pages with mismatched checksum and LSN.
- `LSN` — replace only pages with LSN greater than point of divergence.
- `NONE` — regular restore.

Partial Restore Options

This section describes the options for partial cluster restore. These options can be used with the `restore` command.

`--db-exclude=dbname`

Specifies the name of the database to exclude from restore. All other databases in the cluster will be restored as usual, including `template0` and `template1`. This option can be specified multiple times for multiple databases.

`--db-include=dbname`

Specifies the name of the database to restore from a backup. All other databases in the cluster will not be restored, with the exception of `template0` and `template1`. This option can be specified multiple times for multiple databases.

Replica Options

This section describes the options related to taking a backup from standby.

Note

Starting from `pg_probackup 2.0.24`, backups can be taken from standby without connecting to the master server, so these options are no longer required. In lower versions, `pg_probackup` had to connect to the master to determine recovery time — the earliest moment for which you can restore a consistent state of the database cluster.

`--master-db=dbname`

Deprecated. Specifies the name of the database on the master server to connect to. The connection is used only for managing the backup process, so you can connect to any existing database. Can be set in the `pg_probackup.conf` using the `set-config` command.

Default: `postgres`, the default Postgres Pro database

`--master-host=host`

Deprecated. Specifies the host name of the system on which the master server is running.

`--master-port=port`

Deprecated. Specifies the TCP port or the local Unix domain socket file extension on which the master server is listening for connections.

Default: 5432, the Postgres Pro default port

`--master-user=username`

Deprecated. User name to connect as.

Default: postgres, the Postgres Pro default user name

`--replica-timeout=timeout`

Deprecated. Wait time for WAL segment streaming via replication, in seconds. By default, `pg_probackup` waits 300 seconds. You can also define this parameter in the `pg_probackup.conf` configuration file using the [set-config](#) command.

Default: 300 sec

How-To

All examples below assume the remote mode of operations via SSH. If you are planning to run backup and restore operation locally, skip the “Setup passwordless SSH connection” step and omit all `--remote-*` options.

Examples are based on Ubuntu 18.04, Postgres Pro 11, and `pg_probackup 2.2.0`.

- `backup` — Postgres Pro role used for connection to Postgres Pro cluster.
- `backupdb` — database used for connection to Postgres Pro cluster.
- `backup_host` — host with backup catalog.
- `backupman` — user on `backup_host` running all `pg_probackup` operations.
- `/mnt/backups` — directory on `backup_host` where backup catalog is stored.
- `postgres_host` — host with Postgres Pro cluster.
- `postgres` — user on `postgres_host` that has started the Postgres Pro cluster.
- `/var/lib/postgresql/11/main` — Postgres Pro data directory on `postgres_host`.

Minimal Setup

This scenario illustrates setting up standalone FULL and DELTA backups.

1. **Set up passwordless SSH connection from `backup_host` to `postgres_host`:**

```
[backupman@backup_host] ssh-copy-id postgres@postgres_host
```

2. **Configure your Postgres Pro cluster.**

For security purposes, it is recommended to use a separate database for backup operations.

```
postgres=#  
CREATE DATABASE backupdb;
```

Connect to the `backupdb` database, create the `probackup` role, and grant the following permissions to this role:

```
backupdb=#  
BEGIN;  
CREATE ROLE backup WITH LOGIN REPLICATION;  
GRANT USAGE ON SCHEMA pg_catalog TO backup;
```

```
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_start_backup(text, boolean, boolean) TO
  backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_stop_backup(boolean, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_wal() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_last_wal_replay_lsn() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_control_checkpoint() TO backup;
COMMIT;
```

3. Initialize the backup catalog:

```
[backupman@backup_host]$ pg_probackup-11 init -B /mnt/backups
INFO: Backup catalog '/mnt/backups' successfully initied
```

4. Add instance pg-11 to the backup catalog:

```
[backupman@backup_host]$ pg_probackup-11 add-instance -B /mnt/backups --instance
  'pg-11' --remote-host=postgres_host --remote-user=postgres -D /var/lib/
postgresql/11/main
INFO: Instance 'node' successfully initied
```

5. Take a FULL backup:

```
[backupman@backup_host] pg_probackup-11 backup -B /mnt/backups --instance 'pg-11'
  -b FULL --stream --remote-host=postgres_host --remote-user=postgres -U backup -d
  backupdb
INFO: Backup start, pg_probackup version: 2.2.0, instance: node, backup ID: PZ7YK2,
  backup mode: FULL, wal mode: STREAM, remote: true, compress-algorithm: none,
  compress-level: 1
INFO: Start transferring data files
INFO: Data files are transferred
INFO: wait for pg_stop_backup()
INFO: pg_stop_backup() successfully executed
INFO: Validating backup PZ7YK2
INFO: Backup PZ7YK2 data files are valid
INFO: Backup PZ7YK2 resident size: 196MB
INFO: Backup PZ7YK2 completed
```

6. Let's take a look at the backup catalog:

```
[backupman@backup_host] pg_probackup-11 show -B /mnt/backups --instance 'pg-11'
```

```
BACKUP INSTANCE 'pg-11'
```

```
=====
Instance  Version  ID          Recovery Time          Mode  WAL Mode  TLI  Time
Data    WAL  Zratio  Start LSN  Stop LSN    Status
=====
node      11      PZ7YK2  2019-10-11 19:45:45+03  FULL  STREAM    1/0  11s
180MB  16MB    1.00  0/3C000028  0/3C000198  OK
=====
```

7. Take an incremental backup in the DELTA mode:

```
[backupman@backup_host] pg_probackup-11 backup -B /mnt/backups --instance 'pg-11'
  -b delta --stream --remote-host=postgres_host --remote-user=postgres -U backup -d
  backupdb
INFO: Backup start, pg_probackup version: 2.2.0, instance: node, backup ID: PZ7YMP,
  backup mode: DELTA, wal mode: STREAM, remote: true, compress-algorithm: none,
  compress-level: 1
```

```
INFO: Parent backup: PZ7YK2
INFO: Start transferring data files
INFO: Data files are transferred
INFO: wait for pg_stop_backup()
INFO: pg_stop_backup() successfully executed
INFO: Validating backup PZ7YMP
INFO: Backup PZ7YMP data files are valid
INFO: Backup PZ7YMP resident size: 32MB
INFO: Backup PZ7YMP completed
```

8. **Let's add some parameters to pg_probackup configuration file, so that you can omit them from the command line:**

```
[backupman@backup_host] pg_probackup-11 set-config -B /mnt/backups --instance
'pg-11' --remote-host=postgres_host --remote-user=postgres -U backup -d backupdb
```

9. **Take another incremental backup in the DELTA mode, omitting some of the previous parameters:**

```
[backupman@backup_host] pg_probackup-11 backup -B /mnt/backups --instance 'pg-11' -
b delta --stream
INFO: Backup start, pg_probackup version: 2.2.0, instance: node, backup ID: PZ7YR5,
  backup mode: DELTA, wal mode: STREAM, remote: true, compress-algorithm: none,
  compress-level: 1
INFO: Parent backup: PZ7YMP
INFO: Start transferring data files
INFO: Data files are transferred
INFO: wait for pg_stop_backup()
INFO: pg_stop_backup() successfully executed
INFO: Validating backup PZ7YR5
INFO: Backup PZ7YR5 data files are valid
INFO: Backup PZ7YR5 resident size: 32MB
INFO: Backup PZ7YR5 completed
```

10. **Let's take a look at the instance configuration:**

```
[backupman@backup_host] pg_probackup-11 show-config -B /mnt/backups --instance
'pg-11'
```

```
# Backup instance information
pgdata = /var/lib/postgresql/11/main
system-identifier = 6746586934060931492
xlog-seg-size = 16777216
# Connection parameters
pgdatabase = backupdb
pghost = postgres_host
pguser = backup
# Replica parameters
replica-timeout = 5min
# Archive parameters
archive-timeout = 5min
# Logging parameters
log-level-console = INFO
log-level-file = OFF
log-filename = pg_probackup.log
log-rotation-size = 0
log-rotation-age = 0
# Retention parameters
retention-redundancy = 0
retention-window = 0
wal-depth = 0
```

```
# Compression parameters
compress-algorithm = none
compress-level = 1
# Remote access parameters
remote-proto = ssh
remote-host = postgres_host
```

Note that we are getting the default values for other options that were not overwritten by the `set-config` command.

11. Let's take a look at the backup catalog:

```
[backupman@backup_host] pg_probackup-11 show -B /mnt/backups --instance 'pg-11'
```

Versioning

pg_probackup follows *semantic* versioning.

Authors

Postgres Professional, Moscow, Russia.

Credits

pg_probackup utility is based on pg_arman, which was originally written by NTT and then developed and maintained by Michael Paquier.

pg_repack

pg_repack — utility and Postgres Pro Enterprise extension to reorganize tables

Synopsis

```
pg_repack [option...] [dbname]
```

Description

pg_repack is a Postgres Pro Enterprise extension which lets you remove bloat from tables and indexes, and optionally restore the physical order of clustered indexes. Unlike `CLUSTER` and `VACUUM FULL` it works online, without holding an exclusive lock on the processed tables during processing. *pg_repack* is efficient to boot, with performance comparable to using `CLUSTER` directly.

pg_repack is a fork of the previous <http://reorg.projects.pgfoundry.org/> project. Please check the https://github.com/reorg/pg_repack for bug report and development information.

You can choose one of the following methods to reorganize data:

- Online `CLUSTER` (ordered by cluster index)
- Ordering by specified columns
- Online `VACUUM FULL` (packing rows only)
- Rebuild or relocate only the indexes of a table

Note

Only superusers can use the utility.

Note

Target table must have a PRIMARY KEY, or at least a UNIQUE total index on a NOT NULL column.

Installation

On Linux systems, *pg_repack* is provided together with Postgres Pro as a separate pre-built package and requires the `postgrespro-ent-9.6-server` package to be installed with all the dependencies. For the list of available packages and detailed installation instructions, see [Chapter 17](#). On Windows systems, *pg_repack* is automatically installed as part of Postgres Pro.

Once you have *pg_repack* installed, load the *pg_repack* extension in the database you want to process, as follows:

```
$ psql -c "CREATE EXTENSION pg_repack" -d your_database
```

You can later remove *pg_repack* from a Postgres Pro installation using `DROP EXTENSION pg_repack`.

If you are upgrading from a previous version of *pg_repack*, just drop the old version from the database as explained above and install the new version.

Options

Reorganization Options

```
-a  
--all
```

Attempt to repack all the databases of the cluster. Databases where the *pg_repack* extension is not installed will be skipped.

`-t table`
`--table=table`

Reorganize the specified table(s) only. Multiple tables may be reorganized by writing multiple `-t` switches. By default, all eligible tables in the target databases are reorganized.

`-c schema`
`--schema=schema`

Repack the tables in the specified schema(s) only. Multiple schemas may be repacked by writing multiple `-c` switches. Can be used in conjunction with `--tablespace` to move tables to a different tablespace.

`-o column[, ...]`
`--order-by=column[, ...]`

Perform an online `CLUSTER` ordered by the specified columns.

`-n`
`--no-order`

Perform an online `VACUUM FULL`. Since version 1.2 this is the default for non-clustered tables.

`-N`
`--dry-run`

Show what would be repacked and exit.

`-j num_jobs`
`--jobs=num_jobs`

Create the specified number of extra connections to Postgres Pro Enterprise, and use these extra connections to parallelize the rebuild of indexes on each table. Parallel index builds are only supported for full-table repacks, not with `--index` or `--only-indexes` options. If your server has extra cores and disk I/O available, this can be a useful way to speed up `pg_repack`.

`-s tablespace`
`--tablespace=tablespace`

Move the repacked tables to the specified tablespace: essentially an online version of `ALTER TABLE ... SET TABLESPACE`. The tables' indexes are left in the original tablespace unless `--moveidx` is specified too.

`-S`
`--moveidx`

Also move the indexes of the repacked tables to the tablespace specified by the `--tablespace` option.

`-i index`
`--index=index`

Repack the specified index(es) only. Multiple indexes may be repacked by writing multiple `-i` switches. May be used in conjunction with `--tablespace` to move the index(es) to a different tablespace.

`-x`
`--only-indexes`

Repack only the indexes of the specified table(s), which must be specified with the `--table` option.

`-T secs`
`--wait-timeout=secs`

`pg_repack` needs to take an exclusive lock at the end of the reorganization. This setting controls how many seconds `pg_repack` will wait to acquire this lock. If the lock cannot be taken after this duration,

`pg_repack` will forcibly cancel the conflicting queries. If you are using Postgres Pro or PostgreSQL version 8.4 or newer, `pg_repack` will fall back to using `pg_terminate_backend()` to disconnect any remaining backends after this timeout has passed twice. The default is 60 seconds.

`-Z`
`--no-analyze`

Disable `ANALYZE` after a full-table reorganization. If not specified, `ANALYZE` is executed after the reorganization.

Connection Options

`[-d] dbname`
`[--dbname=] dbname`

Specifies the name of the database to be reorganized. If this is not specified and `-a` (or `--all`) is not used, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used.

`-h host`
`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`
`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

`-U username`
`--username=username`

User name to connect as.

`-w`
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`
`--password`

Force `pg_repack` to prompt for a password before connecting to a database.

This option is never essential, since `pg_repack` will automatically prompt for a password if the server demands password authentication. However, `pg_repack` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

Generic Options

`-e`
`--echo`

Echo the commands that `pg_repack` generates and sends to the server.

`-E level`
`--elevel=level`

Choose the output message level from `DEBUG`, `INFO`, `NOTICE`, `WARNING`, `ERROR`, `LOG`, `FATAL`, and `PANIC`. The default is `INFO`.

`--help`

Show help about `pg_repack` command line arguments, and exit.

`-V`

`--version`

Print the `pg_repack` version and exit.

Environment

`PGDATABASE`

`PGHOST`

`PGPORT`

`PGUSER`

Default connection parameters

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by `libpq` (see [Section 32.14](#)).

Examples

Perform an online `CLUSTER` of all the clustered tables in the database `test`, and perform an online `VACUUM FULL` of all the non-clustered tables:

```
$ pg_repack test
```

Perform an online `VACUUM FULL` on the tables `foo` and `bar` in the database `test` (an eventual cluster index is ignored):

```
$ pg_repack --no-order --table foo --table bar test
```

Move all indexes of table `foo` to tablespace `tbs`:

```
$ pg_repack -d test --table foo --only-indexes --tablespace tbs
```

Move the specified index to tablespace `tbs`:

```
$ pg_repack -d test --index idx --tablespace tbs
```

Diagnostics

Error messages are reported when `pg_repack` fails. The following list shows the cause of errors.

You need to cleanup by hand after fatal errors. To cleanup, just remove `pg_repack` from the database and install it again.

For Postgres Pro or PostgreSQL 9.1 and newer execute:

```
DROP EXTENSION pg_repack CASCADE
```

in the database where the error occurred, followed by

```
CREATE EXTENSION pg_repack
```

For previous versions load the script `$$SHAREDIR/contrib/uninstall_pg_repack.sql` into the database where the error occurred and then load `$$SHAREDIR/contrib/pg_repack.sql` again.

```
INFO: database "db" skipped:
```

```
pg_repack VER is not installed in the database:
```

```
pg_repack is not installed in the database when the --all option is specified.
```

Create the `pg_repack` extension in the database.

```
ERROR: pg_repack VER is not installed in the database:
pg_repack is not installed in the database specified by --dbname
```

Create the `pg_repack` extension in the database.

```
ERROR: program 'pg_repack V1' does not match database library 'pg_repack V2':
There is a mismatch between the pg_repack binary and the database library
(.so or .dll).
```

The mismatch could be due to the wrong binary in the `PATH` or the wrong database being addressed. Check the program directory and the database; if they are what expected you may need to repeat `pg_repack` installation.

```
ERROR: extension 'pg_repack V1' required, found extension 'pg_repack V2':
The SQL extension found in the database does not match the version required by the
pg_repack program.
```

You should drop the extension from the database and reload it as described in [the section called “Installation”](#).

```
ERROR: relation "table" must have a primary key or not-null unique keys:
The target table doesn't have a PRIMARY KEY or any UNIQUE constraints defined.
```

Define a `PRIMARY KEY` or a `UNIQUE` constraint on the table.

```
ERROR: query failed: ERROR: column "col" does not exist:
The target table doesn't have columns specified by --order-by option.
```

Specify existing columns.

```
WARNING: the table "tbl" already has a trigger called z_repack_trigger:
The trigger was probably installed during a previous attempt
to run pg_repack on the table which was interrupted
and for some reason failed to clean up the temporary objects.
```

You can remove all the temporary objects by dropping and re-creating the extension: see [the section called “Installation”](#) for the details.

```
WARNING: trigger "trg" conflicting on table "tbl":
The target table has a trigger whose name follows z_repack_trigger
in alphabetical order.
```

The `z_repack_trigger` should be the last `BEFORE` trigger to fire. Please rename your trigger so that it sorts alphabetically before `pg_repack` one; you can use:

```
ALTER TRIGGER zzz_my_trigger
ON sometable RENAME TO yyy_my_trigger;
```

ERROR: Another `pg_repack` command may be running on the table. Please try again later.

There is a chance of deadlock when two concurrent `pg_repack` commands are run on the same table. So, try to run the command after some time.

WARNING: Cannot create index "schema"."index_xxxxx", already exists
DETAIL: An invalid index may have been left behind by a previous `pg_repack` on the table which was interrupted. Please use `DROP INDEX "schema"."index_xxxxx"` to remove this index and try again.

A temporary index apparently created by `pg_repack` has been left behind, and we do not want to risk dropping this index ourselves. If the index was in fact created by an old `pg_repack` job which didn't get cleaned up, you should just use `DROP INDEX` and try the `repack` command again.

Restrictions

`pg_repack` comes with the following restrictions.

Temporary tables

`pg_repack` cannot reorganize temporary tables.

GiST indexes

`pg_repack` cannot reorganize tables using GiST indexes.

DDL commands

You will not be able to perform DDL commands of the target table(s) *except* `VACUUM` or `ANALYZE` while `pg_repack` is working. `pg_repack` will hold an `ACCESS SHARE` lock on the target table during a full-table repack, to enforce this restriction.

If you are using version 1.1.8 or earlier, you must not attempt to perform any DDL commands on the target table(s) while `pg_repack` is running. In many cases `pg_repack` would fail and rollback correctly, but there were some cases in these earlier versions which could result in data corruption.

[clusterdb](#), [vacuumdb](#)

vacuumlo

vacuumlo — remove orphaned large objects from a Postgres Pro database

Synopsis

```
vacuumlo [option...] dbname...
```

Description

vacuumlo is a simple utility program that will remove any “orphaned” large objects from a Postgres Pro database. An orphaned large object (LO) is considered to be any LO whose OID does not appear in any `oid` or `lo` data column of the database.

If you use this, you may also be interested in the `lo_manage` trigger in the [lo](#) module. `lo_manage` is useful to try to avoid creating orphaned LOs in the first place.

All databases named on the command line are processed.

Options

vacuumlo accepts the following command-line arguments:

`-l limit`

Remove no more than *limit* large objects per transaction (default 1000). Since the server acquires a lock per LO removed, removing too many LOs in one transaction risks exceeding [max_locks_per_transaction](#). Set the limit to zero if you want all removals done in a single transaction.

`-n`

Don't remove anything, just show what would be done.

`-v`

Write a lot of progress messages.

`-V`

`--version`

Print the vacuumlo version and exit.

`-?`

`--help`

Show help about vacuumlo command line arguments, and exit.

vacuumlo also accepts the following command-line arguments for connection parameters:

`-h hostname`

Database server's host.

`-p port`

Database server's port.

`-U username`

User name to connect as.

`-w`

`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W

Force vacuumlo to prompt for a password before connecting to a database.

This option is never essential, since vacuumlo will automatically prompt for a password if the server demands password authentication. However, vacuumlo will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.

Notes

vacuumlo works by the following method: First, vacuumlo builds a temporary table which contains all of the OIDs of the large objects in the selected database. It then scans through all columns in the database that are of type `oid` or `lo`, and removes matching entries from the temporary table. (Note: Only types with these names are considered; in particular, domains over them are not considered.) The remaining entries in the temporary table identify orphaned LOs. These are removed.

Author

Peter Mount <peter@retep.org.uk>

G.2. Server Applications

This section covers Postgres Pro Enterprise server-related applications. They are typically run on the host where the database server resides. See also [Postgres Pro Server Applications](#) for information about server applications that are part of the core Postgres Pro Enterprise distribution.

mamonsu

mamonsu — a monitoring agent for collecting Postgres Pro and system metrics.

Synopsis

```
mamonsu agent [agent_action]  
  
mamonsu bootstrap -M mamonsu_user [connection_options]  
  
mamonsu export {template | config} filename [export_options]  
  
mamonsu report [report_options]  
  
mamonsu tune [tuning_options]  
  
mamonsu upload [upload_options]  
  
mamonsu zabbix {template | host | hostgroup} server_action  
  
mamonsu zabbix item {error | lastvalue | lastclock} host_id  
  
mamonsu --version  
  
mamonsu --help
```

Description

mamonsu is a monitoring agent for collecting Postgres Pro and system metrics that can be visualized on the Zabbix server. Unlike the native Zabbix Agent configured to collect Postgres Pro metrics, mamonsu uses a single database connection, which allows to minimize performance impact on the monitored system.

The mamonsu agent includes the following components:

- A supervisor process that monitors database and system activity.
- Plugins that specify which Postgres Pro and system metrics to collect.
- Customizable configuration and template files that define which plugins to use and how to visualize the collected data.

mamonsu is an active agent, which means that it sends the data to the Zabbix server once it is collected. Pre-configured to monitor multiple Postgres Pro and system metrics out of the box, mamonsu can be extended with your own custom plugins to track other metrics critical for your system.

mamonsu also provides the command-line interface for updating some Zabbix server settings, as well as getting an overview of the monitored system configuration and tuning Postgres Pro and system settings on the fly. You can find the list of all mamonsu commands in [the section called “Command-Line Reference”](#).

Installation and Setup

To use mamonsu, you must create a Zabbix account and set up a Zabbix server as explained in [Zabbix documentation](#). Naturally, you must also have a Postgres Pro instance up and running if you are going to monitor Postgres Pro metrics. If you are configuring your Postgres Pro cluster from scratch, see [Chapter 17](#) and [Section 18.2](#) for Postgres Pro installation and setup instructions, respectively.

Note

While mamonsu can collect Postgres Pro metrics from a remote cluster, system metrics are only collected locally. If you choose to collect Postgres Pro metrics remotely, make sure to disable

collection of system metrics to avoid confusion, as they will be displayed under the same host in Zabbix.

A pre-built mamonsu package is provided together with Postgres Pro Enterprise, but has a separate installer. Once you have installed mamonsu, complete the following steps to set up metrics collection:

1. Optionally, bootstrap mamonsu

If you omit this step, metrics can only be collected on behalf of a superuser, which is not recommended.

1. Create a non-privileged database user for mamonsu. For example:

```
CREATE USER mamonsu_user WITH PASSWORD 'mamonsu_password';
```

2. Create a database that will be used for connection to Postgres Pro. For example:

```
CREATE DATABASE mamonsu_database OWNER mamonsu_user;
```

3. Run the following command to bootstrap mamonsu:

```
mamonsu bootstrap -M mamonsu_user [connection_options]
```

where *connection_options* can be `--host`, `--port`, `--dbname`, `--username`, and `--password`. These options provide connection parameters for the Postgres Pro cluster you are going to monitor. The `--dbname` option should specify the `mamonsu_database` created for monitoring purposes. Note that the `--username` option must specify a superuser that can access the cluster.

If you omit connection options, mamonsu checks the corresponding environment variables for these settings. If they are missing, mamonsu tries to connect to the `postgres` database of the server instance running locally on port 5432, on behalf of the `postgres` user. Make sure to provide the actual connection parameters if your Postgres Pro cluster is located elsewhere.

Note that `-M` option must be present and should specify the name of a non-privileged user.

As the result of this operation, monitoring functions are created in the `mamonsu_database`, and the right to execute them is granted to the `mamonsu_user`. Thus, a superuser connection is no longer required. mamonsu also creates several tables with the `mamonsu` prefix in the specified database. Do not delete these tables as they are required for mamonsu to work.

2. Configure mamonsu

Edit the `agent.conf` configuration file, which is located in the `/etc/mamonsu/` directory by default.

- Configure Zabbix-related settings. The `address` field must point to the running Zabbix server, while the `client` field must provide the name of the Zabbix host. You can find the list of hosts available for your account in the Zabbix web interface under **Configuration > Hosts**.

```
[zabbix]
; enabled by default
enabled = True
client = zabbix_host_name
address = zabbix_server
```

- By default, mamonsu will collect both Postgres Pro and system metrics. If required, you can disable metrics collection of either type by setting the `enabled` parameter to `False` in the `[postgres]` or `[system]` section of the `agent.conf` file, respectively.

```
[system]
; enabled by default
enabled = True
```

Note

While mamonsu can collect Postgres Pro metrics from a remote cluster, system metrics are only collected locally. If you choose to collect Postgres Pro metrics remotely, make sure to disable collection of system metrics to avoid confusion, as they will be displayed under the same host in Zabbix.

- If you are going to collect Postgres Pro metrics, specify connection parameters for the Postgres Pro cluster you are going to monitor. In the `user`, `password`, and `database` fields, you must specify the `mamonsu_user`, `mamonsu_password`, and the `mamonsu_database` used for bootstrap, respectively. If you skipped the bootstrap, specify a superuser credentials and the database to connect to.

```
[postgres]
; enabled by default
enabled = True
user = mamonsu_user
database = mamonsu_database
password = mamonsu_password
port = 5432
```

These are the main mamonsu settings to get started. You can also fine-tune other mamonsu settings as explained in [the section called “Configuration Parameters”](#).

3. Configure how to display metrics on the Zabbix server

1. Generate a template that defines how to visualize the collected metrics on the Zabbix server:

```
mamonsu export template template.xml
```

mamonsu generates the `template.xml` file in your current directory. By default, the name of the template that will be displayed in the Zabbix account is `PostgresPro-OS`, where `OS` is the name of your operating system. To get a template with a different display name, you can run the above command with the `--template-name` option.

2. Optionally, specify your Zabbix account settings in the following environment variables on your monitoring system:
 - Set the `ZABBIX_USER` and `ZABBIX_PASSWD` variables to the login and password of your Zabbix account, respectively.
 - Set the `ZABBIX_URL` to `http://zabbix/`

If you skip this step, you will have to add the following options to all `mamonsu zabbix` commands that you run:

```
--url=http://zabbix/ --user=zabbix_login --password=zabbix_password
```

3. Upload the `template.xml` to the Zabbix server.

```
mamonsu zabbix template export template.xml
```

Alternatively, you can upload the template through the Zabbix web interface: log in to your Zabbix account and select **Templates > Import**.

4. Link the generated template to the host to be monitored.

In the Zabbix web interface, select your host, go to **Templates > Add**, select your template, and click **Update**.

Tip

If you would like to link a template with a new Zabbix host, you can do it from the command line using `mamonsu zabbix` commands. See [the section called “Managing Zabbix Server Settings from the Command Line”](#) for details.

When the setup is complete, start `mamonsu`. For example, on Linux systems, you can start `mamonsu` as a service with the following command:

```
service mamonsu start
```

`mamonsu` picks up all the parameters from the `mamonsu` configuration file and starts monitoring your system.

Command-Line Reference

agent

Syntax:

```
mamonsu agent { metric-list | metric-get metric_name | version }
```

Provides information on the collected metrics from the command line. You can specify one of the following parameters:

```
metric-list
```

Show the list of metrics that `mamonsu` is collecting. The output of this command provides the item key of each metric, its latest value, and the time when this value was received.

```
metric-get metric_name
```

Check the latest value for the specified metric. You can get the list of available metrics using the `metric-list` option.

```
version
```

Display `mamonsu` version.

bootstrap

Syntax:

```
mamonsu bootstrap -M mamonsu_user [connection_options]
```

Bootstrap `mamonsu`. The mandatory `-M` option must specify a non-privileged user that will own all `mamonsu` processes.

connection_options can be `--host`, `--port`, `--dbname`, `--username`, and `--password`. These options provide connection parameters for the Postgres Pro cluster you are going to monitor. Note that the `--username` option must specify a superuser that can access the cluster.

If you omit connection options, `mamonsu` checks the corresponding environment variables for these settings. If they are missing, `mamonsu` tries to connect to the `postgres` database of the server instance running locally on port 5432, on behalf of the `postgres` user. Make sure to provide the actual connection parameters if your Postgres Pro cluster is located elsewhere.

export

Syntax:

```
mamonsu export config filename.conf [--add-plugins=plugin_directory]
```

```
mamonsu export template filename.xml [--add-plugins=plugin_directory]  
                                         [--template-name=template_name]  
                                         [--application=application_name]  
                                         [--old-zabbix]
```

Generate a template or configuration file for metrics collection. The optional parameters to customize metrics collection are as follows:

`--add-plugins=plugin_directory`

Collect metrics that are defined in custom plugins located in the specified *plugin_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

`--template-name=template_name`

Specify the name of the template that will be displayed on the Zabbix server.

Default: `PostgresPro-OS`, where *OS* is the name of your operating system

`--application=application_name`

Specify an identifier under which the collected metrics will be displayed on the Zabbix server.

Default: `App-PostgresPro-OS`, where *OS* is the name of your operating system

`--old-zabbix`

Export a template for Zabbix server version 4.2 or lower. By default, the template is generated in a format compatible with Zabbix 4.4 or higher.

export zabbix-parameters

Syntax:

```
mamonsu export zabbix-parameters filename.conf [--add-plugins=plugin_directory]  
                                         [--plugin-type={pg | sys | all}]  
                                         [--pg-version=version]  
                                         [--config=config_file]
```

Export metrics configuration for use with the native [Zabbix agent](#). The optional parameters to customize metrics collection are as follows:

`--add-plugins=plugin_directory`

Collect metrics that are defined in custom plugins located in the specified *plugin_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

`--plugin-type={pg | sys | all}`

Specify the type of metrics to collect:

- `pg` for Postgres Pro metrics.
- `sys` for system metrics.
- `all` for both Postgres Pro and system metrics.

Default: `all`

`--pg-version=version`

Specify the major version of the server for which to configure metrics collection. `mamonsu` can collect metrics for all supported Postgres Pro versions, as well as PostgreSQL versions starting from 9.5.

Default: `10`

`--config=config_file`

Specify the `agent.conf` file to be used as the source for metrics definitions.

Default: `/etc/mamonsu/agent.conf`

export zabbix-template

Syntax:

```
mamonsu export zabbix-template filename.conf [--add-plugins=plugin_directory]
                                         [--plugin-type={pg | sys | all}]
                                         [--template-name=template_name]
                                         [--application=application_name]
                                         [--config=config_file]
                                         [--old-zabbix]
```

Export a template for use with the native Zabbix agent. The optional parameters to customize metrics collection are as follows:

`--add-plugins=plugin_directory`

Collect metrics that are defined in custom plugins located in the specified `plugin_directory`. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

`--plugin-type={pg | sys | all}`

Specify the type of metrics to collect:

- `pg` configures Postgres Pro metrics.
- `sys` configures system metrics.
- `all` configures both Postgres Pro and system metrics.

Default: `all`

`--template-name=template_name`

Specify the name of the template that will be displayed on the Zabbix server.

Default: `PostgresPro-OS`, where `OS` is the name of your operating system

`--application=application_name`

Specify an identifier under which the collected metrics will be displayed on the Zabbix server.

Default: `App-PostgresPro-OS`, where `OS` is the name of your operating system

`--config=config_file`

Specify the `agent.conf` file to be used as the source for metrics definitions.

Default: `/etc/mamonsu/agent.conf`

`--old-zabbix`

Export a template for Zabbix server version 4.2 or lower. By default, the template is generated in a format compatible with Zabbix 4.4 or higher.

report

Syntax:

```
mamonsu report [--run-system=Boolean] [--run-postgres=Boolean]
```

```
[--print-report=Boolean] [--report-path=report_file]  
[--disable-sudo] [connection_options]
```

Display detailed information about the hardware, operating system, memory usage and other parameters of the monitored system, as well as Postgres Pro configuration. The following optional parameters customize the report:

`--run-system=Boolean`

Include system information into the generated report.

Default: `True`

`--run-postgres=Boolean`

Include information on Postgres Pro into the generated report.

Default: `True`

`--print-report=Boolean`

Print the report to stdout.

Default: `True`

`--report-path=report_file`

Save the report into the specified file.

Default: `/tmp/report.txt`

`--disable-sudo`

Do not report data that can only be received with superuser rights. This option is only available for Linux systems.

connection_options

Provide connection parameters for the Postgres Pro cluster you are going to monitor. *connection_options* can be `--host`, `--port`, `--dbname`, `--username`, and `--password`. Note that the `--username` option must specify a superuser that can access the cluster.

If you omit connection options, mamonsu checks the corresponding environment variables for these settings. If they are missing, mamonsu tries to connect to the `postgres` database of the server instance running locally on port 5432, on behalf of the `postgres` user. Make sure to provide the actual connection parameters if your Postgres Pro cluster is located elsewhere.

tune

Syntax:

```
mamonsu tune [--dry-run] [--disable-sudo] [--log-level {INFO|DEBUG|WARN}]  
             [--dont-tune-pgbadger] [--dont-reload-postgresql]
```

Optimize Postgres Pro and system configuration based on the collected statistics. You can use the following options:

`--dry-run`

Display the settings to be tuned without changing the actual system and Postgres Pro configuration.

`--disable-sudo`

Do not tune the settings that can only be changed by a superuser. This option is only available for Linux systems.

`--dont-tune-pgbadger`

Do not tune pgbadger parameters.

`--log-level { INFO | DEBUG | WARN }`

Change the logging level.

Default: INFO

`--dont-reload-postgresql`

Forbid mamonsu to run the `pg_reload_conf()` function. If you specify this option, the modified settings that require reloading Postgres Pro configuration do not take effect immediately.

upload

Syntax:

```
mamonsu upload [--zabbix-file=metrics_file]
               [--zabbix-address=zabbix_address] [--zabbix-port=port_number]
               [--zabbix-client=zabbix_host_name] [--zabbix-log-level={ INFO|DEBUG|
WARN}]
```

Upload metrics data previously saved into a file onto a Zabbix server for visualization. For details on how to save metrics into a file, see [the section called “Logging Parameters”](#).

This command can take the following options:

`--zabbix-address=zabbix_address`

The address of the Zabbix server.

Default: localhost

`--zabbix-port=port_number`

The port of the Zabbix server.

Default: 10051

`--zabbix-file=metrics_file`

A text file that stores the collected metric data to be visualized, such as `localhost.log`.

`--zabbix-client=zabbix_host_name`

The name of the Zabbix host.

Default: localhost

`--zabbix-log-level={ INFO|DEBUG|WARN }`

Change the logging level.

Default: INFO

zabbix item

Syntax:

```
mamonsu zabbix item {error | lastvalue | lastclock } host_name
```

View the specified property of the latest metrics data received by Zabbix for the specified host.

zabbix host

Syntax:

```
mamonsu zabbix host list
mamonsu zabbix host show host_name
mamonsu zabbix host id host_name
mamonsu zabbix host delete host_id
mamonsu zabbix host create host_name hostgroup_id template_id mamonsu_address
mamonsu zabbix host info {templates | hostgroups | graphs | items} host_id
```

Manage Zabbix hosts using one of the actions described in [the section called “Zabbix Server Actions”](#).

zabbix hostgroup

Syntax:

```
mamonsu zabbix hostgroup list
mamonsu zabbix hostgroup show hostgroup_name
mamonsu zabbix hostgroup id hostgroup_name
mamonsu zabbix hostgroup delete hostgroup_id
mamonsu zabbix hostgroup create hostgroup_name
```

Manage Zabbix host groups using one of the actions described in [the section called “Zabbix Server Actions”](#).

zabbix template

Syntax:

```
mamonsu zabbix template list
mamonsu zabbix template show template_name
mamonsu zabbix template id template_name
mamonsu zabbix template delete template_id
mamonsu zabbix template export file
```

Manage Zabbix templates using one of the actions described in [the section called “Zabbix Server Actions”](#).

--version

Syntax:

```
mamonsu --version
```

Display `mamonsu version`.

--help

Syntax:

```
mamonsu --help
```

Display `mamonsu` command-line help.

Zabbix Server Actions

Using `mamonsu`, you can control some of the Zabbix server functionality from the command line. Specifically, you can create or delete Zabbix hosts and host groups, as well as generate, import, and delete Zabbix templates using one of the following commands. The *object_name* to use must correspond to the type of the Zabbix object specified in the command: `template`, `host`, or `hostgroup`.

```
list
```

Display the list of available templates, hosts, or host groups.

```
show object_name
```

Display the details about the specified template, host, or host group.

`id object_name`

Show the ID of the specified object, which is assigned automatically by the Zabbix server.

`delete object_id`

Delete the object with the specified ID.

`create hostgroup_name`

`create host_name hostgroup_id template_id mamonsu_address`

Create a new host or a host group.

`export template_name`

Generate a Zabbix template.

`info {templates | hostgroups | graphs | items} host_id`

Display detailed information about the templates, host groups, graphs, and metrics available on the host with the specified ID.

Configuration Parameters

The `agent.conf` configuration file is located in the `/etc/mamonsu` directory by default. It provides several groups of parameters that control which metrics to collect and how to log the collected data:

- [connection parameters](#)
- [logging parameters](#)
- [plugin parameters](#)

All parameters must be specified in the `parameter = value` format.

Connection Parameters

[postgres]

The `[postgres]` section controls Postgres Pro metrics collection and can contain the following parameters:

`enabled`

Enables/disables Postgres Pro metrics collection if set to `True` or `False`, respectively.

Default: `True`

`user`

The user on behalf of which the cluster will be monitored. It must be the same user that you specified in the `-M` option of the `bootstrap` command, or a superuser if you skipped the bootstrap.

Default: `postgres`

`password`

The password for the specified user.

`database`

The database to connect to for metrics collection.

Default: `postgres`

`host`

The server address to connect to.

Default: localhost

port

The port to connect to.

Default: 5432

application_name

Application name that identifies mamonsu connected to the Postgres Pro cluster.

Default: mamonsu

query_timeout

[statement_timeout](#) for the mamonsu session, in seconds. If a Postgres Pro metric query does not complete within this time interval, it gets terminated.

Default: 10

[system]

The [system] section controls system metrics collection and can contain the following parameters:

enabled

Enables/disables system metrics collection if set to `True` or `False`, respectively.

Default: `True`

[zabbix]

The [zabbix] section provides connection settings for the Zabbix server and can contain the following parameters:

enabled

Enables/disables sending the collected metric data to the Zabbix server if set to `True` or `False`, respectively.

Default: `True`

client

The name of the Zabbix host.

address

The address of the Zabbix server.

Default: 127.0.0.1

port

The port of the Zabbix server.

Default: 10051

[agent]

The [agent] section specifies the location of mamonsu and whether it is allowed to access metrics from the command line:

enabled

Enables/disables metrics collection from the command line using the `agent` command.

Default: `True`

host

The address of the system on which mamonsu is running.

Default: 127.0.0.1

port

The port on which mamonsu is running.

Default: 10052

[sender]

The `[sender]` section controls the queue size of the data to be sent to the Zabbix server:

queue

The maximum number of collected metric values that can be accumulated locally before mamonsu sends them to the Zabbix server. Once the accumulated data is sent, the queue is cleared.

Default: 2048

Logging Parameters

[metric_log]

The `[metric_log]` section enables storing the collected metric data in text files locally. This section can contain the following parameters:

enabled

Enables/disables storing the collected metric data in a text file. If this option is set to `True`, mamonsu creates the `localhost.log` file for storing metric values.

Default: `False`

directory

Specifies the directory where log files with metric data will be stored.

Default: `/var/log/mamonsu`

max_size_mb

The maximum size of a log file, in MB. When the specified size is reached, it is renamed to `localhost.log.archive`, and an empty `localhost.log` file is created.

Default: 1024

[log]

The `[log]` section specifies logging settings for mamonsu and can contain the following parameters:

file

Specifies the log filename, which can be preceded by the full path.

level

Specifies the debug level. This option can take `DEBUG`, `ERROR`, or `INFO` values.

Default: `INFO`

format

The format of the logged data.

Default: `[(levelname)s] %(asctime)s - %(name)s - %(message)s`

where `levelname` is the debug level, `asctime` returns the current time, `name` specifies the plugin that emitted this log entry or `root` otherwise, and `message` provides the actual log message.

Plugin Parameters

[plugins]

The `[plugins]` section specifies custom plugins to be added for metrics collection and can contain the following parameters:

`enabled`

Enables/disables using custom plugins for metrics collection if set to `True` or `False`, respectively.

Default: `False`

`directory`

Specifies the directory that contains custom plugins for metrics collection. Setting this parameter to `None` forbids using custom plugins.

Default: `/etc/mamonsu/plugins`

If you need to configure any of the plugins you add to `mamonsu` after installation, you have to add this plugin section to the `agent.conf` file.

The syntax of this section should follow the syntax used with the examples shown below in [the section called “Individual Plugin Sections”](#).

Individual Plugin Sections

All built-in plugins are installed along with `mamonsu`. To configure a built-in plugin you should find a corresponding section below the Individual Plugin Sections heading and edit its parameter values.

To disable any plugin you should set the `enabled` parameter to `False` and to enable it — set it to `True`. These values are case sensitive.

The example below shows individual plugin sections corresponding to the `preparedtransaction` and the `pgprobackup` built-in plugins:

```
[preparedtransaction]
max_prepared_transaction_time = 60
interval = 60

[pgprobackup]
enabled = false
interval = 300
backup_dirs = /backup_dir1,/backup_dir2
pg_probackup_path = /usr/bin/pg_probackup-11
```

[preparedtransaction]

This plugin gets age in seconds of the oldest prepared transaction and number of all transactions prepared for a two-phase commit. For additional information refer to [PREPARE TRANSACTION](#) and [Section 50.69](#).

The `max_prepared_transaction_time` parameter specifies the threshold in seconds for the age of the prepared transaction.

The `interval` parameter allows you to change the metrics collection interval.

The plugin collects two metrics: `pgsql.prepared.count` (number of prepared transactions) and `pgsql.prepared.oldest` (oldest prepared transaction age in seconds).

If `pgsql.prepared.oldest` value exceeds the threshold specified by the `max_prepared_transaction_time` parameter, a trigger with the following message is fired: "PostgreSQL prepared transaction is too old on {host}".

[pgprobackup]

This plugin uses `pg_probackup` to track its backups' state and gets size of backup directories which store all backup files.

Please note that this plugin counts the total size of all files in the target directory. Make sure that extraneous files are not stored in this directory.

The `backup_dirs` parameter specifies a comma-separated list of paths to directories for which metrics should be collected.

The `pg_probackup_path` parameter specifies the path to `pg_probackup`.

The `interval` parameter allows you to change the metrics collection interval.

By default this plugin is disabled. To enable it set the `enabled` parameter to `True`.

This plugin collects two metrics: `pg_probackup.dir.size[#backup_directory]` (the size of the target directory) and `pg_probackup.dir.error[#backup_directory]` (backup errors) for each specified `backup_directory`.

If any generated backup has bad status, like `ERROR`, `CORRUPT`, `ORPHAN`, a trigger is fired.

Usage

Collecting and Viewing Metrics Data

Once started, `mamonsu` begins collecting system and Postgres Pro metrics. The `agent` command enables you to get an overview of the collected metrics from the command line in real time.

To view the list of available metrics, use the `agent metric-list` command:

```
mamonsu agent metric-list
```

The output of this command provides the item key of each metric, its latest value, and the time when this value was received. For example:

```
system.memory[active]          7921004544    1564570818
system.memory[swap_cache]      868352      1564570818
pgsql.connections[idle]        6.0         1564570818
pgsql.archive_command[failed_trying_to_archive] 0         1564570818
```

To view the current value for a specific metric, you can use the `agent metric-get` command:

```
mamonsu agent metric-get metric_name
```

where `metric_name` is the item key of the metric to monitor, as returned by the `metric-list` command. For example, `pgsql.connections[idle]`.

You can view graphs for the collected metrics in the Zabbix web interface under the **Graphs** menu. For details on working with Zabbix, see its official documentation at <https://www.zabbix.com/documentation/current/>.

If you have chosen to save all the collected metrics data into a file, as explained in [the section called "Logging Parameters"](#), you can later upload these metrics onto a Zabbix server for visualization using the `upload` command.

Adding Custom Plugins

You can extend `mamonsu` with your own custom plugins, as follows:

1. Save all custom plugins in a single directory, such as `/etc/mamonsu/plugins`.
2. Make sure this directory is specified in your configuration file under the `[plugins]` section:

```
[plugins]
directory = /etc/mamonsu/plugins
```

3. Generate a new Zabbix template to include custom plugins:

```
mamonsu export template template.xml --add-plugins=/etc/mamonsu/plugins
```

4. Upload the generated `template.xml` to the Zabbix server as explained in [the section called “Installation and Setup”](#).

Tuning Postgres Pro and System Configuration

Based on the collected metrics data, mamonsu can tune your Postgres Pro and system configuration for optimal performance.

You can get detailed information about the hardware, operating system, memory usage and other parameters of the monitored system, as well as Postgres Pro configuration, as follows:

```
mamonsu report
```

To view the suggested optimizations without applying them, run the `tune` command with the `--dry-run` option:

```
mamonsu tune --dry-run
```

To apply all the suggested changes, run the `tune` command without any parameters:

```
mamonsu tune
```

You can exclude some settings from the report or disable some of the optimizations by passing optional parameters. See [the section called “Command-Line Reference”](#) for the full list of parameters available for `report` and `tune` commands.

Managing Zabbix Server Settings from the Command Line

mamonsu enables you to work with the Zabbix server from the command line. You can upload template files to Zabbix, create and delete Zabbix hosts and host groups, link templates with hosts and check the latest metric values.

To set up your Zabbix host from scratch, you can follow these steps:

1. Optionally, specify your Zabbix account settings in the following environment variables on your monitoring system:

- Set the `ZABBIX_USER` and `ZABBIX_PASSWD` variables to the login and password of your Zabbix account, respectively.
- Set the `ZABBIX_URL` to `http://zabbix/`

If you skip this step, you will have to add the following options to all `mamonsu zabbix` commands that you run:

```
--url=http://zabbix/ --user=zabbix_login --password=zabbix_password
```

2. Generate a new template file and upload it to the Zabbix server:

```
mamonsu export template template.xml
mamonsu zabbix template export template.xml
```

3. Create a new host group:

```
mamonsu zabbix hostgroup create hostgroup_name
```

4. Check the IDs for this host group and the uploaded template, which are assigned automatically by the Zabbix server:

```
mamonsu zabbix hostgroup id hostgroup_name
mamonsu zabbix template id template_name
```

5. Create a host associated with this group and link it with the uploaded template using a single command:

```
mamonsu zabbix host create host_name hostgroup_id template_id mamonsu_address
```

where *host_name* is the name of the host, *hostgroup_id* and *template_id* are the unique IDs returned in the previous step, and *mamonsu_address* is the IP address of the system on which mamonsu runs.

Once your Zabbix host is configured, complete the setup of your monitoring system as explained in [the section called “Installation and Setup”](#).

Exporting Metrics for Native Zabbix Agent

Using mamonsu, you can convert system and Postgres Pro metrics definitions to the format supported by the native [Zabbix agent](#).

This feature currently has the following limitations:

- You cannot export metrics if you run mamonsu on Windows systems.
- Metrics definitions for `pg_wait_sampling` and CFS features available in Postgres Pro Enterprise are not converted.

To collect metrics provided by mamonsu using the native Zabbix agent, do the following:

1. Generate a configuration file that is compatible with the native Zabbix agent and place it under `/etc/zabbix/zabbix_agent.d/`. You can prepend the filename with the required path:

```
mamonsu export zabbix-parameters /etc/zabbix/zabbix_agent.d/zabbix_agent.conf
```

For all possible options of the `export zabbix-parameters` command, see [the section called “Command-Line Reference”](#).

2. Generate a template for the native Zabbix agent:

```
mamonsu export zabbix-template template.xml
```

For all possible options of the `export zabbix-template` command, see [the section called “Command-Line Reference”](#).

3. Upload the generated template to the Zabbix server, as explained in [the section called “Installation and Setup”](#).
4. If you are going to collect Postgres Pro metrics, change the following macros in the template after the upload:
 - For `{$PG_CONNINFO}`, provide connection parameters for the Postgres Pro server to be monitored.
 - For `{$PG_PATH}`, specify psql installation directory.

pgbouncer

pgbouncer — a Postgres Pro connection pooler

Synopsis

On Linux systems:

```
pgbouncer [ -d ] [ -R ] [ -v ] [ -u user ] pgbouncer.ini
```

```
pgbouncer -V | -h
```

On Windows systems:

```
pgbouncer [ -v ] [ -u user ] pgbouncer.ini
```

```
pgbouncer -V | -h
```

To use pgbouncer as a Windows service:

```
pgbouncer.exe --regservice pgbouncer.ini
```

```
pgbouncer.exe --unregservice pgbouncer.ini
```

Description

pgbouncer is a Postgres Pro connection pooler. Any target application can be connected to pgbouncer as if it were a Postgres Pro server, and pgbouncer will create a connection to the actual server, or it will reuse one of its existing connections.

The aim of pgbouncer is to lower the performance impact of opening new connections to Postgres Pro.

In order not to compromise transaction semantics for connection pooling, pgbouncer supports several types of pooling when rotating connections:

Session pooling

Most polite method. When a client connects, a server connection will be assigned to it for the whole duration the client stays connected. When the client disconnects, the server connection will be put back into the pool. This is the default method.

Transaction pooling

A server connection is assigned to a client only during a transaction. When pgbouncer notices that transaction is over, the server connection will be put back into the pool.

Statement pooling

Most aggressive method. The server connection will be put back into the pool immediately after a query completes. Multi-statement transactions are disallowed in this mode as they would break.

The administration interface of pgbouncer consists of some new `SHOW` commands available when connected to a special “virtual” database `pgbouncer`.

Quick Start

Basic setup and usage is as follows.

1. Create a `pgbouncer.ini` file. Details in the `pgbouncer(5)` man page. Simple example:

```
[databases]
template1 = host=127.0.0.1 port=5432 dbname=template1
```

```
[pgbouncer]
listen_port = 6543
listen_addr = 127.0.0.1
auth_type = md5
auth_file = userlist.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
```

2. Create a `userlist.txt` file that contains the users allowed in:

```
"someuser" "same_password_as_in_server"
```

3. Launch pgbouncer:

```
$ pgbouncer -d pgbouncer.ini
```

Note

The above command does not work on Windows systems. Instead, pgbouncer must be launched as a service that first needs to be registered, as follows:

```
pgbouncer --regservice
```

4. Have your application (or the `psql` client) connect to pgbouncer instead of directly to the PostgreSQL server:

```
$ psql -p 6543 -U someuser template1
```

5. Manage pgbouncer by connecting to the special administration database pgbouncer and issuing `SHOW HELP`; to begin:

```
$ psql -p 6543 -U someuser pgbouncer
pgbouncer=# SHOW HELP;
NOTICE:  Console usage
DETAIL:
SHOW [HELP|CONFIG|DATABASES|FDS|POOLS|CLIENTS|SERVERS|SOCKETS|LISTS|VERSION|...]
SET key = arg
RELOAD
PAUSE
SUSPEND
RESUME
SHUTDOWN
[...]
```

6. If you made changes to the `pgbouncer.ini` file, you can reload it with:

```
pgbouncer=# RELOAD;
```

Options

`-d`

Run in the background. Without it, the process will run in the foreground.

Note

Does not work on Windows, pgbouncer needs to run as service there.

-R

Do an online restart. That means connecting to the running process, loading the open sockets from it, and then using them. If there is no active process, boot normally.

Note

Works only if OS supports Unix sockets and the `unix_socket_dir` is not disabled in configuration. Does not work on Windows. Does not work with TLS connections, they are dropped.

-u *user*

Switch to the given user on startup.

-v

Increase verbosity. Can be used multiple times.

-q

Be quiet: do not log to `stdout`. This does not affect logging verbosity, only that `stdout` is not to be used. For use in `init.d` scripts.

-V

Show version.

-h

Show short help.

--regservice

Win32: Register to run as Windows service. The `service_name` configuration parameter value is used as the name to register under.

--unregservice

Win32: Unregister Windows service.

Admin Console

The console is available by connecting as normal to the database `pgbouncer`:

```
$ psql -p 6543 pgbouncer
```

Only users listed in the configuration parameters `admin_users` or `stats_users` are allowed to log in to the console. (Except when `auth_mode=any`, then any user is allowed in as a `stats_user`.)

Additionally, the user name `pgbouncer` is allowed to log in without password, if the login comes via the Unix socket and the client has same Unix user uid as the running process.

Show Commands

The `SHOW` commands output information. Each command is described below.

SHOW STATS

Shows statistics. In this and related commands, the total figures are since process start, the averages are updated every `stats_period`.

database

Statistics are presented per database.

`total_xact_count`

Total number of SQL transactions pooled by pgbouncer.

`total_query_count`

Total number of SQL queries pooled by pgbouncer.

`total_received`

Total volume in bytes of network traffic received by pgbouncer.

`total_sent`

Total volume in bytes of network traffic sent by pgbouncer.

`total_xact_time`

Total number of microseconds spent by pgbouncer when connected to Postgres Pro in a transaction, either idle in transaction or executing queries.

`total_query_time`

Total number of microseconds spent by pgbouncer when actively connected to Postgres Pro, executing queries.

`total_wait_time`

Time spent by clients waiting for a server, in microseconds.

`avg_xact_count`

Average transactions per second in last stat period.

`avg_query_count`

Average queries per second in last stat period.

`avg_recv`

Average received (from clients) bytes per second.

`avg_sent`

Average sent (to clients) bytes per second.

`avg_xact_time`

Average transaction duration, in microseconds.

`avg_query_time`

Average query duration, in microseconds.

`avg_wait_time`

Time spent by clients waiting for a server, in microseconds (average per second).

SHOW STATS_TOTALS

Subset of `SHOW STATS` showing the total values (`total_`).

SHOW STATS_AVERAGES

Subset of `SHOW STATS` showing the average values (`avg_`).

SHOW TOTALS

Like `SHOW STATS` but aggregated across all databases.

SHOW SERVERS

type

S, for server.

user

User name pgbouncer uses to connect to server.

database

Database name.

state

State of the pgbouncer server connection, one of active, used or idle.

addr

IP address of Postgres Pro server.

port

Port of Postgres Pro server.

local_addr

Connection start address on local machine.

local_port

Connection start port on local machine.

connect_time

When the connection was made.

request_time

When last request was issued.

wait

Current waiting time in seconds.

wait_us

Microsecond part of the current waiting time.

close_needed

1 if the connection will be closed as soon as possible, because a configuration file reload or DNS update changed the connection information or RECONNECT was issued.

ptr

Address of internal object for this connection. Used as unique ID.

link

Address of client connection the server is paired with.

remote_pid

PID of backend server process. In case connection is made over Unix socket and OS supports getting process ID info, its OS PID. Otherwise it's extracted from cancel packet the server sent, which should

be the PID in case the server is Postgres Pro, but it's a random number in case the server is another pgbouncer.

tls

A string with TLS connection information, or empty if not using TLS.

SHOW CLIENTS

type

C, for client.

user

Client connected user.

database

Database name.

state

State of the client connection, one of active, used, waiting or idle.

addr

IP address of client.

port

Port client is connected to.

local_addr

Connection end address on local machine.

local_port

Connection end port on local machine.

connect_time

Timestamp of connect time.

request_time

Timestamp of latest client request.

wait

Current waiting time in seconds.

wait_us

Microsecond part of the current waiting time.

close_needed

Not used for clients.

ptr

Address of internal object for this connection. Used as unique ID.

link

Address of server connection the client is paired with.

`remote_pid`

Process ID, in case client connects over Unix socket and OS supports getting it.

`tls`

A string with TLS connection information, or empty if not using TLS.

SHOW POOLS

A new pool entry is made for each couple of (database, user).

`database`

Database name.

`user`

User name.

`cl_active`

Client connections that are linked to server connection and can process queries.

`cl_waiting`

Client connections have sent queries but have not yet got a server connection.

`sv_active`

Server connections that linked to a client.

`sv_idle`

Server connections that are unused and immediately usable for client queries.

`sv_used`

Server connections that have been idle for more than `server_check_delay`, so they need `server_check_query` to run on them before they can be used again.

`sv_tested`

Server connections that are currently running either `server_reset_query` or `server_check_query`.

`sv_login`

Server connections currently in the process of logging in.

`maxwait`

How long the first (oldest) client in the queue has waited, in seconds. If this starts increasing, then the current pool of servers does not handle requests quickly enough. The reason may be either an overloaded server or just too small of a `pool_size` setting.

`maxwait_us`

Microsecond part of the maximum waiting time.

`pool_mode`

The pooling mode in use.

SHOW LISTS

Show following internal information, in columns (not rows):

`databases`

Count of databases.

users

Count of users.

pools

Count of pools.

free_clients

Count of free clients.

used_clients

Count of used clients.

login_clients

Count of clients in login state.

free_servers

Count of free servers.

used_servers

Count of used servers.

dns_names

Count of DNS names in the cache.

dns_zones

Count of DNS zones in the cache.

dns_queries

Count of in-flight DNS queries.

dns_pending

Not used.

SHOW USERS

name

The user name.

pool_mode

The user's override `pool_mode`, or `NULL` if the default will be used instead.

SHOW DATABASES

name

Name of configured database entry.

host

Host pgbouncer connects to.

port

Port pgbouncer connects to.

database

Actual database name pgbouncer connects to.

`force_user`

When the user is part of the connection string, the connection between pgbouncer and Postgres Pro is forced to the given user, whatever the client user.

`pool_size`

Maximum number of server connections.

`reserve_pool`

Maximum number of additional connections for this database.

`pool_mode`

The database's override `pool_mode`, or `NULL` if the default will be used instead.

`max_connections`

Maximum number of allowed connections for this database, as set by `max_db_connections`, either globally or per database.

`current_connections`

Current number of connections for this database.

`paused`

1 if this database is currently paused, else 0.

`disabled`

1 if this database is currently disabled, else 0.

SHOW FDS

Internal command — shows list of file descriptors (FDs) in use with internal state attached to them.

When the connected user has the user name `pgbouncer`, connects through the Unix socket and has the same UID as the running process, the actual FDs are passed over the connection. This mechanism is used to do an online restart.

Note

This does not work on Windows systems.

This command also blocks the internal event loop, so it should not be used while pgbouncer is in use.

`fd`

File descriptor numeric value.

`task`

One of `pooler`, `client` or `server`.

`user`

User of the connection using the FD.

`database`

Database of the connection using the FD.

`addr`

IP address of the connection using the FD, `unix` if a Unix socket is used.

port

Port used by the connection using the FD.

cancel

Cancel key for this connection.

link

File descriptor for corresponding server/client. `NULL` if idle.

SHOW SOCKETS, SHOW ACTIVE_SOCKETS

Shows low-level information about sockets or only active sockets. This includes the information shown under `SHOW CLIENTS` and `SHOW SERVERS` as well as other more low-level information.

SHOW CONFIG

Show the current configuration settings, one per row, with the following columns:

key

Configuration variable name.

value

Configuration value.

changeable

Either `yes` or `no`, shows if the variable can be changed while running. If `no`, the variable can be changed only at boot-time. Use `SET` to change a variable at run time.

SHOW MEM

Shows low-level information about the current sizes of various internal memory allocations. The information presented is subject to change.

SHOW DNS_HOSTS

Show host names in DNS cache.

hostname

Host name.

ttd

How many seconds until next lookup.

addrs

Comma separated list of addresses.

SHOW DNS_ZONES

Show DNS zones in cache.

zonename

Zone name.

serial

Current serial.

count

Host names belonging to this zone.

Process Controlling Commands

PAUSE [*db*]

pgbouncer tries to disconnect from all servers, first waiting for all queries to complete. The command will not return before all queries are finished. To be used at the time of database restart.

If database name is given, only that database will be paused.

New client connections to a paused database will wait until `RESUME` is called.

DISABLE *db*

Reject all new client connections on the given database.

ENABLE *db*

Allow new client connections after a previous `DISABLE` command.

RECONNECT *db*

Close each open server connection for the given database, or all databases, after it is released (according to the pooling mode), even if its lifetime is not up yet. New server connections can be made immediately and will connect as necessary according to the pool size settings.

This command is useful when the server connection setup has changed, for example to perform a gradual switchover to a new server. It is not necessary to run this command when the connection string in `pgbouncer.ini` has been changed and reloaded (see `RELOAD`) or when DNS resolution has changed, because then the equivalent of this command will be run automatically. This command is only necessary if something downstream of pgbouncer routes the connections.

After this command is run, there could be an extended period where some server connections go to an old destination and some server connections go to a new destination. This is likely only sensible when switching read-only traffic between read-only replicas, or when switching between nodes of a multimaster replication setup. If all connections need to be switched at the same time, `PAUSE` is recommended instead. To close server connections without waiting (for example, in emergency failover rather than gradual switchover scenarios), also consider `KILL`.

KILL *db*

Immediately drop all client and server connections on given database.

New client connections to a killed database will wait until `RESUME` is called.

SUSPEND

All socket buffers are flushed and pgbouncer stops listening for data on them. The command will not return before all buffers are empty. To be used at the time of pgbouncer online reboot.

New client connections to a suspended database will wait until `RESUME` is called.

RESUME [*db*]

Resume work from previous `KILL`, `PAUSE`, or `SUSPEND` command.

SHUTDOWN

The pgbouncer process will exit.

RELOAD

The pgbouncer process will reload its configuration file and update changeable settings.

PgBouncer notices when a configuration file reload changes the connection parameters of a database definition. An existing server connection to the old destination will be closed when the server connection is next released (according to the pooling mode), and new server connections will immediately use the updated connection parameters.

WAIT_CLOSE [db]

Wait until all server connections, either of the specified database or of all databases, have cleared the `close_needed` state (see [the section called “SHOW SERVERS”](#)). This can be called after a `RECONNECT` or `RELOAD` to wait until the respective configuration change has been fully activated, for example in switchover scripts.

Other Commands**SET key = arg**

Changes a configuration setting (see also [the section called “SHOW CONFIG”](#)). For example:

```
SET log_connections = 1;
SET server_check_query = 'select 2';
```

(Note that this command is run on the pgbouncer admin console and sets pgbouncer settings. A `SET` command run on another database will be passed to the Postgres Pro backend like any other SQL command.)

Signals

`SIGHUP`

Reload config. Same as issuing the command `RELOAD` on the console.

`SIGINT`

Safe shutdown. Same as issuing `PAUSE` and `SHUTDOWN` on the console.

`SIGTERM`

Immediate shutdown. Same as issuing `SHUTDOWN` on the console.

`SIGUSR1`

Same as issuing `PAUSE` on the console.

`SIGUSR2`

Same as issuing `RESUME` on the console.

Libevent Settings

From the libevent documentation:

It is possible to disable support for `epoll`, `kqueue`, `devpoll`, `poll`, or `select` by setting the environment variable `EVENT_NOEPOLL`, `EVENT_NOKQUEUE`, `EVENT_NODEVPOLL`, `EVENT_NOPOLL` or `EVENT_NOSELECT`, respectively.

By setting the environment variable `EVENT_SHOW_METHOD`, libevent displays the kernel notification method that it uses.

pgbouncer.ini Configuration File

The configuration file is in the `.ini` format. Section names are between "[" and "]". Lines starting with ";" or "#" are taken as comments and ignored. The characters ";" and "#" are not recognized when they appear later in the line.

Generic Settings

`logfile`

Specifies log file. Log file is kept open so after rotation `kill -HUP` or on console `RELOAD`; should be done. Note: On Windows systems, the service must be stopped and started.

Default: not set

`pidfile`

Specifies the PID file. Without a `pidfile`, daemonization is not allowed.

Default: not set

`listen_addr`

Specifies list of addresses, where to listen for TCP connections. You may also use `*` meaning "listen on all addresses". When not set, only Unix socket connections are allowed.

Addresses can be specified numerically (IPv4/IPv6) or by name.

Default: not set

`listen_port`

Which port to listen on. Applies to both TCP and Unix sockets.

Default: 6432

`unix_socket_dir`

Specifies location for Unix sockets. Applies to both listening socket and server connections. If set to an empty string, Unix sockets are disabled. Required for online reboot (-R) to work. Note: Not supported on Windows systems.

Default: /tmp

`unix_socket_mode`

File system mode for Unix socket.

Default: 0777

`unix_socket_group`

Group name to use for Unix socket.

Default: not set

`user`

If set, specifies the Unix user to change to after startup. Works only if `pgbouncer` is started as root or if it's already running as given user.

Note: Not supported on Windows systems.

Default: not set

`auth_file`

The name of the file to load user names and passwords from. See [the section called "Authentication File Format"](#) for details.

Default: not set

`auth_hba_file`

HBA configuration file to use when `auth_type` is `hba`. Supported from version 1.7 onwards.

Default: not set

`auth_type`

How to authenticate users.

pam

Pluggable Authentication Modules (PAM) method is used to authenticate users, `auth_file` is ignored. This method is not compatible with databases using `auth_user` option. Service name reported to PAM is `pgbouncer`. Also, PAM is still not supported in HBA configuration file.

hba

Actual authentication type is loaded from `auth_hba_file`. This allows different authentication methods different access paths. Example: connection over Unix socket uses `peer` authentication method, connection over TCP must use TLS. Supported from version 1.7 onwards.

cert

Client must connect over TLS connection with valid client certificate. Username is then taken from `CommonName` field from certificate.

md5

Use MD5-based password check. This is the default authentication method. `auth_file` may contain both MD5-encrypted or plain-text passwords. If `md5` is configured and a user has a SCRAM secret, then SCRAM authentication is used automatically instead.

scram-sha-256

Use password check with SCRAM-SHA-256. `auth_file` has to contain SCRAM secrets or plain-text passwords. Note that SCRAM secrets can only be used for verifying the password of a client but not for logging into a server. To be able to use SCRAM on server connections, use plain-text passwords.

plain

Clear-text password is sent over wire. Deprecated.

trust

No authentication is done. Username must still exist in `auth_file`.

any

Like the `trust` method, but the username given is ignored. Requires that all databases are configured to log in as specific user. Additionally, the console database allows any user to log in as admin.

auth_query

Query to load user's password from database.

Direct access to `pg_shadow` requires admin rights. It's preferable to use non-admin user that calls `SECURITY DEFINER` function instead.

Note that the query is run inside target database, so if a function is used it needs to be installed into each database.

Default: `SELECT username, passwd FROM pg_shadow WHERE username=$1`

auth_user

If `auth_user` is set, any user not specified in `auth_file` will be queried through the `auth_query` query from `pg_shadow` in the database using `auth_user`. `auth_user`'s password will be taken from `auth_file`.

Direct access to `pg_shadow` requires admin rights. It's preferable to use non-admin user that calls `SECURITY DEFINER` function instead.

Default: not set

`pool_mode`

Specifies when a server connection can be reused by other clients.

`session`

Server is released back to pool after client disconnects. Default.

`transaction`

Server is released back to pool after transaction finishes.

`statement`

Server is released back to pool after query finishes. Long transactions spanning multiple statements are disallowed in this mode.

`max_client_conn`

Maximum number of client connections allowed. When increased, the file descriptor limits should also be increased. Note that actual number of file descriptors used is more than `max_client_conn`. If each user connects under its own username to server, theoretical maximum used is:

`max_client_conn + (max pool_size * total databases * total users)`

If a database user is specified in connect string (all users connect under same username), the theoretical maximum is:

`max_client_conn + (max pool_size * total databases)`

The theoretical maximum should be never reached, unless somebody deliberately crafts special load for it. Still, it means you should set the number of file descriptors to a safely high number.

Search for `ulimit` in your favorite shell man page. Note: `ulimit` does not apply in a Windows environment.

Default: 100

`default_pool_size`

How many server connections to allow per user/database pair. Can be overridden in the per-database configuration.

Default: 20

`min_pool_size`

Add more server connections to pool if below this number. Improves behavior when usual load suddenly comes back after a period of total inactivity.

Default: 0 (disabled)

`reserve_pool_size`

How many additional connections to allow to a pool. The 0 value disables this parameter.

Default: 0 (disabled)

`reserve_pool_timeout`

If a client has not been serviced in this many seconds, `pgbouncer` enables use of additional connections from reserve pool. The 0 value disables this parameter.

Default: 5.0

`max_db_connections`

Do not allow more than this many connections per-database (regardless of pool — i.e. user). It should be noted that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: unlimited

`max_user_connections`

Do not allow more than this many connections per-user (regardless of pool — i.e. user). It should be noted that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

`server_round_robin`

By default, pgbouncer reuses server connections in LIFO (last-in, first-out) manner, so that few connections get the most load. This gives best performance if you have a single server serving a database. But if there is TCP round-robin behind a database IP, then it is better if pgbouncer also uses connections in that manner, thus achieving uniform load.

Default: 0

`ignore_startup_parameters`

By default, pgbouncer allows only parameters it can keep track of in startup packets — `client_encoding`, `datestyle`, `timezone` and `standard_conforming_strings`.

All other parameters will raise an error. To allow other parameters, they can be specified here, so that pgbouncer knows that they are handled by admin and it can ignore them.

Default: empty

`disable_pqexec`

Disable Simple Query protocol (PQexec). Unlike Extended Query protocol, Simple Query allows multiple queries in one packet, which allows some classes of SQL-injection attacks. Disabling it can improve security. Obviously this means only clients that exclusively use Extended Query protocol will stay working.

Default: 0

`application_name_add_host`

Add the client host address and port to the application name setting set on connection start. This helps in identifying the source of bad queries, etc. This logic applies only on start of connection, if `application_name` is later changed with `SET`, pgbouncer does not change it again.

Default: 0

`conffile`

Show location of current configuration file. Changing it will make pgbouncer use another configuration file for next `RELOAD` / `SIGHUP`.

Default: file from command line.

`service_name`

Used on win32 service registration.

Default: pgbouncer

job_name

Alias for [service_name](#).

stats_period

Sets how often the averages shown in various `SHOW` commands are updated and how often aggregated statistics are written to the log (but see [log_stats](#)). [seconds]

Default: 60

Log Settings

syslog

Toggles syslog on/off. On Windows systems, eventlog is used instead.

Default: 0

syslog_ident

Under what name to send logs to syslog.

Default: pgbouncer (program name)

syslog_facility

Under what facility to send logs to syslog. Possibilities: auth, authpriv, daemon, user, local0-7.

Default: daemon

log_connections

Log successful logins.

Default: 1

log_disconnections

Log disconnections with reasons.

Default: 1

log_pooler_errors

Log error messages pooler sends to clients.

Default: 1

stats_period

Period for writing aggregated stats into log.

Default: 60

log_stats

Write aggregated statistics into the log, every `stats_period`. This can be disabled if external monitoring tools are used to grab the same data from `SHOW` commands.

Default: 1

verbose

Increase verbosity. Mirrors "-v" switch on command line. Using "-v -v" on command line is same as `verbose=2` in configuration file.

Default: 0

Console Access Control

`admin_users`

Comma-separated list of database users that are allowed to connect and run all commands on console. Ignored when `auth_type` is `any`, in which case any username is allowed in as admin.

Default: empty

`stats_users`

Comma-separated list of database users that are allowed to connect and run read-only queries on console. That means all SHOW commands except SHOW FDS.

Default: empty.

Connection Sanity Checks, Timeouts

`server_reset_query`

Query sent to server on connection release, before making it available to other clients. At that moment no transaction is in progress so it should not include ABORT or ROLLBACK.

The query is supposed to clean any changes made to database session so that next client gets connection in well-defined state. Default is `DISCARD ALL` which cleans everything, but that leaves next client no pre-cached state. It can be made lighter, e.g. `DEALLOCATE ALL` to just drop prepared statements, if application does not break when some state is kept around.

When transaction pooling is used, the `server_reset_query` is not used, as clients must not use any session-based features as each transaction ends up in different connection and thus gets different session state.

Default: DISCARD ALL

`server_reset_query_always`

Whether `server_reset_query` should be run in all pooling modes. When this setting is off (default), the `server_reset_query` will be run only in pools that are in sessions-pooling mode. Connections in transaction-pooling mode should not have any need for reset query.

It is workaround for broken setups that run apps that use session features over transaction-pooled pgbouncer. It changes non-deterministic breakage to deterministic breakage — client always lose their state after each transaction.

Default: 0

`server_check_delay`

How long to keep released connections available for immediate re-use, without running sanity-check queries on it. If 0 then the query is always run.

Default: 30.0

`server_check_query`

Simple do-nothing query to check if the server connection is alive.

If an empty string, then sanity checking is disabled.

Default: SELECT 1;

`server_fast_close`

Disconnect a server in session pooling mode immediately or after the end of the current transaction if it is in `close_needed` mode (set by RECONNECT, RELOAD that changes connection settings, or DNS

change), rather than waiting for the session end. In statement or transaction pooling mode, this has no effect since that is the default behavior there.

If because of this setting a server connection is closed before the end of the client session, the client connection is also closed. This ensures that the client notices that the session has been interrupted.

This setting makes connection configuration changes take effect sooner if session pooling and long-running sessions are used. The downside is that client sessions are liable to be interrupted by a configuration change, so client applications will need logic to reconnect and reestablish session state. But note that no transactions will be lost, because running transactions are not interrupted, only idle sessions.

Default: 0

`server_lifetime`

The pooler will close an unused server connection that has been connected longer than this. Setting it to 0 means the connection is to be used only once, then closed. [seconds]

Default: 3600.0

`server_idle_timeout`

If a server connection has been idle more than this many seconds it will be dropped. If 0 then timeout is disabled. [seconds]

Default: 600.0

`server_connect_timeout`

If connection and login won't finish in this amount of time, the connection will be closed. [seconds]

Default: 15.0

`server_login_retry`

If login failed, because of failure from connect() or authentication that pooler waits this much before retrying to connect. [seconds]

Default: 15.0

`client_login_timeout`

If a client connects but does not manage to login in this amount of time, it will be disconnected. Mainly needed to avoid dead connections stalling SUSPEND and thus online restart. [seconds]

Default: 60.0

`autodb_idle_timeout`

If the automatically created (via `"*`") database pools have been unused this many seconds, they are freed. The negative aspect of that is that their statistics are also forgotten. [seconds]

Default: 3600.0

`dns_max_ttl`

How long the DNS lookups can be cached. If a DNS lookup returns several answers, pgbouncer will robin-between them in the meantime. Actual DNS TTL is ignored. [seconds]

Default: 15.0

`dns_nxdomain_ttl`

How long error and NXDOMAIN DNS lookups can be cached. [seconds]

Default: 15.0

`dns_zone_check_period`

Period to check if zone serial has changed.

pgbouncer can collect DNS zones from host names (everything after first dot) and then periodically check if zone serial changes. If it notices changes, all host names under that zone are looked up again. If any host IP changes, it's connections are invalidated.

Works only with UDNS and c-ares backends (`--with-udns` or `--with-cares` to configure).

Default: 0.0 (disabled)

TLS Settings

`client_tls_sslmode`

TLS mode to use for connections from clients. TLS connections are disabled by default. When enabled, `client_tls_key_file` and `client_tls_cert_file` must be also configured to set up key and cert pgbouncer uses to accept client connections.

`disable`

Plain TCP. If client requests TLS, it's ignored. Default.

`allow`

If client requests TLS, it is used. If not, plain TCP is used. If client uses client-certificate, it is not validated.

`prefer`

Same as `allow`.

`require`

Client must use TLS. If not, client connection is rejected. If client uses client-certificate, it is not validated.

`verify-ca`

Client must use TLS with valid client certificate.

`verify-full`

Same as `verify-ca`.

`client_tls_key_file`

Private key for pgbouncer to accept client connections.

Default: not set.

`client_tls_cert_file`

Certificate for private key. Clients can validate it.

Default: not set.

`client_tls_ca_file`

Root certificate file to validate client certificates.

Default: unset.

`client_tls_protocols`

Which TLS protocol versions are allowed. Allowed values: `tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`. Shortcuts: `all` (`tlsv1.0,tlsv1.1,tlsv1.2,tlsv1.3`), `secure` (`tlsv1.2,tlsv1.3`), `legacy` (`all`).

Default: `all`

`client_tls_ciphers`

Default: `fast`

`client_tls_ecdhcurve`

Elliptic Curve name to use for ECDH key exchanges.

Allowed values: `none` (DH is disabled), `auto` (256-bit ECDH), curve name.

Default: `auto`

`client_tls_dheparams`

DHE key exchange type.

Allowed values: `none` (DH is disabled), `auto` (2048-bit DH), `legacy` (1024-bit DH).

Default: `auto`

`server_tls_sslmode`

TLS mode to use for connections to Postgres Pro servers. TLS connections are disabled by default.

`disable`

Plain TCP. TLS is not even requested from server. Default.

`prefer`

TLS connection is always requested first from Postgres Pro, when refused connection will be established over plain TCP. Server certificate is not validated.

`require`

Connection must go over TLS. If server rejects it, plain TCP is not attempted. Server certificate is not validated.

`verify-ca`

Connection must go over TLS and server certificate must be valid according to [server_tls_ca_file](#). Server host name is not checked against certificate.

`verify-full`

Connection must go over TLS and server certificate must be valid according to [server_tls_ca_file](#). Server host name must match certificate info.

`server_tls_ca_file`

Root certificate file to validate Postgres Pro server certificates.

Default: `unset`.

`server_tls_key_file`

Private key for pgbouncer to authenticate against Postgres Pro server.

Default: `not set`.

`server_tls_cert_file`

Certificate for private key. Postgres Pro server can validate it.

Default: not set.

`server_tls_protocols`

Which TLS protocol versions are allowed. Allowed values: `tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`. Shortcuts: `all` (`tlsv1.0,tlsv1.1,tlsv1.2,tlsv1.3`), `secure` (`tlsv1.2,tlsv1.3`), `legacy` (`all`).

Default: `all`

`server_tls_ciphers`

Default: `fast`

Dangerous Timeouts

Setting the following timeouts causes unexpected errors.

`query_timeout`

Queries running longer than that are canceled. This should be used only with slightly smaller server-side `statement_timeout`, to apply only for network problems. [seconds]

Default: 0.0 (disabled)

`query_wait_timeout`

Maximum time queries are allowed to spend waiting for execution. If the query is not assigned to a server during that time, the client is disconnected. This is used to prevent unresponsive servers from grabbing up connections. [seconds]

It also helps when server is down or database rejects connections for any reason. If this is disabled, clients will be queued infinitely.

Default: 120

`client_idle_timeout`

Client connections idling longer than this many seconds are closed. This should be larger than the client-side connection lifetime settings, and only used for network problems. [seconds]

Default: 0.0 (disabled)

`idle_transaction_timeout`

If client has been in "idle in transaction" state longer, it will be disconnected. [seconds]

Default: 0.0 (disabled)

Low-Level Network Settings

`pkt_buf`

Internal buffer size for packets. Affects size of TCP packets sent and general memory usage. Actual libpq packets can be larger than this, so, no need to set it large.

Default: 4096

`max_packet_size`

Maximum size for Postgres Pro packets that pgbouncer allows through. One packet is either one query or one result set row. Full result set can be larger.

Default: 2147483647

`listen_backlog`

Backlog argument for `listen(2)`. Determines how many new unanswered connection attempts are kept in queue. When queue is full, further new connections are dropped.

Default: 128

`sbuf_loopcnt`

How many times to process data on one connection, before proceeding. Without this limit, one connection with a big result set can stall pgbouncer for a long time. One loop processes one `pkt_buf` amount of data. 0 means no limit.

Default: 5

`suspend_timeout`

How many seconds to wait for buffer flush during SUSPEND or reboot (-R). Connection is dropped if flush does not succeed.

Default: 10

`tcp_defer_accept`

For details on this and other TCP options, please see `man 7 tcp`.

Default: 45 on Linux, otherwise 0

`tcp_socket_buffer`

Default: not set

`tcp_keepalive`

Turns on basic keepalive with OS defaults.

On Linux, the system defaults are **`tcp_keepidle=7200`**, **`tcp_keepintvl=75`**, **`tcp_keepcnt=9`**. They are probably similar on other operating systems.

Default: 1

`tcp_keepcnt`

Default: not set

`tcp_keepidle`

Default: not set

`tcp_keepintvl`

Default: not set

Section [databases]

This contains key=value pairs where key will be taken as a database name and value as a libpq connect-string style list of key=value pairs. As actual libpq is not used, not all features from libpq can be used (service=, .pgpass).

Database name can contain characters `_0-9A-Za-z` without quoting. Names that contain other chars need to be quoted with standard SQL ident quoting: double quotes where `""` is taken as single quote.

`""` acts as fallback database: if the exact name does not exist, its value is taken as connect string for requested database. Such automatically created database entries are cleaned up if they stay idle longer than the time specified in `autodb_idle_timeout` parameter.

`dbname`

Destination database name.

Default: same as client-side database name.

`host`

Host name or IP address to connect to. Host names are resolved at connect time, the result is cached per `dns_max_ttl` parameter. When a host name's resolution changes, existing server connections are automatically closed when they are released (according to the pooling mode), and new server connections immediately use the new resolution. If DNS returns several results, they are used in round-robin manner.

Default: not set, meaning to use a Unix socket.

`port`

Default: 5432

`user`

If `user=` is set, all connections to the destination database will be done with the specified user, meaning that there will be only one pool for this database.

Otherwise `pgbouncer` tries to log into the destination database with client username, meaning that there will be one pool per user.

`password`

The length for `password` is limited to 160 characters maximum.

If no password is specified here, the password from the `auth_file` or `auth_query` will be used.

`auth_user`

Override of the global `auth_user` setting, if specified.

`pool_size`

Set maximum size of pools for this database. If not set, the `default_pool_size` is used.

`reserve_pool`

Set additional connections for this database. If not set, `reserve_pool_size` is used.

`connect_query`

Query to be executed after a connection is established, but before allowing the connection to be used by any clients. If the query raises errors, they are logged but ignored otherwise.

`pool_mode`

Set the pool mode specific to this database. If not set, the default `pool_mode` is used.

`max_db_connections`

Configure a database-wide maximum (i.e. all pools within the database will not have more than this many server connections).

`client_encoding`

Ask specific `client_encoding` from server.

`datestyle`

Ask specific `datestyle` from server.

`timezone`

Ask specific `timezone` from server.

Section [users]

This contains key=value pairs where the key will be taken as a user name and the value as a libpq connect-string style list of key=value pairs of configuration settings specific for this user. Only a few settings are available here.

`pool_mode`

Set the pool mode to be used for all connections from this user. If not set, the database or default `pool_mode` is used.

`max_user_connections`

Configure a maximum for the user (i.e. all pools with the user will not have more than this many server connections).

Include Directive

The pgbouncer config file can contain include directives, which specify another configuration file to read and process. This allows for splitting the configuration file into physically separate parts. The include directives look like this:

```
%include filename
```

If the file name is not absolute path it is taken as relative to current working directory.

Authentication File Format

pgbouncer needs its own user database. The users are loaded from a text file in following format:

```
"username1" "password" ...
"username2" "md5abcdef012342345" ...
"username2" "SCRAM-SHA-256$iterations:salt$storedkey:serverkey"
```

There should be at least two fields, surrounded by double quotes. The first field is the username and the second is either a plain-text, a MD5-hidden password, or a SCRAM secret. pgbouncer ignores the rest of the line.

Postgres Pro MD5-hidden password format:

```
"md5" + md5(password + username)
```

So user admin with password 1234 will have MD5-hidden password
md545f2603610af569b6155c45067268c6b.

Postgres Pro SCRAM secret format:

```
SCRAM-SHA-256$iterations:salt$storedkey:serverkey
```

The authentication file can be written by hand, but it's also useful to generate it from some other list of users and passwords. See `./etc/mkauth.py` for a sample script to generate the authentication file from the `pg_shadow` system table.

HBA File Format

It follows the format of Postgres Pro `pg_hba.conf` file described in [Section 20.1](#).

- Supported record types: `local`, `host`, `hostssl`, `hostnossl`.
- Database field: Supports `all`, `sameuser`, `@file`, multiple names. Not supported: `replication`, `samerole`, `samegroup`.
- Username field: Supports `all`, `@file`, multiple names. Not supported: `+groupname`.
- Address field: Supported `IPv4`, `IPv6`. Not supported: DNS names, domain prefixes.

- **Auth-method field:** Only methods supported by pgbouncer's `auth_type` are supported, except any and `pam`, which only work globally. Username map (`map=`) parameter is not supported.

Example

Minimal config:

```
[databases]
template1 = host=127.0.0.1 dbname=template1 auth_user=someuser

[pgbouncer]
pool_mode = session
listen_port = 6543
listen_addr = 127.0.0.1
auth_type = md5
auth_file = users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
stats_users = stat_collector
```

Database defaults:

```
[databases]

; foodb over Unix socket
foodb =

; redirect bardb to bazdb on localhost
bardb = host=127.0.0.1 dbname=bazdb

; access to destination database will go with single user
forcedb = host=127.0.0.1 port=300 user=baz password=foo client_encoding=UNICODE
datestyle=ISO
```

Example of a secure function for `auth_query`:

```
CREATE OR REPLACE FUNCTION pgbouncer.user_lookup(in i_username text, out uname text,
out phash text)
RETURNS record AS $$
BEGIN
    SELECT username, passwd FROM pg_catalog.pg_shadow
    WHERE username = i_username INTO uname, phash;
    RETURN;
END;
$$ LANGUAGE plpgsql SECURITY DEFINER;
REVOKE ALL ON FUNCTION pgbouncer.user_lookup(text) FROM public, pgbouncer;
GRANT EXECUTE ON FUNCTION pgbouncer.user_lookup(text) TO pgbouncer;
```

pgpro_controldata

pgpro_controldata — display control information of a PostgreSQL/Postgres Pro database cluster and compatibility information for a cluster and/or server

Synopsis

```
pgpro_controldata [option...]
```

Description

pgpro_controldata prints control information, such as the catalog version, initialized by `initdb` command of any PostgreSQL/Postgres Pro server. It also shows information about write-ahead logging and checkpoint processing. This information is cluster-wide and not specific to any database.

pgpro_controldata also helps to check compatibility between PostgreSQL/Postgres Pro database servers and clusters. It can print server or cluster parameters that can affect the compatibility and check whether a cluster and server are compatible by comparing those parameters.

Options

pgpro_controldata accepts the following command-line arguments. If no arguments are specified, pgpro_controldata just prints the control information like [pg_controldata](#) does. Note that compatibility-related command-line arguments `-P` and `-S` specified together work the same way as `-C`.

General-Purpose

`-B`
`--bindir`
Specifies the PostgreSQL/Postgres Pro executable directory, needed to get server compatibility parameters.

`-D datadir`
`--pgdata=datadir`
Specifies the file system location of the database configuration files. If this option is omitted, the environment variable `PGDATA` is used.

`-V`
`--version`
Print the pgpro_controldata version, then exit.

`-?`
`--help`
Show help about pgpro_controldata command-line arguments, then exit.

Compatibility-Related

`-C`
`--compatibility-check`
Display all parameters that can affect compatibility between the specified server and cluster and check whether they are compatible.

Use the `-D` option or the environment variable `PGDATA` to provide the path to the data directory, where read access is required.

If the `-B` option is omitted, the current server is assumed.

The cluster data and the server must have the same byte order and architecture type for this option to work correctly.

`-P`
`--cluster-compatibility-params`

Display all parameters of the specified cluster that can affect the compatibility.

Use the `-D` option or the environment variable `PGDATA` to provide the path to the data directory, where read access is required.

The cluster data and the server must have the same byte order and architecture type for this option to work correctly.

`-S`
`--server-compatibility-params`

Display all parameters of the specified or current server that can affect the compatibility.

If the `-B` option is omitted, the current server is assumed.

Environment

`PGDATA`
Default data directory location

`PG_COLOR`
Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

[pg_controldata](#)

pg_standby

`pg_standby` — supports the creation of a Postgres Pro warm standby server

Synopsis

```
pg_standby [option...] archivelocation nextwalfile xlogfilepath [restartwalfile]
```

Description

`pg_standby` supports creation of a “warm standby” database server. It is designed to be a production-ready program, as well as a customizable template should you require specific modifications.

`pg_standby` is designed to be a waiting `restore_command`, which is needed to turn a standard archive recovery into a warm standby operation. Other configuration is required as well, all of which is described in the main server manual (see [Section 26.2](#)).

To configure a standby server to use `pg_standby`, put this into its `recovery.conf` configuration file:

```
restore_command = 'pg_standby archiveDir %f %p %r'
```

where *archiveDir* is the directory from which WAL segment files should be restored.

If *restartwalfile* is specified, normally by using the `%r` macro, then all WAL files logically preceding this file will be removed from *archivelocation*. This minimizes the number of files that need to be retained, while preserving crash-restart capability. Use of this parameter is appropriate if the *archivelocation* is a transient staging area for this particular standby server, but *not* when the *archivelocation* is intended as a long-term WAL archive area.

`pg_standby` assumes that *archivelocation* is a directory readable by the server-owning user. If *restartwalfile* (or `-k`) is specified, the *archivelocation* directory must be writable too.

There are two ways to fail over to a “warm standby” database server when the master server fails:

Smart Failover

In smart failover, the server is brought up after applying all WAL files available in the archive. This results in zero data loss, even if the standby server has fallen behind, but if there is a lot of unapplied WAL it can be a long time before the standby server becomes ready. To trigger a smart failover, create a trigger file containing the word `smart`, or just create it and leave it empty.

Fast Failover

In fast failover, the server is brought up immediately. Any WAL files in the archive that have not yet been applied will be ignored, and all transactions in those files are lost. To trigger a fast failover, create a trigger file and write the word `fast` into it. `pg_standby` can also be configured to execute a fast failover automatically if no new WAL file appears within a defined interval.

Options

`pg_standby` accepts the following command-line arguments:

- `-c`
Use `cp` or `copy` command to restore WAL files from archive. This is the only supported behavior so this option is useless.
- `-d`
Print lots of debug logging output on `stderr`.
- `-k`
Remove files from *archivelocation* so that no more than this many WAL files before the current one are kept in the archive. Zero (the default) means not to remove any files from *archivelocation*. This

parameter will be silently ignored if *restartwalfile* is specified, since that specification method is more accurate in determining the correct archive cut-off point. Use of this parameter is *deprecated* as of PostgreSQL 8.3; it is safer and more efficient to specify a *restartwalfile* parameter. A too small setting could result in removal of files that are still needed for a restart of the standby server, while a too large setting wastes archive space.

`-r maxretries`

Set the maximum number of times to retry the copy command if it fails (default 3). After each failure, we wait for *sleeptime* * *num_retries* so that the wait time increases progressively. So by default, we will wait 5 secs, 10 secs, then 15 secs before reporting the failure back to the standby server. This will be interpreted as end of recovery and the standby will come up fully as a result.

`-s sleeptime`

Set the number of seconds (up to 60, default 5) to sleep between tests to see if the WAL file to be restored is available in the archive yet. The default setting is not necessarily recommended; consult [Section 26.2](#) for discussion.

`-t triggerfile`

Specify a trigger file whose presence should cause failover. It is recommended that you use a structured file name to avoid confusion as to which server is being triggered when multiple servers exist on the same system; for example `/tmp/pgsql.trigger.5432`.

`-V`

`--version`

Print the `pg_standby` version and exit.

`-w maxwaittime`

Set the maximum number of seconds to wait for the next WAL file, after which a fast failover will be performed. A setting of zero (the default) means wait forever. The default setting is not necessarily recommended; consult [Section 26.2](#) for discussion.

`-?`

`--help`

Show help about `pg_standby` command line arguments, and exit.

Notes

`pg_standby` is designed to work with PostgreSQL 8.2 and later.

PostgreSQL 8.3 provides the `%r` macro, which is designed to let `pg_standby` know the last file it needs to keep. With PostgreSQL 8.2, the `-k` option must be used if archive cleanup is required. This option remains available in 8.3, but its use is deprecated.

PostgreSQL 8.4 provides the `recovery_end_command` option. Without this option a leftover trigger file can be hazardous.

`pg_standby` is written in C and has an easy-to-modify source code, with specifically designated sections to modify for your own needs

Examples

On Linux or Unix systems, you might use:

```
archive_command = 'cp %p .../archive/%f'
```

```
restore_command = 'pg_standby -d -s 2 -t /tmp/pgsql.trigger.5442 .../archive %f %p %r  
2>>standby.log'
```

```
recovery_end_command = 'rm -f /tmp/pgsql.trigger.5442'
```

where the archive directory is physically located on the standby server, so that the `archive_command` is accessing it across NFS, but the files are local to the standby (enabling use of `ln`). This will:

- produce debugging output in `standby.log`
- sleep for 2 seconds between checks for next WAL file availability
- stop waiting only when a trigger file called `/tmp/pgsql.trigger.5442` appears, and perform failover according to its content
- remove the trigger file when recovery ends
- remove no-longer-needed files from the archive directory

On Windows, you might use:

```
archive_command = 'copy %p ...\\archive\\%f'
```

```
restore_command = 'pg_standby -d -s 5 -t C:\pgsql.trigger.5442 ...\\archive %f %p %r  
2>>standby.log'
```

```
recovery_end_command = 'del C:\pgsql.trigger.5442'
```

Note that backslashes need to be doubled in the `archive_command`, but *not* in the `restore_command` or `recovery_end_command`. This will:

- use the `copy` command to restore WAL files from archive
- produce debugging output in `standby.log`
- sleep for 5 seconds between checks for next WAL file availability
- stop waiting only when a trigger file called `C:\pgsql.trigger.5442` appears, and perform failover according to its content
- remove the trigger file when recovery ends
- remove no-longer-needed files from the archive directory

The `copy` command on Windows sets the final file size before the file is completely copied, which would ordinarily confuse `pg_standby`. Therefore `pg_standby` waits *sleep_time* seconds once it sees the proper file size. GNUWin32's `cp` sets the file size only after the file copy is complete.

Since the Windows example uses `copy` at both ends, either or both servers might be accessing the archive directory across the network.

Appendix H. External Projects

Postgres Pro is a complex software project, and managing the project is difficult. We have found that many enhancements to Postgres Pro can be more efficiently developed separately from the core project.

H.1. Client Interfaces

There are only two client interfaces included in the base Postgres Pro Enterprise distribution:

- **libpq** is included because it is the primary C language interface, and because many other client interfaces are built on top of it.
- **ECPG** is included because it depends on the server-side SQL grammar, and is therefore sensitive to changes in Postgres Pro itself.

All other language interfaces are external projects and are distributed separately. [Table H.1](#) includes a list of some of these projects. Note that some of these packages might not be released under the same license as Postgres Pro. For more information on each language interface, including licensing terms, refer to its website and documentation.

Table H.1. Externally Maintained Client Interfaces

Name	Language	Comments	Website
DBD::Pg	Perl	Perl DBI driver	https://metacpan.org/release/DBD-Pg/
JDBC	Java	Type 4 JDBC driver	https://jdbc.postgresql.org/
libpqxx	C++	C++ interface	https://pqxx.org/
node-postgres	JavaScript	Node.js driver	https://node-postgres.com/
Npgsql	.NET	.NET data provider	https://www.npgsql.org/
pgtcl	Tcl		https://github.com/flightaware/Pgtcl
pgtclng	Tcl		http://sourceforge.net/projects/pgtclng/
pq	Go	Pure Go driver for Go's database/sql	https://github.com/lib/pq
psqlODBC	ODBC	ODBC driver	https://odbc.postgresql.org/
psycopg	Python	DB API 2.0-compliant	https://www.psycopg.org/

H.2. Administration Tools

There are several administration tools available for Postgres Pro. The most popular is [pgAdmin](#), and there are several commercially available ones as well.

H.3. Procedural Languages

Postgres Pro includes several procedural languages with the base distribution: [PL/pgSQL](#), [PL/Tcl](#), [PL/Perl](#), and [PL/Python](#).

In addition, there are a number of procedural languages that are developed and maintained outside the core Postgres Pro distribution. [Table H.2](#) lists some of these packages. Note that some of these projects might not be released under the same license as Postgres Pro. For more information on each procedural language, including licensing information, refer to its website and documentation.

Table H.2. Externally Maintained Procedural Languages

Name	Language	Website
PL/Java	Java	https://github.com/tada/pljava
PL/PHP	PHP	https://public.commandprompt.com/projects/plphp
PL/Py	Python	http://python.projects.postgresql.org/backend/
PL/R	R	https://github.com/postgres-plr/plr
PL/Ruby	Ruby	http://raa.ruby-lang.org/project/pl-ruby/
PL/Scheme	Scheme	http://plscheme.projects.postgresql.org/
PL/sh	Unix shell	https://github.com/petere/plsh

H.4. Extensions

Postgres Pro is designed to be easily extensible. For this reason, extensions loaded into the database can function just like features that are built in. The `contrib/` directory shipped with the source code contains several extensions, which are described in [Appendix F](#). Other extensions are developed independently, like *PostGIS*. Even Postgres Pro replication solutions can be developed externally. For example, *Slony-I* is a popular master/standby replication solution that is developed independently from the core project.

Appendix I. Configuring Postgres Pro for 1C Solutions

You can install and use Postgres Pro with 1C solutions in a client/server model. For optimal performance and stability, modify the following settings in the `postgresql.conf` configuration file of Postgres Pro server:

1. Increase the maximum number of allowed concurrent connections to the database server, up to 1000 connections. 1C solutions can open a large number of connections, even if not all of them are used, so it is recommended to allow not less than 500 connections.

```
max_connections = 1000
```

2. To ensure that temporary tables are handled correctly, modify the following parameters:

- Increase the buffer size for temporary tables:

```
temp_buffers = 32MB
```

- Increase the number of allowed locks of tables or indexes per transaction to 256:

```
max_locks_per_transaction = 256
```

Typically, 1C solutions use a lot of temporary tables. Every backend process usually contains multiple temporary tables. When closing a connection, Postgres Pro tries to drop all temporary tables in a single transaction, so this transaction may use a lot of locks. If the number of locks exceeds the `max_locks_per_transaction` value, the transaction will fail, leaving multiple orphaned temporary tables.

3. Enable backslash escapes in all strings, and switch off the warning about using the backslash escape symbol:

```
standard_conforming_strings = off  
escape_string_warning = off
```

4. Set the `effective_cache_size` parameter to at least half of RAM available on the system. Postgres Pro query optimizer performance depends on the amount of allocated RAM.

5. Optimize query planning using [online_analyze](#) and [plantuner](#) extensions, as follows:

- Add `online_analyze` and `plantuner` to the `shared_preload_libraries` variable.

```
shared_preload_libraries = 'online_analyze, plantuner'
```

- Enable automatic analysis of temporary tables when they are modified:

```
online_analyze.table_type = 'temporary'
```

- Tune Postgres Pro optimizer to improve planning for recently created empty tables:

```
plantuner.fix_empty_table = 'on'
```

- Suppress detailed messages from the `online_analyze` extension:

```
online_analyze.verbose = 'off'
```

Appendix J. Demo Database “Airlines”

This is an overview of a demo database for Postgres Pro. This appendix describes the database schema, which consists of eight tables and several views. The subject field of this database is airline flights in Russia. You can download the database from [our website](#). See [Section J.1](#) for details.

Figure J.1. Airlines in Russia

You can use this database for various purposes, such as:

- learning SQL language on your own
- preparing books, manuals, and courses on SQL
- showing Postgres Pro features in stories and articles

When developing this demo database, we pursued several goals:

- Database schema must be simple enough to be understood without extra explanations.
- At the same time, database schema must be complex enough to allow writing meaningful queries.
- The database must contain true-to-life data that will be interesting to work with.

This demo database is distributed under the [PostgreSQL license](#).

You can send us your feedback to edu@postgrespro.ru.

J.1. Installation

The demo database is available at edu.postgrespro.com in three flavors, which differ only in the data size:

- [demo-small-en.zip](#) (21 MB) — flight data for one month (DB size is 265 MB)
- [demo-medium-en.zip](#) (62 MB) — flight data for three months (DB size is 666 MB)
- [demo-big-en.zip](#) (232 MB) — flight data for one year (DB size is 2502 MB)

The small database is good for writing queries, and it will not take up much disk space. The large database can help you understand the query behavior on large data volumes and consider query optimization.

The files include an SQL script that creates the `demo` database and fills it with data (virtually, it is a backup copy created with the `pg_dump` utility). Note that if the `demo` database already exists, it will be deleted and recreated! The owner of the `demo` database will be the DBMS user who run the script.

J.2. Schema Diagram

Figure J.2. Bookings Schema Diagram

J.3. Schema Description

The main entity is a booking (`bookings`).

One booking can include several passengers, with a separate ticket (`tickets`) issued to each passenger. A ticket has a unique number and includes information about the passenger. As such, the passenger is not a separate entity. Both the passenger's name and identity document number can change over time, so it is impossible to uniquely identify all the tickets of a particular person; for simplicity, we can assume that all passengers are unique.

The ticket includes one or more flight segments (`ticket_flights`). Several flight segments can be included into a single ticket if there are no non-stop flights between the points of departure and destination (connecting flights), or if it is a round-trip ticket. Although there is no constraint in the schema, it is assumed that all tickets in the booking have the same flight segments.

Each flight (`flights`) goes from one airport (`airports`) to another. Flights with the same flight number have the same points of departure and destination, but differ in departure date.

At flight check-in, the passenger is issued a boarding pass (`boarding_passes`), where the seat number is specified. The passenger can check in for the flight only if this flight is included into the ticket. The flight-seat combination must be unique to avoid issuing two boarding passes for the same seat.

The number of seats (*seats*) in the aircraft and their distribution between different travel classes depends on the model of the aircraft (*aircrafts*) performing the flight. It is assumed that every aircraft model has only one cabin configuration. Database schema does not check that seat numbers in boarding passes have the corresponding seats in the aircraft (such verification can be done using table triggers, or at the application level).

J.4. Schema Objects

J.4.1. List of Relations

Name	Type	Small	Medium	Big	Description
aircrafts	table	16 kB	16 kB	16 kB	Aircraft
airports	table	48 kB	48 kB	48 kB	Airports
boarding_passes	table	31 MB	102 MB	427 MB	Boarding passes
bookings	table	13 MB	30 MB	105 MB	Bookings
flights	table	3 MB	6 MB	19 MB	Flights
flights_v	view	0 kb	0 kB	0 kB	Flights
routes	mat. view	136 kB	136 kB	136 kB	Routes
seats	table	88 kB	88 kB	88 kB	Seats
ticket_flights	table	64 MB	145 MB	516 MB	Flight segments
tickets	table	47 MB	107 MB	381 MB	Tickets

J.4.2. Table `bookings.aircrafts`

Each aircraft model is identified by its three-digit code (*aircraft_code*). The table also includes the name of the aircraft model (*model*) and the maximal flying distance, in kilometers (*range*).

Column	Type	Modifiers	Description
aircraft_code	char(3)	NOT NULL	Aircraft code, IATA
model	text	NOT NULL	Aircraft model
range	integer	NOT NULL	Maximal flying distance, km

Indexes:

PRIMARY KEY, btree (*aircraft_code*)

Check constraints:

CHECK (*range* > 0)

Referenced by:

TABLE "flights" FOREIGN KEY (*aircraft_code*)

REFERENCES *aircrafts*(*aircraft_code*)

TABLE "seats" FOREIGN KEY (*aircraft_code*)

REFERENCES *aircrafts*(*aircraft_code*) ON DELETE CASCADE

J.4.3. Table `bookings.airports`

An airport is identified by a three-letter code (*airport_code*) and has a name (*airport_name*).

There is no separate entity for the city, but there is a city name (*city*) to identify the airports of the same city. The table also includes longitude (*longitude*), latitude (*latitude*), and the time zone (*timezone*).

Column	Type	Modifiers	Description
airport_code	char(3)	NOT NULL	Airport code
airport_name	text	NOT NULL	Airport name
city	text	NOT NULL	City
longitude	float	NOT NULL	Airport coordinates: longitude
latitude	float	NOT NULL	Airport coordinates: latitude

```
timezone      | text      | NOT NULL      | Airport time zone
```

Indexes:

```
PRIMARY KEY, btree (airport_code)
```

Referenced by:

```
TABLE "flights" FOREIGN KEY (arrival_airport)
```

```
REFERENCES airports(airport_code)
```

```
TABLE "flights" FOREIGN KEY (departure_airport)
```

```
REFERENCES airports(airport_code)
```

J.4.4. Table bookings.boarding_passes

At the time of check-in, which opens twenty-four hours before the scheduled departure, the passenger is issued a boarding pass. Like the flight segment, the boarding pass is identified by the ticket number and the flight number.

Boarding passes are assigned sequential numbers (boarding_no), in the order of check-ins for the flight (this number is unique only within the context of a particular flight). The boarding pass specifies the seat number (seat_no).

Column	Type	Modifiers	Description
ticket_no	char(13)	NOT NULL	Ticket number
flight_id	integer	NOT NULL	Flight ID
boarding_no	integer	NOT NULL	Boarding pass number
seat_no	varchar(4)	NOT NULL	Seat number

Indexes:

```
PRIMARY KEY, btree (ticket_no, flight_id)
```

```
UNIQUE CONSTRAINT, btree (flight_id, boarding_no)
```

```
UNIQUE CONSTRAINT, btree (flight_id, seat_no)
```

Foreign-key constraints:

```
FOREIGN KEY (ticket_no, flight_id)
```

```
REFERENCES ticket_flights(ticket_no, flight_id)
```

J.4.5. Table bookings.bookings

Passengers book tickets for themselves, and, possibly, for several other passengers, in advance (book_date, not earlier than one month before the flight). The booking is identified by its number (book_ref, a six-position combination of letters and digits).

The total_amount field stores the total cost of all tickets included into the booking, for all passengers.

Column	Type	Modifiers	Description
book_ref	char(6)	NOT NULL	Booking number
book_date	timestampz	NOT NULL	Booking date
total_amount	numeric(10,2)	NOT NULL	Total booking cost

Indexes:

```
PRIMARY KEY, btree (book_ref)
```

Referenced by:

```
TABLE "tickets" FOREIGN KEY (book_ref) REFERENCES bookings(book_ref)
```

J.4.6. Table bookings.flights

The natural key of the bookings.flights table consists of two fields — flight_no and scheduled_departure. To make foreign keys for this table more compact, a surrogate key is used as the primary key (flight_id).

A flight always connects two points — the airport of departure (`departure_airport`) and arrival (`arrival_airport`). There is no such entity as a “connecting flight”: if there are no non-stop flights from one airport to another, the ticket simply includes several required flight segments.

Each flight has a scheduled date and time of departure (`scheduled_departure`) and arrival (`scheduled_arrival`). The actual departure time (`actual_departure`) and arrival time (`actual_arrival`) can differ: the difference is usually not very big, but sometimes can be up to several hours if the flight is delayed.

Flight status (`status`) can take one of the following values:

Scheduled

The flight is available for booking. It happens one month before the planned departure date; before that time, there is no entry for this flight in the database.

On Time

The flight is open for check-in (in twenty-four hours before the scheduled departure) and is not delayed.

Delayed

The flight is open for check-in (in twenty-four hours before the scheduled departure) but is delayed.

Departed

The aircraft has already departed and is airborne.

Arrived

The aircraft has reached the point of destination.

Cancelled

The flight is canceled.

Column	Type	Modifiers	Description
<code>flight_id</code>	<code>serial</code>	<code>NOT NULL</code>	Flight ID
<code>flight_no</code>	<code>char(6)</code>	<code>NOT NULL</code>	Flight number
<code>scheduled_departure</code>	<code>timestampz</code>	<code>NOT NULL</code>	Scheduled departure time
<code>scheduled_arrival</code>	<code>timestampz</code>	<code>NOT NULL</code>	Scheduled arrival time
<code>departure_airport</code>	<code>char(3)</code>	<code>NOT NULL</code>	Airport of departure
<code>arrival_airport</code>	<code>char(3)</code>	<code>NOT NULL</code>	Airport of arrival
<code>status</code>	<code>varchar(20)</code>	<code>NOT NULL</code>	Flight status
<code>aircraft_code</code>	<code>char(3)</code>	<code>NOT NULL</code>	Aircraft code, IATA
<code>actual_departure</code>	<code>timestampz</code>		Actual departure time
<code>actual_arrival</code>	<code>timestampz</code>		Actual arrival time

Indexes:

```
PRIMARY KEY, btree (flight_id)
UNIQUE CONSTRAINT, btree (flight_no, scheduled_departure)
```

Check constraints:

```
CHECK (scheduled_arrival > scheduled_departure)
CHECK ((actual_arrival IS NULL)
OR ((actual_departure IS NOT NULL AND actual_arrival IS NOT NULL)
AND (actual_arrival > actual_departure)))
CHECK (status IN ('On Time', 'Delayed', 'Departed',
'Arrived', 'Scheduled', 'Cancelled'))
```

Foreign-key constraints:

```
FOREIGN KEY (aircraft_code)
REFERENCES aircrafts(aircraft_code)
```

```

FOREIGN KEY (arrival_airport)
  REFERENCES airports(airport_code)
FOREIGN KEY (departure_airport)
  REFERENCES airports(airport_code)
Referenced by:
  TABLE "ticket_flights" FOREIGN KEY (flight_id)
    REFERENCES flights(flight_id)

```

J.4.7. Table bookings.seats

Seats define the cabin configuration of each aircraft model. Each seat is defined by its number (`seat_no`) and has an assigned travel class (`fare_conditions`): Economy, Comfort or Business.

Column	Type	Modifiers	Description
aircraft_code	char(3)	NOT NULL	Aircraft code, IATA
seat_no	varchar(4)	NOT NULL	Seat number
fare_conditions	varchar(10)	NOT NULL	Travel class

Indexes:

```
PRIMARY KEY, btree (aircraft_code, seat_no)
```

Check constraints:

```
CHECK (fare_conditions IN ('Economy', 'Comfort', 'Business'))
```

Foreign-key constraints:

```
FOREIGN KEY (aircraft_code)
  REFERENCES aircrafts(aircraft_code) ON DELETE CASCADE
```

J.4.8. Table bookings.ticket_flights

A flight segment connects a ticket with a flight and is identified by their numbers.

Each flight has its cost (`amount`) and travel class (`fare_conditions`).

Column	Type	Modifiers	Description
ticket_no	char(13)	NOT NULL	Ticket number
flight_id	integer	NOT NULL	Flight ID
fare_conditions	varchar(10)	NOT NULL	Travel class
amount	numeric(10,2)	NOT NULL	Travel cost

Indexes:

```
PRIMARY KEY, btree (ticket_no, flight_id)
```

Check constraints:

```
CHECK (amount >= 0)
```

```
CHECK (fare_conditions IN ('Economy', 'Comfort', 'Business'))
```

Foreign-key constraints:

```
FOREIGN KEY (flight_id) REFERENCES flights(flight_id)
```

```
FOREIGN KEY (ticket_no) REFERENCES tickets(ticket_no)
```

Referenced by:

```
TABLE "boarding_passes" FOREIGN KEY (ticket_no, flight_id)
  REFERENCES ticket_flights(ticket_no, flight_id)
```

J.4.9. Table bookings.tickets

A ticket has a unique number (`ticket_no`) that consists of 13 digits.

The ticket includes a passenger ID (`passenger_id`) — the identity document number, — their first and last names (`passenger_name`), and contact information (`contact_data`).

Neither the passenger ID, nor the name is permanent (for example, one can change the last name or passport), so it is impossible to uniquely identify all tickets of a particular passenger.

Column	Type	Modifiers	Description
ticket_no	char(13)	NOT NULL	Ticket number
book_ref	char(6)	NOT NULL	Booking number
passenger_id	varchar(20)	NOT NULL	Passenger ID
passenger_name	text	NOT NULL	Passenger name
contact_data	jsonb		Passenger contact information

Indexes:

PRIMARY KEY, btree (ticket_no)

Foreign-key constraints:

FOREIGN KEY (book_ref) REFERENCES bookings(book_ref)

Referenced by:

TABLE "ticket_flights" FOREIGN KEY (ticket_no) REFERENCES tickets(ticket_no)

J.4.10. View bookings.flights_v

There is a `flights_v` view over the `flights` table that provides additional information:

- Details about the airport of departure — `departure_airport`, `departure_airport_name`, `departure_city`
- Details about the airport of arrival — `arrival_airport`, `arrival_airport_name`, `arrival_city`
- Local departure time — `scheduled_departure_local`, `actual_departure_local`
- Local arrival time — `scheduled_arrival_local`, `actual_arrival_local`
- Flight duration — `scheduled_duration`, `actual_duration`.

Column	Type	Description
flight_id	integer	Flight ID
flight_no	char(6)	Flight number
scheduled_departure	timestamptz	Scheduled departure time
scheduled_departure_local	timestamp	Scheduled departure time, local time at the point of departure
scheduled_arrival	timestamptz	Scheduled arrival time
scheduled_arrival_local	timestamp	Scheduled arrival time, local time at the point of destination
scheduled_duration	interval	Scheduled flight duration
departure_airport	char(3)	Departure airport code
departure_airport_name	text	Departure airport name
departure_city	text	City of departure
arrival_airport	char(3)	Arrival airport code
arrival_airport_name	text	Arrival airport name
arrival_city	text	City of arrival
status	varchar(20)	Flight status
aircraft_code	char(3)	Aircraft code, IATA
actual_departure	timestamptz	Actual departure time
actual_departure_local	timestamp	Actual departure time, local time at the point of departure
actual_arrival	timestamptz	Actual arrival time
actual_arrival_local	timestamp	Actual arrival time, local time at the point of destination
actual_duration	interval	Actual flight duration

J.4.11. Materialized View `bookings.routes`

The `bookings.flights` table contains some redundancies, which you can use to single out route information (flight number, airports of departure and destination) that does not depend on the exact flight dates.

Such information constitutes the `routes` materialized view.

Column	Type	Description
<code>flight_no</code>	<code>char(6)</code>	Flight number
<code>departure_airport</code>	<code>char(3)</code>	Departure airport code
<code>departure_airport_name</code>	<code>text</code>	Departure airport name
<code>departure_city</code>	<code>text</code>	City of departure
<code>arrival_airport</code>	<code>char(3)</code>	Arrival airport code
<code>arrival_airport_name</code>	<code>text</code>	Arrival airport name
<code>arrival_city</code>	<code>text</code>	City of arrival
<code>aircraft_code</code>	<code>char(3)</code>	Aircraft code, IATA
<code>duration</code>	<code>interval</code>	Flight duration
<code>days_of_week</code>	<code>integer[]</code>	Days of the week on which flights are performed

J.4.12. Function `now`

The demo database contains “snapshots” of data — similar to a backup copy of a real system captured at some point in time. For example, if a flight has the `Departed` status, it means that the aircraft had already departed and was airborne at the time of the backup copy.

The “snapshot” time is saved in the `bookings.now()` function. You can use this function in demo queries for cases where you would use the `now()` function in a real database.

In addition, the return value of this function determines the version of the demo database. The latest version available is of October 13, 2016.

J.5. Usage

J.5.1. Schema `bookings`

The `bookings` schema contains all objects of the demo database. It means that when you access database objects, you either have to explicitly specify the schema name (for example: `bookings.flights`), or modify the `search_path` configuration parameter beforehand (for example: `SET search_path = bookings, public;`).

However, for the `bookings.now` function, you always have to specify the schema to distinguish this function from the standard `now` function.

J.5.2. Sample Queries

To better understand the contents of the demo database, let's take a look at the results of several simple queries.

The results displayed below were received on a small database version (`demo_small`) of October 13, 2016. If the same queries return different data on your system, check your demo database version (using the `bookings.now` function). Some minor deviations may be caused by the difference between your local time and Moscow time, or your locale settings.

All flights are operated by several types of aircraft:

```
SELECT * FROM aircrafts;
```

aircraft_code	model	range
773	Boeing 777-300	11100
763	Boeing 767-300	7900
SU9	Sukhoi SuperJet-100	3000
320	Airbus A320-200	5700
321	Airbus A321-200	5600
319	Airbus A319-100	6700
733	Boeing 737-300	4200
CN1	Cessna 208 Caravan	1200
CR2	Bombardier CRJ-200	2700

(9 rows)

For each aircraft type, a separate list of seats is supported. For example, in a small Cessna 208 Caravan, one can select the following seats:

```

SELECT  a.aircraft_code,
        a.model,
        s.seat_no,
        s.fare_conditions
FROM    aircrafts a
        JOIN seats s ON a.aircraft_code = s.aircraft_code
WHERE   a.model = 'Cessna 208 Caravan'
ORDER BY s.seat_no;

```

aircraft_code	model	seat_no	fare_conditions
CN1	Cessna 208 Caravan	1A	Economy
CN1	Cessna 208 Caravan	1B	Economy
CN1	Cessna 208 Caravan	2A	Economy
CN1	Cessna 208 Caravan	2B	Economy
CN1	Cessna 208 Caravan	3A	Economy
CN1	Cessna 208 Caravan	3B	Economy
CN1	Cessna 208 Caravan	4A	Economy
CN1	Cessna 208 Caravan	4B	Economy
CN1	Cessna 208 Caravan	5A	Economy
CN1	Cessna 208 Caravan	5B	Economy
CN1	Cessna 208 Caravan	6A	Economy
CN1	Cessna 208 Caravan	6B	Economy

(12 rows)

Bigger aircraft have more seats of various travel classes:

```

SELECT  s2.aircraft_code,
        string_agg (s2.fare_conditions || '(' || s2.num::text || ')',
                    ', ') as fare_conditions
FROM    (
        SELECT  s.aircraft_code, s.fare_conditions, count(*) as num
        FROM    seats s
        GROUP BY s.aircraft_code, s.fare_conditions
        ORDER BY s.aircraft_code, s.fare_conditions
        ) s2
GROUP BY s2.aircraft_code
ORDER BY s2.aircraft_code;

```

aircraft_code	fare_conditions
319	Business (20), Economy (96)
320	Business (20), Economy (120)
321	Business (28), Economy (142)
733	Business (12), Economy (118)
763	Business (30), Economy (192)
773	Business (30), Comfort (48), Economy (324)
CN1	Economy (12)
CR2	Economy (50)
SU9	Business (12), Economy (85)

(9 rows)

The demo database contains the list of airports of almost all major Russian cities. Most cities have only one airport. The exceptions are:

```

SELECT  a.airport_code as code,
        a.airport_name,
        a.city,
        a.longitude,
        a.latitude,
        a.timezone
FROM    airports a
WHERE   a.city IN (
        SELECT  aa.city
        FROM    airports aa
        GROUP BY aa.city
        HAVING  COUNT(*) > 1
      )
ORDER BY a.city, a.airport_code;

```

code	airport_name	city	longitude	latitude	timezone
DME	Домодедово	Москва	37.906111	55.408611	Europe/Moscow
SVO	Шереметьево	Москва	37.414589	55.972642	Europe/Moscow
VKO	Внуково	Москва	37.261486	55.591531	Europe/Moscow
ULV	Баратаевка	Ульяновск	48.2267	54.268299	Europe/Samara
ULY	Ульяновск-Восточный	Ульяновск	48.8027	54.401	Europe/Samara

(5 rows)

To learn about your flying options from one point to another, it is convenient to use the routes materialized view that aggregates information on all flights. For example, here are the destinations where you can get from Volgograd on specific days of the week, with flight duration:

```

SELECT r.arrival_city as city,
       r.arrival_airport as airport_code,
       r.arrival_airport_name as airport_name,
       r.days_of_week,
       r.duration
FROM   routes r
WHERE  r.departure_city = 'Волгоград';

```

city	airport_code	airport_name	days_of_week	duration
Москва	SVO	Шереметьево	{1,2,3,4,5,6,7}	01:15:00
Челябинск	CEK	Челябинск	{1,2,3,4,5,6,7}	01:50:00

```

Ростов-на-Дону | ROV          | Ростов-на-Дону | {1,2,3,4,5,6,7} | 00:30:00
Москва         | VKO          | Внуково        | {1,2,3,4,5,6,7} | 01:10:00
Чебоксары     | CSY          | Чебоксары     | {1,2,3,4,5,6,7} | 02:45:00
Томск         | TOF          | Богашёво      | {3}              | 03:50:00
(6 rows)

```

The database was formed at the moment returned by the `bookings.now()` function:

```
SELECT bookings.now() as now;
```

```

          now
-----
2016-10-13 17:00:00+03

```

In relation to this moment, all flights are classified as past and future flights:

```

SELECT  status,
        count(*) as count,
        min(scheduled_departure) as min_scheduled_departure,
        max(scheduled_departure) as max_scheduled_departure
FROM    flights
GROUP BY status
ORDER BY min_scheduled_departure;
```

```

 status | count | min_scheduled_departure | max_scheduled_departure
-----+-----+-----+-----
Arrived | 16707 | 2016-09-13 00:50:00+03 | 2016-10-13 16:25:00+03
Cancelled | 414 | 2016-09-16 10:35:00+03 | 2016-11-12 19:55:00+03
Departed | 58 | 2016-10-13 08:55:00+03 | 2016-10-13 16:50:00+03
Delayed | 41 | 2016-10-13 14:15:00+03 | 2016-10-14 16:25:00+03
On Time | 518 | 2016-10-13 16:55:00+03 | 2016-10-14 17:00:00+03

(6 rows)

```

Let's find the next flight from Yekaterinburg to Moscow. The `flight` table is not very convenient for such queries, as it does not include information on the cities of departure and arrival. That is why we will use the `flights_v` view:

```

\x
SELECT  f.*
FROM    flights_v f
WHERE    f.departure_city = 'Екатеринбург'
AND      f.arrival_city = 'Москва'
AND      f.scheduled_departure > bookings.now()
ORDER BY f.scheduled_departure
LIMIT   1;
```

```

-[ RECORD 1 ]-----+-----
flight_id      | 10927
flight_no      | PG0226
scheduled_departure | 2016-10-14 07:10:00+03
scheduled_departure_local | 2016-10-14 09:10:00
scheduled_arrival | 2016-10-14 08:55:00+03
scheduled_arrival_local | 2016-10-14 08:55:00
scheduled_duration | 01:45:00
departure_airport | SVX

```

departure_airport_name		Кольцово
departure_city		Екатеринбург
arrival_airport		SVO
arrival_airport_name		Шереметьево
arrival_city		Москва
status		On Time
aircraft_code		773
actual_departure		
actual_departure_local		
actual_arrival		
actual_arrival_local		
actual_duration		

Note that the `flights_v` view shows both Moscow time and local time at the airports of departure and arrival.

J.5.3. Bookings

Each booking can include several tickets, one for each passenger. The ticket, in its turn, can include several flight segments. The complete information about the booking is stored in three tables: `bookings`, `tickets`, and `ticket_flights`.

Let's find several most expensive bookings:

```
SELECT  *
FROM    bookings
ORDER BY total_amount desc
LIMIT   10;
```

book_ref		book_date		total_amount
-----+-----+-----				
3B54BB		2016-09-02 16:08:00+03		1204500.00
3AC131		2016-09-28 00:06:00+03		1087100.00
65A6EA		2016-08-31 05:28:00+03		1065600.00
D7E9AA		2016-10-06 04:29:00+03		1062800.00
EF479E		2016-09-30 14:58:00+03		1035100.00
521C53		2016-09-05 08:25:00+03		985500.00
514CA6		2016-09-24 04:07:00+03		955000.00
D70BD9		2016-09-02 11:47:00+03		947500.00
EC7EDA		2016-08-30 15:13:00+03		946800.00
8E4370		2016-09-25 01:04:00+03		945700.00
(10 rows)				

Let's take a look at the tickets included into the booking with code 521C53:

```
SELECT ticket_no,
       passenger_id,
       passenger_name
FROM   tickets
WHERE  book_ref = '521C53';
```

ticket_no		passenger_id		passenger_name
-----+-----+-----				
0005432661914		8234 547529		IVAN IVANOV
0005432661915		2034 201228		ANTONINA KUZNECOVA
(2 rows)				

If we would like to know, which flight segments are included into Antonina Kuznecova's ticket, we can use the following query:

```
SELECT    to_char(f.scheduled_departure, 'DD.MM.YYYY') as when,
          f.departure_city || '(' || f.departure_airport || ')' as departure,
          f.arrival_city || '(' || f.arrival_airport || ')' as arrival,
          tf.fare_conditions as class,
          tf.amount
FROM      ticket_flights tf
          JOIN flights_v f ON tf.flight_id = f.flight_id
WHERE     tf.ticket_no = '0005432661915'
ORDER BY  f.scheduled_departure;
```

when	departure	arrival	class	amount
26.09.2016	Москва (SVO)	Анадырь (DYR)	Business	185300.00
30.09.2016	Анадырь (DYR)	Хабаровск (KHV)	Business	92200.00
01.10.2016	Хабаровск (KHV)	Благовещенск (BQS)	Business	18000.00
06.10.2016	Благовещенск (BQS)	Хабаровск (KHV)	Business	18000.00
10.10.2016	Хабаровск (KHV)	Анадырь (DYR)	Economy	30700.00
15.10.2016	Анадырь (DYR)	Москва (SVO)	Business	185300.00

(6 rows)

As we can see, high booking cost is explained by multiple long-haul flights in business class.

Some of the flight segments in this ticket have earlier dates than the `bookings.now()` return value: it means that these flights had already happened. The last flight had not happened yet at the time of the database creation. After the check-in, a boarding pass with the allocated seat number is issued. We can check the exact seats occupied by Antonina (note the outer left join with table `boarding_passes`):

```
SELECT    to_char(f.scheduled_departure, 'DD.MM.YYYY') as when,
          f.departure_city || '(' || f.departure_airport || ')' as departure,
          f.arrival_city || '(' || f.arrival_airport || ')' as arrival,
          f.status,
          bp.seat_no
FROM      ticket_flights tf
          JOIN flights_v f ON tf.flight_id = f.flight_id
          LEFT JOIN boarding_passes bp ON tf.flight_id = bp.flight_id
          AND tf.ticket_no = bp.ticket_no
WHERE     tf.ticket_no = '0005432661915'
ORDER BY  f.scheduled_departure;
```

when	departure	arrival	status	seat_no
26.09.2016	Москва (SVO)	Анадырь (DYR)	Arrived	5C
30.09.2016	Анадырь (DYR)	Хабаровск (KHV)	Arrived	1D
01.10.2016	Хабаровск (KHV)	Благовещенск (BQS)	Arrived	2C
06.10.2016	Благовещенск (BQS)	Хабаровск (KHV)	Arrived	2D
10.10.2016	Хабаровск (KHV)	Анадырь (DYR)	Arrived	20B
15.10.2016	Анадырь (DYR)	Москва (SVO)	Scheduled	

(6 rows)

J.5.4. New Booking

Let's try to send Aleksandr Radishchev from Saint Petersburg to Moscow — the route that made him famous. Naturally, he will travel for free and in business class. We have already found a flight for tomorrow, and a return flight a week later.

```
BEGIN;

INSERT INTO bookings (book_ref, book_date, total_amount)
VALUES      ('_QWE12', bookings.now(), 0);

INSERT INTO tickets (ticket_no, book_ref, passenger_id, passenger_name)
VALUES      ('_0000000000001', '_QWE12', '1749 051790', 'ALEKSANDR RADISHCHEV');

INSERT INTO ticket_flights (ticket_no, flight_id, fare_conditions, amount)
VALUES      ('_0000000000001', 9720, 'Business', 0),
            ('_0000000000001', 6662, 'Business', 0);

COMMIT;
```

To avoid conflicts with the range of values present in the database, identifiers are started with an underscore.

We will check in Aleksandr for tomorrow's flight right away:

```
INSERT INTO boarding_passes (ticket_no, flight_id, boarding_no, seat_no)
VALUES      ('_0000000000001', 9720, 1, '1A');
```

Now let's check the booking information:

```
SELECT      b.book_ref,
            t.ticket_no,
            t.passenger_id,
            t.passenger_name,
            tf.fare_conditions,
            tf.amount,
            f.scheduled_departure_local,
            f.scheduled_arrival_local,
            f.departure_city || '(' || f.departure_airport || ')' as departure,
            f.arrival_city || '(' || f.arrival_airport || ')' as arrival,
            f.status,
            bp.seat_no
FROM        bookings b
            JOIN tickets t ON b.book_ref = t.book_ref
            JOIN ticket_flights tf ON tf.ticket_no = t.ticket_no
            JOIN flights_v f ON tf.flight_id = f.flight_id
            LEFT JOIN boarding_passes bp ON tf.flight_id = bp.flight_id
                                AND tf.ticket_no = bp.ticket_no

WHERE       b.book_ref = '_QWE12'
ORDER BY   t.ticket_no, f.scheduled_departure;
```

```
-[ RECORD 1 ]-----+-----
book_ref          | _QWE12
ticket_no         | _0000000000001
passenger_id      | 1749 051790
passenger_name    | ALEKSANDR RADISHCHEV

scheduled_arrival_local   | 2016-10-14 09:35:00
departure         | Санкт-Петербург (LED)
arrival           | Москва (SVO)
status            | On Time
```

```
seat_no          | 1A
-[ RECORD 2 ]-----+-----
book_ref         | _QWE12
ticket_no        | _0000000000001
passenger_id     | 1749 051790
passenger_name   | ALEKSANDR RADISHCHEV
fare_conditions  | Business
amount           | 0.00
scheduled_departure_local | 2016-10-21 09:20:00
scheduled_arrival_local   | 2016-10-21 10:10:00
departure        | Москва (SVO)
arrival          | Санкт-Петербург (LED)
status           | Scheduled
seat_no          |
```

We hope that these simple examples helped you get an idea of this demo database.

Appendix K. Acronyms

This is a list of acronyms commonly used in the Postgres Pro documentation and in discussions about Postgres Pro.

ANSI

American National Standards Institute

API

Application Programming Interface

ASCII

American Standard Code for Information Interchange

BKI

Backend Interface

CA

Certificate Authority

CIDR

Classless Inter-Domain Routing

CPAN

Comprehensive Perl Archive Network

CRL

Certificate Revocation List
