- Limit the amount of cleanup work done by `get_actual_variable_range` (Simon Riggs)

  Planner runs occurring just after deletion of a large number of tuples appearing at the end of an index could expend significant amounts of work setting the “killed” bits for those index entries. Limit the amount of work done in any one query by giving up on this process after examining 100 heap pages. All the cleanup will still happen eventually, but without so large a performance hiccup.

- Fix under-parenthesized display of `AT TIME ZONE` constructs (Tom Lane)

  This could result in dump/restore failures for rules or views in which an argument of `AT TIME ZONE` is itself an expression.

- Prevent clobbering of cached parsetrees for utility statements in SQL functions (Tom Lane, Daniel Gustafsson)

  If a SQL-language function executes the same utility command more than once within a single calling query, it could crash or report strange errors such as “unrecognized node type”.

- Ensure that execution of full-text-search queries can be cancelled while they are performing phrase matches (Tom Lane)

- Fix memory leak in hashing strings with nondeterministic collations (Jeff Davis)

- Fix deadlock between `DROP DATABASE` and logical replication worker process (Hou Zhijie)

This was caused by an ill-advised choice to block interrupts while creating a logical replication slot in the worker. In version 15 that could lead to an undetected deadlock. In version 14, no deadlock has been observed, but it's still a bad idea to block interrupts while waiting for network I/O.

- Clean up the libpq connection object after a failed replication connection attempt (Andres Freund)

  The previous coding leaked the connection object. In background code paths that's pretty harmless because the calling process will give up and exit. But in commands such as `CREATE SUBSCRIPTION`, such a failure resulted in a small session-lifespan memory leak.

- In hot-standby servers, reduce processing effort for tracking XIDs known to be active on the primary (Simon Riggs, Michail Nikolaev)

  Insufficiently-aggressive cleanup of the KnownAssignedXids array could lead to poor performance, particularly when `max_connections` is set to a large value on the standby.

- Ignore invalidated logical-replication slots while determining oldest catalog xmin (Sirisha Chamarthi)

  A replication slot could prevent cleanup of dead tuples in the system catalogs even after it becomes invalidated due to exceeding `max_slot_wal_keep_size`. Thus, failure of a replication consumer could lead to indefinitely-large catalog bloat.

- In logical decoding, notify the remote node when a transaction is detected to have crashed (Hou Zhijie)

  After a server restart, we'll re-stream the changes for transactions occurring shortly before the restart. Some of these transactions probably never completed; when we realize that one didn't we throw away the relevant decoding state locally, but we neglected to tell the subscriber about it. That led to the subscriber keeping useless streaming files until it's next restarted.

- Fix uninitialized-memory usage in logical decoding (Masahiko Sawada)

  In certain cases, resumption of logical decoding could try to re-use XID data that had already been freed, leading to unpredictable behavior.

- Avoid rare “failed to acquire cleanup lock” panic during WAL replay of hash-index page split operations (Robert Haas)

- Advance a heap page's LSN when setting its all-visible bit during WAL replay (Jeff Davis)

  Failure to do this left the page possibly different on standby servers than the primary, and violated some other expectations about when the LSN changes. This seems only a theoretical hazard so far as PostgreSQL itself is concerned, but it could upset third-party tools.

- Prevent unsafe usage of a relation cache entry's `rd_smgr` pointer (Amul Sul)

  Remove various assumptions that `rd_smgr` would stay valid over a series of operations, by wrapping all uses of it in a function that will recompute it if needed. This prevents bugs occurring when an unexpected cache flush occurs partway through such a series.

- Fix `int64_div_fast_to_numeric()` to work for a wider range of inputs (Dean Rasheed)

  This function misbehaved with some values of its second argument. No such usages exist in core PostgreSQL, but it's clearly a hazard for external modules, so repair.

- Fix latent buffer-overrun problem in `WaitEventSet` logic (Thomas Munro)

  The `epoll`-based and `kqueue`-based implementations could ask the kernel for too many events if the size of their internal buffer was different from the size of the caller's output buffer. That case is not known to occur in released PostgreSQL versions, but this error is a hazard for external modules and future bug fixes.

- Avoid nominally-undefined behavior when accessing shared memory in 32-bit builds (Andres Freund)

clang's undefined-behavior sanitizer complained about use of a pointer that was less aligned than it should be. It's very unlikely that this would cause a problem in non-debug builds, but it's worth fixing for testing purposes.

- Fix assertion failure in BRIN minmax-multi opclasses (Tomas Vondra)

  The assertion was overly strict, so this mistake was harmless in non-assert builds.
- Remove faulty assertion in useless-RESULT-RTE optimization logic (Tom Lane)
- Fix copy-and-paste errors in cache-lookup-failure messages for ACL checks (Justin Pryzby)

  In principle these errors should never be reached. But if they are, some of them reported the wrong type of object.
- In pg_dump, avoid calling unsafe server functions before we have locks on the tables to be examined (Tom Lane, Gilles Darold)

  pg_dump uses certain server functions that can fail if examining a table that gets dropped concurrently. Avoid this type of failure by ensuring that we obtain access share lock before inquiring too deeply into a table's properties, and that we don't apply such functions to tables we don't intend to dump at all.
- Fix psql's `\sf` and `\ef` commands to handle SQL-language functions that have SQL-standard function bodies (Tom Lane)

  These commands misidentified the start of the function body when it used new-style syntax.
- Fix tab completion of `ALTER FUNCTION/PROCEDURE/ROUTINE ... SET SCHEMA` (Dean Rasheed)
- Fix `contrib/seg` to not crash or print garbage if an input number has more than 127 digits (Tom Lane)
- Fix build on Microsoft Visual Studio 2013 (Tom Lane)

  A previous patch supposed that all platforms of interest have `snprintf()`, but MSVC 2013 isn't quite there yet. Revert to using `sprintf()` on that platform.
- Fix compile failure in building PL/Perl with MSVC when using Strawberry Perl (Andrew Dunstan)
- Fix mismatch of PL/Perl built with MSVC versus a Perl library built with gcc (Andrew Dunstan)

  Such combinations could previously fail with “loadable library and perl binaries are mismatched” errors.
- Suppress compiler warnings from Perl's header files (Andres Freund)

  Our preferred compiler options provoke warnings about constructs appearing in recent versions of Perl's header files. When using gcc, we can suppress these warnings with a pragma.
- Fix pg_waldump to build on compilers that don't discard unused static-inline functions (Tom Lane)
- Update time zone data files to tzdata release 2022g for DST law changes in Greenland and Mexico, plus historical corrections for northern Canada, Colombia, and Singapore. (Tom Lane)

  Notably, a new timezone America/Ciudad_Juarez has been split off from America/Ojinaga.

E.37. Release 14.6

Release date: 2022-11-10

This release contains a variety of fixes from 14.5. For information about new features in major release 14, see Section E.43.

E.37.1. Migration to Version 14.6

A dump/restore is not required for those running 14.X.

However, if you are upgrading from a version earlier than 14.4, see Section E.39.

E.37.2. Changes

- Avoid rare PANIC during updates occurring concurrently with VACUUM (Tom Lane, Jeff Davis)

  If a concurrent VACUUM sets the all-visible flag bit in a page that UPDATE or DELETE is in process of modifying, the updating command needs to clear that bit again; but some code paths failed to do so, ending in a PANIC exit and database restart.

  This is known to be possible in versions 14 and 15. It may be only latent in previous branches.

- Fix handling of DEFAULT tokens that appear in a multi-row VALUES clause of an INSERT on an updatable view (Tom Lane)

  This oversight could lead to “cache lookup failed for type” errors, or in older branches even to crashes.

- Disallow rules named _RETURN that are not ON SELECT (Tom Lane)

  This avoids confusion between a view's ON SELECT rule and any other rules it may have.

- Fix resource management bug in saving tuples for AFTER triggers (Tom Lane)

  Given the right circumstances, this manifested as a “tupdesc reference *NNNN* is not owned by resource owner” error followed by a PANIC exit.

- Avoid failure in EXPLAIN VERBOSE for a query using SEARCH BREADTH FIRST with constant initial values (Tom Lane)

- Fix construction of per-partition foreign key constraints while doing ALTER TABLE ATTACH PARTITION (Jehan-Guillaume de Rorthais, Álvaro Herrera)

  Previously, incorrect or duplicate constraints could be constructed for the newly-added partition.

- Fix generation of constraint names for per-partition foreign key constraints (Jehan-Guillaume de Rorthais)

  If the initially-given name is already in use for some constraint of the partition, a new one is selected; but it wasn't being spelled as intended.

- Fix incorrect matching of index expressions and predicates when creating a partitioned index (Richard Guo, Tom Lane)

  While creating a partitioned index, we try to identify any existing indexes on the partitions that match the partitioned index, so that we can absorb those as child indexes instead of building new ones. Matching of expressions was not done right, so that a usable child index might be ignored, leading to creation of a duplicative index.

- Prevent WAL corruption after a standby promotion (Dilip Kumar, Robert Haas)

  When a PostgreSQL instance performing archive recovery (but not using standby mode) is promoted, and the last WAL segment that it attempted to read ended in a partial record, the instance would write an invalid WAL segment on the new timeline.

- Fix mis-ordering of WAL operations in fast insert path for GIN indexes (Matthias van de Meent, Zhang Mingli)

  This mistake is not known to have any negative consequences within core PostgreSQL, but it did cause issues for some extensions.

- Fix bugs in logical decoding when replay starts from a point between the beginning of a transaction and the beginning of its subtransaction (Masahiko Sawada, Kuroda Hayato)

  These errors could lead to assertion failures in debug builds, and otherwise to memory leaks.

- Prevent examining system catalogs with the wrong snapshot during logical decoding (Masahiko Sawada)

  If decoding begins partway through a transaction that modifies system catalogs, the decoder may not recognize that, causing it to fail to treat that transaction as in-progress for catalog lookups.

- Accept interrupts in more places during logical decoding (Amit Kapila, Masahiko Sawada)

  This ameliorates problems with slow shutdown of replication workers.

- Prevent attempts to replicate into a foreign-table partition in replication workers (Shi Yu, Tom Lane)

  Although partitioned tables can have foreign tables as partitions, replicating into such a partition isn't currently supported. The logical replication worker process would crash if it was attempted. Now, an error is thrown.

- Remove pointless check on replica identity setting of partitioned tables (Hou Zhijie)

  What matters is the replica identity setting of the leaf partitions, so there's no need to throw error if it's not set on the parent.

- Avoid crash after function syntax error in replication workers (Maxim Orlov, Anton Melnikov, Masahiko Sawada, Tom Lane)

  If a syntax error occurred in a SQL-language or PL/pgSQL-language `CREATE FUNCTION` or `DO` command executed in a logical replication worker, the worker process would crash with a null pointer dereference or assertion failure.

- Fix handling of read-write expanded datums that are passed to SQL functions (Tom Lane)

  If a non-inlined SQL function uses a parameter in more than one place, and one of those functions expects to be able to modify read-write datums in place, then later uses of the parameter would observe the wrong value. (Within core PostgreSQL, the expanded-datum mechanism is only used for array and composite-type values; but extensions might use it for other structured types.)

- Fix type `circle`'s equality comparator to handle NaNs properly (Ranier Vilela)

  If the left-hand circle had a floating-point NaN for its radius, it would be considered equal to a circle with the same center and any radius.

- In Snowball dictionaries, don't try to stem excessively-long words (Olly Betts, Tom Lane)

  If the input word exceeds 1000 bytes, return it as-is after case folding, rather than trying to run it through the Snowball code. This restriction protects against a known recursion-to-stack-overflow problem in the Turkish stemmer, and it seems like good insurance against any other safety or performance issues that may exist in the Snowball stemmers. Such a long string is surely not a word in any human language, so it's doubtful that the stemmer would have done anything desirable with it anyway.

- Fix use-after-free hazard in string comparisons (Tom Lane)

  Improper memory management in the string comparison functions could result in scribbling on no-longer-allocated buffers, potentially breaking things for whatever is using that memory now. This would only happen with fairly long strings (more than 1kB), and only if an ICU collation is in use.

- Add plan-time check for attempted access to a table that has no table access method (Tom Lane)

  This prevents a crash in some catalog-corruption scenarios, for example use of a view whose `ON SELECT` rule is missing.

- Prevent postmaster crash when shared-memory state is corrupted (Tom Lane)

  The postmaster process is supposed to survive and initiate a database restart if shared memory becomes corrupted, but one bit of code was being insufficiently cautious about that.

- Add some more defenses against recursion till stack overrun (Richard Guo, Tom Lane)
- Avoid misbehavior when choosing hash table size with very small `work_mem` and large tuples (Zhang Mingli)
- Avoid long-term memory leakage in the autovacuum launcher process (Reid Thompson)

  The lack of field reports suggests that this problem is only latent in pre-v15 branches; but it's not very clear why, so back-patch the fix anyway.
- Improve PL/pgSQL's ability to handle parameters declared as `RECORD` (Tom Lane)

  Build a separate function cache entry for each concrete type passed to the `RECORD` parameter during a session, much as we do for polymorphic parameters. This allows some usages to work that previously failed with errors such as “type of parameter does not match that when preparing the plan”.
- In libpq, handle single-row mode correctly when pipelining (Denis Laxalde)

  The single-row flag was not reset at the correct time if pipeline mode was also active.
- Add missing guards for `NULL` connection pointer in libpq (Daniele Varrazzo, Tom Lane)

  There's a convention that libpq functions should check for a NULL PGconn argument, and fail gracefully instead of crashing. `PQflush()` and `PQisnonblocking()` didn't get that memo, so fix them.
- In ecpg, fix omission of variable storage classes when multiple `varchar` or `bytea` variables are declared in the same declaration (Andrey Sokolov)

  For example, ecpg translated `static varchar str1[10], str2[20], str3[30];` in such a way that only `str1` was marked `static`.
- Allow cross-platform tablespace relocation in pg_basebackup (Robert Haas)

  Allow the remote path in `--tablespace-mapping` to be either a Unix-style or Windows-style absolute path, since the source server could be on a different OS than the local system.
- In pg_stat_statements, fix access to already-freed memory (zhaoqigui)

  This occurred if pg_stat_statements tracked a `ROLLBACK` command issued via extended query protocol. In debug builds it consistently led to an assertion failure. In production builds there would often be no visible ill effect; but if the freed memory had already been reused, the likely result would be to store garbage for the query string.
- In postgres_fdw, ensure that target lists constructed for EvalPlanQual plans will have all required columns (Richard Guo, Etsuro Fujita)

  This avoids “variable not found in subplan target list” errors in rare cases.
- Reject unwanted output from the platform's `uuid_create()` function (Nazir Bilal Yavuz)

  The uuid-ossp module expects libc's `uuid_create()` to produce a version-1 UUID, but recent NetBSD releases produce a version-4 (random) UUID instead. Check for that, and complain if so. Drop the documentation's claim that the NetBSD implementation is usable for uuid-ossp. (If a version-4 UUID is okay for your purposes, you don't need uuid-ossp at all; just use `gen_random_uuid()`.)
- Include new Perl test modules in standard installations (Álvaro Herrera)

  Add `PostgreSQL/Test/Cluster.pm` and `PostgreSQL/Test/Utils.pm` to the standard installation file set in pre-version-15 branches. This is for the benefit of extensions that want to use newly-written test code in older branches.
- On NetBSD, force dynamic symbol resolution at postmaster start (Andres Freund, Tom Lane)

  This avoids a risk of deadlock in the dynamic linker on NetBSD 10.

- Fix incompatibilities with LLVM 15 (Thomas Munro, Andres Freund)
- Allow use of `__sync_lock_test_and_set()` for spinlocks on any machine (Tom Lane)

  This eases porting to new machine architectures, at least if you're using a compiler that supports this GCC builtin function.
- Rename symbol `REF` to `REF_P` to avoid compile failure on recent macOS (Tom Lane)
- Avoid using `sprintf`, to avoid compile-time deprecation warnings (Tom Lane)
- Silence assorted compiler warnings from clang 15 and later (Tom Lane)
- Update time zone data files to tzdata release 2022f for DST law changes in Chile, Fiji, Iran, Jordan, Mexico, Palestine, and Syria, plus historical corrections for Chile, Crimea, Iran, and Mexico. (Tom Lane)

  Also, the Europe/Kiev zone has been renamed to Europe/Kyiv. Also, the following zones have been merged into nearby, more-populous zones whose clocks have agreed with them since 1970: Antarctica/Vostok, Asia/Brunei, Asia/Kuala_Lumpur, Atlantic/Reykjavik, Europe/Amsterdam, Europe/Copenhagen, Europe/Luxembourg, Europe/Monaco, Europe/Oslo, Europe/Stockholm, Indian/Christmas, Indian/Cocos, Indian/Kerguelen, Indian/Mahe, Indian/Reunion, Pacific/Chuuk, Pacific/Funafuti, Pacific/Majuro, Pacific/Pohnpei, Pacific/Wake and Pacific/Wallis. (This indirectly affects zones that were already links to one of these: Arctic/Longyearbyen, Atlantic/Jan_Mayen, Iceland, Pacific/Ponape, Pacific/Truk, and Pacific/Yap.) America/Nipigon, America/Rainy_River, America/Thunder_Bay, Europe/Uzhgorod, and Europe/Zaporozhye were also merged into nearby zones after discovering that their claimed post-1970 differences from those zones seem to have been errors. In all these cases, the previous zone name remains as an alias; but the actual data is that of the zone that was merged into.

  These zone mergers result in loss of pre-1970 timezone history for the merged zones, which may be troublesome for applications expecting consistency of `timestamptz` display. As an example, the stored value `1944-06-01 12:00 UTC` would previously display as `1944-06-01 13:00:00+01` if the Europe/Stockholm zone is selected, but now it will read out as `1944-06-01 14:00:00+02`.

  It is possible to build the time zone data files with options that will restore the older zone data, but that choice also inserts a lot of other old (and typically poorly-attested) zone data, resulting in more total changes from the previous release than accepting these upstream changes does. PostgreSQL has chosen to ship the tzdb data as-recommended, and so far as we are aware most major operating system distributions are doing likewise. However, if these changes cause significant problems for your application, a possible solution is to install a local build of the time zone data files using tzdb's backwards-compatibility options (see their `PACKRATDATA` and `PACKRATLIST` options).

E.38. Release 14.5

Release date: 2022-08-11

This release contains a variety of fixes from 14.4. For information about new features in major release 14, see Section E.43.

E.38.1. Migration to Version 14.5

A dump/restore is not required for those running 14.X.

However, if you are upgrading from a version earlier than 14.4, see Section E.39.

E.38.2. Changes

- Do not let extension scripts replace objects not already belonging to the extension (Tom Lane)

  This change prevents extension scripts from doing `CREATE OR REPLACE` if there is an existing object that does not belong to the extension. It also prevents `CREATE IF NOT EXISTS` in the same situation. This prevents a form of trojan-horse attack in which a hostile database user could become the

owner of an extension object and then modify it to compromise future uses of the object by other users. As a side benefit, it also reduces the risk of accidentally replacing objects one did not mean to.

The PostgreSQL Project thanks Sven Klemm for reporting this problem. (CVE-2022-2625)

- Fix replay of `CREATE DATABASE` WAL records on standby servers (Kyotaro Horiguchi, Asim R Praveen, Paul Guo)

  Standby servers may encounter missing tablespace directories when replaying database-creation WAL records. Prior to this patch, a standby would fail to recover in such a case; however, such directories could be legitimately missing. Create the tablespace (as a plain directory), then check that it has been dropped again once replay reaches a consistent state.

- Support “in place” tablespaces (Thomas Munro, Michael Paquier, Álvaro Herrera)

  Normally a Postgres tablespace is a symbolic link to a directory on some other filesystem. This change allows it to just be a plain directory. While this has no use for separating tables onto different filesystems, it is a convenient setup for testing. Moreover, it is necessary to support the `CREATE DATABASE` replay fix, which transiently creates a missing tablespace as an “in place” tablespace.

- Fix permissions checks in `CREATE INDEX` (Nathan Bossart, Noah Misch)

  The fix for CVE-2022-1552 caused `CREATE INDEX` to apply the table owner's permissions while performing lookups of operator classes and other objects, where formerly the calling user's permissions were used. This broke dump/restore scenarios, because pg_dump issues `CREATE INDEX` before re-granting permissions.

- In extended query protocol, force an immediate commit after `CREATE DATABASE` and other commands that can't run in a transaction block (Tom Lane)

  If the client does not send a Sync message immediately after such a command, but instead sends another command, any failure in that command would lead to rolling back the preceding command, typically leaving inconsistent state on-disk (such as a missing or extra database directory). The mechanisms intended to prevent that situation turn out to work for multiple commands in a simple-Query message, but not for a series of extended-protocol messages. To prevent inconsistency without breaking use-cases that work today, force an implicit commit after such commands.

- Fix race condition when checking transaction visibility (Simon Riggs)

  `TransactionIdIsInProgress` could report `false` before the subject transaction is considered visible, leading to various misbehaviors. The race condition window is normally very narrow, but use of synchronous replication makes it much wider, because the wait for a synchronous replica happens in that window.

- Fix incorrect plans when sorting by an expression that contains a non-top-level set-returning function (Richard Guo, Tom Lane)

- Fix incorrect permissions-checking code for extended statistics (Richard Guo)

  If there are extended statistics on a table that the user has only partial `SELECT` permissions on, some queries would fail with “unrecognized node type” errors.

- Fix extended statistics machinery to handle MCV-type statistics on boolean-valued expressions (Tom Lane)

  Statistics collection worked fine, but a query containing such an expression in `WHERE` would fail with “unknown clause type”.

- Avoid planner core dump with *`constant`* `= ANY(`*`array`*`)` clauses when there are MCV-type extended statistics on the *`array`* variable (Tom Lane)

- Fix `ALTER TABLE ... ENABLE/DISABLE TRIGGER` to handle recursion correctly for triggers on partitioned tables (Álvaro Herrera, Amit Langote)

In certain cases, a “trigger does not exist” failure would occur because the command would try to adjust the trigger on a child partition that doesn't have it.

- Allow cancellation of `ANALYZE` while it is computing extended statistics (Tom Lane, Justin Pryzby)

  In some scenarios with high statistics targets, it was possible to spend many seconds in an un-cancellable sort operation.

- Improve syntax error messages for type `jsonpath` (Andrew Dunstan)
- Ensure that `pg_stop_backup()` cleans up session state properly (Fujii Masao)

  This omission could lead to assertion failures or crashes later in the session.

- Fix `trim_array()` to handle a zero-dimensional array argument sanely (Martin Kalcher)
- Fix join alias matching in `FOR [KEY] UPDATE/SHARE` clauses (Dean Rasheed)

  In corner cases, a misleading error could be reported.

- Reject `ROW()` expressions and functions in `FROM` that have too many columns (Tom Lane)

  Cases with more than about 1600 columns are unsupported, and have always failed at execution. However, it emerges that some earlier code could be driven to assertion failures or crashes by queries with more than 32K columns. Add a parse-time check to prevent that.

- Fix dumping of a view using a function in `FROM` that returns a composite type, when column(s) of the composite type have been dropped since the view was made (Tom Lane)

  This oversight could lead to dump/reload or pg_upgrade failures, as the dumped view would have too many column aliases for the function.

- Disallow nested backup operations in logical replication walsenders (Fujii Masao)
- Fix memory leak in logical replication subscribers (Hou Zhijie)
- Fix logical replication's checking of replica identity when the target table is partitioned (Shi Yu, Hou Zhijie)

  The replica identity columns have to be re-identified for the child partition.

- Fix failures to update cached schema data in a logical replication subscriber after a schema change on the publisher (Shi Yu, Hou Zhijie)
- Fix WAL consistency checking logic to correctly handle `BRIN_EVACUATE_PAGE` flags (Haiyang Wang)
- Fix erroneous assertion checks in shared hashtable management (Thomas Munro)
- Avoid assertion failure when `min_dynamic_shared_memory` is set to a non-default value (Thomas Munro)
- Arrange to clean up after commit-time errors within `SPI_commit()`, rather than expecting callers to do that (Peter Eisentraut, Tom Lane)

  Proper cleanup is complicated and requires use of low-level facilities, so it's not surprising that no known caller got it right. This led to misbehaviors when a PL procedure issued `COMMIT` but a failure occurred (such as a deferred constraint check). To improve matters, redefine `SPI_commit()` as starting a new transaction, so that it becomes equivalent to `SPI_commit_and_chain()` except that you get default transaction characteristics instead of preserving the prior transaction's characteristics. To make this somewhat transparent API-wise, redefine `SPI_start_transaction()` as a no-op. All known callers of `SPI_commit()` immediately call `SPI_start_transaction()`, so they will not notice any change. Similar remarks apply to `SPI_rollback()`.

  Also fix PL/Python, which omitted any handling of such errors at all, resulting in jumping out of the Python interpreter. This is reported to crash Python 3.11. Older Python releases leak some memory but seem okay with it otherwise.

- Improve libpq's handling of idle states in pipeline mode (Álvaro Herrera, Kyotaro Horiguchi)

  This fixes “message type 0x33 arrived from server while idle” warnings, as well as possible loss of end-of-query NULL results from `PQgetResult()`.

- Avoid core dump in ecpglib with unexpected orders of operations (Tom Lane)

  Certain operations such as `EXEC SQL PREPARE` would crash (rather than reporting an error as expected) if called before establishing any database connection.

- In ecpglib, avoid redundant `newlocale()` calls (Noah Misch)

  Allocate a C locale object once per process when first connecting, rather than creating and freeing locale objects once per query. This mitigates a libc memory leak on AIX, and may offer some performance benefit everywhere.

- In psql's `\watch` command, echo a newline after cancellation with control-C (Pavel Stehule)

  This prevents libedit (and possibly also libreadline) from becoming confused about which column the cursor is in.

- Fix pg_upgrade to detect non-upgradable usages of functions taking `anyarray` (Justin Pryzby)

  Version 14 changed some built-in functions to take type `anycompatiblearray` instead of `anyarray`. While this is mostly transparent, user-defined aggregates and operators built atop these functions have to be declared with exactly matching types. The presence of an object referencing the old signature will cause pg_upgrade to fail, so change it to detect and report such cases before beginning the upgrade.

- Fix possible report of wrong error condition after `clone()` failure in pg_upgrade with `--clone` option (Justin Pryzby)

- Fix `contrib/pg_stat_statements` to avoid problems with very large query-text files on 32-bit platforms (Tom Lane)

- In `contrib/postgres_fdw`, prevent batch insertion when there are `WITH CHECK OPTION` constraints (Etsuro Fujita)

  Such constraints cannot be checked properly if more than one row is inserted at a time.

- Fix `contrib/postgres_fdw` to detect failure to send an asynchronous data fetch query (Fujii Masao)

- Ensure that `contrib/postgres_fdw` sends constants of `regconfig` and other `reg*` types with proper schema qualification (Tom Lane)

- Block signals while allocating dynamic shared memory on Linux (Thomas Munro)

  This avoids problems when a signal interrupts `posix_fallocate()`.

- Detect unexpected `EEXIST` error from `shm_open()` (Thomas Munro)

  This avoids a possible crash on Solaris.

- Avoid using `signalfd()` on illumos systems (Thomas Munro)

  This appears to trigger hangs and kernel panics, so avoid the function until a fix is available.

E.39. Release 14.4

Release date: 2022-06-16

This release contains a variety of fixes from 14.3. For information about new features in major release 14, see Section E.43.

E.39.1. Migration to Version 14.4

A dump/restore is not required for those running 14.X.

However, if you have any indexes that were created using the CONCURRENTLY option under 14.X, you should re-index them after updating. See the first changelog entry below.

Also, if you are upgrading from a version earlier than 14.3, see Section E.40.

E.39.2. Changes

- Prevent possible corruption of indexes created or rebuilt with the CONCURRENTLY option (Álvaro Herrera)

  An optimization added in v14 caused CREATE INDEX ... CONCURRENTLY and REINDEX ... CONCURRENTLY to sometimes miss indexing rows that were updated during the index build. Revert that optimization. It is recommended that any indexes made with the CONCURRENTLY option be rebuilt after installing this update. (Alternatively, rebuild them without CONCURRENTLY.)

- Harden Memoize plan node against non-deterministic equality functions (David Rowley)

  Memoize could crash if a data type's equality or hash functions gave inconsistent results across different calls. Throw a runtime error instead.

- Fix incorrect cost estimates for Memoize plans (David Rowley)

  This mistake could lead to Memoize being used when it isn't really the best plan, or to very long executor startup times due to initializing an overly-large hash table for a Memoize node.

- Fix queries in which a “whole-row variable” references the result of a function that returns a domain over composite type (Tom Lane)

- Fix “variable not found in subplan target list” planner error when pulling up a sub-SELECT that's referenced in a GROUPING function (Richard Guo)

- Prevent pg_stat_get_subscription() from possibly returning an extra row containing garbage values (Kuntal Ghosh)

- Fix COPY FROM's error checking in the case where the database encoding is SQL_ASCII while the client's encoding is a multi-byte encoding (Heikki Linnakangas)

  This mistake could lead to false complaints of invalidly-encoded input data.

- Avoid crashing if too many column aliases are attached to an XMLTABLE or JSON_TABLE construct (Álvaro Herrera)

- When decompiling a view or rule, show a SELECT output column's AS "?column?" alias clause if it could be referenced elsewhere (Tom Lane)

  Previously, this auto-generated alias was always hidden; but there are corner cases where doing so results in a non-restorable view or rule definition.

- Report implicitly-created operator families to event triggers (Masahiko Sawada)

  If CREATE OPERATOR CLASS results in the implicit creation of an operator family, that object was not reported to event triggers that should capture such events.

- Fix control file updates made when a restartpoint is running during promotion of a standby server (Kyotaro Horiguchi)

  Previously, when the restartpoint completed it could incorrectly update the last-checkpoint fields of the control file, potentially leading to PANIC and failure to restart if the server crashes before the next normal checkpoint completes.

- Prevent triggering of standby's wal_receiver_timeout during logical replication of large transactions (Wang Wei, Amit Kapila)

If a large transaction on the primary server sends no data to the standby (perhaps because no table it changes is published), it was possible for the standby to timeout. Fix that by ensuring we send keepalive messages periodically in such situations.

- Prevent open-file leak when reading an invalid timezone abbreviation file (Kyotaro Horiguchi)

  Such cases could result in harmless warning messages.

- Allow custom server parameters to have short descriptions that are NULL (Steve Chavez)

  Previously, although extensions could choose to create such settings, some code paths would crash while processing them.

- Remove misguided SSL key file ownership check in libpq (Tom Lane)

  In the previous minor releases, we copied the server's permission checking rules for SSL private key files into libpq. But we should not have also copied the server's file-ownership check. While that works in normal use-cases, it can result in an unexpected failure for clients running as root, and perhaps in other cases.

- Ensure ecpg reports server connection loss sanely (Tom Lane)

  Misprocessing of a libpq-generated error result, such as a report of lost connection, would lead to printing “(null)” instead of a useful error message; or in older releases it would lead to a crash.

- Prevent crash after server connection loss in pg_amcheck (Tom Lane)

  Misprocessing of a libpq-generated error result, such as a report of lost connection, would lead to a crash.

- Adjust PL/Perl test case so it will work under Perl 5.36 (Dagfinn Ilmari Mannsåker)
- Avoid incorrectly using an out-of-date libldap_r library when multiple OpenLDAP installations are present while building PostgreSQL (Tom Lane)

E.40. Release 14.3

Release date: 2022-05-12

This release contains a variety of fixes from 14.2. For information about new features in major release 14, see Section E.43.

E.40.1. Migration to Version 14.3

A dump/restore is not required for those running 14.X.

However, if you have any GiST indexes on columns of type `ltree` (supplied by the `contrib/ltree` extension), you should re-index them after updating. See the second changelog entry below.

Also, if you are upgrading from a version earlier than 14.2, see Section E.41.

E.40.2. Changes

- Confine additional operations within “security restricted operation” sandboxes (Sergey Shinderuk, Noah Misch)

  Autovacuum, `CLUSTER`, `CREATE INDEX`, `REINDEX`, `REFRESH MATERIALIZED VIEW`, and pg_amcheck activated the “security restricted operation” protection mechanism too late, or even not at all in some code paths. A user having permission to create non-temporary objects within a database could define an object that would execute arbitrary SQL code with superuser permissions the next time that autovacuum processed the object, or that some superuser ran one of the affected commands against it.

  The PostgreSQL Project thanks Alexander Lakhin for reporting this problem. (CVE-2022-1552)

- Fix default signature length for `gist_ltree_ops` indexes (Tomas Vondra, Alexander Korotkov)

  The default signature length (hash size) for GiST indexes on `ltree` columns was accidentally changed while upgrading that operator class to support operator class parameters. If any operations had been done on such an index without first upgrading the `ltree` extension to version 1.2, they were done assuming that the signature length was 28 bytes rather than the intended 8. This means it is very likely that such indexes are now corrupt. For safety we recommend re-indexing all GiST indexes on `ltree` columns after installing this update. (Note that GiST indexes on `ltree[]` columns, that is arrays of `ltree`, are not affected.)

- Stop using query-provided column aliases for the columns of whole-row variables that refer to plain tables (Tom Lane)

  The column names in tuples produced by a whole-row variable (such as `tbl.*` in contexts other than the top level of a `SELECT` list) are now always those of the associated named composite type, if there is one. We'd previously attempted to make them track any column aliases that had been applied to the `FROM` entry the variable refers to. But that's semantically dubious, because really then the output of the variable is not at all of the composite type it claims to be. Previous attempts to deal with that inconsistency had bad results up to and including storing unreadable data on disk, so just give up on the whole idea.

  In cases where it's important to be able to relabel such columns, a workaround is to introduce an extra level of sub-`SELECT`, so that the whole-row variable is referring to the sub-`SELECT`'s output and not to a plain table. Then the variable is of type `record` to begin with and there's no issue.

- Fix incorrect roundoff when extracting epoch values from intervals (Peter Eisentraut)

  The new `numeric`-based code for `EXTRACT()` failed to yield results equivalent to the old `float`-based code, as a result of accidentally truncating the `DAYS_PER_YEAR` value to an integer.

- Defend against `pg_stat_get_replication_slot(NULL)` (Andres Freund)

  This function should be marked strict in the catalog data, but it was not in v14, so add a run-time check instead.

- Fix incorrect output for types `timestamptz` and `timetz` in `table_to_xmlschema()` and allied functions (Renan Soares Lopes)

  The xmlschema output for these types included a malformed regular expression.

- Avoid core dump in parser for a `VALUES` clause with zero columns (Tom Lane)

- Fix planner failure when a Result plan node appears immediately underneath an Append node (Etsuro Fujita)

  Recently-added code to support asynchronous remote queries failed to handle this case, leading to crashes or errors about unrecognized node types.

- Fix planner failure if a query using `SEARCH` or `CYCLE` features contains a duplicate CTE name (Tom Lane, Kyotaro Horiguchi)

  When the name of the recursive `WITH` query is re-used within itself, the planner could crash or report odd errors such as “could not find attribute 2 in subquery targetlist”.

- Fix planner errors for `GROUPING()` constructs that reference outer query levels (Richard Guo, Tom Lane)

- Fix plan generation for index-only scans on indexes with both returnable and non-returnable columns (Tom Lane)

  The previous coding could try to read non-returnable columns in addition to the returnable ones. This was fairly harmless because it didn't actually do anything with the bogus values, but it fell foul of a recently-added error check that rejected such a plan.

- Avoid accessing a no-longer-pinned shared buffer while attempting to lock an outdated tuple during EvalPlanQual (Tom Lane)

  The code would touch the buffer a couple more times after releasing its pin. In theory another process could recycle the buffer (or more likely, try to defragment its free space) as soon as the pin is gone, probably leading to failure to find the newer version of the tuple.

- Fix query-lifespan memory leak in an IndexScan node that is performing reordering (Aliaksandr Kalenik)

- Fix `ALTER FUNCTION` to support changing a function's parallelism property and its `SET`-variable list in the same command (Tom Lane)

  The parallelism property change was lost if the same command also updated the function's `SET` clause.

- Tighten lookup of the index “owned by” a constraint (Tom Lane, Japin Li)

  Some code paths mistook the index depended on by a foreign key constraint for one owned by a unique or primary key constraint, resulting in odd errors during certain `ALTER TABLE` operations on tables having foreign key constraints.

- Fix bogus errors from attempts to alter system columns of tables (Tom Lane)

  The system should just tell you that you can't do it, but sometimes it would report “no owned sequence found” instead.

- Fix mis-sorting of table rows when `CLUSTER`ing using an index whose leading key is an expression (Peter Geoghegan, Thomas Munro)

  The table would be rebuilt with the correct data, but in an order having little to do with the index order.

- Prevent data loss if a system crash occurs shortly after a sorted GiST index build (Heikki Linnakangas)

  The code path for building GiST indexes using sorting neglected to `fsync` the file upon completion. This could result in a corrupted index if the operating system crashed shortly later.

- Fix risk of deadlock failures while dropping a partitioned index (Jimmy Yih, Gaurab Dey, Tom Lane)

  Ensure that the required table and index locks are taken in the standard order (parents before children, tables before indexes). The previous coding for `DROP INDEX` did it differently, and so could deadlock against concurrent queries taking these locks in the standard order.

- Fix race condition between `DROP TABLESPACE` and checkpointing (Nathan Bossart)

  The checkpoint forced by `DROP TABLESPACE` could sometimes fail to remove all dead files from the tablespace's directory, leading to a bogus “tablespace is not empty” error.

- Fix possible trouble in crash recovery after a `TRUNCATE` command that overlaps a checkpoint (Kyotaro Horiguchi, Heikki Linnakangas, Robert Haas)

  `TRUNCATE` must ensure that the table's disk file is truncated before the checkpoint is allowed to complete. Otherwise, replay starting from that checkpoint might find unexpected data in the supposedly-removed pages, possibly causing replay failure.

- Fix unsafe toast-data accesses during temporary object cleanup (Andres Freund)

  Temporary-object deletion during server process exit could fail with “FATAL: cannot fetch toast data without an active snapshot”. This was usually harmless since the next use of that temporary schema would clean up successfully.

- Re-allow underscore as the first character in a custom parameter name (Japin Li)

Such names were unintentionally disallowed in v14.

- Add `regress` option for the `compute_query_id` parameter (Michael Paquier)

  This is intended to facilitate testing, by allowing query IDs to be computed but not shown in `EXPLAIN` output.

- Improve wait logic in RegisterSyncRequest (Thomas Munro)

  If we run out of space in the checkpointer sync request queue (which is hopefully rare on real systems, but is common when testing with a very small buffer pool), we wait for it to drain. While waiting, we should report that as a wait event so that users know what is going on, and also watch for postmaster death, since otherwise the loop might never terminate if the checkpointer has already exited.

- Wake up for latch events when the checkpointer is waiting between writes (Thomas Munro)

  This improves responsiveness to backends sending sync requests. The change also creates a proper wait event class for these waits.

- Fix “PANIC: xlog flush request is not satisfied” failure during standby promotion when there is a missing WAL continuation record (Sami Imseih)

- Fix possibility of self-deadlock in hot standby conflict handling (Andres Freund)

  With unlucky timing, the WAL-applying process could get stuck while waiting for some other process to release a buffer lock.

- Fix possible mis-identification of the correct ancestor relation to publish logical replication changes through (Tomas Vondra, Hou zj, Amit Kapila)

  If `publish_via_partition_root` is enabled, and there are multiple publications naming different ancestors of the currently-modified relation, the wrong ancestor might be chosen for reporting the change.

- Ensure that logical replication apply workers can be restarted even when we're up against the `max_sync_workers_per_subscription` limit (Amit Kapila)

  Faulty coding of the limit check caused a restarted worker to exit immediately, leaving fewer workers than there should be.

- Include unchanged replica identity key columns in the WAL log for an update, if they are stored out-of-line (Dilip Kumar, Amit Kapila)

  Otherwise subscribers cannot see the values and will fail to replicate the update.

- Cope correctly with platforms that have no support for altering the server process's display in ps(1) (Andrew Dunstan)

  Few platforms are like this (the only supported one is Cygwin), so we'd managed not to notice that refactoring introduced a potential memory clobber.

- Make the server more robust against missed timer interrupts (Michael Harris, Tom Lane)

  An optimization added in v14 meant that if a server process somehow missed a timer interrupt, it would never again ask the kernel for another one, thus breaking timeout detection for the remainder of the session. This seems unduly fragile, so add a recovery path.

- Disallow execution of SPI functions during PL/Perl function compilation (Tom Lane)

  Perl can be convinced to execute user-defined code during compilation of a PL/Perl function. However, it's not okay for such code to try to invoke SQL operations via SPI. That results in a crash, and if it didn't crash it would be a security hazard, because we really don't want code execution during function validation. Put in a check to give a friendlier error message instead.

- Make libpq accept root-owned SSL private key files (David Steele)

This change synchronizes libpq's rules for safe ownership and permissions of SSL key files with the rules the server has used since release 9.6. Namely, in addition to the current rules, allow the case where the key file is owned by root and has permissions `rw-r-----` or less. This is helpful for system-wide management of key files.

- Fix behavior of libpq's `PQisBusy()` function after a connection failure (Tom Lane)

  If we'd detected a write failure, `PQisBusy()` would always return true, which is the wrong thing: we want input processing to carry on normally until we've read whatever is available from the server. The practical effect of this error is that applications using libpq's async-query API would typically detect connection loss only when `PQconsumeInput()` returns a hard failure. With this fix, a connection loss will normally be reported via an error `PGresult` object, which is a much cleaner behavior for most applications.

- Re-allow *`database`*.*`schema`*.*`table`* patterns in psql, pg_dump, and pg_amcheck (Mark Dilger)

  Versions before v14 silently ignored all but the *`schema`* and *`table`* fragments of a pattern containing more than one dot. Refactoring in v14 accidentally broke that use-case. Reinstate it, but now complain if the first fragment is not the name of the current database.

- Make pg_ctl recheck postmaster aliveness while waiting for stop/restart/promote actions (Tom Lane)

  pg_ctl would verify that the postmaster is alive as a side-effect of sending the stop or promote signal, but then it just naively waited to see the on-disk state change. If the postmaster died uncleanly without having removed its PID file or updated the control file, pg_ctl would wait until timeout. Instead make it recheck every so often that the postmaster process is still there.

- Fix error handling in pg_waldump (Kyotaro Horiguchi, Andres Freund)

  While trying to read a WAL file to determine the WAL segment size, pg_waldump would report an incorrect error for the case of a too-short file. In addition, the file name reported in this and related error messages could be garbage.

- Ensure that `contrib/pageinspect` functions cope with all-zero pages (Michael Paquier)

  This is a legitimate edge case, but the module was mostly unprepared for it. Arrange to return nulls, or no rows, as appropriate; that seems more useful than raising an error.

- In `contrib/pageinspect`, add defenses against incorrect page “special space” contents, tighten checks for correct page size, and add some missing checks that an index is of the expected type (Michael Paquier, Justin Pryzby, Julien Rouhaud)

  These changes make it less likely that the module will crash on bad data.

- In `contrib/postgres_fdw`, disable batch insertion when `BEFORE INSERT ... FOR EACH ROW` triggers exist on the foreign table (Etsuro Fujita)

  Such a trigger might query the table it's on and expect to see previously-inserted rows. With batch insertion, those rows might not be visible yet, so disable the feature to avoid unexpected behavior.

- In `contrib/postgres_fdw`, verify that `ORDER BY` clauses are safe to ship before requesting a remotely-ordered query, and include a `USING` clause if necessary (Ronan Dunklau)

  This fix prevents situations where the remote server might sort in a different order than we intend. While sometimes that would be only cosmetic, it could produce thoroughly wrong results if the remote data is used as input for a locally-performed merge join.

- Fix configure to handle platforms that have `sys/epoll.h` but not `sys/signalfd.h` (Tom Lane)

- Update JIT code to work with LLVM 14 (Thomas Munro)

- Clean up assorted failures under clang's `-fsanitize=undefined` checks (Tom Lane, Andres Freund, Zhihong Yu)

Most of these changes are just for pro-forma compliance with the letter of the C and POSIX standards, and are unlikely to have any effect on production builds.

- Do not add OpenSSL dependencies to libpq's `pkg-config` file when building without OpenSSL (Fabrice Fontaine)
- Fix PL/Perl so it builds on C compilers that don't support statements nested within expressions (Tom Lane)
- Fix possible build failure of pg_dumpall on Windows, when not using MSVC to build (Andres Freund)
- In Windows builds, use gendef instead of pexports to build DEF files (Andrew Dunstan)

  This adapts the build process to work on recent MSys tool chains.
- Prevent extra expansion of shell wildcard patterns in programs built under MinGW (Andrew Dunstan)

  For some reason the C library provided by MinGW will expand shell wildcard characters in a program's command-line arguments by default. This is confusing, not least because it doesn't happen under MSVC, so turn it off.
- Update time zone data files to tzdata release 2022a for DST law changes in Palestine, plus historical corrections for Chile and Ukraine. (Tom Lane)

E.41. Release 14.2

Release date: 2022-02-10

This release contains a variety of fixes from 14.1. For information about new features in major release 14, see Section E.43.

E.41.1. Migration to Version 14.2

A dump/restore is not required for those running 14.X.

However, some bugs have been found that may have resulted in corrupted indexes, as explained in the first two changelog entries. If any of those cases apply to you, it's recommended to reindex possibly-affected indexes after updating.

Also, if you are upgrading from a version earlier than 14.1, see Section E.42.

E.41.2. Changes

- Enforce standard locking protocol for TOAST table updates, to prevent problems with `REINDEX CONCURRENTLY` (Michael Paquier)

  If applied to a TOAST table or TOAST table's index, `REINDEX CONCURRENTLY` tended to produce a corrupted index. This happened because sessions updating TOAST entries released their `ROW EXCLUSIVE` locks immediately, rather than holding them until transaction commit as all other updates do. The fix is to make TOAST updates hold the table lock according to the normal rule. Any existing corrupted indexes can be repaired by reindexing again.
- Fix corruption of HOT chains when a RECENTLY_DEAD tuple changes state to fully DEAD during page pruning (Andres Freund)

  It was possible for `VACUUM` to remove a recently-dead tuple while leaving behind a redirect item that pointed to it. When the tuple's item slot is later re-used by some new tuple, that tuple would be seen as part of the pre-existing HOT chain, creating a form of index corruption. If this has hap-

pened, reindexing the table should repair the damage. However, this is an extremely low-probability scenario, so we do not recommend reindexing just on the chance that it might have happened.

- Fix crash in EvalPlanQual rechecks for tables with a mix of local and foreign partitions (Etsuro Fujita)
- Fix dangling pointer in `COPY TO` (Bharath Rupireddy)

  This oversight could cause an incorrect error message or a crash after an error in `COPY`.
- Avoid null-pointer crash in `ALTER STATISTICS` when the statistics object is dropped concurrently (Tomas Vondra)
- Correctly handle alignment padding when extracting a range from a multirange (Alexander Korotkov)

  This error could cause crashes when handling multiranges over variable-length data types.
- Fix over-optimistic use of hashing for anonymous `RECORD` data types (Tom Lane)

  This prevents some cases of “could not identify a hash function for type record” errors.
- Fix incorrect plan creation for parallel single-child Append nodes (David Rowley)

  In some cases the Append would be simplified away when it should not be, leading to wrong query results (duplicated rows).
- Fix index-only scan plans for cases where not all index columns can be returned (Tom Lane)

  If an index has both returnable and non-returnable columns, and one of the non-returnable columns is an expression using a table column that appears in a returnable index column, then a query using that expression could result in an index-only scan plan that attempts to read the non-returnable column, instead of recomputing the expression from the returnable column as intended. The non-returnable column would read as NULL, resulting in wrong query results.
- Fix Memoize plan nodes to handle subplans that use parameters coming from above the Memoize (David Rowley)
- Fix Memoize plan nodes to work correctly with non-hashable join operators (David Rowley)
- Ensure that casting to an unspecified typmod generates a RelabelType node rather than a length-coercion function call (Tom Lane)

  While the coercion function should do the right thing (nothing), this translation is undesirably inefficient.
- Fix checking of `anycompatible`-family data type matches (Tom Lane)

  In some cases the parser would think that a function or operator with `anycompatible`-family polymorphic parameters matches a set of arguments that it really shouldn't match. In reported cases, that led to matching more than one operator to a call, leading to ambiguous-operator errors; but a failure later on is also possible.
- Fix WAL replay failure when database consistency is reached exactly at a WAL page boundary (Álvaro Herrera)
- Fix startup of a physical replica to tolerate transaction ID wraparound (Abhijit Menon-Sen, Tomas Vondra)

  If a replica server is started while the set of active transactions on the primary crosses a wraparound boundary (so that there are some newer transactions with smaller XIDs than older ones), the replica would fail with “out-of-order XID insertion in KnownAssignedXids”. The replica would retry, but could never get past that error.
- In logical replication, avoid double transmission of a child table's data (Hou Zhijie)

If a publication includes both child and parent tables, and has the `publish_via_partition_root` option set, subscribers uselessly initiated synchronization on both child and parent tables. Ensure that only the parent table is synchronized in such cases.

- Remove lexical limitations for SQL commands issued on a logical replication connection (Tom Lane)

  The walsender process would fail for a SQL command containing an unquoted semicolon, or with dollar-quoted literals containing odd numbers of single or double quote marks, or when the SQL command starts with a comment. Moreover, faulty error recovery could lead to unexpected errors in later commands too.

- Ensure that replication origin timestamp is set while replicating a `ROLLBACK PREPARED` operation (Masahiko Sawada)

- Fix possible loss of the commit timestamp for the last subtransaction of a transaction (Alex Kingsborough, Kyotaro Horiguchi)

- Be sure to `fsync` the `pg_logical/mappings` subdirectory during checkpoints (Nathan Bossart)

  On some filesystems this oversight could lead to losing logical rewrite status files after a system crash.

- Build extended statistics for partitioned tables (Justin Pryzby)

  A previous bug fix disabled building of extended statistics for old-style inheritance trees, but it also prevented building them for partitioned tables, which was an unnecessary restriction. This change allows `ANALYZE` to compute values for statistics objects for partitioned tables. (But note that autovacuum does not process partitioned tables as such, so you must periodically issue manual `ANALYZE` on the partitioned table if you want to maintain such statistics.)

- Ignore extended statistics for inheritance trees (Justin Pryzby)

  Currently, extended statistics values are only computed locally for each table, not for entire inheritance trees. However the values were mistakenly consulted when planning queries across inheritance trees, possibly resulting in worse-than-default estimates.

- Disallow altering data type of a partitioned table's columns when the partitioned table's row type is used as a composite type elsewhere (Tom Lane)

  This restriction has long existed for regular tables, but through an oversight it was not checked for partitioned tables.

- Disallow `ALTER TABLE ... DROP NOT NULL` for a column that is part of a replica identity index (Haiying Tang, Hou Zhijie)

  The same prohibition already existed for primary key indexes.

- Correctly update cached table state during `ALTER TABLE ADD PRIMARY KEY USING INDEX` (Hou Zhijie)

  Concurrent sessions failed to update their opinion of whether the table has a primary key, possibly causing incorrect logical replication behavior.

- Correctly update cached table state when switching `REPLICA IDENTITY` index (Tang Haiying, Hou Zhijie)

  Concurrent sessions failed to update their opinion of which index is the replica identity one, possibly causing incorrect logical replication behavior.

- Fix failure of SP-GiST indexes when the indexed column's data type is binary-compatible with the declared input type of the operator class (Tom Lane)

  Such cases should work, but failed with “compress method must be defined when leaf type is different from input type”.

- Allow parallel vacuuming and concurrent index building to be ignored while computing oldest xmin (Masahiko Sawada)

  Non-parallelized instances of these operations were already ignored, but the logic did not work for parallelized cases. Holding back the xmin horizon has undesirable effects such as delaying vacuum cleanup.

- Fix memory leak when updating expression indexes (Peter Geoghegan)

  An `UPDATE` affecting many rows could consume significant amounts of memory.

- Avoid leaking memory during `REASSIGN OWNED BY` operations that reassign ownership of many objects (Justin Pryzby)

- Improve performance of walsenders sending logical changes by avoiding unnecessary cache accesses (Hou Zhijie)

- Fix display of `cert` authentication method's options in `pg_hba_file_rules` view (Magnus Hagander)

  The `cert` authentication method implies `clientcert=verify-full`, but the `pg_hba_file_rules` view incorrectly reported `clientcert=verify-ca`.

- Ensure that the session targeted by `pg_log_backend_memory_contexts()` sends its results only to the server's log (Fujii Masao)

  Previously, a sufficiently high setting of `client_min_messages` could result in the log message also being sent to the connected client. Since that client hadn't requested it, that would be surprising (and possibly a wire protocol violation).

- Fix display of whole-row variables appearing in `INSERT ... VALUES` rules (Tom Lane)

  A whole-row variable would be printed as “var.*”, but that allows it to be expanded to individual columns when the rule is reloaded, resulting in different semantics. Attach an explicit cast to prevent that, as we do elsewhere.

- When reverse-listing a SQL-standard function body, display function parameters appropriately within `INSERT ... SELECT` (Tom Lane)

  Previously, they'd come out as `$N` even when the parameter had a name.

- Fix one-byte buffer overrun when applying Unicode string normalization to an empty string (Michael Paquier)

  The practical impact of this is limited thanks to alignment considerations; but in debug builds, a warning was raised.

- Fix or remove some incorrect assertions (Simon Riggs, Michael Paquier, Alexander Lakhin)

  These errors should affect only debug builds, not production.

- Fix race condition that could lead to failure to localize error messages that are reported early in multi-threaded use of libpq or ecpglib (Tom Lane)

- Avoid calling `strerror` from libpq's `PQcancel` function (Tom Lane)

  `PQcancel` is supposed to be safe to call from a signal handler, but `strerror` is not safe. The faulty usage only occurred in the unlikely event of failure to send the cancel message to the server, perhaps explaining the lack of reports.

- Make psql's `\password` command default to setting the password for `CURRENT_USER`, not the connection's original user name (Tom Lane)

  This agrees with the documented behavior, and avoids probable permissions failure if `SET ROLE` or `SET SESSION AUTHORIZATION` has been done since the session began. To prevent confusion, the role name to be acted on is now included in the password prompt.

- Fix psql `\d` command's query for identifying parent triggers (Justin Pryzby)

  The previous coding failed with “more than one row returned by a subquery used as an expression” if a partition had triggers and there were unrelated statement-level triggers of the same name on some parent partitioned table.
- Make psql's `\d` command sort a table's extended statistics objects by name not OID (Justin Pryzby)
- Fix psql's tab-completion of label values for enum types (Tom Lane)
- Fix failures on Windows when using the terminal as data source or destination (Dmitry Koval, Juan José Santamaría Flecha, Michael Paquier)

  This affects psql's `\copy` command, as well as pg_recvlogical with `-f -`.
- In psql and some other client programs, avoid trying to invoke `gettext()` from a control-C signal handler (Tom Lane)

  While no reported failures have been traced to this mistake, it seems highly unlikely to be a safe thing to do.
- Allow canceling the initial password prompt in pg_receivewal and pg_recvlogical (Tom Lane, Nathan Bossart)

  Previously it was impossible to terminate these programs via control-C while they were prompting for a password.
- Fix pg_dump's dump ordering for user-defined casts (Tom Lane)

  In rare cases, the output script might refer to a user-defined cast before it had been created.
- Fix pg_dump's `--inserts` and `--column-inserts` modes to handle tables containing both generated columns and dropped columns (Tom Lane)
- Fix possible mis-reporting of errors in pg_dump and pg_basebackup (Tom Lane)

  The previous code failed to check for errors from some kernel calls, and could report the wrong errno values in other cases.
- Fix results of index-only scans on `contrib/btree_gist` indexes on `char(`*N*`)` columns (Tom Lane)

  Index-only scans returned column values with trailing spaces removed, which is not the expected behavior. That happened because that's how the data was stored in the index. This fix changes the code to store `char(`*N*`)` values with the expected amount of space padding. The behavior of such an index will not change immediately unless you `REINDEX` it; otherwise space-stripped values will be gradually replaced over time during updates. Queries that do not use index-only scan plans will be unaffected in any case.
- Fix edge cases in `postgres_fdw`'s handling of asynchronous queries (Etsuro Fujita)

  These errors could lead to crashes or incorrect results when attempting to parallelize scans of foreign tables.
- Change configure to use Python's sysconfig module, rather than the deprecated distutils module, to determine how to build PL/Python (Peter Eisentraut, Tom Lane, Andres Freund)

  With Python 3.10, this avoids configure-time warnings about distutils being deprecated and scheduled for removal in Python 3.12. Presumably, once 3.12 is out, `configure --with-python` would fail altogether. This future-proofing does come at a cost: sysconfig did not exist before Python 2.7, nor before 3.2 in the Python 3 branch, so it is no longer possible to build PL/Python against long-dead Python versions.
- Re-allow cross-compilation without OpenSSL (Tom Lane)

  configure should assume that `/dev/urandom` will be available on the target system, but it failed instead.

- Fix PL/Perl compile failure on Windows with Perl 5.28 and later (Victor Wagner)
- Fix PL/Python compile failure with Python 3.11 and later (Peter Eisentraut)
- Add support for building with Visual Studio 2022 (Hans Buschmann)
- Allow the `.bat` wrapper scripts in our MSVC build system to be called without first changing into their directory (Anton Voloshin, Andrew Dunstan)

E.42. Release 14.1

Release date: 2021-11-11

This release contains a variety of fixes from 14.0. For information about new features in major release 14, see Section E.43.

E.42.1. Migration to Version 14.1

A dump/restore is not required for those running 14.X.

However, note that installations using physical replication should update standby servers before the primary server, as explained in the third changelog entry below.

Also, several bugs have been found that may have resulted in corrupted indexes, as explained in the next several changelog entries. If any of those cases apply to you, it's recommended to reindex possibly-affected indexes after updating.

E.42.2. Changes

- Make the server reject extraneous data after an SSL or GSS encryption handshake (Tom Lane)

  A man-in-the-middle with the ability to inject data into the TCP connection could stuff some cleartext data into the start of a supposedly encryption-protected database session. This could be abused to send faked SQL commands to the server, although that would only work if the server did not demand any authentication data. (However, a server relying on SSL certificate authentication might well not do so.)

  The PostgreSQL Project thanks Jacob Champion for reporting this problem. (CVE-2021-23214)

- Make libpq reject extraneous data after an SSL or GSS encryption handshake (Tom Lane)

  A man-in-the-middle with the ability to inject data into the TCP connection could stuff some cleartext data into the start of a supposedly encryption-protected database session. This could probably be abused to inject faked responses to the client's first few queries, although other details of libpq's behavior make that harder than it sounds. A different line of attack is to exfiltrate the client's password, or other sensitive data that might be sent early in the session. That has been shown to be possible with a server vulnerable to CVE-2021-23214.

  The PostgreSQL Project thanks Jacob Champion for reporting this problem. (CVE-2021-23222)

- Fix physical replication for cases where the primary crashes after shipping a WAL segment that ends with a partial WAL record (Álvaro Herrera)

  If the primary did not survive long enough to finish writing the rest of the incomplete WAL record, then the previous crash-recovery logic had it back up and overwrite WAL starting from the beginning of the incomplete WAL record. This is problematic since standby servers may already have copies of that WAL segment. They will then see an inconsistent next segment, and will not be able to recover without manual intervention. To fix, do not back up over a WAL segment boundary when restarting after a crash. Instead write a new type of WAL record at the start of the next WAL segment, informing readers that the incomplete WAL record will never be finished and must be disregarded.

When applying this update, it's best to update standby servers before the primary, so that they will be ready to handle this new WAL record type if the primary happens to crash.

- Ensure that parallel `VACUUM` doesn't miss any indexes (Peter Geoghegan, Masahiko Sawada)

  A parallel `VACUUM` would fail to process indexes that are below the `min_parallel_index_scan_size` cutoff, if the table also has at least two indexes that are above that size. This could result in those indexes becoming corrupt, since they'd still contain references to any heap entries removed by the `VACUUM`; subsequent queries using such indexes would be likely to return rows they shouldn't. This problem does not affect autovacuum, since it doesn't use parallel vacuuming. However, it is advisable to reindex any manually-vacuumed tables that have the right mix of index sizes.

- Fix `CREATE INDEX CONCURRENTLY` to wait for the latest prepared transactions (Andrey Borodin)

  Rows inserted by just-prepared transactions might be omitted from the new index, causing queries relying on the index to miss such rows. The previous fix for this type of problem failed to account for `PREPARE TRANSACTION` commands that were still in progress when `CREATE INDEX CONCURRENTLY` checked for them. As before, in installations that have enabled prepared transactions (`max_prepared_transactions` > 0), it's recommended to reindex any concurrently-built indexes in case this problem occurred when they were built.

- Avoid race condition that can cause backends to fail to add entries for new rows to an index being built concurrently (Noah Misch, Andrey Borodin)

  While it's apparently rare in the field, this case could potentially affect any index built or reindexed with the `CONCURRENTLY` option. It is recommended to reindex any such indexes to make sure they are correct.

- Fix `REINDEX CONCURRENTLY` to preserve operator class parameters that were attached to the target index (Michael Paquier)

- Fix incorrect creation of shared dependencies when cloning a database that contains non-builtin objects (Aleksander Alekseev)

  The effects of this error are probably limited in practice. In principle, it could allow a role to be dropped while it still owns objects; but most installations would never want to drop a role that had been used for objects they'd added to `template1`.

- Ensure that the relation cache is invalidated for a table being attached to or detached from a partitioned table (Amit Langote, Álvaro Herrera)

  This oversight could allow misbehavior of subsequent inserts/updates addressed directly to the partition, but only in currently-existing sessions.

- Fix corruption of parse tree while creating a range type (Alex Kozhemyakin, Sergey Shinderuk)

  `CREATE TYPE` incorrectly freed an element of the parse tree, which could cause problems for a later event trigger, or if the `CREATE TYPE` command was stored in the plan cache and used again later.

- Fix updates of element fields in arrays of domain over composite (Tom Lane)

  A command such as `UPDATE tab SET fld[1].subfld = val` failed if the array's elements were domains rather than plain composites.

- Disallow the combination of `FETCH FIRST WITH TIES` and `FOR UPDATE SKIP LOCKED` (David Christensen)

  `FETCH FIRST WITH TIES` necessarily fetches one more row than requested, since it cannot stop until it finds a row that is not a tie. In our current implementation, if `FOR UPDATE` is used then that row will also get locked even though it is not returned. That results in undesirable behavior if the `SKIP LOCKED` option is specified. It's difficult to change this without introducing a different set of undesirable behaviors, so for now, forbid the combination.

- Disallow `ALTER INDEX index ALTER COLUMN col SET (options)` (Nathan Bossart, Michael Paquier)

  While the parser accepted this, it's undocumented and doesn't actually work.

- Fix corner-case loss of precision in numeric `power()` (Dean Rasheed)

  The result could be inaccurate when the first argument is very close to 1.

- Avoid choosing the wrong hash equality operator for Memoize plans (David Rowley)

  This error could result in crashes or incorrect query results.

- Fix planner error with pulling up subquery expressions into function rangetable entries (Tom Lane)

  If a function in `FROM` laterally references the output of some sub-`SELECT` earlier in the `FROM` clause, and we are able to flatten that sub-`SELECT` into the outer query, the expression(s) copied into the function expression were not fully processed. This could lead to crashes at execution.

- Avoid using MCV-only statistics to estimate the range of a column (Tom Lane)

  There are corner cases in which `ANALYZE` will build a most-common-values (MCV) list but not a histogram, even though the MCV list does not account for all the observed values. In such cases, keep the planner from using the MCV list alone to estimate the range of column values.

- Fix restoration of a Portal's snapshot inside a subtransaction (Bertrand Drouvot)

  If a procedure commits or rolls back a transaction, and then its next significant action is inside a new subtransaction, snapshot management went wrong, leading to a dangling pointer and probable crash. A typical example in PL/pgSQL is a `COMMIT` immediately followed by a `BEGIN ... EXCEPTION` block that performs a query.

- Clean up correctly if a transaction fails after exporting its snapshot (Dilip Kumar)

  This oversight would only cause a problem if the same session attempted to export a snapshot again. The most likely scenario for that is creation of a replication slot (followed by rollback) and then creation of another replication slot.

- Prevent wraparound of overflowed-subtransaction tracking on standby servers (Kyotaro Horiguchi, Alexander Korotkov)

  This oversight could cause significant performance degradation (manifesting as excessive SubtransSLRU traffic) on standby servers.

- Ensure that prepared transactions are properly accounted for during promotion of a standby server (Michael Paquier, Andres Freund)

  There was a narrow window where a prepared transaction could be omitted from a snapshot taken by a concurrently-running session. If that session then used the snapshot to perform data updates, erroneous results or data corruption could occur.

- Fix “could not find RecursiveUnion” error when `EXPLAIN` tries to print a filter condition attached to a WorkTableScan node (Tom Lane)

- Ensure that the correct lock level is used when renaming a table (Nathan Bossart, Álvaro Herrera)

  For historical reasons, `ALTER INDEX ... RENAME` can be applied to any sort of relation. The lock level required to rename an index is lower than that required to rename a table or other kind of relation, but the code got this wrong and would use the weaker lock level whenever the command is spelled `ALTER INDEX`.

- Avoid null-pointer-dereference crash when dropping a role that owns objects being dropped concurrently (Álvaro Herrera)

- Prevent “snapshot reference leak” warning when `lo_export()` or a related function fails (Heikki Linnakangas)

- Fix inefficient code generation for CoerceToDomain expression nodes (Ranier Vilela)
- Avoid O(N^2) behavior in some list-manipulation operations (Nathan Bossart, Tom Lane)

  These changes fix slow processing in several scenarios, including: when a standby replays a transaction that held many exclusive locks on the primary; when many files are due to be unlinked after a checkpoint; when hash aggregation involves many batches; and when `pg_trgm` extracts indexable conditions from a complex regular expression. Only the first of these scenarios has actually been reported from the field, but they all seem like plausible consequences of inefficient list deletions.
- Add more defensive checks around B-tree posting list splits (Peter Geoghegan)

  This change should help detect index corruption involving duplicate table TIDs.
- Avoid assertion failure when inserting NaN into a BRIN float8 or float4 minmax_multi_ops index (Tomas Vondra)

  In production builds, such cases would result in a somewhat inefficient, but not actually incorrect, index.
- Allow the autovacuum launcher process to respond to `pg_log_backend_memory_contexts()` requests more quickly (Koyu Tanigawa)
- Fix memory leak in HMAC hash calculations (Sergey Shinderuk)
- Disallow setting `huge_pages` to `on` when `shared_memory_type` is `sysv` (Thomas Munro)

  Previously, this setting was accepted, but it did nothing for lack of any implementation.
- Fix checking of query type in PL/pgSQL's `RETURN QUERY` statement (Tom Lane)

  `RETURN QUERY` should accept any query that can return tuples, e.g. `UPDATE RETURNING`. v14 accidentally disallowed anything but `SELECT`; moreover, the `RETURN QUERY EXECUTE` variant failed to apply any query-type check at all.
- Fix pg_dump to dump non-global default privileges correctly (Neil Chen, Masahiko Sawada)

  If a global (unrestricted) `ALTER DEFAULT PRIVILEGES` command revoked some present-by-default privilege, for example `EXECUTE` for functions, and then a restricted `ALTER DEFAULT PRIVILEGES` command granted that privilege again for a selected role or schema, pg_dump failed to dump the restricted privilege grant correctly.
- Make pg_dump acquire shared lock on partitioned tables that are to be dumped (Tom Lane)

  This oversight was usually pretty harmless, since once pg_dump has locked any of the leaf partitions, that would suffice to prevent significant DDL on the partitioned table itself. However problems could ensue when dumping a childless partitioned table, since no relevant lock would be held.
- Fix crash in pg_dump when attempting to dump trigger definitions from a pre-8.3 server (Tom Lane)
- Fix incorrect filename in pg_restore's error message about an invalid large object TOC file (Daniel Gustafsson)
- Ensure that pgbench exits with non-zero status after a socket-level failure (Yugo Nagata, Fabien Coelho)

  The desired behavior is to finish out the run but then exit with status 2. Also, fix the reporting of such errors.
- Prevent pg_amcheck from checking temporary relations, as well as indexes that are invalid or not ready (Mark Dilger)

  This avoids unhelpful checks of relations that will almost certainly appear inconsistent.
- Make `contrib/amcheck` skip unlogged tables when running on a standby server (Mark Dilger)

It's appropriate to do this since such tables will be empty, and unlogged indexes were already handled similarly.

- Change `contrib/pg_stat_statements` to read its “query texts” file in units of at most 1GB (Tom Lane)

  Such large query text files are very unusual, but if they do occur, the previous coding would fail on Windows 64 (which rejects individual read requests of more than 2GB).

- Fix null-pointer crash when `contrib/postgres_fdw` tries to report a data conversion error (Tom Lane)

- Ensure that `GetSharedSecurityLabel()` can be used in a newly-started session that has not yet built its critical relation cache entries (Jeff Davis)

- When running a TAP test, include the module's own directory in `PATH` (Andrew Dunstan)

  This allows tests to find built programs that are not installed, such as custom test drivers.

- Use the CLDR project's data to map Windows time zone names to IANA time zones (Tom Lane)

  When running on Windows, initdb attempts to set the new cluster's `timezone` parameter to the IANA time zone matching the system's prevailing time zone. We were using a mapping table that we'd generated years ago and updated only fitfully; unsurprisingly, it contained a number of errors as well as omissions of recently-added zones. It turns out that CLDR has been tracking the most appropriate mappings, so start using their data. This change will not affect any existing installation, only newly-initialized clusters.

- Update time zone data files to tzdata release 2021e for DST law changes in Fiji, Jordan, Palestine, and Samoa, plus historical corrections for Barbados, Cook Islands, Guyana, Niue, Portugal, and Tonga. (Tom Lane)

  Also, the Pacific/Enderbury zone has been renamed to Pacific/Kanton. Also, the following zones have been merged into nearby, more-populous zones whose clocks have agreed with them since 1970: Africa/Accra, America/Atikokan, America/Blanc-Sablon, America/Creston, America/Curacao, America/Nassau, America/Port_of_Spain, Antarctica/DumontDUrville, and Antarctica/Syowa. In all these cases, the previous zone name remains as an alias.

E.43. Release 14

Release date: 2021-09-30

E.43.1. Overview

PostgreSQL 14 contains many new features and enhancements, including:

- Stored procedures can now return data via `OUT` parameters.
- The SQL-standard `SEARCH` and `CYCLE` options for common table expressions have been implemented.
- Subscripting can now be applied to any data type for which it is a useful notation, not only arrays. In this release, the `jsonb` and `hstore` types have gained subscripting operators.
- Range types have been extended by adding multiranges, allowing representation of noncontiguous data ranges.
- Numerous performance improvements have been made for parallel queries, heavily-concurrent workloads, partitioned tables, logical replication, and vacuuming.
- B-tree index updates are managed more efficiently, reducing index bloat.
- `VACUUM` automatically becomes more aggressive, and skips inessential cleanup, if the database starts to approach a transaction ID wraparound condition.

- Extended statistics can now be collected on expressions, allowing better planning results for complex queries.
- libpq now has the ability to pipeline multiple queries, which can boost throughput over high-latency connections.

The above items and other new features of PostgreSQL 14 are explained in more detail in the sections below.

E.43.2. Migration to Version 14

A dump/restore using pg_dumpall or use of pg_upgrade or logical replication is required for those wishing to migrate data from any previous release. See Section 17.6 for general information on migrating to new major releases.

Version 14 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

- User-defined objects that reference certain built-in array functions along with their argument types must be recreated (Tom Lane)

  Specifically, `array_append()`, `array_prepend()`, `array_cat()`, `array_position()`, `array_positions()`, `array_remove()`, `array_replace()`, and `width_bucket()` used to take `anyarray` arguments but now take `anycompatiblearray`. Therefore, user-defined objects like aggregates and operators that reference those array function signatures must be dropped before upgrading, and recreated once the upgrade completes.

- Remove deprecated containment operators `@` and `~` for built-in geometric data types and contrib modules cube, hstore, intarray, and seg (Justin Pryzby)

  The more consistently named `<@` and `@>` have been recommended for many years.

- Fix `to_tsquery()` and `websearch_to_tsquery()` to properly parse query text containing discarded tokens (Alexander Korotkov)

  Certain discarded tokens, like underscore, caused the output of these functions to produce incorrect tsquery output, e.g., both `websearch_to_tsquery('"pg_class pg"')` and `to_tsquery('pg_class <-> pg')` used to output `( 'pg' & 'class' ) <-> 'pg'`, but now both output `'pg' <-> 'class' <-> 'pg'`.

- Fix `websearch_to_tsquery()` to properly parse multiple adjacent discarded tokens in quotes (Alexander Korotkov)

  Previously, quoted text that contained multiple adjacent discarded tokens was treated as multiple tokens, causing incorrect tsquery output, e.g., `websearch_to_tsquery('"aaa: bbb"')` used to output `'aaa' <2> 'bbb'`, but now outputs `'aaa' <-> 'bbb'`.

- Change `EXTRACT()` to return type `numeric` instead of `float8` (Peter Eisentraut)

  This avoids loss-of-precision issues in some usages. The old behavior can still be obtained by using the old underlying function `date_part()`.

  Also, `EXTRACT(date)` now throws an error for units that are not part of the `date` data type.

- Change `var_samp()` and `stddev_samp()` with numeric parameters to return NULL when the input is a single NaN value (Tom Lane)

  Previously `NaN` was returned.

- Return false for `has_column_privilege()` checks on non-existent or dropped columns when using attribute numbers (Joe Conway)

  Previously such attribute numbers returned an invalid-column error.

- Fix handling of infinite window function ranges (Tom Lane)

  Previously window frame clauses like `'inf' PRECEDING AND 'inf' FOLLOWING` returned incorrect results.

- Remove factorial operators `!` and `!!`, as well as function `numeric_fac()` (Mark Dilger)

  The `factorial()` function is still supported.

- Disallow `factorial()` of negative numbers (Peter Eisentraut)

  Previously such cases returned 1.

- Remove support for postfix (right-unary) operators (Mark Dilger)

  pg_dump and pg_upgrade will warn if postfix operators are being dumped.

- Allow `\D` and `\W` shorthands to match newlines in regular expression newline-sensitive mode (Tom Lane)

  Previously they did not match newlines in this mode, but that disagrees with the behavior of other common regular expression engines. `[^[:digit:]]` or `[^[:word:]]` can be used to get the old behavior.

- Disregard constraints when matching regular expression back-references (Tom Lane)

  For example, in `(^\d+).*\1`, the `^` constraint should be applied at the start of the string, but not when matching `\1`.

- Disallow `\w` as a range start or end in regular expression character classes (Tom Lane)

  This previously was allowed but produced unexpected results.

- Require custom server parameter names to use only characters that are valid in unquoted SQL identifiers (Tom Lane)

- Change the default of the password_encryption server parameter to `scram-sha-256` (Peter Eisentraut)

  Previously it was `md5`. All new passwords will be stored as SHA256 unless this server setting is changed or the password is specified in MD5 format. Also, the legacy (and undocumented) Boolean-like values which were previously synonyms for `md5` are no longer accepted.

- Remove server parameter `vacuum_cleanup_index_scale_factor` (Peter Geoghegan)

  This setting was ignored starting in PostgreSQL version 13.3.

- Remove server parameter `operator_precedence_warning` (Tom Lane)

  This setting was used for warning applications about PostgreSQL 9.5 changes.

- Overhaul the specification of `clientcert` in `pg_hba.conf` (Kyotaro Horiguchi)

  Values `1`/`0`/`no-verify` are no longer supported; only the strings `verify-ca` and `verify-full` can be used. Also, disallow `verify-ca` if cert authentication is enabled since cert requires `verify-full` checking.

- Remove support for SSL compression (Daniel Gustafsson, Michael Paquier)

  This was already disabled by default in previous PostgreSQL releases, and most modern OpenSSL and TLS versions no longer support it.

- Remove server and libpq support for the version 2 wire protocol (Heikki Linnakangas)

  This was last used as the default in PostgreSQL 7.3 (released in 2002).

- Disallow single-quoting of the language name in the `CREATE/DROP LANGUAGE` command (Peter Eisentraut)
- Remove the composite types that were formerly created for sequences and toast tables (Tom Lane)
- Process doubled quote marks in ecpg SQL command strings correctly (Tom Lane)

  Previously `'abc''def'` was passed to the server as `'abc'def'`, and `"abc""def"` was passed as `"abc"def"`, causing syntax errors.
- Prevent the containment operators (`<@` and `@>`) for intarray from using GiST indexes (Tom Lane)

  Previously a full GiST index scan was required, so just avoid that and scan the heap, which is faster. Indexes created for this purpose should be removed.
- Remove contrib program pg_standby (Justin Pryzby)
- Prevent tablefunc's function `normal_rand()` from accepting negative values (Ashutosh Bapat)

  Negative values produced undesirable results.

E.43.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 14 and the previous major release.

E.43.3.1. Server

- Add predefined roles `pg_read_all_data` and `pg_write_all_data` (Stephen Frost)

  These non-login roles can be used to give read or write permission to all tables, views, and sequences.
- Add predefined role `pg_database_owner` that contains only the current database's owner (Noah Misch)

  This is especially useful in template databases.
- Remove temporary files after backend crashes (Euler Taveira)

  Previously, such files were retained for debugging purposes. If necessary, deletion can be disabled with the new server parameter remove_temp_files_after_crash.
- Allow long-running queries to be canceled if the client disconnects (Sergey Cherkashin, Thomas Munro)

  The server parameter client_connection_check_interval allows control over whether loss of connection is checked for intra-query. (This is supported on Linux and a few other operating systems.)
- Add an optional timeout parameter to `pg_terminate_backend()` (Magnus Hagander)
- Allow wide tuples to be always added to almost-empty heap pages (John Naylor, Floris van Nee)

  Previously tuples whose insertion would have exceeded the page's fill factor were instead added to new pages.
- Add Server Name Indication (SNI) in SSL connection packets (Peter Eisentraut)

  This can be disabled by turning off client connection option `sslsni`.

E.43.3.1.1. Vacuuming

- Allow vacuum to skip index vacuuming when the number of removable index entries is insignificant (Masahiko Sawada, Peter Geoghegan)

  The vacuum parameter `INDEX_CLEANUP` has a new default of `auto` that enables this optimization.

- Allow vacuum to more eagerly add deleted btree pages to the free space map (Peter Geoghegan)

  Previously vacuum could only add pages to the free space map that were marked as deleted by previous vacuums.

- Allow vacuum to reclaim space used by unused trailing heap line pointers (Matthias van de Meent, Peter Geoghegan)

- Allow vacuum to be more aggressive in removing dead rows during minimal-locking index operations (Álvaro Herrera)

  Specifically, `CREATE INDEX CONCURRENTLY` and `REINDEX CONCURRENTLY` no longer limit the dead row removal of other relations.

- Speed up vacuuming of databases with many relations (Tatsuhito Kasahara)

- Reduce the default value of vacuum_cost_page_miss to better reflect current hardware capabilities (Peter Geoghegan)

- Add ability to skip vacuuming of TOAST tables (Nathan Bossart)

  `VACUUM` now has a `PROCESS_TOAST` option which can be set to false to disable TOAST processing, and vacuumdb has a `--no-process-toast` option.

- Have `COPY FREEZE` appropriately update page visibility bits (Anastasia Lubennikova, Pavan Deolasee, Jeff Janes)

- Cause vacuum operations to be more aggressive if the table is near xid or multixact wraparound (Masahiko Sawada, Peter Geoghegan)

  This is controlled by vacuum_failsafe_age and vacuum_multixact_failsafe_age.

- Increase warning time and hard limit before transaction id and multi-transaction wraparound (Noah Misch)

  This should reduce the possibility of failures that occur without having issued warnings about wraparound.

- Add per-index information to autovacuum logging output (Masahiko Sawada)

E.43.3.1.2. Partitioning

- Improve the performance of updates and deletes on partitioned tables with many partitions (Amit Langote, Tom Lane)

  This change greatly reduces the planner's overhead for such cases, and also allows updates/deletes on partitioned tables to use execution-time partition pruning.

- Allow partitions to be detached in a non-blocking manner (Álvaro Herrera)

  The syntax is `ALTER TABLE ... DETACH PARTITION ... CONCURRENTLY`, and `FINALIZE`.

- Ignore `COLLATE` clauses in partition boundary values (Tom Lane)

  Previously any such clause had to match the collation of the partition key; but it's more consistent to consider that it's automatically coerced to the collation of the partition key.

E.43.3.1.3. Indexes

- Allow btree index additions to remove expired index entries to prevent page splits (Peter Geoghegan)

  This is particularly helpful for reducing index bloat on tables whose indexed columns are frequently updated.

- Allow BRIN indexes to record multiple min/max values per range (Tomas Vondra)

This is useful if there are groups of values in each page range.

- Allow BRIN indexes to use bloom filters (Tomas Vondra)

  This allows BRIN indexes to be used effectively with data that is not well-localized in the heap.

- Allow some GiST indexes to be built by presorting the data (Andrey Borodin)

  Presorting happens automatically and allows for faster index creation and smaller indexes.

- Allow SP-GiST indexes to contain `INCLUDE`'d columns (Pavel Borisov)

E.43.3.1.4. Optimizer

- Allow hash lookup for `IN` clauses with many constants (James Coleman, David Rowley)

  Previously the code always sequentially scanned the list of values.

- Increase the number of places extended statistics can be used for `OR` clause estimation (Tomas Vondra, Dean Rasheed)

- Allow extended statistics on expressions (Tomas Vondra)

  This allows statistics on a group of expressions and columns, rather than only columns like previously. System view `pg_stats_ext_exprs` reports such statistics.

- Allow efficient heap scanning of a range of `TIDs` (Edmund Horner, David Rowley)

  Previously a sequential scan was required for non-equality `TID` specifications.

- Fix `EXPLAIN CREATE TABLE AS` and `EXPLAIN CREATE MATERIALIZED VIEW` to honor `IF NOT EXISTS` (Bharath Rupireddy)

  Previously, if the object already existed, `EXPLAIN` would fail.

E.43.3.1.5. General Performance

- Improve the speed of computing MVCC visibility snapshots on systems with many CPUs and high session counts (Andres Freund)

  This also improves performance when there are many idle sessions.

- Add executor method to memoize results from the inner side of a nested-loop join (David Rowley)

  This is useful if only a small percentage of rows is checked on the inner side. It can be disabled via server parameter enable_memoize.

- Allow window functions to perform incremental sorts (David Rowley)

- Improve the I/O performance of parallel sequential scans (Thomas Munro, David Rowley)

  This was done by allocating blocks in groups to parallel workers.

- Allow a query referencing multiple foreign tables to perform foreign table scans in parallel (Robert Haas, Kyotaro Horiguchi, Thomas Munro, Etsuro Fujita)

  postgres_fdw supports this type of scan if `async_capable` is set.

- Allow analyze to do page prefetching (Stephen Frost)

  This is controlled by maintenance_io_concurrency.

- Improve performance of regular expression searches (Tom Lane)

- Dramatically improve Unicode normalization performance (John Naylor)

  This speeds `normalize()` and `IS NORMALIZED`.

- Add ability to use LZ4 compression on TOAST data (Dilip Kumar)

This can be set at the column level, or set as a default via server parameter default_toast_compression. The server must be compiled with `--with-lz4` to support this feature. The default setting is still pglz.

E.43.3.1.6. Monitoring

- If server parameter compute_query_id is enabled, display the query id in `pg_stat_activity`, `EXPLAIN VERBOSE`, csvlog, and optionally in log_line_prefix (Julien Rouhaud)

  A query id computed by an extension will also be displayed.

- Improve logging of auto-vacuum and auto-analyze (Stephen Frost, Jakub Wartak)

  This reports I/O timings for auto-vacuum and auto-analyze if track_io_timing is enabled. Also, report buffer read and dirty rates for auto-analyze.

- Add information about the original user name supplied by the client to the output of log_connections (Jacob Champion)

E.43.3.1.7. System Views

- Add system view `pg_stat_progress_copy` to report `COPY` progress (Josef Šimánek, Matthias van de Meent)
- Add system view `pg_stat_wal` to report WAL activity (Masahiro Ikeda)
- Add system view `pg_stat_replication_slots` to report replication slot activity (Masahiko Sawada, Amit Kapila, Vignesh C)

  The function `pg_stat_reset_replication_slot()` resets slot statistics.

- Add system view `pg_backend_memory_contexts` to report session memory usage (Atsushi Torikoshi, Fujii Masao)
- Add function `pg_log_backend_memory_contexts()` to output the memory contexts of arbitrary backends (Atsushi Torikoshi)
- Add session statistics to the `pg_stat_database` system view (Laurenz Albe)
- Add columns to `pg_prepared_statements` to report generic and custom plan counts (Atsushi Torikoshi, Kyotaro Horiguchi)
- Add lock wait start time to `pg_locks` (Atsushi Torikoshi)
- Make the archiver process visible in `pg_stat_activity` (Kyotaro Horiguchi)
- Add wait event `WalReceiverExit` to report WAL receiver exit wait time (Fujii Masao)
- Implement information schema view `routine_column_usage` to track columns referenced by function and procedure default expressions (Peter Eisentraut)

E.43.3.1.8. Authentication

- Allow an SSL certificate's distinguished name (DN) to be matched for client certificate authentication (Andrew Dunstan)

  The new `pg_hba.conf` option `clientname=DN` allows comparison with certificate attributes beyond the `CN` and can be combined with ident maps.

- Allow `pg_hba.conf` and `pg_ident.conf` records to span multiple lines (Fabien Coelho)

  A backslash at the end of a line allows record contents to be continued on the next line.

- Allow the specification of a certificate revocation list (CRL) directory (Kyotaro Horiguchi)

  This is controlled by server parameter ssl_crl_dir and libpq connection option sslcrldir. Previously only single CRL files could be specified.

- Allow passwords of an arbitrary length (Tom Lane, Nathan Bossart)

E.43.3.1.9. Server Configuration

- Add server parameter idle_session_timeout to close idle sessions (Li Japin)

  This is similar to idle_in_transaction_session_timeout.
- Change checkpoint_completion_target default to 0.9 (Stephen Frost)

  The previous default was 0.5.
- Allow `%P` in log_line_prefix to report the parallel group leader's PID for a parallel worker (Justin Pryzby)
- Allow unix_socket_directories to specify paths as individual, comma-separated quoted strings (Ian Lawrence Barwick)

  Previously all the paths had to be in a single quoted string.
- Allow startup allocation of dynamic shared memory (Thomas Munro)

  This is controlled by min_dynamic_shared_memory. This allows more use of huge pages.
- Add server parameter huge_page_size to control the size of huge pages used on Linux (Odin Ugedal)

E.43.3.2. Streaming Replication and Recovery

- Allow standby servers to be rewound via pg_rewind (Heikki Linnakangas)
- Allow the restore_command setting to be changed during a server reload (Sergei Kornilov)

  You can also set `restore_command` to an empty string and reload to force recovery to only read from the `pg_wal` directory.
- Add server parameter log_recovery_conflict_waits to report long recovery conflict wait times (Bertrand Drouvot, Masahiko Sawada)
- Pause recovery on a hot standby server if the primary changes its parameters in a way that prevents replay on the standby (Peter Eisentraut)

  Previously the standby would shut down immediately.
- Add function `pg_get_wal_replay_pause_state()` to report the recovery state (Dilip Kumar)

  It gives more detailed information than `pg_is_wal_replay_paused()`, which still exists.
- Add new read-only server parameter in_hot_standby (Haribabu Kommi, Greg Nancarrow, Tom Lane)

  This allows clients to easily detect whether they are connected to a hot standby server.
- Speed truncation of small tables during recovery on clusters with a large number of shared buffers (Kirk Jamison)
- Allow file system sync at the start of crash recovery on Linux (Thomas Munro)

  By default, PostgreSQL opens and fsyncs each data file in the database cluster at the start of crash recovery. A new setting, recovery_init_sync_method=`syncfs`, instead syncs each filesystem used by the cluster. This allows for faster recovery on systems with many database files.
- Add function `pg_xact_commit_timestamp_origin()` to return the commit timestamp and replication origin of the specified transaction (Movead Li)
- Add the replication origin to the record returned by `pg_last_committed_xact()` (Movead Li)
- Allow replication origin functions to be controlled using standard function permission controls (Martín Marqués)

Previously these functions could only be executed by superusers, and this is still the default.

E.43.3.2.1. Logical Replication

- Allow logical replication to stream long in-progress transactions to subscribers (Dilip Kumar, Amit Kapila, Ajin Cherian, Tomas Vondra, Nikhil Sontakke, Stas Kelvich)

  Previously transactions that exceeded logical_decoding_work_mem were written to disk until the transaction completed.

- Enhance the logical replication API to allow streaming large in-progress transactions (Tomas Vondra, Dilip Kumar, Amit Kapila)

  The output functions begin with `stream`. test_decoding also supports these.

- Allow multiple transactions during table sync in logical replication (Peter Smith, Amit Kapila, Takamichi Osumi)

- Immediately WAL-log subtransaction and top-level `XID` association (Tomas Vondra, Dilip Kumar, Amit Kapila)

  This is useful for logical decoding.

- Enhance logical decoding APIs to handle two-phase commits (Ajin Cherian, Amit Kapila, Nikhil Sontakke, Stas Kelvich)

  This is controlled via `pg_create_logical_replication_slot()`.

- Add cache invalidation messages to the WAL during command completion when using logical replication (Dilip Kumar, Tomas Vondra, Amit Kapila)

  This allows logical streaming of in-progress transactions. When logical replication is disabled, invalidation messages are generated only at transaction completion.

- Allow logical decoding to more efficiently process cache invalidation messages (Dilip Kumar)

  This allows logical decoding to work efficiently in presence of a large amount of DDL.

- Allow control over whether logical decoding messages are sent to the replication stream (David Pirotte, Euler Taveira)

- Allow logical replication subscriptions to use binary transfer mode (Dave Cramer)

  This is faster than text mode, but slightly less robust.

- Allow logical decoding to be filtered by xid (Markus Wanner)

E.43.3.3. `SELECT`, `INSERT`

- Reduce the number of keywords that can't be used as column labels without `AS` (Mark Dilger)

  There are now 90% fewer restricted keywords.

- Allow an alias to be specified for `JOIN`'s `USING` clause (Peter Eisentraut)

  The alias is created by writing `AS` after the `USING` clause. It can be used as a table qualification for the merged `USING` columns.

- Allow `DISTINCT` to be added to `GROUP BY` to remove duplicate `GROUPING SET` combinations (Vik Fearing)

  For example, `GROUP BY CUBE (a,b), CUBE (b,c)` will generate duplicate grouping combinations without `DISTINCT`.

- Properly handle `DEFAULT` entries in multi-row `VALUES` lists in `INSERT` (Dean Rasheed)

Such cases used to throw an error.

- Add SQL-standard `SEARCH` and `CYCLE` clauses for common table expressions (Peter Eisentraut)

  The same results could be accomplished using existing syntax, but much less conveniently.

- Allow column names in the `WHERE` clause of `ON CONFLICT` to be table-qualified (Tom Lane)

  Only the target table can be referenced, however.

E.43.3.4. Utility Commands

- Allow `REFRESH MATERIALIZED VIEW` to use parallelism (Bharath Rupireddy)
- Allow `REINDEX` to change the tablespace of the new index (Alexey Kondratov, Michael Paquier, Justin Pryzby)

  This is done by specifying a `TABLESPACE` clause. A `--tablespace` option was also added to reindexdb to control this.

- Allow `REINDEX` to process all child tables or indexes of a partitioned relation (Justin Pryzby, Michael Paquier)
- Allow index commands using `CONCURRENTLY` to avoid waiting for the completion of other operations using `CONCURRENTLY` (Álvaro Herrera)
- Improve the performance of `COPY FROM` in binary mode (Bharath Rupireddy, Amit Langote)
- Preserve SQL standard syntax for SQL-defined functions in view definitions (Tom Lane)

  Previously, calls to SQL-standard functions such as `EXTRACT()` were shown in plain function-call syntax. The original syntax is now preserved when displaying a view or rule.

- Add the SQL-standard clause `GRANTED BY` to `GRANT` and `REVOKE` (Peter Eisentraut)
- Add `OR REPLACE` option for `CREATE TRIGGER` (Takamichi Osumi)

  This allows pre-existing triggers to be conditionally replaced.

- Allow `TRUNCATE` to operate on foreign tables (Kazutaka Onishi, Kohei KaiGai)

  The postgres_fdw module also now supports this.

- Allow publications to be more easily added to and removed from a subscription (Japin Li)

  The new syntax is `ALTER SUBSCRIPTION ... ADD/DROP PUBLICATION`. This avoids having to specify all publications to add/remove entries.

- Add primary keys, unique constraints, and foreign keys to system catalogs (Peter Eisentraut)

  These changes help GUI tools analyze the system catalogs. The existing unique indexes of catalogs now have associated `UNIQUE` or `PRIMARY KEY` constraints. Foreign key relationships are not actually stored or implemented as constraints, but can be obtained for display from the function pg_get_catalog_foreign_keys().

- Allow `CURRENT_ROLE` every place `CURRENT_USER` is accepted (Peter Eisentraut)

E.43.3.5. Data Types

- Allow extensions and built-in data types to implement subscripting (Dmitry Dolgov)

  Previously subscript handling was hard-coded into the server, so that subscripting could only be applied to array types. This change allows subscript notation to be used to extract or assign portions of a value of any type for which the concept makes sense.

- Allow subscripting of `JSONB` (Dmitry Dolgov)

JSONB subscripting can be used to extract and assign to portions of JSONB documents.

- Add support for multirange data types (Paul Jungwirth, Alexander Korotkov)

  These are like range data types, but they allow the specification of multiple, ordered, non-overlapping ranges. An associated multirange type is automatically created for every range type.

- Add support for the stemming of languages Armenian, Basque, Catalan, Hindi, Serbian, and Yiddish (Peter Eisentraut)

- Allow tsearch data files to have unlimited line lengths (Tom Lane)

  The previous limit was 4K bytes. Also remove function t_readline().

- Add support for Infinity and -Infinity values in the numeric data type (Tom Lane)

  Floating-point data types already supported these.

- Add point operators <<| and |>> representing strictly above/below tests (Emre Hasegeli)

  Previously these were called >^ and <^, but that naming is inconsistent with other geometric data types. The old names remain available, but may someday be removed.

- Add operators to add and subtract LSN and numeric (byte) values (Fujii Masao)

- Allow binary data transfer to be more forgiving of array and record OID mismatches (Tom Lane)

- Create composite array types for system catalogs (Wenjing Zeng)

  User-defined relations have long had composite types associated with them, and also array types over those composite types. System catalogs now do as well. This change also fixes an inconsistency that creating a user-defined table in single-user mode would fail to create a composite array type.

E.43.3.6. Functions

- Allow SQL-language functions and procedures to use SQL-standard function bodies (Peter Eisentraut)

  Previously only string-literal function bodies were supported. When writing a function or procedure in SQL-standard syntax, the body is parsed immediately and stored as a parse tree. This allows better tracking of function dependencies, and can have security benefits.

- Allow procedures to have OUT parameters (Peter Eisentraut)

- Allow some array functions to operate on a mix of compatible data types (Tom Lane)

  The functions array_append(), array_prepend(), array_cat(), array_position(), array_positions(), array_remove(), array_replace(), and width_bucket() now take anycompatiblearray instead of anyarray arguments. This makes them less fussy about exact matches of argument types.

- Add SQL-standard trim_array() function (Vik Fearing)

  This could already be done with array slices, but less easily.

- Add bytea equivalents of ltrim() and rtrim() (Joel Jacobson)

- Support negative indexes in split_part() (Nikhil Benesch)

  Negative values start from the last field and count backward.

- Add string_to_table() function to split a string on delimiters (Pavel Stehule)

  This is similar to the regexp_split_to_table() function.

- Add `unistr()` function to allow Unicode characters to be specified as backslash-hex escapes in strings (Pavel Stehule)

  This is similar to how Unicode can be specified in literal strings.
- Add `bit_xor()` XOR aggregate function (Alexey Bashtanov)
- Add function `bit_count()` to return the number of bits set in a bit or byte string (David Fetter)
- Add `date_bin()` function (John Naylor)

  This function "bins" input timestamps, grouping them into intervals of a uniform length aligned with a specified origin.
- Allow `make_timestamp()`/`make_timestamptz()` to accept negative years (Peter Eisentraut)

  Negative values are interpreted as `BC` years.
- Add newer regular expression `substring()` syntax (Peter Eisentraut)

  The new SQL-standard syntax is `SUBSTRING(text SIMILAR pattern ESCAPE escapechar)`. The previous standard syntax was `SUBSTRING(text FROM pattern FOR escapechar)`, which is still accepted by PostgreSQL.
- Allow complemented character class escapes \D, `\S`, and `\W` within regular expression brackets (Tom Lane)
- Add `[[:word:]]` as a regular expression character class, equivalent to `\w` (Tom Lane)
- Allow more flexible data types for default values of `lead()` and `lag()` window functions (Vik Fearing)
- Make non-zero floating-point values divided by infinity return zero (Kyotaro Horiguchi)

  Previously such operations produced underflow errors.
- Make floating-point division of NaN by zero return NaN (Tom Lane)

  Previously this returned an error.
- Cause `exp()` and `power()` for negative-infinity exponents to return zero (Tom Lane)

  Previously they often returned underflow errors.
- Improve the accuracy of geometric computations involving infinity (Tom Lane)
- Mark built-in type coercion functions as leakproof where possible (Tom Lane)

  This allows more use of functions that require type conversion in security-sensitive situations.
- Change `pg_describe_object()`, `pg_identify_object()`, and `pg_identify_object_as_address()` to always report helpful error messages for non-existent objects (Michael Paquier)

E.43.3.7. PL/pgSQL

- Improve PL/pgSQL's expression and assignment parsing (Tom Lane)

  This change allows assignment to array slices and nested record fields.
- Allow plpgsql's `RETURN QUERY` to execute its query using parallelism (Tom Lane)
- Improve performance of repeated CALLs within plpgsql procedures (Pavel Stehule, Tom Lane)

E.43.3.8. Client Interfaces

- Add pipeline mode to libpq (Craig Ringer, Matthieu Garrigues, Álvaro Herrera)

  This allows multiple queries to be sent, only waiting for completion when a specific synchronization message is sent.

- Enhance libpq's `target_session_attrs` parameter options (Haribabu Kommi, Greg Nancarrow, Vignesh C, Tom Lane)

  The new options are `read-only`, `primary`, `standby`, and `prefer-standby`.
- Improve the output format of libpq's `PQtrace()` (Aya Iwata, Álvaro Herrera)
- Allow an ECPG SQL identifier to be linked to a specific connection (Hayato Kuroda)

  This is done via `DECLARE ... STATEMENT`.

E.43.3.9. Client Applications

- Allow vacuumdb to skip index cleanup and truncation (Nathan Bossart)

  The options are `--no-index-cleanup` and `--no-truncate`.
- Allow pg_dump to dump only certain extensions (Guillaume Lelarge)

  This is controlled by option `--extension`.
- Add pgbench `permute()` function to randomly shuffle values (Fabien Coelho, Hironobu Suzuki, Dean Rasheed)
- Include disconnection times in the reconnection overhead measured by pgbench with `-C` (Yugo Nagata)
- Allow multiple verbose option specifications (`-v`) to increase the logging verbosity (Tom Lane)

  This behavior is supported by pg_dump, pg_dumpall, and pg_restore.
- Allow psql's `\df` and `\do` commands to specify function and operator argument types (Greg Sabino Mullane, Tom Lane)

  This helps reduce the number of matches printed for overloaded names.
- Add an access method column to psql's `\d[i|m|t]+` output (Georgios Kokolatos)
- Allow psql's `\dt` and `\di` to show TOAST tables and their indexes (Justin Pryzby)
- Add psql command `\dX` to list extended statistics objects (Tatsuro Yamada)
- Fix psql's `\dT` to understand array syntax and backend grammar aliases, like `int` for `integer` (Greg Sabino Mullane, Tom Lane)
- When editing the previous query or a file with psql's `\e`, or using `\ef` and `\ev`, ignore the results if the editor exits without saving (Laurenz Albe)

  Previously, such edits would load the previous query into the query buffer, and typically execute it immediately. This was deemed to be probably not what the user wants.
- Improve tab completion (Vignesh C, Michael Paquier, Justin Pryzby, Georgios Kokolatos, Julien Rouhaud)

E.43.3.10. Server Applications

- Add command-line utility pg_amcheck to simplify running `contrib/amcheck` tests on many relations (Mark Dilger)
- Add `--no-instructions` option to initdb (Magnus Hagander)

  This suppresses the server startup instructions that are normally printed.
- Stop pg_upgrade from creating `analyze_new_cluster` script (Magnus Hagander)

  Instead, give comparable vacuumdb instructions.

- Remove support for the postmaster `-o` option (Magnus Hagander)

  This option was unnecessary since all passed options could already be specified directly.

E.43.3.11. Documentation

- Rename "Default Roles" to "Predefined Roles" (Bruce Momjian, Stephen Frost)
- Add documentation for the `factorial()` function (Peter Eisentraut)

  With the removal of the ! operator in this release, `factorial()` is the only built-in way to compute a factorial.

E.43.3.12. Source Code

- Add configure option `--with-ssl={openssl}` to allow future choice of the SSL library to use (Daniel Gustafsson, Michael Paquier)

  The spelling `--with-openssl` is kept for compatibility.
- Add support for abstract Unix-domain sockets (Peter Eisentraut)

  This is currently supported on Linux and Windows.
- Allow Windows to properly handle files larger than four gigabytes (Juan José Santamaría Flecha)

  For example this allows `COPY`, WAL files, and relation segment files to be larger than four gigabytes.
- Add server parameter debug_discard_caches to control cache flushing for test purposes (Craig Ringer)

  Previously this behavior could only be set at compile time. To invoke it during initdb, use the new option `--discard-caches`.
- Various improvements in valgrind error detection ability (Álvaro Herrera, Peter Geoghegan)
- Add a test module for the regular expression package (Tom Lane)
- Add support for LLVM version 12 (Andres Freund)
- Change SHA1, SHA2, and MD5 hash computations to use the OpenSSL EVP API (Michael Paquier)

  This is more modern and supports FIPS mode.
- Remove separate build-time control over the choice of random number generator (Daniel Gustafsson)

  This is now always determined by the choice of SSL library.
- Add direct conversion routines between EUC_TW and Big5 encodings (Heikki Linnakangas)
- Add collation version support for FreeBSD (Thomas Munro)
- Add `amadjustmembers` to the index access method API (Tom Lane)

  This allows an index access method to provide validity checking during creation of a new operator class or family.
- Provide feature-test macros in `libpq-fe.h` for recently-added libpq features (Tom Lane, Álvaro Herrera)

  Historically, applications have usually used compile-time checks of `PG_VERSION_NUM` to test whether a feature is available. But that's normally the server version, which might not be a good guide to libpq's version. `libpq-fe.h` now offers `#define` symbols denoting application-visible features added in v14; the intent is to keep adding symbols for such features in future versions.

E.43.3.13. Additional Modules

- Allow subscripting of hstore values (Tom Lane, Dmitry Dolgov)
- Allow GiST/GIN pg_trgm indexes to do equality lookups (Julien Rouhaud)

  This is similar to `LIKE` except no wildcards are honored.
- Allow the cube data type to be transferred in binary mode (KaiGai Kohei)
- Allow `pgstattuple_approx()` to report on TOAST tables (Peter Eisentraut)
- Add contrib module pg_surgery which allows changes to row visibility (Ashutosh Sharma)

  This is useful for correcting database corruption.
- Add contrib module old_snapshot to report the `XID`/time mapping used by an active old_snapshot_threshold (Robert Haas)
- Allow amcheck to also check heap pages (Mark Dilger)

  Previously it only checked B-Tree index pages.
- Allow pageinspect to inspect GiST indexes (Andrey Borodin, Heikki Linnakangas)
- Change pageinspect block numbers to be `bigints` (Peter Eisentraut)
- Mark btree_gist functions as parallel safe (Steven Winfield)

E.43.3.13.1. pg_stat_statements

- Move query hash computation from pg_stat_statements to the core server (Julien Rouhaud)

  The new server parameter compute_query_id's default of `auto` will automatically enable query id computation when this extension is loaded.
- Cause pg_stat_statements to track top and nested statements separately (Julien Rohaud)

  Previously, when tracking all statements, identical top and nested statements were tracked as a single entry; but it seems more useful to separate such usages.
- Add row counts for utility commands to pg_stat_statements (Fujii Masao, Katsuragi Yuta, Seino Yuki)
- Add `pg_stat_statements_info` system view to show pg_stat_statements activity (Katsuragi Yuta, Yuki Seino, Naoki Nakamichi)

E.43.3.13.2. postgres_fdw

- Allow postgres_fdw to `INSERT` rows in bulk (Takayuki Tsunakawa, Tomas Vondra, Amit Langote)
- Allow postgres_fdw to import table partitions if specified by `IMPORT FOREIGN SCHEMA ... LIMIT TO` (Matthias van de Meent)

  By default, only the root of a partitioned table is imported.
- Add postgres_fdw function `postgres_fdw_get_connections()` to report open foreign server connections (Bharath Rupireddy)
- Allow control over whether foreign servers keep connections open after transaction completion (Bharath Rupireddy)

  This is controlled by `keep_connections` and defaults to on.
- Allow postgres_fdw to reestablish foreign server connections if necessary (Bharath Rupireddy)

  Previously foreign server restarts could cause foreign table access errors.
- Add postgres_fdw functions to discard cached connections (Bharath Rupireddy)

E.43.4. Acknowledgments

The following individuals (in alphabetical order) have contributed to this release as patch authors, committers, reviewers, testers, or reporters of issues.

E.44. Prior Releases

Release notes for prior versions can be found online. At the time of Postgres Pro Standard 14 release, these prior versions were supported:

- Postgres Pro Standard 13: *https://postgrespro.com/docs/postgrespro/13/release.html*
- Postgres Pro Standard 12: *https://postgrespro.com/docs/postgrespro/12/release.html*
- Postgres Pro Standard 11: *https://postgrespro.com/docs/postgrespro/11/release.html*
- Postgres Pro Standard 10: *https://postgrespro.com/docs/postgrespro/10/release.html*
- Postgres Pro Standard 9.6: *https://postgrespro.com/docs/postgrespro/9.6/release.html*

Appendix F. Additional Supplied Modules and Extensions Shipped in postgrespro-std-14-contrib

This appendix, Appendix G, and Appendix I contain information on the optional components available in the Postgres Pro Standard distribution. These include porting tools, analysis utilities, and plug-in features that are not part of the core Postgres Pro system. They are separate mainly because they address a limited audience or are too experimental to be part of the main source tree. This does not preclude their usefulness.

This appendix and Appendix G cover the extensions and other server plug-in modules. Appendix I covers the utility programs.

Many modules supply new user-defined functions, operators, or types. To make use of one of these modules, after you have installed the code you need to register the new SQL objects in the database system. This is done by executing a CREATE EXTENSION command. In a fresh database, you can simply do

```
CREATE EXTENSION module_name;
```

This command registers the new SQL objects in the current database only, so you need to run it in each database that you want the module's facilities to be available in. Alternatively, run it in database `template1` so that the extension will be copied into subsequently-created databases by default.

For all these modules, `CREATE EXTENSION` must be run by a database superuser, unless the module is considered "trusted", in which case it can be run by any user who has `CREATE` privilege on the current database. Modules that are trusted are identified as such in the sections that follow. Generally, trusted modules are ones that cannot provide access to outside-the-database functionality.

Many modules allow you to install their objects in a schema of your choice. To do that, add `SCHEMA` *schema_name* to the `CREATE EXTENSION` command. By default, the objects will be placed in your current creation target schema, which in turn defaults to `public`.

Note, however, that some of these modules are not "extensions" in this sense, but are loaded into the server in some other way, for instance by way of shared_preload_libraries. See the documentation of each module for details.

This appendix contains modules and extensions that are made available in Postgres Pro Standard as a separate subpackage `postgrespro-std-14-contrib`.

F.1. adminpack

`adminpack` provides a number of support functions which pgAdmin and other administration and management tools can use to provide additional functionality, such as remote management of server log files. Use of all these functions is only allowed to the superuser by default but may be allowed to other users by using the `GRANT` command.

The functions shown in Table F.1 provide write access to files on the machine hosting the server. (See also the functions in Table 9.97, which provide read-only access.) Only files within the database cluster directory can be accessed, unless the user is a superuser or given one of the pg_read_server_files, or pg_write_server_files roles, as appropriate for the function, but either a relative or absolute path is allowable.

Table F.1. `adminpack` Functions

Function Description	
`pg_catalog.pg_file_write`	(*filename* `text`, *data* `text`, *append* `boolean`) → `bigint`

Function Description
Writes, or appends to, a text file.
pg_catalog.pg_file_sync (*filename* text) → void Flushes a file or directory to disk.
pg_catalog.pg_file_rename (*oldname* text, *newname* text [, *archivename* text]) → boolean Renames a file.
pg_catalog.pg_file_unlink (*filename* text) → boolean Removes a file.
pg_catalog.pg_logdir_ls () → setof record Lists the log files in the log_directory directory.

pg_file_write writes the specified *data* into the file named by *filename*. If *append* is false, the file must not already exist. If *append* is true, the file can already exist, and will be appended to if so. Returns the number of bytes written.

pg_file_sync fsyncs the specified file or directory named by *filename*. An error is thrown on failure (e.g., the specified file is not present). Note that data_sync_retry has no effect on this function, and therefore a PANIC-level error will not be raised even on failure to flush database files.

pg_file_rename renames a file. If *archivename* is omitted or NULL, it simply renames *oldname* to *newname* (which must not already exist). If *archivename* is provided, it first renames *newname* to *archivename* (which must not already exist), and then renames *oldname* to *newname*. In event of failure of the second rename step, it will try to rename *archivename* back to *newname* before reporting the error. Returns true on success, false if the source file(s) are not present or not writable; other cases throw errors.

pg_file_unlink removes the specified file. Returns true on success, false if the specified file is not present or the unlink() call fails; other cases throw errors.

pg_logdir_ls returns the start timestamps and path names of all the log files in the log_directory directory. The log_filename parameter must have its default setting (postgresql-%Y-%m-%d_%H%M%S.log) to use this function.

F.2. amcheck

The amcheck module provides functions that allow you to verify the logical consistency of the structure of relations.

The B-Tree checking functions verify various *invariants* in the structure of the representation of particular relations. The correctness of the access method functions behind index scans and other important operations relies on these invariants always holding. For example, certain functions verify, among other things, that all B-Tree pages have items in "logical" order (e.g., for B-Tree indexes on text, index tuples should be in collated lexical order). If that particular invariant somehow fails to hold, we can expect binary searches on the affected page to incorrectly guide index scans, resulting in wrong answers to SQL queries. If the structure appears to be valid, no error is raised.

Verification is performed using the same procedures as those used by index scans themselves, which may be user-defined operator class code. For example, B-Tree index verification relies on comparisons made with one or more B-Tree support function 1 routines. See Section 37.16.3 for details of operator class support functions.

Unlike the B-Tree checking functions which report corruption by raising errors, the heap checking function verify_heapam checks a table and attempts to return a set of rows, one row per corruption detected. Despite this, if facilities that verify_heapam relies upon are themselves corrupted, the function may be unable to continue and may instead raise an error.

Permission to execute amcheck functions may be granted to non-superusers, but before granting such permissions careful consideration should be given to data security and privacy concerns. Although the corruption reports generated by these functions do not focus on the contents of the corrupted data so much as on the structure of that data and the nature of the corruptions found, an attacker who gains permission to execute these functions, particularly if the attacker can also induce corruption, might be able to infer something of the data itself from such messages.

F.2.1. Functions

bt_index_check(index regclass, heapallindexed boolean) returns void

bt_index_check tests that its target, a B-Tree index, respects a variety of invariants. Example usage:

```
test=# SELECT bt_index_check(index => c.oid, heapallindexed => i.indisunique),
               c.relname,
               c.relpages
FROM pg_index i
JOIN pg_opclass op ON i.indclass[0] = op.oid
JOIN pg_am am ON op.opcmethod = am.oid
JOIN pg_class c ON i.indexrelid = c.oid
JOIN pg_namespace n ON c.relnamespace = n.oid
WHERE am.amname = 'btree' AND n.nspname = 'pg_catalog'
-- Don't check temp tables, which may be from another session:
AND c.relpersistence != 't'
-- Function may throw an error when this is omitted:
AND c.relkind = 'i' AND i.indisready AND i.indisvalid
ORDER BY c.relpages DESC LIMIT 10;
 bt_index_check |             relname             | relpages
----------------+---------------------------------+----------
                | pg_depend_reference_index       |       43
                | pg_depend_depender_index        |       40
                | pg_proc_proname_args_nsp_index  |       31
                | pg_description_o_c_o_index      |       21
                | pg_attribute_relid_attnam_index |       14
                | pg_proc_oid_index               |       10
                | pg_attribute_relid_attnum_index |        9
                | pg_amproc_fam_proc_index        |        5
                | pg_amop_opr_fam_index           |        5
                | pg_amop_fam_strat_index         |        5
(10 rows)
```

This example shows a session that performs verification of the 10 largest catalog indexes in the database “test”. Verification of the presence of heap tuples as index tuples is requested for the subset that are unique indexes. Since no error is raised, all indexes tested appear to be logically consistent. Naturally, this query could easily be changed to call bt_index_check for every index in the database where verification is supported.

bt_index_check acquires an AccessShareLock on the target index and the heap relation it belongs to. This lock mode is the same lock mode acquired on relations by simple SELECT statements. bt_index_check does not verify invariants that span child/parent relationships, but will verify the presence of all heap tuples as index tuples within the index when *heapallindexed* is true. When a routine, lightweight test for corruption is required in a live production environment, using bt_index_check often provides the best trade-off between thoroughness of verification and limiting the impact on application performance and availability.

bt_index_parent_check(index regclass, heapallindexed boolean, rootdescend boolean) returns void

bt_index_parent_check tests that its target, a B-Tree index, respects a variety of invariants. Optionally, when the *heapallindexed* argument is true, the function verifies the presence of all heap

tuples that should be found within the index. When the optional *rootdescend* argument is `true`, verification re-finds tuples on the leaf level by performing a new search from the root page for each tuple. The checks that can be performed by `bt_index_parent_check` are a superset of the checks that can be performed by `bt_index_check`. `bt_index_parent_check` can be thought of as a more thorough variant of `bt_index_check`: unlike `bt_index_check`, `bt_index_parent_check` also checks invariants that span parent/child relationships, including checking that there are no missing downlinks in the index structure. `bt_index_parent_check` follows the general convention of raising an error if it finds a logical inconsistency or other problem.

A `ShareLock` is required on the target index by `bt_index_parent_check` (a `ShareLock` is also acquired on the heap relation). These locks prevent concurrent data modification from `INSERT`, `UPDATE`, and `DELETE` commands. The locks also prevent the underlying relation from being concurrently processed by `VACUUM`, as well as all other utility commands. Note that the function holds locks only while running, not for the entire transaction.

`bt_index_parent_check`'s additional verification is more likely to detect various pathological cases. These cases may involve an incorrectly implemented B-Tree operator class used by the index that is checked, or, hypothetically, undiscovered bugs in the underlying B-Tree index access method code. Note that `bt_index_parent_check` cannot be used when Hot Standby mode is enabled (i.e., on read-only physical replicas), unlike `bt_index_check`.

Tip

`bt_index_check` and `bt_index_parent_check` both output log messages about the verification process at `DEBUG1` and `DEBUG2` severity levels. These messages provide detailed information about the verification process that may be of interest to PostgreSQL developers. Advanced users may also find this information helpful, since it provides additional context should verification actually detect an inconsistency. Running:

```
SET client_min_messages = DEBUG1;
```

in an interactive psql session before running a verification query will display messages about the progress of verification with a manageable level of detail.

`verify_heapam(relation regclass, on_error_stop boolean, check_toast boolean, skip text, startblock bigint, endblock bigint, blkno OUT bigint, offnum OUT integer, attnum OUT integer, msg OUT text) returns setof record`

Checks a table for structural corruption, where pages in the relation contain data that is invalidly formatted, and for logical corruption, where pages are structurally valid but inconsistent with the rest of the database cluster.

The following optional arguments are recognized:

`on_error_stop`

If true, corruption checking stops at the end of the first block in which any corruptions are found.

Defaults to false.

`check_toast`

If true, toasted values are checked against the target relation's TOAST table.

This option is known to be slow. Also, if the toast table or its index is corrupt, checking it against toast values could conceivably crash the server, although in many cases this would just produce an error.

Defaults to false.

`skip`

If not `none`, corruption checking skips blocks that are marked as all-visible or all-frozen, as specified. Valid options are `all-visible`, `all-frozen` and `none`.

Defaults to `none`.

`startblock`

If specified, corruption checking begins at the specified block, skipping all previous blocks. It is an error to specify a *`startblock`* outside the range of blocks in the target table.

By default, checking begins at the first block.

`endblock`

If specified, corruption checking ends at the specified block, skipping all remaining blocks. It is an error to specify an *`endblock`* outside the range of blocks in the target table.

By default, all blocks are checked.

For each corruption detected, `verify_heapam` returns a row with the following columns:

`blkno`

The number of the block containing the corrupt page.

`offnum`

The OffsetNumber of the corrupt tuple.

`attnum`

The attribute number of the corrupt column in the tuple, if the corruption is specific to a column and not the tuple as a whole.

`msg`

A message describing the problem detected.

F.2.2. Optional *`heapallindexed`* Verification

When the *`heapallindexed`* argument to B-Tree verification functions is `true`, an additional phase of verification is performed against the table associated with the target index relation. This consists of a "dummy" `CREATE INDEX` operation, which checks for the presence of all hypothetical new index tuples against a temporary, in-memory summarizing structure (this is built when needed during the basic first phase of verification). The summarizing structure "fingerprints" every tuple found within the target index. The high level principle behind *`heapallindexed`* verification is that a new index that is equivalent to the existing, target index must only have entries that can be found in the existing structure.

The additional *`heapallindexed`* phase adds significant overhead: verification will typically take several times longer. However, there is no change to the relation-level locks acquired when *`heapallindexed`* verification is performed.

The summarizing structure is bound in size by `maintenance_work_mem`. In order to ensure that there is no more than a 2% probability of failure to detect an inconsistency for each heap tuple that should be represented in the index, approximately 2 bytes of memory are needed per tuple. As less memory is made available per tuple, the probability of missing an inconsistency slowly increases. This approach limits the overhead of verification significantly, while only slightly reducing the probability of detecting a problem, especially for installations where verification is treated as a routine maintenance task. Any single absent or malformed tuple has a new opportunity to be detected with each new verification attempt.

F.2.3. Using amcheck Effectively

amcheck can be effective at detecting various types of failure modes that data checksums will fail to catch. These include:

- Structural inconsistencies caused by incorrect operator class implementations.

  This includes issues caused by the comparison rules of operating system collations changing. Comparisons of datums of a collatable type like text must be immutable (just as all comparisons used for B-Tree index scans must be immutable), which implies that operating system collation rules must never change. Though rare, updates to operating system collation rules can cause these issues. More commonly, an inconsistency in the collation order between a primary server and a standby server is implicated, possibly because the *major* operating system version in use is inconsistent. Such inconsistencies will generally only arise on standby servers, and so can generally only be detected on standby servers.

  If a problem like this arises, it may not affect each individual index that is ordered using an affected collation, simply because *indexed* values might happen to have the same absolute ordering regardless of the behavioral inconsistency. See Section 22.1 and Section 22.2 for further details about how Postgres Pro uses operating system locales and collations.

- Structural inconsistencies between indexes and the heap relations that are indexed (when *heapallindexed* verification is performed).

  There is no cross-checking of indexes against their heap relation during normal operation. Symptoms of heap corruption can be subtle.

- Corruption caused by hypothetical undiscovered bugs in the underlying Postgres Pro access method code, sort code, or transaction management code.

  Automatic verification of the structural integrity of indexes plays a role in the general testing of new or proposed Postgres Pro features that could plausibly allow a logical inconsistency to be introduced. Verification of table structure and associated visibility and transaction status information plays a similar role. One obvious testing strategy is to call amcheck functions continuously when running the standard regression tests.

- File system or storage subsystem faults where checksums happen to simply not be enabled.

  Note that amcheck examines a page as represented in some shared memory buffer at the time of verification if there is only a shared buffer hit when accessing the block. Consequently, amcheck does not necessarily examine data read from the file system at the time of verification. Note that when checksums are enabled, amcheck may raise an error due to a checksum failure when a corrupt block is read into a buffer.

- Corruption caused by faulty RAM, or the broader memory subsystem.

  Postgres Pro does not protect against correctable memory errors and it is assumed you will operate using RAM that uses industry standard Error Correcting Codes (ECC) or better protection. However, ECC memory is typically only immune to single-bit errors, and should not be assumed to provide *absolute* protection against failures that result in memory corruption.

  When *heapallindexed* verification is performed, there is generally a greatly increased chance of detecting single-bit errors, since strict binary equality is tested, and the indexed attributes within the heap are tested.

Structural corruption can happen due to faulty storage hardware, or relation files being overwritten or modified by unrelated software. This kind of corruption can also be detected with data page checksums.

Relation pages which are correctly formatted, internally consistent, and correct relative to their own internal checksums may still contain logical corruption. As such, this kind of corruption cannot be detected with checksums. Examples include toasted values in the main table which lack a corresponding

entry in the toast table, and tuples in the main table with a Transaction ID that is older than the oldest valid Transaction ID in the database or cluster.

Multiple causes of logical corruption have been observed in production systems, including bugs in the PostgreSQL server software, faulty and ill-conceived backup and restore tools, and user error.

Corrupt relations are most concerning in live production environments, precisely the same environments where high risk activities are least welcome. For this reason, `verify_heapam` has been designed to diagnose corruption without undue risk. It cannot guard against all causes of backend crashes, as even executing the calling query could be unsafe on a badly corrupted system. Access to catalog tables is performed and could be problematic if the catalogs themselves are corrupted.

In general, `amcheck` can only prove the presence of corruption; it cannot prove its absence.

F.2.4. Repairing Corruption

No error concerning corruption raised by `amcheck` should ever be a false positive. `amcheck` raises errors in the event of conditions that, by definition, should never happen, and so careful analysis of `amcheck` errors is often required.

There is no general method of repairing problems that `amcheck` detects. An explanation for the root cause of an invariant violation should be sought. pageinspect may play a useful role in diagnosing corruption that `amcheck` detects. A `REINDEX` may not be effective in repairing corruption.

F.3. aqo

The aqo module is a Postgres Pro Standard extension for cost-based query optimization. Using machine learning methods, more precisely, a modification of the k-NN algorithm, aqo improves cardinality estimation, which can optimize execution plans and, consequently, speed up query execution.

The aqo module can collect statistics on all the executed queries, excluding the queries that access system relations. The collected statistics is classified by query class. If the queries differ in their constants only, they belong to the same class. For each query class, aqo stores the cardinality quality, planning time, execution time, and execution statistics for machine learning. Based on this data, aqo builds a new query plan and uses it for the next query of the same class. aqo test runs have shown significant performance improvements for complex queries.

> **Important**
>
> Query optimization using the aqo module is not supported on standby.

aqo saves all the learning data (aqo_data), queries (aqo_query_texts), query settings (aqo_queries), and query execution statistics (aqo_query_stat) to files. When aqo starts, it loads this data to shared memory. You can access aqo data through functions and views.

> **Warning**
>
> Be aware that aqo may not work correctly right after extension upgrades that change its kernel and after Postgres Pro upgrades. Therefore, after each Postgres Pro upgrade, call `aqo_reset()` and run `DROP EXTENSION aqo`. However, after Postgres Pro minor release upgrades to versions to 13.11/14.8/15.3 or higher a call to `aqo_reset()` is not needed as aqo is reset automatically if required.
>
> After a minor release upgrade, also run `ALTER EXTENSION aqo UPDATE` and keep in mind that aqo downgrade is impossible.

In the event of an automatic aqo reset or manually calling `aqo_reset()`, all the machine learning data gets lost, and new learning will be needed for future aqo use. Therefore, if some data, such as query texts, may help in aqo learning, back up this data in advance.

F.3.1. Installation and Setup

The aqo extension is included into Postgres Pro Standard. Once you have Postgres Pro Standard installed, complete the following steps to enable aqo:

1. Add `aqo` to the shared_preload_libraries parameter in the `postgresql.conf` file:

   ```
   shared_preload_libraries = 'aqo'
   ```

   The `aqo` library must be preloaded at the server startup, since adaptive query optimization needs to be enabled per cluster.

2. Create the aqo extension using the following query:

   ```
   CREATE EXTENSION aqo;
   ```

Once the extension is created, you can start optimizing queries.

The command

```
DROP EXTENSION aqo;
```

will only remove aqo interface at the cluster level. aqo will still be running on all the backends while it is listed in `shared_preload_libraries` and at the server restart, will continue working in the operation mode specified in `postgresql.conf`. Besides, aqo will retain its internal state after consequent execution of `DROP EXTENSION` -> `CREATE EXTENSION`.

To remove all the data from the aqo storage, including the collected statistics, call `aqo_reset()`:

```
SELECT aqo_reset();
```

To actually disable aqo at the cluster level, do the following:

```
ALTER SYSTEM SET aqo.mode = 'disabled';
SELECT pg_reload_conf();
DROP EXTENSION aqo;
```

If you do not want aqo to be loaded at the server restart, remove the line

```
shared_preload_libraries = 'aqo'
```

from the `postgresql.conf` file.

F.3.1.1. Configuration

With the default operation mode (`controlled`), aqo does not affect query performance. Depending on your database usage model, you should choose between the following modes:

- `intelligent` — this mode auto-tunes your queries based on statistics collected per query class. See the description of the `auto_tuning` flag of the aqo_queries view for more details.
- `forced` — this mode collects statistics for all queries altogether without any classification.
- `controlled` — this mode uses the default planner for all new queries, but continues using the previously specified planning settings for already known query classes, if any.
- `learn` — this mode collects statistics on all the executed queries and updates the data for query classes without auto-tuning queries.

- `frozen` — this mode reads the collected statistics for already known query classes but does not collect any new data. You can use this mode to reduce the impact of aqo on query planning and execution.
- `disabled` — this mode disables aqo for all queries, even for the known query classes. The collected statistics and aqo settings are saved and can be used in the future. You can use this mode to temporarily disable aqo without losing the collected statistics and configuration.

To dynamically change the aqo mode in your current session, run the following command:

```
ALTER SYSTEM SET aqo.mode = 'mode';
SELECT pg_reload_conf();
```

where *mode* is the name of the operation mode to use.

F.3.2. Usage

F.3.2.1. Choosing Operation Mode for Query Optimization

If you often run queries of the same class, for example, your application limits the number of possible query classes, you can use the `intelligent` mode to improve planning for these queries. In this mode, aqo analyzes each query execution and stores statistics. Statistics on queries of different classes is stored separately. If performance is not improved after 50 iterations, the aqo extension falls back to the default query planner.

> **Note**
>
> You can view the current query plan using the standard Postgres Pro `EXPLAIN` command with the `ANALYZE` option. For details, see the Section 14.1.

Since the `intelligent` mode tries to learn separately for different query classes, aqo may fail to provide performance improvements if queries in the workload are of multiple different classes or if the classes of the queries in the workload are constantly changing. For such workloads, reset the aqo extension to the `controlled` mode, or try using the `forced` mode.

In the `forced` mode, aqo does not classify the collected statistics by query classes and tries to optimize all queries together. Therefore, aqo_query_texts, aqo_queries and aqo_query_stat views do not get updated. Machine learning data collected in any other modes is inapplicable for the `forced` mode and vice versa. This mode can help you optimize workloads with multiple different query classes, and it consumes less memory than the intelligent mode. However, since the `forced` mode lacks intelligent tuning, performance may decrease for some queries. If you see performance issues in this mode, switch aqo to the `controlled` mode.

In the `controlled` mode, aqo does not collect statistics for new query classes, so they will not be optimized. For known query classes, aqo will continue collecting statistics and using optimized planning algorithms. So use the `controlled` mode only after aqo learned in the `learn` or `intelligent` mode. As there are no query classes in the `forced` mode, switching from it to the `controlled` mode actually means disabling aqo.

The `learn` mode collects statistics from all the executed queries and updates the data for query classes. This mode is similar to the `intelligent` mode, except that it does not provide intelligent tuning.

If you want to reduce the impact of aqo on query planning and execution, you can use it in the `frozen` mode. In this mode, aqo only reads the collected statistics for already known query classes but does not collect any new data.

Switching to the `disabled` mode is the only way to actually disable aqo without losing the statistics and aqo settings, which are saved and can be used in the future. Queries in this mode will be executed as though there were no aqo at all.

F.3.2.2. Fine-Tuning aqo

You must have superuser rights to access aqo views and configure advanced query settings.

When run in the `intelligent` or `learn` mode, aqo assigns a unique hash value to each query class to separate the collected statistics. If you switch to the `forced` mode, the statistics for all untracked query classes is stored in a common query class with hash 0. You can view all the processed query classes and their corresponding hash values in the `aqo_query_texts` view:

```
SELECT * FROM aqo_query_texts;
```

To find out the class, that is, hash, of a query and aqo mode, enable `aqo.show_hash` and `aqo.show_details` environment variables and execute the query. The output will contain something like this:

```
...
Planning Time: 23.538 ms
...
Execution Time: 249813.875 ms
...
Using aqo: true
...
AQO mode: LEARN
...
Query hash: -2439501042637610315
```

Each query class has an associated separate space, called *feature space*, in which the statistics for this query class is collected. Each feature space has associated *feature subspaces*, where the information about selectivity and cardinality for each query plan node is collected.

Each query class has its own optimization settings. These settings are shown in the `aqo_queries` view:

```
SELECT * FROM aqo_queries;
```

The settings available are listed in the `aqo_queries` View table.

You can manually change these settings to adjust optimization for a particular query class. For example:

```
 -- Add a new query class into the aqo_queries view:

SET aqo.mode='intelligent';
SELECT * FROM a, b WHERE a.id=b.id;
SET aqo.mode='controlled';

 -- Disable auto_tuning, enable both learn_aqo and use_aqo
 -- for this query class:

SELECT count(*) FROM (SELECT queryid FROM aqo_queries) AS q1,
  LATERAL aqo_queries_update(q1.queryid, NULL, true, true, false) AS q2
  WHERE queryid = (SELECT queryid FROM aqo_query_texts
  WHERE query_text LIKE 'SELECT * FROM a, b WHERE a.id=b.id;');

 -- Run EXPLAIN ANALYZE until the plan changes:

EXPLAIN ANALYZE SELECT * FROM a, b WHERE a.id=b.id;
EXPLAIN ANALYZE SELECT * FROM a, b WHERE a.id=b.id;

 -- Disable learning to stop statistics collection
 -- and use the optimized plan:

 SELECT count(*) FROM (SELECT queryid FROM aqo_queries) AS q1,
  LATERAL aqo_queries_update(q1.queryid, NULL, false, true, false) AS q2
```

```
  WHERE queryid = (SELECT queryid FROM aqo_query_texts
  WHERE query_text LIKE 'SELECT * FROM a, b WHERE a.id=b.id;');
```

To stop intelligent tuning for a particular query class, disable the `auto_tuning` setting:

```
SELECT count(*) FROM (SELECT queryid FROM aqo_queries) AS q1,
  LATERAL aqo_queries_update(q1.queryid, NULL, true, true, false) AS q2
  WHERE queryid = 'hash');
```

where *hash* is the hash value for this query class. As a result, aqo disables automatic change of the `learn_aqo` and `use_aqo` settings.

To disable further learning for a particular query class, use the following command:

```
SELECT count(*) FROM (SELECT queryid FROM aqo_queries) AS q1,
  LATERAL aqo_queries_update(q1.queryid, NULL, false, true, false) AS q2
  WHERE queryid = 'hash');
```

where *hash* is the hash value for this query class.

To fully disable aqo for all queries and use the default Postgres Pro query planner, run:

```
SELECT count(*) FROM (SELECT queryid FROM aqo_queries) AS q1,
  LATERAL aqo_queries_update(q1.queryid, NULL, false, false, false) AS q2
  WHERE queryid IN (SELECT queryid FROM aqo_query_texts);
```

F.3.3. Reference

F.3.3.1. Configuration Parameters

`aqo.mode` (`text`)

Defines the aqo operation mode. Possible values are listed in Section F.3.1.1.

Default: `controlled`.

`aqo.show_hash` (`boolean`)

Show a hash value that is computed from a query tree and uniquely identifies the class of queries or class of plan nodes. Starting with Postgres Pro 14, aqo uses the native query ID to identify a query class for consistency with other extensions, such as pg_stat_statements. So, the query ID can be taken from the `Query Identifier` field in `EXPLAIN ANALYZE` output of a query.

Default: `off`.

`aqo.show_details` (`boolean`)

Add some details to `EXPLAIN` output of a query, such as the prediction or feature-subspace hash, and show some additional aqo-specific on-screen information.

Default: `off`.

`aqo.join_threshold` (`integer`)

Ignore queries that contain smaller number of joins, which means that statistics for such queries will not be collected.

Default: `3`.

`aqo.statement_timeout` (`integer`)

Defines the initial value of the *smart statement timeout*, in milliseconds, which is needed to limit the execution time when manually training aqo on special queries with a poor cardinality forecast.

aqo can dynamically change the value of the smart statement timeout during this training. When the cardinality estimation error on nodes exceeds 0.1, the value of `aqo.statement_timeout` is automatically incremented exponentially, but remains not greater than statement_timeout.

Default: `0`.

`aqo.force_collect_stat` (`boolean`)

Gather statistics on query executions even in the `disabled` mode. Although no predictions are made, some overhead will be added.

Default: `off`.

`aqo.dsm_size_max` (`integer`)

Defines the maximum size of dynamic shared memory, in MB, that aqo can allocate to store learning data. When this number is exceeded, an attempt to load the aqo_data view will fail with "out of memory" error.

Default: `100`.

`aqo.fs_max_items` (`integer`)

Defines the maximum number of feature spaces that aqo can operate with. When this number is exceeded, learning on new query classes will no longer occur, and they will not appear in the views accordingly.

Default: `10000`.

`aqo.fss_max_items` (`integer`)

Defines the maximum number of feature subspaces that aqo can operate with. When this number is exceeded, the selectivity and cardinality for new query plan nodes will no longer be collected, and new feature subspaces will not appear in the aqo_data view accordingly.

Default: `100000`.

`aqo.wide_search` (`boolean`)

Enables searching neighbors with the same feature subspace among different query classes.

Default: `off`.

`aqo.querytext_max_size` (`integer`)

Defines the maximum size of the query in the aqo_query_texts view.

Default: `1000`.

`aqo.min_neighbors_for_predicting` (`integer`)

Defines the minimum number of neighbors needed for the cardinality prediction. If there are fewer of them, aqo will not make any prediction.

Default: `3`.

`aqo.predict_with_few_neighbors` (`boolean`)

Enables aqo to make predictions with fewer neighbors than were found.

Default: `on`.

F.3.3.2. Views

F.3.3.2.1. aqo_query_texts

The aqo_query_texts view classifies all the query classes processed by aqo. For each query class, the view shows the text of the first analyzed query of this class.

Table F.2. aqo_query_texts View

Column Name	Description
queryid	Stores the query ID, that is, the feature-space hash, that uniquely identifies the query class.
query_text	Provides the text of the first analyzed query of the given class.

F.3.3.2.2. aqo_queries

The aqo_queries view shows optimization settings for different query classes.

Table F.3. aqo_queries View

Setting	Description
queryid	Stores the query ID that uniquely identifies the query class.
learn_aqo	Enables statistics collection for this query class.
use_aqo	Enables the aqo cardinality prediction for the next execution of this query class. If the cost estimation model is inaccurate, this may slow down query execution.
fspace_hash	Provides a unique identifier of the separate space in which the statistics for this query class is collected. By default, fspace_hash is equal to queryid. You can change this setting to a different queryid to optimize different query classes together. It may decrease the amount of memory for models and even improve query execution performance. However, changing this setting may cause unexpected aqo behavior, so make sure to use it only if you know what you are doing.
auto_tuning	Shows whether aqo can dynamically change use_aqo and learn_aqo settings for this query class. By default, auto-tuning is only enabled in the intelligent mode. In more detail, when auto_tuning is on, if for several successive executions of a query for which use_aqo is off, the cardinality error remains sufficiently small and stable, aqo turns on use_aqo . For queries with learn_aqo =true (it is so for new queries), several first executions are done both using aqo and without it. The faster the query is executed compared to the execution with the standard planner, the more likely aqo will be used for the next query execution. If after a certain number of executions the execution time with aqo appears to be worse than with the standard planner, aqo will never be used for this query

Setting	Description
	class: auto_tuning , use_aqo and learn_aqo are set to off.
smart_timeout	Shows the value of smart statement timeout for this query class.
count_increase_timeout	Shows how many times the smart statement timeout increased for this query class.

F.3.3.2.3. aqo_data

The aqo_data view shows machine learning data for cardinality estimation refinement. To forget all the collected statistics for a particular query class, you can delete all rows from aqo_data with the corresponding fs.

Table F.4. aqo_data View

Data	Description
fs	Feature-space hash.
fss	Feature-subspace hash.
nfeatures	Feature-subspace size for the query plan node.
features	Logarithm of the selectivity which the cardinality prediction is based on.
targets	Cardinality logarithm for the query plan node.
reliability	Equals: • 1 — indicates data obtained after normal execution of a query • 0.1 — indicates data obtained from a partially executed node (not needed as unreliable) • 0.9 — indicates data obtained from a finished node, but from a partially executed statement
oids	List of IDs of tables that were involved in the prediction for this node.

F.3.3.2.4. aqo_query_stat

The aqo_query_stat view shows statistics on query execution, by query class. The aqo extension uses this data when the auto_tuning option is enabled for a particular query class.

Table F.5. aqo_query_stat View

Data	Description
execution_time_with_aqo	Execution time for queries run with aqo enabled.
execution_time_without_aqo	Execution time for queries run with aqo disabled.
planning_time_with_aqo	Planning time for queries run with aqo enabled.
planning_time_without_aqo	Planning time for queries run with aqo disabled.
cardinality_error_with_aqo	Cardinality estimation error in the selected query plans with aqo enabled.
cardinality_error_without_aqo	Cardinality estimation error in the selected query plans with aqo disabled.
executions_with_aqo	Number of queries run with aqo enabled.
executions_without_aqo	Number of queries run with aqo disabled.

F.3.3.3. Functions

aqo adds several functions to Postgres Pro catalog.

F.3.3.3.1. Storage Management Functions

> **Important**
>
> Functions `aqo_queries_update`, `aqo_query_texts_update`, `aqo_query_stat_update`, and `aqo_data_update` modify data files underlying aqo views. Therefore, call these functions only if you understand the logic of adaptive query optimization.

`aqo_cleanup()` → `setof integer`

Removes data related to query classes that are linked (may be partially) with removed relations. Returns the number of removed feature spaces (classes) and feature subspaces. Insensitive to removing other objects.

`aqo_enable_class (queryid bigint)` → `void`

Sets `learn_aqo`, `use_aqo` and `auto_tuning` (only in the `intelligent` mode) to true for a given query class.

`aqo_disable_class (queryid bigint)` → `void`

Sets `learn_aqo`, `use_aqo` and `auto_tuning` (only in the `intelligent` mode) to false for a given query class.

`aqo_drop_class (queryid bigint)` → `integer`

Removes all data related to a given query class from the aqo storage. Returns the number of records removed from the aqo storage.

`aqo_reset()` → `bigint`

Removes data from the aqo storage: machine learning data, query texts, statistics and query class preferences. Returns the number of records removed from the aqo storage.

`aqo_queries_update (queryid bigint, fs bigint, learn_aqo boolean, use_aqo boolean, auto_tuning boolean)` → `boolean`

Assigns new values to the following settings in the aqo_queries view for a given query class: `fspace_hash`, `learn_aqo`, `use_aqo` and `auto_tuning`. NULL value means “leave as is”.

`aqo_query_texts_update (queryid bigint, query_text text)` → `boolean`

Updates or inserts a record in a data file underlying the aqo_query_texts view for a given *queryid*.

`aqo_query_stat_update (queryid bigint, execution_time_with_aqo double precision[], execution_time_without_aqo double precision[], planning_time_with_aqo double precision[], planning_time_without_aqo double precision[], cardinality_error_with_aqo double precision[], cardinality_error_without_aqo double precision[], executions_with_aqo bigint[], executions_without_aqo bigint[])` → `boolean`

Updates or inserts a record in a data file underlying the aqo_query_stat view for a given *queryid*.

`aqo_data_update (fs bigint, fss integer, nfeatures integer, features double precision[][], targets double precision[], reliability double precision[], oids oid[])` → `boolean`

Updates or inserts a record in a data file underlying the aqo_data view for given *fs* and *fss*.

F.3.3.3.2. Memory Management Functions

`aqo_memory_usage` () → `setof record`

Displays sizes of aqo memory contexts and hash tables.

F.3.3.3.3. Analytics Functions

`aqo_cardinality_error` (*`controlled`* `boolean`) → `setof record`

Shows the cardinality error for each query class. If *`controlled`* is true, shows the error of the last execution with aqo enabled. If *`controlled`* is false, returns the average cardinality error for all logged executions with aqo disabled.

`aqo_execution_time` (*`controlled`* `boolean`) → `setof record`

Shows the execution time for each query class. If *`controlled`* is true, shows the execution time of the last execution with aqo enabled. If *`controlled`* is false, returns the average execution time for all logged executions with aqo disabled.

F.3.4. Examples

Example F.1. Learning on a Query

Consider optimization of a query using aqo.

When the query is executed for the first time, it is missing in tables underlying aqo views. So there is no data for predicting with aqo for each plan node, and "AQO not used" lines appear in the `EXPLAIN` output:

```
postgres=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF) select count(*) from score join
 course on score.cno=course.cno join student on score.sno=student.sno where degree<90
 and test_preparation = 0;
                                                 QUERY PLAN
-------------------------------------------------------------------------------------------
 Aggregate  (cost=308.28..308.29 rows=1 width=8) (actual rows=1 loops=1)
   AQO not used, fss=0
   ->  Hash Join  (cost=124.80..299.47 rows=3526 width=0) (actual rows=3649 loops=1)
         AQO not used, fss=2128507884
         Hash Cond: (score.sno = student.sno)
         ->  Hash Join  (cost=16.30..181.70 rows=3526 width=4) (actual rows=3649
 loops=1)
               AQO not used, fss=-303037802
               Hash Cond: (score.cno = course.cno)
               ->  Seq Scan on score  (cost=0.00..156.00 rows=3526 width=8) (actual
 rows=3649 loops=1)
                     AQO not used, fss=-636613046
                     Filter: ((degree < 90) AND (test_preparation = 0))
                     Rows Removed by Filter: 1351
               ->  Hash  (cost=12.80..12.80 rows=280 width=4) (actual rows=10 loops=1)
                     Buckets: 1024  Batches: 1  Memory Usage: 9kB
                     ->  Seq Scan on course  (cost=0.00..12.80 rows=280 width=4)
 (actual rows=10 loops=1)
                           AQO not used, fss=-1076069505
         ->  Hash  (cost=71.00..71.00 rows=3000 width=4) (actual rows=3000 loops=1)
               Buckets: 4096  Batches: 1  Memory Usage: 138kB
               ->  Seq Scan on student  (cost=0.00..71.00 rows=3000 width=4) (actual
 rows=3000 loops=1)
                     AQO not used, fss=-1838231581
 Using aqo: true
 AQO mode: LEARN
 Query hash: -727505571757520766
```

```
 JOINS: 2
(24 rows)
```

If there is no information on a certain node in the aqo_data view, aqo will add the appropriate record there for future learning and predictions except for nodes with `fss=0` in the `EXPLAIN` output. As each of `features` and `targets` in the `aqo_data` view is a logarithm to base `e`, to get the actual value, raise `e` to this power. For example: exp(0):

```
         fs          |     fss     | nfeatures |
 features                                      |       targets       | reliability |
     oids
---------------------+-------------+-----------
+-------------------------------------------------------------------------------------
+---------------------+-------------+---------------------

 {8.202208436436448} | {1}         | {16579,16555,16563}
 -727505571757520766 | -1076069505 |         0 |
                                                  | {2.302585092994046} | {1}         |
 {16555}
 -727505571757520766 | -1838231581 |         0 |
                                                  | {8.006367567650246} | {1}         |
 {16563}
 -727505571757520766 |  -303037802 |         3 |
 {{-0.03438753143452488,-5.634789603169249,-0.3149847743198556}}                      |
 {8.202208436436448} | {1}         | {16579,16555}
 -727505571757520766 |  -636613046 |         2 |
 {{-0.03438753143452488,-0.3149847743198556}}                                         |
 {8.202208436436448} | {1}         | {16579}
(6 rows)
```

When the query is executed for the second time, aqo recognizes the query and makes a prediction. Pay attention to the cardinality predicted by aqo and the value of aqo error (“error=0%”).

```
postgres=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF) select count(*) from score join
 course on score.cno=course.cno join student on score.sno=student.sno where degree<90
 and test_preparation = 0;
                                                QUERY PLAN
-----------------------------------------------------------------------------------------
 Aggregate  (cost=305.86..305.87 rows=1 width=8) (actual rows=1 loops=1)
   AQO not used, fss=0
   ->  Hash Join  (cost=121.42..296.74 rows=3649 width=0) (actual rows=3649 loops=1)
         AQO: rows=3649, error=0%, fss=2128507884
         Hash Cond: (score.sno = student.sno)
         ->  Hash Join  (cost=12.93..178.65 rows=3649 width=4) (actual rows=3649
 loops=1)
               AQO: rows=3649, error=0%, fss=-303037802
               Hash Cond: (score.cno = course.cno)
               ->  Seq Scan on score  (cost=0.00..156.00 rows=3649 width=8) (actual
 rows=3649 loops=1)
                     AQO: rows=3649, error=0%, fss=-636613046
                     Filter: ((degree < 90) AND (test_preparation = 0))
                     Rows Removed by Filter: 1351
               ->  Hash  (cost=12.80..12.80 rows=10 width=4) (actual rows=10 loops=1)
                     Buckets: 1024  Batches: 1  Memory Usage: 9kB
                     ->  Seq Scan on course  (cost=0.00..12.80 rows=10 width=4) (actual
 rows=10 loops=1)
                           AQO: rows=10, error=0%, fss=-1076069505
         ->  Hash  (cost=71.00..71.00 rows=3000 width=4) (actual rows=3000 loops=1)
```

```
               Buckets: 4096  Batches: 1  Memory Usage: 138kB
               ->  Seq Scan on student  (cost=0.00..71.00 rows=3000 width=4) (actual
 rows=3000 loops=1)
                     AQO: rows=3000, error=0%, fss=-1838231581
 Using aqo: true
 AQO mode: LEARN
 Query hash: -727505571757520766
 JOINS: 2
(24 rows)
```

In case of an error, values of `features` and `targets` must change, but as there was no error above, they did not change.

```
         fs          |     fss     | nfeatures |
 features                                      |       targets       | reliability |
     oids
---------------------+-------------+-----------

 {8.202208436436448} | {1}         | {16579}
(6 rows)
```

Let's change a constant in the query, and you will notice that the prediction is made with an error:

```
    postgres=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF) select count(*) from score
 join course on score.cno=course.cno join student on score.sno=student.sno where
 degree<80 and test_preparation = 0;
                                                    QUERY PLAN
-------------------------------------------------------------------------------------------------
 Aggregate  (cost=305.86..305.87 rows=1 width=8) (actual rows=1 loops=1)
   AQO not used, fss=0
   ->  Hash Join  (cost=121.42..296.74 rows=3649 width=0) (actual rows=3551 loops=1)
         AQO: rows=3649, error=3%, fss=2128507884
         Hash Cond: (score.sno = student.sno)
         ->  Hash Join  (cost=12.93..178.65 rows=3649 width=4) (actual rows=3551
 loops=1)
               AQO: rows=3649, error=3%, fss=-303037802
               Hash Cond: (score.cno = course.cno)
               ->  Seq Scan on score  (cost=0.00..156.00 rows=3649 width=8) (actual
 rows=3551 loops=1)
                     AQO: rows=3649, error=3%, fss=-636613046
                     Filter: ((degree < 80) AND (test_preparation = 0))
                     Rows Removed by Filter: 1449
               ->  Hash  (cost=12.80..12.80 rows=10 width=4) (actual rows=10 loops=1)
                     Buckets: 1024  Batches: 1  Memory Usage: 9kB
```

```
                      ->  Seq Scan on course  (cost=0.00..12.80 rows=10 width=4) (actual
 rows=10 loops=1)
                            AQO: rows=10, error=0%, fss=-1076069505
         ->  Hash  (cost=71.00..71.00 rows=3000 width=4) (actual rows=3000 loops=1)
               Buckets: 4096  Batches: 1  Memory Usage: 138kB
               ->  Seq Scan on student  (cost=0.00..71.00 rows=3000 width=4) (actual
 rows=3000 loops=1)
                     AQO: rows=3000, error=0%, fss=-1838231581
 Using aqo: true
 AQO mode: LEARN
 Query hash: -727505571757520766
 JOINS: 2
(24 rows)
```

However, instead of recalculating `features` and `targets`, aqo added new values of selectivity and cardinality for this query to `aqo_data`:

```
         fs           |     fss     | nfeatures |
                                          features
                                            |                targets                |
 reliability |        oids
---------------------+-------------+-----------
+-----------------------------------------------------------------------------------------
+--------------------------------------+-------------+---------------------
 -727505571757520766 |  1141621836 |         0 |

                                         | {0}                                    | {1}
       | {16579,16555,16563}
 -727505571757520766 |  2128507884 |         4 |
 {{-0.030949078292235133,-5.634789603169249,-0.3149847743198556,-8.006367567650246},
{-0.34221288089027607,-5.634789603169249,-0.3149847743198556,-8.006367567650246}} |
 {8.202208436436448,8.174984532943087} | {1,1}       | {16579,16555,16563}
 -727505571757520766 | -1076069505 |         0 |

Example F.2. Using the aqo_query_stat View

The `aqo_query_stats` view shows statistics on the query planning time, query execution time and cardinality error. Based on this data you can make a decision whether to use aqo predictions for different query classes.

Let's query the `aqo_query_stats` view:

```
select queryid, cardinality_error_with_aqo,
 cardinality_error_without_aqo,execution_time_with_aqo, execution_time_without_aqo,
 planning_time_with_aqo, planning_time_without_aqo from aqo_query_stat \gx
-[ RECORD 1 ]-----------------
+-------------------------------------------------------------------------------------------------------------
queryid                       | 8041624334006338922
cardinality_error_with_aqo    |
 {0.14932737556062836,0,0.507421202801325,0.00040469447777891077}
cardinality_error_without_aqo | {0.1493979460962751,0.018403615483185476}
execution_time_with_aqo       | {0.004760108,0.008743075,0.006608304,0.012392751}
execution_time_without_aqo    | {0.005775926,0.012730316}
planning_time_with_aqo        | {0.006927997,0.004247339,0.005005022,0.004169717}
planning_time_without_aqo     | {0.001783542,0.001706121}
```

The retrieved data is for the query from Example F.1, which was executed once without aqo for each of the parameters `degree<80` and `degree<90` and twice with aqo for each of these parameters. It is clear that with aqo, the cardinality error decreases to 0.0004, while the minimum cardinality error without aqo is 0.15. Besides, the execution time with aqo is lower than without it. So the conclusion is that aqo learns well on this query, and the prediction can be used for this query class.

F.3.5. Author

Oleg Ivanov

F.4. auth_delay

auth_delay causes the server to pause briefly before reporting authentication failure, to make brute-force attacks on database passwords more difficult. Note that it does nothing to prevent denial-of-service attacks, and may even exacerbate them, since processes that are waiting before reporting authentication failure will still consume connection slots.

In order to function, this module must be loaded via shared_preload_libraries in postgresql.conf.

F.4.1. Configuration Parameters

auth_delay.milliseconds (int)

The number of milliseconds to wait before reporting an authentication failure. The default is 0.

These parameters must be set in postgresql.conf. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'auth_delay'

auth_delay.milliseconds = '500'
```

F.4.2. Author

KaiGai Kohei <kaigai@ak.jp.nec.com>

F.5. auto_explain

The auto_explain module provides a means for logging execution plans of slow statements automatically, without having to run EXPLAIN by hand. This is especially helpful for tracking down un-optimized queries in large applications.

The module provides no SQL-accessible functions. To use it, simply load it into the server. You can load it into an individual session:

```
LOAD 'auto_explain';
```

(You must be superuser to do that.) More typical usage is to preload it into some or all sessions by including auto_explain in session_preload_libraries or shared_preload_libraries in postgresql.conf. Then you can track unexpectedly slow queries no matter when they happen. Of course there is a price in overhead for that.

F.5.1. Configuration Parameters

There are several configuration parameters that control the behavior of auto_explain. Note that the default behavior is to do nothing, so you must set at least auto_explain.log_min_duration if you want any results.

auto_explain.log_min_duration (integer)

auto_explain.log_min_duration is the minimum statement execution time, in milliseconds, that will cause the statement's plan to be logged. Setting this to 0 logs all plans. -1 (the default) disables logging of plans. For example, if you set it to 250ms then all statements that run 250ms or longer will be logged. Only superusers can change this setting.

auto_explain.log_analyze (boolean)

auto_explain.log_analyze causes EXPLAIN ANALYZE output, rather than just EXPLAIN output, to be printed when an execution plan is logged. This parameter is off by default. Only superusers can change this setting.

> **Note**
>
> When this parameter is on, per-plan-node timing occurs for all statements executed, whether or not they run long enough to actually get logged. This can have an extremely negative impact

on performance. Turning off auto_explain.log_timing ameliorates the performance cost, at the price of obtaining less information.

auto_explain.log_buffers (boolean)

auto_explain.log_buffers controls whether buffer usage statistics are printed when an execution plan is logged; it's equivalent to the BUFFERS option of EXPLAIN. This parameter has no effect unless auto_explain.log_analyze is enabled. This parameter is off by default. Only superusers can change this setting.

auto_explain.log_wal (boolean)

auto_explain.log_wal controls whether WAL usage statistics are printed when an execution plan is logged; it's equivalent to the WAL option of EXPLAIN. This parameter has no effect unless auto_explain.log_analyze is enabled. This parameter is off by default. Only superusers can change this setting.

auto_explain.log_timing (boolean)

auto_explain.log_timing controls whether per-node timing information is printed when an execution plan is logged; it's equivalent to the TIMING option of EXPLAIN. The overhead of repeatedly reading the system clock can slow down queries significantly on some systems, so it may be useful to set this parameter to off when only actual row counts, and not exact times, are needed. This parameter has no effect unless auto_explain.log_analyze is enabled. This parameter is on by default. Only superusers can change this setting.

auto_explain.log_triggers (boolean)

auto_explain.log_triggers causes trigger execution statistics to be included when an execution plan is logged. This parameter has no effect unless auto_explain.log_analyze is enabled. This parameter is off by default. Only superusers can change this setting.

auto_explain.log_verbose (boolean)

auto_explain.log_verbose controls whether verbose details are printed when an execution plan is logged; it's equivalent to the VERBOSE option of EXPLAIN. This parameter is off by default. Only superusers can change this setting.

auto_explain.log_settings (boolean)

auto_explain.log_settings controls whether information about modified configuration options is printed when an execution plan is logged. Only options affecting query planning with value different from the built-in default value are included in the output. This parameter is off by default. Only superusers can change this setting.

auto_explain.log_format (enum)

auto_explain.log_format selects the EXPLAIN output format to be used. The allowed values are text, xml, json, and yaml. The default is text. Only superusers can change this setting.

auto_explain.log_level (enum)

auto_explain.log_level selects the log level at which auto_explain will log the query plan. Valid values are DEBUG5, DEBUG4, DEBUG3, DEBUG2, DEBUG1, INFO, NOTICE, WARNING, and LOG. The default is LOG. Only superusers can change this setting.

auto_explain.log_nested_statements (boolean)

auto_explain.log_nested_statements causes nested statements (statements executed inside a function) to be considered for logging. When it is off, only top-level query plans are logged. This parameter is off by default. Only superusers can change this setting.

`auto_explain.sample_rate` (`real`)

`auto_explain.sample_rate` causes auto_explain to only explain a fraction of the statements in each session. The default is 1, meaning explain all the queries. In case of nested statements, either all will be explained or none. Only superusers can change this setting.

In ordinary usage, these parameters are set in `postgresql.conf`, although superusers can alter them on-the-fly within their own sessions. Typical usage might be:

```
# postgresql.conf
session_preload_libraries = 'auto_explain'

auto_explain.log_min_duration = '3s'
```

F.5.2. Example

```
postgres=# LOAD 'auto_explain';
postgres=# SET auto_explain.log_min_duration = 0;
postgres=# SET auto_explain.log_analyze = true;
postgres=# SELECT count(*)
           FROM pg_class, pg_index
           WHERE oid = indrelid AND indisunique;
```

This might produce log output such as:

```
LOG:  duration: 0.196 ms plan:
  Query Text: SELECT count(*)
              FROM pg_class, pg_index
              WHERE oid = indrelid AND indisunique;
  Aggregate  (cost=16.79..16.80 rows=1 width=0) (actual time=3.626..3.627 rows=1
 loops=1)
    ->  Hash Join  (cost=4.17..16.55 rows=92 width=0) (actual time=3.349..3.594 rows=92
 loops=1)
          Hash Cond: (pg_class.oid = pg_index.indrelid)
          ->  Seq Scan on pg_class  (cost=0.00..9.55 rows=255 width=4) (actual
 time=0.016..0.140 rows=255 loops=1)
          ->  Hash  (cost=3.02..3.02 rows=92 width=4) (actual time=3.238..3.238 rows=92
 loops=1)
                Buckets: 1024  Batches: 1  Memory Usage: 4kB
                ->  Seq Scan on pg_index  (cost=0.00..3.02 rows=92 width=4) (actual
 time=0.008..3.187 rows=92 loops=1)
                      Filter: indisunique
  Planning Time: 0.548 ms
```

Note that Postgres Pro added a new field to the output to show planning time.

Postgres Professional, Moscow, Russia

F.6. bloom

`bloom` provides an index access method based on *Bloom filters*.

A Bloom filter is a space-efficient data structure that is used to test whether an element is a member of a set. In the case of an index access method, it allows fast exclusion of non-matching tuples via signatures whose size is determined at index creation.

A signature is a lossy representation of the indexed attribute(s), and as such is prone to reporting false positives; that is, it may be reported that an element is in the set, when it is not. So index search results

must always be rechecked using the actual attribute values from the heap entry. Larger signatures reduce the odds of a false positive and thus reduce the number of useless heap visits, but of course also make the index larger and hence slower to scan.

This type of index is most useful when a table has many attributes and queries test arbitrary combinations of them. A traditional btree index is faster than a bloom index, but it can require many btree indexes to support all possible queries where one needs only a single bloom index. Note however that bloom indexes only support equality queries, whereas btree indexes can also perform inequality and range searches.

F.6.1. Parameters

A `bloom` index accepts the following parameters in its `WITH` clause:

`length`

Length of each signature (index entry) in bits. It is rounded up to the nearest multiple of `16`. The default is `80` bits and the maximum is `4096`.

`col1 — col32`

Number of bits generated for each index column. Each parameter's name refers to the number of the index column that it controls. The default is `2` bits and the maximum is `4095`. Parameters for index columns not actually used are ignored.

F.6.2. Examples

This is an example of creating a bloom index:

```
CREATE INDEX bloomidx ON tbloom USING bloom (i1,i2,i3)
       WITH (length=80, col1=2, col2=2, col3=4);
```

The index is created with a signature length of 80 bits, with attributes i1 and i2 mapped to 2 bits, and attribute i3 mapped to 4 bits. We could have omitted the `length`, `col1`, and `col2` specifications since those have the default values.

Here is a more complete example of bloom index definition and usage, as well as a comparison with equivalent btree indexes. The bloom index is considerably smaller than the btree index, and can perform better.

```
=# CREATE TABLE tbloom AS
   SELECT
     (random() * 1000000)::int as i1,
     (random() * 1000000)::int as i2,
     (random() * 1000000)::int as i3,
     (random() * 1000000)::int as i4,
     (random() * 1000000)::int as i5,
     (random() * 1000000)::int as i6
   FROM
  generate_series(1,10000000);
SELECT 10000000
```

A sequential scan over this large table takes a long time:

```
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
                                                      QUERY PLAN
----------------------------------------------------------------------
----------------------------------
 Seq Scan on tbloom  (cost=0.00..213744.00 rows=250 width=24) (actual
 time=357.059..357.059 rows=0 loops=1)
   Filter: ((i2 = 898732) AND (i5 = 123451))
   Rows Removed by Filter: 10000000
 Planning Time: 0.346 ms
```

```
 Execution Time: 357.076 ms
(5 rows)
```

Even with the btree index defined the result will still be a sequential scan:

```
=# CREATE INDEX btreeidx ON tbloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('btreeidx'));
 pg_size_pretty
----------------
 386 MB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
                                                      QUERY PLAN
----------------------------------------------------------------------------
-----------------------------------
 Seq Scan on tbloom  (cost=0.00..213744.00 rows=2 width=24) (actual
 time=351.016..351.017 rows=0 loops=1)
   Filter: ((i2 = 898732) AND (i5 = 123451))
   Rows Removed by Filter: 10000000
 Planning Time: 0.138 ms
 Execution Time: 351.035 ms
(5 rows)
```

Having the bloom index defined on the table is better than btree in handling this type of search:

```
=# CREATE INDEX bloomidx ON tbloom USING bloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('bloomidx'));
 pg_size_pretty
----------------
 153 MB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
                                                          QUERY PLAN
----------------------------------------------------------------------------
-------------------------------------------------
 Bitmap Heap Scan on tbloom  (cost=1792.00..1799.69 rows=2 width=24) (actual
 time=22.605..22.606 rows=0 loops=1)
   Recheck Cond: ((i2 = 898732) AND (i5 = 123451))
   Rows Removed by Index Recheck: 2300
   Heap Blocks: exact=2256
   ->  Bitmap Index Scan on bloomidx  (cost=0.00..178436.00 rows=1 width=0) (actual
 time=20.005..20.005 rows=2300 loops=1)
         Index Cond: ((i2 = 898732) AND (i5 = 123451))
 Planning Time: 0.099 ms
 Execution Time: 22.632 ms
(8 rows)
```

Now, the main problem with the btree search is that btree is inefficient when the search conditions do not constrain the leading index column(s). A better strategy for btree is to create a separate index on each column. Then the planner will choose something like this:

```
=# CREATE INDEX btreeidx1 ON tbloom (i1);
CREATE INDEX
=# CREATE INDEX btreeidx2 ON tbloom (i2);
CREATE INDEX
=# CREATE INDEX btreeidx3 ON tbloom (i3);
CREATE INDEX
=# CREATE INDEX btreeidx4 ON tbloom (i4);
```

```
CREATE INDEX
=# CREATE INDEX btreeidx5 ON tbloom (i5);
CREATE INDEX
=# CREATE INDEX btreeidx6 ON tbloom (i6);
CREATE INDEX
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
                                                          QUERY PLAN
------------------------------------------------------------------------------
-------------------------------------------------------
 Bitmap Heap Scan on tbloom  (cost=9.29..13.30 rows=1 width=24) (actual
 time=0.032..0.033 rows=0 loops=1)
   Recheck Cond: ((i5 = 123451) AND (i2 = 898732))
   ->  BitmapAnd  (cost=9.29..9.29 rows=1 width=0) (actual time=0.047..0.047 rows=0
 loops=1)
         ->  Bitmap Index Scan on btreeidx5  (cost=0.00..4.52 rows=11 width=0) (actual
 time=0.026..0.026 rows=7 loops=1)
               Index Cond: (i5 = 123451)
         ->  Bitmap Index Scan on btreeidx2  (cost=0.00..4.52 rows=11 width=0) (actual
 time=0.007..0.007 rows=8 loops=1)
               Index Cond: (i2 = 898732)
 Planning Time: 0.264 ms
 Execution Time: 0.047 ms
(9 rows)
```

Although this query runs much faster than with either of the single indexes, we pay a penalty in index size. Each of the single-column btree indexes occupies 88.5 MB, so the total space needed is 531 MB, over three times the space used by the bloom index.

F.6.3. Operator Class Interface

An operator class for bloom indexes requires only a hash function for the indexed data type and an equality operator for searching. This example shows the operator class definition for the `text` data type:

```
CREATE OPERATOR CLASS text_ops
DEFAULT FOR TYPE text USING bloom AS
    OPERATOR    1   =(text, text),
    FUNCTION    1   hashtext(text);
```

F.6.4. Limitations

- Only operator classes for `int4` and `text` are included with the module.
- Only the = operator is supported for search. But it is possible to add support for arrays with union and intersection operations in the future.
- `bloom` access method doesn't support `UNIQUE` indexes.
- `bloom` access method doesn't support searching for `NULL` values.

F.6.5. Authors

Teodor Sigaev <teodor@postgrespro.ru>, Postgres Professional, Moscow, Russia

Alexander Korotkov <a.korotkov@postgrespro.ru>, Postgres Professional, Moscow, Russia

Oleg Bartunov <obartunov@postgrespro.ru>, Postgres Professional, Moscow, Russia

F.7. btree_gin

`btree_gin` provides sample GIN operator classes that implement B-tree equivalent behavior for the data types `int2`, `int4`, `int8`, `float4`, `float8`, `timestamp with time zone`, `timestamp without time zone`,

time with time zone, time without time zone, date, interval, oid, money, "char", varchar, text, bytea, bit, varbit, macaddr, macaddr8, inet, cidr, uuid, name, bool, bpchar, and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they are useful for GIN testing and as a base for developing other GIN operator classes. Also, for queries that test both a GIN-indexable column and a B-tree-indexable column, it might be more efficient to create a multicolumn GIN index that uses one of these operator classes than to create two separate indexes that would have to be combined via bitmap ANDing.

This module is considered "trusted", that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.7.1. Example Usage

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIN (a);
-- query
SELECT * FROM test WHERE a < 10;
```

F.7.2. Authors

Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See *http://www.sai.msu.su/~megera/oddmuse/index.cgi/Gin* for additional information.

F.8. btree_gist

btree_gist provides GiST index operator classes that implement B-tree equivalent behavior for the data types int2, int4, int8, float4, float8, numeric, timestamp with time zone, timestamp without time zone, time with time zone, time without time zone, date, interval, oid, money, char, varchar, text, bytea, bit, varbit, macaddr, macaddr8, inet, cidr, uuid, and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they provide some other features that are not available with a B-tree index, as described below. Also, these operator classes are useful when a multicolumn GiST index is needed, wherein some of the columns are of data types that are only indexable with GiST but other columns are just simple data types. Lastly, these operator classes are useful for GiST testing and as a base for developing other GiST operator classes.

In addition to the typical B-tree search operators, btree_gist also provides index support for <> ("not equals"). This may be useful in combination with an exclusion constraint, as described below.

Also, for data types for which there is a natural distance metric, btree_gist defines a distance operator <->, and provides GiST index support for nearest-neighbor searches using this operator. Distance operators are provided for int2, int4, int8, float4, float8, timestamp with time zone, timestamp without time zone, time without time zone, date, interval, oid, and money.

This module is considered "trusted", that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.8.1. Example Usage

Simple example using btree_gist instead of btree:

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIST (a);
-- query
SELECT * FROM test WHERE a < 10;
```

```
-- nearest-neighbor search: find the ten entries closest to "42"
SELECT *, a <-> 42 AS dist FROM test ORDER BY a <-> 42 LIMIT 10;
```

Use an exclusion constraint to enforce the rule that a cage at a zoo can contain only one kind of animal:

```
=> CREATE TABLE zoo (
  cage   INTEGER,
  animal TEXT,
  EXCLUDE USING GIST (cage WITH =, animal WITH <>)
);

=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'lion');
ERROR:  conflicting key value violates exclusion constraint "zoo_cage_animal_excl"
DETAIL:  Key (cage, animal)=(123, lion) conflicts with existing key (cage,
 animal)=(123, zebra).
=> INSERT INTO zoo VALUES(124, 'lion');
INSERT 0 1
```

F.8.2. Authors

Teodor Sigaev (<teodor@stack.net>), Oleg Bartunov (<oleg@sai.msu.su>), Janko Richter (<janko-richter@yahoo.de>), and Paul Jungwirth (<pj@illuminatedcomputing.com>). See *http://www.sai.msu.su/~megera/postgres/gist/* for additional information.

F.9. citext

The `citext` module provides a case-insensitive character string type, `citext`. Essentially, it internally calls `lower` when comparing values. Otherwise, it behaves almost exactly like `text`.

> **Tip**
>
> Consider using *nondeterministic collations* (see Section 22.2.2.4) instead of this module. They can be used for case-insensitive comparisons, accent-insensitive comparisons, and other combinations, and they handle more Unicode special cases correctly.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.9.1. Rationale

The standard approach to doing case-insensitive matches in Postgres Pro has been to use the `lower` function when comparing values, for example

```
SELECT * FROM tab WHERE lower(col) = LOWER(?);
```

This works reasonably well, but has a number of drawbacks:

- It makes your SQL statements verbose, and you always have to remember to use `lower` on both the column and the query value.
- It won't use an index, unless you create a functional index using `lower`.
- If you declare a column as `UNIQUE` or `PRIMARY KEY`, the implicitly generated index is case-sensitive. So it's useless for case-insensitive searches, and it won't enforce uniqueness case-insensitively.

The `citext` data type allows you to eliminate calls to `lower` in SQL queries, and allows a primary key to be case-insensitive. `citext` is locale-aware, just like `text`, which means that the matching of upper

case and lower case characters is dependent on the rules of the database's LC_CTYPE setting. Again, this behavior is identical to the use of lower in queries. But because it's done transparently by the data type, you don't have to remember to do anything special in your queries.

F.9.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE users (
    nick CITEXT PRIMARY KEY,
    pass TEXT   NOT NULL
);

INSERT INTO users VALUES ( 'larry',  sha256(random()::text::bytea) );
INSERT INTO users VALUES ( 'Tom',    sha256(random()::text::bytea) );
INSERT INTO users VALUES ( 'Damian', sha256(random()::text::bytea) );
INSERT INTO users VALUES ( 'NEAL',   sha256(random()::text::bytea) );
INSERT INTO users VALUES ( 'Bjørn',  sha256(random()::text::bytea) );

SELECT * FROM users WHERE nick = 'Larry';
```

The SELECT statement will return one tuple, even though the nick column was set to larry and the query was for Larry.

F.9.3. String Comparison Behavior

citext performs comparisons by converting each string to lower case (as though lower were called) and then comparing the results normally. Thus, for example, two strings are considered equal if lower would produce identical results for them.

In order to emulate a case-insensitive collation as closely as possible, there are citext-specific versions of a number of string-processing operators and functions. So, for example, the regular expression operators ~ and ~* exhibit the same behavior when applied to citext: they both match case-insensitively. The same is true for !~ and !~*, as well as for the LIKE operators ~~ and ~~*, and !~~ and !~~*. If you'd like to match case-sensitively, you can cast the operator's arguments to text.

Similarly, all of the following functions perform matching case-insensitively if their arguments are citext:

- regexp_match()
- regexp_matches()
- regexp_replace()
- regexp_split_to_array()
- regexp_split_to_table()
- replace()
- split_part()
- strpos()
- translate()

For the regexp functions, if you want to match case-sensitively, you can specify the “c” flag to force a case-sensitive match. Otherwise, you must cast to text before using one of these functions if you want case-sensitive behavior.

F.9.4. Limitations

- citext's case-folding behavior depends on the LC_CTYPE setting of your database. How it compares values is therefore determined when the database is created. It is not truly case-insensitive in the

terms defined by the Unicode standard. Effectively, what this means is that, as long as you're happy with your collation, you should be happy with citext's comparisons. But if you have data in different languages stored in your database, users of one language may find their query results are not as expected if the collation is for another language.

- As of PostgreSQL 9.1, you can attach a COLLATE specification to citext columns or data values. Currently, citext operators will honor a non-default COLLATE specification while comparing case-folded strings, but the initial folding to lower case is always done according to the database's LC_CTYPE setting (that is, as though COLLATE "default" were given). This may be changed in a future release so that both steps follow the input COLLATE specification.
- citext is not as efficient as text because the operator functions and the B-tree comparison functions must make copies of the data and convert it to lower case for comparisons. Also, only text can support B-Tree deduplication. However, citext is slightly more efficient than using lower to get case-insensitive matching.
- citext doesn't help much if you need data to compare case-sensitively in some contexts and case-insensitively in other contexts. The standard answer is to use the text type and manually use the lower function when you need to compare case-insensitively; this works all right if case-insensitive comparison is needed only infrequently. If you need case-insensitive behavior most of the time and case-sensitive infrequently, consider storing the data as citext and explicitly casting the column to text when you want case-sensitive comparison. In either situation, you will need two indexes if you want both types of searches to be fast.
- The schema containing the citext operators must be in the current search_path (typically public); if it is not, the normal case-sensitive text operators will be invoked instead.
- The approach of lower-casing strings for comparison does not handle some Unicode special cases correctly, for example when one upper-case letter has two lower-case letter equivalents. Unicode distinguishes between *case mapping* and *case folding* for this reason. Use nondeterministic collations instead of citext to handle that correctly.

F.9.5. Author

David E. Wheeler <david@kineticode.com>

Inspired by the original citext module by Donald Fraser.

F.10. cube

This module implements a data type cube for representing multidimensional cubes.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.10.1. Syntax

Table F.6 shows the valid external representations for the cube type. *x*, *y*, etc. denote floating-point numbers.

Table F.6. Cube External Representations

External Syntax	Meaning
x	A one-dimensional point (or, zero-length one-dimensional interval)
(*x*)	Same as above
x1, *x2*,..., *xn*	A point in n-dimensional space, represented internally as a zero-volume cube
(*x1*, *x2*,..., *xn*)	Same as above

External Syntax	Meaning
`( x),(  y)`	A one-dimensional interval starting at *x* and ending at *y* or vice versa; the order does not matter
`[( x),(  y)]`	Same as above
`( x1,...,  xn),(  y1,...,  yn)`	An n-dimensional cube represented by a pair of its diagonally opposite corners
`[( x1,...,  xn),(  y1,...,  yn)]`	Same as above

It does not matter which order the opposite corners of a cube are entered in. The `cube` functions automatically swap values if needed to create a uniform "lower left — upper right" internal representation. When the corners coincide, `cube` stores only one corner along with an "is point" flag to avoid wasting space.

White space is ignored on input, so `[(x),(y)]` is the same as `[ ( x ), ( y ) ]`.

F.10.2. Precision

Values are stored internally as 64-bit floating point numbers. This means that numbers with more than about 16 significant digits will be truncated.

F.10.3. Usage

Table F.7 shows the specialized operators provided for type `cube`.

Table F.7. Cube Operators

Operator Description
`cube && cube → boolean` Do the cubes overlap?
`cube @> cube → boolean` Does the first cube contain the second?
`cube <@ cube → boolean` Is the first cube contained in the second?
`cube -> integer → float8` Extracts the *n*-th coordinate of the cube (counting from 1).
`cube ~> integer → float8` Extracts the *n*-th coordinate of the cube, counting in the following way: *n* = 2 * *k* - 1 means lower bound of *k*-th dimension, *n* = 2 * *k* means upper bound of *k*-th dimension. Negative *n* denotes the inverse value of the corresponding positive coordinate. This operator is designed for KNN-GiST support.
`cube <-> cube → float8` Computes the Euclidean distance between the two cubes.
`cube <#> cube → float8` Computes the taxicab (L-1 metric) distance between the two cubes.
`cube <=> cube → float8` Computes the Chebyshev (L-inf metric) distance between the two cubes.

In addition to the above operators, the usual comparison operators shown in Table 9.1 are available for type `cube`. These operators first compare the first coordinates, and if those are equal, compare the second coordinates, etc. They exist mainly to support the b-tree index operator class for `cube`, which can be useful for example if you would like a UNIQUE constraint on a `cube` column. Otherwise, this ordering is not of much practical use.

The cube module also provides a GiST index operator class for cube values. A cube GiST index can be used to search for values using the =, &&, @>, and <@ operators in WHERE clauses.

In addition, a cube GiST index can be used to find nearest neighbors using the metric operators <->, <#>, and <=> in ORDER BY clauses. For example, the nearest neighbor of the 3-D point (0.5, 0.5, 0.5) could be found efficiently with:

```
SELECT c FROM test ORDER BY c <-> cube(array[0.5,0.5,0.5]) LIMIT 1;
```

The ~> operator can also be used in this way to efficiently retrieve the first few values sorted by a selected coordinate. For example, to get the first few cubes ordered by the first coordinate (lower left corner) ascending one could use the following query:

```
SELECT c FROM test ORDER BY c ~> 1 LIMIT 5;
```

And to get 2-D cubes ordered by the first coordinate of the upper right corner descending:

```
SELECT c FROM test ORDER BY c ~> 3 DESC LIMIT 5;
```

Table F.8 shows the available functions.

Table F.8. Cube Functions

Function Description Example(s)
cube (float8) → cube Makes a one dimensional cube with both coordinates the same. cube(1) → (1)
cube (float8, float8) → cube Makes a one dimensional cube. cube(1, 2) → (1),(2)
cube (float8[]) → cube Makes a zero-volume cube using the coordinates defined by the array. cube(ARRAY[1,2,3]) → (1, 2, 3)
cube (float8[], float8[]) → cube Makes a cube with upper right and lower left coordinates as defined by the two arrays, which must be of the same length. cube(ARRAY[1,2], ARRAY[3,4]) → (1, 2),(3, 4)
cube (cube, float8) → cube Makes a new cube by adding a dimension on to an existing cube, with the same values for both endpoints of the new coordinate. This is useful for building cubes piece by piece from calculated values. cube('(1,2),(3,4)'::cube, 5) → (1, 2, 5),(3, 4, 5)
cube (cube, float8, float8) → cube Makes a new cube by adding a dimension on to an existing cube. This is useful for building cubes piece by piece from calculated values. cube('(1,2),(3,4)'::cube, 5, 6) → (1, 2, 5),(3, 4, 6)
cube_dim (cube) → integer Returns the number of dimensions of the cube. cube_dim('(1,2),(3,4)') → 2
cube_ll_coord (cube, integer) → float8 Returns the *n*-th coordinate value for the lower left corner of the cube. cube_ll_coord('(1,2),(3,4)', 2) → 2

Function
Description
Example(s)

`cube_ur_coord ( cube, integer ) → float8`
Returns the *n*-th coordinate value for the upper right corner of the cube.
`cube_ur_coord('(1,2),(3,4)', 2)` → `4`

`cube_is_point ( cube ) → boolean`
Returns true if the cube is a point, that is, the two defining corners are the same.
`cube_is_point(cube(1,1))` → `t`

`cube_distance ( cube, cube ) → float8`
Returns the distance between two cubes. If both cubes are points, this is the normal distance function.
`cube_distance('(1,2)', '(3,4)')` → `2.8284271247461903`

`cube_subset ( cube, integer[] ) → cube`
Makes a new cube from an existing cube, using a list of dimension indexes from an array. Can be used to extract the endpoints of a single dimension, or to drop dimensions, or to reorder them as desired.
`cube_subset(cube('(1,3,5),(6,7,8)'), ARRAY[2])` → `(3),(7)`
`cube_subset(cube('(1,3,5),(6,7,8)'), ARRAY[3,2,1,1])` → `(5, 3, 1, 1),(8, 7, 6, 6)`

`cube_union ( cube, cube ) → cube`
Produces the union of two cubes.
`cube_union('(1,2)', '(3,4)')` → `(1, 2),(3, 4)`

`cube_inter ( cube, cube ) → cube`
Produces the intersection of two cubes.
`cube_inter('(1,2)', '(3,4)')` → `(3, 4),(1, 2)`

`cube_enlarge ( c cube, r double, n integer ) → cube`
Increases the size of the cube by the specified radius *r* in at least *n* dimensions. If the radius is negative the cube is shrunk instead. All defined dimensions are changed by the radius *r*. Lower-left coordinates are decreased by *r* and upper-right coordinates are increased by *r*. If a lower-left coordinate is increased to more than the corresponding upper-right coordinate (this can only happen when $r < 0$) than both coordinates are set to their average. If *n* is greater than the number of defined dimensions and the cube is being enlarged ($r > 0$), then extra dimensions are added to make *n* altogether; 0 is used as the initial value for the extra coordinates. This function is useful for creating bounding boxes around a point for searching for nearby points.
`cube_enlarge('(1,2),(3,4)', 0.5, 3)` → `(0.5, 1.5, -0.5),(3.5, 4.5, 0.5)`

F.10.4. Defaults

I believe this union:

```
select cube_union('(0,5,2),(2,3,1)', '0');
cube_union
-------------------
(0, 0, 0),(2, 5, 2)
(1 row)
```

does not contradict common sense, neither does the intersection

```
select cube_inter('(0,-1),(1,1)', '(-2),(2)');
```

```
cube_inter
-------------
(0, 0),(1, 0)
(1 row)
```

In all binary operations on differently-dimensioned cubes, I assume the lower-dimensional one to be a Cartesian projection, i. e., having zeroes in place of coordinates omitted in the string representation. The above examples are equivalent to:

```
cube_union('(0,5,2),(2,3,1)','(0,0,0),(0,0,0)');
cube_inter('(0,-1),(1,1)','(-2,0),(2,0)');
```

The following containment predicate uses the point syntax, while in fact the second argument is internally represented by a box. This syntax makes it unnecessary to define a separate point type and functions for (box,point) predicates.

```
select cube_contains('(0,0),(1,1)', '0.5,0.5');
cube_contains
--------------
t
(1 row)
```

F.10.5. Notes

For examples of usage, see the regression test `sql/cube.sql`.

To make it harder for people to break things, there is a limit of 100 on the number of dimensions of cubes. This is set in `cubedata.h` if you need something bigger.

F.10.6. Credits

Original author: Gene Selkov, Jr. `<selkovjr@mcs.anl.gov>`, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (*https://dsf.berkeley.edu/jmh/*) for elucidating the gist of the GiST (*http://gist.cs.berkeley.edu/*), and to his former student Andy Dong for his example written for Illustra. I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

Minor updates to this package were made by Bruno Wolff III `<bruno@wolff.to>` in August/September of 2002. These include changing the precision from single precision to double precision and adding some new functions.

Additional updates were made by Joshua Reich `<josh@root.net>` in July 2006. These include `cube(float8[], float8[])` and cleaning up the code to use the V1 call protocol instead of the deprecated V0 protocol.

F.11. daterange_inclusive

`daterange_inclusive` is an extension to the built-in `daterange` range type. By default, `daterange` excludes the upper bound of the range — `[)`, whereas `daterange_inclusive` does not — `[]`. Other than the covered range bound, there are no other differences between `daterange` and `daterange_inclusive`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.11.1. Rationale

At times, it is more convenient to output date ranges with inclusive upper bounds. For example, it may apply to employees' absences. If an employee is absent from January 1, 2025, to January 10, 2025, using

the daterange range type will prevent the database from outputting this date range in its entirety. In such cases, you would need to manually subtract one day from the output. The daterange_inclusive extension addresses this issue.

F.11.2. Example Usage

```
CREATE EXTENSION daterange_inclusive;
SELECT daterange('[2024-01-01,2024-06-01]');
      daterange
-------------------------
[2024-01-01,2024-06-02)

SELECT daterange_inclusive('[2024-01-01,2024-06-01]');
   daterange_inclusive
-------------------------
[2024-01-01,2024-06-01]
```

F.12. dblink

dblink is a module that supports connections to other Postgres Pro databases from within a database session.

See also postgres_fdw, which provides roughly the same functionality using a more modern and standards-compliant infrastructure.

dblink_connect

dblink_connect — opens a persistent connection to a remote database

Synopsis

```
dblink_connect(text connstr) returns text
dblink_connect(text connname, text connstr) returns text
```

Description

`dblink_connect()` establishes a connection to a remote Postgres Pro database. The server and database to be contacted are identified through a standard libpq connection string. Optionally, a name can be assigned to the connection. Multiple named connections can be open at once, but only one unnamed connection is permitted at a time. The connection will persist until closed or until the database session is ended.

The connection string may also be the name of an existing foreign server. It is recommended to use the foreign-data wrapper `dblink_fdw` when defining the foreign server. See the example below, as well as CREATE SERVER and CREATE USER MAPPING.

Arguments

connname

The name to use for this connection; if omitted, an unnamed connection is opened, replacing any existing unnamed connection.

connstr

libpq-style connection info string, for example `hostaddr=127.0.0.1 port=5432 dbname=mydb user=postgres password=mypasswd options=-csearch_path=`. For details see Section 33.1.1. Alternatively, the name of a foreign server.

Return Value

Returns status, which is always `OK` (since any error causes the function to throw an error instead of returning).

Notes

If untrusted users have access to a database that has not adopted a secure schema usage pattern, begin each session by removing publicly-writable schemas from `search_path`. One could, for example, add `options=-csearch_path=` to *connstr*. This consideration is not specific to `dblink`; it applies to every interface for executing arbitrary SQL commands.

Only superusers may use `dblink_connect` to create non-password-authenticated connections. If non-superusers need this capability, use `dblink_connect_u` instead.

It is unwise to choose connection names that contain equal signs, as this opens a risk of confusion with connection info strings in other `dblink` functions.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
 dblink_connect
----------------
 OK
(1 row)

SELECT dblink_connect('myconn', 'dbname=postgres options=-csearch_path=');
```

```
 dblink_connect
----------------
 OK
(1 row)

-- FOREIGN DATA WRAPPER functionality
-- Note: local connection must require password authentication for this to work
 properly
--       Otherwise, you will receive the following error from dblink_connect():
--       ERROR:  password is required
--       DETAIL:  Non-superuser cannot connect if the server does not request a
 password.
--       HINT:  Target server's authentication method must be changed.

CREATE SERVER fdtest FOREIGN DATA WRAPPER dblink_fdw OPTIONS (hostaddr '127.0.0.1',
 dbname 'contrib_regression');

CREATE USER regress_dblink_user WITH PASSWORD 'secret';
CREATE USER MAPPING FOR regress_dblink_user SERVER fdtest OPTIONS (user
 'regress_dblink_user', password 'secret');
GRANT USAGE ON FOREIGN SERVER fdtest TO regress_dblink_user;
GRANT SELECT ON TABLE foo TO regress_dblink_user;

\set ORIGINAL_USER :USER
\c - regress_dblink_user
SELECT dblink_connect('myconn', 'fdtest');
 dblink_connect
----------------
 OK
(1 row)

SELECT * FROM dblink('myconn', 'SELECT * FROM foo') AS t(a int, b text, c text[]);
 a  | b |       c
----+---+---------------
  0 | a | {a0,b0,c0}
  1 | b | {a1,b1,c1}
  2 | c | {a2,b2,c2}
  3 | d | {a3,b3,c3}
  4 | e | {a4,b4,c4}
  5 | f | {a5,b5,c5}
  6 | g | {a6,b6,c6}
  7 | h | {a7,b7,c7}
  8 | i | {a8,b8,c8}
  9 | j | {a9,b9,c9}
 10 | k | {a10,b10,c10}
(11 rows)

\c - :ORIGINAL_USER
REVOKE USAGE ON FOREIGN SERVER fdtest FROM regress_dblink_user;
REVOKE SELECT ON TABLE foo FROM regress_dblink_user;
DROP USER MAPPING FOR regress_dblink_user SERVER fdtest;
DROP USER regress_dblink_user;
DROP SERVER fdtest;
```

dblink_connect_u

dblink_connect_u — opens a persistent connection to a remote database, insecurely

Synopsis

```
dblink_connect_u(text connstr) returns text
dblink_connect_u(text connname, text connstr) returns text
```

Description

`dblink_connect_u()` is identical to `dblink_connect()`, except that it will allow non-superusers to connect using any authentication method.

If the remote server selects an authentication method that does not involve a password, then impersonation and subsequent escalation of privileges can occur, because the session will appear to have originated from the user as which the local Postgres Pro server runs. Also, even if the remote server does demand a password, it is possible for the password to be supplied from the server environment, such as a `~/.pgpass` file belonging to the server's user. This opens not only a risk of impersonation, but the possibility of exposing a password to an untrustworthy remote server. Therefore, `dblink_connect_u()` is initially installed with all privileges revoked from `PUBLIC`, making it un-callable except by superusers. In some situations it may be appropriate to grant `EXECUTE` permission for `dblink_connect_u()` to specific users who are considered trustworthy, but this should be done with care. It is also recommended that any `~/.pgpass` file belonging to the server's user *not* contain any records specifying a wildcard host name.

For further details see `dblink_connect()`.

dblink_disconnect

dblink_disconnect — closes a persistent connection to a remote database

Synopsis

```
dblink_disconnect() returns text
dblink_disconnect(text connname) returns text
```

Description

`dblink_disconnect()` closes a connection previously opened by `dblink_connect()`. The form with no arguments closes an unnamed connection.

Arguments

connname

The name of a named connection to be closed.

Return Value

Returns status, which is always `OK` (since any error causes the function to throw an error instead of returning).

Examples

```
SELECT dblink_disconnect();
 dblink_disconnect
-------------------
 OK
(1 row)

SELECT dblink_disconnect('myconn');
 dblink_disconnect
-------------------
 OK
(1 row)
```

dblink

dblink — executes a query in a remote database

Synopsis

```
dblink(text connname, text sql [, bool fail_on_error]) returns setof record
dblink(text connstr, text sql [, bool fail_on_error]) returns setof record
dblink(text sql [, bool fail_on_error]) returns setof record
```

Description

`dblink` executes a query (usually a `SELECT`, but it can be any SQL statement that returns rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

connstr

A connection info string, as previously described for `dblink_connect`.

sql

The SQL query that you wish to execute in the remote database, for example `select * from foo`.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

Return Value

The function returns the row(s) produced by the query. Since `dblink` can be used with any query, it is declared to return `record`, rather than specifying any particular set of columns. This means that you must specify the expected set of columns in the calling query — otherwise Postgres Pro would not know what to expect. Here is an example:

```
SELECT *
    FROM dblink('dbname=mydb options=-csearch_path=',
                'select proname, prosrc from pg_proc')
      AS t1(proname name, prosrc text)
    WHERE proname LIKE 'bytea%';
```

The “alias” part of the `FROM` clause must specify the column names and types that the function will return. (Specifying column names in an alias is actually standard SQL syntax, but specifying column types is a Postgres Pro extension.) This allows the system to understand what `*` should expand to, and what `proname` in the `WHERE` clause refers to, in advance of trying to execute the function. At run time, an error will be thrown if the actual query result from the remote database does not have the same number of columns shown in the `FROM` clause. The column names need not match, however, and `dblink` does not insist on exact type matches either. It will succeed so long as the returned data strings are valid input for the column type declared in the `FROM` clause.

Notes

A convenient way to use `dblink` with predetermined queries is to create a view. This allows the column type information to be buried in the view, instead of having to spell it out in every query. For example,

```
CREATE VIEW myremote_pg_proc AS
  SELECT *
    FROM dblink('dbname=postgres options=-csearch_path=',
                'select proname, prosrc from pg_proc')
    AS t1(proname name, prosrc text);

SELECT * FROM myremote_pg_proc WHERE proname LIKE 'bytea%';
```

Examples

```
SELECT * FROM dblink('dbname=postgres options=-csearch_path=',
                     'select proname, prosrc from pg_proc')
  AS t1(proname name, prosrc text) WHERE proname LIKE 'bytea%';
  proname   |   prosrc
------------+------------

```

dblink_exec

dblink_exec — executes a command in a remote database

Synopsis

```
dblink_exec(text connname, text sql [, bool fail_on_error]) returns text
dblink_exec(text connstr, text sql [, bool fail_on_error]) returns text
dblink_exec(text sql [, bool fail_on_error]) returns text
```

Description

`dblink_exec` executes a command (that is, any SQL statement that doesn't return rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

connstr

A connection info string, as previously described for `dblink_connect`.

sql

The SQL command that you wish to execute in the remote database, for example `insert into foo values(0, 'a', '{"a0","b0","c0"}')`.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

Return Value

Returns status, either the command's status string or `ERROR`.

Examples

```
SELECT dblink_connect('dbname=dblink_test_standby');
 dblink_connect
----------------
 OK
(1 row)

SELECT dblink_exec('insert into foo values(21, ''z'', ''{"a0","b0","c0"}'');');
   dblink_exec
-----------------
 INSERT 943366 1
(1 row)

SELECT dblink_connect('myconn', 'dbname=regression');
 dblink_connect
```

```
----------------
 OK
(1 row)

SELECT dblink_exec('myconn', 'insert into foo values(21, ''z'',
 ''{"a0","b0","c0"}'');');
   dblink_exec
------------------
 INSERT 6432584 1
(1 row)

SELECT dblink_exec('myconn', 'insert into pg_class values (''foo'')',false);
NOTICE:  sql error
DETAIL:  ERROR:  null value in column "relnamespace" violates not-null constraint

 dblink_exec
-------------
 ERROR
(1 row)
```

dblink_open

dblink_open — opens a cursor in a remote database

Synopsis

```
dblink_open(text cursorname, text sql [, bool fail_on_error]) returns text
dblink_open(text connname, text cursorname, text sql [, bool fail_on_error]) returns
 text
```

Description

`dblink_open()` opens a cursor in a remote database. The cursor can subsequently be manipulated with `dblink_fetch()` and `dblink_close()`.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

cursorname

The name to assign to this cursor.

sql

The `SELECT` statement that you wish to execute in the remote database, for example `select * from pg_class`.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

Return Value

Returns status, either `OK` or `ERROR`.

Notes

Since a cursor can only persist within a transaction, `dblink_open` starts an explicit transaction block (`BEGIN`) on the remote side, if the remote side was not already within a transaction. This transaction will be closed again when the matching `dblink_close` is executed. Note that if you use `dblink_exec` to change data between `dblink_open` and `dblink_close`, and then an error occurs or you use `dblink_disconnect` before `dblink_close`, your change *will be lost* because the transaction will be aborted.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
 dblink_connect
----------------
 OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
 dblink_open
-------------
 OK
(1 row)
```

dblink_fetch

dblink_fetch — returns rows from an open cursor in a remote database

Synopsis

```
dblink_fetch(text cursorname, int howmany [, bool fail_on_error]) returns setof record
dblink_fetch(text connname, text cursorname, int howmany [, bool fail_on_error])
 returns setof record
```

Description

`dblink_fetch` fetches rows from a cursor previously established by `dblink_open`.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

cursorname

The name of the cursor to fetch from.

howmany

The maximum number of rows to retrieve. The next *howmany* rows are fetched, starting at the current cursor position, moving forward. Once the cursor has reached its end, no more rows are produced.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

Return Value

The function returns the row(s) fetched from the cursor. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

Notes

On a mismatch between the number of return columns specified in the `FROM` clause, and the actual number of columns returned by the remote cursor, an error will be thrown. In this event, the remote cursor is still advanced by as many rows as it would have been if the error had not occurred. The same is true for any other error occurring in the local query after the remote `FETCH` has been done.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
 dblink_connect
----------------
 OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc where proname like
 ''bytea%''');
 dblink_open
-------------
 OK
(1 row)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
 funcname |  source
----------+----------
 byteacat | byteacat
 byteacmp | byteacmp
 byteaeq  | byteaeq
 byteage  | byteage
 byteagt  | byteagt
(5 rows)

SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
 funcname  |  source
-----------+-----------
 byteain   | byteain
 byteale   | byteale
 bytealike | bytealike
 bytealt   | bytealt
 byteane   | byteane
(5 rows)

SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
  funcname  |   source
------------+------------
 byteanlike | byteanlike
 byteaout   | byteaout
(2 rows)

SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
 funcname | source
----------+--------
(0 rows)
```

dblink_close

dblink_close — closes a cursor in a remote database

Synopsis

```
dblink_close(text cursorname [, bool fail_on_error]) returns text
dblink_close(text connname, text cursorname [, bool fail_on_error]) returns text
```

Description

`dblink_close` closes a cursor previously opened with `dblink_open`.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

cursorname

The name of the cursor to close.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

Return Value

Returns status, either `OK` or `ERROR`.

Notes

If `dblink_open` started an explicit transaction block, and this is the last remaining open cursor in this connection, `dblink_close` will issue the matching `COMMIT`.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
 dblink_connect
----------------
 OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
 dblink_open
-------------
 OK
(1 row)

SELECT dblink_close('foo');
 dblink_close
--------------
 OK
(1 row)
```

dblink_get_connections

dblink_get_connections — returns the names of all open named dblink connections

Synopsis

```
dblink_get_connections() returns text[]
```

Description

`dblink_get_connections` returns an array of the names of all open named `dblink` connections.

Return Value

Returns a text array of connection names, or NULL if none.

Examples

```
SELECT dblink_get_connections();
```

dblink_error_message

dblink_error_message — gets last error message on the named connection

Synopsis

```
dblink_error_message(text connname) returns text
```

Description

`dblink_error_message` fetches the most recent remote error message for a given connection.

Arguments

connname

Name of the connection to use.

Return Value

Returns last error message, or `OK` if there has been no error in this connection.

Notes

When asynchronous queries are initiated by `dblink_send_query`, the error message associated with the connection might not get updated until the server's response message is consumed. This typically means that `dblink_is_busy` or `dblink_get_result` should be called prior to `dblink_error_message`, so that any error generated by the asynchronous query will be visible.

Examples

```
SELECT dblink_error_message('dtest1');
```

dblink_send_query

dblink_send_query — sends an async query to a remote database

Synopsis

```
dblink_send_query(text connname, text sql) returns int
```

Description

`dblink_send_query` sends a query to be executed asynchronously, that is, without immediately waiting for the result. There must not be an async query already in progress on the connection.

After successfully dispatching an async query, completion status can be checked with `dblink_is_busy`, and the results are ultimately collected with `dblink_get_result`. It is also possible to attempt to cancel an active async query using `dblink_cancel_query`.

Arguments

connname

Name of the connection to use.

sql

The SQL statement that you wish to execute in the remote database, for example `select * from pg_class`.

Return Value

Returns 1 if the query was successfully dispatched, 0 otherwise.

Examples

```
SELECT dblink_send_query('dtest1', 'SELECT * FROM foo WHERE f1 < 3');
```

dblink_is_busy

dblink_is_busy — checks if connection is busy with an async query

Synopsis

```
dblink_is_busy(text connname) returns int
```

Description

`dblink_is_busy` tests whether an async query is in progress.

Arguments

connname

Name of the connection to check.

Return Value

Returns 1 if connection is busy, 0 if it is not busy. If this function returns 0, it is guaranteed that `dblink_get_result` will not block.

Examples

```
SELECT dblink_is_busy('dtest1');
```

dblink_get_notify

dblink_get_notify — retrieve async notifications on a connection

Synopsis

```
dblink_get_notify() returns setof (notify_name text, be_pid int, extra text)
dblink_get_notify(text connname) returns setof (notify_name text, be_pid int, extra
 text)
```

Description

`dblink_get_notify` retrieves notifications on either the unnamed connection, or on a named connection if specified. To receive notifications via dblink, `LISTEN` must first be issued, using `dblink_exec`. For details see LISTEN and NOTIFY.

Arguments

connname

The name of a named connection to get notifications on.

Return Value

Returns `setof (notify_name text, be_pid int, extra text)`, or an empty set if none.

Examples

```
SELECT dblink_exec('LISTEN virtual');
 dblink_exec
-------------
 LISTEN
(1 row)

SELECT * FROM dblink_get_notify();
 notify_name | be_pid | extra
-------------+--------+-------
(0 rows)

NOTIFY virtual;
NOTIFY

SELECT * FROM dblink_get_notify();
 notify_name | be_pid | extra
-------------+--------+-------
 virtual     |   1229 |
(1 row)
```

dblink_get_result

dblink_get_result — gets an async query result

Synopsis

```
dblink_get_result(text connname [, bool fail_on_error]) returns setof record
```

Description

`dblink_get_result` collects the results of an asynchronous query previously sent with `dblink_send_query`. If the query is not already completed, `dblink_get_result` will wait until it is.

Arguments

connname

Name of the connection to use.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

Return Value

For an async query (that is, an SQL statement returning rows), the function returns the row(s) produced by the query. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

For an async command (that is, an SQL statement not returning rows), the function returns a single row with a single text column containing the command's status string. It is still necessary to specify that the result will have a single text column in the calling `FROM` clause.

Notes

This function *must* be called if `dblink_send_query` returned 1. It must be called once for each query sent, and one additional time to obtain an empty set result, before the connection can be used again.

When using `dblink_send_query` and `dblink_get_result`, dblink fetches the entire remote query result before returning any of it to the local query processor. If the query returns a large number of rows, this can result in transient memory bloat in the local session. It may be better to open such a query as a cursor with `dblink_open` and then fetch a manageable number of rows at a time. Alternatively, use plain `dblink()`, which avoids memory bloat by spooling large result sets to disk.

Examples

```
contrib_regression=# SELECT dblink_connect('dtest1', 'dbname=contrib_regression');
 dblink_connect
----------------
 OK
(1 row)

contrib_regression=# SELECT * FROM
contrib_regression-# dblink_send_query('dtest1', 'select * from foo where f1 < 3') AS
 t1;
 t1
----
  1
(1 row)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
 f3 text[]);
 f1 | f2 |     f3
----+----+------------
  0 | a  | {a0,b0,c0}
  1 | b  | {a1,b1,c1}
  2 | c  | {a2,b2,c2}
(3 rows)

contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
 f3 text[]);
 f1 | f2 | f3
----+----+----
(0 rows)

contrib_regression=# SELECT * FROM
contrib_regression-# dblink_send_query('dtest1', 'select * from foo where f1 < 3;
 select * from foo where f1 > 6') AS t1;
 t1
----
  1
(1 row)

contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
 f3 text[]);
 f1 | f2 |     f3
----+----+------------
  0 | a  | {a0,b0,c0}
  1 | b  | {a1,b1,c1}
  2 | c  | {a2,b2,c2}
(3 rows)

contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
 f3 text[]);
 f1 | f2 |      f3
----+----+---------------
  7 | h  | {a7,b7,c7}
  8 | i  | {a8,b8,c8}
  9 | j  | {a9,b9,c9}
 10 | k  | {a10,b10,c10}
(4 rows)

contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
 f3 text[]);
 f1 | f2 | f3
----+----+----
(0 rows)
```

dblink_cancel_query

dblink_cancel_query — cancels any active query on the named connection

Synopsis

```
dblink_cancel_query(text connname) returns text
```

Description

`dblink_cancel_query` attempts to cancel any query that is in progress on the named connection. Note that this is not certain to succeed (since, for example, the remote query might already have finished). A cancel request simply improves the odds that the query will fail soon. You must still complete the normal query protocol, for example by calling `dblink_get_result`.

Arguments

connname

Name of the connection to use.

Return Value

Returns `OK` if the cancel request has been sent, or the text of an error message on failure.

Examples

```
SELECT dblink_cancel_query('dtest1');
```

dblink_get_pkey

dblink_get_pkey — returns the positions and field names of a relation's primary key fields

Synopsis

```
dblink_get_pkey(text relname) returns setof dblink_pkey_results
```

Description

`dblink_get_pkey` provides information about the primary key of a relation in the local database. This is sometimes useful in generating queries to be sent to remote databases.

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

Return Value

Returns one row for each primary key field, or no rows if the relation has no primary key. The result row type is defined as

```
CREATE TYPE dblink_pkey_results AS (position int, colname text);
```

The `position` column simply runs from 1 to *N*; it is the number of the field within the primary key, not the number within the table's columns.

Examples

```
CREATE TABLE foobar (
    f1 int,
    f2 int,
    f3 int,
    PRIMARY KEY (f1, f2, f3)
);
CREATE TABLE

SELECT * FROM dblink_get_pkey('foobar');
 position | colname
----------+---------
        1 | f1
        2 | f2
        3 | f3
(3 rows)
```

dblink_build_sql_insert

dblink_build_sql_insert — builds an INSERT statement using a local tuple, replacing the primary key field values with alternative supplied values

Synopsis

```
dblink_build_sql_insert(text relname,
                        int2vector primary_key_attnums,
                        integer num_primary_key_atts,
                        text[] src_pk_att_vals_array,
                        text[] tgt_pk_att_vals_array) returns text
```

Description

`dblink_build_sql_insert` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds an SQL `INSERT` command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.)

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

primary_key_attnums

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

num_primary_key_atts

The number of primary key fields.

src_pk_att_vals_array

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

tgt_pk_att_vals_array

Values of the primary key fields to be placed in the resulting `INSERT` command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in *primary_key_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_insert('foo', '1 2', 2, '{"1", "a"}', '{"1", "b''a"}');
             dblink_build_sql_insert
------------------------------------------------
```

```
 INSERT INTO foo(f1,f2,f3) VALUES('1','b''a','1')
(1 row)
```

dblink_build_sql_delete

dblink_build_sql_delete — builds a DELETE statement using supplied values for primary key field values

Synopsis

```
dblink_build_sql_delete(text relname,
                        int2vector primary_key_attnums,
                        integer num_primary_key_atts,
                        text[] tgt_pk_att_vals_array) returns text
```

Description

`dblink_build_sql_delete` can be useful in doing selective replication of a local table to a remote database. It builds an SQL `DELETE` command that will delete the row with the given primary key values.

Arguments

`relname`

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

`primary_key_attnums`

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

`num_primary_key_atts`

The number of primary key fields.

`tgt_pk_att_vals_array`

Values of the primary key fields to be used in the resulting `DELETE` command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in *`primary_key_attnums`* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_delete('"MyFoo"', '1 2', 2, '{"1", "b"}');
           dblink_build_sql_delete
---------------------------------------------
 DELETE FROM "MyFoo" WHERE f1='1' AND f2='b'
(1 row)
```

dblink_build_sql_update

dblink_build_sql_update — builds an UPDATE statement using a local tuple, replacing the primary key field values with alternative supplied values

Synopsis

```
dblink_build_sql_update(text relname,
                        int2vector primary_key_attnums,
                        integer num_primary_key_atts,
                        text[] src_pk_att_vals_array,
                        text[] tgt_pk_att_vals_array) returns text
```

Description

`dblink_build_sql_update` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds an SQL `UPDATE` command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.) The `UPDATE` command always assigns all fields of the row — the main difference between this and `dblink_build_sql_insert` is that it's assumed that the target row already exists in the remote table.

Arguments

`relname`

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

`primary_key_attnums`

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

`num_primary_key_atts`

The number of primary key fields.

`src_pk_att_vals_array`

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

`tgt_pk_att_vals_array`

Values of the primary key fields to be placed in the resulting `UPDATE` command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in *`primary_key_attnums`* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_update('foo', '1 2', 2, '{"1", "a"}', '{"1", "b"}');
                   dblink_build_sql_update
-------------------------------------------------------------
```

```
 UPDATE foo SET f1='1',f2='b',f3='1' WHERE f1='1' AND f2='b'
(1 row)
```

F.13. dict_int

dict_int is an example of an add-on dictionary template for full-text search. The motivation for this example dictionary is to control the indexing of integers (signed and unsigned), allowing such numbers to be indexed while preventing excessive growth in the number of unique words, which greatly affects the performance of searching.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.13.1. Configuration

The dictionary accepts three options:

- The maxlen parameter specifies the maximum number of digits allowed in an integer word. The default value is 6.
- The rejectlong parameter specifies whether an overlength integer should be truncated or ignored. If rejectlong is false (the default), the dictionary returns the first maxlen digits of the integer. If rejectlong is true, the dictionary treats an overlength integer as a stop word, so that it will not be indexed. Note that this also means that such an integer cannot be searched for.
- The absval parameter specifies whether leading “+” or “-” signs should be removed from integer words. The default is false. When true, the sign is removed before maxlen is applied.

F.13.2. Usage

Installing the dict_int extension creates a text search template intdict_template and a dictionary intdict based on it, with the default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY intdict (MAXLEN = 4, REJECTLONG = true);
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb# select ts_lexize('intdict', '12345678');
 ts_lexize
-----------
 {123456}
```

but real-world usage will involve including it in a text search configuration as described in Chapter 12. That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
    ALTER MAPPING FOR int, uint WITH intdict;
```

F.14. dict_xsyn

dict_xsyn (Extended Synonym Dictionary) is an example of an add-on dictionary template for full-text search. This dictionary type replaces words with groups of their synonyms, and so makes it possible to search for a word using any of its synonyms.

F.14.1. Configuration

A dict_xsyn dictionary accepts the following options:

- matchorig controls whether the original word is accepted by the dictionary. Default is true.
- matchsynonyms controls whether the synonyms are accepted by the dictionary. Default is false.
- keeporig controls whether the original word is included in the dictionary's output. Default is true.

- `keepsynonyms` controls whether the synonyms are included in the dictionary's output. Default is `true`.
- `rules` is the base name of the file containing the list of synonyms. This file must be stored in `$SHAREDIR/tsearch_data/` (where `$SHAREDIR` means the Postgres Pro installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `rules` parameter).

The rules file has the following format:

- Each line represents a group of synonyms for a single word, which is given first on the line. Synonyms are separated by whitespace, thus:

  ```
  word syn1 syn2 syn3
  ```

- The sharp (`#`) sign is a comment delimiter. It may appear at any position in a line. The rest of the line will be skipped.

Look at `xsyn_sample.rules`, which is installed in `$SHAREDIR/tsearch_data/`, for an example.

F.14.2. Usage

Installing the `dict_xsyn` extension creates a text search template `xsyn_template` and a dictionary `xsyn` based on it, with default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false);
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb=# SELECT ts_lexize('xsyn', 'word');
      ts_lexize
-----------------------
 {syn1,syn2,syn3}

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true);
ALTER TEXT SEARCH DICTIONARY

mydb=# SELECT ts_lexize('xsyn', 'word');
      ts_lexize
-----------------------
 {word,syn1,syn2,syn3}

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false,
 MATCHSYNONYMS=true);
ALTER TEXT SEARCH DICTIONARY

mydb=# SELECT ts_lexize('xsyn', 'syn1');
      ts_lexize
-----------------------
 {syn1,syn2,syn3}

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true,
 MATCHORIG=false, KEEPSYNONYMS=false);
ALTER TEXT SEARCH DICTIONARY

mydb=# SELECT ts_lexize('xsyn', 'syn1');
      ts_lexize
-----------------------
 {word}
```

Real-world usage will involve including it in a text search configuration as described in Chapter 12. That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
    ALTER MAPPING FOR word, asciiword WITH xsyn, english_stem;
```

F.15. dump_stat

The dump_stat module provides functions that allow you to backup and recover the contents of the pg_statistic table. When performing a dump/restore, you can use dump_stat to migrate the original statistics to the new server instead of running the ANALYZE command for the whole database cluster, which can significantly reduce downtime for large databases. The dump_statistic function generates INSERT statements which can later be applied to a compatible database. To successfully restore statistical data, you must install the extension on both the original and the recipient servers since these statements rely on the provided dump_stat functions.

Note that the definition of the pg_statistic table might change occasionally, which means that generated dump might be incompatible with future releases of Postgres Pro.

F.15.1. Installation

The dump_stat extension is included into Postgres Pro. Once you have Postgres Pro installed, you must execute the CREATE EXTENSION command to enable dump_stat, as follows:

```
CREATE EXTENSION dump_stat;
```

F.15.2. Functions

```
anyarray_to_text(array anyarray) returns text
```

Returns the given array as text.

```
dump_statistic() returns setof text
```

dump_statistic dumps the contents of the pg_statistic system catalog. It produces an INSERT statement per each tuple of the pg_statistic, excluding the ones that contain statistical data for tables in the information_schema and pg_catalog schemas.

The INSERT statement takes form of

```
WITH upsert as (
  UPDATE pg_catalog.pg_statistic SET column_name = expression [, ...]
  WHERE starelid = t_relname::regclass
    AND to_attname(t_relname, staattnum) = t_attname
    AND to_atttype(t_relname, staattnum) = t_atttype
    AND stainherit = t_stainherit
  RETURNING *)
ins as (
  SELECT expression [, ...]
  WHERE NOT EXISTS (SELECT * FROM upsert)
    AND to_attnum(t_relname, t_attname) IS NOT NULL
    AND to_atttype(t_relname, t_attname) = t_atttype)
INSERT INTO pg_catalog.pg_statistic SELECT * FROM ins;

where expression can be one of:

array_in(array_text, type_name::regtype::oid, -1)
value::type_name
```

To save the produced statements, redirect the psql output into a file using standard psql options. For details on the available psql options, see psql. Meta-commands starting with a backslash are not supported.

For example, to save statistics for the *dbname* database into a dump_stat.sql file, run:

```
$ psql -XAtq -c "SELECT dump_statistic()" dbname > dump_stat.sql
```

`dump_statistic(schema_name text) returns setof text`

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic` that relates to some table in the `schema_name` schema.

`dump_statistic(schema_name text, table_name text) returns setof text`

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic` that relates to the specified `schema_name.table_name` table.

`dump_statistic(relation regclass) returns setof text`

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic` that contains statistical data for the specified `relation`.

`to_schema_qualified_operator(opid oid) returns text`

Fetches the schema-qualified operator name by operator id `opid`. For example:

```
test=# SELECT to_schema_qualified_operator('+(int,int)'::regoperator);
          to_schema_qualified_operator
-----------------------------------------------
 pg_catalog.+(pg_catalog.int4, pg_catalog.int4)
(1 row)
```

`to_schema_qualified_type(typid oid) returns text`

Fetches the schema-qualified type name by type id `typid`.

`to_schema_qualified_relation(relid oid) returns text`

Fetches the schema-qualified relation name by relation id `relid`.

`anyarray_elemtype(arr anyarray) returns oid`

Returns the element type of the given array as `oid`. For example:

```
test=# SELECT anyarray_elemtype(array_in('{1,2,3}', 'int'::regtype, -1));
 anyarray_elemtype
-------------------
                23
(1 row)
```

`to_attname(relation regclass, colnum int2) returns text`

Given a relation name `relation` and a column number `colnum`, returns the column name as `text`.

`to_attnum(relation regclass, col text) returns int2`

Given a relation name `relation` and a column name `col`, returns the column number as `int2`.

`to_atttype(relation regclass, col text) returns text`

Given a relation name `relation` and a column name `col`, returns the schema-qualified column type as `text`.

`to_atttype(relation regclass, colnum int2) returns text`

Given a relation name `relation` and a column number `colnum`, returns the schema-qualified column type as `text`.

`to_namespace(nsp text) returns oid`

`to_namespace` duplicates the behavior of the cast to the `regnamespace` type, which is not present in the PostgreSQL 9.4 release (and prior releases). This function returns the `oid` of the given schema.

`get_namespace(relation oid) returns oid`

`get_namespace` returns the schema of the given relation as `oid`.

F.16. earthdistance

The `earthdistance` module provides two different approaches to calculating great circle distances on the surface of the Earth. The one described first depends on the `cube` module. The second one is based on the built-in `point` data type, using longitude and latitude for the coordinates.

In this module, the Earth is assumed to be perfectly spherical. (If that's too inaccurate for you, you might want to look at the *PostGIS* project.)

The `cube` module must be installed before `earthdistance` can be installed (although you can use the `CASCADE` option of `CREATE EXTENSION` to install both in one command).

> **Caution**
>
> It is strongly recommended that `earthdistance` and `cube` be installed in the same schema, and that that schema be one for which CREATE privilege has not been and will not be granted to any untrusted users. Otherwise there are installation-time security hazards if `earthdistance`'s schema contains objects defined by a hostile user. Furthermore, when using `earthdistance`'s functions after installation, the entire search path should contain only trusted schemas.

F.16.1. Cube-Based Earth Distances

Data is stored in cubes that are points (both corners are the same) using 3 coordinates representing the x, y, and z distance from the center of the Earth. A domain `earth` over `cube` is provided, which includes constraint checks that the value meets these restrictions and is reasonably close to the actual surface of the Earth.

The radius of the Earth is obtained from the `earth()` function. It is given in meters. But by changing this one function you can change the module to use some other units, or to use a different value of the radius that you feel is more appropriate.

This package has applications to astronomical databases as well. Astronomers will probably want to change `earth()` to return a radius of `180/pi()` so that distances are in degrees.

Functions are provided to support input in latitude and longitude (in degrees), to support output of latitude and longitude, to calculate the great circle distance between two points and to easily specify a bounding box usable for index searches.

The provided functions are shown in Table F.9.

Table F.9. Cube-Based Earthdistance Functions

Function Description
`earth` () → `float8` Returns the assumed radius of the Earth.
`sec_to_gc` (`float8`) → `float8` Converts the normal straight line (secant) distance between two points on the surface of the Earth to the great circle distance between them.
`gc_to_sec` (`float8`) → `float8` Converts the great circle distance between two points on the surface of the Earth to the normal straight line (secant) distance between them.
`ll_to_earth` (`float8`, `float8`) → `earth`

Function Description
Returns the location of a point on the surface of the Earth given its latitude (argument 1) and longitude (argument 2) in degrees.
`latitude` (`earth`) → `float8` Returns the latitude in degrees of a point on the surface of the Earth.
`longitude` (`earth`) → `float8` Returns the longitude in degrees of a point on the surface of the Earth.
`earth_distance` (`earth`, `earth`) → `float8` Returns the great circle distance between two points on the surface of the Earth.
`earth_box` (`earth`, `float8`) → `cube` Returns a box suitable for an indexed search using the `cube @>` operator for points within a given great circle distance of a location. Some points in this box are further than the specified great circle distance from the location, so a second check using `earth_distance` should be included in the query.

F.16.2. Point-Based Earth Distances

The second part of the module relies on representing Earth locations as values of type `point`, in which the first component is taken to represent longitude in degrees, and the second component is taken to represent latitude in degrees. Points are taken as (longitude, latitude) and not vice versa because longitude is closer to the intuitive idea of x-axis and latitude to y-axis.

A single operator is provided, shown in Table F.10.

Table F.10. Point-Based Earthdistance Operators

Operator Description
`point <@> point` → `float8` Computes the distance in statute miles between two points on the Earth's surface.

Note that unlike the `cube`-based part of the module, units are hardwired here: changing the `earth()` function will not affect the results of this operator.

One disadvantage of the longitude/latitude representation is that you need to be careful about the edge conditions near the poles and near +/- 180 degrees of longitude. The `cube`-based representation avoids these discontinuities.

F.17. fasttrun

The `fasttrun` module provides transaction unsafe function to truncate temporary tables without growing pg_class size.

This module is required for 1C Enterprise support.

Fast truncate operation is not transactional, so its results cannot be rolled back and become immediately visible in all sessions regardless of isolation level.

F.17.1. Function

There is a function call example:

```
select fasttruncate('TABLE_NAME');
```

F.17.2. Test example

For tests you can use this example:

```
create or replace function f() returns void as $$
begin
  for i in 1..1000
    loop
      PERFORM fasttruncate('tt1');
    end loop;
  end;
$$ language plpgsql;
```

F.17.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

F.18. file_fdw

The file_fdw module provides the foreign-data wrapper file_fdw, which can be used to access data files in the server's file system, or to execute programs on the server and read their output. The data file or program output must be in a format that can be read by COPY FROM; see COPY for details. Access to data files is currently read-only.

A foreign table created using this wrapper can have the following options:

filename

Specifies the file to be read. Relative paths are relative to the data directory. Either filename or program must be specified, but not both.

program

Specifies the command to be executed. The standard output of this command will be read as though COPY FROM PROGRAM were used. Either program or filename must be specified, but not both.

format

Specifies the data format, the same as COPY's FORMAT option.

header

Specifies whether the data has a header line, the same as COPY's HEADER option.

delimiter

Specifies the data delimiter character, the same as COPY's DELIMITER option.

quote

Specifies the data quote character, the same as COPY's QUOTE option.

escape

Specifies the data escape character, the same as COPY's ESCAPE option.

null

Specifies the data null string, the same as COPY's NULL option.

encoding

Specifies the data encoding, the same as COPY's ENCODING option.

Note that while COPY allows options such as HEADER to be specified without a corresponding value, the foreign table option syntax requires a value to be present in all cases. To activate COPY options typically written without a value, you can pass the value TRUE, since all such options are Booleans.

A column of a foreign table created using this wrapper can have the following options:

`force_not_null`

This is a Boolean option. If true, it specifies that values of the column should not be matched against the null string (that is, the table-level `null` option). This has the same effect as listing the column in `COPY`'s `FORCE_NOT_NULL` option.

`force_null`

This is a Boolean option. If true, it specifies that values of the column which match the null string are returned as `NULL` even if the value is quoted. Without this option, only unquoted values matching the null string are returned as `NULL`. This has the same effect as listing the column in `COPY`'s `FORCE_NULL` option.

`COPY`'s `FORCE_QUOTE` option is currently not supported by `file_fdw`.

These options can only be specified for a foreign table or its columns, not in the options of the `file_fdw` foreign-data wrapper, nor in the options of a server or user mapping using the wrapper.

Changing table-level options requires being a superuser or having the privileges of the role `pg_read_server_files` (to use a filename) or the role `pg_execute_server_program` (to use a program), for security reasons: only certain users should be able to control which file is read or which program is run. In principle regular users could be allowed to change the other options, but that's not supported at present.

When specifying the `program` option, keep in mind that the option string is executed by the shell. If you need to pass any arguments to the command that come from an untrusted source, you must be careful to strip or escape any characters that might have special meaning to the shell. For security reasons, it is best to use a fixed command string, or at least avoid passing any user input in it.

For a foreign table using `file_fdw`, `EXPLAIN` shows the name of the file to be read or program to be run. For a file, unless `COSTS OFF` is specified, the file size (in bytes) is shown as well.

Example F.3. Create a Foreign Table for Postgres Pro CSV Logs

One of the obvious uses for `file_fdw` is to make the Postgres Pro activity log available as a table for querying. To do this, first you must be logging to a CSV file, which here we will call `pglog.csv`. First, install `file_fdw` as an extension:

```
CREATE EXTENSION file_fdw;
```

Then create a foreign server:

```
CREATE SERVER pglog FOREIGN DATA WRAPPER file_fdw;
```

Now you are ready to create the foreign data table. Using the `CREATE FOREIGN TABLE` command, you will need to define the columns for the table, the CSV file name, and its format:

```
CREATE FOREIGN TABLE pglog (
  log_time timestamp(3) with time zone,
  user_name text,
  database_name text,
  process_id integer,
  connection_from text,
  session_id text,
  session_line_num bigint,
  command_tag text,
  session_start_time timestamp with time zone,
  virtual_transaction_id text,
  transaction_id bigint,
  error_severity text,
  sql_state_code text,
  message text,
  detail text,
  hint text,
```

```
    internal_query text,
    internal_query_pos integer,
    context text,
    query text,
    query_pos integer,
    location text,
    application_name text,
    backend_type text,
    leader_pid integer,
    query_id bigint
) SERVER pglog
OPTIONS ( filename 'log/pglog.csv', format 'csv' );
```

That's it — now you can query your log directly. In production, of course, you would need to define some way to deal with log rotation.

F.19. fulleq

The `fulleq` module provides additional equivalence operator for compatibility with Microsoft SQL Server.

This module is required for 1C Enterprise support.

F.19.1. Overview

The Postgres Pro equivalence operator is defined to return NULL when both operands are NULLs. However, the Microsoft SQL Servers family traditionally defines other semantic for equivalence operator, where operator returns TRUE in the case of both nulled operands. This module provides such operator with MS SQL semantic.

F.19.2. Operator fulleq

The == operator is defined for the following data types:

- bool
- bytea
- char
- name
- int2
- int4
- int8
- int2vector
- text
- oid
- xid
- cid
- oidvector
- float4
- float8
- abstime
- reltime
- macaddr
- inet

- cidr
- varchar
- date
- time
- timestamp
- timestamptz
- interval
- timetz

F.19.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

F.20. fuzzystrmatch

The fuzzystrmatch module provides several functions to determine similarities and distance between strings.

> **Caution**
>
> At present, the soundex, metaphone, dmetaphone, and dmetaphone_alt functions do not work well with multibyte encodings (such as UTF-8).

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.20.1. Soundex

The Soundex system is a method of matching similar-sounding names by converting them to the same code. It was initially used by the United States Census in 1880, 1900, and 1910. Note that Soundex is not very useful for non-English names.

The fuzzystrmatch module provides two functions for working with Soundex codes:

```
soundex(text) returns text
difference(text, text) returns int
```

The soundex function converts a string to its Soundex code. The difference function converts two strings to their Soundex codes and then reports the number of matching code positions. Since Soundex codes have four characters, the result ranges from zero to four, with zero being no match and four being an exact match. (Thus, the function is misnamed — similarity would have been a better name.)

Here are some usage examples:

```
SELECT soundex('hello world!');

SELECT soundex('Anne'), soundex('Ann'), difference('Anne', 'Ann');
SELECT soundex('Anne'), soundex('Andrew'), difference('Anne', 'Andrew');
SELECT soundex('Anne'), soundex('Margaret'), difference('Anne', 'Margaret');

CREATE TABLE s (nm text);

INSERT INTO s VALUES ('john');
INSERT INTO s VALUES ('joan');
INSERT INTO s VALUES ('wobbly');
```

```
INSERT INTO s VALUES ('jack');

SELECT * FROM s WHERE soundex(nm) = soundex('john');

SELECT * FROM s WHERE difference(s.nm, 'john') > 2;
```

F.20.2. Levenshtein

This function calculates the Levenshtein distance between two strings:

```
levenshtein(text source, text target, int ins_cost, int del_cost, int sub_cost) returns
 int
levenshtein(text source, text target) returns int
levenshtein_less_equal(text source, text target, int ins_cost, int del_cost, int
 sub_cost, int max_d) returns int
levenshtein_less_equal(text source, text target, int max_d) returns int
```

Both `source` and `target` can be any non-null string, with a maximum of 255 characters. The cost parameters specify how much to charge for a character insertion, deletion, or substitution, respectively. You can omit the cost parameters, as in the second version of the function; in that case they all default to 1.

`levenshtein_less_equal` is an accelerated version of the Levenshtein function for use when only small distances are of interest. If the actual distance is less than or equal to `max_d`, then `levenshtein_less_equal` returns the correct distance; otherwise it returns some value greater than `max_d`. If `max_d` is negative then the behavior is the same as `levenshtein`.

Examples:

```
test=# SELECT levenshtein('GUMBO', 'GAMBOL');
 levenshtein
-------------
           2
(1 row)

test=# SELECT levenshtein('GUMBO', 'GAMBOL', 2, 1, 1);
 levenshtein
-------------
           3
(1 row)

test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 2);
 levenshtein_less_equal
------------------------
                      3
(1 row)

test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 4);
 levenshtein_less_equal
------------------------
                      4
(1 row)
```

F.20.3. Metaphone

Metaphone, like Soundex, is based on the idea of constructing a representative code for an input string. Two strings are then deemed similar if they have the same codes.

This function calculates the metaphone code of an input string:

```
metaphone(text source, int max_output_length) returns text
```

source has to be a non-null string with a maximum of 255 characters. max_output_length sets the maximum length of the output metaphone code; if longer, the output is truncated to this length.

Example:

```
test=# SELECT metaphone('GUMBO', 4);
 metaphone
-----------
 KM
(1 row)
```

F.20.4. Double Metaphone

The Double Metaphone system computes two “sounds like” strings for a given input string — a “primary” and an “alternate”. In most cases they are the same, but for non-English names especially they can be a bit different, depending on pronunciation. These functions compute the primary and alternate codes:

```
dmetaphone(text source) returns text
dmetaphone_alt(text source) returns text
```

There is no length limit on the input strings.

Example:

```
test=# SELECT dmetaphone('gumbo');
 dmetaphone
------------
 KMP
(1 row)
```

F.21. hstore

This module implements the hstore data type for storing sets of key/value pairs within a single Postgres Pro value. This can be useful in various scenarios, such as rows with many attributes that are rarely examined, or semi-structured data. Keys and values are simply text strings.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.21.1. hstore External Representation

The text representation of an hstore, used for input and output, includes zero or more *key* => *value* pairs separated by commas. Some examples:

```
k => v
foo => bar, baz => whatever
"1-a" => "anything at all"
```

The order of the pairs is not significant (and may not be reproduced on output). Whitespace between pairs or around the => sign is ignored. Double-quote keys and values that include whitespace, commas, =s or >s. To include a double quote or a backslash in a key or value, escape it with a backslash.

Each key in an hstore is unique. If you declare an hstore with duplicate keys, only one will be stored in the hstore and there is no guarantee as to which will be kept:

```
SELECT 'a=>1,a=>2'::hstore;
  hstore
----------
 "a"=>"1"
```

A value (but not a key) can be an SQL NULL. For example:

```
key => NULL
```

The NULL keyword is case-insensitive. Double-quote the NULL to treat it as the ordinary string “NULL”.

> **Note**
>
> Keep in mind that the `hstore` text format, when used for input, applies *before* any required quoting or escaping. If you are passing an `hstore` literal via a parameter, then no additional processing is needed. But if you're passing it as a quoted literal constant, then any single-quote characters and (depending on the setting of the `standard_conforming_strings` configuration parameter) backslash characters need to be escaped correctly. See Section 4.1.2.1 for more on the handling of string constants.

On output, double quotes always surround keys and values, even when it's not strictly necessary.

F.21.2. `hstore` Operators and Functions

The operators provided by the `hstore` module are shown in Table F.11, the functions in Table F.12.

Table F.11. `hstore` Operators

Operator Description Example(s)

`hstore -> text → text`
Returns value associated with given key, or `NULL` if not present.
`'a=>x, b=>y'::hstore -> 'a'  → x`

`hstore -> text[] → text[]`
Returns values associated with given keys, or `NULL` if not present.
`'a=>x, b=>y, c=>z'::hstore -> ARRAY['c','a']  → {"z","x"}`

`hstore || hstore → hstore`
Concatenates two `hstore`s.
`'a=>b, c=>d'::hstore || 'c=>x, d=>q'::hstore  → "a"=>"b", "c"=>"x", "d"=>"q"`

`hstore ? text → boolean`
Does `hstore` contain key?
`'a=>1'::hstore ? 'a' → t`

`hstore ?& text[] → boolean`
Does `hstore` contain all the specified keys?
`'a=>1,b=>2'::hstore ?& ARRAY['a','b']  → t`

`hstore ?| text[] → boolean`
Does `hstore` contain any of the specified keys?
`'a=>1,b=>2'::hstore ?| ARRAY['b','c']  → t`

`hstore @> hstore → boolean`
Does left operand contain right?
`'a=>b, b=>1, c=>NULL'::hstore @> 'b=>1'  → t`

`hstore <@ hstore → boolean`
Is left operand contained in right?
`'a=>c'::hstore <@ 'a=>b, b=>1, c=>NULL'  → f`

`hstore - text → hstore`
Deletes key from left operand.
`'a=>1, b=>2, c=>3'::hstore - 'b'::text  → "a"=>"1", "c"=>"3"`

`hstore - text[] → hstore` Deletes keys from left operand.

Operator Description Example(s)
`'a=>1, b=>2, c=>3'::hstore - ARRAY['a','b']` → `"c"=>"3"`

`hstore - hstore → hstore`
Deletes pairs from left operand that match pairs in the right operand.
`'a=>1, b=>2, c=>3'::hstore - 'a=>4, b=>2'::hstore` → `"a"=>"1", "c"=>"3"`

`anyelement #= hstore → anyelement`
Replaces fields in the left operand (which must be a composite type) with matching values from `hstore`.
`ROW(1,3) #= 'f1=>11'::hstore` → `(11,3)`

`%% hstore → text[]`
Converts `hstore` to an array of alternating keys and values.
`%% 'a=>foo, b=>bar'::hstore` → `{a,foo,b,bar}`

`%# hstore → text[]`
Converts `hstore` to a two-dimensional key/value array.
`%# 'a=>foo, b=>bar'::hstore` → `{{a,foo},{b,bar}}`

Table F.12. `hstore` Functions

Function Description Example(s)

`hstore ( record ) → hstore`
Constructs an `hstore` from a record or row.
`hstore(ROW(1,2))` → `"f1"=>"1", "f2"=>"2"`

`hstore ( text[] ) → hstore`
Constructs an `hstore` from an array, which may be either a key/value array, or a two-dimensional array.
`hstore(ARRAY['a','1','b','2'])` → `"a"=>"1", "b"=>"2"`
`hstore(ARRAY[['c','3'],['d','4']])` → `"c"=>"3", "d"=>"4"`

`hstore ( text[], text[] ) → hstore`
Constructs an `hstore` from separate key and value arrays.
`hstore(ARRAY['a','b'], ARRAY['1','2'])` → `"a"=>"1", "b"=>"2"`

`hstore ( text, text ) → hstore`
Makes a single-item `hstore`.
`hstore('a', 'b')` → `"a"=>"b"`

`akeys ( hstore ) → text[]`
Extracts an `hstore`'s keys as an array.
`akeys('a=>1,b=>2')` → `{a,b}`

`skeys ( hstore ) → setof text`
Extracts an `hstore`'s keys as a set.
`skeys('a=>1,b=>2')` →
`a`
`b`

`avals ( hstore ) → text[]` Extracts an `hstore`'s values as an array.

Function
Description
Example(s)

```
avals('a=>1,b=>2')   → {1,2}
```

svals (hstore) → setof text

Extracts an hstore's values as a set.

```
svals('a=>1,b=>2')   →

1
2
```

hstore_to_array (hstore) → text[]

Extracts an hstore's keys and values as an array of alternating keys and values.

```
hstore_to_array('a=>1,b=>2')     → {a,1,b,2}
```

hstore_to_matrix (hstore) → text[]

Extracts an hstore's keys and values as a two-dimensional array.

```
hstore_to_matrix('a=>1,b=>2')     → {{a,1},{b,2}}
```

hstore_to_json (hstore) → json

Converts an hstore to a json value, converting all non-null values to JSON strings.
This function is used implicitly when an hstore value is cast to json.

```
hstore_to_json('"a key"=>1, b=>t, c=>null, d=>12345, e=>012345,
f=>1.234, g=>2.345e+4')  → {"a key": "1", "b": "t", "c": null, "d": "12345",
"e": "012345", "f": "1.234", "g": "2.345e+4"}
```

hstore_to_jsonb (hstore) → jsonb

Converts an hstore to a jsonb value, converting all non-null values to JSON strings.
This function is used implicitly when an hstore value is cast to jsonb.

```
hstore_to_jsonb('"a key"=>1, b=>t, c=>null, d=>12345, e=>012345,
f=>1.234, g=>2.345e+4')  → {"a key": "1", "b": "t", "c": null, "d": "12345",
"e": "012345", "f": "1.234", "g": "2.345e+4"}
```

hstore_to_json_loose (hstore) → json

Converts an hstore to a json value, but attempts to distinguish numerical and Boolean values so they are unquoted in the JSON.

```
hstore_to_json_loose('"a key"=>1, b=>t, c=>null, d=>12345, e=>012345,
 f=>1.234, g=>2.345e+4')   → {"a key": 1, "b": true, "c": null, "d": 12345,
"e": "012345", "f": 1.234, "g": 2.345e+4}
```

hstore_to_jsonb_loose (hstore) → jsonb

Converts an hstore to a jsonb value, but attempts to distinguish numerical and Boolean values so they are unquoted in the JSON.

```
hstore_to_jsonb_loose('"a key"=>1, b=>t, c=>null, d=>12345, e=>012345,
 f=>1.234, g=>2.345e+4')   → {"a key": 1, "b": true, "c": null, "d": 12345,
"e": "012345", "f": 1.234, "g": 2.345e+4}
```

slice (hstore, text[]) → hstore

Extracts a subset of an hstore containing only the specified keys.

```
slice('a=>1,b=>2,c=>3'::hstore, ARRAY['b','c','x'])       → "b"=>"2", "c"=>"3"
```

each (hstore) → setof record (*key* text, *value* text)

Extracts an hstore's keys and values as a set of records.

```
select * from each('a=>1,b=>2')   →

 key | value
-----+-------
```

Function Description Example(s)
a | 1 b | 2
exist (hstore, text) → boolean Does hstore contain key? exist('a=>1', 'a') → t
defined (hstore, text) → boolean Does hstore contain a non-NULL value for key? defined('a=>NULL', 'a') → f
delete (hstore, text) → hstore Deletes pair with matching key. delete('a=>1,b=>2', 'b') → "a"=>"1"
delete (hstore, text[]) → hstore Deletes pairs with matching keys. delete('a=>1,b=>2,c=>3', ARRAY['a','b']) → "c"=>"3"
delete (hstore, hstore) → hstore Deletes pairs matching those in the second argument. delete('a=>1,b=>2', 'a=>4,b=>2'::hstore) → "a"=>"1"
populate_record (anyelement, hstore) → anyelement Replaces fields in the left operand (which must be a composite type) with matching values from hstore. populate_record(ROW(1,2), 'f1=>42'::hstore) → (42,2)

In addition to these operators and functions, values of the hstore type can be subscripted, allowing them to act like associative arrays. Only a single subscript of type text can be specified; it is interpreted as a key and the corresponding value is fetched or stored. For example,

```
CREATE TABLE mytable (h hstore);
INSERT INTO mytable VALUES ('a=>b, c=>d');
SELECT h['a'] FROM mytable;
 h
---
 b
(1 row)

UPDATE mytable SET h['c'] = 'new';
SELECT h FROM mytable;
          h
----------------------
 "a"=>"b", "c"=>"new"
(1 row)
```

A subscripted fetch returns NULL if the subscript is NULL or that key does not exist in the hstore. (Thus, a subscripted fetch is not greatly different from the -> operator.) A subscripted update fails if the subscript is NULL; otherwise, it replaces the value for that key, adding an entry to the hstore if the key does not already exist.

F.21.3. Indexes

hstore has GiST and GIN index support for the @>, ?, ?& and ?| operators. For example:

```
CREATE INDEX hidx ON testhstore USING GIST (h);
```

```
CREATE INDEX hidx ON testhstore USING GIN (h);
```

`gist_hstore_ops` GiST opclass approximates a set of key/value pairs as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default length is 16 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

```
CREATE INDEX hidx ON testhstore USING GIST (h gist_hstore_ops(siglen=32));
```

`hstore` also supports `btree` or `hash` indexes for the = operator. This allows `hstore` columns to be declared `UNIQUE`, or to be used in `GROUP BY`, `ORDER BY` or `DISTINCT` expressions. The sort ordering for `hstore` values is not particularly useful, but these indexes may be useful for equivalence lookups. Create indexes for = comparisons as follows:

```
CREATE INDEX hidx ON testhstore USING BTREE (h);

CREATE INDEX hidx ON testhstore USING HASH (h);
```

F.21.4. Examples

Add a key, or update an existing key with a new value:

```
UPDATE tab SET h['c'] = '3';
```

Another way to do the same thing is:

```
UPDATE tab SET h = h || hstore('c', '3');
```

If multiple keys are to be added or changed in one operation, the concatenation approach is more efficient than subscripting:

```
UPDATE tab SET h = h || hstore(array['q', 'w'], array['11', '12']);
```

Delete a key:

```
UPDATE tab SET h = delete(h, 'k1');
```

Convert a `record` to an `hstore`:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');

SELECT hstore(t) FROM test AS t;
                  hstore
-------------------------------------------
 "col1"=>"123", "col2"=>"foo", "col3"=>"bar"
(1 row)
```

Convert an `hstore` to a predefined `record` type:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);

SELECT * FROM populate_record(null::test,
                              '"col1"=>"456", "col2"=>"zzz"');
 col1 | col2 | col3
------+------+------
  456 | zzz  |
(1 row)
```

Modify an existing record using the values from an `hstore`:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');

SELECT (r).* FROM (SELECT t #= '"col3"=>"baz"' AS r FROM test t) s;
 col1 | col2 | col3
------+------+------
  123 | foo  | baz
(1 row)
```

F.21.5. Statistics

The `hstore` type, because of its intrinsic liberality, could contain a lot of different keys. Checking for valid keys is the task of the application. The following examples demonstrate several techniques for checking keys and obtaining statistics.

Simple example:

```
SELECT * FROM each('aaa=>bq, b=>NULL, ""=>1');
```

Using a table:

```
CREATE TABLE stat AS SELECT (each(h)).key, (each(h)).value FROM testhstore;
```

Online statistics:

```
SELECT key, count(*) FROM
  (SELECT (each(h)).key FROM testhstore) AS stat
  GROUP BY key
  ORDER BY count DESC, key;
    key    | count
-----------+-------
 line      |   883
 query     |   207
 pos       |   203
 node      |   202
 space     |   197
 status    |   195
 public    |   194
 title     |   190
 org       |   189
...................
```

F.21.6. Compatibility

As of PostgreSQL 9.0, `hstore` uses a different internal representation than previous versions. This presents no obstacle for dump/restore upgrades since the text representation (used in the dump) is unchanged.

In the event of a binary upgrade, upward compatibility is maintained by having the new code recognize old-format data. This will entail a slight performance penalty when processing data that has not yet been modified by the new code. It is possible to force an upgrade of all values in a table column by doing an `UPDATE` statement as follows:

```
UPDATE tablename SET hstorecol = hstorecol || '';
```

Another way to do it is:

```
ALTER TABLE tablename ALTER hstorecol TYPE hstore USING hstorecol || '';
```

The `ALTER TABLE` method requires an `ACCESS EXCLUSIVE` lock on the table, but does not result in bloating the table with old row versions.

F.21.7. Transforms

Additional extensions are available that implement transforms for the `hstore` type for the languages PL/Perl and PL/Python. The extensions for PL/Perl are called `hstore_plperl` and `hstore_plperlu`, for trusted and untrusted PL/Perl. If you install these transforms and specify them when creating a function, `hstore` values are mapped to Perl hashes. The extensions for PL/Python are called `hstore_plpythonu`, `hstore_plpython2u`, and `hstore_plpython3u` (see Section 45.1 for the PL/Python naming convention). If you use them, `hstore` values are mapped to Python dictionaries.

> **Caution**
>
> It is strongly recommended that the transform extensions be installed in the same schema as `hstore`. Otherwise there are installation-time security hazards if a transform extension's schema contains objects defined by a hostile user.

F.21.8. Authors

Oleg Bartunov `<oleg@sai.msu.su>`, Moscow, Moscow University, Russia

Teodor Sigaev `<teodor@sigaev.ru>`, Moscow, Delta-Soft Ltd., Russia

Additional enhancements by Andrew Gierth `<andrew@tao11.riddles.org.uk>`, United Kingdom

F.22. Hunspell Dictionaries Modules

These modules provide Hunspell dictionaries for various languages. Upon installation of the module into database using `CREATE EXTENSION` command, text search dictionary and configuration objects in the public schema appear.

Table F.13. Modules

Language	Extension name	Dictionary name	Configuration name
American English	`hunspell_en_us`	`english_hunspell`	`english_hunspell`
Dutch	`hunspell_nl_nl`	`dutch_hunspell`	`dutch_hunspell`
French	`hunspell_fr`	`french_hunspell`	`french_hunspell`
Russian	`hunspell_ru_ru`	`russian_hunspell`	`russian_hunspell`

F.22.1. Examples

Text search objects will be created after installation of a dictionary module. We can test created configuration:

```
SELECT * FROM ts_debug('english_hunspell', 'abilities');
   alias   |   description   |   token   |          dictionaries          |
 dictionary    |  lexemes
-----------+-----------------+-----------+--------------------------------
+-----------------+-----------
 asciiword | Word, all ASCII | abilities | {english_hunspell,english_stem} |
 english_hunspell | {ability}
(1 row)
```

Or you can create your own text search configuration. For example, with the created dictionaries and with the `Snowball` dictionary you can create mixed russian-english configuration:

```
CREATE TEXT SEARCH CONFIGURATION russian_en (
  COPY = simple
);
```

```
ALTER TEXT SEARCH CONFIGURATION russian_en
  ALTER MAPPING FOR asciiword, asciihword, hword_asciipart
  WITH english_hunspell, english_stem;

ALTER TEXT SEARCH CONFIGURATION russian_en
  ALTER MAPPING FOR word, hword, hword_part
  WITH russian_hunspell, russian_stem;
```

You can create mixed dictionaries only for languages with different alphabets. If languages have similar alphabets then Postgres Pro can not decide which dictionary should be used.

A text search configuration which is created with a dictionary module is ready to use. For example, in this text you can search some words:

```
SELECT to_tsvector('english_hunspell', 'The blue whale is the largest animal');
               to_tsvector
-----------------------------------------
 'animal':7 'blue':2 'large':6 'whale':3
(1 row)
```

Search query might looks like this:

```
SELECT to_tsvector('english_hunspell', 'The blue whale is the largest animal')
  @@ to_tsquery('english_hunspell', 'large & whale');
 ?column?
----------
 t
(1 row)
```

With this configurations you can search a text using GIN or GIST indexes. For example, there is a table with GIN index:

```
CREATE TABLE table1 (t varchar);
INSERT INTO table1 VALUES ('The blue whale is the largest animal');
CREATE INDEX t_idx ON table1 USING GIN (to_tsvector('english_hunspell', "t"));
```

For this table you can execute the following query:

```
SELECT * FROM table1 where to_tsvector('english_hunspell', t)
  @@ to_tsquery('english_hunspell', 'blue & animal');
                  t
-------------------------------------
 The blue whale is the largest animal
(1 row)
```

F.23. intagg

The `intagg` module provides an integer aggregator and an enumerator. `intagg` is now obsolete, because there are built-in functions that provide a superset of its capabilities. However, the module is still provided as a compatibility wrapper around the built-in functions.

F.23.1. Functions

The aggregator is an aggregate function `int_array_aggregate(integer)` that produces an integer array containing exactly the integers it is fed. This is a wrapper around `array_agg`, which does the same thing for any array type.

The enumerator is a function `int_array_enum(integer[])` that returns `setof integer`. It is essentially the reverse operation of the aggregator: given an array of integers, expand it into a set of rows. This is a wrapper around `unnest`, which does the same thing for any array type.

F.23.2. Sample Uses

Many database systems have the notion of a one to many table. Such a table usually sits between two indexed tables, for example:

```
CREATE TABLE left (id INT PRIMARY KEY, ...);
CREATE TABLE right (id INT PRIMARY KEY, ...);
CREATE TABLE one_to_many(left INT REFERENCES left, right INT REFERENCES right);
```

It is typically used like this:

```
SELECT right.* from right JOIN one_to_many ON (right.id = one_to_many.right)
  WHERE one_to_many.left = item;
```

This will return all the items in the right hand table for an entry in the left hand table. This is a very common construct in SQL.

Now, this methodology can be cumbersome with a very large number of entries in the `one_to_many` table. Often, a join like this would result in an index scan and a fetch for each right hand entry in the table for a particular left hand entry. If you have a very dynamic system, there is not much you can do. However, if you have some data which is fairly static, you can create a summary table with the aggregator.

```
CREATE TABLE summary AS
  SELECT left, int_array_aggregate(right) AS right
  FROM one_to_many
  GROUP BY left;
```

This will create a table with one row per left item, and an array of right items. Now this is pretty useless without some way of using the array; that's why there is an array enumerator. You can do

```
SELECT left, int_array_enum(right) FROM summary WHERE left = item;
```

The above query using `int_array_enum` produces the same results as

```
SELECT left, right FROM one_to_many WHERE left = item;
```

The difference is that the query against the summary table has to get only one row from the table, whereas the direct query against `one_to_many` must index scan and fetch a row for each entry.

On one system, an `EXPLAIN` showed a query with a cost of 8488 was reduced to a cost of 329. The original query was a join involving the `one_to_many` table, which was replaced by:

```
SELECT right, count(right) FROM
  ( SELECT left, int_array_enum(right) AS right
    FROM summary JOIN (SELECT left FROM left_table WHERE left = item) AS lefts
         ON (summary.left = lefts.left)
  ) AS list
  GROUP BY right
  ORDER BY count DESC;
```

F.24. intarray

The `intarray` module provides a number of useful functions and operators for manipulating null-free arrays of integers. There is also support for indexed searches using some of the operators.

All of these operations will throw an error if a supplied array contains any NULL elements.

Many of these operations are only sensible for one-dimensional arrays. Although they will accept input arrays of more dimensions, the data is treated as though it were a linear array in storage order.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.24.1. `intarray` Functions and Operators

The functions provided by the `intarray` module are shown in Table F.14, the operators in Table F.15.

Table F.14. `intarray` Functions

Function Description Example(s)

`icount ( integer[] ) → integer`
Returns the number of elements in the array.
`icount('{1,2,3}'::integer[])  → 3`

`sort ( integer[], dir text ) → integer[]`
Sorts the array in either ascending or descending order. *dir* must be `asc` or `desc`.
`sort('{1,3,2}'::integer[], 'desc')  → {3,2,1}`

`sort ( integer[] ) → integer[]`
`sort_asc ( integer[] ) → integer[]`
Sorts in ascending order.
`sort(array[11,77,44])  → {11,44,77}`

`sort_desc ( integer[] ) → integer[]`
Sorts in descending order.
`sort_desc(array[11,77,44])  → {77,44,11}`

`uniq ( integer[] ) → integer[]`
Removes adjacent duplicates. Often used with `sort` to remove all duplicates.
`uniq('{1,2,2,3,1,1}'::integer[])  → {1,2,3,1}`
`uniq(sort('{1,2,3,2,1}'::integer[]))  → {1,2,3}`

`idx ( integer[], item integer ) → integer`
Returns index of the first array element matching *item*, or 0 if no match.
`idx(array[11,22,33,22,11], 22)  → 2`

`subarray ( integer[], start integer, len integer ) → integer[]`
Extracts the portion of the array starting at position *start*, with *len* elements.
`subarray('{1,2,3,2,1}'::integer[], 2, 3)  → {2,3,2}`

`subarray ( integer[], start integer ) → integer[]`
Extracts the portion of the array starting at position *start*.
`subarray('{1,2,3,2,1}'::integer[], 2)  → {2,3,2,1}`

`intset ( integer ) → integer[]`
Makes a single-element array.
`intset(42)  → {42}`

Table F.15. `intarray` Operators

Operator Description
`integer[] && integer[] → boolean` Do arrays overlap (have at least one element in common)?
`integer[] @> integer[] → boolean` Does left array contain right array?
`integer[] <@ integer[] → boolean` Is left array contained in right array?
`# integer[] → integer` Returns the number of elements in the array.

Operator Description
`integer[] # integer → integer` Returns index of the first array element matching the right argument, or 0 if no match. (Same as `idx` function.)
`integer[] + integer → integer[]` Adds element to end of array.
`integer[] + integer[] → integer[]` Concatenates the arrays.
`integer[] - integer → integer[]` Removes entries matching the right argument from the array.
`integer[] - integer[] → integer[]` Removes elements of the right array from the left array.
`integer[] | integer → integer[]` Computes the union of the arguments.
`integer[] | integer[] → integer[]` Computes the union of the arguments.
`integer[] & integer[] → integer[]` Computes the intersection of the arguments.
`integer[] @@ query_int → boolean` Does array satisfy query? (see below)
`query_int ~~ integer[] → boolean` Does array satisfy query? (commutator of `@@`)

The operators `&&`, `@>` and `<@` are equivalent to Postgres Pro's built-in operators of the same names, except that they work only on integer arrays that do not contain nulls, while the built-in operators work for any array type. This restriction makes them faster than the built-in operators in many cases.

The `@@` and `~~` operators test whether an array satisfies a *query*, which is expressed as a value of a specialized data type `query_int`. A *query* consists of integer values that are checked against the elements of the array, possibly combined using the operators `&` (AND), `|` (OR), and `!` (NOT). Parentheses can be used as needed. For example, the query `1&(2|3)` matches arrays that contain 1 and also contain either 2 or 3.

F.24.2. Index Support

`intarray` provides index support for the `&&`, `@>`, and `@@` operators, as well as regular array equality.

Two parameterized GiST index operator classes are provided: `gist__int_ops` (used by default) is suitable for small- to medium-size data sets, while `gist__intbig_ops` uses a larger signature and is more suitable for indexing large data sets (i.e., columns containing a large number of distinct array values). The implementation uses an RD-tree data structure with built-in lossy compression.

`gist__int_ops` approximates an integer set as an array of integer ranges. Its optional integer parameter `numranges` determines the maximum number of ranges in one index key. The default value of `numranges` is 100. Valid values are between 1 and 253. Using larger arrays as GiST index keys leads to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

`gist__intbig_ops` approximates an integer set as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 16 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

There is also a non-default GIN operator class `gin__int_ops`, which supports these operators as well as `<@`.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

F.24.3. Example

```
-- a message can be in one or more “sections”
CREATE TABLE message (mid INT PRIMARY KEY, sections INT[], ...);

-- create specialized index with signature length of 32 bytes
CREATE INDEX message_rdtree_idx ON message USING GIST (sections gist__intbig_ops
 (siglen = 32));

-- select messages in section 1 OR 2 - OVERLAP operator
SELECT message.mid FROM message WHERE message.sections && '{1,2}';

-- select messages in sections 1 AND 2 - CONTAINS operator
SELECT message.mid FROM message WHERE message.sections @> '{1,2}';

-- the same, using QUERY operator
SELECT message.mid FROM message WHERE message.sections @@ '1&2'::query_int;
```

F.24.4. Authors

All work was done by Teodor Sigaev (`<teodor@sigaev.ru>`) and Oleg Bartunov (`<oleg@sai.msu.su>`). See *http://www.sai.msu.su/~megera/postgres/gist/* for additional information. Andrey Oktyabrski did a great work on adding new functions and operations.

F.25. isn

The `isn` module provides data types for the following international product numbering standards: EAN13, UPC, ISBN (books), ISMN (music), and ISSN (serials). Numbers are validated on input according to a hard-coded list of prefixes; this list of prefixes is also used to hyphenate numbers on output. Since new prefixes are assigned from time to time, the list of prefixes may be out of date. It is hoped that a future version of this module will obtain the prefix list from one or more tables that can be easily updated by users as needed; however, at present, the list can only be updated by modifying the source code and recompiling. Alternatively, prefix validation and hyphenation support may be dropped from a future version of this module.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.25.1. Data Types

Table F.16 shows the data types provided by the `isn` module.

Table F.16. `isn` Data Types

Data Type	Description
`EAN13`	European Article Numbers, always displayed in the EAN13 display format
`ISBN13`	International Standard Book Numbers to be displayed in the new EAN13 display format
`ISMN13`	International Standard Music Numbers to be displayed in the new EAN13 display format
`ISSN13`	International Standard Serial Numbers to be displayed in the new EAN13 display format

Data Type	Description
ISBN	International Standard Book Numbers to be displayed in the old short display format
ISMN	International Standard Music Numbers to be displayed in the old short display format
ISSN	International Standard Serial Numbers to be displayed in the old short display format
UPC	Universal Product Codes

Some notes:

1. ISBN13, ISMN13, ISSN13 numbers are all EAN13 numbers.
2. EAN13 numbers aren't always ISBN13, ISMN13 or ISSN13 (some are).
3. Some ISBN13 numbers can be displayed as ISBN.
4. Some ISMN13 numbers can be displayed as ISMN.
5. Some ISSN13 numbers can be displayed as ISSN.
6. UPC numbers are a subset of the EAN13 numbers (they are basically EAN13 without the first `0` digit).
7. All UPC, ISBN, ISMN and ISSN numbers can be represented as EAN13 numbers.

Internally, all these types use the same representation (a 64-bit integer), and all are interchangeable. Multiple types are provided to control display formatting and to permit tighter validity checking of input that is supposed to denote one particular type of number.

The `ISBN`, `ISMN`, and `ISSN` types will display the short version of the number (ISxN 10) whenever it's possible, and will show ISxN 13 format for numbers that do not fit in the short version. The `EAN13`, `ISBN13`, `ISMN13` and `ISSN13` types will always display the long version of the ISxN (EAN13).

F.25.2. Casts

The `isn` module provides the following pairs of type casts:

- ISBN13 <=> EAN13
- ISMN13 <=> EAN13
- ISSN13 <=> EAN13
- ISBN <=> EAN13
- ISMN <=> EAN13
- ISSN <=> EAN13
- UPC <=> EAN13
- ISBN <=> ISBN13
- ISMN <=> ISMN13
- ISSN <=> ISSN13

When casting from `EAN13` to another type, there is a run-time check that the value is within the domain of the other type, and an error is thrown if not. The other casts are simply relabelings that will always succeed.

F.25.3. Functions and Operators

The `isn` module provides the standard comparison operators, plus B-tree and hash indexing support for all these data types. In addition there are several specialized functions; shown in Table F.17. In this table, `isn` means any one of the module's data types.

Table F.17. `isn` Functions

Function Description
`isn_weak ( boolean ) → boolean` Sets the weak input mode, and returns new setting.
`isn_weak () → boolean` Returns the current status of the weak mode.
`make_valid ( isn ) → isn` Validates an invalid number (clears the invalid flag).
`is_valid ( isn ) → boolean` Checks for the presence of the invalid flag.

Weak mode is used to be able to insert invalid data into a table. Invalid means the check digit is wrong, not that there are missing numbers.

Why would you want to use the weak mode? Well, it could be that you have a huge collection of ISBN numbers, and that there are so many of them that for weird reasons some have the wrong check digit (perhaps the numbers were scanned from a printed list and the OCR got the numbers wrong, perhaps the numbers were manually captured... who knows). Anyway, the point is you might want to clean the mess up, but you still want to be able to have all the numbers in your database and maybe use an external tool to locate the invalid numbers in the database so you can verify the information and validate it more easily; so for example you'd want to select all the invalid numbers in the table.

When you insert invalid numbers in a table using the weak mode, the number will be inserted with the corrected check digit, but it will be displayed with an exclamation mark (`!`) at the end, for example `0-11-000322-5!`. This invalid marker can be checked with the `is_valid` function and cleared with the `make_valid` function.

You can also force the insertion of invalid numbers even when not in the weak mode, by appending the `!` character at the end of the number.

Another special feature is that during input, you can write `?` in place of the check digit, and the correct check digit will be inserted automatically.

F.25.4. Examples

```
--Using the types directly:
SELECT isbn('978-0-393-04002-9');
SELECT isbn13('0901690546');
SELECT issn('1436-4522');

--Casting types:
-- note that you can only cast from ean13 to another type when the
-- number would be valid in the realm of the target type;
-- thus, the following will NOT work: select isbn(ean13('0220356483481'));
-- but these will:
SELECT upc(ean13('0220356483481'));
SELECT ean13(upc('220356483481'));

--Create a table with a single column to hold ISBN numbers:
CREATE TABLE test (id isbn);
INSERT INTO test VALUES('9780393040029');

--Automatically calculate check digits (observe the '?'):
INSERT INTO test VALUES('220500896?');
INSERT INTO test VALUES('978055215372?');
```

```
SELECT issn('3251231?');
SELECT ismn('979047213542?');

--Using the weak mode:
SELECT isn_weak(true);
INSERT INTO test VALUES('978-0-11-000533-4');
INSERT INTO test VALUES('9780141219307');
INSERT INTO test VALUES('2-205-00876-X');
SELECT isn_weak(false);

SELECT id FROM test WHERE NOT is_valid(id);
UPDATE test SET id = make_valid(id) WHERE id = '2-205-00876-X!';

SELECT * FROM test;

SELECT isbn13(id) FROM test;
```

F.25.5. Bibliography

The information to implement this module was collected from several sites, including:

- *https://www.isbn-international.org/*
- *https://www.issn.org/*
- *https://www.ismn-international.org/*
- *https://www.wikipedia.org/*

The prefixes used for hyphenation were also compiled from:

- *https://www.gs1.org/standards/id-keys*
- *https://en.wikipedia.org/wiki/List_of_ISBN_identifier_groups*
- *https://www.isbn-international.org/content/isbn-users-manual/29*
- *https://en.wikipedia.org/wiki/International_Standard_Music_Number*
- *https://www.ismn-international.org/ranges/tools*

Care was taken during the creation of the algorithms and they were meticulously verified against the suggested algorithms in the official ISBN, ISMN, ISSN User Manuals.

F.25.6. Author

Germán Méndez Bravo (Kronuz), 2004–2006

This module was inspired by Garrett A. Wollman's `isbn_issn` code.

F.26. jsquery

JsQuery is a language to query `jsonb` data type. Its primary goal is to provide an additional functionality for `jsonb`, such as a simple and effective way for search in nested objects and arrays, as well as additional comparison operators with index support.

JsQuery is implemented by means of a `jsquery` data type (similar to `tsquery`) and the `@@` match operator for `jsonb`.

F.26.1. Installation

Postgres Pro Standard distribution includes jsquery as a contrib module. Once you complete Postgres Pro Standard installation, create the jsquery extension, as follows:

```
CREATE EXTENSION jsquery;
```

F.26.2. JSON query language

JsQuery extension contains `jsquery` datatype which represents whole JSON query as a single value (like `tsquery` does for fulltext search). The query is an expression on JSON-document values.

Simple expression is specified as *`path binary_operator value`* or *`path unary_operator`*. See the following examples.

- `x = "abc"` - value of key "x" is equal to "abc";
- `$ @> [4, 5, "zzz"]` - the JSON document is an array containing values 4, 5 and "zzz";
- `"abc xyz" >= 10` - value of key "abc xyz" is greater than or equal to 10;
- `volume IS NUMERIC` - type of key "volume" is numeric.
- `$ = true` - the whole JSON document is just a true.
- `similar_ids.@# > 5` - `similar_ids` is an array or object of length greater than 5;
- `similar_product_ids.# = "0684824396"` - array `similar_product_ids` contains string "0684824396".
- `*.color = "red"` - there is object somewhere which key "color" has value "red".
- `foo = *` - key "foo" exists in object.

Path selects set of JSON values to be checked using given operators. In the simplest case, path is just a key name. In general, path is key names and placeholders combined by dot signs. Path can use the following placeholders:

- `#` - any index of array;
- `#N` - Nth index of array;
- `%` - any key of object;
- `*` - any sequence of array indexes and object keys;
- `@#` - length of array or object, could be only used as last component of path;
- `$` - the whole JSON document as single value, could be only the whole path.

Expression is true when operator is true against at least one value selected by path.

Key names could be given either with or without double quotes. Key names without double quotes shouldn't contain spaces, start with number, or concur with jsquery keyword.

The supported binary operators are:

- Equality operator: `=`;
- Numeric comparison operators: `>`, `>=`, `<`, `<=`;
- Search in the list of scalar values using `IN` operator;
- Array comparison operators: `&&` (overlap), `@>` (contains), `<@` (contained in).
- Filtering operator: `~~`. Taking `jsonb` data as the left operand and a `jsquery` expression as the right operand, this operator checks that `jsonb` data contains any entries that satisfy the condition provided in a `jsquery` expression and returns an array of such entries, if any.

The supported unary operators are:

- Check for existence operator: `= *`;
- Check for type operators: `IS ARRAY`, `IS NUMERIC`, `IS OBJECT`, `IS STRING` and `IS BOOLEAN`.

Expressions could be complex. Complex expression is a set of expressions combined by logical operators (`AND`, `OR`, `NOT`) and grouped using parentheses.

Examples of complex expressions are given below.

- `a = 1 AND (b = 2 OR c = 3) AND NOT d = 1`
- `x.% = true OR x.# = true`

Prefix expressions are expressions given in the form path (subexpression). In this case path selects JSON values to be checked using given subexpression. Check results are aggregated in the same way as in simple expressions.

- `#(a = 1 AND b = 2)` - an array contains an element where the `a` key is 2 and the `b` key is 2
- `%($ >= 10 AND $ <= 20)` - an object contains a key with a value between 10 and 20

Path also could contain the following special placeholders with "every" semantics:

- `#:` - every index of array;
- `%:` - every key of object;
- `*:` - every sequence of array indexes and object keys.

Consider the following example.

```
%.#:($ >= 0 AND $ <= 1)
```

This example could be read as follows: there is at least one key for which the value is an array of numerics between 0 and 1.

We can rewrite this example in the following form with extra parentheses.

```
%(#:($ >= 0 AND $ <= 1))
```

The first placeholder `%` checks that expression in parentheses is true for at least one value in object. The second placeholder `#:` checks that the value is an array and all its elements satisfy expressions in parentheses.

We can rewrite this example without `#:` placeholder as follows.

```
%(NOT #(NOT ($ >= 0 AND $ <= 1)) AND $ IS ARRAY)
```

In this example we transform assertion that every element of array satisfies some condition to assertion that there is no one element which doesn't satisfy the same condition.

Some examples of using paths are given below.

- `numbers.#: IS NUMERIC` - every element of "numbers" array is numeric.
- `*:($ IS OBJECT OR $ IS BOOLEAN)` - JSON is a structure of nested objects with booleans as leaf values.
- `#:.%:($ >= 0 AND $ <= 1)` - each element of array is object containing only numeric values between 0 and 1.
- `documents.#:.% = *` - "documents" is an array of objects containing at least one key.
- `%.#: ($ IS STRING)` - JSON object contains at least one array of strings.
- `#.% = true` - at least one array element is an object that contains at least one "true" value.

Usage of path operators and parentheses needs some explanation. When same path operators are used multiple times they may refer to different values while you can refer to the same value multiple times by using parentheses and `$` operator. See the following examples.

- `# < 10 AND # > 20` - there is an element less than 10 and another element greater than 20.
- `#($ < 10 AND $ > 20)` - there is an element that is both less than 10 and greater than 20 (impossible).
- `#($ >= 10 AND $ <= 20)` - there is an element between 10 and 20.
- `# >= 10 AND # <= 20` - there is an element greater than or equal to 10 and another element less than or equal to 20. The query can be satisfied by an array with no elements between 10 and 20, for instance [0,30].

Same rules apply when you search inside objects and branchy structures.

Type checking operators and "every" placeholders are useful for document schema validation. JsQuery matching operator `@@` is immutable and can be used in CHECK constraint. See the following example.

```
CREATE TABLE js (
    id serial,
    data jsonb,
```

```
    CHECK (data @@ '
        name IS STRING AND
        similar_ids.#: IS NUMERIC AND
        points.#:(x IS NUMERIC AND y IS NUMERIC)'::jsquery));
```

In this example check constraint validates that in "data" jsonb column: value of "name" key is string, value of "similar_ids" key is array of numerics, value of "points" key is array of objects which contain numeric values in "x" and "y" keys.

See our *pgconf.eu presentation* for more examples.

F.26.3. GIN indexes

JsQuery extension contains two operator classes (opclasses) for GIN which provide different kinds of query optimization.

- jsonb_path_value_ops
- jsonb_value_path_ops

In each of two GIN opclasses jsonb documents are decomposed into entries. Each entry is associated with a particular value and its path. Difference between opclasses is in the entry representation, comparison, and usage for search optimization.

For example, jsonb document `{"a": [{"b": "xyz", "c": true}, 10], "d": {"e": [7, false]}}` would be decomposed into the following entries:

- `"a".#."b"."xyz"`
- `"a".#."c".true`
- `"a".#.10`
- `"d"."e".#.7`
- `"d"."e".#.false`

Since JsQuery doesn't support search in a particular array index, we consider all array elements to be equivalent. Thus, each array element is marked with the same `#` sign in the path.

Major problem in the entries representation is its size. In the given example key "a" is presented three times. In the large branchy documents with long keys size of naive entries representation becomes unreasonable. Both opclasses address this issue but in a slightly different way.

F.26.3.1. jsonb_path_value_ops

jsonb_path_value_ops represents entry as pair of path hash and value. The following pseudocode illustrates it.

```
(hash(path_item_1.path_item_2. ... .path_item_n); value)
```

In comparison of entries path hash is the higher part of entry and value is its lower part. This determines the features of this opclass. Since path is hashed and it is higher part of entry we need to know the full path to the value in order to use it for search. However, once path is specified we can use both exact and range searches very efficiently.

F.26.3.2. jsonb_value_path_ops

jsonb_value_path_ops represents entry as pair of value and bloom filter of path.

```
(value; bloom(path_item_1) | bloom(path_item_2) | ... | bloom(path_item_n))
```

In comparison of entries value is the higher part of entry and bloom filter of path is its lower part. This determines the features of this opclass. Since value is the higher part of entry we can perform only exact value search efficiently. Range value search is possible as well but we would have to filter all the different paths where matching values occur. Bloom filter over path items allows index usage for conditions containing `%` and `*` in their paths.

F.26.3.3. Query optimization

JsQuery opclasses perform complex query optimization. Thus it's valuable for developer or administrator to see the result of such optimization. Unfortunately, opclasses aren't allowed to do any custom output to the EXPLAIN. That's why JsQuery provides the following functions which allows to see how particular opclass optimizes given query.

- gin_debug_query_path_value(jsquery) - for jsonb_path_value_ops
- gin_debug_query_value_path(jsquery) - for jsonb_value_path_ops

Result of these functions is a textual representation of query tree which leaves are GIN search entries. The following examples show different results of query optimization by different opclasses.

```
# SELECT gin_debug_query_path_value('x = 1 AND (*.y = 1 OR y = 2)');
 gin_debug_query_path_value
----------------------------
 x = 1 , entry 0           +

# SELECT gin_debug_query_value_path('x = 1 AND (*.y = 1 OR y = 2)');
 gin_debug_query_value_path
----------------------------
 AND                       +
   x = 1 , entry 0         +
   OR                      +
     *.y = 1 , entry 1     +
     y = 2 , entry 2       +
```

Unfortunately, jsonb has no statistics yet. That's why JsQuery optimizer has to do imperative decision while selecting conditions to be evaluated using index. This decision is made by assumption that some condition types are less selective than others. Optimizer divides conditions into the following selectivity class (listed by descending of selectivity).

1. Equality (x = c)
2. Range (c1 < x < c2)
3. Inequality (x > c)
4. Is (x is type)
5. Any (x = *)

Optimizer evades index evaluation of less selective conditions when possible. For example, in the `x = 1 AND y > 0` query `x = 1` is assumed to be more selective than `y > 0`. That's why index isn't used for evaluation of `y > 0`.

```
# SELECT gin_debug_query_path_value('x = 1 AND y > 0');
 gin_debug_query_path_value
----------------------------
 x = 1 , entry 0           +
```

With lack of statistics decisions made by optimizer can be inaccurate. That's why JsQuery supports hints. Comments `/*-- index */` and `/*-- noindex */` placed in the conditions force optimizer to use and not to use index correspondingly.

```
SELECT gin_debug_query_path_value('x = 1 AND y /*-- index */ > 0');
 gin_debug_query_path_value
----------------------------
 AND                       +
   x = 1 , entry 0         +
   y > 0 , entry 1         +

SELECT gin_debug_query_path_value('x /*-- noindex */ = 1 AND y > 0');
 gin_debug_query_path_value
 ----------------------------
```

```
        y > 0 , entry 0           +
```

F.26.5. Credits

Development is sponsored by *Wargaming.net*.

F.27. lo

The `lo` module provides support for managing Large Objects (also called LOs or BLOBs). This includes a data type `lo` and a trigger `lo_manage`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.27.1. Rationale

One of the problems with the JDBC driver (and this affects the ODBC driver also), is that the specification assumes that references to BLOBs (Binary Large OBjects) are stored within a table, and if that entry is changed, the associated BLOB is deleted from the database.

As Postgres Pro stands, this doesn't occur. Large objects are treated as objects in their own right; a table entry can reference a large object by OID, but there can be multiple table entries referencing the same large object OID, so the system doesn't delete the large object just because you change or remove one such entry.

Now this is fine for Postgres Pro-specific applications, but standard code using JDBC or ODBC won't delete the objects, resulting in orphan objects — objects that are not referenced by anything, and simply occupy disk space.

The `lo` module allows fixing this by attaching a trigger to tables that contain LO reference columns. The trigger essentially just does a `lo_unlink` whenever you delete or modify a value referencing a large object. When you use this trigger, you are assuming that there is only one database reference to any large object that is referenced in a trigger-controlled column!

The module also provides a data type `lo`, which is really just a domain of the `oid` type. This is useful for differentiating database columns that hold large object references from those that are OIDs of other things. You don't have to use the `lo` type to use the trigger, but it may be convenient to use it to keep track of which columns in your database represent large objects that you are managing with the trigger. It is also rumored that the ODBC driver gets confused if you don't use `lo` for BLOB columns.

F.27.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE image (title text, raster lo);

CREATE TRIGGER t_raster BEFORE UPDATE OR DELETE ON image
    FOR EACH ROW EXECUTE FUNCTION lo_manage(raster);
```

For each column that will contain unique references to large objects, create a `BEFORE UPDATE OR DELETE` trigger, and give the column name as the sole trigger argument. You can also restrict the trigger to only execute on updates to the column by using `BEFORE UPDATE OF` *`column_name`*. If you need multiple `lo` columns in the same table, create a separate trigger for each one, remembering to give a different name to each trigger on the same table.

F.27.3. Limitations

- Dropping a table will still orphan any objects it contains, as the trigger is not executed. You can avoid this by preceding the `DROP TABLE` with `DELETE FROM *table*`.

  `TRUNCATE` has the same hazard.

  If you already have, or suspect you have, orphaned large objects, see the vacuumlo module to help you clean them up. It's a good idea to run vacuumlo occasionally as a back-stop to the `lo_manage` trigger.

- Some frontends may create their own tables, and will not create the associated trigger(s). Also, users may not remember (or know) to create the triggers.

F.27.4. Author

Peter Mount `<peter@retep.org.uk>`

F.28. ltree

This module implements a data type `ltree` for representing labels of data stored in a hierarchical tree-like structure. Extensive facilities for searching through label trees are provided.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.28.1. Definitions

A *label* is a sequence of alphanumeric characters and underscores (for example, in C locale the characters `A-Za-z0-9_` are allowed). Labels must be less than 256 characters long.

Examples: `42`, `Personal_Services`

A *label path* is a sequence of zero or more labels separated by dots, for example `L1.L2.L3`, representing a path from the root of a hierarchical tree to a particular node. The length of a label path cannot exceed 65535 labels.

Example: `Top.Countries.Europe.Russia`

The `ltree` module provides several data types:

- `ltree` stores a label path.
- `lquery` represents a regular-expression-like pattern for matching `ltree` values. A simple word matches that label within a path. A star symbol (`*`) matches zero or more labels. These can be joined with dots to form a pattern that must match the whole label path. For example:

  ```
  foo         Match the exact label path foo
  *.foo.*     Match any label path containing the label foo
  *.foo       Match any label path whose last label is foo
  ```

  Both star symbols and simple words can be quantified to restrict how many labels they can match:

  ```
  *{n}        Match exactly n labels
  *{n,}       Match at least n labels
  *{n,m}      Match at least n but not more than m labels
  *{,m}       Match at most m labels — same as *{0,m}
  foo{n,m}    Match at least n but not more than m occurrences of foo
  foo{,}      Match any number of occurrences of foo, including zero
  ```

  In the absence of any explicit quantifier, the default for a star symbol is to match any number of labels (that is, `{,}`) while the default for a non-star item is to match exactly once (that is, `{1}`).

There are several modifiers that can be put at the end of a non-star `lquery` item to make it match more than just the exact match:

```
@           Match case-insensitively, for example a@ matches A
*           Match any label with this prefix, for example foo* matches foobar
%           Match initial underscore-separated words
```

The behavior of `%` is a bit complicated. It tries to match words rather than the entire label. For example `foo_bar%` matches `foo_bar_baz` but not `foo_barbaz`. If combined with `*`, prefix matching applies to each word separately, for example `foo_bar%*` matches `foo1_bar2_baz` but not `foo1_br2_baz`.

Also, you can write several possibly-modified non-star items separated with `|` (OR) to match any of those items, and you can put `!` (NOT) at the start of a non-star group to match any label that doesn't match any of the alternatives. A quantifier, if any, goes at the end of the group; it means some number of matches for the group as a whole (that is, some number of labels matching or not matching any of the alternatives).

Here's an annotated example of `lquery`:

```
Top.*{0,2}.sport*@.!football|tennis{1,}.Russ*|Spain
a.  b.     c.      d.                   e.
```

This query will match any label path that:

a. begins with the label `Top`

b. and next has zero to two labels before

c. a label beginning with the case-insensitive prefix `sport`

d. then has one or more labels, none of which match `football` nor `tennis`

e. and then ends with a label beginning with `Russ` or exactly matching `Spain`.

- `ltxtquery` represents a full-text-search-like pattern for matching `ltree` values. An `ltxtquery` value contains words, possibly with the modifiers `@`, `*`, `%` at the end; the modifiers have the same meanings as in `lquery`. Words can be combined with `&` (AND), `|` (OR), `!` (NOT), and parentheses. The key difference from `lquery` is that `ltxtquery` matches words without regard to their position in the label path.

  Here's an example `ltxtquery`:

  ```
  Europe & Russia*@ & !Transportation
  ```

  This will match paths that contain the label `Europe` and any label beginning with `Russia` (case-insensitive), but not paths containing the label `Transportation`. The location of these words within the path is not important. Also, when `%` is used, the word can be matched to any underscore-separated word within a label, regardless of position.

Note: `ltxtquery` allows whitespace between symbols, but `ltree` and `lquery` do not.

F.28.2. Operators and Functions

Type `ltree` has the usual comparison operators `=`, `<>`, `<`, `>`, `<=`, `>=`. Comparison sorts in the order of a tree traversal, with the children of a node sorted by label text. In addition, the specialized operators shown in Table F.18 are available.

Table F.18. `ltree` Operators

Operator Description
`ltree @> ltree` → `boolean`

Operator Description
Is left argument an ancestor of right (or equal)?
`ltree <@ ltree → boolean` Is left argument a descendant of right (or equal)?

`ltree ~ lquery → boolean`
`lquery ~ ltree → boolean`
Does `ltree` match `lquery`?

`ltree ? lquery[] → boolean`
`lquery[] ? ltree → boolean`
Does `ltree` match any `lquery` in array?

`ltree @ ltxtquery → boolean`
`ltxtquery @ ltree → boolean`
Does `ltree` match `ltxtquery`?

`ltree || ltree → ltree` Concatenates `ltree` paths.

`ltree || text → ltree`
`text || ltree → ltree`
Converts text to `ltree` and concatenates.

`ltree[] @> ltree → boolean`
`ltree <@ ltree[] → boolean`
Does array contain an ancestor of `ltree`?

`ltree[] <@ ltree → boolean`
`ltree @> ltree[] → boolean`
Does array contain a descendant of `ltree`?

`ltree[] ~ lquery → boolean`
`lquery ~ ltree[] → boolean`
Does array contain any path matching `lquery`?

`ltree[] ? lquery[] → boolean`
`lquery[] ? ltree[] → boolean`
Does `ltree` array contain any path matching any `lquery`?

`ltree[] @ ltxtquery → boolean`
`ltxtquery @ ltree[] → boolean`
Does array contain any path matching `ltxtquery`?

`ltree[] ?@> ltree → ltree` Returns first array entry that is an ancestor of `ltree`, or `NULL` if none.
`ltree[] ?<@ ltree → ltree` Returns first array entry that is a descendant of `ltree`, or `NULL` if none.
`ltree[] ?~ lquery → ltree` Returns first array entry that matches `lquery`, or `NULL` if none.
`ltree[] ?@ ltxtquery → ltree` Returns first array entry that matches `ltxtquery`, or `NULL` if none.

The operators `<@`, `@>`, `@` and `~` have analogues `^<@`, `^@>`, `^@`, `^~`, which are the same except they do not use indexes. These are useful only for testing purposes.

The available functions are shown in Table F.19.

Table F.19. `ltree` Functions

Function Description Example(s)

`subltree ( ltree, start integer, end integer ) → ltree`
Returns subpath of `ltree` from position *`start`* to position *`end`*-1 (counting from 0).
`subltree('Top.Child1.Child2', 1, 2)` → `Child1`

`subpath ( ltree, offset integer, len integer ) → ltree`
Returns subpath of `ltree` starting at position *`offset`*, with length *`len`*. If *`offset`* is negative, subpath starts that far from the end of the path. If *`len`* is negative, leaves that many labels off the end of the path.
`subpath('Top.Child1.Child2', 0, 2)` → `Top.Child1`

`subpath ( ltree, offset integer ) → ltree`
Returns subpath of `ltree` starting at position *`offset`*, extending to end of path. If *`offset`* is negative, subpath starts that far from the end of the path.
`subpath('Top.Child1.Child2', 1)` → `Child1.Child2`

`nlevel ( ltree ) → integer`
Returns number of labels in path.
`nlevel('Top.Child1.Child2')` → `3`

`index ( a ltree, b ltree ) → integer`
Returns position of first occurrence of *`b`* in *`a`*, or -1 if not found.
`index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6')` → `6`

`index ( a ltree, b ltree, offset integer ) → integer`
Returns position of first occurrence of *`b`* in *`a`*, or -1 if not found. The search starts at position *`offset`*; negative *`offset`* means start *`-offset`* labels from the end of the path.
`index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6', -4)` → `9`

`text2ltree ( text ) → ltree` Casts `text` to `ltree`.
`ltree2text ( ltree ) → text` Casts `ltree` to `text`.

`lca ( ltree [, ltree [, ... ]] ) → ltree`
Computes longest common ancestor of paths (up to 8 arguments are supported).
`lca('1.2.3', '1.2.3.4.5.6')` → `1.2`

`lca ( ltree[] ) → ltree`
Computes longest common ancestor of paths in array.
`lca(array['1.2.3'::ltree,'1.2.3.4'])` → `1.2`

F.28.3. Indexes

`ltree` supports several types of indexes that can speed up the indicated operators:

- B-tree index over `ltree`: `<`, `<=`, `=`, `>=`, `>`
- GiST index over `ltree` (`gist_ltree_ops` opclass): `<`, `<=`, `=`, `>=`, `>`, `@>`, `<@`, `@`, `~`, `?`

  `gist_ltree_ops` GiST opclass approximates a set of path labels as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 8 bytes. The length must be a positive multiple of `int` alignment (4 bytes on most machines)) up to

2024. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with the default signature length of 8 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (path);
```

Example of creating such an index with a signature length of 100 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (path gist_ltree_ops(siglen=100));
```

- GiST index over `ltree[]` (`gist__ltree_ops` opclass): `ltree[] <@ ltree`, `ltree @> ltree[]`, `@`, `~`, `?`

  `gist__ltree_ops` GiST opclass works similarly to `gist_ltree_ops` and also takes signature length as a parameter. The default value of `siglen` in `gist__ltree_ops` is 28 bytes.

  Example of creating such an index with the default signature length of 28 bytes:

  ```
  CREATE INDEX path_gist_idx ON test USING GIST (array_path);
  ```

  Example of creating such an index with a signature length of 100 bytes:

  ```
  CREATE INDEX path_gist_idx ON test USING GIST (array_path
   gist__ltree_ops(siglen=100));
  ```

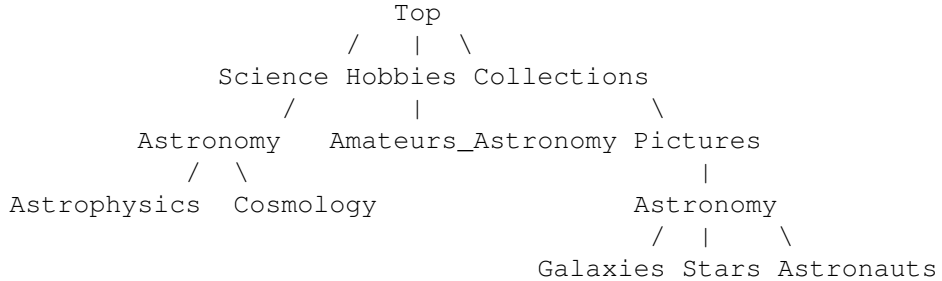
  Note: This index type is lossy.

F.28.4. Example

This example uses the following data (also available in file `contrib/ltree/ltreetest.sql` in the source distribution):

```
CREATE TABLE test (path ltree);
INSERT INTO test VALUES ('Top');
INSERT INTO test VALUES ('Top.Science');
INSERT INTO test VALUES ('Top.Science.Astronomy');
INSERT INTO test VALUES ('Top.Science.Astronomy.Astrophysics');
INSERT INTO test VALUES ('Top.Science.Astronomy.Cosmology');
INSERT INTO test VALUES ('Top.Hobbies');
INSERT INTO test VALUES ('Top.Hobbies.Amateurs_Astronomy');
INSERT INTO test VALUES ('Top.Collections');
INSERT INTO test VALUES ('Top.Collections.Pictures');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Stars');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Galaxies');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Astronauts');
CREATE INDEX path_gist_idx ON test USING GIST (path);
CREATE INDEX path_idx ON test USING BTREE (path);
```

Now, we have a table `test` populated with data describing the hierarchy shown below:



We can do inheritance:

```
ltreetest=> SELECT path FROM test WHERE path <@ 'Top.Science';
                path
-----------------------------------
 Top.Science
 Top.Science.Astronomy
 Top.Science.Astronomy.Astrophysics
 Top.Science.Astronomy.Cosmology
(4 rows)
```

Here are some examples of path matching:

```
ltreetest=> SELECT path FROM test WHERE path ~ '*.Astronomy.*';
                     path
-----------------------------------------------
 Top.Science.Astronomy
 Top.Science.Astronomy.Astrophysics
 Top.Science.Astronomy.Cosmology
 Top.Collections.Pictures.Astronomy
 Top.Collections.Pictures.Astronomy.Stars
 Top.Collections.Pictures.Astronomy.Galaxies
 Top.Collections.Pictures.Astronomy.Astronauts
(7 rows)

ltreetest=> SELECT path FROM test WHERE path ~ '*.!pictures@.Astronomy.*';
                path
-----------------------------------
 Top.Science.Astronomy
 Top.Science.Astronomy.Astrophysics
 Top.Science.Astronomy.Cosmology
(3 rows)
```

Here are some examples of full text search:

```
ltreetest=> SELECT path FROM test WHERE path @ 'Astro*% & !pictures@';
                path
-----------------------------------
 Top.Science.Astronomy
 Top.Science.Astronomy.Astrophysics
 Top.Science.Astronomy.Cosmology
 Top.Hobbies.Amateurs_Astronomy
(4 rows)

ltreetest=> SELECT path FROM test WHERE path @ 'Astro* & !pictures@';
                path
-----------------------------------
 Top.Science.Astronomy
 Top.Science.Astronomy.Astrophysics
 Top.Science.Astronomy.Cosmology
(3 rows)
```

Path construction using functions:

```
ltreetest=> SELECT subpath(path,0,2)||'Space'||subpath(path,2) FROM test WHERE path <@
 'Top.Science.Astronomy';
                 ?column?
-----------------------------------------
 Top.Science.Space.Astronomy
 Top.Science.Space.Astronomy.Astrophysics
 Top.Science.Space.Astronomy.Cosmology
(3 rows)
```

We could simplify this by creating an SQL function that inserts a label at a specified position in a path:

```
CREATE FUNCTION ins_label(ltree, int, text) RETURNS ltree
    AS 'select subpath($1,0,$2) || $3 || subpath($1,$2);'
    LANGUAGE SQL IMMUTABLE;

ltreetest=> SELECT ins_label(path,2,'Space') FROM test WHERE path <@
 'Top.Science.Astronomy';
                ins_label
-----------------------------------------
 Top.Science.Space.Astronomy
 Top.Science.Space.Astronomy.Astrophysics
 Top.Science.Space.Astronomy.Cosmology
(3 rows)
```

F.28.5. Transforms

Additional extensions are available that implement transforms for the `ltree` type for PL/Python. The extensions are called `ltree_plpythonu`, `ltree_plpython2u`, and `ltree_plpython3u` (see Section 45.1 for the PL/Python naming convention). If you install these transforms and specify them when creating a function, `ltree` values are mapped to Python lists. (The reverse is currently not supported, however.)

> **Caution**
>
> It is strongly recommended that the transform extensions be installed in the same schema as `ltree`. Otherwise there are installation-time security hazards if a transform extension's schema contains objects defined by a hostile user.

F.28.6. Authors

All work was done by Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See *http://www.sai.msu.su/~megera/postgres/gist/* for additional information. Authors would like to thank Eugeny Rodichev for helpful discussions. Comments and bug reports are welcome.

F.29. mchar

The `mchar` module provides additional data types for compatibility with Microsoft SQL Server (MS SQL).

F.29.1. Overview

This module has been designed to improve 1C Enterprise support, most popular Russian CRM and ERP system.

It implements types MCHAR and MVARCHAR, which are bug-to-bug compatible with MS SQL CHAR and VARCHAR respectively. Additionally, these types use the ICU library for comparison and case conversion, so their behavior is identical across different operating systems.

Postgres Pro also includes citext extension which provides types similar to MCHAR. But this extension doesn't emulate MS-SQL behavior concerning end-of-value whitespace.

Differences from Postgres Pro standard CHAR and VARCHAR are:

- Case insensitive comparison
- Handling of the whitespace at the end of string
- These types are always stored as two-byte unicode value regardless of database encoding.

F.29.2. Additional types

- `mchar` — analog of the MS SQL char type
- `mvarchar` — analog of the MS SQL varchar type

F.29.3. MCHAR and MVARCHAR features

- Defines `length(str)` function
- Defines `substr(str, pos[, length])` function
- Defines `||` operator, which would be applied to concatenate any (mchar and mvarchar) arguments
- Defines set of operators: `<`, `<=`, `=`, `>=`, `>` for case-insensitive comparison (ICU)
- Defines set of operators: `&<`, `&<=`, `&=`, `&>=`, `&>` to case-sensitive comparison (ICU)
- Implicit cast between `mchar` and `mvarchar` types
- B-tree and Hash-index support
- The `LIKE [ESCAPE]` operator support
- The `SIMILAR TO [ESCAPE]` operator support
- The ~ operator (POSIX regexp) support
- Index support for the *LIKE* operator

F.29.4. Authors

Oleg Bartunov `<oleg@sai.msu.ru>`
Teodor Sigaev `<teodor@sigaev.ru>`

F.30. online_analyze

The `online_analyze` module provides a set of features that immediately update statistics after `INSERT`, `UPDATE`, `DELETE`, `SELECT INTO`, or `COPY` operations for the affected tables.

F.30.1. Module Loading

To use `online_analyze` module, load the shared library:

```
LOAD 'online_analyze';
```

F.30.2. Module Configuration

You can configure `online_analyze` using the following custom variables (default values are shown):

- online_analyze.enable = on

  Enables `online_analyze`.

- online_analyze.verbose = on

  Executes `ANALYZE VERBOSE`.

> **Note**
>
> Since `verbose` is a reserved SQL key word, this parameter has to be double-quoted when used in SQL queries. For example:

```
ALTER SYSTEM SET "online_analyze.verbose" = 'off';
```

- online_analyze.scale_factor = 0.1

  Fraction of table size to start online analysis (similar to autovacuum_analyze_scale_factor).

- online_analyze.threshold = 50

  Minimum number of row updates before starting online analysis (similar to autovacuum_analyze_threshold).

- online_analyze.min_interval = 10000

  Minimum time interval between `ANALYZE` calls per table, in milliseconds.

- online_analyze.table_type = "all"

  Type(s) of tables for online analysis. Possible values are: `all`, `persistent`, `temporary`, `none`.

- online_analyze.exclude_tables = ""

  List of tables to exclude from online analysis.

- online_analyze.include_tables = ""

  List of tables to include in online analysis (`online_analyze.include_tables` overrides `online_analyze.exclude_tables`).

- online_analyze.local_tracking = off

  Enables per-backend tracking for temporary tables by `online_analyze`. When this variable is set to `off`, `online_analyze` uses the default system statistics for temporary tables.

- online_analyze.lower_limit = 0

  Minimum number of rows in a table required to trigger `online_analyze`.

- online_analyze.capacity_threshold = 100000

  Maximum number of temporary tables to store in local cache.

F.30.3. Authors

Teodor Sigaev `<teodor@sigaev.ru>`

F.31. old_snapshot

The `old_snapshot` module allows inspection of the server state that is used to implement old_snapshot_threshold.

F.31.1. Functions

`pg_old_snapshot_time_mapping(array_offset OUT int4, end_timestamp OUT timestamptz, newest_xmin OUT xid) returns setof record`

Returns all of the entries in the server's timestamp to XID mapping. Each entry represents the newest xmin of any snapshot taken in the corresponding minute.

F.32. pageinspect

The pageinspect module provides functions that allow you to inspect the contents of database pages at a low level, which is useful for debugging purposes. All of these functions may be used only by superusers.

F.32.1. General Functions

`get_raw_page(relname text, fork text, blkno bigint) returns bytea`

get_raw_page reads the specified block of the named relation and returns a copy as a bytea value. This allows a single time-consistent copy of the block to be obtained. *fork* should be 'main' for the main data fork, 'fsm' for the free space map, 'vm' for the visibility map, or 'init' for the initialization fork.

`get_raw_page(relname text, blkno bigint) returns bytea`

A shorthand version of get_raw_page, for reading from the main fork. Equivalent to get_raw_page(relname, 'main', blkno)

`page_header(page bytea) returns record`

page_header shows fields that are common to all Postgres Pro heap and index pages.

A page image obtained with get_raw_page should be passed as argument. For example:

```
test=# SELECT * FROM page_header(get_raw_page('pg_class', 0));
    lsn    | checksum | flags  | lower | upper | special | pagesize | version |
 prune_xid
-----------+----------+--------+-------+-------+---------+----------+---------
+-----------
 0/24A1B50 |        0 |      1 |   232 |   368 |    8192 |     8192 |       4 |
    0
```

The returned columns correspond to the fields in the PageHeaderData struct.

The checksum field is the checksum stored in the page, which might be incorrect if the page is somehow corrupted. If data checksums are not enabled for this instance, then the value stored is meaningless.

`page_checksum(page bytea, blkno bigint) returns smallint`

page_checksum computes the checksum for the page, as if it was located at the given block.

A page image obtained with get_raw_page should be passed as argument. For example:

```
test=# SELECT page_checksum(get_raw_page('pg_class', 0), 0);
 page_checksum
---------------
         13443
```

Note that the checksum depends on the block number, so matching block numbers should be passed (except when doing esoteric debugging).

The checksum computed with this function can be compared with the checksum result field of the function page_header. If data checksums are enabled for this instance, then the two values should be equal.

`fsm_page_contents(page bytea) returns text`

fsm_page_contents shows the internal node structure of an FSM page. For example:

```
test=# SELECT fsm_page_contents(get_raw_page('pg_class', 'fsm', 0));
```

The output is a multiline string, with one line per node in the binary tree within the page. Only those nodes that are not zero are printed. The so-called "next" pointer, which points to the next slot to be returned from the page, is also printed.

F.32.2. Heap Functions

`heap_page_items(page bytea) returns setof record`

`heap_page_items` shows all line pointers on a heap page. For those line pointers that are in use, tuple headers as well as tuple raw data are also shown. All tuples are shown, whether or not the tuples were visible to an MVCC snapshot at the time the raw page was copied.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_items(get_raw_page('pg_class', 0));
```

The `heap_tuple_infomask_flags` function can be used to unpack the flag bits of `t_infomask` and `t_infomask2` for heap tuples.

`tuple_data_split(rel_oid oid, t_data bytea, t_infomask integer, t_infomask2 integer, t_bits text [, do_detoast bool]) returns bytea[]`

`tuple_data_split` splits tuple data into attributes in the same way as backend internals.

```
test=# SELECT tuple_data_split('pg_class'::regclass, t_data, t_infomask,
 t_infomask2, t_bits) FROM heap_page_items(get_raw_page('pg_class', 0));
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

If *`do_detoast`* is `true`, attributes will be detoasted as needed. Default value is `false`.

`heap_page_item_attrs(page bytea, rel_oid regclass [, do_detoast bool]) returns setof record`

`heap_page_item_attrs` is equivalent to `heap_page_items` except that it returns tuple raw data as an array of attributes that can optionally be detoasted by *`do_detoast`* which is `false` by default.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_item_attrs(get_raw_page('pg_class', 0),
 'pg_class'::regclass);
```

`heap_tuple_infomask_flags(t_infomask integer, t_infomask2 integer) returns record`

`heap_tuple_infomask_flags` decodes the `t_infomask` and `t_infomask2` returned by `heap_page_items` into a human-readable set of arrays made of flag names, with one column for all the flags and one column for combined flags. For example:

```
test=# SELECT t_ctid, raw_flags, combined_flags
         FROM heap_page_items(get_raw_page('pg_class', 0)),
           LATERAL heap_tuple_infomask_flags(t_infomask, t_infomask2)
         WHERE t_infomask IS NOT NULL OR t_infomask2 IS NOT NULL;
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

Combined flags are displayed for source-level macros that take into account the value of more than one raw bit, such as `HEAP_XMIN_FROZEN`.

F.32.3. B-Tree Functions

`bt_metap(relname text) returns record`

`bt_metap` returns information about a B-tree index's metapage. For example:

```
test=# SELECT * FROM bt_metap('pg_cast_oid_index');
-[ RECORD 1 ]-------------+-------
magic                    | 340322
version                  | 4
```

```
root                        | 1
level                       | 0
fastroot                    | 1
fastlevel                   | 0
last_cleanup_num_delpages | 0
last_cleanup_num_tuples   | 230
allequalimage               | f
```

`bt_page_stats(relname text, blkno bigint) returns record`

`bt_page_stats` returns summary information about single pages of B-tree indexes. For example:

```
test=# SELECT * FROM bt_page_stats('pg_cast_oid_index', 1);
-[ RECORD 1 ]-+-----
blkno         | 1
type          | l
live_items    | 224
dead_items    | 0
avg_item_size | 16
page_size     | 8192
free_size     | 3668
btpo_prev     | 0
btpo_next     | 0
btpo_level    | 0
btpo_flags    | 3
```

`bt_page_items(relname text, blkno bigint) returns setof record`

`bt_page_items` returns detailed information about all of the items on a B-tree index page. For example:

```
test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data, dead, htid, tids[0:2] AS
 some_tids
       FROM bt_page_items('tenk2_hundred', 5);
 itemoffset |   ctid    | itemlen | nulls | vars |          data           | dead |
 htid  |      some_tids
------------+-----------+---------+-------+------+-------------------------+------
+--------+--------------------
          1 | (16,1)    |      16 | f     | f    | 30 00 00 00 00 00 00 00 |      |
       |
          2 | (16,8292) |     616 | f     | f    | 24 00 00 00 00 00 00 00 | f    |
 (1,6)  | {"(1,6)","(10,22)"}
          3 | (16,8292) |     616 | f     | f    | 25 00 00 00 00 00 00 00 | f    |
 (1,18) | {"(1,18)","(4,22)"}
          4 | (16,8292) |     616 | f     | f    | 26 00 00 00 00 00 00 00 | f    |
 (4,18) | {"(4,18)","(6,17)"}
          5 | (16,8292) |     616 | f     | f    | 27 00 00 00 00 00 00 00 | f    |
 (1,2)  | {"(1,2)","(1,19)"}
          6 | (16,8292) |     616 | f     | f    | 28 00 00 00 00 00 00 00 | f    |
 (2,24) | {"(2,24)","(4,11)"}
          7 | (16,8292) |     616 | f     | f    | 29 00 00 00 00 00 00 00 | f    |
 (2,17) | {"(2,17)","(11,2)"}
          8 | (16,8292) |     616 | f     | f    | 2a 00 00 00 00 00 00 00 | f    |
 (0,25) | {"(0,25)","(3,20)"}
          9 | (16,8292) |     616 | f     | f    | 2b 00 00 00 00 00 00 00 | f    |
 (0,10) | {"(0,10)","(0,14)"}
         10 | (16,8292) |     616 | f     | f    | 2c 00 00 00 00 00 00 00 | f    |
 (1,3)  | {"(1,3)","(3,9)"}
         11 | (16,8292) |     616 | f     | f    | 2d 00 00 00 00 00 00 00 | f    |
 (6,28) | {"(6,28)","(11,1)"}
```

```
          12 | (16,8292) |     616 | f      | f     | 2e 00 00 00 00 00 00 00 | f     |
 (0,27) | {"(0,27)","(1,13)"}
          13 | (16,8292) |     616 | f      | f     | 2f 00 00 00 00 00 00 00 | f     |
 (4,17) | {"(4,17)","(4,21)"}
(13 rows)
```

This is a B-tree leaf page. All tuples that point to the table happen to be posting list tuples (all of which store a total of 100 6 byte TIDs). There is also a “high key” tuple at `itemoffset` number 1. `ctid` is used to store encoded information about each tuple in this example, though leaf page tuples often store a heap TID directly in the `ctid` field instead. `tids` is the list of TIDs stored as a posting list.

In an internal page (not shown), the block number part of `ctid` is a “downlink”, which is a block number of another page in the index itself. The offset part (the second number) of `ctid` stores encoded information about the tuple, such as the number of columns present (suffix truncation may have removed unneeded suffix columns). Truncated columns are treated as having the value “minus infinity”.

`htid` shows a heap TID for the tuple, regardless of the underlying tuple representation. This value may match `ctid`, or may be decoded from the alternative representations used by posting list tuples and tuples from internal pages. Tuples in internal pages usually have the implementation level heap TID column truncated away, which is represented as a NULL `htid` value.

Note that the first item on any non-rightmost page (any page with a non-zero value in the `btpo_next` field) is the page's “high key”, meaning its `data` serves as an upper bound on all items appearing on the page, while its `ctid` field does not point to another block. Also, on internal pages, the first real data item (the first item that is not a high key) reliably has every column truncated away, leaving no actual value in its `data` field. Such an item does have a valid downlink in its `ctid` field, however.

For more details about the structure of B-tree indexes, see Section 61.4.1. For more details about deduplication and posting lists, see Section 61.4.3.

`bt_page_items(page bytea) returns setof record`

It is also possible to pass a page to `bt_page_items` as a `bytea` value. A page image obtained with `get_raw_page` should be passed as argument. So the last example could also be rewritten like this:

```
test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data, dead, htid, tids[0:2] AS
 some_tids
       FROM bt_page_items(get_raw_page('tenk2_hundred', 5));
 itemoffset |   ctid    | itemlen | nulls | vars |          data           | dead |
 htid  |      some_tids
------------+-----------+---------+-------+------+-------------------------+------
+--------+--------------------
          1 | (16,1)    |      16 | f     | f    | 30 00 00 00 00 00 00 00 |      |
       |
          2 | (16,8292) |     616 | f     | f    | 24 00 00 00 00 00 00 00 | f    |
 (1,6)  | {"(1,6)","(10,22)"}
          3 | (16,8292) |     616 | f     | f    | 25 00 00 00 00 00 00 00 | f    |
 (1,18) | {"(1,18)","(4,22)"}
          4 | (16,8292) |     616 | f     | f    | 26 00 00 00 00 00 00 00 | f    |
 (4,18) | {"(4,18)","(6,17)"}
          5 | (16,8292) |     616 | f     | f    | 27 00 00 00 00 00 00 00 | f    |
 (1,2)  | {"(1,2)","(1,19)"}
          6 | (16,8292) |     616 | f     | f    | 28 00 00 00 00 00 00 00 | f    |
 (2,24) | {"(2,24)","(4,11)"}
          7 | (16,8292) |     616 | f     | f    | 29 00 00 00 00 00 00 00 | f    |
 (2,17) | {"(2,17)","(11,2)"}
          8 | (16,8292) |     616 | f     | f    | 2a 00 00 00 00 00 00 00 | f    |
 (0,25) | {"(0,25)","(3,20)"}
```

```
           9 | (16,8292) |     616 | f     | f    | 2b 00 00 00 00 00 00 00 | f    |
 (0,10) | {"(0,10)","(0,14)"}
          10 | (16,8292) |     616 | f     | f    | 2c 00 00 00 00 00 00 00 | f    |
 (1,3)  | {"(1,3)","(3,9)"}
          11 | (16,8292) |     616 | f     | f    | 2d 00 00 00 00 00 00 00 | f    |
 (6,28) | {"(6,28)","(11,1)"}
          12 | (16,8292) |     616 | f     | f    | 2e 00 00 00 00 00 00 00 | f    |
 (0,27) | {"(0,27)","(1,13)"}
          13 | (16,8292) |     616 | f     | f    | 2f 00 00 00 00 00 00 00 | f    |
 (4,17) | {"(4,17)","(4,21)"}
(13 rows)
```

All the other details are the same as explained in the previous item.

F.32.4. BRIN Functions

`brin_page_type(page bytea) returns text`

`brin_page_type` returns the page type of the given BRIN index page, or throws an error if the page is not a valid BRIN page. For example:

```
test=# SELECT brin_page_type(get_raw_page('brinidx', 0));
 brin_page_type
----------------
 meta
```

`brin_metapage_info(page bytea) returns record`

`brin_metapage_info` returns assorted information about a BRIN index metapage. For example:

```
test=# SELECT * FROM brin_metapage_info(get_raw_page('brinidx', 0));
   magic    | version | pagesperrange | lastrevmappage
------------+---------+---------------+---------------
 0xA8109CFA |       1 |             4 |              2
```

`brin_revmap_data(page bytea) returns setof tid`

`brin_revmap_data` returns the list of tuple identifiers in a BRIN index range map page. For example:

```
test=# SELECT * FROM brin_revmap_data(get_raw_page('brinidx', 2)) LIMIT 5;
  pages
---------
 (6,137)
 (6,138)
 (6,139)
 (6,140)
 (6,141)
```

`brin_page_items(page bytea, index oid) returns setof record`

`brin_page_items` returns the data stored in the BRIN data page. For example:

```
test=# SELECT * FROM brin_page_items(get_raw_page('brinidx', 5),
                                     'brinidx')
       ORDER BY blknum, attnum LIMIT 6;
 itemoffset | blknum | attnum | allnulls | hasnulls | placeholder |    value
------------+--------+--------+----------+----------+-------------+-------------
        137 |      0 |      1 | t        | f        | f           |
        137 |      0 |      2 | f        | f        | f           | {1 .. 88}
        138 |      4 |      1 | t        | f        | f           |
        138 |      4 |      2 | f        | f        | f           | {89 .. 176}
        139 |      8 |      1 | t        | f        | f           |
```

```
          139 |      8 |      2 | f        | f        | f           | {177 .. 264}
```

The returned columns correspond to the fields in the `BrinMemTuple` and `BrinValues` structs.

F.32.5. GIN Functions

`gin_metapage_info(page bytea) returns record`

`gin_metapage_info` returns information about a GIN index metapage. For example:

```
test=# SELECT * FROM gin_metapage_info(get_raw_page('gin_index', 0));
-[ RECORD 1 ]----+-----------
pending_head     | 4294967295
pending_tail     | 4294967295
tail_free_size   | 0
n_pending_pages  | 0
n_pending_tuples | 0
n_total_pages    | 7
n_entry_pages    | 6
n_data_pages     | 0
n_entries        | 693
version          | 2
```

`gin_page_opaque_info(page bytea) returns record`

`gin_page_opaque_info` returns information about a GIN index opaque area, like the page type. For example:

```
test=# SELECT * FROM gin_page_opaque_info(get_raw_page('gin_index', 2));
 rightlink | maxoff |         flags
-----------+--------+-----------------------
         5 |      0 | {data,leaf,compressed}
(1 row)
```

`gin_leafpage_items(page bytea) returns setof record`

`gin_leafpage_items` returns information about the data stored in a GIN leaf page. For example:

```
test=# SELECT first_tid, nbytes, tids[0:5] AS some_tids
        FROM gin_leafpage_items(get_raw_page('gin_test_idx', 2));
 first_tid | nbytes |                          some_tids
-----------+--------+-------------------------------------------------------------
 (8,41)    |    244 | {"(8,41)","(8,43)","(8,44)","(8,45)","(8,46)"}
 (10,45)   |    248 | {"(10,45)","(10,46)","(10,47)","(10,48)","(10,49)"}
 (12,52)   |    248 | {"(12,52)","(12,53)","(12,54)","(12,55)","(12,56)"}
 (14,59)   |    320 | {"(14,59)","(14,60)","(14,61)","(14,62)","(14,63)"}
 (167,16)  |    376 | {"(167,16)","(167,17)","(167,18)","(167,19)","(167,20)"}
 (170,30)  |    376 | {"(170,30)","(170,31)","(170,32)","(170,33)","(170,34)"}
 (173,44)  |    197 | {"(173,44)","(173,45)","(173,46)","(173,47)","(173,48)"}
(7 rows)
```

F.32.6. GiST Functions

`gist_page_opaque_info(page bytea) returns record`

`gist_page_opaque_info` returns information from a GiST index page's opaque area, such as the NSN, rightlink and page type. For example:

```
test=# SELECT * FROM gist_page_opaque_info(get_raw_page('test_gist_idx', 2));
 lsn | nsn | rightlink | flags
-----+-----+-----------+--------
 0/1 | 0/0 |         1 | {leaf}
```

```
(1 row)
```

```
gist_page_items(page bytea, index_oid regclass) returns setof record
```

`gist_page_items` returns information about the data stored in a page of a GiST index. For example:

```
test=# SELECT * FROM gist_page_items(get_raw_page('test_gist_idx', 0),
 'test_gist_idx');
 itemoffset |   ctid    | itemlen | dead |             keys
------------+-----------+---------+------+------------------------------
          1 | (1,65535) |      40 | f    | (p)=("(166,166),(1,1)")
          2 | (2,65535) |      40 | f    | (p)=("(332,332),(167,167)")
          3 | (3,65535) |      40 | f    | (p)=("(498,498),(333,333)")
          4 | (4,65535) |      40 | f    | (p)=("(664,664),(499,499)")
          5 | (5,65535) |      40 | f    | (p)=("(830,830),(665,665)")
          6 | (6,65535) |      40 | f    | (p)=("(996,996),(831,831)")
          7 | (7,65535) |      40 | f    | (p)=("(1000,1000),(997,997)")
(7 rows)
```

```
gist_page_items_bytea(page bytea) returns setof record
```

Same as `gist_page_items`, but returns the key data as a raw `bytea` blob. Since it does not attempt to decode the key, it does not need to know which index is involved. For example:

```
test=# SELECT * FROM gist_page_items_bytea(get_raw_page('test_gist_idx', 0));
 itemoffset |   ctid    | itemlen | dead |
 key_data
------------+-----------+---------+------+----------------------------------------
----------------------------------------
          1 | (1,65535) |      40 | f    |

(7 rows)
```

F.32.7. Hash Functions

```
hash_page_type(page bytea) returns text
```

`hash_page_type` returns page type of the given HASH index page. For example:

```
test=# SELECT hash_page_type(get_raw_page('con_hash_index', 0));
 hash_page_type
----------------
 metapage
```

```
hash_page_stats(page bytea) returns setof record
```

`hash_page_stats` returns information about a bucket or overflow page of a HASH index. For example:

```
test=# SELECT * FROM hash_page_stats(get_raw_page('con_hash_index', 1));
-[ RECORD 1 ]---+-----------
```

```
live_items      | 407
dead_items      | 0
page_size       | 8192
free_size       | 8
hasho_prevblkno | 4096
hasho_nextblkno | 8474
hasho_bucket    | 0
hasho_flag      | 66
hasho_page_id   | 65408
```

`hash_page_items(page bytea) returns setof record`

`hash_page_items` returns information about the data stored in a bucket or overflow page of a HASH index page. For example:

```
test=# SELECT * FROM hash_page_items(get_raw_page('con_hash_index', 1)) LIMIT 5;
 itemoffset |   ctid    |    data
------------+-----------+------------
          1 | (899,77)  | 1053474816
          2 | (897,29)  | 1053474816
          3 | (894,207) | 1053474816
          4 | (892,159) | 1053474816
          5 | (890,111) | 1053474816
```

`hash_bitmap_info(index oid, blkno bigint) returns record`

`hash_bitmap_info` shows the status of a bit in the bitmap page for a particular overflow page of HASH index. For example:

```
test=# SELECT * FROM hash_bitmap_info('con_hash_index', 2052);
 bitmapblkno | bitmapbit | bitstatus
-------------+-----------+-----------
          65 |         3 | t
```

`hash_metapage_info(page bytea) returns record`

`hash_metapage_info` returns information stored in the meta page of a HASH index. For example:

```
test=# SELECT magic, version, ntuples, ffactor, bsize, bmsize, bmshift,
test-#     maxbucket, highmask, lowmask, ovflpoint, firstfree, nmaps, procid,
test-#     regexp_replace(spares::text, '(,0)*}', '}') as spares,
test-#     regexp_replace(mapp::text, '(,0)*}', '}') as mapp
test-# FROM hash_metapage_info(get_raw_page('con_hash_index', 0));
-[ RECORD 1 ]-------------------------------------------------
------------------------------
magic     | 105121344
version   | 4
ntuples   | 500500
ffactor   | 40
bsize     | 8152
bmsize    | 4096
bmshift   | 15
maxbucket | 12512
highmask  | 16383
lowmask   | 8191
ovflpoint | 28
firstfree | 1204
nmaps     | 1
procid    | 450
spares    | {0,0,0,0,0,0,1,1,1,1,1,1,1,1,3,4,4,4,45,55,58,59,
508,567,628,704,1193,1202,1204}
```

```
 mapp       | {65}
```

F.33. passwordcheck

The passwordcheck module checks users' passwords whenever they are set with CREATE ROLE or ALTER ROLE (it doesn't work, if a non-default profile is assigned to the user). If a password is considered too weak, it will be rejected and the command will terminate with an error.

To enable this module, add '$libdir/passwordcheck' to shared_preload_libraries in postgresql.conf, then restart the server.

> **Caution**
>
> To prevent unencrypted passwords from being sent across the network, written to the server log or otherwise stolen by a database administrator, Postgres Pro allows the user to supply pre-encrypted passwords. Many client programs make use of this functionality and encrypt the password before sending it to the server.
>
> This limits the usefulness of the passwordcheck module, because in that case it can only try to guess the password. For this reason, passwordcheck is not recommended if your security requirements are high. It is more secure to use an external authentication method such as GSSAPI (see Chapter 19) than to rely on passwords within the database.

F.34. pg_buffercache

The pg_buffercache module provides a means for examining what's happening in the shared buffer cache in real time.

The module provides a C function pg_buffercache_pages that returns a set of records, plus a view pg_buffercache that wraps the function for convenient use.

By default, use is restricted to superusers and members of the pg_monitor role. Access may be granted to others using GRANT.

F.34.1. The pg_buffercache View

The definitions of the columns exposed by the view are shown in Table F.20.

Table F.20. pg_buffercache Columns

Column Type Description
bufferid integer ID, in the range 1..shared_buffers
relfilenode oid (references pg_class .relfilenode) Filenode number of the relation
reltablespace oid (references pg_tablespace .oid) Tablespace OID of the relation
reldatabase oid (references pg_database .oid) Database OID of the relation
relforknumber smallint Fork number within the relation
relblocknumber bigint Page number within the relation

Column Type Description
isdirty boolean Is the page dirty?
usagecount smallint Clock-sweep access count
pinning_backends integer Number of backends pinning this buffer

There is one row for each buffer in the shared cache. Unused buffers are shown with all fields null except bufferid. Shared system catalogs are shown as belonging to database zero.

Because the cache is shared by all the databases, there will normally be pages from relations not belonging to the current database. This means that there may not be matching join rows in pg_class for some rows, or that there could even be incorrect joins. If you are trying to join against pg_class, it's a good idea to restrict the join to rows having reldatabase equal to the current database's OID or zero.

Since buffer manager locks are not taken to copy the buffer state data that the view will display, accessing pg_buffercache view has less impact on normal buffer activity but it doesn't provide a consistent set of results across all buffers. However, we ensure that the information of each buffer is self-consistent.

F.34.2. Sample Output

```
regression=# SELECT n.nspname, c.relname, count(*) AS buffers
             FROM pg_buffercache b JOIN pg_class c
             ON b.relfilenode = pg_relation_filenode(c.oid) AND
                b.reldatabase IN (0, (SELECT oid FROM pg_database
                                      WHERE datname = current_database()))
             JOIN pg_namespace n ON n.oid = c.relnamespace
             GROUP BY n.nspname, c.relname
             ORDER BY 3 DESC
             LIMIT 10;

```

F.34.3. Authors

Mark Kirkwood <markir@paradise.net.nz>

Design suggestions: Neil Conway <neilc@samurai.com>

Debugging advice: Tom Lane <tgl@sss.pgh.pa.us>

F.35. pgcrypto

The pgcrypto module provides cryptographic functions for Postgres Pro.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.35.1. General Hashing Functions

F.35.1.1. `digest()`

```
digest(data text, type text) returns bytea
digest(data bytea, type text) returns bytea
```

Computes a binary hash of the given *`data`*. *`type`* is the algorithm to use. Standard algorithms are `md5`, `sha1`, `sha224`, `sha256`, `sha384` and `sha512`. If `pgcrypto` was built with OpenSSL, more algorithms are available, as detailed in Table F.24.

If you want the digest as a hexadecimal string, use `encode()` on the result. For example:

```
CREATE OR REPLACE FUNCTION sha1(bytea) returns text AS $$
    SELECT encode(digest($1, 'sha1'), 'hex')
$$ LANGUAGE SQL STRICT IMMUTABLE;
```

F.35.1.2. `hmac()`

```
hmac(data text, key text, type text) returns bytea
hmac(data bytea, key bytea, type text) returns bytea
```

Calculates hashed MAC for *`data`* with key *`key`*. *`type`* is the same as in `digest()`.

This is similar to `digest()` but the hash can only be recalculated knowing the key. This prevents the scenario of someone altering data and also changing the hash to match.

If the key is larger than the hash block size it will first be hashed and the result will be used as key.

F.35.2. Password Hashing Functions

The functions `crypt()` and `gen_salt()` are specifically designed for hashing passwords. `crypt()` does the hashing and `gen_salt()` prepares algorithm parameters for it.

The algorithms in `crypt()` differ from the usual MD5 or SHA1 hashing algorithms in the following respects:

1. They are slow. As the amount of data is so small, this is the only way to make brute-forcing passwords hard.
2. They use a random value, called the *salt*, so that users having the same password will have different encrypted passwords. This is also an additional defense against reversing the algorithm.
3. They include the algorithm type in the result, so passwords hashed with different algorithms can coexist.
4. Some of them are adaptive — that means when computers get faster, you can tune the algorithm to be slower, without introducing incompatibility with existing passwords.

Table F.21 lists the algorithms supported by the `crypt()` function.

Table F.21. Supported Algorithms for `crypt()`

Algorithm	Max Password Length	Adaptive?	Salt Bits	Output Length	Description
`bf`	72	yes	128	60	Blowfish-based, variant 2a
`md5`	unlimited	no	48	34	MD5-based crypt

Algorithm	Max Password Length	Adaptive?	Salt Bits	Output Length	Description
xdes	8	yes	24	20	Extended DES
des	8	no	12	13	Original UNIX crypt

F.35.2.1. crypt()

```
crypt(password text, salt text) returns text
```

Calculates a crypt(3)-style hash of *password*. When storing a new password, you need to use `gen_salt()` to generate a new *salt* value. To check a password, pass the stored hash value as *salt*, and test whether the result matches the stored value.

Example of setting a new password:

```
UPDATE ... SET pswhash = crypt('new password', gen_salt('md5'));
```

Example of authentication:

```
SELECT (pswhash = crypt('entered password', pswhash)) AS pswmatch FROM ... ;
```

This returns `true` if the entered password is correct.

F.35.2.2. gen_salt()

```
gen_salt(type text [, iter_count integer ]) returns text
```

Generates a new random salt string for use in `crypt()`. The salt string also tells `crypt()` which algorithm to use.

The *type* parameter specifies the hashing algorithm. The accepted types are: `des`, `xdes`, `md5` and `bf`.

The *iter_count* parameter lets the user specify the iteration count, for algorithms that have one. The higher the count, the more time it takes to hash the password and therefore the more time to break it. Although with too high a count the time to calculate a hash may be several years — which is somewhat impractical. If the *iter_count* parameter is omitted, the default iteration count is used. Allowed values for *iter_count* depend on the algorithm and are shown in Table F.22.

Table F.22. Iteration Counts for crypt()

Algorithm	Default	Min	Max
xdes	725	1	16777215
bf	6	4	31

For `xdes` there is an additional limitation that the iteration count must be an odd number.

To pick an appropriate iteration count, consider that the original DES crypt was designed to have the speed of 4 hashes per second on the hardware of that time. Slower than 4 hashes per second would probably dampen usability. Faster than 100 hashes per second is probably too fast.

Table F.23 gives an overview of the relative slowness of different hashing algorithms. The table shows how much time it would take to try all combinations of characters in an 8-character password, assuming that the password contains either only lower case letters, or upper- and lower-case letters and numbers. In the `crypt-bf` entries, the number after a slash is the *iter_count* parameter of `gen_salt`.

Table F.23. Hash Algorithm Speeds

Algorithm	Hashes/sec	For `[a-z]`	For `[A-Za-z0-9]`	Duration relative to `md5 hash`
crypt-bf/8	1792	4 years	3927 years	100k

Algorithm	**Hashes/sec**	**For** [a-z]	**For** [A-Za-z0-9]	**Duration relative to** md5 hash
crypt-bf/7	3648	2 years	1929 years	50k
crypt-bf/6	7168	1 year	982 years	25k
crypt-bf/5	13504	188 days	521 years	12.5k
crypt-md5	171584	15 days	41 years	1k
crypt-des	23221568	157.5 minutes	108 days	7
sha1	37774272	90 minutes	68 days	4
md5 (hash)	150085504	22.5 minutes	17 days	1

Notes:

- The machine used is an Intel Mobile Core i3.
- crypt-des and crypt-md5 algorithm numbers are taken from John the Ripper v1.6.38 -test output.
- md5 hash numbers are from mdcrack 1.2.
- sha1 numbers are from lcrack-20031130-beta.
- crypt-bf numbers are taken using a simple program that loops over 1000 8-character passwords. That way I can show the speed with different numbers of iterations. For reference: john -test shows 13506 loops/sec for crypt-bf/5. (The very small difference in results is in accordance with the fact that the crypt-bf implementation in pgcrypto is the same one used in John the Ripper.)

Note that “try all combinations” is not a realistic exercise. Usually password cracking is done with the help of dictionaries, which contain both regular words and various mutations of them. So, even somewhat word-like passwords could be cracked much faster than the above numbers suggest, while a 6-character non-word-like password may escape cracking. Or not.

F.35.3. PGP Encryption Functions

The functions here implement the encryption part of the OpenPGP (*RFC 4880*) standard. Supported are both symmetric-key and public-key encryption.

An encrypted PGP message consists of 2 parts, or *packets*:

- Packet containing a session key — either symmetric-key or public-key encrypted.
- Packet containing data encrypted with the session key.

When encrypting with a symmetric key (i.e., a password):

1. The given password is hashed using a String2Key (S2K) algorithm. This is rather similar to crypt() algorithms — purposefully slow and with random salt — but it produces a full-length binary key.
2. If a separate session key is requested, a new random key will be generated. Otherwise the S2K key will be used directly as the session key.
3. If the S2K key is to be used directly, then only S2K settings will be put into the session key packet. Otherwise the session key will be encrypted with the S2K key and put into the session key packet.

When encrypting with a public key:

1. A new random session key is generated.
2. It is encrypted using the public key and put into the session key packet.

In either case the data to be encrypted is processed as follows:

1. Optional data-manipulation: compression, conversion to UTF-8, and/or conversion of line-endings.

2. The data is prefixed with a block of random bytes. This is equivalent to using a random IV.
3. A SHA1 hash of the random prefix and data is appended.
4. All this is encrypted with the session key and placed in the data packet.

F.35.3.1. pgp_sym_encrypt()

```
pgp_sym_encrypt(data text, psw text [, options text ]) returns bytea
pgp_sym_encrypt_bytea(data bytea, psw text [, options text ]) returns bytea
```

Encrypt *data* with a symmetric PGP key *psw*. The *options* parameter can contain option settings, as described below.

F.35.3.2. pgp_sym_decrypt()

```
pgp_sym_decrypt(msg bytea, psw text [, options text ]) returns text
pgp_sym_decrypt_bytea(msg bytea, psw text [, options text ]) returns bytea
```

Decrypt a symmetric-key-encrypted PGP message.

Decrypting `bytea` data with `pgp_sym_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_sym_decrypt_bytea` is fine.

The *options* parameter can contain option settings, as described below.

F.35.3.3. pgp_pub_encrypt()

```
pgp_pub_encrypt(data text, key bytea [, options text ]) returns bytea
pgp_pub_encrypt_bytea(data bytea, key bytea [, options text ]) returns bytea
```

Encrypt *data* with a public PGP key *key*. Giving this function a secret key will produce an error.

The *options* parameter can contain option settings, as described below.

F.35.3.4. pgp_pub_decrypt()

```
pgp_pub_decrypt(msg bytea, key bytea [, psw text [, options text ]]) returns text
pgp_pub_decrypt_bytea(msg bytea, key bytea [, psw text [, options text ]]) returns
 bytea
```

Decrypt a public-key-encrypted message. *key* must be the secret key corresponding to the public key that was used to encrypt. If the secret key is password-protected, you must give the password in *psw*. If there is no password, but you want to specify options, you need to give an empty password.

Decrypting `bytea` data with `pgp_pub_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_pub_decrypt_bytea` is fine.

The *options* parameter can contain option settings, as described below.

F.35.3.5. pgp_key_id()

```
pgp_key_id(bytea) returns text
```

`pgp_key_id` extracts the key ID of a PGP public or secret key. Or it gives the key ID that was used for encrypting the data, if given an encrypted message.

It can return 2 special key IDs:

- `SYMKEY`

  The message is encrypted with a symmetric key.

- `ANYKEY`

The message is public-key encrypted, but the key ID has been removed. That means you will need to try all your secret keys on it to see which one decrypts it. `pgcrypto` itself does not produce such messages.

Note that different keys may have the same ID. This is rare but a normal event. The client application should then try to decrypt with each one, to see which fits — like handling `ANYKEY`.

F.35.3.6. `armor()`, `dearmor()`

```
armor(data bytea [ , keys text[], values text[] ]) returns text
dearmor(data text) returns bytea
```

These functions wrap/unwrap binary data into PGP ASCII-armor format, which is basically Base64 with CRC and additional formatting.

If the *`keys`* and *`values`* arrays are specified, an *armor header* is added to the armored format for each key/value pair. Both arrays must be single-dimensional, and they must be of the same length. The keys and values cannot contain any non-ASCII characters.

F.35.3.7. `pgp_armor_headers`

```
pgp_armor_headers(data text, key out text, value out text) returns setof record
```

`pgp_armor_headers()` extracts the armor headers from *`data`*. The return value is a set of rows with two columns, key and value. If the keys or values contain any non-ASCII characters, they are treated as UTF-8.

F.35.3.8. Options for PGP Functions

Options are named to be similar to GnuPG. An option's value should be given after an equal sign; separate options from each other with commas. For example:

```
pgp_sym_encrypt(data, psw, 'compress-algo=1, cipher-algo=aes256')
```

All of the options except `convert-crlf` apply only to encrypt functions. Decrypt functions get the parameters from the PGP data.

The most interesting options are probably `compress-algo` and `unicode-mode`. The rest should have reasonable defaults.

F.35.3.8.1. cipher-algo

Which cipher algorithm to use.

Values: bf, aes128, aes192, aes256 (OpenSSL-only: `3des`, `cast5`)
Default: aes128
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.35.3.8.2. compress-algo

Which compression algorithm to use. Only available if Postgres Pro was built with zlib.

Values:
0 - no compression
1 - ZIP compression
2 - ZLIB compression (= ZIP plus meta-data and block CRCs)
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.35.3.8.3. compress-level

How much to compress. Higher levels compress smaller but are slower. 0 disables compression.

Values: 0, 1-9
Default: 6
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.35.3.8.4. convert-crlf

Whether to convert `\n` into `\r\n` when encrypting and `\r\n` to `\n` when decrypting. RFC 4880 specifies that text data should be stored using `\r\n` line-feeds. Use this to get fully RFC-compliant behavior.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt, pgp_sym_decrypt, pgp_pub_decrypt

F.35.3.8.5. disable-mdc

Do not protect data with SHA-1. The only good reason to use this option is to achieve compatibility with ancient PGP products, predating the addition of SHA-1 protected packets to RFC 4880. Recent gnupg.org and pgp.com software supports it fine.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.35.3.8.6. sess-key

Use separate session key. Public-key encryption always uses a separate session key; this option is for symmetric-key encryption, which by default uses the S2K key directly.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt

F.35.3.8.7. s2k-mode

Which S2K algorithm to use.

Values:
  0 - Without salt. Dangerous!
  1 - With salt but with fixed iteration count.
  3 - Variable iteration count.
Default: 3
Applies to: pgp_sym_encrypt

F.35.3.8.8. s2k-count

The number of iterations of the S2K algorithm to use. It must be a value between 1024 and 65011712, inclusive.

Default: A random value between 65536 and 253952
Applies to: pgp_sym_encrypt, only with s2k-mode=3

F.35.3.8.9. s2k-digest-algo

Which digest algorithm to use in S2K calculation.

Values: md5, sha1
Default: sha1
Applies to: pgp_sym_encrypt

F.35.3.8.10. s2k-cipher-algo

Which cipher to use for encrypting separate session key.

Values: bf, aes, aes128, aes192, aes256
Default: use cipher-algo
Applies to: pgp_sym_encrypt

F.35.3.8.11. unicode-mode

Whether to convert textual data from database internal encoding to UTF-8 and back. If your database already is UTF-8, no conversion will be done, but the message will be tagged as UTF-8. Without this option it will not be.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.35.3.9. Generating PGP Keys with GnuPG

To generate a new key:

```
gpg --gen-key
```

The preferred key type is “DSA and Elgamal”.

For RSA encryption you must create either DSA or RSA sign-only key as master and then add an RSA encryption subkey with `gpg --edit-key`.

To list keys:

```
gpg --list-secret-keys
```

To export a public key in ASCII-armor format:

```
gpg -a --export KEYID > public.key
```

To export a secret key in ASCII-armor format:

```
gpg -a --export-secret-keys KEYID > secret.key
```

You need to use `dearmor()` on these keys before giving them to the PGP functions. Or if you can handle binary data, you can drop `-a` from the command.

For more details see `man gpg`, *The GNU Privacy Handbook* and other documentation on *https://www.gnupg.org/*.

F.35.3.10. Limitations of PGP Code

- No support for signing. That also means that it is not checked whether the encryption subkey belongs to the master key.
- No support for encryption key as master key. As such practice is generally discouraged, this should not be a problem.
- No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with `pgcrypto`, but create new ones, as the usage scenario is rather different.

F.35.4. Raw Encryption Functions

These functions only run a cipher over data; they don't have any advanced features of PGP encryption. Therefore they have some major problems:

1. They use user key directly as cipher key.
2. They don't provide any integrity checking, to see if the encrypted data was modified.

3. They expect that users manage all encryption parameters themselves, even IV.

4. They don't handle text.

So, with the introduction of PGP encryption, usage of raw encryption functions is discouraged.

```
encrypt(data bytea, key bytea, type text) returns bytea
decrypt(data bytea, key bytea, type text) returns bytea

encrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea
decrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea
```

Encrypt/decrypt data using the cipher method specified by *type*. The syntax of the *type* string is:

algorithm [- *mode*] [/pad: *padding*]

where *algorithm* is one of:

- bf — Blowfish
- aes — AES (Rijndael-128, -192 or -256)

and *mode* is one of:

- cbc — next block depends on previous (default)
- ecb — each block is encrypted separately (for testing only)

and *padding* is one of:

- pkcs — data may be any length (default)
- none — data must be multiple of cipher block size

So, for example, these are equivalent:

```
encrypt(data, 'fooz', 'bf')
encrypt(data, 'fooz', 'bf-cbc/pad:pkcs')
```

In encrypt_iv and decrypt_iv, the *iv* parameter is the initial value for the CBC mode; it is ignored for ECB. It is clipped or padded with zeroes if not exactly block size. It defaults to all zeroes in the functions without this parameter.

F.35.5. Random-Data Functions

```
gen_random_bytes(count integer) returns bytea
```

Returns *count* cryptographically strong random bytes. At most 1024 bytes can be extracted at a time. This is to avoid draining the randomness generator pool.

```
gen_random_uuid() returns uuid
```

Returns a version 4 (random) UUID. (Obsolete, this function internally calls the core function of the same name.)

F.35.6. Notes

F.35.6.1. Configuration

pgcrypto configures itself according to the findings of the main Postgres Pro configure script. The options that affect it are --with-zlib and --with-ssl=openssl.

When compiled with zlib, PGP encryption functions are able to compress data before encrypting.

When compiled with OpenSSL, there will be more algorithms available. Also public-key encryption functions will be faster as OpenSSL has more optimized BIGNUM functions.

Table F.24. Summary of Functionality with and without OpenSSL

Functionality	Built-in	With OpenSSL
MD5	yes	yes
SHA1	yes	yes
SHA224/256/384/512	yes	yes
Other digest algorithms	no	yes (Note 1)
Blowfish	yes	yes
AES	yes	yes
DES/3DES/CAST5	no	yes
Raw encryption	yes	yes
PGP Symmetric encryption	yes	yes
PGP Public-Key encryption	yes	yes

When compiled against OpenSSL 3.0.0 and later versions, the legacy provider must be activated in the `openssl.cnf` configuration file in order to use older ciphers like DES or Blowfish.

Notes:

1. Any digest algorithm OpenSSL supports is automatically picked up. This is not possible with ciphers, which need to be supported explicitly.

F.35.6.2. NULL Handling

As is standard in SQL, all functions return NULL, if any of the arguments are NULL. This may create security risks on careless usage.

F.35.6.3. Security Limitations

All `pgcrypto` functions run inside the database server. That means that all the data and passwords move between `pgcrypto` and client applications in clear text. Thus you must:

1. Connect locally or use SSL connections.
2. Trust both system and database administrator.

If you cannot, then better do crypto inside client application.

The implementation does not resist *side-channel attacks*. For example, the time required for a `pgcrypto` decryption function to complete varies among ciphertexts of a given size.

F.35.7. Author

Marko Kreen `<markokr@gmail.com>`

`pgcrypto` uses code from the following sources:

Algorithm	Author	Source origin
DES crypt	David Burren and others	FreeBSD libcrypt
MD5 crypt	Poul-Henning Kamp	FreeBSD libcrypt
Blowfish crypt	Solar Designer	www.openwall.com
Blowfish cipher	Simon Tatham	PuTTY

Algorithm	Author	Source origin
Rijndael cipher	Brian Gladman	OpenBSD sys/crypto
MD5 hash and SHA1	WIDE Project	KAME kame/sys/crypto
SHA256/384/512	Aaron D. Gifford	OpenBSD sys/crypto
BIGNUM math	Michael J. Fromberger	dartmouth.edu/~sting/sw/imath

F.36. pg_freespacemap

The pg_freespacemap module provides a means for examining the free space map (FSM). It provides a function called pg_freespace, or two overloaded functions, to be precise. The functions show the value recorded in the free space map for a given page, or for all pages in the relation.

By default use is restricted to superusers and members of the pg_stat_scan_tables role. Access may be granted to others using GRANT.

F.36.1. Functions

pg_freespace(rel regclass IN, blkno bigint IN) returns int2

Returns the amount of free space on the page of the relation, specified by blkno, according to the FSM.

pg_freespace(rel regclass IN, blkno OUT bigint, avail OUT int2)

Displays the amount of free space on each page of the relation, according to the FSM. A set of (blkno bigint, avail int2) tuples is returned, one tuple for each page in the relation.

The values stored in the free space map are not exact. They're rounded to precision of 1/256th of BLCKSZ (32 bytes with default BLCKSZ), and they're not kept fully up-to-date as tuples are inserted and updated.

For indexes, what is tracked is entirely-unused pages, rather than free space within pages. Therefore, the values are not meaningful, just whether a page is in-use or empty.

F.36.2. Sample Output

```
postgres=# SELECT * FROM pg_freespace('foo');
 blkno | avail
-------+-------
     0 |     0
     1 |     0
     2 |     0
     3 |    32
     4 |   704
     5 |   704
     6 |   704
     7 |  1216
     8 |   704
     9 |   704
    10 |   704
    11 |   704
    12 |   704
    13 |   704
    14 |   704
    15 |   704
    16 |   704
    17 |   704
    18 |   704
```

```
    19 |  3648
(20 rows)

postgres=# SELECT * FROM pg_freespace('foo', 7);
 pg_freespace
--------------
         1216
(1 row)
```

F.37. pg_pathman

> **Important**
>
> Starting from Postgres Pro 12, using pg_pathman is not recommended. Use vanilla declarative partitioning instead, as described in Section 5.11.

The pg_pathman is a Postgres Pro extension that provides an optimized partitioning solution for large and distributed databases. Using pg_pathman, you can:

- Partition large databases without downtime.
- Speed up query execution for partitioned tables.
- Manage existing partitions and add new partitions on the fly.
- Add foreign tables as partitions.
- Join partitioned tables for read and write operations.

The extension is compatible with Postgres Pro 9.5 or higher.

F.37.1. Installation and Setup

The pg_pathman extension is included into the Postgres Pro. Once you have Postgres Pro installed, complete the following steps to enable pg_pathman:

1. Add pg_pathman to the shared_preload_libraries variable in the postgresql.conf file:

   ```
   shared_preload_libraries = 'pg_pathman'
   ```

   > **Important**
   >
   > pg_pathman may have conflicts with other extensions that use the same hook functions. For example, pg_pathman may interfere with the pg_stat_statements extension as they both use ProcessUtility_hook. To avoid such issues, pg_pathman must always be the last in the list of libraries: shared_preload_libraries = 'pg_stat_statements, pg_pathman'

2. Restart the Postgres Pro instance for the settings to take effect.
3. Create the pg_pathman extension as follows:

   ```
   CREATE SCHEMA pathman;
   GRANT USAGE ON SCHEMA pathman TO PUBLIC;
   ```

```
CREATE EXTENSION pg_pathman WITH SCHEMA pathman;
```

> **Important**
>
> To ensure that your calls to pg_pathman's functions are always secure against search_path-based attacks (see CREATE EXTENSION for details), install it only into a clean schema where nobody except superusers has the CREATE privilege for database objects.

Once pg_pathman is enabled, you can start partitioning tables.

> **Note**
>
> During installation, pg_pathman creates a few RLS policies to restrict access to its own tables. Postgres Pro core, however, does not support dump/restore of databases where extensions issuing CREATE POLICY statements are installed. Therefore, when restoring a dump of a database where pg_pathman is installed, you will get error messages such as:
>
> ```
> ERROR: policy "allow_select" for table "pathman_config" already exists
> ```
>
> Ignore them since they do not affect whether the data being restored is complete.

> **Tip**
>
> You can also build pg_pathman from source code by executing the following command in the pg_pathman directory:
>
> ```
> make install USE_PGXS=1
> ```
>
> When this operation is complete, follow the steps described above to complete the setup.
>
> In addition, do not forget to set the PG_CONFIG variable if you want to test pg_pathman on a custom build of Postgres Pro. For details, see *Building and Installing PostgreSQL Extension Modules*.

You can toggle pg_pathman or its specific custom nodes on and off using GUC variables. For details, see Section F.37.5.1.

If you want to permanently disable pg_pathman for a previously partitioned table, use the disable_pathman_for() function:

```
SELECT disable_pathman_for('range_rel');
```

All sections and data will remain unchanged and will be handled by the standard Postgres Pro inheritance mechanism.

F.37.1.1. Updating pg_pathman

If you already have a previous version of pg_pathman installed, complete the following steps to upgrade to a newer version:

1. Install Postgres Pro.
2. Restart your Postgres Pro cluster.
3. If you are running a previous major version of pg_pathman (the second digit in the version number is different), complete the update as follows:

```
ALTER EXTENSION pg_pathman UPDATE TO version;
SET pg_pathman.enable = t;
```

where *version* is the pg_pathman major version number, such as 1.5.

You can check the current pg_pathman version by running the pathman_version() function.

F.37.2. Usage

Choosing Partitioning Strategies

Running Non-Blocking Data Migration

Partitioning by a Single Expression

Partitioning by Composite Key

Running Multilevel Partitioning

Managing Partitions

As your database grows, indexing mechanisms may become inefficient and cause high latency as you run queries. To improve performance, ensure scalability, and optimize database administration processes you can use partitioning — splitting a large table into smaller pieces, with each row moved to a single partition according to the partitioning key.

Traditionally, Postgres Pro has supported partitioning via table inheritance, with each partition created as a child table with a CHECK constraint. In Postgres Pro 10, support for declarative partitioning was added, which also relies on inheritance. With these approaches, the query planner has to perform an exhaustive search and check constraints on each partition to build a query plan, which may slow down queries for tables with a large number of partitions. The pg_pathman extension uses an optimized planning algorithms and partitioning functions based on the internal structure of the partitioned tables, which allows to achieve better performance results. For details on pg_pathman implementation specifics, see Section F.37.4.

F.37.2.1. Choosing Partitioning Strategies

The pg_pathman extension supports the following partitioning strategies:

- Hash — maps rows to partitions using a generic hash function. Choose this strategy if most of your queries will be of the exact-match type.
- Range — maps rows to partitions based on partitioning key ranges assigned to each partition. Choose this strategy if your database contains numeric data that you are likely to query or manage by ranges. For example, you may want to query historical data by years, or review experiment results by specific numeric ranges. To achieve performance gains, pg_pathman uses the binary search algorithm.

By default, pg_pathman migrates all data from the parent table to the newly created partitions at once (*blocking partitioning*). This approach enables you to restructure the table in a single transaction, but may cause downtime if you have a lot of data. If it is critical to avoid downtime, you can use *concurrent partitioning*. In this case, pg_pathman writes all the updates to the newly created partitions, but keeps the original data in the parent table until you explicitly migrate it. This enables you to partition large databases without downtime, as you can choose convenient time for migration and copy data in small batches without blocking other transactions. For details on concurrent partitioning, see Section F.37.2.2.

F.37.2.1.1. Setting up Hash Partitioning

To perform hash partitioning with pg_pathman, run the create_hash_partitions() function:

```
create_hash_partitions(parent_relid     REGCLASS,
```

```
                          expression       TEXT,
                          partitions_count INTEGER,
                          partition_data   BOOLEAN DEFAULT TRUE,
                          partition_names  TEXT[] DEFAULT NULL,
                          tablespaces      TEXT[] DEFAULT NULL)
```

The pg_pathman module creates the specified number of partitions based on the hash function. Optionally, you can specify partition names and tablespaces by setting partition_names and tablespaces options, respectively.

You cannot add or remove partitions after the parent table is split. If required, you can replace the specified partition with another table:

```
replace_hash_partition(old_partition       REGCLASS,
                       new_partition       REGCLASS,
                       lock_parent         BOOL DEFAULT TRUE);
```

When set to true, lock_parent parameter will prevent any INSERT/UPDATE/ALTER TABLE queries to parent table.

If you omit the optional partition_data parameter or set it to true, all the data from the parent table gets migrated to partitions. The pg_pathman module blocks the table for other transactions until data migration completes. To avoid downtime, you can set the partition_data parameter to false and later use the partition_table_concurrently() function to migrate your data to partitions without blocking other queries. For details, see the Section F.37.2.2.

F.37.2.1.2. Setting up Range Partitioning

The pg_pathman module provides the create_range_partitions() for range partitioning. This function creates partitions based on the specified interval and the initial partitioning key value. New partitions are created automatically when you insert data outside of the already covered range.

```
create_range_partitions(parent_relid   REGCLASS,
                        expression     TEXT,
                        start_value    ANYELEMENT,
                        p_interval     ANYELEMENT | INTERVAL,
                        p_count        INTEGER DEFAULT NULL,
                        partition_data BOOLEAN DEFAULT TRUE)
```

The pg_pathman module creates partitions based on the specified parameters. If you omit the optional p_count parameter, pg_pathman calculates the required number of partitions based on the specified start value and interval. If you insert new data outside of the existing partition range, pg_pathman creates new partitions automatically, keeping the specified interval. This approach ensures that all partitions are of the same size, which can improve query performance and facilitate database management.

Alternatively, you can specify an array defining the bounds of partitions to be created using the bounds parameter:

```
create_range_partitions(parent_relid    REGCLASS,
                        expression      TEXT,
                        bounds          ANYARRAY,
                        partition_names TEXT[] DEFAULT NULL,
                        tablespaces     TEXT[] DEFAULT NULL,
                        partition_data  BOOLEAN DEFAULT TRUE)
```

If required, you can also use partition management functions to add partitions manually. For example, if there is a gap between the created partitions, pg_pathman cannot fill it with a new partition in an automated mode.

By default, all the data from the parent table gets migrated to the specified number of partitions. The pg_pathman module blocks the table for other transactions until data migration completes. To avoid

downtime, you can set the `partition_data` parameter to `false` and later use the `partition_table_concurrently()` function to migrate your data to partitions without blocking other queries. For details, see the Section F.37.2.2.

F.37.2.2. Running Non-Blocking Data Migration

If it is critical to avoid downtime, you can perform concurrent partitioning by setting the `partition_data` parameter of the partitioning function to `false`. In this case, `pg_pathman` creates empty partitions, keeping all the original data in the parent table. At the same time, all the database updates are written to the newly created partitions. You can later migrate the original data to partitions without blocking other queries using the `partition_table_concurrently()` function:

```
partition_table_concurrently(relation   REGCLASS,
                             batch_size INTEGER DEFAULT 1000,
                             sleep_time FLOAT8 DEFAULT 1.0)
```

where:

- `relation` is the parent table.
- `batch_size` is the number of rows to copy from the parent table to partitions at a time. You can set this parameter to any integer value from 1 to 10000.
- `sleep_time` is the time interval between migration attempts, in seconds.

The `pg_pathman` module starts a background worker to move the data from the parent table to partitions in small batches of the specified `batch_size`. If one or more rows in the batch are locked by other queries, `pg_pathman` waits for the specified `sleep_time` and tries again, up to 60 times. You can monitor the migration process in the `pathman_concurrent_part_tasks` view that shows the number of rows migrated so far:

```
[user]postgres: select * from pathman_concurrent_part_tasks ;
 userid |  pid  | dbid  | relid | processed | status
--------+-------+-------+-------+-----------+---------
 user   | 20012 | 12413 | test  |    334000 | working
(1 row)
```

If you need to stop data migration, run the `stop_concurrent_part_task()` function at any time:

```
SELECT stop_concurrent_part_task(relation REGCLASS);
```

`pg_pathman` completes the migration of the current batch and terminates the migration process.

> **Tip**
>
> When `pg_pathman` migrates all the data from the parent table, you can exclude the parent table from the query plan. See the `set_enable_parent()` function description for details.

F.37.2.3. Partitioning by a Single Expression

For both range and hash partitioning strategies, `pg_pathman` supports partitioning by expression that returns a single scalar value. The partitioning expression can reference a table column, as well as calculate the partitioning key based on one or more column values.

> **Tip**
>
> If you would like to partition a table by a tuple, see Section F.37.2.4.

To partition a table by expression, use pg_pathman partitioning functions. The partitioning expression must satisfy the following conditions:

- Expression must reference at least one column of the partitioned table.
- All referenced columns must be marked as NOT NULL.
- Expression cannot reference system attributes, such as oid, xmin, xmax, etc.
- Expression cannot include subqueries.
- All functions used by expression must be marked as IMMUTABLE.

As the expression can return a value of virtually any type, make sure to convert it to the type you need for partitioning.

To access a partition, you must use the exact expression used for partitioning. Otherwise, pg_pathman cannot optimize the query. You can view the partitioning expression for each partitioned table in the pathman_config table.

F.37.2.3.1. Examples

Suppose you have the test table that stores some jsonb data:

```
CREATE TABLE test(col jsonb NOT NULL);
INSERT INTO test
SELECT format('{"key": %s, "date": "%s", "value": "%s"}',
              i, current_date, md5(i::text))::jsonb
FROM generate_series(1, 10000 * 10) as g(i);
```

To partition this data by range of the key value, you need to extract this value from the jsonb object and convert it to a numeric type, such as bigint:

```
SELECT create_range_partitions('test', '(col->>''key'')::bigint', 1, 10000, 10);
```

pg_pathman splits the parent table into ten partitions, with each partition storing 10000 rows:

```
SELECT * FROM pathman_partition_list;
 parent | partition | parttype |              expr               | range_min |
 range_max
--------+-----------+----------+---------------------------------+-----------
+-----------
 test   | test_1    |        2 | ((col ->> 'key'::text))::bigint | 1         | 10001
 test   | test_2    |        2 | ((col ->> 'key'::text))::bigint | 10001     | 20001
 test   | test_3    |        2 | ((col ->> 'key'::text))::bigint | 20001     | 30001
 test   | test_4    |        2 | ((col ->> 'key'::text))::bigint | 30001     | 40001
 test   | test_5    |        2 | ((col ->> 'key'::text))::bigint | 40001     | 50001
 test   | test_6    |        2 | ((col ->> 'key'::text))::bigint | 50001     | 60001
 test   | test_7    |        2 | ((col ->> 'key'::text))::bigint | 60001     | 70001
 test   | test_8    |        2 | ((col ->> 'key'::text))::bigint | 70001     | 80001
 test   | test_9    |        2 | ((col ->> 'key'::text))::bigint | 80001     | 90001
 test   | test_10   |        2 | ((col ->> 'key'::text))::bigint | 90001     | 100001
(10 rows)
```

F.37.2.4. Partitioning by Composite Key

Using pg_pathman, you can also perform range partitioning by composite key. A composite key consists of two or more comma-separated values, which can be columns or expressions extracting the values from the table. The expressions defining the composite key must satisfy the conditions described in Section F.37.2.3.

Although pg_pathman does not support automatic partition creation by composite key, you can add partitions using the add_range_partition() function. A typical workflow is as follows:

1. Enable automatic partition naming for your table by running the `create_naming_sequence()` function.
2. Create a composite partitioning key.
3. Register a table you are going to partition with `pg_pathman` using the `add_to_pathman_config()` function.
4. Add a partition based on the defined composite partitioning key using the `add_range_partition()` function.

F.37.2.4.1. Examples

Suppose you have the `test` table that stores some temporal data:

```
CREATE TABLE test (logdate date NOT NULL, comment text);
```

To partition this data by month and year, you have to create a composite key:

```
CREATE TYPE test_key AS (year float8, month float8);
```

To enable automatic partition naming, run the `create_naming_sequence()` function passing the table name as an argument:

```
SELECT create_naming_sequence('test');
```

Register the `test` table with `pg_pathman`, specifying the partitioning key you are going to use:

```
SELECT add_to_pathman_config('test',
                             '( extract(year from logdate),
                                extract(month from logdate) )::test_key',
                             NULL);
```

Create a partition that includes all the data in the range of ten years, starting from January of the current year:

```
SELECT add_range_partition('test',
                           (extract(year from current_date), 1)::test_key,
                           (extract(year from current_date + '10 years'::interval),
 1)::test_key);
```

F.37.2.5. Running Multilevel Partitioning

`pg_pathman` supports multilevel partitioning for both hash and range partitioning strategies. You can use partitioning strategies in any combination: a hash- or range-partitioned table can be further partitioned by both hash or range.

To split an existing partition into several child ones, use the regular `pg_pathman` partitioning functions as explained in Section F.37.2.1, passing the name of the partition to be split as the *`parent_relid`* parameter. You can check the exact partition names in the pathman_partition_list view.

When opting for the range-range partitioning combination, you can either choose a different partitioning expression, or use the same expression as for the parent table. In the latter case, if the selected range is larger than that of the parent partition, only those child partitions that intersect with the parent range will be in use. Other child partitions will remain empty unless their parent is merged with an adjacent partition that covers at least a part of their range.

F.37.2.5.1. Examples

Suppose you have the `journal` table with some logs, which is partitioned by month:

```
-- create an empty table
CREATE TABLE journal (
```

```
id      SERIAL,
dt      TIMESTAMP NOT NULL,
level   INTEGER,
msg     TEXT);

-- generate some log data into the table
INSERT INTO journal (dt, level, msg)
SELECT g, random() * 6, md5(g::text)
FROM generate_series('2015-01-01'::date, '2015-12-31'::date, '1 minute') as g;

-- partition the table by range
SELECT create_range_partitions('journal', 'dt', '2015-01-01'::date, '1
 month'::interval);
```

If having smaller partitions makes more sense at some point, you can further split the partitions by hash or range. For example, to split the `journal_1` partition into subpartitions by day, run:

```
SELECT create_range_partitions('journal_1', 'dt', '2015-01-01'::date, '1
 day'::interval);
```

Similarly, you can use hash partitioning to create child partitions. For example, split the `journal_2` partition into five partitions by hash using the `id` column as the partitioning key:

```
SELECT create_hash_partitions('journal_2', 'id', '5');
```

F.37.2.6. Managing Partitions

`pg_pathman` provides multiple functions for easy partition management. For details, see Section F.37.5.3.4.

F.37.3. Examples

F.37.3.1. Common Tips

- You can add `partition` column containing the names of the underlying partitions using the system attribute called `tableoid`:

  ```
  SELECT tableoid::regclass AS partition, * FROM partitioned_table;
  ```

- Though indices on a parent table are not particularly useful (since the parent table is supposed to be empty), they act as prototypes for indices on partitions. For each index on the parent table, `pg_pathman` creates a similar index on each partition.

- All running concurrent partitioning tasks can be listed using the `pathman_concurrent_part_tasks` view:

  ```
  SELECT * FROM pathman_concurrent_part_tasks;
  userid  | pid  | dbid  | relid | processed | status
  --------+------+-------+-------+-----------+---------
  user    | 7367 | 16384 | test  |    472000 | working
  (1 row)
  ```

- The `pathman_partition_list` in conjunction with `drop_range_partition()` can be used to drop range partitions in a more flexible way compared to `DROP TABLE`:

  ```
  SELECT drop_range_partition(partition, false) /* move data to parent */
  FROM pathman_partition_list
  WHERE parent = 'part_test'::regclass AND range_min::int < 500;
  NOTICE:  1 rows copied from part_test_11
  NOTICE:  100 rows copied from part_test_1
  NOTICE:  100 rows copied from part_test_2
  ```

```
drop_range_partition
----------------------
dummy_test_11
dummy_test_1
dummy_test_2
(3 rows)
```

- You can turn foreign tables into partitions using the `attach_range_partition()` function. Rows that were meant to be inserted into the parent will be redirected to foreign partitions using `PartitionFilter`. By default, it is only allowed to insert rows into partitions provided by `postgres_fdw`. This setting is controlled by the `pg_pathman.insert_into_fdw` variable. You must have superuser rights to change this setting.

F.37.3.2. Hash Partitioning

Consider an example of hash partitioning. First create a table with an integer column:

```
CREATE TABLE items (
id       SERIAL PRIMARY KEY,
name     TEXT,
code     BIGINT);

INSERT INTO items (id, name, code)
SELECT g, md5(g::text), random() * 100000
FROM generate_series(1, 100000) as g;
```

Now run the `create_hash_partitions()` function with appropriate arguments:

```
SELECT create_hash_partitions('items', 'id', 100);
```

This will create new partitions and move the data from the parent table to partitions.

Here is an example of the query performing filtering by partitioning key:

```
SELECT * FROM items WHERE id = 1234;
  id  |               name               | code
------+----------------------------------+------
 1234 | 81dc9bdb52d04dc20036dbd8313ed055 | 1855
(1 row)

EXPLAIN SELECT * FROM items WHERE id = 1234;
QUERY PLAN
-------------------------------------------------------------------------------------
Append  (cost=0.28..8.29 rows=0 width=0)
->  Index Scan using items_34_pkey on items_34  (cost=0.28..8.29 rows=0 width=0)
Index Cond: (id = 1234)
```

Notice that the `Append` node contains only one child scan, which corresponds to the `WHERE` clause.

> **Important**
>
> Pay attention to the fact that `pg_pathman` excludes the parent table from the query plan.

To access the parent table, use the `ONLY` modifier:

```
EXPLAIN SELECT * FROM ONLY items;
QUERY PLAN
---------------------------------------------------
Seq Scan on items  (cost=0.00..0.00 rows=1 width=45)
```

F.37.3.3. Range Partitioning

Consider an example of range partitioning. Let's create a table containing some dummy logs:

```
CREATE TABLE journal (
id      SERIAL,
dt      TIMESTAMP NOT NULL,
level   INTEGER,
msg     TEXT);

-- similar index will also be created for each partition
CREATE INDEX ON journal(dt);

-- generate some data
INSERT INTO journal (dt, level, msg)
SELECT g, random() * 6, md5(g::text)
FROM generate_series('2015-01-01'::date, '2015-12-31'::date, '1 minute') as g;
```

Run the `create_range_partitions()` function to create partitions so that each partition would contain the data for one day:

```
SELECT create_range_partitions('journal', 'dt', '2015-01-01'::date, '1 day'::interval);
```

It will create 364 partitions and move the data from the parent table to partitions.

New partitions are appended automatically by insert trigger, but it can be done manually with the following functions:

```
-- add new partition with specified range
SELECT add_range_partition('journal', '2016-01-01'::date, '2016-01-07'::date);

-- append new partition with default range
SELECT append_range_partition('journal');
```

The first one creates a partition with specified range. The second one creates a partition with default interval and appends it to the partition list. It is also possible to attach an existing table as partition. For example, we may want to attach an archive table (or even foreign table from another server) for some outdated data:

```
CREATE FOREIGN TABLE journal_archive (
id      INTEGER NOT NULL,
dt      TIMESTAMP NOT NULL,
level   INTEGER,
msg     TEXT)
SERVER archive_server;

SELECT attach_range_partition('journal', 'journal_archive', '2014-01-01'::date,
 '2015-01-01'::date);
```

> **Important**
>
> The attached table must have the same columns as the partitioned table, except for the dropped columns. The attached columns must have the same type, collation, and `NOT NULL` settings as the original columns.

To merge two adjacent partitions, use the `merge_range_partitions()` function:

```
SELECT merge_range_partitions('journal_archive', 'journal_1');
```

To split partition by value, use the `split_range_partition()` function:

```
SELECT split_range_partition('journal_366', '2016-01-03'::date);
```

To detach partition, use the `detach_range_partition()` function:

```
SELECT detach_range_partition('journal_archive');
```

Here is an example of the query performing filtering by partitioning key:

```
SELECT * FROM journal WHERE dt >= '2015-06-01' AND dt < '2015-06-03';
id      |         dt          | level |               msg
--------+---------------------+-------+----------------------------------
217441  | 2015-06-01 00:00:00 |     2 | 15053892d993ce19f580a128f87e3dbf
217442  | 2015-06-01 00:01:00 |     1 | 3a7c46f18a952d62ce5418ac2056010c
217443  | 2015-06-01 00:02:00 |     0 | 92c8de8f82faf0b139a3d99f2792311d
...
(2880 rows)

EXPLAIN SELECT * FROM journal WHERE dt >= '2015-06-01' AND dt < '2015-06-03';
QUERY PLAN
------------------------------------------------------------------
Append  (cost=0.00..58.80 rows=0 width=0)
->  Seq Scan on journal_152  (cost=0.00..29.40 rows=0 width=0)
->  Seq Scan on journal_153  (cost=0.00..29.40 rows=0 width=0)
(3 rows)
```

F.37.4. Internals

`pg_pathman` stores partitioning configuration in the `pathman_config` table; each row contains a single entry for a partitioned table (relation name, partitioning column and its type). During the initialization stage the `pg_pathman` module caches some information about child partitions in the shared memory, which is used later for plan construction. Before a `SELECT` query is executed, `pg_pathman` traverses the condition tree in search of expressions like:

```
VARIABLE OP CONST
```

where `VARIABLE` is a partitioning key, `OP` is a comparison operator (supported operators are =, <, <=, >, >=), `CONST` is a scalar value. For example:

```
WHERE id = 150
```

Based on the partitioning type and condition's operator, `pg_pathman` searches for the corresponding partitions and builds the plan.

F.37.4.1. Custom Plan Nodes

`pg_pathman` provides a couple of *custom plan nodes* which aim to reduce execution time, namely:

- `RuntimeAppend` (overrides `Append` plan node)
- `RuntimeMergeAppend` (overrides `MergeAppend` plan node)
- `PartitionFilter` (drop-in replacement for INSERT triggers)
- `PartitionRouter` for cross-partition UPDATE queries instead of triggers

`PartitionFilter` acts as a *proxy node* for INSERT's child scan, which means it can redirect output tuples to the corresponding partition:

```
EXPLAIN (COSTS OFF)
INSERT INTO partitioned_table
SELECT generate_series(1, 10), random();
```

```
                QUERY PLAN
----------------------------------------
 Insert on partitioned_table
   ->  Custom Scan (PartitionFilter)
         ->  Subquery Scan on "*SELECT*"
               ->  Result
(4 rows)
```

`PartitionRouter` is another proxy node used in conjunction with `PartitionFilter` to enable cross-partition `UPDATE` operations, for example, when you update any column of a partitioning key.

> **Important**
>
> The `PartitionRouter` node transforms cross-partition `UPDATE` commands into `DELETE` + `INSERT`. On Postgres Pro versions prior to 11, this operation is unsafe as `pg_pathman` cannot determine whether the updated row has been deleted or moved to another partition.

By default, `PartitionRouter` is disabled to avoid undesirable side effects. To enable this node, set the `pg_pathman.enable_partitionrouter` to `on`.

```
EXPLAIN (COSTS OFF)
UPDATE partitioned_table
SET value = value + 1 WHERE value = 2;
                    QUERY PLAN
--------------------------------------------------
 Update on partitioned_table_0
   ->  Custom Scan (PartitionRouter)
         ->  Custom Scan (PartitionFilter)
               ->  Seq Scan on partitioned_table_0
                     Filter: (value = 2)
(5 rows)
```

`RuntimeAppend` and `RuntimeMergeAppend` have much in common: they come in handy in a case when WHERE condition takes form of:

```
VARIABLE OP PARAM
```

This kind of expressions can no longer be optimized at planning time since the parameter's value is not known until the execution stage takes place. The problem can be solved by embedding the *WHERE condition analysis routine* into the original `Append`'s code, thus making it pick only required scans out of a whole bunch of planned partition scans. This effectively boils down to creation of a custom node capable of performing such a check.

There are at least several cases that demonstrate usefulness of these nodes:

```
/* create table we're going to partition */
CREATE TABLE partitioned_table(id INT NOT NULL, payload REAL);

/* insert some data */
INSERT INTO partitioned_table

- `NestLoop` **involving a partitioned table**, which is omitted since it's occasionally shown above.

To learn more about custom nodes, see Alexander Korotkov's *blog*.

F.37.5. Reference

F.37.5.1. GUC Variables

There are several user-accessible GUC variables designed to toggle `pg_pathman` or its specific custom nodes on and off.

- `pg_pathman.enable` — enable/disable the `pg_pathman` module.

  Default: `on`
- `pg_pathman.enable_runtimeappend` — toggle the `RuntimeAppend` custom node on/off.

  Default: `on`
- `pg_pathman.enable_runtimemergeappend` — toggle the `RuntimeMergeAppend` custom node on/off.

  Default: `on`
- `pg_pathman.enable_partitionfilter` — toggle the `PartitionFilter` custom node on/off to enable/disable cross-partition `INSERT` operations.

  Default: `on`
- `pg_pathman.enable_partitionrouter` — toggle the `PartitionRouter` custom node on/off to enable/disable cross-partition `UPDATE` operations.

  Default: `off`
- `pg_pathman.enable_auto_partition` — toggle automatic partition creation on/off (per session).

Default: on

- pg_pathman.enable_bounds_cache — toggle bounds cache on/off.

  Default: on
- pg_pathman.insert_into_fdw — allow INSERT operations into various foreign-data wrappers. Possible values: disabled, postgres, and any_fdw.

  Default: postgres
- pg_pathman.override_copy — toggle COPY statement hooking on/off.

  Default: on

F.37.5.2. Views and Tables

F.37.5.2.1. pathman_config

This table stores the list of partitioned tables. This is the main configuration storage.

```
CREATE TABLE IF NOT EXISTS pathman_config (
    partrel         REGCLASS NOT NULL PRIMARY KEY,
    attname         TEXT NOT NULL,
    parttype        INTEGER NOT NULL,
    range_interval  TEXT);
```

F.37.5.2.2. pathman_config_params

This table stores optional parameters that override standard pg_pathman behavior.

```
CREATE TABLE IF NOT EXISTS pathman_config_params (
    partrel        REGCLASS NOT NULL PRIMARY KEY,
    enable_parent  BOOLEAN NOT NULL DEFAULT TRUE,
    auto           BOOLEAN NOT NULL DEFAULT TRUE,
    init_callback  REGPROCEDURE NOT NULL DEFAULT 0,
    spawn_using_bgw BOOLEAN NOT NULL DEFAULT FALSE);
```

F.37.5.2.3. pathman_concurrent_part_tasks

This view lists all currently running concurrent partitioning tasks.

```
-- helper SRF function
CREATE OR REPLACE FUNCTION show_concurrent_part_tasks()
RETURNS TABLE (
    userid     REGROLE,
    pid        INT,
    dbid       OID,
    relid      REGCLASS,
    processed  INT,
    status     TEXT)
AS 'pg_pathman', 'show_concurrent_part_tasks_internal'
LANGUAGE C STRICT;

CREATE OR REPLACE VIEW pathman_concurrent_part_tasks
AS SELECT * FROM show_concurrent_part_tasks();
```

F.37.5.2.4. pathman_partition_list

This view lists all existing partitions, as well as their parents and range boundaries (NULL for hash partitions).

```
-- helper SRF function
```

```
CREATE OR REPLACE FUNCTION show_partition_list()
RETURNS TABLE (
    parent     REGCLASS,
    partition  REGCLASS,
    parttype   INT4,
    expr       TEXT,
    range_min  TEXT,
    range_max  TEXT)
AS 'pg_pathman', 'show_partition_list_internal'
LANGUAGE C STRICT;

CREATE OR REPLACE VIEW pathman_partition_list
AS SELECT * FROM show_partition_list();
```

F.37.5.3. Functions

F.37.5.3.1. Partitioning Functions

```
create_hash_partitions(parent_relid     REGCLASS,
                       expression       TEXT,
                       partitions_count INTEGER,
                       partition_data   BOOLEAN DEFAULT TRUE,
                       partition_names  TEXT[] DEFAULT NULL,
                       tablespaces      TEXT[] DEFAULT NULL)
```

Performs hash partitioning for `relation` by integer key `expression`. The `partitions_count` parameter specifies the number of partitions to create; it cannot be changed afterwards. If `partition_data` is `true`, all the data will be automatically migrated from the parent table to partitions. Note that data migration may take a while to finish and the table will be locked until transaction commits. See `partition_table_concurrently()` for a lock-free way to migrate data. Partition creation callback is invoked for each partition if set beforehand (see `set_init_callback()`).

```
create_range_partitions(relation       REGCLASS,
                        expression     TEXT,
                        start_value    ANYELEMENT,
                        p_interval     ANYELEMENT,
                        p_count        INTEGER DEFAULT NULL,
                        partition_data BOOLEAN DEFAULT TRUE)

create_range_partitions(relation       REGCLASS,
                        expression     TEXT,
                        start_value    ANYELEMENT,
                        p_interval     INTERVAL,
                        p_count        INTEGER DEFAULT NULL,
                        partition_data BOOLEAN DEFAULT TRUE)

create_range_partitions(relation        REGCLASS,
                        expression      TEXT,
                        bounds          ANYARRAY,
                        partition_names TEXT[] DEFAULT NULL,
                        tablespaces     TEXT[] DEFAULT NULL,
                        partition_data  BOOLEAN DEFAULT TRUE)
```

Performs range partitioning for `relation` by partitioning key defined by `expression`. The `start_value` argument specifies the initial value, `p_interval` sets the default range for automatically created partitions or partitions created with `append_range_partition()` or `prepend_range_partition()`. If `p_interval` is set to `NULL`, automatic partition creation is disabled. `p_count` is the number of premade partitions. If `p_count` is not set, than `pg_pathman` tries to determine the number of partitions based on the `expression` value. The `bounds` array defines the bounds for partitions to be created. You can build

this array using the `generate_range_bounds()` function. Partition creation callback is invoked for each partition if set beforehand.

F.37.5.3.2. Data Migration Functions

```
partition_table_concurrently(relation REGCLASS,
                             batch_size INTEGER DEFAULT 1000,
                             sleep_time FLOAT8 DEFAULT 1.0)
```

Starts a background worker to move data from parent table to partitions. The worker utilizes short transactions to copy small batches of data (up to 10K rows per transaction) and thus doesn't significantly interfere with user's activity.

```
stop_concurrent_part_task(relation REGCLASS)
```

Stops a background worker performing a concurrent partitioning task. Note: worker will exit after it finishes relocating a current batch.

F.37.5.3.3. Triggers

Triggers are no longer required for `INSERT` and cross-partition `UPDATE` operations. However, user-supplied triggers are supported:

- Each inserted row results in execution of BEFORE/AFTER INSERT trigger functions of a corresponding partition.
- Each updated row results in execution of BEFORE/AFTER UPDATE trigger functions of a corresponding partition.
- Each moved row (cross-partition update) results in execution of BEFORE UPDATE + BEFORE/AFTER DELETE + BEFORE/AFTER INSERT trigger functions of corresponding partitions.

F.37.5.3.4. Partition Management Functions

```
replace_hash_partition(old_partition       REGCLASS,
                       new_partition       REGCLASS,
                       lock_parent         BOOLEAN DEFAULT TRUE)
```

Replaces the specified partition of hash-partitioned table with another table. When set to `true`, the `lock_parent` parameter prevents any `INSERT`/`UPDATE`/`ALTER TABLE` queries to the parent table.

```
split_range_partition(partition_relid  REGCLASS,
                      split_value      ANYELEMENT,
                      partition_name   TEXT DEFAULT NULL,
                      tablespace       TEXT DEFAULT NULL)
```

Split range `partition` in two by `value`, with the specified `value` included into the second partition. Partition creation callback is invoked for a new partition if available.

```
merge_range_partitions(variadic partitions REGCLASS[])
```

Merge several adjacent range partitions. Partitions are automatically ordered by increasing bounds. All the data will be accumulated in the first partition, while other merged partitions are removed. If the remaining partition has any child partitions, new child partitions for the merged data will be created as required using the same partitioning expression.

```
append_range_partition(parent_relid   REGCLASS,
                       partition_name TEXT DEFAULT NULL,
                       tablespace     TEXT DEFAULT NULL)
```

Append new range partition with `pathman_config.range_interval` as interval.

```
prepend_range_partition(parent_relid   REGCLASS,
```

```
                          partition_name TEXT DEFAULT NULL,
                          tablespace     TEXT DEFAULT NULL)
```

Prepend new range partition with `pathman_config.range_interval` as interval.

```
add_range_partition(parent_relid   REGCLASS,
                    start_value    ANYELEMENT,
                    end_value      ANYELEMENT,
                    partition_name TEXT DEFAULT NULL,
                    tablespace     TEXT DEFAULT NULL)
```

Create a new range partition for `relation` with the specified range bounds. If the `start_value` or the `end_value` is NULL, the corresponding range bound will be infinite.

```
drop_range_partition(partition_relid TEXT, delete_data BOOLEAN DEFAULT TRUE)
```

Drop range partition and all of its data if `delete_data` is true.

```
attach_range_partition(parent_relid    REGCLASS,
                       partition_relid REGCLASS,
                       start_value     ANYELEMENT,
                       end_value       ANYELEMENT)
```

Attach partition to the existing range-partitioned relation. The attached table must have exactly the same structure as the parent table, including the dropped columns. Partition creation callback is invoked if set (see Section F.37.5.2.2).

```
detach_range_partition(partition_relid REGCLASS)
```

Detach partition from the existing range-partitioned relation.

```
disable_pathman_for(parent_relid REGCLASS)
```

Permanently disable `pg_pathman` partitioning mechanism for the specified parent table and remove the insert trigger if it exists. All partitions and data remain unchanged.

```
drop_partitions(parent_relid REGCLASS,
                delete_data  BOOLEAN DEFAULT FALSE)
```

Drop partitions of the parent table (both foreign and local relations). If `delete_data` is `false`, the data is copied to the parent table first. Default is `false`.

F.37.5.3.5. Additional Functions

```
pathman_version()
```

Returns the `pg_pathman` version number.

```
set_interval(relation REGCLASS, value ANYELEMENT)
```

Update range-partitioned table interval. Note that interval must not be negative and it must not be trivial, i.e. its value should be greater than zero for numeric types, at least 1 microsecond for `timestamp` and at least 1 day for `date`.

```
set_enable_parent(relation REGCLASS, value BOOLEAN)
```

Include/exclude parent table into/from query plan. In original Postgres Pro planner parent table is always included into query plan even if it's empty, which can lead to additional overhead. You can use `disable_parent()` if you are never going to use parent table as a storage. Default value depends on the `partition_data` parameter specified during initial partitioning with the `create_range_partitions()` function. If the `partition_data` parameter was `true`, then all data have already been migrated to partitions and the parent table is disabled. Otherwise, it is enabled.

```
set_auto(relation REGCLASS, value BOOLEAN)
```

Enable/disable auto partition propagation (only for range partitioning). It is enabled by default.

```
set_init_callback(relation REGCLASS, callback REGPROCEDURE DEFAULT 0)
```

Set partition creation callback to be invoked for each attached or created partition (both hash and range). If callback is marked with `SECURITY INVOKER`, it is executed with the privileges of the user who produced a statement that has led to creation of a new partition. For example:

```
INSERT INTO partitioned_table VALUES (-5)
```

The callback must have the following signature: `part_init_callback(args JSONB) RETURNS VOID`. Parameter `arg` consists of several fields whose presence depends on partitioning type:

```
/* Range-partitioned table abc (child abc_4) */
{
    "parent":    "abc",
    "parttype":  "2",
    "partition": "abc_4",
    "range_max": "401",
    "range_min": "301"
}

/* Hash-partitioned table abc (child abc_0) */
{
    "parent":    "abc",
    "parttype":  "1",
    "partition": "abc_0"
}
```

```
set_spawn_using_bgw(relation REGCLASS, value BOOLEAN)
```

When inserting new data beyond the partitioning range, use SpawnPartitionsWorker to create new partitions in a separate transaction.

```
create_naming_sequence(parent_relid REGCLASS)
```

Enable automatic partition naming for the specified `relation` table. You must run this function when partitioning this table by composite key.

```
add_to_pathman_config(parent_relid     REGCLASS,
                      expression       TEXT,
                      range_interval   TEXT)
add_to_pathman_config(parent_relid     REGCLASS,
                      expression       TEXT)
```

Register the specified `relation` table with `pg_pathman` to enable partitioning by the provided `expression`. For range partitioning, the `range_interval` argument is mandatory. You can set it to `NULL` if you are going to add partition manually.

```
generate_range_bounds(p_start     ANYELEMENT,
                      p_interval  INTERVAL,
                      p_count     INTEGER)

generate_range_bounds(p_start     ANYELEMENT,
                      p_interval  ANYELEMENT,
```

```
                p_count     INTEGER)
```

Build the `bounds` array that defines the bounds for partitions to be created. You can pass this array as an argument to the `create_range_partitions()` function.

F.38. pg_proaudit

The `pg_proaudit` extension enables detailed logging of various security events.

`pg_proaudit` works in parallel with the standard PostgreSQL logging solutions (logging collector) and does not depend on them. Security event log of the `pg_proaudit` extension is stored separately from the server log. At the Postgres Pro Standard startup, `pg_proaudit` launches a special background process to log security events.

Logging rules are stored in the `pg_proaudit.conf` configuration file located in the cluster data directory (`PGDATA`). It is a text file that can be edited directly using operating system facilities. To modify the file using SQL, you can use several `pg_proaudit` functions. The `pg_proaudit_settings` view displays the current `pg_proaudit` rules, even if they have not been saved into the `pg_proaudit.conf` file yet.

All the logged events belong to the following classes:

- DDL commands for creating, changing, and deleting DBMS objects (databases, tablespaces, schemas, tables, views, sequences, languages, functions)
- access control commands for database objects (`GRANT`, `REVOKE`)
- DML commands for access to database objects (`INSERT`, `UPDATE`, `DELETE`, `SELECT`, `TRUNCATE` for tables and/or views, `EXECUTE` for functions)
- database authentication/disconnection events
- all commands executed by a particular user

Security events can be logged both in the centralized logging solution of the operating system (syslog) and in the standard file-system files. Event logs can be written both into the syslog and into the files simultaneously. For clear identification, all `pg_proaudit` records in the syslog are marked with `AUDIT`. Event log files can be written in the CEF (Common Event Format) and CSV (Comma-Separated Values) formats. Each event is logged on a separate line that contains the following fields:

- date and time of the event
- current user name
- database name
- server process ID (PID)
- severity level: `INFO` or `ERROR`
- serial number of the command in a session
- subcommand number in complex commands (`CREATE TABLE ... AS SELECT ...`)
- operator name
- object type
- object name
- operator execution results: `SUCCESS` or `FAILURE`
- additional information like error message in case of `FAILURE` or connection parameters for the `AUTHENTICATE` event; unfinished authentication attempts are marked as [EOF. No credentials provided]
- text of the SQL command

- parameters of the command (for example, for PREPARE)
- session user name
- unique ID of the event (in the *UUIDv7* format)
- transaction ID (XID)
- virtual transaction ID (VXID)

An event contains the information about both session_user and current_user of the session. Therefore, it will be possible to identify the user, even if they execute the SET ROLE command to change user identifier.

The XID and VXID values can be zero if an event does not relate to a transaction (e. g. the DISCONNECT event).

You can define a directory to store security log files and set up log file rotation. pg_proaudit can switch to a new log file either after the specified time interval, or when the specified size of the log file is exceeded. This enables you to define a workflow for cleaning up security event logs.

Postgres Pro user with the SUPERUSER attribute should grant access to the pg_proaudit extension and security event log files only to the user with the information security administrator role.

F.38.1. Installing the pg_proaudit Extension

The pg_proaudit extension is a built-in extension included into Postgres Pro Standard. To enable pg_proaudit, complete the following steps:

1. Add pg_proaudit to the shared_preload_libraries variable in the postgresql.conf file:

   ```
   shared_preload_libraries = 'pg_proaudit'
   ```

2. Restart the database server for the changes to take effect. To verify that the pg_proaudit library was installed correctly, you can run the following command:

   ```
   SHOW shared_preload_libraries;
   ```

3. In each database for which you are going to log security events, create the pg_proaudit extension using the following query:

   ```
   CREATE EXTENSION pg_proaudit;
   ```

   The pg_proaudit extension adds several functions for managing the pg_proaudit.conf file, the pg_proaudit_settings view that displays the current pg_proaudit rules and event triggers.

F.38.2. Uninstalling the pg_proaudit Extension

To properly uninstall pg_proaudit, complete the following steps:

1. Delete the pg_proaudit extension using the following query:

   ```
   DROP EXTENSION pg_proaudit;
   ```

2. Remove pg_proaudit from the shared_preload_libraries variable in the postgresql.conf file.

   Skip this step if you have several databases in the cluster and you want to remove the extension only for one of them. In this case, it is recommended to remove logging rules related to the corresponding database prior to uninstalling the extension.

F.38.3. Functions to Configure Security Event Logging

To configure security event logging, pg_proaudit provides an SQL interface that consists of several functions and the pg_proaudit_settings view.

```
pg_proaudit_set_rule(db_name text, event_type text, object_type text, object_name text,
 role_name text, comment text)
```

Creates the logging rule with the specified parameters. When the `pg_proaudit_set_rule()` function completes, security event logging starts immediately, but the `pg_proaudit.conf` file is not updated. To save the changes in the `pg_proaudit.conf` file, call the `pg_proaudit_save()` function.

Arguments:

- *`db_name`* — name of the database for which the logging rule is established. An empty string or NULL specified in this argument means that events are logged for all databases where the `pg_proaudit` extension is created. When set to current_database(), events for the current database are logged.
- *`event_type`* — type of the event that needs to be logged, including SQL operator names, as well as `AUTHENTICATE` and `DISCONNECT` events. When set to `ALL`, as well as when an empty string or NULL is specified, enables logging for all events available for the specified object type. For example, for the `TABLE` object type, the `ALL` keyword enables logging for commands `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, `COPY`, as well as `CREATE`, `ALTER`, `DROP`. You can also set up logging of event classes by specifying the following values: `ALL_DDL`, `ALL_DDL_NONTEMP`, `ALL_DML`, `ALL_DML_NONTEMP`, `ALL_MOD`, `ALL_PROC`, and `ALL_ROLE`. For the full list of possible *`event_type`* values, see Section F.38.5.
- *`object_type`* — type of the object for which security events need to be logged. When set to `ALL`, as well as when an empty string or the NULL is specified, enables logging of events for all object types. For example, specify `FOREIGN TABLE` object type for the `SELECT` event to log all attempts to access foreign tables. Use NULL if *`event_type`* is set to `AUTHENTICATE`, `DISCONNECT`, `SET`, or `RESET`, and the `ROLE` value for all events that reference user actions, such as `CREATE USER` or `DROP USER`. The following object types are supported: `COMPOSITE TYPE`, `DATABASE`, `EVENT TRIGGER`, `FUNCTION`, `INDEX`, `PREPARED STATEMENT`, `ROLE`, `SEQUENCE`, `SCHEMA`, `TABLE`, `FOREIGN TABLE`, `TOAST TABLE`, `TABLESPACE`, `VIEW`, `MATERIALIZED VIEW`, `CATALOG RELATION`, and `CATALOG FUNCTION`.

  > **Note**
  >
  > To log security events for system catalog objects, it is required to enable the pg_proaudit.log_catalog_access configuration parameter. Otherwise, these events will not be logged, even if the `CATALOG RELATION`, `CATALOG FUNCTION`, or `ALL` object type is specified in the rule.

- *`object_name`* — name of the object for which the logging rule is established. When an empty string or NULL is specified, enables logging of events for all object names.
- *`role_name`* — name of the role for which the logging rule is established. If specified, allows logging the actions caused by the user who has the privileges of the role. This means that at least one of the user session attributes, `session_user` or `current_user`, should either be equal to the `role_name`, or be directly or indirectly a member of this role. When an empty string or NULL is specified, enables logging of actions caused by any user. When set to current_role, the logging rule is established for the user current role.
- *`comment`* — comment to describe the created logging rule. This argument does not affect the rule execution and is not reflected in the log.

```
pg_proaudit_remove_rule(db_name text, event_type text, object_type text, object_name
 text, role_name text)
```

Removes the specific logging rule with the set parameters. To save the changes in the `pg_proaudit.conf` file, call the `pg_proaudit_save()` function.

> **Note**
>
> If the rule that you want to remove is configured to log the `DISCONNECT` event type, then disconnect events may still be logged after the rule is removed. For additional information, see Section F.38.3.1.

Arguments:

- *db_name* — name of the database for which the logging rule needs to be removed.
- *event_type* — type of the event for which the logging rule needs to be removed. For the full list of possible *event_type* values, see Section F.38.5.
- *object_type* — type of the object for which the logging rule needs to be removed.
- *object_name* — name of the object for which the logging rule needs to be removed.
- *role_name* — name of the role for which the logging rule needs to be removed.

`pg_proaudit_show()`

Returns logged events in a table view. This function is used by the `pg_proaudit_settings` view.

`pg_proaudit_reload()`

Reads logging configuration from the `pg_proaudit.conf` file. You must call this function if the `pg_proaudit.conf` file was modified manually using the operating system facilities.

`pg_proaudit_reset()`

Removes all logging rules. To save information about the canceled logging in the `pg_proaudit.conf` file, call the `pg_proaudit_save()` function.

`pg_proaudit_save()`

Saves logging rules from memory into the `pg_proaudit.conf` file. The `pg_proaudit.conf` file is located in the cluster data directory (`PGDATA`). You cannot change the `pg_proaudit.conf` file location.

F.38.3.1. Handling Database Disconnection Events

When a logging rule is configured for `DISCONNECT` event type, and a user authenticates in a database, then the `pg_proaudit` extension checks whether the corresponding disconnection event satisfies the rule and must be logged.

If the event must be logged, then the removal of the logging rule has no effect on the event. This event will be logged no matter if the logging rule exists at the moment of disconnect.

Consider the following example:

1. An administrator configures the following logging rule:

   ```
   SELECT pg_proaudit_set_rule ('postgres', 'DISCONNECT', null, null, null, 'Any
    disconnect from the postgres DB');
   ```

2. A user connects to the `postgres` database and goes through authentication.

   For the rule in effect, a corresponding disconnection event will be logged later.

3. The administrator removes the logging rule, while the user is still connected to the database:

   ```
   SELECT pg_proaudit_remove_rule('postgres', 'DISCONNECT', null, null, null);
   ```

4. The user disconnects from the database.

   The corresponding disconnection event is logged despite the removal of the logging rule.

F.38.3.2. Handling Object Names

Comparison of string representations of names for database, user, role and other objects is case-insensitive even if the object name in the database is enclosed in quotes. These string representations are stored as lower-case strings.

Strings representing object names need to be passed to functions pg_proaudit_set_rule and pg_proaudit_remove_rule as regular strings: a single quote needs repeating, and other characters are passed as is, without escaping or wrapping.

For example, rules for tables table1 and "TaBlE1" will be the same, and their names can be passed in upper-case or lower-case characters. The same holds for roles. As for databases, before creating a rule, pg_proaudit checks whether this database actually exists, and this check is case-sensitive.

The following examples illustrate creation of "weird" object names and specifying correct audit rules for them.

```
create table "TAbLe''123"();
SELECT pg_proaudit_set_rule(current_database(), null, null, 'public.TabLe''''123',
 null, 'tst cmnt');

create table "taBlE""123"();
SELECT pg_proaudit_set_rule(null, null, null, 'public.taBlE"123', null);

create schema "(BIG!) Schema";
create table "(BIG!) Schema"."My Tab.lE"();
SELECT pg_proaudit_set_rule(null, null, null, '(BIG!) Schema.My Tab.lE', null);

create role "Some '@#$%' person" with login;
SELECT pg_proaudit_set_rule(null, 'authenticate', null, null, 'Some ''@#$%'' person');

create role "Some '@#$%' person" with superuser;
\c - "Some '@#$%' person"
SELECT pg_proaudit_set_rule(null, 'disconnect', null, null, current_user);

create database " D B 1";
SELECT pg_proaudit_set_rule(' D B 1', 'authenticate', null, null, null);

create database " D b 2";
\c " D b 2"
create extension pg_proaudit;
SELECT pg_proaudit_set_rule(current_database(), 'disconnect', null, null, null);
```

F.38.4. pg_proaudit_settings View

This view displays the current pg_proaudit rules, even if they have not been saved into the pg_proaudit.conf file yet. The pg_proaudit_settings view consists of the following columns:

- *db_name* (text) — name of the database for which to log security events.
- *event_type* (text) — event type to log.
- *object_type* (text) — type of the object for which security events are to be logged.
- *object_name* (text) — name of the object for which security events are to be logged.
- *role_name* (text) — the role on behalf of which logged actions are performed.
- *comment* (text) — comment to describe the created logging rule.

F.38.5. Security Events

You can configure the pg_proaudit extension to log classes of security events and specific events by specifying the respective value in the *event_type* argument of the pg_proaudit_set_rule() function.

The following classes of security events are supported:

- ALL_DDL: CREATE, ALTER, DROP for any database object except stored procedures and functions.
- ALL_DDL_NONTEMP: same as ALL_DDL but the scope is limited to the objects that are not contained in pg_temp_*nnn* temporary schemas.

- ALL_DML: SELECT, INSERT, UPDATE, DELETE, TRUNCATE for any table type; EXECUTE for functions and stored procedures.
- ALL_DML_NONTEMP: same as ALL_DML but the scope is limited to the objects that are not contained in pg_temp_*nnn* temporary schemas.
- ALL_MOD: INSERT, UPDATE, DELETE, TRUNCATE for any table type.
- ALL_PROC: CREATE, ALTER, DROP for any function and stored procedure.
- ALL_ROLE: CREATE, ALTER, DROP for USER, ROLE, GROUP, PROFILE, as well as execution of the GRANT command.

The following specific security events are supported:

- AUTHENTICATE
- DISCONNECT
- ALTER AGGREGATE
- ALTER COLLATION
- ALTER CONVERSION
- ALTER DATABASE
- ALTER DEFAULT PRIVILEGES
- ALTER DOMAIN
- ALTER EVENT TRIGGER
- ALTER EXTENSION
- ALTER FOREIGN DATA WRAPPER
- ALTER FOREIGN TABLE
- ALTER FUNCTION
- ALTER INDEX
- ALTER LANGUAGE
- ALTER LARGE OBJECT
- ALTER MATERIALIZED VIEW
- ALTER OPERATOR
- ALTER OPERATOR CLASS
- ALTER OPERATOR FAMILY
- ALTER POLICY
- ALTER PROFILE
- ALTER ROLE, ALTER USER, ALTER GROUP
- ALTER RULE
- ALTER SCHEMA
- ALTER SEQUENCE
- ALTER SERVER
- ALTER SYSTEM
- ALTER TABLE
- ALTER TABLESPACE
- ALTER TEXT SEARCH CONFIGURATION
- ALTER TEXT SEARCH DICTIONARY
- ALTER TEXT SEARCH PARSER
- ALTER TEXT SEARCH TEMPLATE
- ALTER TRIGGER
- ALTER TYPE
- ALTER USER MAPPING
- ALTER VIEW
- CLUSTER
- COMMENT
- COPY

- CREATE ACCESS METHOD
- CREATE AGGREGATE
- CREATE CAST
- CREATE COLLATION
- CREATE CONVERSION
- CREATE DATABASE
- CREATE DOMAIN
- CREATE EVENT TRIGGER
- CREATE EXTENSION
- CREATE FOREIGN DATA WRAPPER
- CREATE FOREIGN TABLE
- CREATE FUNCTION
- CREATE INDEX
- CREATE LANGUAGE
- CREATE MATERIALIZED VIEW
- CREATE OPERATOR
- CREATE OPERATOR CLASS
- CREATE OPERATOR FAMILY
- CREATE POLICY
- CREATE PROFILE
- CREATE ROLE, CREATE USER, CREATE GROUP
- CREATE RULE
- CREATE SCHEMA
- CREATE SEQUENCE
- CREATE SERVER
- CREATE TABLE, CREATE TABLE AS, SELECT INTO
- CREATE TABLESPACE
- CREATE TEXT SEARCH CONFIGURATION
- CREATE TEXT SEARCH DICTIONARY
- CREATE TEXT SEARCH PARSER
- CREATE TEXT SEARCH TEMPLATE
- CREATE TRANSFORM
- CREATE TRIGGER
- CREATE TYPE
- CREATE USER MAPPING
- CREATE VIEW
- DEALLOCATE
- DELETE
- DO
- DROP ACCESS METHOD
- DROP AGGREGATE
- DROP CAST
- DROP COLLATION
- DROP CONVERSION
- DROP DATABASE
- DROP DOMAIN
- DROP EVENT TRIGGER
- DROP EXTENSION
- DROP FOREIGN DATA WRAPPER
- DROP FOREIGN TABLE
- DROP FUNCTION

- DROP INDEX
- DROP LANGUAGE
- DROP MATERIALIZED VIEW
- DROP OPERATOR
- DROP OPERATOR CLASS
- DROP OPERATOR FAMILY
- DROP OWNED
- DROP POLICY
- DROP PROFILE
- DROP ROLE, DROP USER, DROP GROUP
- DROP RULE
- DROP SCHEMA
- DROP SEQUENCE
- DROP SERVER
- DROP TABLE
- DROP TABLESPACE
- DROP TEXT SEARCH CONFIGURATION
- DROP TEXT SEARCH DICTIONARY
- DROP TEXT SEARCH PARSER
- DROP TEXT SEARCH TEMPLATE
- DROP TRANSFORM
- DROP TRIGGER
- DROP TYPE
- DROP USER MAPPING
- DROP VIEW
- EXECUTE
- GRANT
- INSERT
- PREPARE
- REASSIGN OWNED
- REFRESH MATERIALIZED VIEW
- REINDEX
- RESET
- REVOKE
- SECURITY LABEL
- SELECT
- SET
- UPDATE
- TRUNCATE TABLE

F.38.6. Security Event Log Configuration Parameters

The `pg_proaudit` extension provides several configuration parameters for managing security event log files. These parameters can be set in the `postgresql.conf` configuration file, or with the help of the `ALTER SYSTEM` command. For the changes to take effect, call the `pg_reload_conf()` function or restart the database server. For additional configuration, the syslog_ident and syslog_facility configuration parameters can be used.

`pg_proaudit.log_destination` (`string`)

Defines the method for logging security events. Possible values are:

- `csvlog` — log security events in a CSV file.

- `ceflog` — log security events in a CEF file. CEF is an open text-based format designed for log records. It contains a standard header and a variable extension formatted as key-value pairs.
- `syslog` — log security events in syslog.

You can specify one or more values separated by commas.

Default: `csvlog`

`pg_proaudit.log_catalog_access` (`boolean`)

Specifies whether to log access to system catalog objects in the `pg_catalog` schema.

When set to `off`, no events will be logged, even if there are rules for the `CATALOG RELATION`, `CATALOG FUNCTION`, or `ALL` object types.

It is not recommended to set the parameter to `on`, if you do not plan to log events for system catalog objects. Doing otherwise may impact Postgres Pro performance, even if there are no rules for the aforementioned object types.

Default: `off`

`pg_proaudit.log_command_text` (`boolean`)

Specifies whether to log the SQL command text for security events.

Default: `on`

`pg_proaudit.log_directory` (`string`)

Specifies the path to the directory that stores CSV and CEF log files. This can be an absolute path or a relative path to the cluster data directory (`PGDATA`). This parameter is used if the `csvlog` or `ceflog` value is specified in the pg_proaudit.log_destination parameter.

Default: `pg_proaudit`

`pg_proaudit.log_filename` (`string`)

Defines the filenames of the created security event log files. The filename template can contain %-escapes, similar to the ones listed in the `strftime` specification of the Open Group (*http://pubs.opengroup.org/onlinepubs/009695399/functions/strftime.html*). This parameter is used if the `csvlog` or `ceflog` value is specified in the pg_proaudit.log_destination parameter.

Default: `postgresql-%Y-%m-%d_%H%M%S.log`

`pg_proaudit.log_rotation_size` (`integer`)

Sets the maximum size of a log file, in kilobytes. When this size is achieved, `pg_proaudit` creates a new file for logging security events. If set to `0`, disables size-based creation of new log files. This parameter is used if the `csvlog` or `ceflog` value is specified in the pg_proaudit.log_destination parameter.

Default: 10MB

`pg_proaudit.log_rotation_age` (`integer`)

Sets the maximum lifetime of a log file, in minutes. After this timeframe is elapsed, `pg_proaudit` creates a new file for logging security events. If set to `0`, disables time-based creation of new log files. This parameter is used if the `csvlog` or `ceflog` value is specified in the pg_proaudit.log_destination parameter.

Default: 1 day

`pg_proaudit.log_truncate_on_rotation` (`boolean`)

Specifies whether to truncate log files when logging is switched to an existing log file. If set to `off`, `pg_proaudit` appends new log entries to the end of the file. This parameter is used if the `csvlog` or `ceflog` value is specified in the pg_proaudit.log_destination parameter.

Default: `off`

`pg_proaudit.max_rules_count` (`integer`)

Specifies the maximum number of rules allowed. For the parameter changes to take effect, the database server must be restarted.

Default: 500

F.38.7. Viewing Security Event Log

Security event log files are text files that can be viewed by the operating system facilities. To access log files using SQL, you can use the `file_fdw` extension — a foreign data wrapper for accessing files on the database server. To use this method, complete the following steps:

1. Install the `file_fdw` and create an external server:

```
CREATE EXTENSION file_fdw;
CREATE SERVER pg_proauditlog FOREIGN DATA WRAPPER file_fdw;
```

2. Create a foreign table, specifying the columns and the absolute path to the log file. The actual log file location is determined by the `pg_proaudit.log_directory` and `pg_proaudit.log_filename` parameters.

```
CREATE FOREIGN TABLE pg_proaudit_log
      ( log_time timestamp(3) with time zone,
        current_usr_name text,
        database_name text,
        session_pid text,
        error_severity text,
        session_line_num bigint,
        session_line_subcommand_num bigint,
        event_type text,
        object_type text,
        object_name text,
        status text,
        error_message text,
        query_text text,
        query_args text,
        session_usr_name text,
        uuid text,
        xid text,
        vxid text )

SERVER pg_proauditlog
OPTIONS (filename 'absolute_file_path_to_log_file.csv', FORMAT 'csv' );
```

Make sure that the `pg_proaudit.log_destination` parameter contains the `csvlog` value, which enables writing security event logs to CSV files.

F.38.8. Examples

As an example, let's set up logging for the following security events:

- authentications/disconnections to the `postgres` database

- all actions of the user if at least one of the user session attributes, `session_user` or `current_user`, is either explicitly set to the `postgres` role, or is directly or indirectly a member of this role
- creating, updating, and deleting any tables
- all operations on the `app_table` table that belongs to the `public` schema

All events must be logged in the CSV format and stored for a week. It is required to set up SQL access to the security event log. To complete the scenario, do the following:

In psql, check that the preliminary setup of the `pg_proaudit` extension is complete in the `postgres` database:

```
SHOW shared_preload_libraries;
 shared_preload_libraries
--------------------------
 pg_proaudit

\dx pg_proaudit
                   List of installed extensions
    Name     | Version | Schema |           Description
-------------+---------+--------+---------------------------------
 pg_proaudit | 2.0     | public | provides auditing functionality
```

Add the following lines to the `postgresql.conf` configuration file:

```
pg_proaudit.log_destination = 'csvlog'
pg_proaudit.log_directory = 'audit'
pg_proaudit.log_filename = 'audit-%u.csv'
pg_proaudit.log_rotation_age = 1440
pg_proaudit.log_rotation_size = 0
pg_proaudit.log_truncate_on_rotation = on
pg_proaudit.log_command_text = on
```

For the changes to take effect, run the following query:

```
SELECT pg_reload_conf();
```

Check that the following parameters are set as expected:

```
SHOW pg_proaudit.log_destination;
SHOW pg_proaudit.log_directory;
SHOW pg_proaudit.log_filename;
SHOW pg_proaudit.log_rotation_age;
SHOW pg_proaudit.log_rotation_size;
SHOW pg_proaudit.log_truncate_on_rotation;
SHOW pg_proaudit.log_command_text;
```

Suppose your `PGDATA` environment variable points to the cluster data directory. Since the `pg_proaudit.log_directory` defines a relative path to the log files, they will be located in the `$PGDATA/audit` directory. Let's create an empty file for each day of the week and make them available to their owner only:

```
touch $PGDATA/audit/audit-1.csv
touch $PGDATA/audit/audit-2.csv
touch $PGDATA/audit/audit-3.csv
touch $PGDATA/audit/audit-4.csv
touch $PGDATA/audit/audit-5.csv
touch $PGDATA/audit/audit-6.csv
touch $PGDATA/audit/audit-7.csv
chmod 600 $PGDATA/audit/audit-*.csv
```

Create a table for reading log entries:

```
CREATE TABLE pg_proaudit_log (
```

```
  log_time timestamp(3) with time zone,
  current_usr_name text,
  database_name text,
  session_pid text,
  error_severity text,
  session_line_num bigint,
  session_line_subcommand_num bigint,
  event_type text,
  object_type text,
  object_name text,
  status text,
  error_message text,
  query_text text,
  query_args text,
  session_usr_name text,
  uuid text,
  xid text,
  vxid text
);
```

Install the `file_fdw` extension and create an external server:

```
CREATE EXTENSION file_fdw;
CREATE SERVER pg_proauditlog FOREIGN DATA WRAPPER file_fdw;
```

Now let's create seven child foreign tables for the `pg_proaudit_log` table, for each day of the week:

```
CREATE FOREIGN TABLE pg_proaudit_log_1 () INHERITS (pg_proaudit_log) SERVER
 pg_proauditlog
   OPTIONS (filename '/path_to_PGDATA/audit/audit-1.csv',  FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_2 () INHERITS (pg_proaudit_log) SERVER
 pg_proauditlog
   OPTIONS (filename '/path_to_PGDATA/audit/audit-2.csv',  FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_3 () INHERITS (pg_proaudit_log) SERVER
 pg_proauditlog
   OPTIONS (filename '/path_to_PGDATA/audit/audit-3.csv',  FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_4 () INHERITS (pg_proaudit_log) SERVER
 pg_proauditlog
   OPTIONS (filename '/path_to_PGDATA/audit/audit-4.csv',  FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_5 () INHERITS (pg_proaudit_log) SERVER
 pg_proauditlog
   OPTIONS (filename '/path_to_PGDATA/audit/audit-5.csv',  FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_6 () INHERITS (pg_proaudit_log) SERVER
 pg_proauditlog
   OPTIONS (filename '/path_to_PGDATA/audit/audit-6.csv',  FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_7 () INHERITS (pg_proaudit_log) SERVER
 pg_proauditlog
   OPTIONS (filename '/path_to_PGDATA/audit/audit-7.csv',  FORMAT 'csv');
```

To set up logging for the required security events, connect to the `postgres` database and execute the following commands:

```
SELECT pg_proaudit_set_rule (current_database(), 'AUTHENTICATE', null, null, null, 'Any
 authentication in the current DB');
SELECT pg_proaudit_set_rule (current_database(), 'DISCONNECT', null, null, null, 'Any
 disconnect from the current DB');
SELECT pg_proaudit_set_rule (current_database(), 'ALL', 'TABLE', null, null, 'Any
 operations with any table in the current DB');
SELECT pg_proaudit_set_rule (current_database(), 'ALL', null, null, 'postgres', 'Any
 operation by "postgres" user in the current DB');
```

Create the app_table table and enable logging for all operations on this table:

```
CREATE TABLE app_table (id int, name text);
SELECT pg_proaudit_set_rule (current_database(), 'ALL', null, 'public.app_table',
 null);
```

Check that event logging is configured as expected:

```
SELECT * FROM pg_proaudit_settings;
 db_name  |  event_type  | object_type |   object_name    | role_name |
      comment
----------+--------------+-------------+------------------+-----------
+-------------------------------------------------
 postgres | authenticate | ALL         |                  |           | Any
 authentication in the current DB
 postgres | disconnect   | ALL         |                  |           | Any disconnect
 from the current DB
 postgres | ALL          | table       |                  |           | Any operations
 with any table in the current DB
 postgres | ALL          | ALL         |                  | postgres  | Any operation
 by "postgres" user in the current DB
 postgres | ALL          | ALL         | public.app_table |           |
(5 rows)
```

Save these logging rules into the pg_proaudit.conf file, so that they are not lost after the server restart:

```
SELECT pg_proaudit_save();
```

Let's run several queries on the app_table table:

```
INSERT INTO app_table VALUES (1, 'first');
SELECT * FROM app_table;
```

Check the log entries for the app_table table:

```
SELECT to_char(log_time, 'DD.MM.YY HH24:MI:SS') AS when, current_usr_name,
      session_pid, event_type, query_text, session_usr_name
FROM pg_proaudit_log
WHERE object_name = 'public.app_table';
       when        | current_usr_name | session_pid |  event_type  |
 query_text                  | session_usr_name
-------------------+------------------+-------------+--------------
+-------------------------------------------+------------------
 27.09.23 12:44:27 | postgres         | 2010        | CREATE TABLE | CREATE TABLE
 app_table (id int, name text); | postgres
 27.09.23 12:45:55 | postgres         | 2010        | INSERT       | INSERT INTO
 app_table VALUES (1, 'first');  | postgres
 27.09.23 12:46:00 | postgres         | 2010        | SELECT       | SELECT * FROM
 app_table;                    | postgres
(3 rows)
```

We have set up a weekly rotation of log files, with the log file switched once a day. It means that queries to the pg_proaudit_log table will return only those security events that have happened in the latest week. Older events will be automatically removed at log file rotation. To define additional access constraints for specific log entries, you can create separate views based on queries to the pg_proaudit_log table and grant read rights to such views using built-in Postgres Pro access control methods.

F.39. pgpro_bindump

pgpro_bindump is a module designed to implement additional commands for the Postgres Pro replication protocol, specifically for use with the *pg_probackup3* utility. pgpro_bindump offers the following benefits:

- Simplified communication: pgpro_bindump does not require the SSH protocol and associated configurations to connect to a database server.
- Integrated WAL transfer: WAL files are transferred together with data files, reducing the risk of data loss during backups.
- Optimized storage: Files are not copied as they are, but are archived using the pg_probackup3 own format, CBOR (RFC 8949 Concise Binary Object Representation), which enhances the storage efficiency.

F.39.1. Architecture

A dedicated backend process is created to handle connections from external applications. You can use the pg_probackup3 utility or a custom application to send requests to this backend.

Multiple connections can be established for the same application if needed.

Since the pgpro_bindump module has direct access to the database files, it does not require any additional permissions.

pgpro_bindump uses the *libpgprobackup*, along with its built-in encoder module, to send data to the application.

The walsender_plugin_libraries plugin has been added to simplify the process of adding and utilizing new replication commands, including custom ones.

F.39.2. Limitations and Requirements

pgpro_bindump currently has the following limitations and requirements:

- libpgprobackup.so and libpb3_encoder.so are required for pgpro_bindump operation.

F.39.3. Installation and Setup

The pgpro_bindump module is included in Postgres Pro as part of the postgrespro-std-14-contrib package (for the installation instructions, see Chapter 16). Once you complete Postgres Pro installation, follow the steps below.

1. Specify the following parameters in the postgresql.conf file:

```
shared_preload_libraries = 'pgpro_bindump'
wal_level = 'replica' # or 'logical'
walsender_plugin_libraries = 'pgpro_bindump'
```

2. Restart the Postgres Pro instance.

F.39.4. Replication Commands

The pgpro_bindump module implements the following replication commands:

- just-noop — a do-nothing command.
- start_backup — starts the backup process.
- copy_files — copies files in the CBOR format.
- stop_backup — stops the backup process.

The backup process runs in the PRO mode — an advanced data source mode that incorporates all available optimizations and enhancements, including the proprietary replication protocol and specialized replication commands.

To send commands from a user application to pgpro_bindump and to receive the output data from pgpro_bindump by the application, use libpq.

> **Note**
>
> An established connection to a running Postgres Pro server is required.

F.39.4.1. start_backup

```
start_backup LABEL label, INCR_MODE incr_mode, START_LSN start_lsn,
 TRANSFER_MODE transfer_mode,
[TRANSFER_BUFFER_SIZE buffer_size]
```

Starts the backup process. Sends the following data to the application:

- `start_lsn` — LSN at the start of the backup.
- `start_tli` — the timeline ID at the start of the backup.
- `min_xid` — the minimal transaction ID at the start of the backup.
- `min_multixact` — the minimal `multixact` ID at the start of the backup.
- `tablespace_list` — a list of tablespaces included in the backup.
- `database_list` — a list of databases included in the backup.

`LABEL` *label*

The name of the backup.

`INCR_MODE` *incr_mode*

The type of incremental backup. Possible values: `PTRACK`, `DELTA`.

`START_LSN` *start_lsn*

An `XLogRecPtr` value representing LSN at the start of the backup.

`TRANSFER_MODE` *transfer_mode*

The method to be used for sending data from a server to an application. Possible values:

- `raw` — unpacked data is sent in random blocks of arbitrary size.
- `packed` — packed data is sent in blocks of 128 KB with a common header.

`packed` is the default value.

`TRANSFER_BUFFER_SIZE` *buffer_size*

A numeric value representing the buffer size. The preset (unchanged) value is 131072 (128 KB).

F.39.4.2. copy_files

```
copy_files VERIFY_CHECKSUMS [TRUE | FALSE], COMPRESS_ALG compress_alg,
 COMPRESS_LVL compress_lvl, TRANSFER_MODE transfer_mode,
[INCR_MODE incr_mode], [START_LSN start_lsn], [TRANSFER_BUFFER_SIZE buffer_size],
[WORKER_INFO number_of_workers:worker_id]
```

Forwards blocks of data files and WAL files packaged in the `CBOR` format.

`VERIFY_CHECKSUMS`

A boolean value (`true` or `false`) indicating whether to verify checksums.

`COMPRESS_ALG` *`compress_alg`*

The compression algorithm to be used. Possible values: `zlib`, `zstd`, `lz4`, `none`.

`COMPRESS_LVL` *`compress_lvl`*

The compression level. Possible values: 1, 2, 3, 4, 5.

`TRANSFER_MODE` *`transfer_mode`*

The method to be used for sending data from a server to an application. Possible values:

- `raw` — unpacked data is sent in random blocks of arbitrary size.
- `packed` — packed data is sent in blocks of 128 KB with a common header.

`packed` is the default value.

`INCR_MODE` *`incr_mode`*

The type of incremental backup. Possible values: `PTRACK`, `DELTA`.

`START_LSN` *`start_lsn`*

An `XLogRecPtr` value representing LSN at the start of the backup.

`TRANSFER_BUFFER_SIZE` *`buffer_size`*

A numeric value representing the buffer size. The preset (unchanged) value is 131072 (128 KB).

`WORKER_INFO` *`number_of_workers`*`:`*`worker_id`*

The number of workers and the worker ID.

F.39.4.3. stop_backup

```
stop_backup STREAM [TRUE | FALSE], COMPRESS_ALG compress_alg,
 COMPRESS_LVL compress_lvl,
[EXTERNALS externals] [TRANSFER_BUFFER_SIZE buffer_size], [TRANSFER_MODE transfer_mode]
```

Completes the copy process and closes the existing connection. Sends the following data to the application:

- `stop_lsn` — LSN at the end of the backup.
- `stop_tli` — the timeline ID at the end of the backup.
- The `backup.control` file.
- A set of WAL files (only if WAL streaming is enabled).

`STREAM`

A boolean value (`true` or `false`) indicating whether WAL streaming is enabled.

`COMPRESS_ALG` *`compress_alg`*

The compression algorithm to be used. Possible values: `zlib`, `zstd`, `lz4`, `none`.

`COMPRESS_LVL` *`compress_lvl`*

The compression level. Possible values: 1, 2, 3, 4, 5.

`EXTERNALS` *externals*

A list of external directories.

`TRANSFER_BUFFER_SIZE` *buffer_size*

A numeric value representing the buffer size. The preset (unchanged) value is 131072 (128 KB).

`TRANSFER_MODE` *transfer_mode*

The method to be used for sending data from a server to an application. Possible values:

- `raw` — unpacked data is sent in random blocks of arbitrary size.
- `packed` — packed data is sent in blocks of 128 KB with a common header.

`packed` is the default value.

F.39.5. Authors

Postgres Professional, Moscow, Russia.

F.40. pg_prewarm

The `pg_prewarm` module provides a convenient way to load relation data into either the operating system buffer cache or the Postgres Pro buffer cache. Prewarming can be performed manually using the `pg_prewarm` function, or can be performed automatically by including `pg_prewarm` in shared_preload_libraries. In the latter case, the system will run a background worker which periodically records the contents of shared buffers in a file called `autoprewarm.blocks` and will, using 2 background workers, reload those same blocks after a restart.

F.40.1. Functions

```
pg_prewarm(regclass, mode text default 'buffer', fork text default 'main',
           first_block int8 default null,
           last_block int8 default null) RETURNS int8
```

The first argument is the relation to be prewarmed. The second argument is the prewarming method to be used, as further discussed below; the third is the relation fork to be prewarmed, usually `main`. The fourth argument is the first block number to prewarm (`NULL` is accepted as a synonym for zero). The fifth argument is the last block number to prewarm (`NULL` means prewarm through the last block in the relation). The return value is the number of blocks prewarmed.

There are three available prewarming methods. `prefetch` issues asynchronous prefetch requests to the operating system, if this is supported, or throws an error otherwise. `read` reads the requested range of blocks; unlike `prefetch`, this is synchronous and supported on all platforms and builds, but may be slower. `buffer` reads the requested range of blocks into the database buffer cache.

Note that with any of these methods, attempting to prewarm more blocks than can be cached — by the OS when using `prefetch` or `read`, or by Postgres Pro when using `buffer` — will likely result in lower-numbered blocks being evicted as higher numbered blocks are read in. Prewarmed data also enjoys no special protection from cache evictions, so it is possible that other system activity may evict the newly prewarmed blocks shortly after they are read; conversely, prewarming may also evict other data from cache. For these reasons, prewarming is typically most useful at startup, when caches are largely empty.

```
autoprewarm_start_worker() RETURNS void
```

Launch the main autoprewarm worker. This will normally happen automatically, but is useful if automatic prewarm was not configured at server startup time and you wish to start up the worker at a later time.

```
autoprewarm_dump_now() RETURNS int8
```

Update `autoprewarm.blocks` immediately. This may be useful if the autoprewarm worker is not running but you anticipate running it after the next restart. The return value is the number of records written to `autoprewarm.blocks`.

F.40.2. Configuration Parameters

`pg_prewarm.autoprewarm` (`boolean`)

Controls whether the server should run the autoprewarm worker. This is on by default. This parameter can only be set at server start.

`pg_prewarm.autoprewarm_interval` (`int`)

This is the interval between updates to `autoprewarm.blocks`. The default is 300 seconds. If set to 0, the file will not be dumped at regular intervals, but only when the server is shut down.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'pg_prewarm'

pg_prewarm.autoprewarm = true
pg_prewarm.autoprewarm_interval = 300s
```

F.41. pg_query_state

The `pg_query_state` module provides facility to know the current state of query execution on working backend.

F.41.1. Overview

Each non-utility query statement (SELECT/INSERT/UPDATE/DELETE) after optimization/planning stage is translated into plan tree, which is kind of imperative representation of declarative SQL query. EXPLAIN ANALYZE request allows to demonstrate execution statistics gathered from each node of plan tree (full time of execution, number of rows emitted to upper nodes, etc). But this statistics is collected after execution of query. This module allows to show actual statistics of query running on external backend. At that, format of resulting output is almost identical to ordinal EXPLAIN ANALYZE. Thus users are able to track of query execution in progress. In fact, this module is able to explore external backend and determine its actual state. Particularly it's helpful when backend executes a heavy query or gets stuck.

F.41.2. Use cases

Using this module there can help in the following things:

- detect a long query (along with other monitoring tools);
- supervise query execution.

F.41.3. Installation

To install pg_query_state, complete the following steps:

1. Add the library name to the `shared_preload_libraries` parameter in the `postgresql.conf` file as follows:

```
shared_preload_libraries = 'pg_query_state'
```

2. Reload the database server for the changes to take effect.
3. Create the pg_query_state extension using the following query:

```
CREATE EXTENSION pg_query_state;
```

4. If you need to upgrade the pg_query_state extension, use `ALTER EXTENSION UPDATE`.

F.41.4. Functions

F.41.4.1. pg_query_state

```
pg_query_state (integer  pid,
                verbose  boolean DEFAULT FALSE,
                costs    boolean DEFAULT FALSE,
                timing   boolean DEFAULT FALSE,
                buffers  boolean DEFAULT FALSE,
                triggers boolean DEFAULT FALSE,
                format   text    DEFAULT 'text')
  returns TABLE (pid integer,
                 frame_number integer,
                 query_text text,
                 plan text,
                 leader_pid integer)
```

Extract current query state from backend with specified `pid`. Since parallel query can spawn multiple workers and function call causes nested subqueries so that state of execution may be viewed as stack of running queries, return value of pg_query_state has type `TABLE (pid integer, frame_number integer, query_text text, plan text, leader_pid integer)`. It represents tree structure consisting of leader process and its spawned workers identified by `pid`. Each worker refers to leader through `leader_pid` column. For leader process the value of this column is `null`. The state of each process is represented as stack of function calls. Each frame of that stack is specified as correspondence between `frame_number` starting from zero, `query_text` and `plan` with online statistics columns.

Thus, user can see the states of main query and queries generated from function calls for leader process and all workers spawned from it.

In process of execution some nodes of plan tree can take loops of full execution. Therefore statistics for each node consists of two parts: average statistics for previous loops just like in EXPLAIN ANALYZE output and statistics for current loop if node have not finished.

Optional arguments:

- verbose - use EXPLAIN VERBOSE for plan printing;
- costs - costs for each node;
- timing - print timing data for each node, if collecting of timing statistics is turned off on called side resulting output will contain WARNING message `timing statistics disabled`;
- buffers - print buffers usage, if collecting of buffers statistics is turned off on called side resulting output will contain WARNING message `buffers statistics disabled`;
- triggers - include triggers statistics in result plan trees;
- format - EXPLAIN format to be used for plans printing, possible values: text, xml, json, yaml.

If callable backend is not executing any query the function prints INFO message about backend's state taken from `pg_stat_activity` view if it exists there.

Calling role have to be superuser or member of the role whose backend is being called. Otherwise function prints ERROR message `permission denied`.

F.41.4.2. pg_progress_bar

```
pg_progress_bar (integer pid)
  returns FLOAT
```

Returns the current progress of query execution. This function extracts the state of the current query from the backend process with the specified `pid`. Then, it collects the actual and expected row counts from all plan nodes, and computes the overall progress ratio for the entire execution tree. As a result, the function returns a numeric value from `0` to `1` that means the query execution progress.

This function can be used in the Postgres Pro GUI to display the graphical progress bar indicator.

If there is no information about the current query state or it is impossible to calculate the query execution progress, the corresponding message is displayed.

This function can be called only by members of the role that owns the backend process or superusers.

F.41.4.3. pg_progress_bar_visual

```
pg_progress_bar_visual (integer pid,
                        integer delay)
  returns VOID
```

Cyclically calculates the current progress of query execution and prints it in the text form. The function extracts the state of the current query from the backend process with the specified `pid` with the interval defined in the *`delay`* parameter (in seconds).

This function is a cyclic version of the pg_progress_bar function but returns `void`. Unlike `pg_progress_bar`, the `pg_progress_bar_visual` function can be used to track the query execution progress without using the GUI.

If there is no information about the current query state or it is impossible to calculate the query execution progress, the corresponding message is displayed.

This function can be called only by members of the role that owns the backend process or superusers.

F.41.5. Configuration settings

There are several user-accessible GUC variables designed to toggle the whole module and the collecting of specific statistic parameters while query is running:

- pg_query_state.enable - disable (or enable) pg_query_state completely, default value is `true`
- pg_query_state.enable_timing - collect timing data for each node, default value is `false`
- pg_query_state.enable_buffers - collect buffers usage, default value is `false`

These parameters are set on called side before running any queries whose states are attempted to extract. `WARNING`: if pg_query_state.enable_timing is turned off the calling side cannot get time statistics, similarly for pg_query_state.enable_buffers parameter.

F.41.6. Usage Examples

Set maximum number of parallel workers on `gather` node equals 2:

```
postgres=# set max_parallel_workers_per_gather = 2;
```

Assume one backend with `pid` = 49265 performs a simple query:

```
postgres=# select pg_backend_pid();
pg_backend_pid
```

```
----------------
    49265
(1 row)
postgres=# select count(*) from foo join bar on foo.c1=bar.c1;
```

Other backend can extract intermediate state of execution that query:

```
postgres=# \x
postgres=# select * from pg_query_state(49265);
-[ RECORD
 1 ]+-----------------------------------------------------------------------------------
pid          | 49265
frame_number | 0
query_text   | select count(*) from foo join bar on foo.c1=bar.c1;
plan         | Finalize Aggregate (Current loop: actual rows=0, loop number=1)
                                                 +
             |   ->  Gather (Current loop: actual rows=0, loop number=1)
                                                 +
             |         Workers Planned: 2
                                                 +
             |         Workers Launched: 2
                                                 +
             |         ->  Partial Aggregate (Current loop: actual rows=0, loop
 number=1)                                         +
             |               ->  Nested Loop (Current loop: actual rows=12, loop
 number=1)                                        +
             |                     Join Filter: (foo.c1 = bar.c1)
                                                 +
             |                     Rows Removed by Join Filter: 5673232
                                                 +
             |                     ->  Parallel Seq Scan on foo (Current loop: actual
 rows=12, loop number=1)                           +
             |                     ->  Seq Scan on bar (actual rows=500000 loops=11)
 (Current loop: actual rows=173244, loop number=12)
leader_pid   | (null)
-[ RECORD
 2 ]+-----------------------------------------------------------------------------------
pid          | 49324
frame_number | 0
query_text   | <parallel query>
plan         | Partial Aggregate (Current loop: actual rows=0, loop number=1)
                                                 +
             |   ->  Nested Loop (Current loop: actual rows=10, loop number=1)
                                                 +
             |         Join Filter: (foo.c1 = bar.c1)
                                                 +
             |         Rows Removed by Join Filter: 4896779
                                                 +
             |         ->  Parallel Seq Scan on foo (Current loop: actual rows=10, loop
 number=1)                                       +
             |         ->  Seq Scan on bar (actual rows=500000 loops=9) (Current loop:
 actual rows=396789, loop number=10)
leader_pid   | 49265
-[ RECORD
 3 ]+-----------------------------------------------------------------------------------
pid          | 49323
frame_number | 0
query_text   | <parallel query>
```

```
plan         | Partial Aggregate (Current loop: actual rows=0, loop number=1)
                                        +
             |   ->  Nested Loop (Current loop: actual rows=11, loop number=1)
                                        +
             |         Join Filter: (foo.c1 = bar.c1)
                                        +
             |         Rows Removed by Join Filter: 5268783
                                        +
             |         ->  Parallel Seq Scan on foo (Current loop: actual rows=11, loop
 number=1)                              +
             |         ->  Seq Scan on bar (actual rows=500000 loops=10) (Current loop:
 actual rows=268794, loop number=11)
leader_pid   | 49265
```

In example above working backend spawns two parallel workers with pids 49324 and 49323. Their `leader_pid` column's values clarify that these workers belong to the main backend. `Seq Scan` node has statistics on passed loops (average number of rows delivered to `Nested Loop` and number of passed loops are shown) and statistics on current loop. Other nodes has statistics only for current loop as this loop is first (loop number = 1).

Assume first backend executes some function:

```
postgres=# select n_join_foo_bar();
```

Other backend can get the follow output:

```
postgres=# select * from pg_query_state(49265);
-[ RECORD
 1 ]+-----------------------------------------------------------------------------------------
pid          | 49265
frame_number | 0
query_text   | select n_join_foo_bar();
plan         | Result (Current loop: actual rows=0, loop number=1)
leader_pid   | (null)
-[ RECORD
 2 ]+-----------------------------------------------------------------------------------------
pid          | 49265
frame_number | 1
query_text   | SELECT (select count(*) from foo join bar on foo.c1=bar.c1)
plan         | Result (Current loop: actual rows=0, loop number=1)
                                     +
             |   InitPlan 1 (returns $0)
                                     +
             |     ->  Aggregate (Current loop: actual rows=0, loop number=1)
                                     +
             |           ->  Nested Loop (Current loop: actual rows=51, loop number=1)
                                     +
             |                 Join Filter: (foo.c1 = bar.c1)
                                     +
             |                 Rows Removed by Join Filter: 51636304
                                     +
             |                 ->  Seq Scan on bar (Current loop: actual rows=52, loop
 number=1)                             +
             |                 ->  Materialize (actual rows=1000000 loops=51) (Current
 loop: actual rows=636355, loop number=52)+
             |                       ->  Seq Scan on foo (Current loop: actual
 rows=1000000, loop number=1)
leader_pid   | (null)
```

First row corresponds to function call, second - to query which is in the body of that function.

We can get result plans in different format (e.g. json):

```
postgres=# select * from pg_query_state(pid := 49265, format := 'json');
-[ RECORD 1 ]+------------------------------------------------------------
pid          | 49265
frame_number | 0
query_text   | select * from n_join_foo_bar();
plan         | {                                                          +
             |   "Plan": {                                                +
             |     "Node Type": "Function Scan",                          +
             |     "Parallel Aware": false,                               +
             |     "Function Name": "n_join_foo_bar",                     +
             |     "Alias": "n_join_foo_bar",                             +
             |     "Current loop": {                                      +
             |       "Actual Loop Number": 1,                             +
             |       "Actual Rows": 0                                     +
             |     }                                                      +

                |        }                                                    +
                |      ]                                                      +
                |    }                                                        +
                |  }
 leader_pid     |  (null)
```

F.41.7. Progress Bar Usage Examples

The first backend process executes the following sample query:

```
postgres=# insert into table_name select generate_series(1,10000000);
```

Another backend process can get the execution process of the query above as follows:

```
postgres=# SELECT pid FROM pg_stat_activity where query like 'insert%';
  pid
-------
 23877
```

```
(1 row)

postgres=# SELECT pg_progress_bar(23877);
 pg_progress_bar
-----------------
       0.6087927
(1 row)
```

To display a visual representation of the query execution progress, run the following query:

```
postgres=# SELECT pg_progress_bar_visual(23877, 1);
Progress = 0.043510
Progress = 0.085242
Progress = 0.124921
Progress = 0.168168
Progress = 0.213803
Progress = 0.250362
Progress = 0.292632
Progress = 0.331454
Progress = 0.367509
Progress = 0.407450
Progress = 0.448646
Progress = 0.488171
Progress = 0.530559
Progress = 0.565558
Progress = 0.608039
Progress = 0.645778
Progress = 0.654842
Progress = 0.699006
Progress = 0.735760
Progress = 0.787641
Progress = 0.832160
Progress = 0.871077
Progress = 0.911858
Progress = 0.956362
Progress = 0.995097
Progress = 1.000000
 pg_progress_bar_visual
------------------------
                      1
(1 row)
```

F.42. pgrowlocks

The `pgrowlocks` module provides a function to show row locking information for a specified table.

By default use is restricted to superusers, members of the `pg_stat_scan_tables` role, and users with `SELECT` permissions on the table.

F.42.1. Overview

```
pgrowlocks(text) returns setof record
```

The parameter is the name of a table. The result is a set of records, with one row for each locked row within the table. The output columns are shown in Table F.25.

Table F.25. `pgrowlocks` Output Columns

Name	Type	Description
`locked_row`	`tid`	Tuple ID (TID) of locked row

Name	Type	Description
locker	xid	Transaction ID of locker, or multixact ID if multitransaction
multi	boolean	True if locker is a multitransaction
xids	xid[]	Transaction IDs of lockers (more than one if multitransaction)
modes	text[]	Lock mode of lockers (more than one if multitransaction), an array of Key Share, Share, For No Key Update, No Key Update, For Update, Update.
pids	integer[]	Process IDs of locking backends (more than one if multitransaction)

pgrowlocks takes AccessShareLock for the target table and reads each row one by one to collect the row locking information. This is not very speedy for a large table. Note that:

1. If an ACCESS EXCLUSIVE lock is taken on the table, pgrowlocks will be blocked.
2. pgrowlocks is not guaranteed to produce a self-consistent snapshot. It is possible that a new row lock is taken, or an old lock is freed, during its execution.

pgrowlocks does not show the contents of locked rows. If you want to take a look at the row contents at the same time, you could do something like this:

```
SELECT * FROM accounts AS a, pgrowlocks('accounts') AS p
  WHERE p.locked_row = a.ctid;
```

Be aware however that such a query will be very inefficient.

F.42.2. Sample Output

```
=# SELECT * FROM pgrowlocks('t1');
 locked_row | locker | multi | xids  |     modes      |  pids
------------+--------+-------+-------+----------------+--------
 (0,1)      |    609 | f     | {609} | {"For Share"}  | {3161}
 (0,2)      |    609 | f     | {609} | {"For Share"}  | {3161}
 (0,3)      |    607 | f     | {607} | {"For Update"} | {3107}
 (0,4)      |    607 | f     | {607} | {"For Update"} | {3107}
(4 rows)
```

Tatsuo Ishii

F.43. pg_stat_statements

The pg_stat_statements module provides a means for tracking planning and execution statistics of all SQL statements executed by a server.

The module must be loaded by adding pg_stat_statements to shared_preload_libraries in postgresql.conf, because it requires additional shared memory. This means that a server restart is needed to add or remove the module. In addition, query identifier calculation must be enabled in order for the module to be active, which is done automatically if compute_query_id is set to auto or on, or any third-party module that calculates query identifiers is loaded.

When pg_stat_statements is active, it tracks statistics across all databases of the server. To access and manipulate these statistics, the module provides views pg_stat_statements and pg_stat_state-

ments_info, and the utility functions pg_stat_statements_reset and pg_stat_statements. These are not available globally but can be enabled for a specific database with CREATE EXTENSION pg_stat_statements.

F.43.1. The pg_stat_statements View

The statistics gathered by the module are made available via a view named pg_stat_statements. This view contains one row for each distinct combination of database ID, user ID, query ID and whether it's a top-level statement or not (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in Table F.26.

Table F.26. pg_stat_statements Columns

Column Type Description
userid oid (references pg_authid .oid) OID of user who executed the statement
dbid oid (references pg_database .oid) OID of database in which the statement was executed
toplevel bool True if the query was executed as a top-level statement (always true if pg_stat_statements.track is set to top)
queryid bigint Hash code to identify identical normalized queries.
query text Text of a representative statement
plans bigint Number of times the statement was planned (if pg_stat_statements.track_planning is enabled, otherwise zero)
total_plan_time double precision Total time spent planning the statement, in milliseconds (if pg_stat_statements.track_planning is enabled, otherwise zero)
min_plan_time double precision Minimum time spent planning the statement, in milliseconds (if pg_stat_statements.track_planning is enabled, otherwise zero)
max_plan_time double precision Maximum time spent planning the statement, in milliseconds (if pg_stat_statements.track_planning is enabled, otherwise zero)
mean_plan_time double precision Mean time spent planning the statement, in milliseconds (if pg_stat_statements.track_planning is enabled, otherwise zero)
stddev_plan_time double precision Population standard deviation of time spent planning the statement, in milliseconds (if pg_stat_statements.track_planning is enabled, otherwise zero)
calls bigint Number of times the statement was executed
total_exec_time double precision Total time spent executing the statement, in milliseconds
min_exec_time double precision Minimum time spent executing the statement, in milliseconds
max_exec_time double precision Maximum time spent executing the statement, in milliseconds

Column Type Description
mean_exec_time double precision Mean time spent executing the statement, in milliseconds
stddev_exec_time double precision Population standard deviation of time spent executing the statement, in milliseconds
rows bigint Total number of rows retrieved or affected by the statement
shared_blks_hit bigint Total number of shared block cache hits by the statement
shared_blks_read bigint Total number of shared blocks read by the statement
shared_blks_dirtied bigint Total number of shared blocks dirtied by the statement
shared_blks_written bigint Total number of shared blocks written by the statement
local_blks_hit bigint Total number of local block cache hits by the statement
local_blks_read bigint Total number of local blocks read by the statement
local_blks_dirtied bigint Total number of local blocks dirtied by the statement
local_blks_written bigint Total number of local blocks written by the statement
temp_blks_read bigint Total number of temp blocks read by the statement
temp_blks_written bigint Total number of temp blocks written by the statement
blk_read_time double precision Total time the statement spent reading blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
blk_write_time double precision Total time the statement spent writing blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
wal_records bigint Total number of WAL records generated by the statement
wal_fpi bigint Total number of WAL full page images generated by the statement
wal_bytes numeric Total amount of WAL generated by the statement in bytes

For security reasons, only superusers and members of the pg_read_all_stats role are allowed to see the SQL text and queryid of queries executed by other users. Other users can see the statistics, however, if the view has been installed in their database.

Plannable queries (that is, SELECT, INSERT, UPDATE, and DELETE) are combined into a single pg_stat_statements entry whenever they have identical query structures according to an internal hash calculation. Typically, two queries will be considered the same for this purpose if they are semantically equivalent except for the values of literal constants appearing in the query. Utility commands (that is, all other commands) are compared strictly on the basis of their textual query strings, however.

Note

The following details about constant replacement and queryid only apply when compute_query_id is enabled. If you use an external module instead to compute queryid, you should refer to its documentation for details.

When a constant's value has been ignored for purposes of matching the query to other queries, the constant is replaced by a parameter symbol, such as $1, in the pg_stat_statements display. The rest of the query text is that of the first query that had the particular queryid hash value associated with the pg_stat_statements entry.

In some cases, queries with visibly different texts might get merged into a single pg_stat_statements entry. Normally this will happen only for semantically equivalent queries, but there is a small chance of hash collisions causing unrelated queries to be merged into one entry. (This cannot happen for queries belonging to different users or databases, however.)

Since the queryid hash value is computed on the post-parse-analysis representation of the queries, the opposite is also possible: queries with identical texts might appear as separate entries, if they have different meanings as a result of factors such as different search_path settings.

Consumers of pg_stat_statements may wish to use queryid (perhaps in combination with dbid and userid) as a more stable and reliable identifier for each entry than its query text. However, it is important to understand that there are only limited guarantees around the stability of the queryid hash value. Since the identifier is derived from the post-parse-analysis tree, its value is a function of, among other things, the internal object identifiers appearing in this representation. This has some counterintuitive implications. For example, pg_stat_statements will consider two apparently-identical queries to be distinct, if they reference a table that was dropped and recreated between the executions of the two queries. The hashing process is also sensitive to differences in machine architecture and other facets of the platform. Furthermore, it is not safe to assume that queryid will be stable across major versions of Postgres Pro.

Two servers participating in replication based on physical WAL replay can be expected to have identical queryid values for the same query. However, logical replication schemes do not promise to keep replicas identical in all relevant details, so queryid will not be a useful identifier for accumulating costs across a set of logical replicas. If in doubt, direct testing is recommended.

Generally, it can be assumed that queryid values are stable between minor version releases of PostgreSQL, providing that instances are running on the same machine architecture and the catalog metadata details match. Compatibility will only be broken between minor versions as a last resort.

The parameter symbols used to replace constants in representative query texts start from the next number after the highest $*n* parameter in the original query text, or $1 if there was none. It's worth noting that in some cases there may be hidden parameter symbols that affect this numbering. For example, PL/pgSQL uses hidden parameter symbols to insert values of function local variables into queries, so that a PL/pgSQL statement like SELECT i + 1 INTO j would have representative text like SELECT i + $2.

The representative query texts are kept in an external disk file, and do not consume shared memory. Therefore, even very lengthy query texts can be stored successfully. However, if many long query texts are accumulated, the external file might grow unmanageably large. As a recovery method if that happens, pg_stat_statements may choose to discard the query texts, whereupon all existing entries in the pg_stat_statements view will show null query fields, though the statistics associated with each queryid are preserved. If this happens, consider reducing pg_stat_statements.max to prevent recurrences.

plans and calls aren't always expected to match because planning and execution statistics are updated at their respective end phase, and only for successful operations. For example, if a statement is successfully planned but fails during the execution phase, only its planning statistics will be updated. If planning is skipped because a cached plan is used, only its execution statistics will be updated.

F.43.2. The pg_stat_statements_info View

The statistics of the pg_stat_statements module itself are tracked and made available via a view named pg_stat_statements_info. This view contains only a single row. The columns of the view are shown in Table F.27.

Table F.27. pg_stat_statements_info Columns

Column Type Description
dealloc bigint Total number of times pg_stat_statements entries about the least-executed statements were deallocated because more distinct statements than pg_stat_statements.max were observed
stats_reset timestamp with time zone Time at which all statistics in the pg_stat_statements view were last reset.

F.43.3. Functions

pg_stat_statements_reset(userid Oid, dbid Oid, queryid bigint) returns void

pg_stat_statements_reset discards statistics gathered so far by pg_stat_statements corresponding to the specified userid, dbid and queryid. If any of the parameters are not specified, the default value 0(invalid) is used for each of them and the statistics that match with other parameters will be reset. If no parameter is specified or all the specified parameters are 0(invalid), it will discard all statistics. If all statistics in the pg_stat_statements view are discarded, it will also reset the statistics in the pg_stat_statements_info view. By default, this function can only be executed by superusers. Access may be granted to others using GRANT.

pg_stat_statements(showtext boolean) returns setof record

The pg_stat_statements view is defined in terms of a function also named pg_stat_statements. It is possible for clients to call the pg_stat_statements function directly, and by specifying showtext := false have query text be omitted (that is, the OUT argument that corresponds to the view's query column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all pg_stat_statements itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the pg_stat_statements data.

F.43.4. Configuration Parameters

pg_stat_statements.max (integer)

pg_stat_statements.max is the maximum number of statements tracked by the module (i.e., the maximum number of rows in the pg_stat_statements view). If more distinct statements than that are observed, information about the least-executed statements is discarded. The number of times such information was discarded can be seen in the pg_stat_statements_info view. The default value is 5000. This parameter can only be set at server start.

pg_stat_statements.track (enum)

pg_stat_statements.track controls which statements are counted by the module. Specify top to track top-level statements (those issued directly by clients), all to also track nested statements (such as statements invoked within functions), or none to disable statement statistics collection. The default value is top. Only superusers can change this setting.

pg_stat_statements.track_utility (boolean)

pg_stat_statements.track_utility controls whether utility commands are tracked by the module. Utility commands are all those other than SELECT, INSERT, UPDATE and DELETE. The default value is on. Only superusers can change this setting.

`pg_stat_statements.track_planning` (`boolean`)

`pg_stat_statements.track_planning` controls whether planning operations and duration are tracked by the module. Enabling this parameter may incur a noticeable performance penalty, especially when statements with identical query structure are executed by many concurrent connections which compete to update a small number of `pg_stat_statements` entries. The default value is `off`. Only superusers can change this setting.

`pg_stat_statements.save` (`boolean`)

`pg_stat_statements.save` specifies whether to save statement statistics across server shutdowns. If it is `off` then statistics are not saved at shutdown nor reloaded at server start. The default value is `on`. This parameter can only be set in the `postgresql.conf` file or on the server command line.

The module requires additional shared memory proportional to `pg_stat_statements.max`. Note that this memory is consumed whenever the module is loaded, even if `pg_stat_statements.track` is set to `none`.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'pg_stat_statements'

compute_query_id = on
pg_stat_statements.max = 10000
pg_stat_statements.track = all
```

F.43.5. Sample Output

```
bench=# SELECT pg_stat_statements_reset();

$ pgbench -i bench
$ pgbench -c10 -t300 bench

F.43.6. Authors

Takahiro Itagaki <itagaki.takahiro@oss.ntt.co.jp>. Query normalization added by Peter Geoghegan <peter@2ndquadrant.com>.

F.44. pgstattuple

The pgstattuple module provides various functions to obtain tuple-level statistics.

Because these functions return detailed page-level information, access is restricted by default. By default, only the role pg_stat_scan_tables has EXECUTE privilege. Superusers of course bypass this restriction. After the extension has been installed, users may issue GRANT commands to change the privileges on the functions to allow others to execute them. However, it might be preferable to add those users to the pg_stat_scan_tables role instead.

F.44.1. Functions

```
pgstattuple(regclass) returns record
```

pgstattuple returns a relation's physical length, percentage of “dead” tuples, and other info. This may help users to determine whether vacuum is necessary or not. The argument is the target relation's name (optionally schema-qualified) or OID. For example:

```
test=> SELECT * FROM pgstattuple('pg_catalog.pg_proc');
-[ RECORD 1 ]------+-------
table_len          | 458752
tuple_count        | 1470
tuple_len          | 438896
tuple_percent      | 95.67
dead_tuple_count   | 11
dead_tuple_len     | 3157
dead_tuple_percent | 0.69
free_space         | 8932
free_percent       | 1.95
```

The output columns are described in Table F.28.

Table F.28. pgstattuple Output Columns

Column	Type	Description
table_len	bigint	Physical relation length in bytes
tuple_count	bigint	Number of live tuples
tuple_len	bigint	Total length of live tuples in bytes
tuple_percent	float8	Percentage of live tuples

Column	Type	Description
dead_tuple_count	bigint	Number of dead tuples
dead_tuple_len	bigint	Total length of dead tuples in bytes
dead_tuple_percent	float8	Percentage of dead tuples
free_space	bigint	Total free space in bytes
free_percent	float8	Percentage of free space

> **Note**
>
> The table_len will always be greater than the sum of the tuple_len, dead_tuple_len and free_space. The difference is accounted for by fixed page overhead, the per-page table of pointers to tuples, and padding to ensure that tuples are correctly aligned.

pgstattuple acquires only a read lock on the relation. So the results do not reflect an instantaneous snapshot; concurrent updates will affect them.

pgstattuple judges a tuple is "dead" if HeapTupleSatisfiesDirty returns false.

pgstattuple(text) returns record

This is the same as pgstattuple(regclass), except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

pgstatindex(regclass) returns record

pgstatindex returns a record showing information about a B-tree index. For example:

```
test=> SELECT * FROM pgstatindex('pg_cast_oid_index');
-[ RECORD 1 ]------+------
version            | 2
tree_level         | 0
index_size         | 16384
root_block_no      | 1
internal_pages     | 0
leaf_pages         | 1
empty_pages        | 0
deleted_pages      | 0
avg_leaf_density   | 54.27
leaf_fragmentation | 0
```

The output columns are:

Column	Type	Description
version	integer	B-tree version number
tree_level	integer	Tree level of the root page
index_size	bigint	Total index size in bytes
root_block_no	bigint	Location of root page (zero if none)
internal_pages	bigint	Number of "internal" (upper-level) pages
leaf_pages	bigint	Number of leaf pages
empty_pages	bigint	Number of empty pages

Column	Type	Description
deleted_pages	bigint	Number of deleted pages
avg_leaf_density	float8	Average density of leaf pages
leaf_fragmentation	float8	Leaf page fragmentation

The reported index_size will normally correspond to one more page than is accounted for by internal_pages + leaf_pages + empty_pages + deleted_pages, because it also includes the index's metapage.

As with pgstattuple, the results are accumulated page-by-page, and should not be expected to represent an instantaneous snapshot of the whole index.

pgstatindex(text) returns record

This is the same as pgstatindex(regclass), except that the target index is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

pgstatginindex(regclass) returns record

pgstatginindex returns a record showing information about a GIN index. For example:

```
test=> SELECT * FROM pgstatginindex('test_gin_index');
-[ RECORD 1 ]--+--
version        | 1
pending_pages  | 0
pending_tuples | 0
```

The output columns are:

Column	Type	Description
version	integer	GIN version number
pending_pages	integer	Number of pages in the pending list
pending_tuples	bigint	Number of tuples in the pending list

pgstathashindex(regclass) returns record

pgstathashindex returns a record showing information about a HASH index. For example:

```
test=> select * from pgstathashindex('con_hash_index');
-[ RECORD 1 ]--+-----------------
version        | 4
bucket_pages   | 33081
overflow_pages | 0
bitmap_pages   | 1
unused_pages   | 32455
live_items     | 10204006
dead_items     | 0
free_percent   | 61.8005949100872
```

The output columns are:

Column	Type	Description
version	integer	HASH version number
bucket_pages	bigint	Number of bucket pages
overflow_pages	bigint	Number of overflow pages

Column	Type	Description
bitmap_pages	bigint	Number of bitmap pages
unused_pages	bigint	Number of unused pages
live_items	bigint	Number of live tuples
dead_tuples	bigint	Number of dead tuples
free_percent	float	Percentage of free space

`pg_relpages(regclass) returns bigint`

`pg_relpages` returns the number of pages in the relation.

`pg_relpages(text) returns bigint`

This is the same as `pg_relpages(regclass)`, except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstattuple_approx(regclass) returns record`

`pgstattuple_approx` is a faster alternative to `pgstattuple` that returns approximate results. The argument is the target relation's name or OID. For example:

```
test=> SELECT * FROM pgstattuple_approx('pg_catalog.pg_proc'::regclass);
-[ RECORD 1 ]--------+-------
table_len            | 573440
scanned_percent      | 2
approx_tuple_count   | 2740
approx_tuple_len     | 561210
approx_tuple_percent | 97.87
dead_tuple_count     | 0
dead_tuple_len       | 0
dead_tuple_percent   | 0
approx_free_space    | 11996
approx_free_percent  | 2.09
```

The output columns are described in Table F.29.

Whereas `pgstattuple` always performs a full-table scan and returns an exact count of live and dead tuples (and their sizes) and free space, `pgstattuple_approx` tries to avoid the full-table scan and returns exact dead tuple statistics along with an approximation of the number and size of live tuples and free space.

It does this by skipping pages that have only visible tuples according to the visibility map (if a page has the corresponding VM bit set, then it is assumed to contain no dead tuples). For such pages, it derives the free space value from the free space map, and assumes that the rest of the space on the page is taken up by live tuples.

For pages that cannot be skipped, it scans each tuple, recording its presence and size in the appropriate counters, and adding up the free space on the page. At the end, it estimates the total number of live tuples based on the number of pages and tuples scanned (in the same way that VACUUM estimates pg_class.reltuples).

Table F.29. `pgstattuple_approx` Output Columns

Column	Type	Description
table_len	bigint	Physical relation length in bytes (exact)
scanned_percent	float8	Percentage of table scanned

Column	Type	Description
approx_tuple_count	bigint	Number of live tuples (estimated)
approx_tuple_len	bigint	Total length of live tuples in bytes (estimated)
approx_tuple_percent	float8	Percentage of live tuples
dead_tuple_count	bigint	Number of dead tuples (exact)
dead_tuple_len	bigint	Total length of dead tuples in bytes (exact)
dead_tuple_percent	float8	Percentage of dead tuples
approx_free_space	bigint	Total free space in bytes (estimated)
approx_free_percent	float8	Percentage of free space

In the above output, the free space figures may not match the pgstattuple output exactly, because the free space map gives us an exact figure, but is not guaranteed to be accurate to the byte.

F.44.2. Authors

Tatsuo Ishii, Satoshi Nagayasu and Abhijit Menon-Sen

F.45. pg_surgery

The pg_surgery module provides various functions to perform surgery on a damaged relation. These functions are unsafe by design and using them may corrupt (or further corrupt) your database. For example, these functions can easily be used to make a table inconsistent with its own indexes, to cause UNIQUE or FOREIGN KEY constraint violations, or even to make tuples visible which, when read, will cause a database server crash. They should be used with great caution and only as a last resort.

F.45.1. Functions

heap_force_kill(regclass, tid[]) returns void

heap_force_kill marks “used” line pointers as “dead” without examining the tuples. The intended use of this function is to forcibly remove tuples that are not otherwise accessible. For example:

```
test=> select * from t1 where ctid = '(0, 1)';
ERROR:  could not access status of transaction 4007513275
DETAIL:  Could not open file "pg_xact/0EED": No such file or directory.

test=# select heap_force_kill('t1'::regclass, ARRAY['(0, 1)']::tid[]);
 heap_force_kill
-----------------

(1 row)

test=# select * from t1 where ctid = '(0, 1)';
(0 rows)
```

heap_force_freeze(regclass, tid[]) returns void

heap_force_freeze marks tuples as frozen without examining the tuple data. The intended use of this function is to make accessible tuples which are inaccessible due to corrupted visibility information, or which prevent the table from being successfully vacuumed due to corrupted visibility information. For example:

```
test=> vacuum t1;
```

```
ERROR:  found xmin 507 from before relfrozenxid 515
CONTEXT:  while scanning block 0 of relation "public.t1"

test=# select ctid from t1 where xmin = 507;
 ctid
-------
 (0,3)
(1 row)

test=# select heap_force_freeze('t1'::regclass, ARRAY['(0, 3)']::tid[]);
 heap_force_freeze
-------------------

(1 row)

test=# select ctid from t1 where xmin = 2;
 ctid
-------
 (0,3)
(1 row)
```

F.45.2. Authors

Ashutosh Sharma <ashu.coek88@gmail.com>

F.46. pg_trgm

The pg_trgm module provides functions and operators for determining the similarity of alphanumeric text based on trigram matching, as well as index operator classes that support fast searching for similar strings.

This module is considered "trusted", that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.46.1. Trigram (or Trigraph) Concepts

A trigram is a group of three consecutive characters taken from a string. We can measure the similarity of two strings by counting the number of trigrams they share. This simple idea turns out to be very effective for measuring the similarity of words in many natural languages.

> **Note**
>
> pg_trgm ignores non-word characters (non-alphanumerics) when extracting trigrams from a string. Each word is considered to have two spaces prefixed and one space suffixed when determining the set of trigrams contained in the string. For example, the set of trigrams in the string "cat" is " c", " ca", "cat", and "at ". The set of trigrams in the string "foo|bar" is " f", " fo", "foo", "oo ", " b", " ba", "bar", and "ar ".

F.46.2. Functions and Operators

The functions provided by the pg_trgm module are shown in Table F.30, the operators in Table F.31.

Table F.30. pg_trgm Functions

Function Description
similarity (text, text) → real

Function Description
Returns a number that indicates how similar the two arguments are. The range of the result is zero (indicating that the two strings are completely dissimilar) to one (indicating that the two strings are identical).
`show_trgm ( text ) → text[]` Returns an array of all the trigrams in the given string. (In practice this is seldom useful except for debugging.)
`word_similarity ( text, text ) → real` Returns a number that indicates the greatest similarity between the set of trigrams in the first string and any continuous extent of an ordered set of trigrams in the second string. For details, see the explanation below.
`strict_word_similarity ( text, text ) → real` Same as `word_similarity` , but forces extent boundaries to match word boundaries. Since we don't have cross-word trigrams, this function actually returns greatest similarity between first string and any continuous extent of words of the second string.
`show_limit () → real` Returns the current similarity threshold used by the `%` operator. This sets the minimum similarity between two words for them to be considered similar enough to be misspellings of each other, for example. (*Deprecated*; instead use `SHOW pg_trgm.similarity_threshold` .)
`set_limit ( real ) → real` Sets the current similarity threshold that is used by the `%` operator. The threshold must be between 0 and 1 (default is 0.3). Returns the same value passed in. (*Deprecated*; instead use `SET pg_trgm.similarity_threshold` .)

Consider the following example:

```
# SELECT word_similarity('word', 'two words');
 word_similarity
-----------------
             0.8
(1 row)
```

In the first string, the set of trigrams is `{" w"," wo","wor","ord","rd "}`. In the second string, the ordered set of trigrams is `{" t"," tw","two","wo "," w"," wo","wor","ord","rds","ds "}`. The most similar extent of an ordered set of trigrams in the second string is `{" w"," wo","wor","ord"}`, and the similarity is `0.8`.

This function returns a value that can be approximately understood as the greatest similarity between the first string and any substring of the second string. However, this function does not add padding to the boundaries of the extent. Thus, the number of additional characters present in the second string is not considered, except for the mismatched word boundaries.

At the same time, `strict_word_similarity` selects an extent of words in the second string. In the example above, `strict_word_similarity` would select the extent of a single word `'words'`, whose set of trigrams is `{" w"," wo","wor","ord","rds","ds "}`.

```
# SELECT strict_word_similarity('word', 'two words'), similarity('word', 'words');
 strict_word_similarity | similarity
------------------------+------------
               0.571429 |   0.571429
(1 row)
```

Thus, the `strict_word_similarity` function is useful for finding the similarity to whole words, while `word_similarity` is more suitable for finding the similarity for parts of words.

Table F.31. `pg_trgm` Operators

Operator Description
`text % text → boolean` Returns `true` if its arguments have a similarity that is greater than the current similarity threshold set by `pg_trgm.similarity_threshold` .
`text <% text → boolean` Returns `true` if the similarity between the trigram set in the first argument and a continuous extent of an ordered trigram set in the second argument is greater than the current word similarity threshold set by `pg_trgm.word_similarity_threshold` parameter.
`text %> text → boolean` Commutator of the `<%` operator.
`text <<% text → boolean` Returns `true` if its second argument has a continuous extent of an ordered trigram set that matches word boundaries, and its similarity to the trigram set of the first argument is greater than the current strict word similarity threshold set by the `pg_trgm.strict_word_similarity_threshold` parameter.
`text %>> text → boolean` Commutator of the `<<%` operator.
`text <-> text → real` Returns the “distance” between the arguments, that is one minus the `similarity()` value.
`text <<-> text → real` Returns the “distance” between the arguments, that is one minus the `word_similarity()` value.
`text <->> text → real` Commutator of the `<<->` operator.
`text <<<-> text → real` Returns the “distance” between the arguments, that is one minus the `strict_word_similarity()` value.
`text <->>> text → real` Commutator of the `<<<->` operator.

F.46.3. GUC Parameters

`pg_trgm.similarity_threshold` (`real`)

Sets the current similarity threshold that is used by the `%` operator. The threshold must be between 0 and 1 (default is 0.3).

`pg_trgm.word_similarity_threshold` (`real`)

Sets the current word similarity threshold that is used by the `<%` and `%>` operators. The threshold must be between 0 and 1 (default is 0.6).

`pg_trgm.strict_word_similarity_threshold` (`real`)

Sets the current strict word similarity threshold that is used by the `<<%` and `%>>` operators. The threshold must be between 0 and 1 (default is 0.5).

F.46.4. Index Support

The `pg_trgm` module provides GiST and GIN index operator classes that allow you to create an index over a text column for the purpose of very fast similarity searches. These index types support the above-

described similarity operators, and additionally support trigram-based index searches for `LIKE`, `ILIKE`, `~`, `~*` and `=` queries. Inequality operators are not supported. Note that those indexes may not be as efficient as regular B-tree indexes for equality operator.

Example:

```
CREATE TABLE test_trgm (t text);
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops);
```

or

```
CREATE INDEX trgm_idx ON test_trgm USING GIN (t gin_trgm_ops);
```

`gist_trgm_ops` GiST opclass approximates a set of trigrams as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default length is 12 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

```
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops(siglen=32));
```

At this point, you will have an index on the `t` column that you can use for similarity searching. A typical query is

```
SELECT t, similarity(t, 'word') AS sml
  FROM test_trgm
  WHERE t % 'word'
  ORDER BY sml DESC, t;
```

This will return all values in the text column that are sufficiently similar to *word*, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

A variant of the above query is

```
SELECT t, t <-> 'word' AS dist
  FROM test_trgm
  ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes. It will usually beat the first formulation when only a small number of the closest matches is wanted.

Also you can use an index on the `t` column for word similarity or strict word similarity. Typical queries are:

```
SELECT t, word_similarity('word', t) AS sml
  FROM test_trgm
  WHERE 'word' <% t
  ORDER BY sml DESC, t;
```

and

```
SELECT t, strict_word_similarity('word', t) AS sml
  FROM test_trgm
  WHERE 'word' <<% t
  ORDER BY sml DESC, t;
```

This will return all values in the text column for which there is a continuous extent in the corresponding ordered trigram set that is sufficiently similar to the trigram set of *word*, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

Possible variants of the above queries are:

```
SELECT t, 'word' <<-> t AS dist
  FROM test_trgm
```

```
  ORDER BY dist LIMIT 10;
```

and

```
SELECT t, 'word' <<<-> t AS dist
  FROM test_trgm
  ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes.

Beginning in PostgreSQL 9.1, these index types also support index searches for `LIKE` and `ILIKE`, for example

```
SELECT * FROM test_trgm WHERE t LIKE '%foo%bar';
```

The index search works by extracting trigrams from the search string and then looking these up in the index. The more trigrams in the search string, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

Beginning in PostgreSQL 9.3, these index types also support index searches for regular-expression matches (`~` and `~*` operators), for example

```
SELECT * FROM test_trgm WHERE t ~ '(foo|bar)';
```

The index search works by extracting trigrams from the regular expression and then looking these up in the index. The more trigrams that can be extracted from the regular expression, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

For both `LIKE` and regular-expression searches, keep in mind that a pattern with no extractable trigrams will degenerate to a full-index scan.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

F.46.5. Text Search Integration

Trigram matching is a very useful tool when used in conjunction with a full text index. In particular it can help to recognize misspelled input words that will not be matched directly by the full text search mechanism.

The first step is to generate an auxiliary table containing all the unique words in the documents:

```
CREATE TABLE words AS SELECT word FROM
        ts_stat('SELECT to_tsvector(''simple'', bodytext) FROM documents');
```

where `documents` is a table that has a text field `bodytext` that we wish to search. The reason for using the `simple` configuration with the `to_tsvector` function, instead of using a language-specific configuration, is that we want a list of the original (unstemmed) words.

Next, create a trigram index on the word column:

```
CREATE INDEX words_idx ON words USING GIN (word gin_trgm_ops);
```

Now, a `SELECT` query similar to the previous example can be used to suggest spellings for misspelled words in user search terms. A useful extra test is to require that the selected words are also of similar length to the misspelled word.

> **Note**
>
> Since the `words` table has been generated as a separate, static table, it will need to be periodically regenerated so that it remains reasonably up-to-date with the document collection. Keeping it exactly current is usually unnecessary.

F.47. pg_tsparser

pg_tsparser is a Postgres Pro extension for text search. This extension modifies the default text parsing strategy for words that include:

- underscores
- numbers and letters separated by the hyphen character

In addition to separate word parts returned by default, pg_tsparser also returns the whole word.

F.47.1. Installation and Setup

pg_tsparser is included into the Postgres Pro distribution. To enable pg_tsparser, once Postgres Pro is installed, create the pg_tsparser extension for each database you are planning to use:

```
CREATE EXTENSION pg_tsparser;
```

Once pg_tsparser is enabled, you can create your own text search configuration. In addition to pg_tsparser, you can use any available dictionary.

For example, you can create english_ts configuration for the English language, as follows:

```
CREATE TEXT SEARCH CONFIGURATION english_ts (
    PARSER = tsparser
);

COMMENT ON TEXT SEARCH CONFIGURATION english_ts IS 'text search configuration for
 english language';

ALTER TEXT SEARCH CONFIGURATION english_ts
    ADD MAPPING FOR email, file, float, host, hword_numpart, int,
    numhword, numword, sfloat, uint, url, url_path, version
    WITH simple;

ALTER TEXT SEARCH CONFIGURATION english_ts
    ADD MAPPING FOR asciiword, asciihword, hword_asciipart,
    word, hword, hword_part
    WITH english_stem;
```

F.47.2. Examples

The following examples illustrate the difference in search results returned by pg_tsparser and the default parser:

```
SELECT to_tsvector('english', 'pg_trgm') as def_parser,
       to_tsvector('english_ts', 'pg_trgm')  as new_parser;
   def_parser    |         new_parser
-----------------+----------------------------
 'pg':1 'trgm':2 | 'pg':2 'pg_trgm':1 'trgm':3
(1 row)

SELECT to_tsvector('english', '123-abc') as def_parser,
       to_tsvector('english_ts', '123-abc')  as new_parser;
   def_parser    |         new_parser
-----------------+----------------------------
 '123':1 'abc':2 | '123':2 '123-abc':1 'abc':3
(1 row)

SELECT to_tsvector('english', 'rel-3.2-A') as def_parser,
       to_tsvector('english_ts', 'rel-3.2-A')  as new_parser;
    def_parser    |          new_parser
------------------+------------------------------
 '-3.2':2 'rel':1 | '3.2':3 'rel':2 'rel-3.2-a':1
(1 row)
```

F.48. pg_variables

The `pg_variables` module provides functions for working with variables of various types. The created variables are only available in the current user session.

F.48.1. Installation

The `pg_variables` extension is included into Postgres Pro. Once you have Postgres Pro installed, you must execute the CREATE EXTENSION command to enable `pg_variables`, as follows:

```
CREATE EXTENSION pg_variables;
```

F.48.2. Usage

The `pg_variables` module provides several functions for creating, reading, and managing variables of scalar, record, and array types. See the following sections for function descriptions and syntax:

- Section F.48.3.1 describes functions for scalar variables.
- Section F.48.3.2 describes functions for collections of record variables.
- Section F.48.3.3 describes functions for array variables.
- Section F.48.3.4 describes functions for general collection variables.
- Section F.48.3.5 describes functions for using iterators to traverse collection variables.
- Section F.48.3.6 lists functions you can use to manage all variables in your current session.

For detailed usage examples, see Section F.48.5.

F.48.2.1. Using Transactional Variables

By default, the created variables are non-transactional. Once successfully set, a variable exists for the whole session, regardless of rollbacks, if any. For example:

```
SELECT pgv_set('vars', 'int1', 101);
BEGIN;
SELECT pgv_set('vars', 'int2', 102);
ROLLBACK;

SELECT * FROM pgv_list() order by package, name;
 package | name | is_transactional
---------+------+------------------
 vars    | int1 | f
 vars    | int2 | f
```

If you would like to use variables that support transactions and savepoints, pass the optional `is_transactional` flag as the last parameter when creating this variable:

```
BEGIN;
SELECT pgv_set('vars', 'trans_int', 101, true);
SAVEPOINT sp1;
SELECT pgv_set('vars', 'trans_int', 102, true);
ROLLBACK TO sp1;
COMMIT;
SELECT pgv_get('vars', 'trans_int', NULL::int);
 pgv_get
---------
     101
```

You must use the `is_transactional` flag every time you change the value of a transactional variable using `pgv_set()` or `pgv_insert()` functions. Otherwise, an error occurs. Other functions do not require this flag.

```
SELECT pgv_insert('pack', 'var_record', row(123::int, 'text'::text), true);

SELECT pgv_insert('pack', 'var_record', row(456::int, 'another text'::text));
ERROR:  variable "var_record" already created as TRANSACTIONAL

SELECT pgv_delete('pack', 'var_record', 123::int);
```

If the `pgv_free()` or `pgv_remove()` function calls are rolled back, the affected transactional variables will be restored, unlike non-transactional variables, which are removed permanently. For example:

```
SELECT pgv_set('pack', 'var_reg', 123);
SELECT pgv_set('pack', 'var_trans', 456, true);
BEGIN;
SELECT pgv_free();
ROLLBACK;
SELECT * FROM pgv_list();
 package |   name    | is_transactional
---------+-----------+------------------
 pack    | var_trans | t
```

F.48.3. Functions

F.48.3.1. Scalar Variables

The following functions support scalar variables:

Function	Returns
`pgv_set(package text, name text, value anynonarray, is_transactional bool default false)`	`void`

Function	Returns
pgv_get(package text, name text, var_type anynonarray, strict bool default true)	anynonarray

To use the pgv_get() function, you must first create a package and a variable using the pgv_set() function. If the specified package or variable does not exist, an error occurs:

```
SELECT pgv_get('vars', 'int1', NULL::int);
ERROR:  unrecognized package "vars"

SELECT pgv_get('vars', 'int1', NULL::int);
ERROR:  unrecognized variable "int1"
```

pgv_get() function checks the variable type. If the specified type does not match the type of the variable, an error is raised:

```
SELECT pgv_get('vars', 'int1', NULL::text);
ERROR:  variable "int1" requires "integer" value
```

F.48.3.2. Collections of Records

The following functions support collections of record variables:

Function	Returns	Description
pgv_insert(package text, name text, r record, is_transactional bool default false)	void	Inserts a record into a collection variable for the specified package. If the package or variable does not exist, it is created automatically. The first column of r is the primary key. If a record with the same primary key already exists or this collection variable has a different structure, an error is raised.
pgv_update(package text, name text, r record)	boolean	Updates a record with the corresponding primary key (the first column of r is the primary key). Returns true if the record was found. If this collection variable has a different structure, an error is raised.
pgv_delete(package text, name text, value anynonarray)	boolean	Deletes a record with the corresponding primary key (the first column of r is the primary key). Returns true if the record was found and false otherwise.
pgv_select(package text, name text)	set of records	Returns the collection variable records.
pgv_select(package text, name text, value anynonarray)	record	Returns the record with the corresponding primary key (the first column of r is a primary key).
pgv_select(package text, name text, value anyarray)	set of records	Returns the collection variable records with the corresponding primary keys (the first column of r is a primary key).

To use pgv_update(), pgv_delete() and pgv_select() functions, you must first create a package and a variable using the pgv_insert() function. The variable type and the record type must be the same; otherwise, an error occurs.

F.48.3.3. Arrays

The following functions support array variables:

Function	Returns
pgv_set(package text, name text, value anyarray, is_transactional bool default false)	void
pgv_get(package text, name text, var_type anyarray, strict bool default true)	anyarray

Usage instructions for these functions are the same as those provided in Section F.48.3.1 for scalar variables.

F.48.3.4. General Collections

The following functions support general collection variables:

Function	Returns	Description
pgv_set_elem(package text, name text, key int, value anyelement, is_transactional bool default false) pgv_set_elem(package text, name text, key text, value anyelement, is_transactional bool default false)	void	Sets a value for the element with the key key of the collection variable name in the package package. If the package or variable does not exist, it is created automatically. Inside one collection, only keys of the same type are allowed. The key argument can have either int or text type. If an element with the specified key already exists, its value is set to the new one. is_transactional shows whether the new variable is transactional and equals false by default. So if the variable already exists, it must be transactional/non-transactional as indicated by is_transactional, otherwise an error is raised. If the collection already exists and its value type does not match the type of the new value, an error is also raised.
pgv_get_elem(package text, name text, key int, val_type anyelement) pgv_get_elem(package text, name text, key text, val_type anyelement)	anyelement	Returns the value of the element with the key key of the collection variable name in the package package. If there is no element with the specified key in this collection, returns NULL. The key argument can have either int or text type. If the package or variable does not exist, an error is raised. If the specified variable is

Function	Returns	Description
		not a collection, an error is also raised. The `val_type` argument is required to properly determine the return type.

`pgv_exists_elem(package text, name text, key int)`
 	
`pgv_exists_elem(package text, name text, key text)`
	`bool`	Returns `true` if an element with the key `key` exists in the collection variable `name` in the package `package` and `false` otherwise. If the package or variable does not exist, also returns `false`. The `key` argument can have either `int` or `text` type. If the specified variable is not a collection, an error is raised.

`pgv_remove_elem(package text, name text, key int)`
 	
`pgv_remove_elem(package text, name text, key text)`
	`void`	Removes the element with the key `key` from the collection variable `name` in the package `package`. If there is no element with the specified key in this collection, does nothing. The `key` argument can have either `int` or `text` type. If the package or variable does not exist, an error is raised. If the specified variable is not a collection, an error is also raised.

> **Important**
>
> Collections initialized with `pgv_set_elem()` and with `pgv_insert()` are not considered compatible.

F.48.3.5. Iterators

The following functions are provided to use iterators to traverse collection variables. These functions work with collections initialized with both `pgv_set_elem()` and `pgv_insert()`.

Function	Returns	Description
`pgv_first(package text, name text, key_type anyelement)`	`anyelement`	Returns the first key from the collection variable. Collections are sorted by the key in ascending order. `key_type` is required to determine the return value. If the `name` passed is the name of a non-collection variable, an error is raised.
`pgv_last(package text, name text, key_type anyelement)`	`anyelement`	Returns the last key from the collection variable. Collections are sorted by the key in ascending order. `key_type` is required to determine the return value. If the `name` passed is the name of a non-collection variable, an error is raised.

Function	Returns	Description
pgv_next(package text, name text, key anyelement)	anyelement	Returns the next key from the collection variable. The key passed may not exist in the collection. Returns NULL if used for the last key in the collection. Collections are sorted by the key in ascending order. If the name passed is the name of a non-collection variable, an error is raised.
pgv_prior(package text, name text, key anyelement)	anyelement	Returns the previous key from the collection variable. The key passed may not exist in the collection. Returns NULL if used for the first key in the collection. Collections are sorted by the key in ascending order. If the name passed is the name of a non-collection variable, an error is raised.
pgv_count(package text, name text)	integer	Returns the number of elements in the collection. If the name passed is the name of a non-collection variable, an error is raised.

F.48.3.6. Miscellaneous Functions

Function	Returns	Description
pgv_exists(package text, name text)	bool	Returns true if the specified package and variable exist and false otherwise.
pgv_exists(package text)	bool	Returns true if the specified package exists and false otherwise.
pgv_remove(package text, name text)	void	Removes the variable with the specified name. The specified package and variable must exist; otherwise, an error is raised.
pgv_remove(package text)	void	Removes the specified package and all the corresponding variables. The specified package must exist; otherwise, an error is raised.
pgv_free()	void	Removes all packages and variables.
pgv_list()	table(package text, name text, is_transactional bool)	Displays all the available variables and the corresponding packages, as well as whether each variable is transactional.
pgv_stats()	table(package text, allocated_memory bigint)	Returns the list of assigned packages and the amount of memory used by variables, in bytes. If you

Function	Returns	Description
		are using transactional variables, this list also includes all deleted packages that still may be restored by a ROLLBACK. This function only supports Postgres Pro 9.6 or higher.

F.48.3.7. Deprecated Functions

F.48.3.7.1. Integer Variables

The following functions are deprecated. Use generic functions for scalar variables instead.

Function	Returns
pgv_set_int(package text, name text, value int, is_transactional bool default false)	void
pgv_get_int(package text, name text, strict bool default true)	int

F.48.3.7.2. Text Variables

The following functions are deprecated. Use generic functions for scalar variables instead.

Function	Returns
pgv_set_text(package text, name text, value text, is_transactional bool default false)	void
pgv_get_text(package text, name text, strict bool default true)	text

F.48.3.7.3. Numeric Variables

The following functions are deprecated. Use generic functions for scalar variables instead.

Function	Returns
pgv_set_numeric(package text, name text, value numeric, is_transactional bool default false)	void
pgv_get_numeric(package text, name text, strict bool default true)	numeric

F.48.3.7.4. Timestamp Variables

The following functions are deprecated. Use generic functions for scalar variables instead.

Function	Returns
pgv_set_timestamp(package text, name text, value timestamp, is_transactional bool default false)	void
pgv_get_timestamp(package text, name text, strict bool default true)	timestamp

F.48.3.7.5. Timestamp with timezone Variables

The following functions are deprecated. Use generic functions for scalar variables instead.

Function	Returns
pgv_set_timestamptz(package text, name text, value timestamptz, is_transactional bool default false)	void
pgv_get_timestamptz(package text, name text, strict bool default true)	timestamptz

F.48.3.7.6. Date Variables

The following functions are deprecated. Use generic functions for scalar variables instead.

Function	Returns
pgv_set_date(package text, name text, value date, is_transactional bool default false)	void
pgv_get_date(package text, name text, strict bool default true)	date

F.48.3.7.7. Jsonb Variables

The following functions are deprecated. Use generic functions for scalar variables instead.

Function	Returns
pgv_set_jsonb(package text, name text, value jsonb, is_transactional bool default false)	void
pgv_get_jsonb(package text, name text, strict bool default true)	jsonb

F.48.4. Important Notes

F.48.4.1. Collations in Collections

Collections are stored in ascending order. In the case of `text` keys, you need a collation to determine the order of elements. If no collation is specified when inserting the first element of a collection, the default collation is used. Otherwise, the specified collation is used.

F.48.4.2. Cursors for Set-Returning Functions

All set-returning functions except `pgv_select(package, variable)` fix their return results at first `FETCH` from the cursor and are not affected by further data manipulation.

The results of `pgv_select(package, variable)` are received dynamically and are affected by transactions/changes in the collection. For `pgv_select()` called for a transactional collection, cursors look at the snapshot of the collection when the first `FETCH` was executed, but consider changes that were made in that transaction and in committed subtransactions.

F.48.5. Examples

Define scalar variables using the `pgv_set()` function, and then return their values using the `pgv_get()` function:

```
SELECT pgv_set('vars', 'int1', 101);
SELECT pgv_set('vars', 'int2', 102);
SELECT pgv_set('vars', 'text1', 'text variable'::text);
```

```
SELECT pgv_get('vars', 'int1', NULL::int);
 pgv_get
-------------
         101

SELECT pgv_get('vars', 'int2', NULL::int);
 pgv_get
-------------
         102

SELECT pgv_get('vars', 'text1', NULL::text);
 pgv_get
---------------
 text variable
```

Let's assume we have the `tab` table and examine several examples of using record variables:

```
CREATE TABLE tab (id int, t varchar);
INSERT INTO tab VALUES (0, 'str00'), (1, 'str11');
```

You can use the following functions to work with record variables:

```
SELECT pgv_insert('vars', 'r1', tab) FROM tab;

SELECT pgv_select('vars', 'r1');
 pgv_select
------------
 (1,str11)
 (0,str00)

SELECT pgv_select('vars', 'r1', 1);
 pgv_select
------------
 (1,str11)

SELECT pgv_select('vars', 'r1', 0);
 pgv_select
------------
 (0,str00)

SELECT pgv_select('vars', 'r1', ARRAY[1, 0]);
 pgv_select
------------
 (1,str11)
 (0,str00)

SELECT pgv_delete('vars', 'r1', 1);

SELECT pgv_select('vars', 'r1');
 pgv_select
------------
 (0,str00)
```

Consider the behavior of a transactional variable `var_text` when changed before and after savepoints:

```
SELECT pgv_set('pack', 'var_text', 'before transaction block'::text, true);
BEGIN;
SELECT pgv_set('pack', 'var_text', 'before savepoint'::text, true);
SAVEPOINT sp1;
SELECT pgv_set('pack', 'var_text', 'savepoint sp1'::text, true);
```

```
SAVEPOINT sp2;
SELECT pgv_set('pack', 'var_text', 'savepoint sp2'::text, true);
RELEASE sp2;
SELECT pgv_get('pack', 'var_text', NULL::text);
    pgv_get
---------------
 savepoint sp2

ROLLBACK TO sp1;
SELECT pgv_get('pack', 'var_text', NULL::text);
     pgv_get
------------------
 before savepoint

ROLLBACK;
SELECT pgv_get('pack', 'var_text', NULL::text);
         pgv_get
--------------------------
 before transaction block
```

If you create a variable after `BEGIN` or `SAVEPOINT` statements and than rollback to the previous state, the transactional variable is removed:

```
BEGIN;
SAVEPOINT sp1;
SAVEPOINT sp2;
SELECT pgv_set('pack', 'var_int', 122, true);
RELEASE SAVEPOINT sp2;
SELECT pgv_get('pack', 'var_int', NULL::int);
pgv_get
---------
     122

ROLLBACK TO sp1;
SELECT pgv_get('pack','var_int', NULL::int);
ERROR:  unrecognized variable "var_int"
COMMIT;
```

List the available packages and variables:

```
SELECT * FROM pgv_list() ORDER BY package, name;
 package |   name   | is_transactional
---------+----------+------------------
 pack    | var_text | t
 vars    | int1     | f
 vars    | int2     | f
 vars    | r1       | f
 vars    | text1    | f
```

Get the amount of memory used by variables, in bytes:

```
SELECT * FROM pgv_stats() ORDER BY package;
 package | allocated_memory
---------+------------------
 pack    |            16384
 vars    |            32768
```

Delete the specified variables or packages:

```
SELECT pgv_remove('vars', 'int1');
SELECT pgv_remove('vars');
```

Delete all packages and variables:

```
SELECT pgv_free();
```

These examples show usage of collection variables and iterator functions:

```
sql
SELECT pgv_set_elem('pack', 'var', 1, 1);
SELECT pgv_set_elem('pack', 'var', 5, 5);
SELECT pgv_set_elem('pack', 'var', 10, 10);

SELECT pgv_first('pack', 'var', NULL::int);
 pgv_first
-----------
         1

SELECT pgv_last('pack', 'var', NULL::int);
 pgv_last
----------
       10

SELECT pgv_next('pack', 'var', pgv_first('pack', 'var', NULL::int));
 pgv_next
----------
        5

SELECT pgv_prior('pack', 'var', pgv_last('pack', 'var', NULL::int));
 pgv_prior
-----------
         5

SELECT pgv_prior('pack', 'var', pgv_first('pack', 'var', NULL::int));
 pgv_prior
-----------

SELECT pgv_next('pack', 'var', pgv_last('pack', 'var', NULL::int));
 pgv_prior
-----------

SELECT pgv_next('pack', 'var', 3);
 pgv_next
----------
        5

SELECT pgv_prior('pack', 'var', 3);
 pgv_prior
-----------
         1

SELECT pgv_get_elem('pack', 'var', pgv_last('pack', 'var', NULL::int), NULL::int);
 pgv_get_elem
--------------
           10

SELECT pgv_remove_elem('pack', 'var', pgv_last('pack', 'var', NULL::int));
 pgv_remove_elem
-----------------
```

```
SELECT pgv_get_elem('pack', 'var', pgv_last('pack', 'var', NULL::int), NULL::int);
 pgv_get_elem
--------------
            5
(1 row)
```

These examples show how the collation affects the order of elements in a collection. They also show how to iterate over a whole collection with PL/pgSQL loops:

```
sql
SELECT pgv_set_elem('pack', 'var1', 'a' COLLATE "ru_RU", 'a'::text);
SELECT pgv_set_elem('pack', 'var1', 'д' COLLATE "ru_RU", 'д'::text);
SELECT pgv_set_elem('pack', 'var1', 'e' COLLATE "ru_RU", 'e'::text);
SELECT pgv_set_elem('pack', 'var1', 'ё' COLLATE "ru_RU", 'ё'::text);
SELECT pgv_set_elem('pack', 'var1', 'ж' COLLATE "ru_RU", 'ж'::text);
SELECT pgv_set_elem('pack', 'var1', 'я' COLLATE "ru_RU", 'я'::text);
DO
$$
DECLARE
        iter text;
BEGIN
        iter := pgv_first('pack', 'var1', NULL::text);
        WHILE iter IS NOT NULL LOOP
          RAISE NOTICE '%', pgv_get_elem('pack', 'var1', iter, NULL::text);
          iter := pgv_next('pack', 'var1', iter);
        END LOOP;
END;
$$;

Postgres Professional, Moscow, Russia

F.49. pg_visibility

The pg_visibility module provides a means for examining the visibility map (VM) and page-level visibility information of a table. It also provides functions to check the integrity of a visibility map and to force it to be rebuilt.

Three different bits are used to store information about page-level visibility. The all-visible bit in the visibility map indicates that every tuple in the corresponding page of the relation is visible to every current and future transaction. The all-frozen bit in the visibility map indicates that every tuple in the page is frozen; that is, no future vacuum will need to modify the page until such time as a tuple is inserted, updated, deleted, or locked on that page. The page header's PD_ALL_VISIBLE bit has the same meaning as the all-visible bit in the visibility map, but is stored within the data page itself rather than in a separate data structure. These two bits will normally agree, but the page's all-visible bit can sometimes be set while the visibility map bit is clear after a crash recovery. The reported values can also disagree because of a change that occurs after pg_visibility examines the visibility map and before it examines the data page. Any event that causes data corruption can also cause these bits to disagree.

Functions that display information about PD_ALL_VISIBLE bits are much more costly than those that only consult the visibility map, because they must read the relation's data blocks rather than only the (much smaller) visibility map. Functions that check the relation's data blocks are similarly expensive.

F.49.1. Functions

pg_visibility_map(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean) returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation.

pg_visibility(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean) returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation, plus the PD_ALL_VISIBLE bit of that block.

pg_visibility_map(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean) returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation.

pg_visibility(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean) returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation, plus the PD_ALL_VISIBLE bit of each block.

pg_visibility_map_summary(relation regclass, all_visible OUT bigint, all_frozen OUT bigint) returns record

Returns the number of all-visible pages and the number of all-frozen pages in the relation according to the visibility map.

pg_check_frozen(relation regclass, t_ctid OUT tid) returns setof tid

Returns the TIDs of non-frozen tuples stored in pages marked all-frozen in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

pg_check_visible(relation regclass, t_ctid OUT tid) returns setof tid

Returns the TIDs of non-all-visible tuples stored in pages marked all-visible in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

`pg_truncate_visibility_map(relation regclass) returns void`

Truncates the visibility map for the given relation. This function is useful if you believe that the visibility map for the relation is corrupt and wish to force rebuilding it. The first `VACUUM` executed on the given relation after this function is executed will scan every page in the relation and rebuild the visibility map. (Until that is done, queries will treat the visibility map as containing all zeroes.)

By default, these functions are executable only by superusers and members of the `pg_stat_scan_tables` role, with the exception of `pg_truncate_visibility_map(relation regclass)` which can only be executed by superusers.

F.50. pg_wait_sampling

`pg_wait_sampling` is a Postgres Pro extension for collecting sampling-based statistics on wait events.

Starting from the 9.6 version, Postgres Pro Standard provides information about the current wait events for particular processes. However, to get descriptive statistics of the server activity, you have to sample wait events multiple times. The `pg_wait_sampling` extension automates wait events sampling by launching a special background worker. With `pg_wait_sampling` enabled, you can get the following sampling-based data:

- *Waits history* — the list of wait events for recent processes, with timestamps.
- *Waits profile* — the number of wait event samples for all processes over time (per wait event type).
- Current wait events for all processes, including background workers.

Using `pg_wait_sampling`, you can troubleshoot dependencies for queries that process longer than expected. You can see what a particular process is waiting for at each moment of time, and analyze wait events statistics. For the list of possible wait events, see Table 26.4.

In combination with `pg_stat_statements`, this extension can also provide per query statistics.

See Also

Viewing Statistics on Wait Events

Reference

F.50.1. Installation

The `pg_wait_sampling` extension is included into Postgres Pro Standard and requires no special prerequisites.

To enable `pg_wait_sampling`, do the following:

1. Add `pg_wait_sampling` to the `shared_preload_libraries` variable in the `postgresql.conf` file:

   ```
   shared_preload_libraries = 'pg_wait_sampling'
   ```

   Important

   When using the `pg_wait_sampling` with the `pg_stat_statements` extension, place `pg_stat_statements` before `pg_wait_sampling` in the `shared_preload_libraries` variable. This ensures that the `pg_stat_statements` extension does not overwrite query IDs that are used by `pg_wait_sampling`.

2. Create the `pg_wait_sampling` extension using the following query:

```
CREATE EXTENSION pg_wait_sampling;
```

3. Restart the server. Since pg_wait_sampling requires additional shared memory and launches a background worker, you must restart the server after adding or removing pg_wait_sampling.

Once the extension is created, pg_wait_sampling starts collecting statistics on wait events for each process. Optionally, you can change the sampling frequency and configure statistics collection modes using GUC variables.

If you want to stop collecting statistics, drop the pg_wait_sampling extension, remove the pg_wait_sampling from the shared_preload_libraries variable, and restart the server again.

F.50.2. Usage

F.50.2.1. Viewing Statistics on Wait Events

When pg_wait_sampling is enabled, wait events are sampled each 10ms by default. You can access the collected statistics through a set of functions and views. If some of your queries appear stalled or take longer than expected, you can review all the current wait events in the pg_wait_sampling_current view:

```
SELECT * FROM pg_wait_sampling_current;
```

The returned statistics covers all the active processes, including background workers. To filter the view for a single process, run pg_wait_sampling_get_current() function specifying the process ID:

```
SELECT * FROM pg_wait_sampling_get_current(pid);
```

To better understand the dynamics of the recent wait events, you can access the pg_wait_sampling_history view that provides the wait events history for the latest processes:

```
SELECT * FROM pg_wait_sampling_history;
```

The returned view displays wait samples per process, with event timestamps. Waits history is implemented as an in-memory ring buffer. By default, the history size is limited to 5000 samples. To save history for a longer period of time, you can modify the pg_wait_sampling.history_size variable, or connect a client application to periodically read waits history and dump it to a local storage.

To monitor wait events in your database over time, use the pg_wait_sampling_profile view:

```
SELECT * FROM pg_wait_sampling_profile;
```

Waits profile is stored as an in-memory hash table that accumulates samples per each process and each wait event. You can reset waits profile by calling the pg_wait_sampling_reset_profile() function. If you connect a client to your database that periodically dumps the wait events data and resets the profile, you can save and compare statistics of wait events intensity over time.

> **Important**
>
> Since wait sampling statistics is stored in RAM, make sure to reset the waits profile from time to time to avoid memory overflow.

If you are not interested in the distribution of wait events between processes, you can set the pg_wait_sampling.profile_pid variable to false. In this case, the pid value for each process is set to zero, and wait samples for all the processes are stored together.

F.50.3. Reference

F.50.3.1. GUC Variables

The pg_wait_sampling extension is configured with GUC variables. They are stored in the local memory and can be changed in the postgresql.conf file or using the ALTER SYSTEM command. For the changes to

take effect, reload the server configuration. You can do it, for example, by calling the pg_reload_conf() function or executing the pg_ctl reload command.

pg_wait_sampling.history_size (int4)

Size of in-memory ring buffer for history sampling, in the number of samples.

Default: 5000

pg_wait_sampling.history_period (int4)

Time interval for history sampling, in milliseconds.

Default: 10

pg_wait_sampling.profile_period (int4)

Time interval for waits profile sampling, in milliseconds.

Default: 10

pg_wait_sampling.profile_pid (bool)

Sampling mode for waits profile. If set to true, waits profile is collected per process. If you set pg_wait_sampling.profile_pid to false, waits profile is collected for all processes together. In this case, the pid value for each process is set to zero, and the corresponding row contains wait samples for all the processes.

Default: true

pg_wait_sampling.profile_queries (enum)

Sampling mode for the waits profile. If pg_wait_sampling.profile_queries is set to none, the queryid field in views will be zero. If it is set to top, query IDs of only the top level statements are recorded. If it is set to all, query IDs of nested statements are recorded. To collect the waits profile per query, ensure that the pg_stat_statements extension is configured and set pg_wait_sampling.profile_queries to top. For version 14 or higher, you can compute query IDs by configuring the compute_query_id parameter and set the pg_wait_sampling.profile_queries value to top or all. For details, see Section 18.9.2.

Default: top

pg_wait_sampling.sample_cpu (bool)

The sampling mode that determines whether to perform sampling of on-CPU backends. If pg_wait_sampling.sample_cpu is set to true, then sampling also includes processes that are not waiting for anything. The wait event columns for such processes will have a NULL value.

Default: true

F.50.3.2. pg_wait_sampling Views

F.50.3.2.1. pg_wait_sampling_current View

The pg_wait_sampling_current view provides the information about the current wait events for all processes, including background workers.

Table F.32. pg_wait_sampling_current View

Column Name	Column Type	Description
pid	int4	Process ID

Column Name	Column Type	Description
event_type	text	Name of wait event type
event	text	Name of wait event
queryid	int8	Query ID

F.50.3.2.2. pg_wait_sampling_history View

The pg_wait_sampling_history view provides the history of wait events. This data is stored as an in-memory ring buffer.

Table F.33. pg_wait_sampling_history View

Column Name	Column Type	Description
pid	int4	Process ID
ts	timestamptz	Sample timestamp
event_type	text	Name of wait event type
event	text	Name of wait event
queryid	int8	Query ID

F.50.3.2.3. pg_wait_sampling_profile View

The pg_wait_sampling_profile view provides the profile of wait events. This data is stored as an in-memory hash table.

Table F.34. pg_wait_sampling_profile View

Column Name	Column Type	Description
pid	int4	Process ID
event_type	text	Name of wait event type
event	text	Name of wait event
queryid	int8	Query ID
count	int8	Number of samples

F.50.3.3. Functions

pg_wait_sampling_get_current(*pid* int4)

Returns the pg_wait_sampling_current view with the list of current wait events. If you set the *pid* argument, the view is filtered for the process with this *pid*.

Arguments:

- *pid* — Optional. The process ID for which to display the current wait events.

pg_wait_sampling_reset_profile()

Resets the waits profile and clears the memory.

F.51. plantuner

The plantuner module provides hints for the planner that can disable or enable indexes for query execution.

F.51.1. Motivation

In some cases, it may be required to control the planner by providing hints that make the optimizer ignore some parts of its algorithm. There are many situations when a developer may want to temporarily disable specific index(es), without dropping them, or to instruct the planner to use a specific index.

This version of `plantuner` provides a possibility to hide the specified indexes from Postgres Pro planner, so it will not use them. For some workloads, Postgres Pro could be too pessimistic about newly created tables and assume that there are much more rows in a table than it actually has. If the `plantuner.fix_empty_table` GUC variable is set to `true`, `plantuner` sets to zero the number of pages/tuples of the table that has no blocks in a file.

F.51.2. GUC Variables

`plantuner.disable_index` — list of indexes invisible to planner.

`plantuner.enable_index` — list of indexes visible to planner even if they are hidden by `plantuner.disable_index`.

F.51.3. Example

To enable the module, you can either load `plantuner` shared library in a `psql` session or specify `shared_preload_libraries` option in `postgresql.conf`.

```
=# LOAD 'plantuner';
=# create table test(id int);
=# create index id_idx on test(id);
=# create index id_idx2 on test(id);
=# \d test
     Table "public.test"
 Column |  Type   | Modifiers
--------+---------+-----------
 id     | integer |
Indexes:
    "id_idx" btree (id)
    "id_idx2" btree (id)
=# explain select id from test where id=1;
                              QUERY PLAN
-----------------------------------------------------------------------
 Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
   Recheck Cond: (id = 1)
   ->  Bitmap Index Scan on id_idx2  (cost=0.00..4.34 rows=12 width=0)
         Index Cond: (id = 1)
(4 rows)
=# set enable_seqscan=off;
=# set plantuner.disable_index='id_idx2';
=# explain select id from test where id=1;
                              QUERY PLAN
-----------------------------------------------------------------------
 Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
   Recheck Cond: (id = 1)
   ->  Bitmap Index Scan on id_idx  (cost=0.00..4.34 rows=12 width=0)
         Index Cond: (id = 1)
(4 rows)
=# set plantuner.disable_index='id_idx2,id_idx';
=# explain select id from test where id=1;
                               QUERY PLAN
-----------------------------------------------------------------------
 Seq Scan on test  (cost=10000000000.00..10000000040.00 rows=12 width=4)
```

```
   Filter: (id = 1)
(2 rows)
=# set plantuner.enable_index='id_idx';
=# explain select id from test where id=1;
                              QUERY PLAN
-----------------------------------------------------------------------
 Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
   Recheck Cond: (id = 1)
   ->  Bitmap Index Scan on id_idx  (cost=0.00..4.34 rows=12 width=0)
         Index Cond: (id = 1)
(4 rows)
```

F.51.4. Authors

All work was done by Teodor Sigaev (teodor@sigaev.ru) and Oleg Bartunov (oleg@sai.msu.su).

The work sponsored by Nomao project (http://www.nomao.com).

F.52. postgres_fdw

The `postgres_fdw` module provides the foreign-data wrapper `postgres_fdw`, which can be used to access data stored in external Postgres Pro servers.

The functionality provided by this module overlaps substantially with the functionality of the older dblink module. But `postgres_fdw` provides more transparent and standards-compliant syntax for accessing remote tables, and can give better performance in many cases.

To prepare for remote access using `postgres_fdw`:

1. Install the `postgres_fdw` extension using CREATE EXTENSION.
2. Create a foreign server object, using CREATE SERVER, to represent each remote database you want to connect to. Specify connection information, except `user` and `password`, as options of the server object.
3. Create a user mapping, using CREATE USER MAPPING, for each database user you want to allow to access each foreign server. Specify the remote user name and password to use as `user` and `password` options of the user mapping.
4. Create a foreign table, using CREATE FOREIGN TABLE or IMPORT FOREIGN SCHEMA, for each remote table you want to access. The columns of the foreign table must match the referenced remote table. You can, however, use table and/or column names different from the remote table's, if you specify the correct remote names as options of the foreign table object.

Now you need only `SELECT` from a foreign table to access the data stored in its underlying remote table. You can also modify the remote table using `INSERT`, `UPDATE`, `DELETE`, `COPY`, or `TRUNCATE`. (Of course, the remote user you have specified in your user mapping must have privileges to do these things.)

Note that the `ONLY` option specified in `SELECT`, `UPDATE`, `DELETE` or `TRUNCATE` has no effect when accessing or modifying the remote table.

Note that `postgres_fdw` currently lacks support for `INSERT` statements with an `ON CONFLICT DO UPDATE` clause. However, the `ON CONFLICT DO NOTHING` clause is supported, provided a unique index inference specification is omitted. Note also that `postgres_fdw` supports row movement invoked by `UPDATE` statements executed on partitioned tables, but it currently does not handle the case where a remote partition chosen to insert a moved row into is also an `UPDATE` target partition that will be updated elsewhere in the same command.

It is generally recommended that the columns of a foreign table be declared with exactly the same data types, and collations if applicable, as the referenced columns of the remote table. Although `postgres_fdw` is currently rather forgiving about performing data type conversions at need, surprising se-

mantic anomalies may arise when types or collations do not match, due to the remote server interpreting query conditions differently from the local server.

Note that a foreign table can be declared with fewer columns, or with a different column order, than its underlying remote table has. Matching of columns to the remote table is by name, not position.

F.52.1. FDW Options of postgres_fdw

F.52.1.1. Connection Options

A foreign server using the `postgres_fdw` foreign data wrapper can have the same options that libpq accepts in connection strings, as described in Section 33.1.2, except that these options are not allowed or have special handling:

- `user`, `password` and `sslpassword` (specify these in a user mapping, instead, or use a service file)
- `client_encoding` (this is automatically set from the local server encoding)
- `fallback_application_name` (always set to `postgres_fdw`)
- `sslkey` and `sslcert` - these may appear in *either or both* a connection and a user mapping. If both are present, the user mapping setting overrides the connection setting.

Only superusers may create or modify user mappings with the `sslcert` or `sslkey` settings.

Only superusers may connect to foreign servers without password authentication, so always specify the `password` option for user mappings belonging to non-superusers.

A superuser may override this check on a per-user-mapping basis by setting the user mapping option `password_required 'false'`, e.g.,

```
ALTER USER MAPPING FOR some_non_superuser SERVER loopback_nopw
OPTIONS (ADD password_required 'false');
```

To prevent unprivileged users from exploiting the authentication rights of the unix user the postgres server is running as to escalate to superuser rights, only the superuser may set this option on a user mapping.

Care is required to ensure that this does not allow the mapped user the ability to connect as superuser to the mapped database per CVE-2007-3278 and CVE-2007-6601. Don't set `password_required=false` on the `public` role. Keep in mind that the mapped user can potentially use any client certificates, `.pgpass`, `.pg_service.conf` etc in the unix home directory of the system user the postgres server runs as. They can also use any trust relationship granted by authentication modes like `peer` or `ident` authentication.

F.52.1.2. Object Name Options

These options can be used to control the names used in SQL statements sent to the remote Postgres Pro server. These options are needed when a foreign table is created with names different from the underlying remote table's names.

`schema_name`

This option, which can be specified for a foreign table, gives the schema name to use for the foreign table on the remote server. If this option is omitted, the name of the foreign table's schema is used.

`table_name`

This option, which can be specified for a foreign table, gives the table name to use for the foreign table on the remote server. If this option is omitted, the foreign table's name is used.

`column_name`

This option, which can be specified for a column of a foreign table, gives the column name to use for the column on the remote server. If this option is omitted, the column's name is used.

F.52.1.3. Cost Estimation Options

postgres_fdw retrieves remote data by executing queries against remote servers, so ideally the estimated cost of scanning a foreign table should be whatever it costs to be done on the remote server, plus some overhead for communication. The most reliable way to get such an estimate is to ask the remote server and then add something for overhead — but for simple queries, it may not be worth the cost of an additional remote query to get a cost estimate. So postgres_fdw provides the following options to control how cost estimation is done:

use_remote_estimate

This option, which can be specified for a foreign table or a foreign server, controls whether postgres_fdw issues remote EXPLAIN commands to obtain cost estimates. A setting for a foreign table overrides any setting for its server, but only for that table. The default is false.

fdw_startup_cost

This option, which can be specified for a foreign server, is a floating point value that is added to the estimated startup cost of any foreign-table scan on that server. This represents the additional overhead of establishing a connection, parsing and planning the query on the remote side, etc. The default value is 100.

fdw_tuple_cost

This option, which can be specified for a foreign server, is a floating point value that is used as extra cost per-tuple for foreign-table scans on that server. This represents the additional overhead of data transfer between servers. You might increase or decrease this number to reflect higher or lower network delay to the remote server. The default value is 0.01.

When use_remote_estimate is true, postgres_fdw obtains row count and cost estimates from the remote server and then adds fdw_startup_cost and fdw_tuple_cost to the cost estimates. When use_remote_estimate is false, postgres_fdw performs local row count and cost estimation and then adds fdw_startup_cost and fdw_tuple_cost to the cost estimates. This local estimation is unlikely to be very accurate unless local copies of the remote table's statistics are available. Running ANALYZE on the foreign table is the way to update the local statistics; this will perform a scan of the remote table and then calculate and store statistics just as though the table were local. Keeping local statistics can be a useful way to reduce per-query planning overhead for a remote table — but if the remote table is frequently updated, the local statistics will soon be obsolete.

F.52.1.4. Remote Execution Options

By default, only WHERE clauses using built-in operators and functions will be considered for execution on the remote server. Clauses involving non-built-in functions are checked locally after rows are fetched. If such functions are available on the remote server and can be relied on to produce the same results as they do locally, performance can be improved by sending such WHERE clauses for remote execution. This behavior can be controlled using the following option:

extensions

This option is a comma-separated list of names of Postgres Pro extensions that are installed, in compatible versions, on both the local and remote servers. Functions and operators that are immutable and belong to a listed extension will be considered shippable to the remote server. This option can only be specified for foreign servers, not per-table.

When using the extensions option, *it is the user's responsibility* that the listed extensions exist and behave identically on both the local and remote servers. Otherwise, remote queries may fail or behave unexpectedly.

fetch_size

This option specifies the number of rows postgres_fdw should get in each fetch operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is 100.

batch_size

This option specifies the number of rows postgres_fdw should insert in each insert operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is 1.

Note the actual number of rows postgres_fdw inserts at once depends on the number of columns and the provided batch_size value. The batch is executed as a single query, and the libpq protocol (which postgres_fdw uses to connect to a remote server) limits the number of parameters in a single query to 65535. When the number of columns * batch_size exceeds the limit, the batch_size will be adjusted to avoid an error.

F.52.1.5. Asynchronous Execution Options

postgres_fdw supports asynchronous execution, which runs multiple parts of an Append node concurrently rather than serially to improve performance. This execution can be controlled using the following option:

async_capable

This option controls whether postgres_fdw allows foreign tables to be scanned concurrently for asynchronous execution. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is false.

In order to ensure that the data being returned from a foreign server is consistent, postgres_fdw will only open one connection for a given foreign server and will run all queries against that server sequentially even if there are multiple foreign tables involved, unless those tables are subject to different user mappings. In such a case, it may be more performant to disable this option to eliminate the overhead associated with running queries asynchronously.

Asynchronous execution is applied even when an Append node contains subplan(s) executed synchronously as well as subplan(s) executed asynchronously. In such a case, if the asynchronous subplans are ones processed using postgres_fdw, tuples from the asynchronous subplans are not returned until after at least one synchronous subplan returns all tuples, as that subplan is executed while the asynchronous subplans are waiting for the results of asynchronous queries sent to foreign servers. This behavior might change in a future release.

F.52.1.6. Updatability Options

By default all foreign tables using postgres_fdw are assumed to be updatable. This may be overridden using the following option:

updatable

This option controls whether postgres_fdw allows foreign tables to be modified using INSERT, UPDATE and DELETE commands. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is true.

Of course, if the remote table is not in fact updatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server. Note however that the information_schema views will report a postgres_fdw foreign table to be updatable (or not) according to the setting of this option, without any check of the remote server.

F.52.1.7. Truncatability Options

By default all foreign tables using postgres_fdw are assumed to be truncatable. This may be overridden using the following option:

truncatable

This option controls whether postgres_fdw allows foreign tables to be truncated using the TRUNCATE command. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is true.

Of course, if the remote table is not in fact truncatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server.

F.52.1.8. Importing Options

`postgres_fdw` is able to import foreign table definitions using IMPORT FOREIGN SCHEMA. This command creates foreign table definitions on the local server that match tables or views present on the remote server. If the remote tables to be imported have columns of user-defined data types, the local server must have compatible types of the same names.

Importing behavior can be customized with the following options (given in the `IMPORT FOREIGN SCHEMA` command):

`import_collate`

This option controls whether column `COLLATE` options are included in the definitions of foreign tables imported from a foreign server. The default is `true`. You might need to turn this off if the remote server has a different set of collation names than the local server does, which is likely to be the case if it's running on a different operating system. If you do so, however, there is a very severe risk that the imported table columns' collations will not match the underlying data, resulting in anomalous query behavior.

Even when this parameter is set to `true`, importing columns whose collation is the remote server's default can be risky. They will be imported with `COLLATE "default"`, which will select the local server's default collation, which could be different.

`import_default`

This option controls whether column `DEFAULT` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `false`. If you enable this option, be wary of defaults that might get computed differently on the local server than they would be on the remote server; `nextval()` is a common source of problems. The `IMPORT` will fail altogether if an imported default expression uses a function or operator that does not exist locally.

`import_generated`

This option controls whether column `GENERATED` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `true`. The `IMPORT` will fail altogether if an imported generated expression uses a function or operator that does not exist locally.

`import_not_null`

This option controls whether column `NOT NULL` constraints are included in the definitions of foreign tables imported from a foreign server. The default is `true`.

Note that constraints other than `NOT NULL` will never be imported from the remote tables. Although Postgres Pro does support check constraints on foreign tables, there is no provision for importing them automatically, because of the risk that a constraint expression could evaluate differently on the local and remote servers. Any such inconsistency in the behavior of a check constraint could lead to hard-to-detect errors in query optimization. So if you wish to import check constraints, you must do so manually, and you should verify the semantics of each one carefully. For more detail about the treatment of check constraints on foreign tables, see CREATE FOREIGN TABLE.

Tables or foreign tables which are partitions of some other table are imported only when they are explicitly specified in `LIMIT TO` clause. Otherwise they are automatically excluded from IMPORT FOREIGN SCHEMA. Since all data can be accessed through the partitioned table which is the root of the partitioning hierarchy, importing only partitioned tables should allow access to all the data without creating extra objects.

F.52.1.9. Connection Management Options

By default, all connections that `postgres_fdw` establishes to foreign servers are kept open in the local session for re-use.

keep_connections

This option controls whether postgres_fdw keeps the connections to the foreign server open so that subsequent queries can re-use them. It can only be specified for a foreign server. The default is on. If set to off, all connections to this foreign server will be discarded at the end of each transaction.

F.52.2. Functions

postgres_fdw_get_connections(OUT server_name text, OUT valid boolean) returns setof record

This function returns the foreign server names of all the open connections that postgres_fdw established from the local session to the foreign servers. It also returns whether each connection is valid or not. false is returned if the foreign server connection is used in the current local transaction but its foreign server or user mapping is changed or dropped (Note that server name of an invalid connection will be NULL if the server is dropped), and then such invalid connection will be closed at the end of that transaction. true is returned otherwise. If there are no open connections, no record is returned. Example usage of the function:

```
postgres=# SELECT * FROM postgres_fdw_get_connections() ORDER BY 1;
 server_name | valid
-------------+-------
 loopback1   | t
 loopback2   | f
```

postgres_fdw_disconnect(server_name text) returns boolean

This function discards the open connections that are established by postgres_fdw from the local session to the foreign server with the given name. Note that there can be multiple connections to the given server using different user mappings. If the connections are used in the current local transaction, they are not disconnected and warning messages are reported. This function returns true if it disconnects at least one connection, otherwise false. If no foreign server with the given name is found, an error is reported. Example usage of the function:

```
postgres=# SELECT postgres_fdw_disconnect('loopback1');
 postgres_fdw_disconnect
-------------------------
 t
```

postgres_fdw_disconnect_all() returns boolean

This function discards all the open connections that are established by postgres_fdw from the local session to foreign servers. If the connections are used in the current local transaction, they are not disconnected and warning messages are reported. This function returns true if it disconnects at least one connection, otherwise false. Example usage of the function:

```
postgres=# SELECT postgres_fdw_disconnect_all();
 postgres_fdw_disconnect_all
-----------------------------
 t
```

F.52.3. Connection Management

postgres_fdw establishes a connection to a foreign server during the first query that uses a foreign table associated with the foreign server. By default this connection is kept and re-used for subsequent queries in the same session. This behavior can be controlled using keep_connections option for a foreign server. If multiple user identities (user mappings) are used to access the foreign server, a connection is established for each user mapping.

When changing the definition of or removing a foreign server or a user mapping, the associated connections are closed. But note that if any connections are in use in the current local transaction, they are kept until the end of the transaction. Closed connections will be re-established when they are necessary by future queries using a foreign table.

Once a connection to a foreign server has been established, it's by default kept until the local or corresponding remote session exits. To disconnect a connection explicitly, `keep_connections` option for a foreign server may be disabled, or `postgres_fdw_disconnect` and `postgres_fdw_disconnect_all` functions may be used. For example, these are useful to close connections that are no longer necessary, thereby releasing connections on the foreign server.

F.52.4. Transaction Management

During a query that references any remote tables on a foreign server, `postgres_fdw` opens a transaction on the remote server if one is not already open corresponding to the current local transaction. The remote transaction is committed or aborted when the local transaction commits or aborts. Savepoints are similarly managed by creating corresponding remote savepoints.

The remote transaction uses `SERIALIZABLE` isolation level when the local transaction has `SERIALIZABLE` isolation level; otherwise it uses `REPEATABLE READ` isolation level. This choice ensures that if a query performs multiple table scans on the remote server, it will get snapshot-consistent results for all the scans. A consequence is that successive queries within a single transaction will see the same data from the remote server, even if concurrent updates are occurring on the remote server due to other activities. That behavior would be expected anyway if the local transaction uses `SERIALIZABLE` or `REPEATABLE READ` isolation level, but it might be surprising for a `READ COMMITTED` local transaction. A future Postgres Pro release might modify these rules.

Note that it is currently not supported by `postgres_fdw` to prepare the remote transaction for two-phase commit.

F.52.5. Remote Query Optimization

`postgres_fdw` attempts to optimize remote queries to reduce the amount of data transferred from foreign servers. This is done by sending query `WHERE` clauses to the remote server for execution, and by not retrieving table columns that are not needed for the current query. To reduce the risk of misexecution of queries, `WHERE` clauses are not sent to the remote server unless they use only data types, operators, and functions that are built-in or belong to an extension that's listed in the foreign server's `extensions` option. Operators and functions in such clauses must be `IMMUTABLE` as well. For an `UPDATE` or `DELETE` query, `postgres_fdw` attempts to optimize the query execution by sending the whole query to the remote server if there are no query `WHERE` clauses that cannot be sent to the remote server, no local joins for the query, no row-level local `BEFORE` or `AFTER` triggers or stored generated columns on the target table, and no `CHECK OPTION` constraints from parent views. In `UPDATE`, expressions to assign to target columns must use only built-in data types, `IMMUTABLE` operators, or `IMMUTABLE` functions, to reduce the risk of misexecution of the query.

When `postgres_fdw` encounters a join between foreign tables on the same foreign server, it sends the entire join to the foreign server, unless for some reason it believes that it will be more efficient to fetch rows from each table individually, or unless the table references involved are subject to different user mappings. While sending the `JOIN` clauses, it takes the same precautions as mentioned above for the `WHERE` clauses.

The query that is actually sent to the remote server for execution can be examined using `EXPLAIN VERBOSE`.

F.52.6. Remote Query Execution Environment

In the remote sessions opened by `postgres_fdw`, the search_path parameter is set to just `pg_catalog`, so that only built-in objects are visible without schema qualification. This is not an issue for queries generated by `postgres_fdw` itself, because it always supplies such qualification. However, this can pose a hazard for functions that are executed on the remote server via triggers or rules on remote tables. For example, if a remote table is actually a view, any functions used in that view will be executed with the restricted search path. It is recommended to schema-qualify all names in such functions, or else attach `SET search_path` options (see CREATE FUNCTION) to such functions to establish their expected search path environment.

postgres_fdw likewise establishes remote session settings for various parameters:

- TimeZone is set to UTC
- DateStyle is set to ISO
- IntervalStyle is set to postgres
- extra_float_digits is set to 3 for remote servers 9.0 and newer and is set to 2 for older versions

These are less likely to be problematic than search_path, but can be handled with function SET options if the need arises.

It is *not* recommended that you override this behavior by changing the session-level settings of these parameters; that is likely to cause postgres_fdw to malfunction.

F.52.7. Cross-Version Compatibility

postgres_fdw can be used with remote servers dating back to PostgreSQL 8.3. Read-only capability is available back to 8.1. A limitation however is that postgres_fdw generally assumes that immutable built-in functions and operators are safe to send to the remote server for execution, if they appear in a WHERE clause for a foreign table. Thus, a built-in function that was added since the remote server's release might be sent to it for execution, resulting in “function does not exist” or a similar error. This type of failure can be worked around by rewriting the query, for example by embedding the foreign table reference in a sub-SELECT with OFFSET 0 as an optimization fence, and placing the problematic function or operator outside the sub-SELECT.

F.52.8. Examples

Here is an example of creating a foreign table with postgres_fdw. First install the extension:

```
CREATE EXTENSION postgres_fdw;
```

Then create a foreign server using CREATE SERVER. In this example we wish to connect to a Postgres Pro server on host 192.83.123.89 listening on port 5432. The database to which the connection is made is named foreign_db on the remote server:

```
CREATE SERVER foreign_server
        FOREIGN DATA WRAPPER postgres_fdw
        OPTIONS (host '192.83.123.89', port '5432', dbname 'foreign_db');
```

A user mapping, defined with CREATE USER MAPPING, is needed as well to identify the role that will be used on the remote server:

```
CREATE USER MAPPING FOR local_user
        SERVER foreign_server
        OPTIONS (user 'foreign_user', password 'password');
```

Now it is possible to create a foreign table with CREATE FOREIGN TABLE. In this example we wish to access the table named some_schema.some_table on the remote server. The local name for it will be foreign_table:

```
CREATE FOREIGN TABLE foreign_table (
        id integer NOT NULL,
        data text
)
        SERVER foreign_server
        OPTIONS (schema_name 'some_schema', table_name 'some_table');
```

It's essential that the data types and other properties of the columns declared in CREATE FOREIGN TABLE match the actual remote table. Column names must match as well, unless you attach column_name options to the individual columns to show how they are named in the remote table. In many cases, use of IMPORT FOREIGN SCHEMA is preferable to constructing foreign table definitions manually.

F.52.9. Author

Shigeru Hanada <shigeru.hanada@gmail.com>

F.53. ptrack

PTRACK is a block-level incremental backup engine for Postgres Pro. If PTRACK is enabled, backup tools like pg_probackup can use its API to get information on the changed blocks on the fly when taking incremental backups. Copying only those blocks that have changed since the previous backup can significantly speed up the creation and minimize the size of backups.

PTRACK is designed to allow false positives, but to never allow false negatives: it means that all changes within the data directory except hint bits are guaranteed to be marked in the PTRACK map file, although some unchanged blocks might be included as well.

F.53.1. Setting up PTRACK

Once you complete Postgres Pro Standard installation, do the following:

1. Add `ptrack` to the shared_preload_libraries parameter in the `postgresql.conf` file:

   ```
   shared_preload_libraries = 'ptrack'
   ```

2. Set ptrack.map_size parameter to a positive integer.

   For optimal performance, it is recommended to set `ptrack.map_size` to *N* `/ 1024`, where *N* is the size of the Postgres Pro cluster, in `MB`. If you set this parameter to a lower value, PTRACK is more likely to map several blocks together, which leads to false-positive results when tracking changed blocks and increases the incremental backup size as unchanged blocks can also be copied into the incremental backup.

   Setting `ptrack.map_size` to a higher value does not affect PTRACK operation, but keep in mind that you need up to `ptrack.map_size * 3 MB` of additional disk space since PTRACK uses two additional temporary files to ensure durability. It is not recommended to set this parameter to a value higher than 1024. Even for Postgres Pro clusters with *N* > 1 `TB`, it makes sense to use a higher value only if the efficiency and sizes of backups are more critical than the potential overhead of maintaining a large PTRACK map.

3. Check the wal_level setting. When using PTRACK, it is required to set the wal_level parameter to `replica` or higher. Otherwise, you can lose some tracked changes if crash-recovery occurs: some commands do not write WAL at all if `wal_level` is `minimal`, and PTRACK map files are flushed to disk only at checkpoint time.

4. Restart the Postgres Pro Standard instance for the changes to take effect, and then create the PTRACK extension:

   ```
   CREATE EXTENSION ptrack;
   ```

   As a result, several PTRACK functions are created, which are required for accessing PTRACK data.

Once this setup is complete, PTRACK starts tracking all the page changes in the Postgres Pro cluster and creates a `ptrack.map` file that stores the latest LSN values for these pages.

> **Note**
>
> The `ptrack.map_size` parameter can only be set at server start. If you change this parameter, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. To avoid losing recent changes, it is recommended to retake a full backup after modifying this setting.

F.53.2. PTRACK Configuration Parameters

`ptrack.map_size` (`integer`)

Specifies the size of a PTRACK map file and the amount of shared memory allocated for this file, in `MB`. The PTRACK map file stores the latest LSN values for all pages of the Postgres Pro cluster that

have changed since PTRACK was enabled. It is not recommended to set this parameter to a value higher than 1GB. The 0 value disables PTRACK and cleans up all the related service files.

The `ptrack.map_size` parameter can only be set at server start. If you change this parameter, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. To avoid losing recent changes, it is recommended to retake a full backup after modifying this setting.

Default: 0

F.53.3. PTRACK Functions

`ptrack_init_lsn() returns pg_lsn`

Returns the LSN of the last PTRACK map initialization.

`ptrack_get_pagemapset(`*`start_lsn`* `pg_lsn) returns setof record`

Returns a list of data files changed since the specified *`start_lsn`* with the number and bitmap of changed pages for each file.

For example:

```
postgres=# SELECT * FROM ptrack_get_pagemapset('0/185C8C0');
        path          | pagecount |                 pagemap
----------------------+-----------+-----------------------------------------
 base/16384/1255      |         3 | \x00100000000050000000000000
 base/16384/2674      |         3 | \x00000009000100000000000000000
 base/16384/2691      |         1 | \x00004000000000000000000000
 base/16384/2608      |         1 | \x00000000000000004000000000000000000000
 base/16384/2690      |         1 | \x00040000000000000000000000
```

`ptrack_get_change_stat(`*`start_lsn`* `pg_lsn) returns record`

Returns the statistics of changes (number of files, number of changed pages and their total size in `MB`) since the specified *`start_lsn`*.

For example:

```
postgres=# SELECT * FROM ptrack_get_change_stat('0/285C8C8');
 files | pages |        size, MB
-------+-------+------------------------
    20 |    25 | 0.19531250000000000000
```

`ptrack_version() returns text`

Returns PTRACK version.

F.54. rum

F.54.1. Introduction

The **rum** module provides access method to work with the `RUM` indexes. It is based on the `GIN` access method code.

`GIN` index allows you to perform fast full-text search using `tsvector` and `tsquery` types. However, full-text search with `GIN` index has some performance issues because positional and other additional information is not stored.

`RUM` solves these issues by storing additional information in a posting tree. As compared to `GIN`, `RUM` index has the following benefits:

- Faster ranking. Ranking requires positional information. And after the index scan we do not need an additional heap scan to retrieve lexeme positions because `RUM` index stores them.

- Faster phrase search. This improvement is related to the previous one as phrase search also needs positional information.
- Faster ordering by timestamp. RUM index stores additional information together with lexemes, so it is not necessary to perform a heap scan.
- A possibility to perform depth-first search and therefore return first results immediately.

The drawback of RUM is that it has slower build and insert time as compared to GIN because RUM stores additional information together with keys and uses generic WAL records.

F.54.2. Installation

rum is a Postgres Pro Standard extension and it has no special prerequisites.

Install extension as follows:

```
$ psql dbname -c "CREATE EXTENSION rum"
```

F.54.3. Common Operators

The operators provided by the rum module are shown in Table F.35:

Table F.35. rum Operators

Operator	Returns	Description
tsvector <=> tsquery	float4	Returns distance between tsvector and tsquery values.
timestamp <=> timestamp	float8	Returns distance between two timestamp values.
timestamp <=| timestamp	float8	Returns distance only for ascending timestamp values.
timestamp |=> timestamp	float8	Returns distance only for descending timestamp values.

> **Note**
>
> rum introduces its own ranking function that is executed inside the <=> operator. It calculates the score (inverted distance) using the specified normalization method. This function is a combination of ts_rank and ts_rank_cd (see Section 9.13 for details). While ts_rank does not support logical operators and ts_rank_cd works poorly with OR queries, the rum-specific ranking function overcomes these drawbacks.

F.54.4. Operator Classes

The rum extension provides the following operator classes:

rum_tsvector_ops

Stores tsvector lexemes with positional information. Supports ordering by <=> operator and prefix search.

rum_tsvector_hash_ops

Stores hash of tsvector lexemes with positional information. Supports ordering by <=> operator, but does not support prefix search.

rum_tsvector_addon_ops

Stores tsvector lexemes with additional data of any type supported by RUM.

> **Note**
>
> To use the rum_tsvector_addon_ops operator class, when creating the RUM index with CREATE INDEX, specify the attach and to storage parameters in the WITH clause.

rum_tsvector_hash_addon_ops

Stores tsvector lexemes with additional data of any type supported by RUM. Does not support prefix search.

rum_tsquery_ops

Stores branches of query tree in additional information.

rum_anyarray_ops

Stores anyarray elements with length of the array. Supports ordering by <=> operator.

Indexable operators: && @> <@ = %

rum_anyarray_addon_ops

Stores anyarray elements with additional data of any type supported by RUM.

rum_*type*_ops

Stores lexemes of the corresponding type with positional information. The *type* placeholder in the class name must be substituted by one of the following type names: int2, int4, int8, float4, float8, money, oid, timestamp, timestamptz, time, timetz, date, interval, macaddr, inet, cidr, text, varchar, char, bytea, bit, varbit, numeric.

rum_*type*_ops supports ordering by <=>, <=|, and |=> operators. This operator class can be used together with rum_tsvector_addon_ops, rum_tsvector_hash_addon_ops, and rum_anyarray_addon_ops operator classes.

Supported indexable operators depend on the data type:

- < <= = >= > <=> <=| |=> are supported for int2, int4, int8, float4, float8, money, oid, timestamp, timestamptz.
- < <= = >= > are supported for time, timetz, date, interval, macaddr, inet, cidr, text, varchar, char, bytea, bit, varbit, numeric.

> **Note**
>
> The following operator classes are now deprecated: rum_tsvector_timestamp_ops, rum_tsvector_timestamptz_ops, rum_tsvector_hash_timestamp_ops, rum_tsvector_hash_timestamptz_ops.

F.54.5. Examples

F.54.5.1. rum_tsvector_ops Example

Let's assume we have the following table:

```
CREATE TABLE test_rum(t text, a tsvector);

CREATE TRIGGER tsvectorupdate
BEFORE UPDATE OR INSERT ON test_rum
```

```
FOR EACH ROW EXECUTE PROCEDURE tsvector_update_trigger('a', 'pg_catalog.english', 't');

INSERT INTO test_rum(t) VALUES ('The situation is most beautiful');
INSERT INTO test_rum(t) VALUES ('It is a beautiful');
INSERT INTO test_rum(t) VALUES ('It looks like a beautiful place');
```

Then we can create a new index:

```
CREATE INDEX rumidx ON test_rum USING rum (a rum_tsvector_ops);
```

And we can execute the following queries:

```
SELECT t, a <=> to_tsquery('english', 'beautiful | place') AS rank
    FROM test_rum
    WHERE a @@ to_tsquery('english', 'beautiful | place')
    ORDER BY a <=> to_tsquery('english', 'beautiful | place');
              t                |   rank
-------------------------------+-----------
 The situation is most beautiful | 0.0303964
 It is a beautiful               | 0.0303964
 It looks like a beautiful place | 0.0607927
(3 rows)

SELECT t, a <=> to_tsquery('english', 'place | situation') AS rank
    FROM test_rum
    WHERE a @@ to_tsquery('english', 'place | situation')
    ORDER BY a <=> to_tsquery('english', 'place | situation');
              t                |   rank
-------------------------------+-----------
 The situation is most beautiful | 0.0303964
 It looks like a beautiful place | 0.0303964
(2 rows)
```

F.54.5.2. rum_tsvector_addon_ops Example

Let's assume we have the following table:

```
CREATE TABLE tsts (id int, t tsvector, d timestamp);

\copy tsts from 'rum/data/tsts.data'

CREATE INDEX tsts_idx ON tsts USING rum (t rum_tsvector_addon_ops, d)
    WITH (attach = 'd', to = 't');
```

Now we can execute the following queries:

```
EXPLAIN (costs off)
    SELECT id, d, d <=> '2016-05-16 14:21:25' FROM tsts WHERE t @@ 'wr&qh' ORDER BY d
 <=> '2016-05-16 14:21:25' LIMIT 5;
                                  QUERY PLAN
-------------------------------------------------------------------------------------
 Limit
   ->  Index Scan using tsts_idx on tsts
         Index Cond: (t @@ '''wr'' & ''qh'''::tsquery)
         Order By: (d <=> 'Mon May 16 14:21:25 2016'::timestamp without time zone)
(4 rows)

SELECT id, d, d <=> '2016-05-16 14:21:25' FROM tsts WHERE t @@ 'wr&qh' ORDER BY d <=>
 '2016-05-16 14:21:25' LIMIT 5;
 id  |                d                |   ?column?
-----+---------------------------------+---------------
```

```
 355 | Mon May 16 14:21:22.326724 2016 |      2.673276
 354 | Mon May 16 13:21:22.326724 2016 |   3602.673276
 371 | Tue May 17 06:21:22.326724 2016 |  57597.326724
 406 | Wed May 18 17:21:22.326724 2016 | 183597.326724
 415 | Thu May 19 02:21:22.326724 2016 | 215997.326724
(5 rows)
```

F.54.5.3. rum_tsquery_ops Example

Suppose we have the table:

```
CREATE TABLE query (q tsquery, tag text);

INSERT INTO query VALUES ('supernova & star', 'sn'),
    ('black', 'color'),
    ('big & bang & black & hole', 'bang'),
    ('spiral & galaxy', 'shape'),
    ('black & hole', 'color');

CREATE INDEX query_idx ON query USING rum(q);
```

We can execute the following fast query:

```
SELECT * FROM query
    WHERE to_tsvector('black holes never exists before we think about them') @@ q;
        q         |  tag
------------------+-------
 'black'          | color
 'black' & 'hole' | color
(2 rows)
```

F.54.5.4. rum_anyarray_ops Example

Let's assume we have the following table:

```
CREATE TABLE test_array (i int2[]);

INSERT INTO test_array VALUES ('{}'), ('{0}'), ('{1,2,3,4}'), ('{1,2,3}'), ('{1,2}'),
 ('{1}');

CREATE INDEX idx_array ON test_array USING rum (i rum_anyarray_ops);
```

Now we can execute the following query using index scan:

```
SET enable_seqscan TO off;

EXPLAIN (COSTS OFF) SELECT * FROM test_array WHERE i && '{1}' ORDER BY i <=> '{1}' ASC;
                QUERY PLAN
------------------------------------------
 Index Scan using idx_array on test_array
   Index Cond: (i && '{1}'::smallint[])
   Order By: (i <=> '{1}'::smallint[])
(3 rows)

SELECT * FROM test_array WHERE i && '{1}' ORDER BY i <=> '{1}' ASC;
     i
-----------
 {1}
 {1,2}
 {1,2,3}
 {1,2,3,4}
(4 rows)
```

Teodor Sigaev

F.55. seg

This module implements a data type `seg` for representing line segments, or floating point intervals. `seg` can represent uncertainty in the interval endpoints, making it especially useful for representing laboratory measurements.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.55.1. Rationale

The geometry of measurements is usually more complex than that of a point in a numeric continuum. A measurement is usually a segment of that continuum with somewhat fuzzy limits. The measurements come out as intervals because of uncertainty and randomness, as well as because the value being measured may naturally be an interval indicating some condition, such as the temperature range of stability of a protein.

Using just common sense, it appears more convenient to store such data as intervals, rather than pairs of numbers. In practice, it even turns out more efficient in most applications.

Further along the line of common sense, the fuzziness of the limits suggests that the use of traditional numeric data types leads to a certain loss of information. Consider this: your instrument reads 6.50, and you input this reading into the database. What do you get when you fetch it? Watch:

```
test=> select 6.50 :: float8 as "pH";
 pH
---
6.5
(1 row)
```

In the world of measurements, 6.50 is not the same as 6.5. It may sometimes be critically different. The experimenters usually write down (and publish) the digits they trust. 6.50 is actually a fuzzy interval contained within a bigger and even fuzzier interval, 6.5, with their center points being (probably) the only common feature they share. We definitely do not want such different data items to appear the same.

Conclusion? It is nice to have a special data type that can record the limits of an interval with arbitrarily variable precision. Variable in the sense that each data element records its own precision.

Check this out:

```
test=> select '6.25 .. 6.50'::seg as "pH";
          pH
------------
6.25 .. 6.50
(1 row)
```

F.55.2. Syntax

The external representation of an interval is formed using one or two floating-point numbers joined by the range operator (`..` or `...`). Alternatively, it can be specified as a center point plus or minus a deviation. Optional certainty indicators (`<`, `>` or `~`) can be stored as well. (Certainty indicators are ignored by all the built-in operators, however.) Table F.36 gives an overview of allowed representations; Table F.37 shows some examples.

In Table F.36, *x*, *y*, and *delta* denote floating-point numbers. *x* and *y*, but not *delta*, can be preceded by a certainty indicator.

Table F.36. seg External Representations

x	Single value (zero-length interval)
x .. *y*	Interval from *x* to *y*
x (+-) *delta*	Interval from *x* - *delta* to *x* + *delta*
x ..	Open interval with lower bound *x*
.. *x*	Open interval with upper bound *x*

Table F.37. Examples of Valid seg Input

5.0	Creates a zero-length segment (a point, if you will)
~5.0	Creates a zero-length segment and records ~ in the data. ~ is ignored by seg operations, but is preserved as a comment.
<5.0	Creates a point at 5.0. < is ignored but is preserved as a comment.
>5.0	Creates a point at 5.0. > is ignored but is preserved as a comment.
5(+-)0.3	Creates an interval 4.7 .. 5.3. Note that the (+-) notation isn't preserved.
50 ..	Everything that is greater than or equal to 50
.. 0	Everything that is less than or equal to 0
1.5e-2 .. 2E-2	Creates an interval 0.015 .. 0.02
1 ... 2	The same as 1...2, or 1 .. 2, or 1..2 (spaces around the range operator are ignored)

Because the ... operator is widely used in data sources, it is allowed as an alternative spelling of the .. operator. Unfortunately, this creates a parsing ambiguity: it is not clear whether the upper bound in 0...23 is meant to be 23 or 0.23. This is resolved by requiring at least one digit before the decimal point in all numbers in seg input.

As a sanity check, seg rejects intervals with the lower bound greater than the upper, for example 5 .. 2.

F.55.3. Precision

seg values are stored internally as pairs of 32-bit floating point numbers. This means that numbers with more than 7 significant digits will be truncated.

Numbers with 7 or fewer significant digits retain their original precision. That is, if your query returns 0.00, you will be sure that the trailing zeroes are not the artifacts of formatting: they reflect the precision of the original data. The number of leading zeroes does not affect precision: the value 0.0067 is considered to have just 2 significant digits.

F.55.4. Usage

The seg module includes a GiST index operator class for seg values. The operators supported by the GiST operator class are shown in Table F.38.

Table F.38. Seg GiST Operators

Operator Description
seg << seg → boolean

Operator Description
Is the first seg entirely to the left of the second? [a, b] << [c, d] is true if b < c.
seg >> seg → boolean Is the first seg entirely to the right of the second? [a, b] >> [c, d] is true if a > d.
seg &< seg → boolean Does the first seg not extend to the right of the second? [a, b] &< [c, d] is true if b <= d.
seg &> seg → boolean Does the first seg not extend to the left of the second? [a, b] &> [c, d] is true if a >= c.
seg = seg → boolean Are the two segs equal?
seg && seg → boolean Do the two segs overlap?
seg @> seg → boolean Does the first seg contain the second?
seg <@ seg → boolean Is the first seg contained in the second?

In addition to the above operators, the usual comparison operators shown in Table 9.1 are available for type seg. These operators first compare (a) to (c), and if these are equal, compare (b) to (d). That results in reasonably good sorting in most cases, which is useful if you want to use ORDER BY with this type.

F.55.5. Notes

For examples of usage, see the regression test sql/seg.sql.

The mechanism that converts (+-) to regular ranges isn't completely accurate in determining the number of significant digits for the boundaries. For example, it adds an extra digit to the lower boundary if the resulting interval includes a power of ten:

```
postgres=> select '10(+-)1'::seg as seg;
      seg
---------
9.0 .. 11             -- should be: 9 .. 11
```

The performance of an R-tree index can largely depend on the initial order of input values. It may be very helpful to sort the input table on the seg column; see the script sort-segments.pl for an example.

F.55.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (*https://dsf.berkeley.edu/jmh/*) for elucidating the gist of the GiST (*http://gist.cs.berkeley.edu/*). I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

F.56. sepgsql

sepgsql is a loadable module that supports label-based mandatory access control (MAC) based on SELinux security policy.

Warning

The current implementation has significant limitations, and does not enforce mandatory access control for all actions. See Section F.56.7.

F.56.1. Overview

This module integrates with SELinux to provide an additional layer of security checking above and beyond what is normally provided by Postgres Pro. From the perspective of SELinux, this module allows Postgres Pro to function as a user-space object manager. Each table or function access initiated by a DML query will be checked against the system security policy. This check is in addition to the usual SQL permissions checking performed by Postgres Pro.

SELinux access control decisions are made using security labels, which are represented by strings such as `system_u:object_r:sepgsql_table_t:s0`. Each access control decision involves two labels: the label of the subject attempting to perform the action, and the label of the object on which the operation is to be performed. Since these labels can be applied to any sort of object, access control decisions for objects stored within the database can be (and, with this module, are) subjected to the same general criteria used for objects of any other type, such as files. This design is intended to allow a centralized security policy to protect information assets independent of the particulars of how those assets are stored.

The `SECURITY LABEL` statement allows assignment of a security label to a database object.

F.56.2. Installation

`sepgsql` can only be used on Linux 2.6.28 or higher with SELinux enabled. It is not available on any other platform. You will also need libselinux 2.1.10 or higher and selinux-policy 3.9.13 or higher (although some distributions may backport the necessary rules into older policy versions).

The `sestatus` command allows you to check the status of SELinux. A typical display is:

```
$ sestatus
SELinux status:                 enabled
SELinuxfs mount:                /selinux
Current mode:                   enforcing
Mode from config file:          enforcing
Policy version:                 24
Policy from config file:        targeted
```

If SELinux is disabled or not installed, you must set that product up first before installing this module.

To build this module, include the option `--with-selinux` in your Postgres Pro `configure` command. Be sure that the `libselinux-devel` RPM is installed at build time.

To use this module, you must include `sepgsql` in the shared_preload_libraries parameter in `postgresql.conf`. The module will not function correctly if loaded in any other manner. Once the module is loaded, you should execute `sepgsql.sql` in each database. This will install functions needed for security label management, and assign initial security labels.

Here is an example showing how to initialize a fresh database cluster with `sepgsql` functions and security labels installed. Adjust the paths shown as appropriate for your installation:

```
$ export PGDATA=/path/to/data/directory
$ initdb
$ vi $PGDATA/postgresql.conf
  change
    #shared_preload_libraries = ''                # (change requires restart)
  to
```

```
    shared_preload_libraries = 'sepgsql'          # (change requires restart)
$ for DBNAME in template0 template1 postgres; do
    postgres --single -F -c exit_on_error=true $DBNAME \
      </usr/local/pgsql/share/contrib/sepgsql.sql >/dev/null
  done
```

Please note that you may see some or all of the following notifications depending on the particular versions you have of libselinux and selinux-policy:

```
/etc/selinux/targeted/contexts/sepgsql_contexts:  line 33 has invalid object type
 db_blobs
/etc/selinux/targeted/contexts/sepgsql_contexts:  line 36 has invalid object type
 db_language
/etc/selinux/targeted/contexts/sepgsql_contexts:  line 37 has invalid object type
 db_language
/etc/selinux/targeted/contexts/sepgsql_contexts:  line 38 has invalid object type
 db_language
/etc/selinux/targeted/contexts/sepgsql_contexts:  line 39 has invalid object type
 db_language
/etc/selinux/targeted/contexts/sepgsql_contexts:  line 40 has invalid object type
 db_language
```

These messages are harmless and should be ignored.

If the installation process completes without error, you can now start the server normally.

F.56.3. Regression Tests

Due to the nature of SELinux, running the regression tests for `sepgsql` requires several extra configuration steps, some of which must be done as root. The regression tests will not be run by an ordinary `make check` or `make installcheck` command; you must set up the configuration and then invoke the test script manually. The tests must be run in the `contrib/sepgsql` directory of a configured Postgres Pro build tree. Although they require a build tree, the tests are designed to be executed against an installed server, that is they are comparable to `make installcheck` not `make check`.

First, set up `sepgsql` in a working database according to the instructions in Section F.56.2. Note that the current operating system user must be able to connect to the database as superuser without password authentication.

Second, build and install the policy package for the regression test. The `sepgsql-regtest` policy is a special purpose policy package which provides a set of rules to be allowed during the regression tests. It should be built from the policy source file `sepgsql-regtest.te`, which is done using `make` with a Makefile supplied by SELinux. You will need to locate the appropriate Makefile on your system; the path shown below is only an example. (This Makefile is usually supplied by the `selinux-policy-devel` or `selinux-policy` RPM.) Once built, install this policy package using the `semodule` command, which loads supplied policy packages into the kernel. If the package is correctly installed, `semodule -l` should list `sepgsql-regtest` as an available policy package:

```
$ cd .../contrib/sepgsql
$ make -f /usr/share/selinux/devel/Makefile
$ sudo semodule -u sepgsql-regtest.pp
$ sudo semodule -l | grep sepgsql
sepgsql-regtest 1.07
```

Third, turn on `sepgsql_regression_test_mode`. For security reasons, the rules in `sepgsql-regtest` are not enabled by default; the `sepgsql_regression_test_mode` parameter enables the rules needed to launch the regression tests. It can be turned on using the `setsebool` command:

```
$ sudo setsebool sepgsql_regression_test_mode on
$ getsebool sepgsql_regression_test_mode
sepgsql_regression_test_mode --> on
```

Fourth, verify your shell is operating in the `unconfined_t` domain:

```
$ id -Z
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023
```

See Section F.56.8 for details on adjusting your working domain, if necessary.

Finally, run the regression test script:

```
$ ./test_sepgsql
```

This script will attempt to verify that you have done all the configuration steps correctly, and then it will run the regression tests for the `sepgsql` module.

After completing the tests, it's recommended you disable the `sepgsql_regression_test_mode` parameter:

```
$ sudo setsebool sepgsql_regression_test_mode off
```

You might prefer to remove the `sepgsql-regtest` policy entirely:

```
$ sudo semodule -r sepgsql-regtest
```

F.56.4. GUC Parameters

`sepgsql.permissive` (`boolean`)

This parameter enables `sepgsql` to function in permissive mode, regardless of the system setting. The default is off. This parameter can only be set in the `postgresql.conf` file or on the server command line.

When this parameter is on, `sepgsql` functions in permissive mode, even if SELinux in general is working in enforcing mode. This parameter is primarily useful for testing purposes.

`sepgsql.debug_audit` (`boolean`)

This parameter enables the printing of audit messages regardless of the system policy settings. The default is off, which means that messages will be printed according to the system settings.

The security policy of SELinux also has rules to control whether or not particular accesses are logged. By default, access violations are logged, but allowed accesses are not.

This parameter forces all possible logging to be turned on, regardless of the system policy.

F.56.5. Features

F.56.5.1. Controlled Object Classes

The security model of SELinux describes all the access control rules as relationships between a subject entity (typically, a client of the database) and an object entity (such as a database object), each of which is identified by a security label. If access to an unlabeled object is attempted, the object is treated as if it were assigned the label `unlabeled_t`.

Currently, `sepgsql` allows security labels to be assigned to schemas, tables, columns, sequences, views, and functions. When `sepgsql` is in use, security labels are automatically assigned to supported database objects at creation time. This label is called a default security label, and is decided according to the system security policy, which takes as input the creator's label, the label assigned to the new object's parent object and optionally name of the constructed object.

A new database object basically inherits the security label of the parent object, except when the security policy has special rules known as type-transition rules, in which case a different label may be applied. For schemas, the parent object is the current database; for tables, sequences, views, and functions, it is the containing schema; for columns, it is the containing table.

F.56.5.2. DML Permissions

For tables, db_table:select, db_table:insert, db_table:update or db_table:delete are checked for all the referenced target tables depending on the kind of statement; in addition, db_table:select is also checked for all the tables that contain columns referenced in the WHERE or RETURNING clause, as a data source for UPDATE, and so on.

Column-level permissions will also be checked for each referenced column. db_column:select is checked on not only the columns being read using SELECT, but those being referenced in other DML statements; db_column:update or db_column:insert will also be checked for columns being modified by UPDATE or INSERT.

For example, consider:

```
UPDATE t1 SET x = 2, y = func1(y) WHERE z = 100;
```

Here, db_column:update will be checked for t1.x, since it is being updated, db_column:{select update} will be checked for t1.y, since it is both updated and referenced, and db_column:select will be checked for t1.z, since it is only referenced. db_table:{select update} will also be checked at the table level.

For sequences, db_sequence:get_value is checked when we reference a sequence object using SELECT; however, note that we do not currently check permissions on execution of corresponding functions such as lastval().

For views, db_view:expand will be checked, then any other required permissions will be checked on the objects being expanded from the view, individually.

For functions, db_procedure:{execute} will be checked when user tries to execute a function as a part of query, or using fast-path invocation. If this function is a trusted procedure, it also checks db_procedure:{entrypoint} permission to check whether it can perform as entry point of trusted procedure.

In order to access any schema object, db_schema:search permission is required on the containing schema. When an object is referenced without schema qualification, schemas on which this permission is not present will not be searched (just as if the user did not have USAGE privilege on the schema). If an explicit schema qualification is present, an error will occur if the user does not have the requisite permission on the named schema.

The client must be allowed to access all referenced tables and columns, even if they originated from views which were then expanded, so that we apply consistent access control rules independent of the manner in which the table contents are referenced.

The default database privilege system allows database superusers to modify system catalogs using DML commands, and reference or modify toast tables. These operations are prohibited when sepgsql is enabled.

F.56.5.3. DDL Permissions

SELinux defines several permissions to control common operations for each object type; such as creation, alter, drop and relabel of security label. In addition, several object types have special permissions to control their characteristic operations; such as addition or deletion of name entries within a particular schema.

Creating a new database object requires create permission. SELinux will grant or deny this permission based on the client's security label and the proposed security label for the new object. In some cases, additional privileges are required:

- CREATE DATABASE additionally requires getattr permission for the source or template database.
- Creating a schema object additionally requires add_name permission on the parent schema.
- Creating a table additionally requires permission to create each individual table column, just as if each table column were a separate top-level object.

- Creating a function marked as LEAKPROOF additionally requires install permission. (This permission is also checked when LEAKPROOF is set for an existing function.)

When DROP command is executed, drop will be checked on the object being removed. Permissions will be also checked for objects dropped indirectly via CASCADE. Deletion of objects contained within a particular schema (tables, views, sequences and procedures) additionally requires remove_name on the schema.

When ALTER command is executed, setattr will be checked on the object being modified for each object types, except for subsidiary objects such as the indexes or triggers of a table, where permissions are instead checked on the parent object. In some cases, additional permissions are required:

- Moving an object to a new schema additionally requires remove_name permission on the old schema and add_name permission on the new one.
- Setting the LEAKPROOF attribute on a function requires install permission.
- Using SECURITY LABEL on an object additionally requires relabelfrom permission for the object in conjunction with its old security label and relabelto permission for the object in conjunction with its new security label. (In cases where multiple label providers are installed and the user tries to set a security label, but it is not managed by SELinux, only setattr should be checked here. This is currently not done due to implementation restrictions.)

F.56.5.4. Trusted Procedures

Trusted procedures are similar to security definer functions or setuid commands. SELinux provides a feature to allow trusted code to run using a security label different from that of the client, generally for the purpose of providing highly controlled access to sensitive data (e.g., rows might be omitted, or the precision of stored values might be reduced). Whether or not a function acts as a trusted procedure is controlled by its security label and the operating system security policy. For example:

```
postgres=# CREATE TABLE customer (
               cid     int primary key,
               cname   text,
               credit  text
           );
CREATE TABLE
postgres=# SECURITY LABEL ON COLUMN customer.credit
               IS 'system_u:object_r:sepgsql_secret_table_t:s0';
SECURITY LABEL
postgres=# CREATE FUNCTION show_credit(int) RETURNS text
             AS 'SELECT regexp_replace(credit, ''-[0-9]+$'', ''-xxxx'', ''g'')
                         FROM customer WHERE cid = $1'
          LANGUAGE sql;
CREATE FUNCTION
postgres=# SECURITY LABEL ON FUNCTION show_credit(int)
               IS 'system_u:object_r:sepgsql_trusted_proc_exec_t:s0';
SECURITY LABEL
```

The above operations should be performed by an administrative user.

```
postgres=# SELECT * FROM customer;
ERROR:  SELinux: security policy violation
postgres=# SELECT cid, cname, show_credit(cid) FROM customer;
 cid | cname  |     show_credit
-----+--------+---------------------
   1 | taro   | 1111-2222-3333-xxxx
   2 | hanako | 5555-6666-7777-xxxx
(2 rows)
```

In this case, a regular user cannot reference customer.credit directly, but a trusted procedure show_credit allows the user to print the credit card numbers of customers with some of the digits masked out.

F.56.5.5. Dynamic Domain Transitions

It is possible to use SELinux's dynamic domain transition feature to switch the security label of the client process, the client domain, to a new context, if that is allowed by the security policy. The client domain needs the `setcurrent` permission and also `dyntransition` from the old to the new domain.

Dynamic domain transitions should be considered carefully, because they allow users to switch their label, and therefore their privileges, at their option, rather than (as in the case of a trusted procedure) as mandated by the system. Thus, the `dyntransition` permission is only considered safe when used to switch to a domain with a smaller set of privileges than the original one. For example:

```
regression=# select sepgsql_getcon();
                    sepgsql_getcon
-----------------------------------------------------
 unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023
(1 row)

regression=# SELECT sepgsql_setcon('unconfined_u:unconfined_r:unconfined_t:s0-
s0:c1.c4');
 sepgsql_setcon
----------------
 t
(1 row)

regression=# SELECT sepgsql_setcon('unconfined_u:unconfined_r:unconfined_t:s0-
s0:c1.c1023');
ERROR:  SELinux: security policy violation
```

In this example above we were allowed to switch from the larger MCS range `c1.c1023` to the smaller range `c1.c4`, but switching back was denied.

A combination of dynamic domain transition and trusted procedure enables an interesting use case that fits the typical process life-cycle of connection pooling software. Even if your connection pooling software is not allowed to run most of SQL commands, you can allow it to switch the security label of the client using the `sepgsql_setcon()` function from within a trusted procedure; that should take some credential to authorize the request to switch the client label. After that, this session will have the privileges of the target user, rather than the connection pooler. The connection pooler can later revert the security label change by again using `sepgsql_setcon()` with `NULL` argument, again invoked from within a trusted procedure with appropriate permissions checks. The point here is that only the trusted procedure actually has permission to change the effective security label, and only does so when given proper credentials. Of course, for secure operation, the credential store (table, procedure definition, or whatever) must be protected from unauthorized access.

F.56.5.6. Miscellaneous

We reject the `LOAD` command across the board, because any module loaded could easily circumvent security policy enforcement.

F.56.6. Sepgsql Functions

Table F.39 shows the available functions.

Table F.39. Sepgsql Functions

Function Description
`sepgsql_getcon ()` → `text` Returns the client domain, the current security label of the client.
`sepgsql_setcon ( text )` → `boolean`

Function Description
Switches the client domain of the current session to the new domain, if allowed by the security policy. It also accepts NULL input as a request to transition to the client's original domain.
sepgsql_mcstrans_in (text) → text Translates the given qualified MLS/MCS range into raw format if the mcstrans daemon is running.
sepgsql_mcstrans_out (text) → text Translates the given raw MLS/MCS range into qualified format if the mcstrans daemon is running.
sepgsql_restorecon (text) → boolean Sets up initial security labels for all objects within the current database. The argument may be NULL, or the name of a specfile to be used as alternative of the system default.

F.56.7. Limitations

Data Definition Language (DDL) Permissions

Due to implementation restrictions, some DDL operations do not check permissions.

Data Control Language (DCL) Permissions

Due to implementation restrictions, DCL operations do not check permissions.

Row-level access control

Postgres Pro supports row-level access, but sepgsql does not.

Covert channels

sepgsql does not try to hide the existence of a certain object, even if the user is not allowed to reference it. For example, we can infer the existence of an invisible object as a result of primary key conflicts, foreign key violations, and so on, even if we cannot obtain the contents of the object. The existence of a top secret table cannot be hidden; we only hope to conceal its contents.

F.56.8. External Resources

SE-PostgreSQL Introduction

This wiki page provides a brief overview, security design, architecture, administration and upcoming features.

SELinux User's and Administrator's Guide

This document provides a wide spectrum of knowledge to administer SELinux on your systems. It focuses primarily on Red Hat operating systems, but is not limited to them.

Fedora SELinux FAQ

This document answers frequently asked questions about SELinux. It focuses primarily on Fedora, but is not limited to Fedora.

F.56.9. Author

KaiGai Kohei <kaigai@ak.jp.nec.com>

F.57. shared_ispell

The shared_ispell module provides a shared ispell dictionary, i.e. a dictionary that's stored in shared segment. The traditional ispell implementation means that each session initializes and stores the dictionary on it's own, which means a lot of CPU/RAM is wasted.

This extension allocates an area in shared segment (you have to choose the size in advance) and then loads the dictionary into it when it's used for the first time.

F.57.1. Functions

The functions provided by the `shared_ispell` module are shown in Table F.40.

Table F.40. `shared_ispell` Functions

Function	Returns	Description
`shared_ispell_reset()`	`void`	Resets the dictionaries (e.g. so that you can reload the updated files from disk). The sessions that already use the dictionaries will be forced to reinitialize them.
`shared_ispell_mem_used()`	`int`	Returns a value of used memory of the shared segment by loaded shared dictionaries in bytes.
`shared_ispell_mem_available()`	`int`	Returns a value of available memory of the shared segment.
`shared_ispell_dicts()`	`setof(dict_name varchar, affix_name varchar, words int, affixes int, bytes int)`	Returns a list of dictionaries loaded in the shared segment.
`shared_ispell_stoplists()`	`setof(stop_name varchar, words int, bytes int)`	Returns a list of stopwords loaded in the shared segment.

F.57.2. GUC Parameters

`shared_ispell.max_size` (`int`)

Defines the maximum size of the shared segment. This is a hard limit, the shared segment is not extensible and you need to set it so that all the dictionaries fit into it and not much memory is wasted.

F.57.3. Using the dictionary

The module needs to allocate space in the shared memory segment. So add this to the config file (or update the current values):

```
# libraries to load
shared_preload_libraries = 'shared_ispell'

# config of the shared memory
shared_ispell.max_size = 32MB
```

To find out how much memory you actually need, use a large value (e.g. 200MB) and load all the dictionaries you want to use. Then use the `shared_ispell_mem_used()` function to find out how much memory was actually used (and set the `shared_ispell.max_size` GUC variable accordingly).

Don't set it exactly to that value, leave there some free space, so that you can reload the dictionaries without changing the GUC max_size limit (which requires a restart of the DB). Something like 512kB should be just fine.

The extension defines a `shared_ispell` template that you may use to define custom dictionaries. E.g. you may do this:

```
CREATE TEXT SEARCH DICTIONARY english_shared (
    TEMPLATE = shared_ispell,
    DictFile = en_us,
    AffFile = en_us,
```

```
    StopWords = english
);

CREATE TEXT SEARCH CONFIGURATION public.english_shared
    ( COPY = pg_catalog.simple );

ALTER TEXT SEARCH CONFIGURATION english_shared
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
                      word, hword, hword_part
    WITH english_shared, english_stem;
```

We can test created configuration:

```
SELECT * FROM ts_debug('english_shared', 'abilities');
   alias   |   description   |   token   |         dictionaries          |   dictionary
   |  lexemes
-----------+-----------------+-----------+-------------------------------
+----------------+-----------
 asciiword | Word, all ASCII | abilities | {english_shared,english_stem} |
 english_shared | {ability}
(1 row)
```

Or you can update your own text search configuration. For example, you have the `public.english` dictionary. You can update it to use the `shared_ispell` template:

```
ALTER TEXT SEARCH CONFIGURATION public.english
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
                      word, hword, hword_part
    WITH english_shared, english_stem;
```

F.58. spi

The spi module provides several workable examples of using the Server Programming Interface (SPI) and triggers. While these functions are of some value in their own right, they are even more useful as examples to modify for your own purposes. The functions are general enough to be used with any table, but you have to specify table and field names (as described below) while creating a trigger.

Each of the groups of functions described below is provided as a separately-installable extension.

F.58.1. refint — Functions for Implementing Referential Integrity

`check_primary_key()` and `check_foreign_key()` are used to check foreign key constraints. (This functionality is long since superseded by the built-in foreign key mechanism, of course, but the module is still useful as an example.)

`check_primary_key()` checks the referencing table. To use, create a `BEFORE INSERT OR UPDATE` trigger using this function on a table referencing another table. Specify as the trigger arguments: the referencing table's column name(s) which form the foreign key, the referenced table name, and the column names in the referenced table which form the primary/unique key. To handle multiple foreign keys, create a trigger for each reference.

`check_foreign_key()` checks the referenced table. To use, create a `BEFORE DELETE OR UPDATE` trigger using this function on a table referenced by other table(s). Specify as the trigger arguments: the number of referencing tables for which the function has to perform checking, the action if a referencing key is found (`cascade` — to delete the referencing row, `restrict` — to abort transaction if referencing keys exist, `setnull` — to set referencing key fields to null), the triggered table's column names which form the primary/unique key, then the referencing table name and column names (repeated for as many ref-

erencing tables as were specified by first argument). Note that the primary/unique key columns should be marked NOT NULL and should have a unique index.

There are examples in `refint.example`.

F.58.2. autoinc — Functions for Autoincrementing Fields

`autoinc()` is a trigger that stores the next value of a sequence into an integer field. This has some overlap with the built-in "serial column" feature, but it is not the same: `autoinc()` will override attempts to substitute a different field value during inserts, and optionally it can be used to increment the field during updates, too.

To use, create a `BEFORE INSERT` (or optionally `BEFORE INSERT OR UPDATE`) trigger using this function. Specify two trigger arguments: the name of the integer column to be modified, and the name of the sequence object that will supply values. (Actually, you can specify any number of pairs of such names, if you'd like to update more than one autoincrementing column.)

There is an example in `autoinc.example`.

F.58.3. insert_username — Functions for Tracking Who Changed a Table

`insert_username()` is a trigger that stores the current user's name into a text field. This can be useful for tracking who last modified a particular row within a table.

To use, create a `BEFORE INSERT` and/or `UPDATE` trigger using this function. Specify a single trigger argument: the name of the text column to be modified.

There is an example in `insert_username.example`.

F.58.4. moddatetime — Functions for Tracking Last Modification Time

`moddatetime()` is a trigger that stores the current time into a `timestamp` field. This can be useful for tracking the last modification time of a particular row within a table.

To use, create a `BEFORE UPDATE` trigger using this function. Specify a single trigger argument: the name of the column to be modified. The column must be of type `timestamp` or `timestamp with time zone`.

There is an example in `moddatetime.example`.

F.59. sslinfo

The `sslinfo` module provides information about the SSL certificate that the current client provided when connecting to Postgres Pro. The module is useless (most functions will return NULL) if the current connection does not use SSL.

Some of the information available through this module can also be obtained using the built-in system view `pg_stat_ssl`.

This extension won't build at all unless the installation was configured with `--with-ssl=openssl`.

F.59.1. Functions Provided

`ssl_is_used() returns boolean`

Returns true if current connection to server uses SSL, and false otherwise.

`ssl_version() returns text`

Returns the name of the protocol used for the SSL connection (e.g., TLSv1.0, TLSv1.1, TLSv1.2 or TLSv1.3).

`ssl_cipher() returns text`

Returns the name of the cipher used for the SSL connection (e.g., DHE-RSA-AES256-SHA).

`ssl_client_cert_present() returns boolean`

Returns true if current client has presented a valid SSL client certificate to the server, and false otherwise. (The server might or might not be configured to require a client certificate.)

`ssl_client_serial() returns numeric`

Returns serial number of current client certificate. The combination of certificate serial number and certificate issuer is guaranteed to uniquely identify a certificate (but not its owner — the owner ought to regularly change their keys, and get new certificates from the issuer).

So, if you run your own CA and allow only certificates from this CA to be accepted by the server, the serial number is the most reliable (albeit not very mnemonic) means to identify a user.

`ssl_client_dn() returns text`

Returns the full subject of the current client certificate, converting character data into the current database encoding. It is assumed that if you use non-ASCII characters in the certificate names, your database is able to represent these characters, too. If your database uses the SQL_ASCII encoding, non-ASCII characters in the name will be represented as UTF-8 sequences.

The result looks like `/CN=Somebody /C=Some country/O=Some organization`.

`ssl_issuer_dn() returns text`

Returns the full issuer name of the current client certificate, converting character data into the current database encoding. Encoding conversions are handled the same as for `ssl_client_dn`.

The combination of the return value of this function with the certificate serial number uniquely identifies the certificate.

This function is really useful only if you have more than one trusted CA certificate in your server's certificate authority file, or if this CA has issued some intermediate certificate authority certificates.

`ssl_client_dn_field(fieldname text) returns text`

This function returns the value of the specified field in the certificate subject, or NULL if the field is not present. Field names are string constants that are converted into ASN1 object identifiers using the OpenSSL object database. The following values are acceptable:

```
commonName (alias CN)
surname (alias SN)
name
givenName (alias GN)
countryName (alias C)
localityName (alias L)
stateOrProvinceName (alias ST)
organizationName (alias O)
organizationalUnitName (alias OU)
title
description
initials
postalCode
streetAddress
generationQualifier
description
dnQualifier
x500UniqueIdentifier
pseudonym
```

role
emailAddress

All of these fields are optional, except commonName. It depends entirely on your CA's policy which of them would be included and which wouldn't. The meaning of these fields, however, is strictly defined by the X.500 and X.509 standards, so you cannot just assign arbitrary meaning to them.

ssl_issuer_field(fieldname text) returns text

Same as ssl_client_dn_field, but for the certificate issuer rather than the certificate subject.

ssl_extension_info() returns setof record

Provide information about extensions of client certificate: extension name, extension value, and if it is a critical extension.

F.60. tablefunc

The tablefunc module includes various functions that return tables (that is, multiple rows). These functions are useful both in their own right and as examples of how to write C functions that return multiple rows.

This module is considered "trusted", that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.60.1. Functions Provided

Table F.41 summarizes the functions provided by the tablefunc module.

Table F.41. tablefunc Functions

Function Description
normal_rand (*numvals* integer, *mean* float8, *stddev* float8) → setof float8 Produces a set of normally distributed random values.
crosstab (*sql* text) → setof record Produces a "pivot table" containing row names plus *N* value columns, where *N* is determined by the row type specified in the calling query.
crosstab*N* (*sql* text) → setof table_crosstab_ *N* Produces a "pivot table" containing row names plus *N* value columns. crosstab2, crosstab3, and crosstab4 are predefined, but you can create additional crosstab*N* functions as described below.
crosstab (*source_sql* text, *category_sql* text) → setof record Produces a "pivot table" with the value columns specified by a second query.
crosstab (*sql* text, *N* integer) → setof record Obsolete version of crosstab(text) . The parameter *N* is now ignored, since the number of value columns is always determined by the calling query.
connectby (*relname* text, *keyid_fld* text, *parent_keyid_fld* text [, *orderby_fld* text], *start_with* text, *max_depth* integer [, *branch_delim* text]) → setof record

Function Description
Produces a representation of a hierarchical tree structure.

F.60.1.1. normal_rand

```
normal_rand(int numvals, float8 mean, float8 stddev) returns setof float8
```

`normal_rand` produces a set of normally distributed random values (Gaussian distribution).

`numvals` is the number of values to be returned from the function. *`mean`* is the mean of the normal distribution of values and *`stddev`* is the standard deviation of the normal distribution of values.

For example, this call requests 1000 values with a mean of 5 and a standard deviation of 3:

```
test=# SELECT * FROM normal_rand(1000, 5, 3);
     normal_rand
----------------------
     1.56556322244898
     9.10040991424657
     5.36957140345079
   -0.369151492880995
    0.283600703686639
       .
       .
       .
     4.82992125404908
     9.71308014517282
     2.49639286969028
(1000 rows)
```

F.60.1.2. crosstab(text)

```
crosstab(text sql)
crosstab(text sql, int N)
```

The `crosstab` function is used to produce “pivot” displays, wherein data is listed across the page rather than down. For example, we might have data like

```
row1    val11
row1    val12
row1    val13
...
row2    val21
row2    val22
row2    val23
...
```

which we wish to display like

```
row1    val11   val12   val13   ...
row2    val21   val22   val23   ...
...
```

The `crosstab` function takes a text parameter that is an SQL query producing raw data formatted in the first way, and produces a table formatted in the second way.

The *`sql`* parameter is an SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. *`N`* is an obsolete parameter, ignored if supplied (formerly this had to match the number of output value columns, but now that is determined by the calling query).

For example, the provided query might produce a set something like:

```
 row_name    cat    value
----------+-------+-------
  row1      cat1    val1
  row1      cat2    val2
  row1      cat3    val3
  row1      cat4    val4
  row2      cat1    val5
  row2      cat2    val6
  row2      cat3    val7
  row2      cat4    val8
```

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...') AS ct(row_name text, category_1 text, category_2 text);
```

This example produces a set something like:

```
           <== value  columns  ==>
 row_name   category_1   category_2
----------+------------+------------
  row1        val1         val2
  row2        val5         val6
```

The `FROM` clause must define the output as one `row_name` column (of the same data type as the first result column of the SQL query) followed by N `value` columns (all of the same data type as the third result column of the SQL query). You can set up as many output value columns as you wish. The names of the output columns are up to you.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. It fills the output `value` columns, left to right, with the `value` fields from these rows. If there are fewer rows in a group than there are output `value` columns, the extra output columns are filled with nulls; if there are more rows, the extra input rows are skipped.

In practice the SQL query should always specify `ORDER BY 1,2` to ensure that the input rows are properly ordered, that is, values with the same `row_name` are brought together and correctly ordered within the row. Notice that `crosstab` itself does not pay any attention to the second column of the query result; it's just there to be ordered by, to control the order in which the third-column values appear across the page.

Here is a complete example:

```
CREATE TABLE ct(id SERIAL, rowid TEXT, attribute TEXT, value TEXT);
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att1','val1');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att2','val2');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att3','val3');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att4','val4');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att1','val5');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att2','val6');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att3','val7');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att4','val8');

SELECT *
FROM crosstab(
  'select rowid, attribute, value
   from ct
   where attribute = ''att2'' or attribute = ''att3''
   order by 1,2')
AS ct(row_name text, category_1 text, category_2 text, category_3 text);
```

```
 row_name | category_1 | category_2 | category_3
----------+------------+------------+------------
 test1    | val2       | val3       |
 test2    | val6       | val7       |
(2 rows)
```

You can avoid always having to write out a FROM clause to define the output columns, by setting up a custom crosstab function that has the desired output row type wired into its definition. This is described in the next section. Another possibility is to embed the required FROM clause in a view definition.

> **Note**
>
> See also the \crosstabview command in psql, which provides functionality similar to crosstab().

F.60.1.3. crosstab*N*(text)

```
crosstabN(text sql)
```

The crosstab*N* functions are examples of how to set up custom wrappers for the general crosstab function, so that you need not write out column names and types in the calling SELECT query. The tablefunc module includes crosstab2, crosstab3, and crosstab4, whose output row types are defined as

```
CREATE TYPE tablefunc_crosstab_N AS (
    row_name TEXT,
    category_1 TEXT,
    category_2 TEXT,
        .
        .
        .
    category_N TEXT
);
```

Thus, these functions can be used directly when the input query produces row_name and value columns of type text, and you want 2, 3, or 4 output values columns. In all other ways they behave exactly as described above for the general crosstab function.

For instance, the example given in the previous section would also work as

```
SELECT *
FROM crosstab3(
  'select rowid, attribute, value
   from ct
   where attribute = ''att2'' or attribute = ''att3''
   order by 1,2');
```

These functions are provided mostly for illustration purposes. You can create your own return types and functions based on the underlying crosstab() function. There are two ways to do it:

- Create a composite type describing the desired output columns, similar to the examples in contrib/tablefunc/tablefunc--1.0.sql. Then define a unique function name accepting one text parameter and returning setof your_type_name, but linking to the same underlying crosstab C function. For example, if your source data produces row names that are text, and values that are float8, and you want 5 value columns:

  ```
  CREATE TYPE my_crosstab_float8_5_cols AS (
      my_row_name text,
      my_category_1 float8,
      my_category_2 float8,
      my_category_3 float8,
      my_category_4 float8,
  ```

```
    my_category_5 float8
);

CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(text)
    RETURNS setof my_crosstab_float8_5_cols
    AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;
```

- Use `OUT` parameters to define the return type implicitly. The same example could also be done this way:

```
CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(
    IN text,
    OUT my_row_name text,
    OUT my_category_1 float8,
    OUT my_category_2 float8,
    OUT my_category_3 float8,
    OUT my_category_4 float8,
    OUT my_category_5 float8)
  RETURNS setof record
  AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;
```

F.60.1.4. `crosstab(text, text)`

```
crosstab(text source_sql, text category_sql)
```

The main limitation of the single-parameter form of `crosstab` is that it treats all values in a group alike, inserting each value into the first available column. If you want the value columns to correspond to specific categories of data, and some groups might not have data for some of the categories, that doesn't work well. The two-parameter form of `crosstab` handles this case by providing an explicit list of the categories corresponding to the output columns.

`source_sql` is an SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. It may also have one or more “extra” columns. The `row_name` column must be first. The `category` and `value` columns must be the last two columns, in that order. Any columns between `row_name` and `category` are treated as “extra”. The “extra” columns are expected to be the same for all rows with the same `row_name` value.

For example, *`source_sql`* might produce a set something like:

```
SELECT row_name, extra_col, cat, value FROM foo ORDER BY 1;

 row_name    extra_col   cat    value
----------+------------+-----+---------
  row1         extra1    cat1    val1
  row1         extra1    cat2    val2
  row1         extra1    cat4    val4
  row2         extra2    cat1    val5
  row2         extra2    cat2    val6
  row2         extra2    cat3    val7
  row2         extra2    cat4    val8
```

`category_sql` is an SQL statement that produces the set of categories. This statement must return only one column. It must produce at least one row, or an error will be generated. Also, it must not produce duplicate values, or an error will be generated. *`category_sql`* might be something like:

```
SELECT DISTINCT cat FROM foo ORDER BY 1;
    cat
  -------
    cat1
    cat2
    cat3
```

```
    cat4
```

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...', '...')
    AS ct(row_name text, extra text, cat1 text, cat2 text, cat3 text, cat4 text);
```

This will produce a result something like:

```
                  <==  value  columns   ==>
row_name   extra   cat1   cat2   cat3   cat4
---------+-------+------+------+------+------
  row1     extra1  val1   val2          val4
  row2     extra2  val5   val6   val7   val8
```

The `FROM` clause must define the proper number of output columns of the proper data types. If there are *`N`* columns in the *`source_sql`* query's result, the first *`N`*-2 of them must match up with the first *`N`*-2 output columns. The remaining output columns must have the type of the last column of the *`source_sql`* query's result, and there must be exactly as many of them as there are rows in the *`category_sql`* query's result.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. The output `row_name` column, plus any “extra” columns, are copied from the first row of the group. The output `value` columns are filled with the `value` fields from rows having matching `category` values. If a row's `category` does not match any output of the *`category_sql`* query, its `value` is ignored. Output columns whose matching category is not present in any input row of the group are filled with nulls.

In practice the *`source_sql`* query should always specify `ORDER BY 1` to ensure that values with the same `row_name` are brought together. However, ordering of the categories within a group is not important. Also, it is essential to be sure that the order of the *`category_sql`* query's output matches the specified output column order.

Here are two complete examples:

```
create table sales(year int, month int, qty int);
insert into sales values(2007, 1, 1000);
insert into sales values(2007, 2, 1500);
insert into sales values(2007, 7, 500);
insert into sales values(2007, 11, 1500);
insert into sales values(2007, 12, 2000);
insert into sales values(2008, 1, 1000);

select * from crosstab(
  'select year, month, qty from sales order by 1',
  'select m from generate_series(1,12) m'
) as (
  year int,
  "Jan" int,
  "Feb" int,
  "Mar" int,
  "Apr" int,
  "May" int,
  "Jun" int,
  "Jul" int,
  "Aug" int,
  "Sep" int,
  "Oct" int,
  "Nov" int,
  "Dec" int
```

```
);
 year | Jan  | Feb  | Mar | Apr | May | Jun | Jul | Aug | Sep | Oct | Nov  | Dec
------+------+------+-----+-----+-----+-----+-----+-----+-----+-----+------+------
 2007 | 1000 | 1500 |     |     |     |     | 500 |     |     |     | 1500 | 2000
 2008 | 1000 |      |     |     |     |     |     |     |     |     |      |
(2 rows)

CREATE TABLE cth(rowid text, rowdt timestamp, attribute text, val text);
INSERT INTO cth VALUES('test1','01 March 2003','temperature','42');
INSERT INTO cth VALUES('test1','01 March 2003','test_result','PASS');
INSERT INTO cth VALUES('test1','01 March 2003','volts','2.6987');
INSERT INTO cth VALUES('test2','02 March 2003','temperature','53');
INSERT INTO cth VALUES('test2','02 March 2003','test_result','FAIL');
INSERT INTO cth VALUES('test2','02 March 2003','test_startdate','01 March 2003');
INSERT INTO cth VALUES('test2','02 March 2003','volts','3.1234');

SELECT * FROM crosstab
(
  'SELECT rowid, rowdt, attribute, val FROM cth ORDER BY 1',
  'SELECT DISTINCT attribute FROM cth ORDER BY 1'
)
AS
(
       rowid text,
       rowdt timestamp,
       temperature int4,
       test_result text,
       test_startdate timestamp,
       volts float8
);
 rowid |          rowdt           | temperature | test_result |      test_startdate
  | volts
-------+--------------------------+-------------+-------------
+--------------------------+--------

```

You can create predefined functions to avoid having to write out the result column names and types in each query. See the examples in the previous section. The underlying C function for this form of `crosstab` is named `crosstab_hash`.

F.60.1.5. `connectby`

```
connectby(text relname, text keyid_fld, text parent_keyid_fld
          [, text orderby_fld ], text start_with, int max_depth
          [, text branch_delim ])
```

The `connectby` function produces a display of hierarchical data that is stored in a table. The table must have a key field that uniquely identifies rows, and a parent-key field that references the parent (if any) of each row. `connectby` can display the sub-tree descending from any row.

Table F.42 explains the parameters.

Table F.42. `connectby` Parameters

Parameter	Description
relname	Name of the source relation

Parameter	Description
keyid_fld	Name of the key field
parent_keyid_fld	Name of the parent-key field
orderby_fld	Name of the field to order siblings by (optional)
start_with	Key value of the row to start at
max_depth	Maximum depth to descend to, or zero for unlimited depth
branch_delim	String to separate keys with in branch output (optional)

The key and parent-key fields can be any data type, but they must be the same type. Note that the *start_with* value must be entered as a text string, regardless of the type of the key field.

The connectby function is declared to return setof record, so the actual names and types of the output columns must be defined in the FROM clause of the calling SELECT statement, for example:

```
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0,
 '~')
    AS t(keyid text, parent_keyid text, level int, branch text, pos int);
```

The first two output columns are used for the current row's key and its parent row's key; they must match the type of the table's key field. The third output column is the depth in the tree and must be of type integer. If a *branch_delim* parameter was given, the next output column is the branch display and must be of type text. Finally, if an *orderby_fld* parameter was given, the last output column is a serial number, and must be of type integer.

The “branch” output column shows the path of keys taken to reach the current row. The keys are separated by the specified *branch_delim* string. If no branch display is wanted, omit both the *branch_delim* parameter and the branch column in the output column list.

If the ordering of siblings of the same parent is important, include the *orderby_fld* parameter to specify which field to order siblings by. This field can be of any sortable data type. The output column list must include a final integer serial-number column, if and only if *orderby_fld* is specified.

The parameters representing table and field names are copied as-is into the SQL queries that connectby generates internally. Therefore, include double quotes if the names are mixed-case or contain special characters. You may also need to schema-qualify the table name.

In large tables, performance will be poor unless there is an index on the parent-key field.

It is important that the *branch_delim* string not appear in any key values, else connectby may incorrectly report an infinite-recursion error. Note that if *branch_delim* is not provided, a default value of ~ is used for recursion detection purposes.

Here is an example:

```
CREATE TABLE connectby_tree(keyid text, parent_keyid text, pos int);

INSERT INTO connectby_tree VALUES('row1',NULL, 0);
INSERT INTO connectby_tree VALUES('row2','row1', 0);
INSERT INTO connectby_tree VALUES('row3','row1', 0);
INSERT INTO connectby_tree VALUES('row4','row2', 1);
INSERT INTO connectby_tree VALUES('row5','row2', 0);
INSERT INTO connectby_tree VALUES('row6','row4', 0);
INSERT INTO connectby_tree VALUES('row7','row3', 0);
INSERT INTO connectby_tree VALUES('row8','row6', 0);
INSERT INTO connectby_tree VALUES('row9','row5', 0);
```

```
-- with branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0, '~')
 AS t(keyid text, parent_keyid text, level int, branch text);
 keyid | parent_keyid | level |       branch
-------+--------------+-------+--------------------
 row2  |              |     0 | row2
 row4  | row2         |     1 | row2~row4
 row6  | row4         |     2 | row2~row4~row6
 row8  | row6         |     3 | row2~row4~row6~row8
 row5  | row2         |     1 | row2~row5
 row9  | row5         |     2 | row2~row5~row9
(6 rows)

-- without branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0)
 AS t(keyid text, parent_keyid text, level int);
 keyid | parent_keyid | level
-------+--------------+-------
 row2  |              |     0
 row4  | row2         |     1
 row6  | row4         |     2
 row8  | row6         |     3
 row5  | row2         |     1
 row9  | row5         |     2
(6 rows)

-- with branch, with orderby_fld (notice that row5 comes before row4)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0,
 '~')
 AS t(keyid text, parent_keyid text, level int, branch text, pos int);
 keyid | parent_keyid | level |       branch        | pos
-------+--------------+-------+---------------------+-----
 row2  |              |     0 | row2                |   1
 row5  | row2         |     1 | row2~row5           |   2
 row9  | row5         |     2 | row2~row5~row9      |   3
 row4  | row2         |     1 | row2~row4           |   4
 row6  | row4         |     2 | row2~row4~row6      |   5
 row8  | row6         |     3 | row2~row4~row6~row8 |   6
(6 rows)

-- without branch, with orderby_fld (notice that row5 comes before row4)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0)
 AS t(keyid text, parent_keyid text, level int, pos int);
 keyid | parent_keyid | level | pos
-------+--------------+-------+-----
 row2  |              |     0 |   1
 row5  | row2         |     1 |   2
 row9  | row5         |     2 |   3
 row4  | row2         |     1 |   4
 row6  | row4         |     2 |   5
 row8  | row6         |     3 |   6
(6 rows)
```

F.60.2. Author

Joe Conway

F.61. tcn

The tcn module provides a trigger function that notifies listeners of changes to any table on which it is attached. It must be used as an AFTER trigger FOR EACH ROW.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

Only one parameter may be supplied to the function in a CREATE TRIGGER statement, and that is optional. If supplied it will be used for the channel name for the notifications. If omitted tcn will be used for the channel name.

The payload of the notifications consists of the table name, a letter to indicate which type of operation was performed, and column name/value pairs for primary key columns. Each part is separated from the next by a comma. For ease of parsing using regular expressions, table and column names are always wrapped in double quotes, and data values are always wrapped in single quotes. Embedded quotes are doubled.

A brief example of using the extension follows.

```
test=# create table tcndata
test-#   (
test(#     a int not null,
test(#     b date not null,
test(#     c text,
test(#     primary key (a, b)
test(#   );
CREATE TABLE
test=# create trigger tcndata_tcn_trigger
test-#   after insert or update or delete on tcndata
test-#   for each row execute function triggered_change_notification();
CREATE TRIGGER
test=# listen tcn;
LISTEN
test=# insert into tcndata values (1, date '2012-12-22', 'one'),
test-#                            (1, date '2012-12-23', 'another'),
test-#                            (2, date '2012-12-23', 'two');
INSERT 0 3
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='1',"b"='2012-12-22'"
 received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='1',"b"='2012-12-23'"
 received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='2',"b"='2012-12-23'"
 received from server process with PID 22770.
test=# update tcndata set c = 'uno' where a = 1;
UPDATE 2
Asynchronous notification "tcn" with payload ""tcndata",U,"a"='1',"b"='2012-12-22'"
 received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",U,"a"='1',"b"='2012-12-23'"
 received from server process with PID 22770.
test=# delete from tcndata where a = 1 and b = date '2012-12-22';
DELETE 1
Asynchronous notification "tcn" with payload ""tcndata",D,"a"='1',"b"='2012-12-22'"
 received from server process with PID 22770.
```

F.62. test_decoding

test_decoding is an example of a logical decoding output plugin. It doesn't do anything especially useful, but can serve as a starting point for developing your own output plugin.

test_decoding receives WAL through the logical decoding mechanism and decodes it into text representations of the operations performed.

Typical output from this plugin, used over the SQL logical decoding interface, might be:

```
postgres=# SELECT * FROM pg_logical_slot_get_changes('test_slot', NULL, NULL, 'include-
xids', '0');
   lsn     | xid |                       data
-----------+-----+-------------------------------------------------
 0/16D30F8 | 691 | BEGIN
 0/16D32A0 | 691 | table public.data: INSERT: id[int4]:2 data[text]:'arg'
 0/16D32A0 | 691 | table public.data: INSERT: id[int4]:3 data[text]:'demo'
 0/16D32A0 | 691 | COMMIT
 0/16D32D8 | 692 | BEGIN
 0/16D3398 | 692 | table public.data: DELETE: id[int4]:2
 0/16D3398 | 692 | table public.data: DELETE: id[int4]:3
 0/16D3398 | 692 | COMMIT
(8 rows)
```

We can also get the changes of the in-progress transaction, and the typical output might be:

```
postgres[33712]=#* SELECT * FROM pg_logical_slot_get_changes('test_slot', NULL, NULL,
 'stream-changes', '1');
    lsn     | xid |                       data
-----------+-----+-------------------------------------------------
 0/16B21F8 | 503 | opening a streamed block for transaction TXN 503
 0/16B21F8 | 503 | streaming change for TXN 503
 0/16B2300 | 503 | streaming change for TXN 503
 0/16B2408 | 503 | streaming change for TXN 503
 0/16BEBA0 | 503 | closing a streamed block for transaction TXN 503
 0/16B21F8 | 503 | opening a streamed block for transaction TXN 503
 0/16BECA8 | 503 | streaming change for TXN 503
 0/16BEDB0 | 503 | streaming change for TXN 503
 0/16BEEB8 | 503 | streaming change for TXN 503
 0/16BEBA0 | 503 | closing a streamed block for transaction TXN 503
(10 rows)
```

F.63. tsm_system_rows

The `tsm_system_rows` module provides the table sampling method `SYSTEM_ROWS`, which can be used in the `TABLESAMPLE` clause of a `SELECT` command.

This table sampling method accepts a single integer argument that is the maximum number of rows to read. The resulting sample will always contain exactly that many rows, unless the table does not contain enough rows, in which case the whole table is selected.

Like the built-in `SYSTEM` sampling method, `SYSTEM_ROWS` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are requested.

`SYSTEM_ROWS` does not support the `REPEATABLE` clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.63.1. Examples

Here is an example of selecting a sample of a table with `SYSTEM_ROWS`. First install the extension:

```
CREATE EXTENSION tsm_system_rows;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_ROWS(100);
```

This command will return a sample of 100 rows from the table `my_table` (unless the table does not have 100 visible rows, in which case all its rows are returned).

F.64. tsm_system_time

The `tsm_system_time` module provides the table sampling method `SYSTEM_TIME`, which can be used in the `TABLESAMPLE` clause of a `SELECT` command.

This table sampling method accepts a single floating-point argument that is the maximum number of milliseconds to spend reading the table. This gives you direct control over how long the query takes, at the price that the size of the sample becomes hard to predict. The resulting sample will contain as many rows as could be read in the specified time, unless the whole table has been read first.

Like the built-in `SYSTEM` sampling method, `SYSTEM_TIME` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are selected.

`SYSTEM_TIME` does not support the `REPEATABLE` clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.64.1. Examples

Here is an example of selecting a sample of a table with `SYSTEM_TIME`. First install the extension:

```
CREATE EXTENSION tsm_system_time;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_TIME(1000);
```

This command will return as large a sample of `my_table` as it can read in 1 second (1000 milliseconds). Of course, if the whole table can be read in under 1 second, all its rows will be returned.

F.65. unaccent

`unaccent` is a text search dictionary that removes accents (diacritic signs) from lexemes. It's a filtering dictionary, which means its output is always passed to the next dictionary (if any), unlike the normal behavior of dictionaries. This allows accent-insensitive processing for full text search.

The current implementation of `unaccent` cannot be used as a normalizing dictionary for the `thesaurus` dictionary.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.65.1. Configuration

An `unaccent` dictionary accepts the following options:

- `RULES` is the base name of the file containing the list of translation rules. This file must be stored in `$SHAREDIR/tsearch_data/` (where `$SHAREDIR` means the Postgres Pro installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `RULES` parameter).

The rules file has the following format:

- Each line represents one translation rule, consisting of a character with accent followed by a character without accent. The first is translated into the second. For example,

  ```
  À        A
  ```

```
Á       A
Â       A
Ã       A
Ä       A
Å       A
Æ       AE
```

The two characters must be separated by whitespace, and any leading or trailing whitespace on a line is ignored.

- Alternatively, if only one character is given on a line, instances of that character are deleted; this is useful in languages where accents are represented by separate characters.
- Actually, each “character” can be any string not containing whitespace, so `unaccent` dictionaries could be used for other sorts of substring substitutions besides diacritic removal.
- As with other Postgres Pro text search configuration files, the rules file must be stored in UTF-8 encoding. The data is automatically translated into the current database's encoding when loaded. Any lines containing untranslatable characters are silently ignored, so that rules files can contain rules that are not applicable in the current encoding.

A more complete example, which is directly useful for most European languages, can be found in `unaccent.rules`, which is installed in `$SHAREDIR/tsearch_data/` when the `unaccent` module is installed. This rules file translates characters with accents to the same characters without accents, and it also expands ligatures into the equivalent series of simple characters (for example, Æ to AE).

F.65.2. Usage

Installing the `unaccent` extension creates a text search template `unaccent` and a dictionary `unaccent` based on it. The `unaccent` dictionary has the default parameter setting `RULES='unaccent'`, which makes it immediately usable with the standard `unaccent.rules` file. If you wish, you can alter the parameter, for example

```
mydb=# ALTER TEXT SEARCH DICTIONARY unaccent (RULES='my_rules');
```

or create new dictionaries based on the template.

To test the dictionary, you can try:

```
mydb=# select ts_lexize('unaccent','Hôtel');
 ts_lexize
-----------
 {Hotel}
(1 row)
```

Here is an example showing how to insert the `unaccent` dictionary into a text search configuration:

```
mydb=# CREATE TEXT SEARCH CONFIGURATION fr ( COPY = french );
mydb=# ALTER TEXT SEARCH CONFIGURATION fr
        ALTER MAPPING FOR hword, hword_part, word
        WITH unaccent, french_stem;
mydb=# select to_tsvector('fr','Hôtels de la Mer');
    to_tsvector
-------------------
 'hotel':1 'mer':4
(1 row)

mydb=# select to_tsvector('fr','Hôtel de la Mer') @@ to_tsquery('fr','Hotels');
 ?column?
----------
 t
(1 row)
```

```
mydb=# select ts_headline('fr','Hôtel de la Mer',to_tsquery('fr','Hotels'));
      ts_headline
------------------------
 <b>Hôtel</b> de la Mer
(1 row)
```

F.65.3. Functions

The `unaccent()` function removes accents (diacritic signs) from a given string. Basically, it's a wrapper around `unaccent`-type dictionaries, but it can be used outside normal text search contexts.

```
unaccent([dictionary regdictionary, ] string text) returns text
```

If the *dictionary* argument is omitted, the text search dictionary named `unaccent` and appearing in the same schema as the `unaccent()` function itself is used.

For example:

```
SELECT unaccent('unaccent', 'Hôtel');
SELECT unaccent('Hôtel');
```

F.66. uuid-ossp

The `uuid-ossp` module provides functions to generate universally unique identifiers (UUIDs) using one of several standard algorithms. There are also functions to produce certain special UUID constants. This module is only necessary for special requirements beyond what is available in core PostgreSQL. See Section 9.14 for built-in ways to generate UUIDs.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.66.1. `uuid-ossp` Functions

Table F.43 shows the functions available to generate UUIDs. The relevant standards ITU-T Rec. X.667, ISO/IEC 9834-8:2005, and *RFC 4122* specify four algorithms for generating UUIDs, identified by the version numbers 1, 3, 4, and 5. (There is no version 2 algorithm.) Each of these algorithms could be suitable for a different set of applications.

Table F.43. Functions for UUID Generation

Function Description
`uuid_generate_v1` () → `uuid` Generates a version 1 UUID. This involves the MAC address of the computer and a time stamp. Note that UUIDs of this kind reveal the identity of the computer that created the identifier and the time at which it did so, which might make it unsuitable for certain security-sensitive applications.
`uuid_generate_v1mc` () → `uuid` Generates a version 1 UUID, but uses a random multicast MAC address instead of the real MAC address of the computer.

`uuid_generate_v3` (*namespace* `uuid`, *name* `text`) → `uuid`
Generates a version 3 UUID in the given namespace using the specified input name. The namespace should be one of the special constants produced by the `uuid_ns_*()` functions shown in Table F.44. (It could be any UUID in theory.) The name is an identifier in the selected namespace.
For example:
`SELECT uuid_generate_v3(uuid_ns_url(), 'http://www.postgresql.org');`

Function Description
The name parameter will be MD5-hashed, so the cleartext cannot be derived from the generated UUID. The generation of UUIDs by this method has no random or environment-dependent element and is therefore reproducible.
`uuid_generate_v4` () → `uuid` Generates a version 4 UUID, which is derived entirely from random numbers.
`uuid_generate_v5` (*namespace* `uuid`, *name* `text`) → `uuid` Generates a version 5 UUID, which works like a version 3 UUID except that SHA-1 is used as a hashing method. Version 5 should be preferred over version 3 because SHA-1 is thought to be more secure than MD5.

Table F.44. Functions Returning UUID Constants

Function Description
`uuid_nil` () → `uuid` Returns a “nil” UUID constant, which does not occur as a real UUID.
`uuid_ns_dns` () → `uuid` Returns a constant designating the DNS namespace for UUIDs.
`uuid_ns_url` () → `uuid` Returns a constant designating the URL namespace for UUIDs.
`uuid_ns_oid` () → `uuid` Returns a constant designating the ISO object identifier (OID) namespace for UUIDs. (This pertains to ASN.1 OIDs, which are unrelated to the OIDs used in Postgres Pro.)
`uuid_ns_x500` () → `uuid` Returns a constant designating the X.500 distinguished name (DN) namespace for UUIDs.

F.66.2. Building `uuid-ossp`

Historically this module depended on the OSSP UUID library, which accounts for the module's name. While the OSSP UUID library can still be found at *http://www.ossp.org/pkg/lib/uuid/*, it is not well maintained, and is becoming increasingly difficult to port to newer platforms. `uuid-ossp` can now be built without the OSSP library on some platforms. On FreeBSD and some other BSD-derived platforms, suitable UUID creation functions are included in the core `libc` library. On Linux, macOS, and some other platforms, suitable functions are provided in the `libuuid` library, which originally came from the `e2fsprogs` project (though on modern Linux it is considered part of `util-linux-ng`). When invoking `configure`, specify `--with-uuid=bsd` to use the BSD functions, or `--with-uuid=e2fs` to use `e2fsprogs`' `libuuid`, or `--with-uuid=ossp` to use the OSSP UUID library. More than one of these libraries might be available on a particular machine, so `configure` does not automatically choose one.

F.66.3. Author

Peter Eisentraut `<peter_e@gmx.net>`

F.67. xml2

The `xml2` module provides XPath querying and XSLT functionality.

F.67.1. Deprecation Notice

From PostgreSQL 8.3 on, there is XML-related functionality based on the SQL/XML standard in the core server. That functionality covers XML syntax checking and XPath queries, which is what this module does, and more, but the API is not at all compatible. It is planned that this module will be removed in a

future version of Postgres Pro in favor of the newer standard API, so you are encouraged to try converting your applications. If you find that some of the functionality of this module is not available in an adequate form with the newer API, please explain your issue to <pgsql-hackers@lists.postgresql.org> so that the deficiency can be addressed.

F.67.2. Description of Functions

Table F.45 shows the functions provided by this module. These functions provide straightforward XML parsing and XPath queries.

Table F.45. `xml2` Functions

Function Description
`xml_valid ( document text ) → boolean` Parses the given document and returns true if the document is well-formed XML. (Note: this is an alias for the standard Postgres Pro function `xml_is_well_formed()`. The name `xml_valid()` is technically incorrect since validity and well-formedness have different meanings in XML.)
`xpath_string ( document text, query text ) → text` Evaluates the XPath query on the supplied document, and casts the result to `text`.
`xpath_number ( document text, query text ) → real` Evaluates the XPath query on the supplied document, and casts the result to `real`.
`xpath_bool ( document text, query text ) → boolean` Evaluates the XPath query on the supplied document, and casts the result to `boolean`.

`xpath_nodeset ( document text, query text, toptag text, itemtag text ) → text`
Evaluates the query on the document and wraps the result in XML tags. If the result is multi-valued, the output will look like:
`<toptag>`
`<itemtag>Value 1 which could be an XML fragment</itemtag>`
`<itemtag>Value 2....</itemtag>`
`</toptag>`
If either *toptag* or *itemtag* is an empty string, the relevant tag is omitted.

`xpath_nodeset ( document text, query text, itemtag text ) → text` Like `xpath_nodeset(document, query, toptag, itemtag)` but result omits *toptag*.
`xpath_nodeset ( document text, query text ) → text` Like `xpath_nodeset(document, query, toptag, itemtag)` but result omits both tags.
`xpath_list ( document text, query text, separator text ) → text` Evaluates the query on the document and returns multiple values separated by the specified separator, for example `Value 1,Value 2,Value 3` if *separator* is `,`.
`xpath_list ( document text, query text ) → text` This is a wrapper for the above function that uses `,` as the separator.

F.67.3. `xpath_table`

```
xpath_table(text key, text document, text relation, text xpaths, text criteria) returns
 setof record
```

`xpath_table` is a table function that evaluates a set of XPath queries on each of a set of documents and returns the results as a table. The primary key field from the original document table is returned as the first column of the result so that the result set can readily be used in joins. The parameters are described in Table F.46.

Table F.46. `xpath_table` Parameters

Parameter	Description
key	the name of the "key" field — this is just a field to be used as the first column of the output table, i.e., it identifies the record from which each output row came (see note below about multiple values)
document	the name of the field containing the XML document
relation	the name of the table or view containing the documents
xpaths	one or more XPath expressions, separated by `|`
criteria	the contents of the WHERE clause. This cannot be omitted, so use `true` or `1=1` if you want to process all the rows in the relation

These parameters (except the XPath strings) are just substituted into a plain SQL SELECT statement, so you have some flexibility — the statement is

```
SELECT <key>, <document> FROM <relation> WHERE <criteria>
```

so those parameters can be *anything* valid in those particular locations. The result from this SELECT needs to return exactly two columns (which it will unless you try to list multiple fields for key or document). Beware that this simplistic approach requires that you validate any user-supplied values to avoid SQL injection attacks.

The function has to be used in a `FROM` expression, with an `AS` clause to specify the output columns; for example

```
SELECT * FROM
xpath_table('article_id',
            'article_xml',
            'articles',
            '/article/author|/article/pages|/article/title',
            'date_entered > ''2003-01-01'' ')
AS t(article_id integer, author text, page_count integer, title text);
```

The `AS` clause defines the names and types of the columns in the output table. The first is the "key" field and the rest correspond to the XPath queries. If there are more XPath queries than result columns, the extra queries will be ignored. If there are more result columns than XPath queries, the extra columns will be NULL.

Notice that this example defines the `page_count` result column as an integer. The function deals internally with string representations, so when you say you want an integer in the output, it will take the string representation of the XPath result and use Postgres Pro input functions to transform it into an integer (or whatever type the `AS` clause requests). An error will result if it can't do this — for example if the result is empty — so you may wish to just stick to `text` as the column type if you think your data has any problems.

The calling `SELECT` statement doesn't necessarily have to be just `SELECT *` — it can reference the output columns by name or join them to other tables. The function produces a virtual table with which you can perform any operation you wish (e.g., aggregation, joining, sorting etc). So we could also have:

```
SELECT t.title, p.fullname, p.email
FROM xpath_table('article_id', 'article_xml', 'articles',
                 '/article/title|/article/author/@id',
                 'xpath_string(article_xml,''/article/@date'') > ''2003-03-20'' ')
       AS t(article_id integer, title text, author_id integer),
     tblPeopleInfo AS p
WHERE t.author_id = p.person_id;
```

as a more complicated example. Of course, you could wrap all of this in a view for convenience.

F.67.3.1. Multivalued Results

The `xpath_table` function assumes that the results of each XPath query might be multivalued, so the number of rows returned by the function may not be the same as the number of input documents. The first row returned contains the first result from each query, the second row the second result from each query. If one of the queries has fewer values than the others, null values will be returned instead.

In some cases, a user will know that a given XPath query will return only a single result (perhaps a unique document identifier) — if used alongside an XPath query returning multiple results, the single-valued result will appear only on the first row of the result. The solution to this is to use the key field as part of a join against a simpler XPath query. As an example:

```
CREATE TABLE test (
    id int PRIMARY KEY,
    xml text
);

INSERT INTO test VALUES (1, '<doc num="C1">
<line num="L1"><a>1</a><b>2</b><c>3</c></line>
<line num="L2"><a>11</a><b>22</b><c>33</c></line>
</doc>');

INSERT INTO test VALUES (2, '<doc num="C2">
<line num="L1"><a>111</a><b>222</b><c>333</c></line>
<line num="L2"><a>111</a><b>222</b><c>333</c></line>
</doc>');

SELECT * FROM
  xpath_table('id','xml','test',
              '/doc/@num|/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
              'true')
  AS t(id int, doc_num varchar(10), line_num varchar(10), val1 int, val2 int, val3 int)
WHERE id = 1 ORDER BY doc_num, line_num

 id | doc_num | line_num | val1 | val2 | val3
----+---------+----------+------+------+------
  1 | C1      | L1       |    1 |    2 |    3
  1 |         | L2       |   11 |   22 |   33
```

To get `doc_num` on every line, the solution is to use two invocations of `xpath_table` and join the results:

```
SELECT t.*,i.doc_num FROM
  xpath_table('id', 'xml', 'test',
              '/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
              'true')
    AS t(id int, line_num varchar(10), val1 int, val2 int, val3 int),
  xpath_table('id', 'xml', 'test', '/doc/@num', 'true')
    AS i(id int, doc_num varchar(10))
WHERE i.id=t.id AND i.id=1
ORDER BY doc_num, line_num;

 id | line_num | val1 | val2 | val3 | doc_num
----+----------+------+------+------+---------
  1 | L1       |    1 |    2 |    3 | C1
  1 | L2       |   11 |   22 |   33 | C1
(2 rows)
```

F.67.4. XSLT Functions

The following functions are available if libxslt is installed:

F.67.4.1. xslt_process

```
xslt_process(text document, text stylesheet, text paramlist) returns text
```

This function applies the XSL stylesheet to the document and returns the transformed result. The `paramlist` is a list of parameter assignments to be used in the transformation, specified in the form `a=1,b=2`. Note that the parameter parsing is very simple-minded: parameter values cannot contain commas!

There is also a two-parameter version of `xslt_process` which does not pass any parameters to the transformation.

F.67.5. Author

John Gray `<jgray@azuli.co.uk>`

Development of this module was sponsored by Torchbox Ltd. (www.torchbox.com). It has the same BSD license as Postgres Pro.

Appendix G. Postgres Pro Modules and Extensions Shipped as Individual Packages

This appendix contains Postgres Pro modules and extensions that are made available in Postgres Pro Standard as individual packages. These packages are listed in Section 16.1.4.1, and the documentation for each module explains which package to choose to install it. Appendix F covers more modules and extensions included in the Postgres Pro Standard distribution. The pg_portal_modify extension is also shipped as an individual package (see Section 16.1.4.1 for details).

G.1. pgpro_pwr — workload reports

The pgpro_pwr module is designed to discover most resource-intensive activities in your database. (PWR, pronounced like "power", is an abbreviation of Postgres Pro Workload Reporting.) This extension is based on Postgres Pro's Statistics Collector views and the pgpro_stats or pg_stat_statements extension.

> **Note**
>
> Although pgpro_pwr can work with the pg_stat_statements extension, it is recommended that you use the pgpro_stats extension since it provides statement plans, wait events sampling and load distribution statistics for databases, roles, client hosts and applications.

Below, use of pgpro_stats is assumed unless otherwise noted.

If you cannot use pgpro_stats for an observed database, but the *pg_stat_kcache* extension is available, pgpro_pwr can process pg_stat_kcache data, which also provides information about CPU resource usage of statements and filesystem load (*rusage*).

pgpro_pwr can obtain summary wait statistics from the pg_wait_sampling extension. When pg_wait_sampling is in use, pgpro_pwr will reset the wait sampling profile on every sample.

pgpro_pwr is based on cumulative statistics sampling. Each sample contains statistic increments for most active objects and queries since the time when the previous sample was taken, or more concisely, *since the previous sample*. This data is later used to generate reports.

pgpro_pwr provides functions to collect samples. Regular sampling allows building a report on the database workload in the past.

pgpro_pwr allows you to take explicit samples during batch processing, load testing, etc.

Any time a sample is taken, `pgpro_stats_statements_reset()` (see pgpro_stats for the function description) is called to ensure that statement statistics will not be lost when the statements count exceed `pgpro_stats.max` (see Section G.2.7.1). The report will also contain a section informing you of whether the count of captured statements in any sample reaches 90% of `pgpro_stats.max`.

pgpro_pwr installed on one Postgres Pro server can also collect statistics from other servers. This feature is useful for gathering workload statistics from hot standbys on the primary server. To benefit from it, make sure that all server names and connection strings are specified and that the pgpro_pwr server can connect to all databases on all servers.

G.1.1. pgpro_pwr Architecture

The extension consists of the following parts:

- *Historical repository* is a storage for sampling data. The repository is a set of extension tables.

> **Note**
>
> Among the rest, pgpro_pwr tables store query texts, which can contain sensitive information. So, for security reasons, restrict access to the repository as appropriate.

- *Sample management engine* comprises functions used to take samples and maintain the repository by removing obsolete sample data.
- *Report engine* comprises functions for generating reports based on data from the historical repository.
- *Administrative functions* allow you to create and manage servers and baselines.

G.1.2. Prerequisites

The prerequisites assume that pgpro_pwr, which is usually installed in a *target* cluster, i.e., the cluster that you will mainly track the workload for, the extension can also collect performance data from other clusters.

G.1.2.1. For the pgpro_pwr Database

The pgpro_pwr extension depends on PL/pgSQL and the dblink extension.

G.1.2.2. For the Target Server

The target server must allow connections to all databases from the server where pgpro_pwr is running. To connect to the target server, provide a connection string where a particular database on this server is specified. This database is of high importance for pgpro_pwr since the functionality of the pgpro_stats or pg_stat_statements extensions will be provided through this database. Note, however, that pgpro_pwr will also connect to all the other databases on this server.

Optionally, for completeness of gathered statistics:

- If statement statistics are needed in reports, pgpro_stats must be installed and configured in the aforementioned database. The following settings may affect the completeness and accuracy of gathered statistics:
  - `pgpro_stats.max`

    Low setting of this parameter may cause some statement statistics to be wiped out before the sample is taken. A report will warn you if the value of `pgpro_stats.max` seems undersized.
  - `pgpro_stats.track`

    Avoid changing the default value of '`top`' (note that the value of '`all`' will affect the accuracy of `%Total` fields for statements-related sections of a report).
- Set the parameters of the Postgres Pro's Statistics Collector as follows:

```
track_activities = on
track_counts = on
track_io_timing = on
track_wal_io_timing = on    # Since PostgreSQL 14
track_functions = all/pl
```

G.1.3. Installation and Setup

pgpro_pwr is provided with Postgres Pro Standard as a separate pre-built package `pgpro-pwr-std-14` (for the detailed installation instructions, see Chapter 16).

> **Note**
>
> pgpro_pwr creates a bunch of database objects, so installation in a dedicated schema is recommended.

Although the use of pgpro_pwr with superuser privileges does not have any issues, superuser privileges are not necessary. So you can choose one of the following setup procedures depending on your configuration and security requirements or customize them to meet your needs:

G.1.3.1. Simple Setup

Use this setup procedure when pgpro_pwr is to be installed on the target cluster to only track its workload as superuser.

Create a schema for the pgpro_pwr installation and create the extension:

```
CREATE SCHEMA profile;
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

G.1.3.2. Complex Setup

Use this setup procedure when you intend to use pgpro_pwr for tracking workload on one or more servers and need to follow the principle of least privilege.

G.1.3.2.1. In the Target Server Database

Create a user for pgpro_pwr on the target server:

```
CREATE USER pwr_collector PASSWORD 'collector_pwd';
```

Make sure this user has permissions to connect to any database in the target cluster (by default, it is true) and that `pg_hba.conf` permits such a connection from the pgpro_pwr database host. Also, grant `pwr_collector` with membership in the `pg_read_all_stats` role and the `EXECUTE` privilege on the following functions:

```
GRANT pg_read_all_stats TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgpro_stats_statements_reset TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgpro_stats_totals_reset(text,bigint) TO pwr_collector;
```

Also ensure the `SELECT` privilege on the `pgpro_stats_archiver` view:

```
GRANT SELECT ON pgpro_stats_archiver TO pwr_collector;
```

G.1.3.2.2. In the pgpro_pwr Database

Create an unprivileged user:

```
CREATE USER pwr_user;
```

This user will be the owner of the extension schema and will collect samples.

Create a schema for the pgpro_pwr installation:

```
CREATE SCHEMA profile AUTHORIZATION pwr_user;
```

Grant the `USAGE` privilege on the schema where the dblink extension resides:

```
GRANT USAGE ON SCHEMA public TO pwr_user;
```

Create the extension using `pwr_user` account:

```
\c - pwr_user
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

Define the connection parameters of the target server for pgpro_pwr. For example:

```
SELECT profile.create_server('target_server_name','host=192.168.1.100 dbname=postgres
 port=5432');
```

The connection string provided will be used in the `dblink_connect()` call while executing the `take_sample()` function.

> **Note**
>
> Connection strings are stored in a pgpro_pwr table in clear-text form. Make sure no other database users can access tables of the pgpro_pwr extension.

G.1.3.3. Setting Up pgpro_pwr Roles

Up to three roles can be distinguished when pgpro_pwr is in operation:

- The *pgpro_pwr owner* role is the owner of the pgpro_pwr extension.
- The *collecting role* is used by pgpro_pwr to connect to databases and collect statistics.
- The *reporting role* is used to generate reports.

If all the actions with pgpro_pwr are performed by the superuser role `postgres`, you can skip most of the setup explained below.

G.1.3.3.1. The pgpro_pwr Owner

This role can be used to perform all actions related to pgpro_pwr. This role will have access to server connection strings, which may contain passwords. You should use this role to call the `take_sample()` function. The dblink extension is needed for this user.

Consider an example assuming each extension in its own schema:

```
\c postgres postgres
CREATE SCHEMA dblink;
CREATE EXTENSION dblink SCHEMA dblink;
CREATE USER pwr_usr with password 'pwr_pwd';
GRANT USAGE ON SCHEMA dblink TO pwr_usr;
CREATE SCHEMA profile AUTHORIZATION pwr_usr;
\c postgres pwr_usr
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

G.1.3.3.2. The Collecting Role

This role should be used by pgpro_pwr to connect to databases and collect statistics. Unprivileged users cannot open connections using dblink without a password, so you need to provide the password in the connection string for each server. This role should have access to all supported statistics extensions. It should also be able to perform a reset of statistics extensions.

Consider an example. If you use pgpro_stats to collect statistics, set up the collecting role as follows:

```
\c postgres postgres
CREATE SCHEMA pgps;
CREATE EXTENSION pgpro_stats SCHEMA pgps;
CREATE USER pwr_collector with password 'collector_pwd';
GRANT pg_read_all_stats TO pwr_collector;
GRANT USAGE ON SCHEMA pgps TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgps.pgpro_stats_statements_reset TO pwr_collector;
```

If you use pg_stat_statements to collect statistics, set up the collecting role as follows:

```
\c postgres postgres
CREATE SCHEMA pgss;
CREATE SCHEMA pgsk;
```

```
CREATE SCHEMA pgws;
CREATE EXTENSION pg_stat_statements SCHEMA pgss;
CREATE EXTENSION pg_stat_kcache SCHEMA pgsk;
CREATE EXTENSION pg_wait_sampling SCHEMA pgws;
CREATE USER pwr_collector with password 'collector_pwd';
GRANT pg_read_all_stats TO pwr_collector;
GRANT USAGE ON SCHEMA pgss TO pwr_collector;
GRANT USAGE ON SCHEMA pgsk TO pwr_collector;
GRANT USAGE ON SCHEMA pgws TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgss.pg_stat_statements_reset TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgsk.pg_stat_kcache_reset TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgws.pg_wait_sampling_reset_profile TO pwr_collector;
```

Now you should set up a connection string pointing to the database with statistics extensions installed:

```
\c postgres pwr_usr
SELECT profile.set_server_connstr('local','dbname=postgres port=5432 host=localhost
user=pwr_collector password=collector_pwd');
```

Password authentication must be configured in the `pg_hba.conf` file for the `pwr_collector` user.

Obviously, the collecting role should be properly configured on all servers observed by pgpro_pwr.

Now you should be able to call `take_sample()` using the `pwr_usr` role:

```
\c postgres pwr_usr
SELECT * FROM take_sample();
```

And now it's time to configure the scheduler (in our example, the `crontab` command of the `postgres` user):

```
*/30 * * * *   psql -U pwr_usr -d postgres -c 'SELECT profile.take_sample()' > /dev/
null 2>&1
```

Note that you can use the Postgres Pro password file to store passwords.

G.1.3.3.3. The Reporting Role

Any user can build a pgpro_pwr report. The minimal privileges needed to generate pgpro_pwr reports are granted to the `public` role. However a full report, with query texts, is only available to the member of the `pg_read_all_stats` role. Anyway, the reporting role cannot access server connection strings, so it cannot get the passwords of servers.

G.1.3.4. Setting Extension Parameters

In `postgresql.conf`, you can define the following pgpro_pwr parameters:

`pgpro_pwr.max` (`integer`)

Number of top objects (statements, relations, etc.) to be reported in each sorted report table. This parameter affects the size of a sample.

The default value is `20`.

`pgpro_pwr.max_sample_age` (`integer`)

Retention time of the sample, in days. Samples aged `pgpro_pwr.max_sample_age` days and older are automatically deleted on the next `take_sample()` call.

The default value is `7` days.

`pgpro_pwr.max_query_length` (`integer`)

Maximum query length allowed in reports. All queries in a report will be truncated to `pgpro_pwr.max_query_length` characters.

The default value is `20 000` characters.

`pgpro_pwr.track_sample_timings` (`boolean`)

Enables collecting detailed timing statistics of pgpro_pwr's own sampling procedures. Set this parameter to diagnose why sampling functions run slowly. Collected timing statistics will be available in the `v_sample_timings` view.

The default value is `off`.

`pgpro_pwr.statements_reset` (`boolean`)

Controls the pgpro_stats/pg_stat_statements statistics reset during taking a sample. Allows you not to reset the statistics during taking a sample due to new techniques employed. When disabled, pgpro_pwr will track statement evictions using the value of the `calls` field. However this method does not completly prevent statistics loss. pg_stat_statements v1.11 and pgpro_stats v1.8 contain time tracking abilities that can reduce the possible data loss. When this setting is disabled, you can temporarily enable it in a session if you want to sometimes perform a reset of pgpro_stats/pg_stat_statements.

The default value is `on`.

`pgpro_pwr.relsize_collect_mode` (`text`)

Defines the mode of collecting relation sizes. Possible values:

- `off` — collection of relation sizes is based on `pg_class`. Although the relation sizes collected this way are rough, their collection consumes almost no resources.
- `on` — accurate relation sizes are collected for each sample using the `pg_relation_size()` function, which requires a lock on the table and is pretty resource intensive.
- `schedule` — accurate relation sizes are collected in the size-collection window, defined for each server.

The default value is `off`.

G.1.4. Managing Servers

Once installed, pgpro_pwr creates one enabled `local` server for the current cluster. If a server is *enabled*, pgpro_pwr includes it in sampling when no server is explicitly specified (see `take_sample()` for details). A server that is not enabled is referred to as *disabled*.

The default connection string for a local node contains only `dbname` and `port` parameters. The values of these parameters are taken from the connection used to create the extension. You can change the server connection string using the `set_server_connstr()` function when needed.

G.1.4.1. Server Management Functions

Use the following pgpro_pwr functions for server management:

`create_server(`*`server`* `name, `*`connstr`* `text, `*`enabled`* `boolean DEFAULT TRUE, `*`max_sample_age`* `integer DEFAULT NULL `*`description`* `text DEFAULT NULL)`

Creates a server definition.

Arguments:

- *`server`* — server name. Must be unique.
- *`connstr`* — connection string. Must contain all the necessary settings to connect from pgpro_pwr server to the target server database.
- *`enabled`* — set to include the server in sampling by the `take_sample()` function without arguments.

- *max_sample_age* — retention time of the sample. Overrides the global pgpro_pwr.max_sample_age setting for this server.
- *description* — server description text, to be included in reports.

Here is an example of how to create a server definition:

```
SELECT profile.create_server('omega','host=192.168.1.100 dbname=postgres
 port=5432');
```

drop_server(*server* name)

Drops a server and all its samples.

set_server_description(*server* name *description* text)

Sets a new server description.

set_server_subsampling(*server* name, *subsample_enabled* boolean, *min_query_duration* interval, *min_xact_duration* interval, *min_xact_age* integer, *min_idle_xact_dur* interval hour to second)

Defines subsample settings for a server.

Arguments:

- *server* — server name.
- *subsample_enabled* — defines whether subsampling is enabled for the server, that is, whether take_subsample() function should actually take a subsample.
- *min_query_duration* — the query duration threshold.
- *min_xact_duration* — the transaction duration threshold.
- *min_xact_age* — the transaction age threshold.
- *min_idle_xact_dur_age* — the idle transaction threshold.

enable_server(*server* name)

Includes a server in sampling by the take_sample() function without arguments.

disable_server(*server* name)

Excludes a server from sampling by the take_sample() function without arguments.

rename_server(*server* name, *new_name* name)

Renames a server.

set_server_max_sample_age(*server* name, *max_sample_age* integer)

Sets the retention period for a server (in days). To reset the server retention, set the value of *max_sample_age* to NULL.

set_server_db_exclude(*server* name, *exclude_db* name[])

Excludes a list of databases on a server from sampling. Use when pgpro_pwr is unable to connect to some databases in a cluster (for example, in Amazon RDS instances).

set_server_connstr(*server* name, *server_connstr* text)

Sets the connection string for a server.

set_server_setting(*server* name, *setting* text, *value* jsonb)

Fine-tunes settings of the server statistics collection. collect* settings control which statistics should be collected, and *value* for these settings accepts bollean values, with the default equal to true. Available settings:

- `collect_pg_stat_statement` — collect statement statistics using pg_stat_statements and pg_stat_kcache extensions.
- `collect_pg_wait_sampling` — collect wait event statistics using the pg_wait_sampling extension.
- `collect_objects` — collect all the schema object statistics, that is, tables, indexes, and functions, from `pg_stat_*` views.
- `collect_relations` — collect statistics on tables and indexes from `pg_stat_*` views.
- `collect_functions` — collect statistics on user functions from the `pg_stat_user_functions` view.
- `collect_vacuum_stats` — collect the extended vacuum statistics.

`show_server_settings(`*`server`* `name)`

Returns the statistics collection settings for the specified server.

`show_servers()`

Displays the list of configured servers.

G.1.5. Managing Samples

A *sample* contains the database workload statistics since the previous sample

G.1.5.1. Sampling Functions

The following pgpro_pwr functions relate to sampling:

`take_sample()`
`take_sample(`*`server`* `name [,` *`skip_sizes`* `boolean])`

Takes samples.

If the parameter is omitted, the function takes a sample on each enabled server. Servers are accessed for sampling sequentially, one by one. The function returns a table with the following columns:

- `server` — server name.
- `result` — result of taking the sample. Can be `OK` if the sample was taken successfully or contain the error trace text in case of exception.
- `elapsed` — time elapsed while the sample was taken.

If called with the parameter, the function takes a sample on the specified server even if this server is disabled. Use when you need different sampling frequencies on specific servers. Returns `0` on success.

Arguments:

- *`server`* — server name.
- *`skip_sizes`* — if omitted or set to null, the size-collection policy applies; if `false`, relation sizes are collected; if `true`, the collection of relation sizes is skipped.

`take_sample_subset([`*`sets_cnt`* `integer,` *`current_set`* `integer])`

Takes a sample on each server in a subset of servers. Use to take samples on servers in parallel if you have many enabled servers. Although PL/pgSQL does not support parallel execution, you can call this function in parallel sessions. This function returns the same type as `take_sample()`. If both parameters are omitted, the function behaves like the `take_sample()` function, i.e., it takes a sample on all enabled servers one by one.

Arguments:

- *sets_cnt* — number of subsets to divide all enabled servers into.
- *current_set* — number of the subset to collect samples for. Takes values from 0 through *sets_cnt* - 1. For the specified subset, samples are collected as usual, server by server.

If a reset of statistics since the previous sample was detected, pgpro_pwr treats corresponding absolute values as differentials; however, the accuracy will be affected anyway.

`show_samples([server name,] [days integer])`

Returns a table with information on server samples (`local` server is assumed if *server* is omitted) for the last *days* days (all existing samples are assumed if omitted). This table has the following columns:

- `sample` — sample identifier.
- `sample_time` — time when this sample was taken.
- `dbstats_reset` — `NULL` or the statistics reset timestamp of the `pg_stat_database` view if the statistics were reset since the previous sample.
- `clustats_reset` — `NULL` or the statistics reset timestamp of the `pg_stat_bgwriter` view if the statistics were reset since the previous sample.
- `archstats_reset` — `NULL` or the statistics reset timestamp of the `pg_stat_archiver` view if the statistics were reset since the previous sample.

Sampling functions also maintain the server repository by deleting obsolete samples and baselines according to the retention policy.

G.1.5.2. Taking Samples

To take samples for all enabled servers, call the `take_sample()` function. Usually, one or two samples per hour is sufficient. You can use a cron-like tool to schedule sampling. Here is an example for a 30-minute sampling period:

```
*/30 * * * *   psql -c 'SELECT profile.take_sample()' &> /dev/null
```

However, the results of such a call are not checked for errors. In a production environment, function results can be used for monitoring. This function returns `OK` for all servers with successfully taken samples and shows error text for failed servers:

```
SELECT * FROM take_sample();
  server   |                                    result
  |   elapsed
-----------
+-------------------------------------------------------------------------------
+-------------
 ok_node   | OK
  | 00:00:00.48
 fail_node | could not establish connection
 +| 00:00:00
           | SQL statement "SELECT dblink_connect('server_connection',server_connstr)"
 +|
           | PL/pgSQL function take_sample(integer) line 69 at PERFORM
 +|
           | PL/pgSQL function take_sample_subset(integer,integer) line 27 at
 assignment+|
           | SQL function "take_sample" statement 1
 +|
           | FATAL:  database "postgresno" does not exist
  |
(2 rows)
```

G.1.5.3. Sample Retention Policy

You can define sample retention at the following levels:

1. *Global*

   The value of the `pgpro_pwr.max_sample_age` parameter in the `postgresql.conf` file defines a common retention setting, which is effective if none of other related settings are defined.

2. *Server*

   Specifying the *`max_sample_age`* parameter while creating a server or calling the `set_server_max_sample_age(`*`server`*`,`*`max_sample_age`*`)` function for an existing server defines the retention for the server. A server retention setting overrides `pgpro_pwr.max_sample_age` for a specific server.

3. *Baseline*

   A baseline created overrides all the other retention periods for included samples.

G.1.6. Managing the Collection of Relation Sizes

It may take considerable time to collect sizes of all relations in a database by Postgres Pro relation-size functions. Besides, those functions require `AccessExclusiveLock` on a relation. However, it may be sufficient for you to collect relation sizes on a daily basis. pgpro_pwr allows you to skip collecting relation sizes by defining the *size-collection policy* for servers. The policy defines:

- A daily window when the collection of relation sizes is permitted.
- A minimum gap between two samples with relation sizes collected.

When the size-collection policy is defined, sampling functions collect relation sizes only when the sample is taken in the defined window and the previous sample with sizes is older than the gap. The following function defines this policy:

```
set_server_size_sampling(server name, window_start time with time zone DEFAULT NULL,
window_duration interval hour to second DEFAULT NULL, sample_interval interval day to
minute DEFAULT NULL, collect_mode text DEFAULT NULL)
```

Defines the size-collection policy for a server.

Arguments:

- *`server`* — server name.
- *`window_start`* — start time of the size-collection window.
- *`window_duration`* — duration of the size-collection window.
- *`sample_interval`* — minimum time gap between two samples with relation sizes collected.
- *`collect_mode`* — when set to `off`, which is the default for new installations, relation sizes are collected from `pg_class`, when set to `on`, relation sizes are collected using the `pg_relation_size()` function, when set to `schedule`, pgpro_pwr collects the relation size in the size-collection window. This parameter overrides the relsize_collect_mode extension parameter. Upgrading from a previous version sets the value of this parameter to `on` or `schedule`, so the previous behavior does not change.

> **Note**
>
> When you build a report between samples either of which lacks relation-size data, relation-growth sections will be based on `pg_class.relpages` data. However, you can expand the report interval bounds to the nearest samples with relation sizes collected using the *`with_growth`* parameter of report generation functions; this makes the growth data more accurate.

Relation sizes are needed to calculate sequentially scanned volume for tables and explicit vacuum load for indexes.

Example:

```
SELECT set_server_size_sampling('local','23:00+03',interval '2 hour',interval '8 hour',
 'schedule');
```

The `show_servers_size_sampling` function shows size collection policies for all servers:

```
postgres=# SELECT * FROM show_servers_size_sampling();
 server_name | window_start | window_end  | window_duration | sample_interval |
 limited_collection
-------------+--------------+-------------+-----------------+-----------------
+--------------------
 local       | 23:00:00+03  | 01:00:00+03 | 02:00:00        | 08:00:00        | t
```

G.1.7. Managing Subsamples

Some performance-related data available in Postgres Pro is not cumulative. For example, the most often used data about session states is available through the pg_stat_activity view and can only be obtained with frequent samples. However, the `take_sample()` function is heavy and can take considerable amount of time. So it is not suitable for collecting session state data.

The *subsample* feature provides a new fast `take_subsample()` function. It can be used to collect relatively fast changing data. Every subsample is bound to the next regular sample and is deleted by the retention policy together with it.

The subsample feature can be used to capture the most interesting session states:

- Long running queries
- Long transactions
- Aged transactions, that is, those that hold a snapshot behind a lot of other transactions
- Transactions being in an idle state for a long time

G.1.7.1. Subsampling Functions

The following pgpro_pwr functions relate to subsampling:

`take_subsample()`
`take_subsample(`*`server`* `name)`

If the parameter is omitted, the function takes a subsample on each *enabled* server with subsampling enabled (see set_server_subsampling for details). Server subsamples are taken sequentially, one by one. The function returns a table with the following columns:

- `server` — server name.
- `result` — result of taking the subsample. Can be `OK` if the subsample was taken successfully or contain the error text in case of exception.
- `elapsed` — time elapsed while the subsample was taken.

This tabular return format makes it easy to control subsample creation using an SQL query.

If called with the parameter, the function takes a subsample for the specified server. Use when you need different subsampling frequencies on servers or if you want to take an explicit subsample on a specific server.

Arguments:

- *server* — server name.

> **Note**
>
> Trying to take a subsample during taking a sample fails.

`take_subsample_subset([sets_cnt integer], [current_set integer])`

Takes subsamples for a subset of enabled servers with subsampling enabled. Although subsamples should be fast enough for serial processing, subsamples can be taken in parallel, like regular samples. This function returns the same type as `take_subsample()`. If both parameters are omitted, the function behaves like the `take_subsample()` function.

Arguments:

- *sets_cnt* — number of server subsets.
- *current_set* — the subset to process. Takes values from 0 through *sets_cnt* - 1. For the specified subset, subsamples are collected as usual, server by server.

G.1.7.2. Configuring the Subsample Feature

The following settings affect the subsample behaviour:

- `pgpro_pwr.subsample_enabled` — defines whether the `take_subsample()` function should actually take a subsample.
- `pgpro_pwr.min_query_duration` — the long running query threshold.
- `pgpro_pwr.min_xact_duration` — the long transaction threshold.
- `pgpro_pwr.min_xact_age` — the transaction age threshold.
- `pgpro_pwr.min_idle_xact_dur_age` — the idle transaction threshold.

The subsample behavior can be defined at the server level using the set_server_subsampling function.

The last observed session state is saved in the repository when either of the following threshold-related events happens:

- During query execution, the difference between `now()` and the `query_start` exceeds the `pgpro_pwr.min_query_duration` threshold.
- During a transaction, the difference between `now()` and the `xact_start` exceeds the `pgpro_pwr.min_xact_duration` threshold.
- During a transaction, the `age(backend_xmin)` exceeds the `pgpro_pwr.min_xact_age` threshold.
- During a transaction in a state `idle in transaction` or `idle in transaction (aborted)`, the difference between `now()` and the `state_change` exceeds the `pgpro_pwr.min_idle_xact_duration` threshold.

See Chapter 26 for details of the mentioned fields. Every subsample can hold at most `pgpro_pwr.max` entries for every threshold type.

G.1.7.3. Scheduling Subsamples

Subsamples are fast enough to take them quite often. However usually you do not need more than 2-4 subsamples per minute. Obviously the subsample frequency depends on the shortest used duration of a threshold setting.

Cron only allows one call per minute, so some effort is needed to schedule more frequent subsamples. For example, the `\watch` psql command can be used:

```
echo "select take_subsample(); \watch 15" | psql &> /dev/null
```

The psql call can be wrapped in the systemd service like this:

```
Description=pgpro_pwr subsampling unit
[Unit]

[Service]
Type=simple
ExecStart=/bin/sh -c 'echo "select take_subsample(); \\watch 15" | /path/to/psql -qo /
dev/null'
User=postgres
Group=postgres

[Install]
WantedBy=multi-user.target
```

G.1.8. Managing Baselines

A *baseline* is a named sequence of samples that has its own retention setting. A baseline can be used as a sample interval in report generation functions. An undefined baseline retention means infinite retention. Use baselines to save information about the database workload for a certain time interval.

G.1.8.1. Baseline Management Functions

Use the following pgpro_pwr functions for baseline management:

`create_baseline([server name,] baseline varchar(25), start_id integer, end_id integer [, days integer])`
`create_baseline([server name,] baseline varchar(25), time_range tstzrange [, days integer])`

Creates a baseline.

Arguments:

- *server* — server name. `local` sever is assumed if omitted.
- *baseline* — baseline name. Must be unique for a server.
- *start_id* — identifier of the first sample in the baseline.
- *end_id* — identifier of the last sample in the baseline.
- *time_range* — time interval for the baseline. The baseline will include all samples for the minimal interval that covers *time_range*.
- *days* — baseline retention time, defined in integer days since `now()`. Omit or set to null for infinite retention.

`drop_baseline([server name,] baseline varchar(25))`

Drops a baseline. For the meaning and usage details of function arguments, see create_baseline. Dropping a baseline does not mean dropping all its samples immediately. The baseline retention just no longer applies to them.

`keep_baseline([server name,] baseline varchar(25) [, days integer])`

Changes the retention of a baseline. For the meaning and usage details of function arguments, see create_baseline. Omit the *baseline* parameter or pass null to it to change the retention of all existing baselines.

`show_baselines([server name])`

Displays existing baselines. Call `show_baselines` to get information about the baselines, such as names, sampling intervals and retention periods. `local` sever is assumed if the *server* parameter is omitted.

G.1.9. Data Export and Import

Collected samples can be exported from one instance of the pgpro_pwr extension and then loaded into another one. This feature helps you to move server data from one instance to another or to send collected data to your support team.

G.1.9.1. Data Export

The export_data function exports data to a regular table. You can use any method available to export this table from your database. For example, you can use the `\copy` meta-command of psql to obtain a single `csv` file:

```
postgres=# \copy (select * from export_data()) to 'export.csv'
```

G.1.9.2. Data Import

Since data can only be imported from a local table, first, load the data you exported. Using the `\copy` meta-command again:

```
postgres=# CREATE TABLE import (section_id bigint, row_data json);
CREATE TABLE
postgres=# \copy import from 'export.csv'
COPY 6437
```

Now you can import the data by providing the `import` table to the import_data function:

```
postgres=# SELECT * FROM import_data('import');
```

After successful import, you can drop the `import` table.

> **Note**
>
> If server data is imported for the first time, your local pgpro_pwr servers with matching names will cause a conflict during import. To avoid this, you can temporarily rename such servers or you can specify the server name prefix for import operations. However, during import of new data for already imported servers, they are matched by system identifiers, so feel free to rename imported severs. Also keep in mind that pgpro_pwr sets servers being imported to the *disabled* state for `take_sample()` to bypass them.

G.1.9.3. Export and Import Functions

Use these functions to export or import data:

`export_data([`*`server`* `name, [`*`min_sample_id`* `integer,] [`*`max_sample_id`* `integer,]] [, `*`obfuscate_queries`* `boolean])`

Exports collected data.

Arguments:

- *`server`* — server name. All configured servers are assumed if omitted.
- *`min_sample_id`*, *`max_sample_id`* — sample identifiers to bound the export (inclusive). If *`min_sample_id`* is omitted or set to null, all samples until *`max_sample_id`* sample are exported; if *`max_sample_id`* is omitted or set to null, all samples since *`min_sample_id`* sample are exported.
- *`obfuscate_queries`* — if `true`, query texts are exported as `MD5` hash.

`import_data(`*`data`* `regclass [, `*`server_name_prefix`* `text])`

Imports previously exported data. Returns the number of actually loaded rows in pgpro_pwr tables.

Arguments:

- *data* is the name of the table containing import data.
- *server_name_prefix* specifies the server name prefix for the import operation. It can be used to avoid name conflicts.

G.1.10. Report Generation Functions

pgpro_pwr reports are generated in HTML format by reporting functions. The following types of reports are available:

- *Regular reports* provide statistics on the workload for an interval.
- *Differential reports* provide statistics on the same objects for two intervals. Corresponding values are located next to each other, which makes it easy to compare the workloads.

Reporting functions take sample identifiers, baselines or time ranges to determine the intervals. For time ranges, these are the minimal intervals that cover the ranges.

G.1.10.1. Regular Reports

Use these functions to generate regular reports:

```
get_report([server name,] start_id integer, end_id integer [, description text [,
with_growth boolean [, db_exclude name[]]]])
get_report([server name,] time_range tstzrange [, description text [, with_growth boolean
[, db_exclude name[]]]])
get_report([server name,] baseline varchar(25) [, description text [, with_growth boolean
[, db_exclude name[]]]])
```

Generates a regular report defined by the arguments.

Arguments:

- *server* — server name. `local` sever is assumed if omitted.
- *start_id* — identifier of the interval starting sample.
- *end_id* — identifier of the interval ending sample.
- *baseline* — baseline name.
- *time_range* — time range.
- *description* — short text to be included in the report as its description.
- *with_growth* — flag requesting interval expansion to the nearest bounds with data on relation growth available. The default value is `false`.
- *db_exclude* — the database exclusion list. Lists databases to be excluded from all report tables having the `Database` column. Use to hide some databases in the report.

```
get_report_latest([server name,])
get_report_latest([server name [, db_exclude name[]]])
```

Generates a regular report for two latest samples.

Arguments:

- *server* — server name. `local` sever is assumed if omitted.
- *db_exclude* — the database exclusion list. Lists databases to be excluded from all report tables having the `Database` column. Use to hide some databases in the report.

G.1.10.2. Differential Reports

Use this function to generate differential reports:

```
get_diffreport([server name,] start1_id integer, end1_id integer, start2_id integer,
end2_id integer [, description text [, with_growth boolean [, db_exclude name[]]]])
get_diffreport([server name,] time_range1 tstzrange, time_range2 tstzrange [, description
text [, with_growth boolean [, db_exclude name[]]]])
get_diffreport([server name,] baseline1 varchar(25), baseline2 varchar(25) [, description
text [, with_growth boolean [, db_exclude name[]]]])
get_diffreport([server name,] baseline1 varchar(25), time_range2 tstzrange [, description
text [, with_growth boolean[, db_exclude name[]]]])
get_diffreport([server name,] time_range1 tstzrange, baseline2 varchar(25) [, description
text [, with_growth boolean[, db_exclude name[]]]])
get_diffreport([server name,] start1_id integer, end1_id integer, baseline2 varchar(25)
[, description text [, with_growth boolean[, db_exclude name[]]]])
get_diffreport([server name,] baseline1 varchar(25), start2_id integer, end2_id integer
[, description text [, with_growth boolean[, db_exclude name[]]]])
```

Generates a differential report for two intervals. The combinations of arguments provide possible ways to specify the two intervals.

Arguments:

- *server* — server name. `local` sever is assumed if omitted.
- *start1_id*, *end1_id* — identifiers of the starting and ending samples for the first interval.
- *start2_id*, *end2_id* — identifiers of the starting and ending samples for the second interval.
- *baseline1* — baseline name for the first interval.
- *baseline2* — baseline name for the second interval.
- *time_range1* — time range for the first interval.
- *time_range2* — time range for the second interval.
- *description* — short text to be included in the report as its description.
- *with_growth* — flag requesting interval expansion to the nearest bounds with data on relation growth available. The default value is `false`.
- *db_exclude* — the database exclusion list. Lists databases to be excluded from all report tables having the `Database` column. Use to hide some databases in the report.

G.1.10.3. Report Generation Example

Generate a report for the `local` server and interval defined by samples:

```
psql -Aqtc "SELECT profile.get_report(480,482)" -o report_480_482.html
```

For any other server, provide its name:

```
psql -Aqtc "SELECT profile.get_report('omega',12,14)" -o report_omega_12_14.html
```

Generate a report using time ranges:

```
psql -Aqtc "SELECT profile.get_report(tstzrange('2020-05-13 11:51:35+03','2020-05-13
 11:52:18+03'))" -o report_range.html
```

Generate a relative time-range report:

```
psql -Aqtc "SELECT profile.get_report(tstzrange(now() - interval '1 day',now()))" -o
 report_last_day.html
```

G.1.11. pgpro_pwr Report Sections

Each pgpro_pwr report is divided into sections, described below. The number of top objects reported in each sorted report table is specified by the `pgpro_pwr.max` parameter.

Almost every item in the report can be accentuated by a single mouse click. The accentuated item will be instantly highlighted in all report sections, making it easy to find. The attributes identifying the item will appear in the bottom-right corner of the page. For example, if you click on a database name in the "Database statistics" report table, you can notice a small table with the database attributes in the bottom-right corner of the page.

When you scroll down the report, its table of contents will be available on the right side of the page. It can be hidden with a single mouse click on the "content" tag.

A substring-based filter is also available that helps limit the report contents to particular objects based on a substring. Specifically, substring-based filtering is applied to query texts.

G.1.11.1. Server statistics

Tables in this section of a pgpro_pwr report are described below.

The report table "Database statistics" provides per-database statistics for the report interval. The statistics are based on the `pg_stat_database` view. Table G.1 lists columns of this report table.

Table G.1. Database statistics

Column	Description	Field/Calculation
`Database`	Database name	`datname`
`Commits`	Number of committed transactions	`xact_commit`
`Rollbacks`	Number of rolled back transactions	`xact_rollback`
`Deadlocks`	Number of deadlocks detected	`deadlocks`
`Checksum Failures`	Number of data page checksum failures detected in this database. This field is only shown if any checksum failures were detected in this database during the report interval.	`checksum_failures`
`Checksums Last`	Time at which the last data page checksum failure was detected in this database. This field is only shown if any checksum failures were detected in this database during the report interval.	`checksum_last_failure`
`Hit%`	Buffer cache hit ratio, i.e., percentage of pages fetched from buffers in all pages fetched	
`Read`	Number of disk blocks read in this database	`blks_read`
`Hit`	Number of times disk blocks were found already in the buffer cache	`blks_hit`
`Ret`	Number of returned tuples	`tup_returned`
`Fet`	Number of fetched tuples	`tup_fetched`
`Ins`	Number of inserted tuples	`tup_inserted`
`Upd`	Number of updated tuples	`tup_updated`
`Del`	Number of deleted tuples	`tup_deleted`

Column	Description	Field/Calculation
Temp Size	Total amount of data written to temporary files by queries in this database	temp_bytes
Temp Files	Number of temporary files created by queries in this database	temp_files
Size	Database size at the time of the last sample in the report interval	pg_database_size()
Growth	Database growth during the report interval	pg_database_size() increment between interval bounds

The report table “Cluster I/O statistics” provides I/O statistics by object types, backend types and contexts. This table is based on the pg_stat_io view of the Cumulative Statistics System, available since Postgres Pro 16. Table G.2 lists columns of this report table. Times are provided in seconds.

Table G.2. Cluster I/O statistics

Column	Description
Object	Target object of an I/O operation
Backend	Type of the backend that performed an I/O operation
Context	The context of an I/O operation
Reads Count	Number of read operations
Reads Bytes	Amount of data read
Reads Time	Time spent in read operations
Writes Count	Number of write operations
Writes Bytes	Amount of data written
Writes Time	Time spent in write operations
Writebacks Count	Number of blocks which the process requested the kernel write out to permanent storage
Writebacks Bytes	Amount of data requested for write out to permanent storage
Writebacks Time	Time spent in writeback operations, including the time spent queueing write-out requests and, potentially, the time spent to write out the dirty data
Extends Count	Number of relation extend operations
Extends Bytes	Amount of space used by extend operations
Extends Time	Time spent in extend operations
Hits	The number of times a desired block was found in a shared buffer
Evictions	Number of times a block has been written out from a shared or local buffer in order to make it available for another use
Reuses	The number of times an existing buffer in a size-limited ring buffer outside of shared buffers was reused as part of an I/O operation in the bulkread, bulkwrite, or vacuum contexts
Fsyncs Count	Number of fsync calls. These are only tracked in context normal.

Column	Description
Fsyncs Time	Time spent in fsync operations

The report table “Cluster SLRU statistics” provides access statistics on SLRU (simple least-recently-used) caches. This table is based on the pg_stat_slru view of the Cumulative Statistics System. Table G.3 lists columns of this report table. Times are provided in seconds.

Table G.3. Cluster SLRU statistics

Column	Description	Field/Calculation
Name	Name of the SLRU	name
Zeroed	Number of blocks zeroed during initializations	blks_zeroed
Hits	Number of times disk blocks were found already in the SLRU, so that a read was not necessary (this only includes hits in the SLRU, not the operating system's file system cache)	blks_hit
Reads	Number of disk blocks read for this SLRU	blks_read
%Hit	Number of disk block hits for this SLRU as the percentage of Reads + Hits	blks_hit *100/blks_read + blks_hit
Writes	Number of disk blocks written for this SLRU	blks_written
Checked	Number of blocks checked for existence for this SLRU	blks_exists
Flushes	Number of flushes of dirty data for this SLRU	flushes
Truncates	Number of truncates for this SLRU	truncates

Table “Session statistics by database” is available in the report for Postgres Pro databases starting with version 14. This table is based on the pg_stat_database view of the Statistics Collector. Table G.4 lists columns of this report table. Times are provided in seconds.

Table G.4. Session statistics by database

Column	Description	Field/Calculation
Database	Database name	
Timing Total	Time spent by database sessions in this database during the report interval (note that statistics are only updated when the state of a session changes, so if sessions have been idle for a long time, this idle time won't be included)	session_time
Timing Active	Time spent executing SQL statements in this database during the report interval (this corresponds to the states active and fastpath function call in pg_stat_activity)	active_time

Column	Description	Field/Calculation
Timing Idle(T)	Time spent idling while in a transaction in this database during the report interval (this corresponds to the states idle in transaction and idle in transaction (aborted) in pg_stat_activity)	idle_in_transaction_time
Sessions Established	Total number of sessions established to this database during the report interval	sessions
Sessions Abandoned	Number of database sessions to this database that were terminated because connection to the client was lost during the report interval	sessions_abandoned
Sessions Fatal	Number of database sessions to this database that were terminated by fatal errors during the report interval	sessions_fatal
Sessions Killed	Number of database sessions to this database that were terminated by operator intervention during the report interval	sessions_killed

In Postgres Pro Standard databases of versions that include pgpro_stats version starting with 1.4, workload statistics of vacuum processes are available. The “Database vacuum statistics” report table provides per-database aggregated total vacuum statistics based on the pgpro_stats_vacuum_tables view. Table G.5 lists columns of this report table. Times are provided in seconds.

Table G.5. Database vacuum statistics

Column	Description	Field/Calculation
Database	Database name	
Blocks fetched	Total number of database blocks fetched by vacuum operations	total_blks_read + total_blks_hit
%Total	Total number of database blocks fetched (read+hit) by vacuum operations as the percentage of all blocks fetched in the cluster	Blocks fetched * 100 / Cluster fetched
Blocks read	Total number of database blocks read by vacuum operations	total_blks_read
%Total	Total number of database blocks read by vacuum operations as the percentage of all blocks read in the cluster	Blocks read * 100 / Cluster read
VM Frozen	Total number of blocks marked all-frozen in the visibility map	pages_frozen
VM Visible	Total number of blocks marked all-visible in the visibility map	pages_all_visible
Tuples deleted	Total number of dead tuples vacuum operations deleted from tables of this database	tuples_deleted

Column	Description	Field/Calculation
Tuples left	Total number of dead tuples vacuum operations left in tables of this database due to their visibility in transactions	dead_tuples
%Eff	Vacuum efficiency in terms of deleted tuples. This is the percentage of tuples deleted from tables of this database in all dead tuples to be deleted from tables of this database.	tuples_deleted * 100 / (tuples_deleted + dead_tuples)
WAL size	Total amount of WAL bytes generated by vacuum operations performed on tables of this database	wal_bytes
Read I/O time	Time spent reading database blocks by vacuum operations performed on tables of this database	blk_read_time
Write I/O time	Time spent writing database blocks by vacuum operations performed on tables of this database	blk_write_time
%Total	Vacuum I/O time spent as the percentage of whole cluster I/O time	
Total vacuum time	Total time of vacuuming tables of this database	total_time
Delay vacuum time	Time spent sleeping in a vacuum delay point by vacuum operations performed on tables of this database	delay_time
User CPU time	User CPU time of vacuuming tables of this database	user_time
System CPU time	System CPU time of vacuuming tables of this database	system_time
Interrupts	Number of times vacuum operations performed on tables of this database were interrupted on any errors	interrupts

If the pgpro_stats extension supporting invalidation statistics was available during the report interval, the "Invalidation messages by database" report table provides per-database aggregated total invalidation message statistics. Table G.6 lists columns of this report table.

Table G.6. Invalidation messages by database

Column	Description	Field/Calculation
Database	Database name	
Invalidation messages sent	Total number of invalidation messages sent by backends in this database. Statistics are provided for corresponding message	Fields of pgpro_stats_totals.inval_msgs

Column	Description	Field/Calculation
	types of pgpro_stats_inval_msgs	
Cache resets	Total number of shared cache resets	pgpro_stats_totals .cache_resets

If the pgpro_stats extension was available during the report interval, the “Statement statistics by database” report table provides per-database aggregated total statistics for the pgpro_stats_statements view data. Table G.7 lists columns of this report table. Times are provided in seconds.

Table G.7. Statement statistics by database

Column	Description	Field/Calculation
Database	Database name	
Calls	Number of times all statements in the database were executed	calls
Plan Time	Time spent planning all statements in the database	Sum of total_plan_time
Exec Time	Time spent executing all statements in the database	Sum of total_exec_time
Read Time	Time spent reading blocks by all statements in the database	Sum of blk_read_time
Write Time	Time spent writing blocks by all statements in the database	Sum of blk_write_time
Trg Time	Time spent executing trigger functions by all statements in the database	
Shared Fetched	Total number of shared blocks fetched by all statements in the database	Sum of (shared_blks_read + shared_blks_hit)
Local Fetched	Total number of local blocks fetched by all statements in the database	Sum of (local_blks_read + local_blks_hit)
Shared Dirtied	Total number of shared blocks dirtied by all statements in the database	Sum of shared_blks_dirtied
Local Dirtied	Total number of local blocks dirtied by all statements in the database	Sum of local_blks_dirtied
Read Temp	Total number of temp blocks read by all statements in the database	Sum of temp_blks_read
Write Temp	Total number of temp blocks written by all statements in the database	Sum of temp_blks_written
Read Local	Total number of local blocks read by all statements in the database	Sum of local_blks_read
Write Local	Total number of local blocks written by all statements in the database	Sum of local_blks_written

Column	Description	Field/Calculation
Statements	Total number of captured statements	
WAL Size	Total amount of WAL generated by all statements in the database	Sum of wal_bytes

The “Statement average min/max timings” report table contains per-database aggregated min/max timing statistics from the one of pgpro_stats or pg_stat_statements extensions that was available during the report interval, with the precedence of pgpro_stats. This report is sensitive to the fastest and slowest planning and execution of every statement in a cluster. That is, you can see execution and planning stability in your database. Table G.8 lists columns of this report table.

Table G.8. Statement average min/max timings

Column	Description
Database	Database name
Min average planning time (ms)	The average value of min_plan_time for all statements and all samples included in the report
Max average planning time (ms)	The average value of max_plan_time for all statements and all samples included in the report
Delta% of average planning times	Difference between the mean max_plan_time and mean min_plan_time as the percentage of the mean min_plan_time . The less this difference, the more stable query planning in your database is.
Min average execution time (ms)	The average value of min_exec_time for all statements and all samples included in the report
Max average execution time (ms)	The average value of max_exec_time for all statements and all samples included in the report
Delta% of average execution times	Difference between the mean max_exec_time and mean min_exec_time as the percentage of the mean min_exec_time . The less this difference, the more stable query execution in your database is.
Statements	Total count of captured statements

If the JIT-related statistics was avaliable in the statement statistics extension during the report interval, the “JIT statistics by database” report table provides per-database aggregated total statistics of JIT executions. Table G.9 lists columns of this report table. Times are provided in seconds.

Table G.9. JIT statistics by database

Column	Description	Field/Calculation
Database	Database name	
Calls	Number of times all statements in the database were executed	calls
Plan Time	Time spent planning all statements in the database	Sum of total_plan_time
Exec Time	Time spent executing all statements in the database	Sum of total_exec_time
Generation count	Total number of functions JIT-compiled by the statements	Sum of jit_functions

Column	Description	Field/Calculation
Generation time	Total time spent by the statements on generating JIT code	Sum of jit_generation_time
Inlining count	Number of times functions have been inlined	Sum of jit_inlining_count
Inlining time	Total time spent by statements on inlining functions	Sum of jit_inlining_time
Optimization count	Number of times statements have been optimized	Sum of jit_optimization_count
Optimization time	Total time spent by statements on optimizing	Sum of jit_optimization_time
Emission count	Number of times code has been emitted	Sum of jit_emission_count
Emission time	Total time spent by statements on emitting code	Sum of jit_emission_time
Deform count	Number of tuple deform functions JIT-compiled by the statement of the database	
Deform time	Total time spent by the statements of the database on JIT-compiling the tuple deform functions	

The report table “Cluster statistics” provides data from the pg_stat_bgwriter view. Table G.10 lists rows of this report table. Times are provided in seconds.

Table G.10. Cluster statistics

Row	Description	Field/Calculation
Scheduled checkpoints	Number of scheduled checkpoints that have been performed	checkpoints_timed
Requested checkpoints	Number of requested checkpoints that have been performed	checkpoints_req
Checkpoint write time (s)	Total amount of time that has been spent in the portion of checkpoint processing where files are written to disk	checkpoint_write_time
Checkpoint sync time (s)	Total amount of time that has been spent in the portion of checkpoint processing where files are synchronized to disk	checkpoint_sync_time
Checkpoint buffers written	Number of buffers written during checkpoints	buffers_checkpoint
Background buffers written	Number of buffers written by the background writer	buffers_clean
Backend buffers written	Number of buffers written directly by a backend. Will not be shown since Postgres Pro 17.	buffers_backend
Backend fsync count	Number of times a backend had to execute its own fsync call (normally the background writer handles those even when the	buffers_backend_fsync

Row	Description	Field/Calculation
	backend does its own write). Will not be shown since Postgres Pro 17.	
Bgwriter interrupts (too many buffers)	Number of times the background writer stopped a cleaning scan because it had written too many buffers	maxwritten_clean
Number of buffers allocated	Total number of buffers allocated	buffers_alloc
WAL generated	Total amount of WAL generated	pg_current_wal_lsn() value increment
Start LSN	Log sequence number at the start of a report interval	pg_current_wal_lsn() at the first sample of a report
End LSN	Log sequence number at the end of a report interval	pg_current_wal_lsn() at the last sample of a report
WAL generated by vacuum	Total amount of WAL generated by vacuum	Based on the wal_bytes field of the pgpro_stats_vacuum_databases view.
WAL segments archived	Total number of archived WAL segments	Based on pg_stat_archiver.archived_count
WAL segments archive failed	Total number of WAL segment archiver failures	Based on pg_stat_archiver.failed_count .
Archiver performance	Average archiver process performance per second	Based on the active_time field of the pgpro_stats_archiver view.
Archive command performance	Average archive_command performance per second	Based on the archive_command_time field of the pgpro_stats_archiver view.

Table “WAL statistics” is available in the report for Postgres Pro databases starting with version 14. This table is based on the pg_stat_wal view of the Statistics Collector. Table G.11 lists columns of this report table. Times are provided in seconds.

Table G.11. WAL statistics

Row	Description	Field/Calculation
WAL generated	Total amount of WAL generated during the report interval	wal_bytes
WAL per second	Average amount of WAL generated per second during the report interval	wal_bytes / report_duration
WAL records	Total number of WAL records generated during the report interval	wal_records
WAL FPI	Total number of WAL full page images generated during the report interval	wal_fpi
WAL buffers full	Number of times WAL data was written to disk because WAL buffers became full during the report interval	wal_buffers_full

Row	Description	Field/Calculation
WAL writes	Number of times WAL buffers were written out to disk via XLogWrite request during the report interval	wal_write
WAL writes per second	Average number of times WAL buffers were written out to disk via XLogWrite request per second during the report interval	wal_write / report_duration
WAL sync	Number of times WAL files were synced to disk via issue_xlog_fsync request during the report interval (if fsync is on and wal_sync_method is either fdatasync, fsync or fsync_writethrough , otherwise zero). See Section 28.5 for more information about the internal WAL function issue_xlog_fsync .	wal_sync
WAL syncs per second	Average number of times WAL files were synced to disk via issue_xlog_fsync request per second during the report interval	wal_sync / report_duration
WAL write time	Total amount of time spent writing WAL buffers to disk via XLogWrite request during the report interval (if track_wal_io_timing is enabled, otherwise zero; for more details, see Section 18.9). This includes the sync time when wal_sync_method is either open_datasync or open_sync .	wal_write_time
WAL write duty	WAL write time as the percentage of the report interval duration	wal_write_time * 100 / report_duration
WAL sync time	Total amount of time spent syncing WAL files to disk via issue_xlog_fsync request during the report interval (if track_wal_io_timing is enabled, fsync is on, and wal_sync_method is either fdatasync, fsync or fsync_writethrough , otherwise zero).	wal_sync_time
WAL sync duty	WAL sync time as the percentage of the report interval duration	wal_sync_time * 100 / report_duration

The report table “Tablespace statistics” provides information on the sizes and growth of tablespaces. Table G.12 lists columns of this report table.

Table G.12. Tablespace statistics

Column	Description	Field/Calculation
`Tablespace`	Tablespace name	`pg_tablespace .spcname`
`Path`	Tablespace path	`pg_tablespace_location()`
`Size`	Tablespace size at the time of the last sample in the report interval	`pg_tablespace_size()`
`Growth`	Tablespace growth during the report interval	`pg_tablespace_size()` increment between interval bounds

If the pgpro_stats extension was available during the report interval, the report table “Wait statistics by database” shows the total wait time by wait event type and database. Table G.13 lists columns of this report table.

Table G.13. Wait statistics by database

Column	Description
`Database`	Database name
`Wait event type`	Type of event for which the backends were waiting. Asterisk means aggregation of all wait event types in the database.
`Waited (s)`	Time spent waiting in events of `Wait event type`, in seconds
`%Total`	Percentage of wait time spent in the database events of `Wait event type` in all wait time for the cluster

If the pgpro_stats extension was available during the report interval, the report table “Top wait events” shows top wait events in the cluster by wait time. Table G.14 lists columns of this report table.

Table G.14. Top wait events

Column	Description
`Database`	Database name
`Wait event type`	The type of event for which the backends were waiting
`Wait event`	Wait event name for which the backends were waiting
`Waited`	Total wait time spent in `Wait event` of the database, in seconds
`%Total`	Percentage of wait time spent in `Wait event` of the database in all wait time in the cluster

G.1.11.2. Load distribution

This section of a pgpro_pwr report is based on the `pgpro_stats_totals` view of the pgpro_stats extension if it was available during the report interval. Each table in this section provides data for the report interval on load distribution for a certain kind of objects for which aggregated statistics are collected, such as databases, applications, hosts, or users. Each table contains one row for each resource (for example, total time or shared blocks written), where load distribution is shown in graphics, as a stacked bar chart for top objects by load of this resource. If the bar chart area that corresponds to an object is too narrow to include captions, point that area to get a hint with the caption, value and percentage.

The report tables “Load distribution among heavily loaded databases”, “Load distribution among heavily loaded applications”, “Load distribution among heavily loaded hosts” and “Load distribution among heavily loaded users” show load distribution for respective objects. Table G.15 lists rows of these report tables.

Table G.15. Load distribution

Row	Description	Calculation
Total time (sec.)	Total time spent in the planning and execution of statements	total_plan_time + total_exec_time
Executed count	Number of queries executed	queries_executed
I/O time (sec.)	Total time the statements spent reading or writing blocks (if track_io_timing is enabled, otherwise zero)	blk_read_time + blk_write_time
Blocks fetched	Total number of shared block cache hits and shared blocks read by the statements	shared_blks_hit + shared_blks_read
Shared blocks read	Total number of shared blocks read by the statements	shared_blks_read
Shared blocks dirtied	Total number of shared blocks dirtied by the statements	shared_blks_dirtied
Shared blocks written	Total number of shared blocks written by the statements	shared_blks_written
WAL generated	Total amount of WAL generated by the statements	wal_bytes
Temp and Local blocks written	Total number of temporary and local blocks written by the statements	temp_blks_written + local_blks_written
Temp and Local blocks read	Total number of temp and local blocks read by the statements	temp_blks_read + local_blks_read
Invalidation messages sent	Total number of all invalidation messages sent by backends in this database	(pgpro_stats_totals.inval_msgs).all
Cache resets	Total number of shared cache resets	pgpro_stats_totals.cache_resets

G.1.11.3. Session states observed by subsamples

This section of a pgpro_pwr report provides information about session states captured by subsamples during the report interval.

Tables of this report section are described below.

The report subsection “Chart with session state” visualizes session states captured by subsamples. It is the timeline chart showing captured session states in backends and transactions. Every state contains a popup with session state attributes. Click on a state to see this state in the table of session states.

The report table “Session state statistics by database” shows the aggregated data on session states. Only session states captured in subsamples are counted. Table G.16 lists columns of this report table.

Table G.16. Session state statistics by database

Column	Description
Database	Database name

Column	Description
Summary Active	Overall time of active states captured in subsamples
Summary Idle in xact	Overall time of idle in transaction states captured in subsamples
Summary Idle in xact (A)	Overall time of idle in transaction (aborted) states captured in subsamples
Maximal Active	Time of the longest active state captured in subsamples
Maximal Idle in xact	Time of the longest idle in transaction state captured in subsamples
Maximal Idle in xact (A)	Time of the longest idle in transaction (aborted) state captured in subsamples
Maximal xact age	Maximal transaction age detected in subsamples

The report table “Top 'idle in transaction' session states by duration” shows top pgpro_pwr.max longest idle in transaction states that were last observed in the pg_stat_activity view for each session. Table G.17 lists columns of this report table.

Table G.17. Top 'idle in transaction' session states by duration

Column	Description	Field/Calculation
Database	Database name	datname
User	User name	usename
App	Application name	application_name
Pid	Process ID	pid
Xact start	Transaction start timestamp	xact_start
State change	State change timestamp	state_change
State duration	State duration	clock_timestamp() - state_change

The report table “Top 'active' session states by duration” shows top pgpro_pwr.max longest active states that were last observed in the pg_stat_activity view for each session. Table G.18 lists columns of this report table.

Table G.18. Top 'active' session states by duration

Column	Description	Field/Calculation
Database	Database name	datname
User	User name	usename
App	Application name	application_name
Pid	Process ID	pid
Xact start	Transaction start timestamp	xact_start
State change	State change timestamp	state_change
State duration	State duration	clock_timestamp() - state_change

The report table “Top states by transaction age” shows top session states by transaction age that were last observed in the pg_stat_activity view for each session. Table G.19 lists columns of this report table.

Table G.19. Top states by transaction age

Column	Description	Field/Calculation
Database	Database name	datname
User	User name	username
App	Application name	application_name
Pid	Process ID	pid
Xact start	Transaction start timestamp	xact_start
Xact duration	Transaction duration	clock_timestamp() - xact_start
Age	Transaction age	age(backend_xmin)
State	Session state at the maximum age detected	
State change	State change timestamp	state_change
State duration	State duration	clock_timestamp() - state_change

The report table “Top states by transaction duration” shows top longest session states that were last observed in the pg_stat_activity view for each session. Table G.20 lists columns of this report table.

Table G.20. Top states by transaction duration

Column	Description	Field/Calculation
Database	Database name	datname
User	User name	username
App	Application name	application_name
Pid	Process ID	pid
Xact start	Transaction start timestamp	xact_start
Xact duration	Transaction duration	clock_timestamp() - xact_start
Age	Transaction age	age(backend_xmin)
State	Session state at the maximum age detected	
State change	State change timestamp	state_change
State duration	State duration	clock_timestamp() - state_change

G.1.11.4. SQL query statistics

This section of a pgpro_pwr report provides data for the report interval on top statements by several important statistics. The data is mainly captured from views of the one of pgpro_stats and pg_stat_statements extensions that was available during the report interval, with the precedence of pgpro_stats. Each statement can be highlighted in all SQL-related sections with a single mouse click on it. This click will also show a query text preview just under the query statistics row. The query text preview can be hidden with a second click on a query.

Tables of this report section are described below.

The report table “Top SQL by elapsed time” shows top statements by the sum of total_plan_time and total_exec_time fields of the pgpro_stats_statements or pg_stat_statements view. Table G.21 lists columns of this report table. Times are provided in seconds.

Table G.21. Top SQL by elapsed time

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
%Total	Percentage of elapsed time of this statement plan in the total elapsed time of all statements in the cluster	
Elapsed Time (s)	Total time spent in planning and execution of the statement plan	total_plan_time + total_exec_time
Plan Time (s)	Total time spent in planning of the statement	total_plan_time
Exec Time (s)	Total time spent in execution of the statement plan	total_exec_time
JIT Time (s)	Total time spent by JIT executing this statement plan, in seconds	jit_generation_time + jit_inlining_time + jit_optimization_time + jit_emission_time
Read I/O time (s)	Total time the statement spent reading blocks	blk_read_time
Write I/O time (s)	Total time the statement spent writing blocks	blk_write_time
Usr CPU time (s)	Time spent on CPU in the user space, in seconds	rusage.user_time
Sys CPU time (s)	Time spent on CPU in the system space, in seconds	rusage.system_time
Plans	Number of times the statement was planned	plans
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by planning time” shows top statements by the value of the total_plan_time field of the pgpro_stats_statements or pg_stat_statements view. Table G.22 lists columns of this report table.

Table G.22. Top SQL by planning time

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Plan elapsed(s)	Total time spent in planning of the statement, in seconds	total_plan_time
%Elapsed	Percentage of total_plan_time in the sum of total_plan_time and total_exec_time of this statement plan	
Mean plan time	Mean time spent planning the statement, in milliseconds	mean_plan_time
Min plan time	Minimum time spent planning the statement, in milliseconds	min_plan_time
Max plan time	Maximum time spent planning the statement, in milliseconds	max_plan_time
StdErr plan time	Population standard deviation of time spent planning the statement, in milliseconds	stddev_plan_time
Plans	Number of times the statement was planned	plans
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by execution time” shows top statements by the value of the total_time field of the pgpro_stats_statements or pg_stat_statements view. Table G.23 lists columns of this report table.

Table G.23. Top SQL by execution time

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	

Column	Description	Field/Calculation
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Exec (s)	Total time spent executing the statement plan, in seconds	total_exec_time
%Elapsed	Percentage of total_exec_time of this statement plan in this statement elapsed time	
%Total	Percentage of total_exec_time of this statement plan in the total elapsed time of all statements in the cluster	
JIT Time (s)	Total time spent by JIT executing this statement plan, in seconds	jit_generation_time + jit_inlining_time + jit_optimization_time + jit_emission_time
Read I/O time (s)	Total time spent in reading pages while executing the statement plan, in seconds	blk_read_time
Write I/O time (s)	Total time spent in writing pages while executing the statement plan, in seconds	blk_write_time
Usr CPU time (s)	Time spent on CPU in the user space, in seconds	rusage.user_time
Sys CPU time (s)	Time spent on CPU in the system space, in seconds	rusage.system_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Mean execution time	Mean time spent executing the statement plan, in milliseconds	mean_exec_time
Min execution time	Minimum time spent executing the statement plan, in milliseconds	min_exec_time
Max execution time	Maximum time spent executing the statement plan, in milliseconds	max_exec_time
StdErr execution time	Population standard deviation of time spent executing the statement plan, in milliseconds	stddev_exec_time
Executions	Number of executions of this statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table "Top SQL by mean execution time" shows top `pgpro_pwr.max` statements by the value of the `mean_time` or `mean_exec_time` field of the `pgpro_stats_statements` or `pg_stat_statements` view. Table G.24 lists columns of this report table.

Table G.24. Top SQL by mean execution time

Column	Description	Field/Calculation
`Query ID`	Hex representation of `queryid`. The hash of the query ID, database ID and user ID is in square brackets. The `(N)` mark will appear here for nested statements (such as statements invoked within top-level statements).	
`Database`	Database name for the statement	Derived from `dbid`
`User`	Name of the user executing the statement	Derived from `userid`
`Mean execution time (ms)`	Mean time spent executing the statement, in milliseconds	`mean_exec_time`
`Min execution time (ms)`	Minimum time spent executing the statement, in milliseconds	`min_exec_time`
`Max execution time (ms)`	Maximum time spent executing the statement, in milliseconds	`max_exec_time`
`StdErr execution time`	Population standard deviation of time spent executing the statement, in milliseconds	`stddev_exec_time (ms)`
`Exec (s)`	Time spent executing this statement, in seconds	`total_exec_time`
`%Elapsed`	Execution time of this statement as the percentage of the statement elapsed time	
`%Total`	Execution time of this statement as the percentage of the total elapsed time of all statements in the cluster	
`JIT time (s)`	Total time spent by JIT executing this statement, in seconds	`jit_generation_time` + `jit_inlining_time` + `jit_optimization_time` + `jit_emission_time`
`Read I/O time (s)`	Time spent reading blocks, in seconds	`blk_read_time`
`Write I/O time (s)`	Time spent writing blocks, in seconds	`blk_write_time`
`Rows`	Number of rows retrieved or affected by the statement	`rows`
`Executions`	Number of times this statement was executed	`calls`
`%Cvr`	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table "Top SQL by executions" shows top statements by the value of the `calls` field of the `pgpro_stats_statements` or `pg_stat_statements` view. Table G.25 lists columns of this report table.

Table G.25. Top SQL by executions

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Executions	Number of executions of the statement plan	calls
%Total	Percentage of calls of this statement plan in the total calls of all statements in the cluster	
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Mean (ms)	Mean time spent executing the statement plan, in milliseconds	mean_exec_time
Min (ms)	Minimum time spent executing the statement plan, in milliseconds	min_exec_time
Max (ms)	Maximum time spent executing the statement plan, in milliseconds	max_exec_time
StdErr (ms)	Population standard deviation of time spent executing the statement plan, in milliseconds	stddev_time
Elapsed(s)	Total time spent executing the statement plan, in seconds	total_exec_time
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by I/O wait time” shows top statements by read and write time, i.e., sum of values of blk_read_time and blk_write_time fields of the pgpro_stats_statements or pg_stat_statements view. Table G.26 lists columns of this report table. Times are provided in seconds.

Table G.26. Top SQL by I/O wait time

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements	

Column	Description	Field/Calculation
	(such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
IO(s)	Total time spent in reading and writing while executing this statement plan, i.e., I/O time	blk_read_time + blk_write_time
R(s)	Total time spent in reading while executing this statement plan	blk_read_time
W(s)	Total time spent in writing while executing this statement plan	blk_write_time
%Total	Percentage of I/O time of this statement plan in the total I/O time of all statements in the cluster	
Shr Reads	Total number of shared blocks read while executing the statement plan	shared_blks_read
Loc Reads	Total number of local blocks read while executing the statement plan	local_blks_read
Tmp Reads	Total number of temp blocks read while executing the statement plan	temp_blks_read
Shr Writes	Total number of shared blocks written while executing the statement plan	shared_blks_written
Loc Writes	Total number of local blocks written while executing the statement plan	local_blks_written
Tmp Writes	Total number of temp blocks written while executing the statement plan	temp_blks_written
Elapsed(s)	Total time spent in execution of the statement plan	total_plan_time + total_exec_time
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by shared blocks fetched” shows top statements by the number of read and hit blocks, which helps to detect the most data-intensive statements. Table G.27 lists columns of this report table.

Table G.27. Top SQL by shared blocks fetched

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Blks fetched	Number of blocks retrieved while executing the statement plan	shared_blks_hit + shared_blks_read
%Total	Percentage of blocks fetched while executing the statement plan in all blocks fetched for all statements in the cluster	
Hits(%)	Percentage of blocks got from buffers in all blocks got	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	total_plan_time + total_exec_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by shared blocks read” shows top statements by the number of shared reads, which helps to detect the most read-intensive statements. Table G.28 lists columns of this report table.

Table G.28. Top SQL by shared blocks read

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid

Column	Description	Field/Calculation
User	Name of the user executing the statement	Derived from userid
Reads	Number of shared blocks read while executing this statement plan	shared_blks_read
%Total	Percentage of shared reads for this statement plan in all shared reads of all statements in the cluster	
Hits(%)	Percentage of blocks got from buffers in all blocks got while executing this statement plan	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	total_plan_time + total_exec_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by shared blocks dirtied” shows top statements by the number of shared dirtied buffers, which helps to detect statements that do most data changes in the cluster. Table G.29 lists columns of this report table.

Table G.29. Top SQL by shared blocks dirtied

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Dirtied	Number of shared buffers dirtied while executing this statement plan	shared_blks_dirtied
%Total	Percentage of dirtied shared buffers for this statement plan in all dirtied shared buffers of all statements in the cluster	

Column	Description	Field/Calculation
Hits(%)	Percentage of blocks got from buffers in all blocks got while executing this statement plan	
WAL	Total amount of WAL bytes generated by the statement plan	wal_bytes
%Total	Percentage of WAL bytes generated by the statement plan in total WAL generated in the cluster	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	total_plan_time + total_exec_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by shared blocks written” shows top statements by the number of blocks written. Table G.30 lists columns of this report table.

Table G.30. Top SQL by shared blocks written

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Written	Number of blocks written while executing this statement plan	shared_blks_written
%Total	Percentage of blocks written by this statement plan in all written blocks in the cluster	Percentage of shared_blks_written in (pg_stat_bgwriter.buffers_checkpoint + pg_stat_bgwriter.buffers_clean + pg_stat_bgwriter.buffers_backend)
%BackendW	Percentage of blocks written by this statement plan in all blocks in the cluster written by backends	Percentage of shared_blks_written in pg_stat_bgwriter.buffers_backend

Column	Description	Field/Calculation
Hits(%)	Percentage of blocks got from buffers in all blocks got while executing this statement plan	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	total_plan_time + total_exec_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by WAL size” shows top statements by the amount of WAL generated. Table G.31 lists columns of this report table.

Table G.31. Top SQL by WAL size

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
WAL	Total amount of WAL bytes generated by the statement plan	wal_bytes
%Total	Percentage of WAL bytes generated by the statement plan in total WAL generated in the cluster	
Dirtied	Number of shared buffers dirtied while executing this statement plan	shared_blks_dirtied
WAL FPI	Total number of WAL full page images generated by the statement plan	wal_fpi
WAL records	Total number of WAL records generated by the statement plan	wal_records
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by temp usage” shows top statements by temporary I/O, which is calculated as the sum of `temp_blks_read`, `temp_blks_written`, `local_blks_read` and `local_blks_written` fields. Table G.32 lists columns of this report table.

Table G.32. Top SQL by temp usage

Column	Description	Field/Calculation
`Query ID`	Hex representation of `queryid`. The hash of the query ID, database ID and user ID is in square brackets. The `(N)` mark will appear here for nested statements (such as statements invoked within top-level statements).	
`Plan ID`	Internal hash code, computed from the tree of the statement plan	`planid`
`Database`	Database name for the statement	Derived from `dbid`
`User`	Name of the user executing the statement	Derived from `userid`
`Local fetched`	Number of local blocks retrieved	`local_blks_hit` + `local_blks_read`
`Hits(%)`	Percentage of local blocks got from buffers in all local blocks got	
`Write Local (blk)`	Number of blocks written by this statement plan that are used in temporary tables	`local_blks_written`
`Write Local %Total`	Percentage of `local_blks_written` of this statement plan in the total of `local_blks_written` for all statements in the cluster	
`Read Local (blk)`	Number of blocks read by this statement plan that are used in temporary tables	`local_blks_read`
`Read Local %Total`	Percentage of `local_blks_read` of this statement plan in the total of `local_blks_read` for all statements in the cluster	
`Write Temp (blk)`	Number of temp blocks written by this statement plan	`temp_blks_written`
`Write Temp %Total`	Percentage of `temp_blks_written` of this statement plan in the total of `temp_blks_written` for all statements in the cluster	
`Read Temp (blk)`	Number of temp blocks read by this statement plan	`temp_blks_read`
`Read Temp %Total`	Percentage of `temp_blks_read` of this statement plan in the to-	

Column	Description	Field/Calculation
	tal of temp_blks_read for all statements in the cluster	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	total_plan_time + total_exec_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by invalidation messages sent” shows top statements by the number of invalidation messages sent. Table G.33 lists columns of this report table.

Table G.33. Top SQL by invalidation messages sent

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	queryid
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Invalidation messages sent	Total number of invalidation messages sent by backends executing this statement. Statistics are provided for corresponding message types of pgpro_stats_inval_msgs	fields of pgpro_stats_statements.inval_msgs

G.1.11.4.1. rusage statistics

This section is included in the report only if the pgpro_stats or pg_stat_kcache extension was available during the report interval.

The report table “Top SQL by system and user time” shows top statements by the sum of user_time and system_time fields of pg_stat_kcache or of the pgpro_stats_totals view. Table G.34 lists columns of this report table.

Table G.34. Top SQL by system and user time

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square	

Column	Description	Field/Calculation
	brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Plan User (s)	User CPU time elapsed during planning, in seconds	plan_user_time
Exec User (s)	User CPU time elapsed during execution, in seconds	exec_user_time
User %Total	Percentage of plan_user_time + exec_user_time in the total user CPU time for all statements	
Plan System (s)	System CPU time elapsed during planning, in seconds	plan_system_time
Exec System (s)	System CPU time elapsed during execution, in seconds	exec_system_time
System %Total	Percentage of plan_system_time + exec_system_time in the total system CPU time for all statements	

The report table “Top SQL by reads/writes done by filesystem layer” shows top statements by the sum of reads and writes fields of pg_stat_kcache. Table G.35 lists columns of this report table.

Table G.35. Top SQL by reads/writes done by filesystem layer

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Plan Read Bytes	Bytes read during planning	plan_reads
Exec Read Bytes	Bytes read during execution	exec_reads
Read Bytes %Total	Percentage of plan_reads + exec_reads in the total number of bytes read by the filesystem layer for all statements	

Column	Description	Field/Calculation
Plan Writes	Bytes written during planning	plan_writes
Exec Writes	Bytes written during execution	exec_writes
Write %Total	Percentage of plan_writes + exec_writes in the total number of bytes written by the filesystem layer for all statements	

G.1.11.5. SQL query wait statistics

If the pgpro_stats extension was available during the report interval, this section of the report will contain a table that is split into sections, each showing top statements by overall wait time or by wait time for a certain wait event type. Table sections related to specific wait events follow in the descending order of the total wait time in wait events of this type. Table G.36 lists columns of this report table. Times are provided in seconds.

Table G.36. SQL query wait statistics

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Hash of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Waited	Total wait time for all wait events of this statement plan	
%Total	Percentage of the total wait time of this statement plan in all the wait time in the cluster	
Details	Waits of this statement plan by wait types	

If the JIT-related statistics was avaliable in the statement statistics extension during the report interval, the report table “Top SQL by JIT elapsed time” shows top statements by the sum of jit_*_time fields of the pgpro_stats_statements or pg_stat_statements view. Table G.37 lists columns of this report table. Times are provided in seconds.

Table G.37. Top SQL by JIT elapsed time

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	

Column	Description	Field/Calculation
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
JIT Time (s)	Total time spent by JIT executing this statement plan	jit_generation_time + jit_inlining_time + jit_optimization_time + jit_emission_time
Generation count	Total number of functions JIT-compiled by this statement	Sum of jit_functions
Generation time	Total time spent by this statement on generating JIT code	Sum of jit_generation_time
Inlining count	Number of times functions have been inlined	Sum of jit_inlining_count
Inlining time	Total time spent by this statement on inlining functions	Sum of jit_inlining_time
Optimization count	Number of times this statement has been optimized	Sum of jit_optimization_count
Optimization time	Total time spent by this statement on optimizing	Sum of jit_optimization_time
Emission count	Number of times code has been emitted	Sum of jit_emission_count
Emission time	Total time spent by this statement on emitting code	Sum of jit_emission_time
Deform count	Number of tuple deform functions JIT-compiled by the statement	
Deform time	Total time spent by the statement on JIT-compiling the tuple deform	
Plan Time (s)	Total time spent in planning of the statement	total_plan_time
Exec Time (s)	Total time spent in execution of the statement plan	total_exec_time
Read I/O time (s)	Total time the statement spent reading blocks	blk_read_time
Write I/O time (s)	Total time the statement spent writing blocks	blk_write_time
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

G.1.11.6. Complete list of SQL texts

The “Complete list of SQL texts” section of the report contains a table that provides query and plan texts for all statements mentioned in the report. Use an appropriate Query ID/Plan ID link in any statistics table to see the corresponding query/plan text. Table G.38 lists columns of this report table.

Table G.38. Complete list of SQL texts

Column	Description
ID	Hex representation of the query or plan identifier
Query/Plan Text	Text of the query or statement plan

G.1.11.7. Schema object statistics

Tables in this section of the report show top database objects by statistics from the Postgres Pro's Statistics Collector views. Report tables that contain data for tables and indexes provide a preview of storage parameters. You can click on a row to see storage parameters of the object right under the row.

The report table “Top tables by estimated sequentially scanned volume” shows top tables by estimated volume read by sequential scans. This can help you find database tables that possibly lack some index. When there are no relation sizes collected with pg_relation_size(), relation-size estimates are based on the pg_class.relpages field. Since such values are less accurate, they are shown in square brackets. The data is based on the pg_stat_all_tables view. Table G.39 lists columns of this report table.

Table G.39. Top tables by estimated sequentially scanned volume

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
~SeqBytes	Estimated volume read by sequential scans	Sum of (pg_relation_size() * seq_scan)
SeqScan	Number of sequential scans performed on the table	seq_scan
IxScan	Number of index scans initiated on the table	idx_scan
IxFet	Number of live rows fetched by index scans	idx_tup_fetch
Ins	Number of rows inserted	n_tup_ins
Upd	Number of rows updated	n_tup_upd
Del	Number of rows deleted	n_tup_del
Upd(HOT)	Number of rows HOT updated	n_tup_hot_upd

In the report table “Top tables by blocks fetched”, blocks fetched include blocks being processed from disk (read) and from shared buffers (hit). This report table shows top database tables by the sum of blocks fetched for the table's heap, indexes, TOAST table (if any) and TOAST table index (if any). This can help you focus on tables with excessive processing of blocks. The data is based on the pg_statio_all_tables view. Table G.40 lists columns of this report table.

Table G.40. Top tables by blocks fetched

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	

Column	Description	Field/Calculation
Table	Table name	
Heap Blks	Number of blocks fetched for the table's heap	heap_blks_read + heap_blks_hit
Heap Blks %Total	Percentage of blocks fetched for the table's heap in all blocks fetched in the cluster	
Ix Blks	Number of blocks fetched for table's indexes	idx_blks_read + idx_blks_hit
Ix Blks %Total	Percentage of blocks fetched for table's indexes in all blocks fetched in the cluster	
TOAST Blks	Number of blocks fetched for the table's TOAST table	toast_blks_read + toast_blks_hit
TOAST Blks %Total	Percentage of blocks fetched for the table's TOAST table in all blocks fetched in the cluster	
TOAST-Ix Blks	Number of blocks fetched for the table's TOAST index	tidx_blks_read + tidx_blks_hit
TOAST-Ix Blks %Total	Percentage of blocks fetched for the table's TOAST index in all blocks fetched in the cluster	

The report table “Top tables by blocks read” shows top database tables by the number of blocks read for the table's heap, indexes, TOAST table (if any) and TOAST table index (if any). This can help you focus on tables with excessive block readings. The data is based on the pg_statio_all_tables view. Table G.41 lists columns of this report table.

Table G.41. Top tables by blocks read

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Heap Blks	Number of blocks read for the table's heap	heap_blks_read
Heap Blks %Total	Percentage of blocks read from the table's heap in all blocks read in the cluster	
Ix Blks	Number of blocks read from table's indexes	idx_blks_read
Ix Blks %Total	Percentage of blocks read from table's indexes in all blocks read in the cluster	
TOAST Blks	Number of blocks read from the table's TOAST table	toast_blks_read
TOAST Blks %Total	Percentage of blocks read from the table's TOAST table in all blocks read in the cluster	

Column	Description	Field/Calculation
TOAST-Ix Blks	Number of blocks read from the table's TOAST index	tidx_blks_read
TOAST-Ix Blks %Total	Percentage of blocks read from the table's TOAST index in all blocks read in the cluster	
Hit(%)	Percentage of table, index, TOAST and TOAST index blocks got from buffers for this table in all blocks got for this table from either file system or buffers	

The report table “Top DML tables” shows top tables by the number of DML-affected rows, i.e., by the sum of n_tup_ins, n_tup_upd and n_tup_del (including TOAST tables). The data is based on the pg_stat_all_tables view. Table G.42 lists columns of this report table.

Table G.42. Top DML tables

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Ins	Number of rows inserted	n_tup_ins
Upd	Number of rows updated, including HOT	n_tup_upd
Del	Number of rows deleted	n_tup_del
Upd(HOT)	Number of rows HOT updated	n_tup_hot_upd
SeqScan	Number of sequential scans performed on the table	seq_scan
SeqFet	Number of live rows fetched by sequential scans	seq_tup_read
IxScan	Number of index scans initiated on this table	idx_scan
IxFet	Number of live rows fetched by index scans	idx_tup_fetch

The report table “Top tables by updated/deleted tuples” shows top tables by tuples modified by UPDATE/DELETE operations, i.e., by the sum of n_tup_upd and n_tup_del (including TOAST tables). The data is based on the pg_stat_all_tables view. Table G.43 lists columns of this report table.

Table G.43. Top tables by updated/deleted tuples

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Upd	Number of rows updated, including HOT	n_tup_upd

Column	Description	Field/Calculation
Upd(HOT)	Number of rows HOT updated	n_tup_hot_upd
Del	Number of rows deleted	n_tup_del
Vacuum	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
AutoVacuum	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count
Analyze	Number of times this table was manually analyzed	analyze_count
AutoAnalyze	Number of times this table was analyzed by the autovacuum daemon	autoanalyze_count

The report table “Top tables by removed all-visible marks” shows top tables by the number of times that the all-visible mark was removed from the visibility map by any backend. This report section is only shown when corresponding statistics are available. Table G.44 lists columns of this report table.

Table G.44. Top tables by removed all-visible marks

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
All-Visible marks cleared	Number of times that the all-visible mark was removed from the relation visibility map	rev_all_visible_pages
All-Visible marks set	Number of times that the all-visible mark was set in the relation visibility map	pages_all_visible
All-Visible marks %Set	Percentage of the number of times that the all-visible mark was set in the number of times that it was set or removed	pages_all_visible * 100% / (rev_all_visible_pages + pages_all_visible)
Vacuum	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
AutoVacuum	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count

The report table “Top tables by removed all-frozen marks” shows top tables by the number of times that the all-frozen mark was removed from the visibility map by any backend. This report section is only shown when corresponding statistics are available. Table G.45 lists columns of this report table.

Table G.45. Top tables by removed all-frozen marks

Column	Description	Field/Calculation
DB	Database name for the table	

Column	Description	Field/Calculation
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
All-Frozen marks cleared	Number of times that the all-frozen mark was removed from the relation visibility map	rev_all_frozen_pages
All-Frozen marks set	Number of times that the all-frozen mark was set in the relation visibility map	pages_frozen
All-Frozen marks %Set	Percentage of the number of times that the all-frozen mark was set in the number of times that it was set or removed	pages_frozen * 100% / (rev_all_frozen_pages + pages_frozen)
Vacuum	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
AutoVacuum	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count

The report table “Top tables by new-page updated tuples” shows top tables by the number of rows updated where the successor version goes onto a *new* heap page, leaving behind an original version with a t_ctid field that points to a different heap page. These are always non-HOT updates. Table G.46 lists columns of this report table.

Table G.46. Top tables by new-page updated tuples

Column	Description
DB	Database name for the table
Tablespace	Name of the tablespace where the table is located
Schema	Schema name for the table
Table	Table name
NP Upd	Number of rows updated to a new heap page
%Upd	Number of new-page updated rows as the percentage of all rows updated
Upd	Number of rows updated, including HOT
Upd(HOT)	Number of rows HOT updated (i.e., with no separate index update required)

The report table “Top growing tables” shows top tables by growth. The data is based on the pg_stat_all_tables view. When there are no relation sizes collected with pg_relation_size(), relation-size estimates are based on the pg_class.relpages field. Since such values are less accurate, they are shown in square brackets. Table G.47 lists columns of this report table.

Table G.47. Top growing tables

Column	Description	Field/Calculation
DB	Database name for the table	

Column	Description	Field/Calculation
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Size	Table size at the time of the last sample in the report interval	pg_table_size() - pg_relation_size(toast)
Growth	Table growth	
Ins	Number of rows inserted	n_tup_ins
Upd	Number of rows updated, including HOT	n_tup_upd
Del	Number of rows deleted	n_tup_del
Upd(HOT)	Number of rows HOT updated	n_tup_hot_upd

In the report table "Top indexes by blocks fetched", blocks fetched include index blocks processed from disk (read) and from shared buffers (hit). The data is based on the pg_statio_all_indexes view. Table G.48 lists columns of this report table.

Table G.48. Top indexes by blocks fetched

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	
Scans	Number of index scans initiated on this index	idx_scan
Blks	Number of blocks fetched for this index	idx_blks_read + idx_blks_hit
%Total	Percentage of blocks fetched for this index in all blocks fetched in the cluster	

The report table "Top indexes by blocks read" is also based on the pg_statio_all_indexes and pg_stat_all_indexes views. Table G.49 lists columns of this report table.

Table G.49. Top indexes by blocks read

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	

Column	Description	Field/Calculation
Scans	Number of index scans initiated on this index	idx_scan
Blk Reads	Number of disk blocks read from this index	idx_blks_read
%Total	Percentage of disk blocks read from this index in all disk blocks read in the cluster	
Hits(%)	Percentage of index blocks got from buffers in all index blocks got for this index	

The report table “Top growing indexes” shows top indexes by growth. The table uses data from the pg_stat_all_tables and pg_stat_all_indexes views. When there are no relation sizes collected with pg_relation_size(), relation-size estimates are based on the pg_class.relpages field. Since such values are less accurate, they are shown in square brackets. Table G.50 lists columns of this report table.

Table G.50. Top growing indexes

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	
Index Size	Index size at the time of the last sample in the report interval	pg_relation_size()
Index Growth	Index growth during the report interval	
Table Ins	Number of rows inserted into the underlying table	n_tup_ins
Table Upd	Number of rows updated in the underlying table, without HOT	n_tup_upd - n_tup_hot_upd
Table Del	Number of rows deleted from the underlying table	n_tup_del

The report table “Unused indexes” shows top non-scanned indexes (during the report interval) by DML operations on underlying tables that caused index support. Constraint indexes are not counted. The table uses data from the pg_stat_all_tables view. Table G.51 lists columns of this report table.

Table G.51. Unused indexes

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	

Column	Description	Field/Calculation
Table	Underlying table name	
Index	Index name	
Index Size	Index size at the time of the last sample in the report interval	pg_relation_size()
Index Growth	Index growth during the report interval	
Table Ins	Number of rows inserted into the underlying table	n_tup_ins
Table Upd	Number of rows updated in the underlying table, without HOT	n_tup_upd - n_tup_hot_upd
Table Del	Number of rows deleted from the underlying table	n_tup_del

G.1.11.8. User function statistics

Tables in this section of the report show top functions in the cluster by statistics from the pg_stat_user_functions view. Times in the tables are provided in seconds.

The report table “Top functions by total time” shows top functions by the total time elapsed. The report table “Top functions by executions” shows top functions by the number of executions. The report table “Top trigger functions by total time” shows top trigger functions by the total time elapsed. Table G.52 lists columns of these report tables.

Table G.52. User function statistics

Column	Description	Field/Calculation
DB	Database name for the function	
Schema	Schema name for the function	
Function	Function name	
Executions	Number of times this function has been called	calls
Total Time (s)	Total time spent in this function and all other functions called by it	total_time
Self Time (s)	Total time spent in this function itself, not including other functions called by it	self_time
Mean Time (s)	Mean time of a single function execution	total_time /calls
Mean self Time (s)	Mean self time of a single function execution	self_time /calls

G.1.11.9. Vacuum-related statistics

The report table “Top tables by vacuum time spent” is available if pgpro_stats can provide extended vacuum statistics. This table shows top tables by total time spent vacuuming them. The data is based on the pgpro_stats_vacuum_tables view. Table G.53 lists columns of this report table.

Table G.53. Top tables by vacuum time spent

Column	Description	Field/Calculation
DB	Database name for the table	

Column	Description	Field/Calculation
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Total vacuum time	Total time of vacuuming this table	total_time
Delay vacuum time	Time spent sleeping in a vacuum delay point by vacuum operations performed on this table	delay_time
Read I/O time	Time spent reading database blocks by vacuum operations performed on this table	blk_read_time
Write I/O time	Time spent writing database blocks by vacuum operations performed on this table	blk_write_time
User CPU time	User CPU time of vacuuming tables of this database	user_time
System CPU time	System CPU time of vacuuming tables of this database	system_time
Vacuum count	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
Autovacuum count	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count
Total fetched	Total number of database blocks fetched by vacuum operations performed on this table	total_blks_read + total_blks_hit
Heap fetched	Total number of blocks fetched from this table by vacuum operations performed on it	rel_blks_read + rel_blks_hit
Scanned	Number of pages examined by vacuum operations performed on this table	pages_scanned

The report table “Top indexes by vacuum time spent” is available if pgpro_stats can provide extended vacuum statistics. This table shows top indexes by total time spent vacuuming them. The data is based on the pgpro_stats_vacuum_indexes view. Table G.54 lists columns of this report table.

Table G.54. Top indexes by vacuum time spent

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Index	Index name	
Total vacuum time	Total time of vacuuming this index	total_time

Column	Description	Field/Calculation
Delay vacuum time	Time spent sleeping in a vacuum delay point by vacuum operations performed on this index	delay_time
Read I/O time	Time spent reading database blocks by vacuum operations performed on this index	blk_read_time
Write I/O time	Time spent writing database blocks by vacuum operations performed on this index	blk_write_time
User CPU time	User CPU time of vacuuming this index	user_time
System CPU time	System CPU time of vacuuming this index	system_time
Vacuum count	Number of times the underlying table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
Autovacuum count	Number of times the underlying table has been vacuumed by the autovacuum daemon	autovacuum_count
Total fetched	Total number of database blocks fetched by vacuum operations performed on the underlying table	total_blks_read + total_blks_hit
Index fetched	Total number of blocks fetched from this index by vacuum operations performed on it	rel_blks_read + rel_blks_hit

The report table “Top tables by blocks vacuum fetched” is available if pgpro_stats can provide extended vacuum statistics. This table shows top tables by blocks fetched vacuuming these tables. The data is based on the pgpro_stats_vacuum_tables view. Table G.55 lists columns of this report table.

Table G.55. Top tables by blocks vacuum fetched

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
DB fetched	Total number of database blocks fetched by vacuum operations performed on this table	total_blks_read + total_blks_hit
%Total	Total number of database blocks fetched by vacuum operations performed on this table as the percentage of all blocks fetched in the cluster	
DB read	Total number of database blocks read by vacuum operations performed on this table	total_blks_read

Column	Description	Field/Calculation
%Total	Total number of database blocks read by vacuum operations performed on this table as the percentage of all blocks read in the cluster	
Heap fetched	Total number of blocks fetched from this table by vacuum operations performed on it	rel_blks_read + rel_blks_hit
%Rel	Total number of table blocks fetched by vacuum operations performed on this table as the percentage of all blocks fetched from this table	
Heap read	Total number of blocks read from this table by vacuum operations performed on it	rel_blks_read
%Rel	Total number of table blocks read by vacuum operations performed on this table as the percentage of all blocks read from this table	
Scanned	Number of pages examined by vacuum operations performed on this table	pages_scanned

The report table “Top indexes by blocks vacuum fetched” is available if pgpro_stats can provide extended vacuum statistics. This table shows top indexes by blocks fetched vacuuming underlying tables. The data is based on the pgpro_stats_vacuum_indexes view. Table G.56 lists columns of this report table.

Table G.56. Top indexes by blocks vacuum fetched

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Index	Index name	
DB fetched	Total number of database blocks fetched by vacuum operations performed on this index	total_blks_read + total_blks_hit
%Total	Total number of database blocks fetched by vacuum operations performed on this index as the percentage of all blocks fetched in the cluster	
DB read	Total number of database blocks read by vacuum operations performed on this index	total_blks_read
%Total	Total number of database blocks read by vacuum operations per-	

Column	Description	Field/Calculation
	formed on this index as the percentage of all blocks read in the cluster	
Idx fetched	Total number of blocks fetched from this index by vacuum operations on it	rel_blks_read + rel_blks_hit
%Idx	Total number of index blocks fetched by vacuum operations performed on this index as the percentage of all blocks fetched from this index	
Idx read	Total number of blocks read from this index by vacuum operations performed on it	rel_blks_read
%Idx	Total number of index blocks read by vacuum operations performed on this index as the percentage of all blocks read from this index	

The report table “Top tables by blocks vacuum read” is available if pgpro_stats can provide extended vacuum statistics. This table shows top tables by blocks read vacuuming these tables. The data is based on the pgpro_stats_vacuum_indexes view. Table G.57 lists columns of this report table.

Table G.57. Top tables by blocks vacuum read

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
DB read	Total number of database blocks read by vacuum operations performed on this table	total_blks_read
%Total	Total number of database blocks read by vacuum operations performed on this table as the percentage of all blocks read in the cluster	
%Hit	Total number of database blocks found in shared buffers by vacuum operations performed on this table as the percentage of all blocks fetched by vacuum operations performed on this table	
Heap read	Total number of database blocks vacuum operations read from this table	rel_blks_read
%Rel	Total number of table blocks read by vacuum operations performed on this table as the per-	

Column	Description	Field/Calculation
	centage of all blocks read from this table	
%Hit	Total number of table blocks found in shared buffers by vacuum operations performed on this table as the percentage of table blocks fetched by vacuum operations performed on this table	
Scanned	Number of pages examined by vacuum operations performed on this table	pages_scanned

The report table “Top indexes by blocks vacuum read” is available if pgpro_stats can provide extended vacuum statistics. This table shows top indexes by blocks read vacuuming underlying tables. The data is based on the pgpro_stats_vacuum_indexes view. Table G.58 lists columns of this report table.

Table G.58. Top indexes by blocks vacuum read

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Index	Index name	
DB read	Total number of database blocks read by vacuum operations performed on this index	total_blks_read
%Total	Total number of database blocks read by vacuum operations performed on this index as the percentage of all blocks read in the cluster	
%Hit	Total number of database blocks found in shared buffers by vacuum operations performed on this index as the percentage of all database blocks fetched by vacuum operations performed on this index	
Idx read	Total number of blocks read from this index by vacuum operations performed on it	rel_blks_read
%Idx	Total number of index blocks read by vacuum operations performed on this index as the percentage of all blocks read from this index	
%Hit	Total number of index blocks found in shared buffers by vacuum operations performed on this index as the percentage of index	

Column	Description	Field/Calculation
	blocks fetched by vacuum operations performed on this index	

The report table “Top tables by dead tuples vacuum left” is available if pgpro_stats can provide extended vacuum statistics. This table shows top tables by the number of dead tuples left by vacuum due to their visibility in transactions. The data is based on the `pgpro_stats_vacuum_tables` view. Table G.59 lists columns of this report table.

Table G.59. Top tables by dead tuples vacuum left

Column	Description	Field/Calculation
`DB`	Database name for the table	
`Tablespace`	Name of the tablespace where the table is located	
`Schema`	Schema name for the table	
`Table`	Table name	
`Dead tuples left`	Total number of dead tuples vacuum operations left in this table due to their visibility in transactions	`dead_tuples`
`Dead tuples deleted`	Total number of dead tuples vacuum operations deleted from this table	`tuples_deleted`
`%Eff`	Vacuum efficiency in terms of deleted tuples. This is the percentage of dead tuples deleted from this table in all dead tuples to be deleted from this table.	`tuples_deleted` * 100 / (`tuples_deleted` + `dead_tuples`)
`Tuples del`	Number of rows deleted	`pg_stat_all_tables .n_tup_del`
`Tuples upd`	Number of rows updated (includes HOT updated rows)	`pg_stat_all_tables .n_tup_upd`
`Vacuum`	Number of times this table has been manually vacuumed (not counting `VACUUM FULL`)	`vacuum_count`
`Autovacuum`	Number of times this table has been vacuumed by the autovacuum daemon	`autovacuum_count`

The report table “Top tables by WAL size generated by vacuum” is available if pgpro_stats can provide extended vacuum statistics. This table shows top tables by the amount of WAL generated by vacuum operations performed on them. The data is based on the `pgpro_stats_vacuum_tables` view. Table G.60 lists columns of this report table.

Table G.60. Top tables by WAL size generated by vacuum

Column	Description	Field/Calculation
`DB`	Database name for the table	
`Tablespace`	Name of the tablespace where the table is located	
`Schema`	Schema name for the table	
`Table`	Table name	

Column	Description	Field/Calculation
WAL size	Total amount of WAL bytes generated by vacuum operations performed on this table	wal_bytes
%Total	Total amount of WAL bytes generated by vacuum operations performed on this table as the percentage of all WAL generated in the cluster	
WAL FPI	Total number of WAL full page images generated by vacuum operations performed on this table	wal_fpi
Scanned blocks	Number of pages examined by vacuum operations performed on this table	pages_scanned
Dirtied blocks	Number of database blocks dirtied by vacuum operations performed on this table	total_blks_dirtied
Removed blocks	Number of pages removed by vacuum operations performed on this table	pages_removed
Vacuum	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
Autovacuum	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count

The report table “Top tables by vacuum operations” shows top tables by the number of vacuum operations performed (vacuum_count + autovacuum_count). The data is based on the pg_stat_all_tables view. Table G.61 lists columns of this report table.

Table G.61. Top tables by vacuum operations

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Vacuum count	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
Autovacuum count	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count
Ins	Number of rows inserted	n_tup_ins
Upd	Number of rows updated (includes HOT updated rows)	n_tup_upd
Del	Number of rows deleted	n_tup_del
Upd(HOT)	Number of rows HOT updated	n_tup_hot_upd

The report table “Top tables by analyze operations” shows top tables by the number of analyze operations performed (analyze_count + autoanalyze_count). The data is based on the pg_stat_all_tables view. Table G.62 lists columns of this report table.

Table G.62. Top tables by analyze operations

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Analyze count	Number of times this table has been manually analyzed	analyze_count
Autoanalyze count	Number of times this table has been analyzed by the autovacuum daemon	autoanalyze_count
Ins	Number of rows inserted	n_tup_ins
Upd	Number of rows updated, including HOT	n_tup_upd
Del	Number of rows deleted	n_tup_del
Upd(HOT)	Number of rows HOT updated	n_tup_hot_upd

The report table “Top indexes by estimated vacuum load” shows top indexes by estimated implicit vacuum load. This load is calculated as the number of vacuum operations performed on the underlying table multiplied by the index size. The data is based on the pg_stat_all_indexes view. When there are no relation sizes collected with pg_relation_size(), relation-size estimates are based on the pg_class.relpages field. Since such values are less accurate, they are shown in square brackets. Table G.63 lists columns of this report table.

Table G.63. Top indexes by estimated vacuum load

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	
~Vacuum bytes	Vacuum load estimation	(vacuum_count + autovacuum_count) * index_size
Vacuum count	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
Autovacuum count	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count
IX size	Average index size during the report interval	
Relsize	Average relation size during the report interval	

The report table “Top tables by dead tuples ratio” shows top tables larger than 5 MB by the ratio of dead tuples. Statistics are valid for the last sample in the report interval. The data is based on the pg_stat_all_tables view. When there are no relation sizes collected with pg_relation_size(), relation-size estimates are based on the pg_class.relpages field. Since such values are less accurate, they are shown in square brackets. Table G.64 lists columns of this report table.

Table G.64. Top tables by dead tuples ratio

Column	Description	Field/Calculation
DB	Database name for the table	
Schema	Schema name for the table	
Table	Table name	
Live	Estimated number of live rows	n_live_tup
Dead	Estimated number of dead rows	n_dead_tup
%Dead	Percentage of dead rows in all table rows	
Last AV	Last time at which this table was vacuumed by the autovacuum daemon	last_autovacuum
Size	Table size	pg_table_size() - pg_relation_size(toast)

The report table “Top tables by modified tuples ratio” shows top tables larger than 5 MB by the ratio of modified tuples. Statistics are valid for the last sample in the report interval. The data is based on the pg_stat_all_tables view. When there are no relation sizes collected with pg_relation_size(), relation-size estimates are based on the pg_class.relpages field. Since such values are less accurate, they are shown in square brackets. Table G.65 lists columns of this report table.

Table G.65. Top tables by modified tuples ratio

Column	Description	Field/Calculation
DB	Database name for the table	
Schema	Schema name for the table	
Table	Table name	
Live	Estimated number of live rows	n_live_tup
Dead	Estimated number of dead rows	n_dead_tup
Mod	Estimated number of rows modified since this table was last analyzed	n_mod_since_analyze
%Mod	Percentage of modified rows in all table rows	
Last AA	Last time at which this table was analyzed by the autovacuum daemon	last_autoanalyze
Size	Table size	pg_table_size() - pg_relation_size(toast)

G.1.11.10. Cluster settings during the report interval

This section of the report contains a table with Postgres Pro GUC parameters, values of functions version(), pg_postmaster_start_time(), pg_conf_load_time() and the system_identifier field of the pg_control_system() function during the report interval. The data in the table is grouped under Defined settings and Default settings. Table G.66 lists columns of this report table.

Table G.66. Cluster settings during the report interval

Column	Description
Setting	Name of the parameter
reset_val	reset_val field of the pg_settings view. Settings changed during the report interval are shown in bold font.
Unit	Unit of the setting
Source	Configuration file where this setting is defined, semicolon, line number
Notes	Timestamp of the sample where this value was first observed

G.1.11.11. Extension versions during the report interval

This section of the report contains a table that lists installed extension versions found in databases during the report interval. First seen and Last seen columns are not shown if the extension versions have not changed during the report interval. Table G.67 lists columns of this report table.

Table G.67. Extension versions during the report interval

Column	Description
Name	Extension name
DB	Database name
First seen	Timestamp of the sample where this extension version appeared first
Last seen	Timestamp of the sample where this extension version appeared last
Version	Version name of the extension

G.1.12. pgpro_pwr Diagnostic Tools

pgpro_pwr provides self-diagnostic tools.

G.1.12.1. Collecting Detailed Timing Statistics for Sampling Procedures

pgpro_pwr collects detailed timing statistics of taking samples when the *pgpro_pwr.track_sample_timings* parameter is on. You can get the results from the v_sample_timings view. Table G.68 lists columns of this view.

Table G.68. v_sample_timings View

Column	Description
server_name	Name of the server
sample_id	Sample identifier
sample_time	Time when the sample was taken
sampling_event	Sampling stage. See Table G.69 for descriptions of sampling stages.
time_spent	Time spent in the event

Table G.69. sampling_event Description

Event	Description
total	Taking the sample (all stages)
connect	Making dblink connection to the server

Event	Description
`get server environment`	Getting server GUC parameters, available extensions, etc.
`collect database stats`	Querying the `pg_stat_database` view for statistics on databases
`calculate database stats`	Calculating differential statistics on databases since the previous sample
`collect tablespace stats`	Querying the `pg_tablespace` view for statistics on tablespaces
`collect statement stats`	Collecting statistics on statements using the pg_pro_stats and pg_stat_kcache extensions
`query pg_stat_bgwriter`	Collecting cluster statistics using the `pg_stat_bgwriter` view
`query pg_stat_archiver`	Collecting cluster statistics using the `pg_stat_archiver` view
`collect object stats`	Collecting statistics on database objects. Includes events from Table G.70.
`maintain repository`	Executing support routines
`calculate tablespace stats`	Calculating differential statistics on tablespaces
`calculate object stats`	Calculating differential statistics on database objects. Includes events from Table G.71.
`calculate cluster stats`	Calculating cluster differential statistics
`calculate archiver stats`	Calculating archiver differential statistics
`delete obsolete samples`	Deleting obsolete baselines and samples

Table G.70. Events of Collecting Statistics on Database Objects

Event	Description
`db:`*`dbname`* `collect tables stats`	Collecting statistics on tables for the *`dbname`* database
`db:`*`dbname`* `collect indexes stats`	Collecting statistics on indexes for the *`dbname`* database
`db:`*`dbname`* `collect functions stats`	Collecting statistics on functions for the *`dbname`* database

Table G.71. Events of Calculating Differences of Statistics on Database Objects

Event	Description
`calculate tables stats`	Calculating differential statistics on tables of all databases
`calculate indexes stats`	Calculating differential statistics on indexes of all databases
`calculate functions stats`	Calculating differential statistics on functions of all databases

G.1.13. Important Notes

When using the pgpro_pwr extension, be aware of the following:

- Postgres Pro collects execution statistics *after* the execution is complete. If a single execution of a statement lasts for several samples, it will only affect statistics of the last sample (in which the ex-

ecution completed). Besides, statistics on statements that are still running are unavailable. Maintenance processes, such as vacuum and checkpointer, will update the statistics only on completion.

- Resetting any Postgres Pro statistics may affect the accuracy of the next sample.
- Exclusive locks on relations conflict with calculation of the relation size. If the `take_sample()` function is unable to acquire a lock for a short period of time (3 seconds), it will fail and no sample will be generated.

G.2. pgpro_stats

The `pgpro_stats` extension provides a means for tracking planning and execution statistics of all SQL statements executed by a server. It is based on the pg_stat_statements module and provides the following additional functionality:

- Storing query plans in addition to query statements.
- Configuring sample rate for statistics collection to reduce overhead.
- Calculating wait event statistics for executed queries.
- Calculating resource usage statistics of statement planning and execution.
- Calculating cache invalidation statistics.
- Calculating additional archiver statistics.
- Providing an interface to statistics about vacuuming databases, tables, and indexes collected by the core system.
- Tracing of application sessions.
- Creating views that emulate other extensions.

> **Note**
>
> When the server gets shut down, pgpro_stats saves the collected statistics to two dump files on disk in the format that depends on the number and order of columns in the `pgpro_stats_statements` and `pgpro_stats_totals` views. If this format has changed in a new pgpro_stats version, during the first server restart after upgrading the extension, the saved statistics will fail to be read with an error reported to the log:
>
> ```
> LOG:  pgpro_stats: could not load statements data file of obsolete format
>  "pg_stat/pgpro_stats.stat"
> ```
>
> or
>
> ```
> LOG:  pgpro_stats: could not load statements data file of obsolete format
>  "pg_stat/pgpro_stats_totals.stat"
> ```
>
> The contents of the files will be ignored, and respective statistics will be nullified. To learn whether the format has changed, see the Release Notes for pgpro_stats version being installed. To retain the previously collected statistics, download them as CSV files before upgrading.

The background information, along with views and types, related to calculating cache invalidation statistics is provided in a separate section Section G.2.9.

G.2.1. Limitations

- `pgpro_stats` can sometimes fail to match identical parameters in the query statement and the corresponding query plan.
- Some SPI queries are not included into statistics.
- Texts and plans of some SPI queries are not normalized.
- `pgpro_stats` is incompatible with pg_stat_statements, as well as other extensions that use parser, planner, or executor hooks to modify parse and plan trees and execution of the queries. Moreover, if both `pgpro_stats` and pg_stat_statements are on the list of `shared_preload_libraries`, the database server will not start. Note also that in order to dump the final versions of the queries

and plans, pgpro_stats should be the last on the list of shared_preload_libraries, but some existing extensions, such as pg_pathman, will not work at all unless they are the last on this list.

- pgpro_stats may not work correctly with third-party extensions that produce CustomScan and ForeignScan nodes.

G.2.2. Installation and Setup

pgpro_stats is provided with Postgres Pro Standard as a separate pre-built package pgpro-stats-std-14 (for the detailed installation instructions, see Chapter 16). Once you have pgpro_stats installed, complete the following steps to enable pgpro_stats:

1. Add pgpro_stats to the shared_preload_libraries parameter in the postgresql.conf file:

   ```
   shared_preload_libraries = 'pgpro_stats'
   ```

2. Restart the Postgres Pro Standard instance for the changes to take effect.

   Once the server is reloaded, pgpro_stats starts tracking statistics across all databases of the cluster. If required, you can change the scope of statistics collection or disable it altogether using pgpro_stats configuration parameters.

3. To access the collected statistics, you have to create pgpro_stats extension:

   ```
   CREATE EXTENSION pgpro_stats;
   ```

In addition, query identifier calculation must be enabled in order for pgpro_stats to be active, which is done automatically if compute_query_id is set to auto or on, or any third-party module that calculates query identifiers is loaded.

G.2.3. Usage

- Collecting Statistics on Query Statements and Plans
- Monitoring Custom Metrics

G.2.3.1. Collecting Statistics on Query Statements and Plans

Once installed, the pgpro_stats extension starts collecting statistics on the executed statements. The collected data is similar to the one provided by pg_stat_statements, but also includes information on query plans and wait events for each query type. The statistics is saved into an in-memory ring buffer and is accessible through the pgpro_stats_statements view.

By default, pgpro_stats collects statistics on all the executed statements that satisfy the pgpro_stats.track and pgpro_stats.track_utility settings. If performance is a concern, you can set a sample rate for queries using the pgpro_stats.query_sample_rate parameter, and pgpro_stats will randomly select queries for statistics calculation at the specified rate.

To collect statistics on wait events, pgpro_stats uses time-based sampling. Wait events are sampled at the time interval specified by the pgpro_stats.profile_period parameter, which is set to 10ms by default. If the sampling shows that the process is waiting, the pgpro_stats.profile_period value is added to the wait event duration. Thus, time estimation for each wait event remains valid even if the pgpro_stats.profile_period parameter value has changed. If you are not interested in wait event statistics, you can disable wait event sampling by setting the pgpro_stats.enable_profile parameter to false.

pgpro_stats_statements.plans and pgpro_stats_statements.calls aren't always expected to match because planning and execution statistics are updated at their respective end phase, and only for successful operations. For example, if a statement is successfully planned but fails during the execution phase, only its planning statistics will be updated. If planning is skipped because a cached plan is used, only its execution statistics will be updated.

As an example, let's create a table with some random data and build an index on this table:

```
CREATE TABLE test AS (SELECT i, random() x FROM generate_series(1,1000000) i);
CREATE INDEX test_x_idx ON test (x);
```

Now run the following query several times using different values for *:x_min* and *:x_max*:

```
select * from test where x >= :x_min and x <= :x_max;
```

The collected statistics should appear in the pgpro_stats_statements view:

```
SELECT queryid, query, planid, plan, wait_stats FROM pgpro_stats_statements WHERE query
 LIKE 'select * from test where%';
-[ RECORD
 1 ]----------------------------------------------------------------------------------------
queryid    | 1109491335754870054
query      | select * from test where x >= $1 and x <= $2
planid     | 8287793242828473388
plan       | Gather
           |   Output: i, x
           |   Workers Planned: 2
           |   ->  Parallel Seq Scan on public.test
           |         Output: i, x
           |         Filter: ((test.x >= $3) AND (test.x <= $4))
           |
wait_stats | {"IO": {"DataFileRead": 10}, "IPC": {"BgWorkerShutdown": 10}, "Total":
 {"IO": 10, "IPC": 10, "Total": 20}}
-[ RECORD
 2 ]----------------------------------------------------------------------------------------
queryid    | 1109491335754870054
query      | select * from test where x >= $1 and x <= $2
planid     | -9045072158333552619
plan       | Bitmap Heap Scan on public.test
           |   Output: i, x
           |   Recheck Cond: ((test.x >= $3) AND (test.x <= $4))
           |   ->  Bitmap Index Scan on test_x_idx
           |         Index Cond: ((test.x >= $5) AND (test.x <= $6))
           |
wait_stats | {"IO": {"DataFileRead": 40}, "Total": {"IO": 40, "Total": 40}}
-[ RECORD
 3 ]----------------------------------------------------------------------------------------
queryid    | 1109491335754870054
query      | select * from test where x >= $1 and x <= $2
planid     | -1062789671372193287
plan       | Seq Scan on public.test
           |   Output: i, x
           |   Filter: ((test.x >= $3) AND (test.x <= $4))
           |

           |   Output: i, x
           |   Index Cond: ((test.x >= $3) AND (test.x <= $4))
           |
wait_stats | NULL
```

G.2.3.2. Monitoring Custom Metrics

With pgpro_stats, you can define custom metrics to be monitored. The collected data will be saved into an in-memory ring buffer and then sent to a monitoring system. Unlike direct polling of a database by a

monitoring system that can lose some data if the connection is interrupted, this approach allows to get all the collected data regardless of connection issues, as long as this data is still available in the ring buffer.

To set up a custom metric to collect, do the following:

1. For each metric, define all configuration parameters listed in Section G.2.7.2. You must specify a unique numeric identifier of each metric in the parameter names.

   For example, to monitor index bloating each 60 seconds, you can define a new metric by setting metrics-related parameters as follows:

   ```
   pgpro_stats.metric_1_name = index_bloat
   pgpro_stats.metric_1_query = 'select iname, ibloat, ipages from bloat'
   pgpro_stats.metric_1_db = 'postgres'
   pgpro_stats.metric_1_user = postgres
   pgpro_stats.metric_1_period = '60s'
   ```

2. Restart the server.

   `pgpro_stats` starts collecting statistics on executed statements and saves it into the ring buffer, and the collected data appears in the `pgpro_stats_metrics` view:

   ```
   SELECT * FROM pgpro_stats_metrics;
   ```

   Once the new metric is added, its parameters can be changed without a server restart by simply reloading the `postgresql.conf` configuration file.

3. If required, set up data export to a monitoring system of your choice.

G.2.4. Views

G.2.4.1. The `pgpro_stats_statements` View

The statistics gathered by the module are made available via a view named `pgpro_stats_statements`. This view contains one row for each distinct database ID, user ID and query ID (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in Table G.72.

Table G.72. `pgpro_stats_statements` Columns

Name	Type	References	Description
`userid`	`oid`	`pg_authid .oid`	OID of user who executed the statement
`dbid`	`oid`	`pg_database .oid`	OID of database in which the statement was executed
`toplevel`	`bool`		True if the query was executed as a top-level statement (always true if pgpro_stats.track is set to `top`)
`queryid`	`bigint`		Internal hash code, computed from the statement's parse tree
`planid`	`bigint`		Internal hash code, computed from the statement's plan tree
`query`	`text`		Text of a representative statement
`plan`	`text`		The text of the query plan, in the format de-

Name	Type	References	Description
			fined by the pgpro_stats.plan_format configuration parameter
plans	int8		Number of times the statement was planned (if pgpro_stats.track_planning is enabled, otherwise zero)
total_plan_time	float8		Total time spent planning the statement, in milliseconds (if pgpro_stats.track_planning is enabled, otherwise zero).
min_plan_time	float8		Minimum time spent planning the statement, in milliseconds (if pgpro_stats.track_planning is enabled, otherwise zero)
max_plan_time	float8		Maximum time spent planning the statement, in milliseconds (if pgpro_stats.track_planning is enabled, otherwise zero)
mean_plan_time	float8		Mean time spent planning the statement, in milliseconds (if pgpro_stats.track_planning is enabled, otherwise zero)
stddev_plan_time	float8		Population standard deviation of time spent planning the statement, in milliseconds (if pgpro_stats.track_planning is enabled, otherwise zero)
plan_rusage	pgpro_stats_rusage		Resource usage statistics of the statement planning.
calls	int8		Number of times the statement was executed
total_exec_time	float8		Total time spent executing the statement, in milliseconds
min_exec_time	float8		Minimum time spent executing the statement, in milliseconds

Name	Type	References	Description
max_exec_time	float8		Maximum time spent executing the statement, in milliseconds
mean_exec_time	float8		Mean time spent executing the statement, in milliseconds
stddev_exec_time	float8		Population standard deviation of time spent executing the statement, in milliseconds
exec_rusage	pgpro_stats_rusage		Resource usage statistics of the statement execution.
rows	int8		Total number of rows retrieved or affected by the statement
shared_blks_hit	int8		Total number of shared block cache hits by the statement
shared_blks_read	int8		Total number of shared blocks read by the statement
shared_blks_dirtied	int8		Total number of shared blocks dirtied by the statement
shared_blks_written	int8		Total number of shared blocks written by the statement
local_blks_hit	int8		Total number of local block cache hits by the statement
local_blks_read	int8		Total number of local blocks read by the statement
local_blks_dirtied	int8		Total number of local blocks dirtied by the statement
local_blks_written	int8		Total number of local blocks written by the statement
temp_blks_read	int8		Total number of temp blocks read by the statement
temp_blks_written	int8		Total number of temp blocks written by the statement
shared_blk_read_time	float8		Total time the statement spent reading shared blocks, in milliseconds (

Name	Type	References	Description
			if track_io_timing is enabled, otherwise zero)
shared_blk_write_time	float8		Total time the statement spent writing shared blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
local_blk_read_time	float8		Total time the statement spent reading local blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 17, contains zero.
local_blk_write_time	float8		Total time the statement spent writing local blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 17, contains zero.
temp_blk_read_time	float8		Total time the statement spent reading temp blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 15, contains zero.
temp_blk_write_time	float8		Total time the statement spent writing temp blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 15, contains zero.
wal_records	int8		Total number of WAL records generated by the statement
wal_fpi	int8		Total number of WAL full page images generated by the statement
wal_bytes	numeric		Total amount of WAL bytes generated by the statement
jit_functions	int8		Total number of functions JIT-compiled by the statement. In Postgres Pro versions lower than 15, contains zero.

Name	Type	References	Description
jit_generation_time	float8		Total time spent by the statement on generating JIT code, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_inlining_count	int8		Number of times functions used in the statement have been inlined. In Postgres Pro versions lower than 15, contains zero.
jit_inlining_time	float8		Total time spent by the statement on inlining functions, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_optimization_count	int8		Number of times the statement has been optimized. In Postgres Pro versions lower than 15, contains zero.
jit_optimization_time	float8		Total time spent by the statement on optimizing, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_emission_count	int8		Number of times code has been emitted by the statement. In Postgres Pro versions lower than 15, contains zero.
jit_emission_time	float8		Total time spent by the statement on emitting code, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_deform_count	int8		Total number of tuple deform functions JIT-compiled by the statement. In Postgres Pro versions lower than 17, contains zero.
jit_deform_time	float8		Total time spent by the statement on JIT-compiling tuple deform functions, in milliseconds. In Postgres Pro versions lower than 17, contains zero.

Name	Type	References	Description
wait_stats	jsonb		A jsonb object containing statistics on wait events, for each execution of the query that uses the corresponding plan. Each statistic is provided in milliseconds and is a multiple of the pgpro_stats.profile_period configuration parameter.
inval_msgs	pgpro_stats_inval_msgs		Number of cache invalidation messages by type generated by the statement (if this is supported by the server, otherwise zero).
stats_since	timestamp with time zone		Time at which statistics gathering started for this statement
minmax_stats_since	timestamp with time zone		Time at which min/max statistics gathering started for this statement (fields min_plan_time , max_plan_time , min_exec_time and max_exec_time)

Take into account that like pg_stat_statements, pgpro_stats normalizes into one record those DML queries (containing SELECT, INSERT, UPDATE, DELETE and MERGE commands) that have equivalent structures according to some internal hash value. Being compared this way, two queries are normally considered equal if they are semantically equivalent up to constants included in the queries. All the other commands are, however, compared strictly as query texts. When the value of a constant in a query is ignored for comparison with other queries, this constant is replaced in the pgpro_stats output with a symbol of a parameter, such as, $k, where k is a positive integer. If a query already contains parameters, the initial value of k equals the number following the last number of a $n parameter in the original query text. If there are no parameters, the initial value of k equals 1. Note that sometimes hidden parameter symbols affect this numbering. For example, PL/pgSQL uses such hidden symbols to insert values of function local variables into queries, so a PL/pgSQL statement SELECT i + 1 INTO j will be represented as SELECT i + $2 in the normalized query text.

pgpro_stats uses a similar technique to normalize plan texts. When doing so, an attempt is made to associate numbers of constants in the plan text with the corresponding numbers of constants in the query text. If such an attempt appears unsuccessful for a certain constant in the plan text, it is assigned the number following the maximum number of a constant replaced in the query text. For example, consider the query:

```
SELECT 1::int, 'abc'::VARCHAR(3), 2::int;
```

pgpro_stats will replace numbers of constants in the query text and in the text of the corresponding plan as follows:

```
postgres=# SELECT query, plan FROM pgpro_stats_statements;
                      query                       |                                 plan
--------------------------------------------------
+-------------------------------------------------
```

```
SELECT $1::int, $2::VARCHAR(3), $3::int          | Result
            +
                                                 |   Output: $1, $4, $3
            +
```

In this plan text, it appeared possible to associate constants numbered 1 and 3 from the query text, but not the constant numbered 2, and the latter was replaced with the number following the maximum number in the query text, that is, number 4.

Replacement of numbers in plan texts has an exception for version numbers of XML documents. If in the original query such a number is represented with a constant, e.g., '1.0', it is retained as is in the plan text rather than replaced with `$k`. If the version number of an XML document is represented with an expression, replacement of constants follows usual rules.

G.2.4.2. The `pgpro_stats_totals` View

The aggregate statistics gathered by the module are made available via a view named `pgpro_stats_totals`. This view contains one row for each distinct object (up to the maximum number of distinct objects that the module can track). The columns of the view are shown in Table G.73.

Table G.73. `pgpro_stats_totals` Columns

Name	Type	Description
`object_type`	`text`	Type of the object for which aggregated statistics are collected: "cluster", "database", "user", "client_addr", "application", "backend", "session"
`object_id`	`bigint`	ID of the object: oid for databases and users, pid for backends, sid for sessions, NULL for others
`object_name`	`text`	Textual name of the object or NULL
`queries_planned`	`int8`	Number of queries planned
`total_plan_time`	`float8`	Total time spent in the planning of statements, in milliseconds
`total_plan_rusage`	pgpro_stats_rusage	Aggregate resource usage statistics of the statement planning
`queries_executed`	`int8`	Number of queries executed
`total_exec_time`	`float8`	Total time spent in the execution of statements, in milliseconds
`total_exec_rusage`	pgpro_stats_rusage	Aggregate resource usage statistics of the statement execution
`rows`	`int8`	Total number of rows retrieved or affected by the statements
`shared_blks_hit`	`int8`	Total number of shared block cache hits by the statements
`shared_blks_read`	`int8`	Total number of shared blocks read by the statements
`shared_blks_dirtied`	`int8`	Total number of shared blocks dirtied by the statements
`shared_blks_written`	`int8`	Total number of shared blocks written by the statements

Name	Type	Description
local_blks_hit	int8	Total number of local block cache hits by the statements
local_blks_read	int8	Total number of local blocks read by the statements
local_blks_dirtied	int8	Total number of local blocks dirtied by the statements
local_blks_written	int8	Total number of local blocks written by the statements
temp_blks_read	int8	Total number of temp blocks read by the statements
temp_blks_written	int8	Total number of temp blocks written by the statements
shared_blk_read_time	float8	Total time the statements spent reading shared blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
shared_blk_write_time	float8	Total time the statements spent writing shared blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
local_blk_read_time	float8	Total time the statements spent reading local blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 17, contains zero.
local_blk_write_time	float8	Total time the statements spent writing local blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 17, contains zero.
temp_blk_read_time	float8	Total time the statements spent reading temp blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 15, contains zero.
temp_blk_write_time	float8	Total time the statements spent writing temp blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 15, contains zero.
wal_records	int8	Total number of WAL records generated by the statements
wal_fpi	int8	Total number of WAL full page images generated by the statements
wal_bytes	numeric	Total amount of WAL bytes generated by the statements

Name	Type	Description
jit_functions	int8	Total number of functions JIT-compiled by the statements. In Postgres Pro versions lower than 15, contains zero.
jit_generation_time	float8	Total time spent by the statements on generating JIT code, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_inlining_count	int8	Number of times functions used in the statements have been inlined. In Postgres Pro versions lower than 15, contains zero.
jit_inlining_time	float8	Total time spent by the statements on inlining functions, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_optimization_count	int8	Number of times the statements have been optimized. In Postgres Pro versions lower than 15, contains zero.
jit_optimization_time	float8	Total time spent by the statements on optimizing, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_emission_count	int8	Number of times code has been emitted by the statements. In Postgres Pro versions lower than 15, contains zero.
jit_emission_time	float8	Total time spent by the statements on emitting code, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_deform_count	int8	Total number of tuple deform functions JIT-compiled by the statements. In Postgres Pro versions lower than 17, contains zero.
jit_deform_time	float8	Total time spent by the statements on JIT-compiling tuple deform functions, in milliseconds. In Postgres Pro versions lower than 17, contains zero.
wait_stats	jsonb	A jsonb object containing statistics on wait events for each execution of the queries. Each statistic is provided in milliseconds and is a multiple of the pgpro_stats.profile_period configuration parameter.

Name	Type	Description
inval_msgs	pgpro_stats_inval_msgs	Number of cache invalidation messages by type generated by the statements (if this is supported by the server, otherwise zero).
cache_resets	int4	Number of shared cache resets (only for cluster, databases and backends). Gets incremented for a backend when it receives a full cache reset message.
stats_since	timestamp with time zone	Time at which statistics gathering started for the statements

G.2.4.3. The pgpro_stats_info View

The statistics of the pgpro_stats module itself are tracked and made available via a view named pgpro_stats_info. This view contains only a single row. The columns of the view are shown in Table G.74.

Table G.74. pgpro_stats_info Columns

Name	Type	Description
dealloc	bigint	Total number of times pgpro_stats_statements entries about the least-executed statements were deallocated because more distinct statements than pgpro_stats.max were observed
stats_reset	timestamp with time zone	Time at which all statistics in the pgpro_stats_statements view were last reset

G.2.4.4. The pgpro_stats_metrics View

The metrics gathered by pgpro_stats are displayed in the pgpro_stats_metrics view. The table below describes the columns of the view.

Table G.75. pgpro_stats_metrics Columns

Name	Type	Description
metric_number	int4	A unique ID of the collected metric assigned by user. This ID is included into parameter names that define the metric.
metric_name	text	The name of the metric defined by the pgpro_stats.metric_*N*_*name* parameter
db_name	text	The name of the database for which a particular metric was collected
ts	timestamptz	The time when the metric value got calculated
value	jsonb	The result of the query used for metric measurement. It is serialized in jsonb as an array of objects received via to_jsonb(

Name	Type	Description
		resulting_row). If an error occurs, a single object is returned that contains code, message, detail, and hint fields.

G.2.4.5. The pgpro_stats_archiver View

The pgpro_stats_archiver view will contain one row showing data about the archiver process of the cluster.

Table G.76. pgpro_stats_archiver Columns

Column	Type	Description
archived_count	bigint	Number of WAL files that have been successfully archived
last_archived_wal	text	Name of the last WAL file successfully archived
last_archived_time	timestamp with time zone	Time of the last successful archive operation
failed_count	bigint	Number of failed attempts for archiving WAL files
last_failed_wal	text	Name of the WAL file of the last failed archival operation
last_failed_time	timestamp with time zone	Time of the last failed archival operation
active_time	int8	Overall time that the archiver process was active
archive_command_time	int8	Overall execution time of the archive command
stats_reset	timestamp with time zone	Time at which these statistics were last reset

G.2.4.6. The pgpro_stats_vacuum_database View

> **Important**
>
> Starting with Postgres Pro 16, this view contains no data because the statistics to be displayed are available through the catalog view pg_stats_vacuum_database (see System Views for details).

The pgpro_stats_vacuum_database view will contain one row for each database in the current cluster, showing statistics about vacuuming that database. These statistics are collected by the core system as explained in Section 26.2. The table below describes the columns of the view.

Table G.77. pgpro_stats_vacuum_database Columns

Column	Type	Description
dbid	oid	OID of a database
total_blks_read	int8	Number of database blocks read by vacuum operations performed on this database
total_blks_hit	int8	Number of times database blocks were found in the buffer cache

Column	Type	Description
		by vacuum operations performed on this database
total_blks_dirtied	int8	Number of database blocks dirtied by vacuum operations performed on this database
total_blks_written	int8	Number of database blocks written by vacuum operations performed on this database
wal_records	int8	Total number of WAL records generated by vacuum operations performed on this database
wal_fpi	int8	Total number of WAL full page images generated by vacuum operations performed on this database
wal_bytes	numeric	Total amount of WAL bytes generated by vacuum operations performed on this database
blk_read_time	float8	Time spent reading database blocks by vacuum operations performed on this database, in milliseconds (if track_io_timing is enabled, otherwise zero)
blk_write_time	float8	Time spent writing database blocks by vacuum operations performed on this database, in milliseconds (if track_io_timing is enabled, otherwise zero)
delay_time	float8	Time spent sleeping in a vacuum delay point by vacuum operations performed on this database, in milliseconds (see Section 18.4.4 for details)
system_time	float8	System CPU time of vacuuming this database, in milliseconds
user_time	float8	User CPU time of vacuuming this database, in milliseconds
total_time	float8	Total time of vacuuming this database, in milliseconds
interrupts	int4	Number of times vacuum operations performed on this database were interrupted on any errors

G.2.4.7. The pgpro_stats_vacuum_tables View

Important

Starting with Postgres Pro 16, this view contains no data because the statistics to be displayed are available through the catalog view pg_stats_vacuum_tables (see System Views for details).

The pgpro_stats_vacuum_tables view will contain one row for each table in the current database (including TOAST tables), showing statistics about vacuuming that specific table. These statistics are collected by the core system as explained in Section 26.2. The table below describes the columns of the view.

Table G.78. pgpro_stats_vacuum_tables Columns

Column	Type	Description
relid	oid	OID of a table
schema	name	Name of the schema this table is in
relname	name	Name of this table
total_blks_read	int8	Number of database blocks read by vacuum operations performed on this table
total_blks_hit	int8	Number of times database blocks were found in the buffer cache by vacuum operations performed on this table
total_blks_dirtied	int8	Number of database blocks dirtied by vacuum operations performed on this table
total_blks_written	int8	Number of database blocks written by vacuum operations performed on this table
rel_blks_read	int8	Number of blocks vacuum operations read from this table
rel_blks_hit	int8	Number of times blocks of this table were already found in the buffer cache by vacuum operations, so that a read was not necessary (this only includes hits in the Postgres Pro buffer cache, not the operating system's file system cache)
pages_scanned	int8	Number of pages examined by vacuum operations performed on this table
pages_removed	int8	Number of pages removed from the physical storage by vacuum operations performed on this table
pages_frozen	int8	Number of times vacuum operations marked pages of this table as all-frozen in the visibility map
pages_all_visible	int8	Number of times vacuum operations marked pages of this table as all-visible in the visibility map
tuples_deleted	int8	Number of dead tuples vacuum operations deleted from this table
tuples_frozen	int8	Number of tuples of this table that vacuum operations marked as frozen

Column	Type	Description
dead_tuples	int8	Number of dead tuples vacuum operations left in this table due to their visibility in transactions
index_vacuum_count	int8	Number of times indexes on this table were vacuumed
rev_all_frozen_pages	int8	Number of times the all-frozen mark in the visibility map was removed for pages of this table
rev_all_visible_pages	int8	Number of times the all-visible mark in the visibility map was removed for pages of this table
wal_records	int8	Total number of WAL records generated by vacuum operations performed on this table
wal_fpi	int8	Total number of WAL full page images generated by vacuum operations performed on this table
wal_bytes	numeric	Total amount of WAL bytes generated by vacuum operations performed on this table
blk_read_time	float8	Time spent reading database blocks by vacuum operations performed on this table, in milliseconds (if track_io_timing is enabled, otherwise zero)
blk_write_time	float8	Time spent writing database blocks by vacuum operations performed on this table, in milliseconds (if track_io_timing is enabled, otherwise zero)
delay_time	float8	Time spent sleeping in a vacuum delay point by vacuum operations performed on this table, in milliseconds (see Section 18.4.4 for details)
system_time	float8	System CPU time of vacuuming this table, in milliseconds
user_time	float8	User CPU time of vacuuming this table, in milliseconds
total_time	float8	Total time of vacuuming this table, in milliseconds
interrupts	integer	Number of times vacuum operations performed on this table were interrupted on any errors

Columns `total_*`, `wal_*` and `blk_*` include data on vacuuming indexes on this table, while columns `system_time` and `user_time` only include data on vacuuming the heap.

G.2.4.8. The `pgpro_stats_vacuum_indexes` View

> **Important**
>
> Starting with Postgres Pro 16, this view contains no data because the statistics to be displayed are available through the catalog view `pg_stats_vacuum_indexes` (see System Views for details).

The `pgpro_stats_vacuum_indexes` view will contain one row for each index in the current database (including TOAST table indexes), showing statistics about vacuuming that specific index. These statistics are collected by the core system as explained in Section 26.2. The table below describes the columns of the view.

Table G.79. `pgpro_stats_vacuum_indexes` Columns

Column	Type	Description
`relid`	`oid`	OID of an index
`schema`	`name`	Name of the schema this index is in
`relname`	`name`	Name of this index
`total_blks_read`	`int8`	Number of database blocks read by vacuum operations performed on this index
`total_blks_hit`	`int8`	Number of times database blocks were found in the buffer cache by vacuum operations performed on this index
`total_blks_dirtied`	`int8`	Number of database blocks dirtied by vacuum operations performed on this index
`total_blks_written`	`int8`	Number of database blocks written by vacuum operations performed on this index
`rel_blks_read`	`int8`	Number of blocks vacuum operations read from this index
`rel_blks_hit`	`int8`	Number of times blocks of this index were already found in the buffer cache by vacuum operations, so that a read was not necessary (this only includes hits in the Postgres Pro buffer cache, not the operating system's file system cache)
`pages_deleted`	`int8`	Number of pages deleted by vacuum operations performed on this index
`tuples_deleted`	`int8`	Number of dead tuples vacuum operations deleted from this index
`wal_records`	`int8`	Total number of WAL records generated by vacuum operations performed on this index

Column	Type	Description
wal_fpi	int8	Total number of WAL full page images generated by vacuum operations performed on this index
wal_bytes	numeric	Total amount of WAL bytes generated by vacuum operations performed on this index
blk_read_time	float8	Time spent reading database blocks by vacuum operations performed on this index, in milliseconds (if track_io_timing is enabled, otherwise zero)
blk_write_time	float8	Time spent writing database blocks by vacuum operations performed on this index, in milliseconds (if track_io_timing is enabled, otherwise zero)
delay_time	float8	Time spent sleeping in a vacuum delay point by vacuum operations performed on this index, in milliseconds (see Section 18.4.4 for details)
system_time	float8	System CPU time of vacuuming this index, in milliseconds
user_time	float8	User CPU time of vacuuming this index, in milliseconds
total_time	float8	Total time of vacuuming this index, in milliseconds
interrupts	integer	Number of times vacuum operations performed on this index were interrupted on any errors

G.2.5. Data Types

G.2.5.1. The pgpro_stats_rusage Type

pgpro_stats_rusage is a record type that contains resource usage statistics of statement planning/execution. The fields of this type are shown in Table G.80.

Table G.80. pgpro_stats_rusage Fields

Name	Type	Description
reads	bigint	Number of bytes read by the filesystem layer
writes	bigint	Number of bytes written by the filesystem layer
user_time	double precision	User CPU time used
system_time	double precision	System CPU time used
minflts	bigint	Number of page reclaims (soft page faults)
majflts	bigint	Number of page faults (hard page faults)
nswaps	bigint	Number of swaps

Name	Type	Description
msgsnds	bigint	Number of IPC messages sent
msgrcvs	bigint	Number of IPC messages received
nsignals	bigint	Number of signals received
nvcsws	bigint	Number of voluntary context switches
nivcsws	bigint	Number of involuntary context switches

G.2.6. Functions

pgpro_stats_statements_reset(userid Oid, dbid Oid, queryid bigint, planid bigint, minmax_only boolean) returns timestamp with time zone

pgpro_stats_statements_reset discards statistics gathered so far by pgpro_stats corresponding to the specified userid, dbid, queryid, and planid. If any of the parameters are not specified, the default value 0(invalid) is used for each of them and the statistics that match with other parameters will be reset. If no parameter is specified or all the specified parameters are 0(invalid), it will discard all statistics. If all statistics in the pgpro_stats_statements view are discarded, it will also reset the statistics in the pgpro_stats_info view. When minmax_only is true only the values of minimum and maximum planning and execution time will be reset (i.e. min_plan_time, max_plan_time, min_exec_time and max_exec_time fields). The default value for minmax_only parameter is false. Time of last min/max reset performed is shown in minmax_stats_since field of the pgpro_stats_statements view. This function returns the time of a reset. This time is saved to stats_reset field of pgpro_stats_info view or to minmax_stats_since field of the pgpro_stats_statements view if the corresponding reset was actually performed. By default, this function can only be executed by superusers. Access may be granted to others using GRANT.

> **Note**
>
> As statistics in the pgpro_stats_vacuum_database, pgpro_stats_vacuum_tables, and pgpro_stats_vacuum_indexes views are collected by the core system, to reset them, call the pg_stat_reset() function (see Section 26.2.22 for details).

pgpro_stats_statements(showtext boolean) returns setof record

The pgpro_stats_statements view is defined in terms of a function also named pgpro_stats_statements. Users can also call the pgpro_stats_statements function directly, and by specifying showtext := false make query text be omitted (that is, the OUT argument that corresponds to the view's query column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all pgpro_stats itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the pgpro_stats_statements data.

pgpro_stats_info() returns record

pgpro_stats_info view is defined in terms of a function also named pgpro_stats_info. Users can also call the pgpro_stats_info function directly.

pgpro_stats_totals_reset(type text, id bigint) returns timestamp with timezone

pgpro_stats_totals_reset discards statistics gathered so far by pgpro_stats corresponding to the specified object type and id. If no parameter is specified or the type parameter is set to 0, all statistics will be discarded. If type is set to a valid object type, then if id is specified, then statistics

will be discarded only for the specified object, else, statistics will be discarded for all objects of the specified type. Otherwise, no statistics will be discarded. This function returns the time of a reset. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

`pgpro_stats_totals() returns setof record`

The `pgpro_stats_totals` view is defined in terms of a function also named `pgpro_stats_totals`. Users can also call the `pgpro_stats_totals` function directly.

`pgpro_stats_metrics() returns setof record`

Defines the `pgpro_stats_metrics` view, which is described in detail in Table G.75.

`pgpro_stats_get_archiver() returns setof record`

Defines the `pgpro_stats_archiver` view, which is described in detail in Table G.76.

`pgpro_stats_wal_sender_crc_errors() returns bigint`

In Postgres Pro Enterprise, returns the number of errors detected by the WAL sender process when the `wal_sender_check_crc` parameter is `on`. In Postgres Pro Standard, returns zero. Note that this counter is reset to zero when the cluster restarts.

`pgpro_stats_vacuum_database(dboid oid) returns setof record`

Defines the row of the `pgpro_stats_vacuum_database` view, which is described in detail in Table G.77, for the database specified by *`dboid`*.

`pgpro_stats_vacuum_tables(dboid oid, relid oid) returns setof record`

Defines the row of the `pgpro_stats_vacuum_tables` view, which is described in detail in Table G.78, for the database specified by *`dboid`* and table specified by *`reloid`*. If *`reloid`* = 0, the statistics for each table in the specified database are returned.

`pgpro_stats_vacuum_indexes(dboid oid, relid oid) returns setof record`

Defines the row of the `pgpro_stats_vacuum_indexes` view, which is described in detail in Table G.79, for the database specified by *`dboid`* and index specified by *`reloid`*. If *`reloid`* = 0, the statistics for each index in the specified database are returned.

G.2.6.1. Functions for Creating Views that Emulate Other Extensions

pgpro_stats can create views similar to those available in pg_stat_statements and *pg_stat_kcache* extensions. Specifically, `pg_stat_statements`, `pg_stat_statements_info`, `pg_stat_kcache` and `pg_stat_kcache_detail` views can be created. Each view is only created in a Postgres Pro version if it is available in pg_stat_statements/pg_stat_kcache extension for the same version of Postgres Pro/PostgreSQL. For example, the `pg_stat_statements_info` view is only created in Postgres Pro versions starting with 14. The following functions enable creating these views:

`pgpro_stats_create_pg_stat_statements_compatible_views() returns void`

Creates `pg_stat_statements` and `pg_stat_statements_info` views.

`pgpro_stats_create_pg_stat_kcache_compatible_views() returns void`

Creates `pg_stat_kcache` and `pg_stat_kcache_detail` views.

By default, these functions can only be executed by superusers. Access may be granted to others using `GRANT`.

To create `pg_stat_statements*` views, drop the pg_stat_statements extension if it was previously installed and call the function:

```
select pgpro_stats_create_pg_stat_statements_compatible_views();
```

To create `pg_stat_kcache*` views, drop the pg_stat_kcache extension if it was previously installed and call the function:

```
select pgpro_stats_create_pg_stat_kcache_compatible_views();
```

Once the views are created, you can work with them as if the pg_stat_statements/pg_stat_kcache extension is installed.

If you need to remove the views created earlier, do it in a regular way:

```
drop view pg_stat_statements;
drop view pg_stat_statements_info;
drop view pg_stat_kcache;
drop view pg_stat_kcache_detail;
```

G.2.7. Configuration Parameters

G.2.7.1. General Settings

`pgpro_stats.max` (`integer`)

pgpro_stats only collects statistics about most frequent queries. The less frequently a query appears during the server opertaion, the less probable its inclusion in the statistics. Rare queries are almost immediately evicted from the statistics by more frequent queries. The `pgpro_stats.max` parameter defines the maximum number of unique pairs (normalized query text, normalized plan text) tracked by the module, (i.e., the maximum number of rows in the `pgpro_stats_statements` view). The larger this value, the larger the number of queries for which the information is stored. But this is achieved at the cost of reduced server performance when waiting for locks trying to access the statistics table in the shared memory and when periodically collecting garbage in the file with texts of queries and plans. The default value is 5000. This parameter can only be set at server start.

`pgpro_stats.max_totals` (`integer`)

`pgpro_stats.max_totals` is the maximum number of objects tracked by the module (i.e., the maximum number of rows in the `pgpro_stats_totals` view). If more distinct objects than that are observed, information about least-used objects is discarded. The default value is 1000. This parameter can only be set at server start.

`pgpro_stats.track` (`enum`)

`pgpro_stats.track` controls which statements are counted by the module. Specify `top` to track top-level statements (those issued directly by clients), `all` to also track nested statements (such as statements invoked within functions) with nesting level not greater than 100, or `none` to disable statement statistics collection. The default value is `top`. Only superusers can change this setting.

`pgpro_stats.track_utility` (`boolean`)

`pgpro_stats.track_utility` controls whether utility commands are tracked by the module. Utility commands are all those other than `SELECT`, `INSERT`, `UPDATE` and `DELETE`. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_planning` (`boolean`)

`pgpro_stats.track_planning` controls whether planning operations and duration are tracked by the module. Enabling this parameter may incur a noticeable performance penalty, especially when statements with identical query structure are executed by many concurrent connections which compete to update a small number of `pgpro_stats_statements` entries. The default value is `off`. Only superusers can change this setting.

`pgpro_stats.track_totals` (`boolean`)

`pgpro_stats.track_totals` controls whether aggregate statistics for objects (cluster, users, databases etc.) are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_cluster` (`boolean`)

`pgpro_stats.track_cluster` controls whether aggregate statistics for the cluster are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_databases` (`boolean`)

`pgpro_stats.track_databases` controls whether aggregate statistics for the databases are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_users` (`boolean`)

`pgpro_stats.track_users` controls whether aggregate statistics for the users are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_applications` (`boolean`)

`pgpro_stats.track_applications` controls whether aggregate statistics for the applications (whose names are set by application_name) are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_client_addr` (`boolean`)

`pgpro_stats.track_client_addr` controls whether aggregate statistics for the client IP addresses are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_backends` (`boolean`)

`pgpro_stats.track_backends` controls whether aggregate statistics for the backends are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.save` (`boolean`)

`pgpro_stats.save` specifies whether to save statement statistics across server shutdowns. If it is `off` then statistics are neither saved at shutdown nor reloaded at server start. The default value is `on`. This parameter can only be set in the `postgresql.conf` file or on the server command line.

`pgpro_stats.plan_format` (`text`)

`pgpro_stats.plan_format` selects the `EXPLAIN` format for the query plan. Possible values are `text`, `xml`, `json`, and `yaml`. The default value is `text`. Changing this parameter requires a server restart.

`pgpro_stats.enable_profile` (`boolean`)

`pgpro_stats.enable_profile` enables sampling of wait events for separate statements. The default value is `true`. Changing this parameter requires a server restart.

`pgpro_stats.query_sample_rate` (`float`)

As pgpro_stats only collects statistics about most frequent queries, and rare queries are not included in the statistics, you can reduce the effect of the statistics collection on the server performance. This is possible because some time later than the statistics collection starts, almost all the statistics collected by the module will contain queries that are not very infrequent, and the set of types of the collected queries will not further change much if the value of pgpro_stats.max is sufficient and the average frequency for most of the frequent queries has no significant changes with the periods larger than the observation time. Such a stationary distribution of collected queries can also be achieved by increasing the time of the statistics collection, for example, twice, but only adding each second query to the statistics instead of every query, or considering each query, but adding queries to the statistics randomly, with a given probability. In this example, it equals 0.5. This allows you to considerably reduce the server load at the cost of increasing the time of the statistics collection. `pgpro_stats.query_sample_rate` is the parameter to implement this approach. For example: if `pgpro_stats.query_sample_rate` is set to 0.2 (1/5), in five hours of the server operation under the above conditions, the statistics will be collected that is similar to the statistics collected with `pgpro_stats.query_sample_rate` = 1 in an hour.

You can set up `pgpro_stats.query_sample_rate` by experiment. Choose the observation time depending on the environment of the server operation, for example: one hour. Look at the collected statistics an hour after the start and then an hour later without resetting the statistics. If the main difference appears to be in the increased number of collected queries (`calls`) rather than in the type of the queries, you can safely reduce `pgpro_stats.query_sample_rate` twice. In the case of

a considerable difference in the types of the collected queries, increase the observtion time and/or the `pgpro_stats.max` parameter.

The default value is `1.0`. Changing this parameter requires a server restart.

`pgpro_stats.profile_period` (`integer`)

`pgpro_stats.profile_period` specifies the period, in milliseconds, during which to sample wait events. The default value is `10`. Only superusers can change this setting.

`pgpro_stats.metrics_buffer_size` (`integer`)

`pgpro_stats.metrics_buffer_size` specifies the size of the ring buffer used for collecting statistical metrics. The default value is `16kB`. Changing this parameter requires a server restart.

`pgpro_stats.metrics_workers` (`integer`)

`pgpro_stats.metrics_workers` specifies the number of workers used to collect statistical metrics. If this parameter is set to 2 or higher, one of the workers serves as the primary worker distributing queries to other workers. If only one worker is available, it gets reloaded to connect to different databases. Setting this parameter to `0` disables metrics collection. The default value is `2`. Changing this parameter requires a server restart.

`pgpro_stats.stats_temp_directory` (`string`)

`pgpro_stats.stats_temp_directory` specifies the directory with the external file to store query texts. This can be a path relative to the data directory or an absolute path. Changing this parameter requires a server restart.

G.2.7.2. Metrics Settings

The following parameters can be used to define a custom metric to collect. The *`N`* placeholder in the parameter name serves as a unique identifier of the metric to which this setting should apply; it must be set to a non-negative integer for each metric.

When you add these parameters for a new metric, you have to restart the server for the changes to take effect. Once the new metric is added, its parameters can be changed without a server restart by simply reloading the `postgresql.conf` configuration file.

`pgpro_stats.metric_`*`N`*`_name` (`text`)

The name of metric *`N`*. This name will be displayed in the `metric_name` column of the `pgpro_stats_metrics` view.

`pgpro_stats.metric_`*`N`*`_query` (`text`)

The query statement that defines the metric to collect.

`pgpro_stats.metric_`*`N`*`_period` (`integer`)

The time interval at which to collect metric *`N`*, in milliseconds. Default: 60000 ms

`pgpro_stats.metric_`*`N`*`_db` (`text`)

The list of databases for which to collect metric *`N`*. Database names must be separated by commas. You can specify the `*` character to select all databases in the cluster except the template databases. If you need to analyze the template databases as well, you have to specify them explicitly.

`pgpro_stats.metric_`*`N`*`_user` (`text`)

The name of the user on behalf of which to collect metric *`N`*. This user must have access to the database for which the metric is collected.

G.2.8. Tracing of Application Sessions

In pgpro_stats, tracing of application sessions is implemented. It is based on filters, which trigger logging the execution of queries that match filtering conditions. Queries and their `EXPLAIN` output are logged in so-called *trace files* specified by the user or in the system log file (if the trace file is not specified).

Filters are stored in a table located in the shared memory. The rows of this table represent filters, and the columns contain filtering conditions and `EXPLAIN` options to be used (see EXPLAIN for details). You should fill this table with filters to start tracing of queries.

Once a database administrator adds a filter in any session, all subsequent executions of queries that match the filter conditions will be traced by all sessions of the instance without a need in the server restart. In other words, filters can be added, deleted, or updated "on the fly", and tracing with these filters immediately starts for existing and future sessions.

> **Note**
>
> Operations of adding, deleting, or updating filters are not transactional. Changes to the table of filters are not rolled back together with the transaction where these changes were made.

Columns of the table that stores filters are also called *filter attributes*. They are described in Table G.81.

Table G.81. Filter Attributes

Name	Type	Description
`filter_id`	`integer`	Unique filter ID, which is automatically assigned to a filter when it is created, numbered from 1.
`active`	`boolean`	With the value of `false`, the filter is not active, which means that queries matching this filter are not logged. Default: `true`.
`alias`	`name`	Filter name, which can be specified for convenience. Only shown in the output of the `pgpro_stats_trace_show()` function. Default: empty string.
`tracefile`	`name`	Name of the trace file, where queries matching the filter and their `EXPLAIN` output are logged. If this filename if not specified, logging is done to the system log with the log level specified by pgpro_stats.trace_log_level. Trace files are created in `PGDATA/pg_stat` directory and have `trace` extension.
`pid`	`integer`	Process ID of the backend that executes the statement
`database_name`	`name`	Name of the database where the statement is executed
`client_addr`	`name`	IP address of the client connected to this backend
`application_name`	`name`	Name of the application that invoked execution of the statement
`username`	`name`	Name of the user who executes the statement
`queryid`	`bigint`	Internal hash code, computed from the statement's parse tree

Name	Type	Description
planid	bigint	Internal hash code, computed from the statement's plan tree
duration	float8	Time spent in the planning and execution of the statement, in milliseconds
plan_time	float8	Time spent in the planning of the statement, in milliseconds
exec_time	float8	Time spent in the execution of the statement, in milliseconds
user_time	float8	User CPU time used in planning and execution of the statement
system_time	float8	System CPU time used in planning and execution of the statement
rows	int8	Total number of rows retrieved or affected by the statement
shared_blks_hit	int8	Total number of shared block cache hits by the statement
shared_blks_read	int8	Total number of shared blocks read by the statement
shared_blks_fetched	int8	Total number of shared blocks fetched from buffers by the statement
shared_blks_dirtied	int8	Total number of shared blocks dirtied by the statement
shared_blks_written	int8	Total number of shared blocks written by the statement
local_blks_hit	int8	Total number of local block cache hits by the statement
local_blks_read	int8	Total number of local blocks read by the statement
local_blks_fetched	int8	Total number of local blocks fetched from buffers by the statement
local_blks_dirtied	int8	Total number of local blocks dirtied by the statement
local_blks_written	int8	Total number of local blocks written by the statement
temp_blks_read	int8	Total number of temp blocks read by the statement
temp_blks_written	int8	Total number of temp blocks written by the statement
wal_bytes	numeric	Total amount of WAL bytes generated by the statement
total_wait_time	float8	Total time execution of this statement spent waiting
total_inval_msgs	bigint	Total number of cache invalidation messages generated by the

Name	Type	Description
		statement (if this is supported by the server)
explain_analyze	boolean	If true, the EXPLAIN output will be logged with the ANALYZE option. By default, defined by the pgpro_stats.explain_analyze_default configuration parameter.
explain_verbose	boolean	If true, the EXPLAIN output will be logged with the VERBOSE option. By default, defined by the pgpro_stats.explain_verbose_default configuration parameter.
explain_costs	boolean	If true, the EXPLAIN output will be logged with the COSTS option. By default, defined by the pgpro_stats.explain_costs_default configuration parameter.
explain_settings	boolean	If true, the EXPLAIN output will be logged with the SETTINGS option. By default, defined by the pgpro_stats.explain_settings_default configuration parameter.
explain_buffers	boolean	If true, the EXPLAIN output will be logged with the BUFFERS option. By default, defined by the pgpro_stats.explain_buffers_default configuration parameter.
explain_wal	boolean	If true, the EXPLAIN output will be logged with the WAL option. By default, defined by the pgpro_stats.explain_wal_default configuration parameter.
explain_timing	boolean	If true, the EXPLAIN output will be logged with the TIMING option. By default, defined by the pgpro_stats.explain_timing_default configuration parameter.
explain_format	text	The value of the FORMAT option of EXPLAIN to be logged, which can be TEXT, XML, JSON, or YAML. By default, defined by the pgpro_stats.plan_format configuration parameter.
time_info	boolean	If true, includes additional information in the session-tracing output in the format defined by explain_format : pid, duration in milliseconds, start time — start time of the query execution, and stop time — end time of the query execution. See Example G.2 for details.

Filter attributes can be divided into the following groups:

- Control attributes, from `filter_id` to `tracefile` in Table G.81.
- Identification attributes, from `pid` to `planid` in Table G.81.
- Threshold attributes, from `duration` to `total_inval_msgs` in Table G.81.
- Attributes that only control the output to the trace file or system log file and do not affect filtering. Most of them specify the `EXPLAIN` options. These are the attributes starting with `explain_analyze` up to the end of Table G.81.

Query execution will be traced if both of these conditions are met:

- For all the specified identification attributes of the filter, the values of the respective characteristics of the query are the same as the values of these attributes.
- For all the specified threshold attributes of the filter, the values of the respective characteristics of the query are greater than or equal to the limits specified in these attributes.

It is allowed not to assign values to attributes. For all the attributes except `active`, you can also explicitly assign the value of NULL. If the value of a control attribute is undefined or it was expclicitly set to NULL, this attribute will be assigned the default value shown in Table G.81. For identification and threshold attributes, undefined or NULL values mean that queries will not be filtered by the respective characteristic. If no values are defined for all identification and all threshold attributes, all the queries are taken to be matching this filter and will be logged. If the attributes specifying `EXPLAIN` options are undefined, the default values defined by the configuration parameters will be used (see Section G.2.8.2 for details).

> **Warning**
>
> Although when specifying a filter, you can assign values to any combination of filter attributes, bear in mind that a too general filter will lead to an excessive size of the trace file and will affect the performance more than desired as the main performance overhead is associated with writing to the trace file rather than with checking the filter conditions.

G.2.8.1. Session-Tracing Functions

Specialized functions enable creation, update and deletion of query filters:

`pgpro_stats_trace_insert(VARIADIC "any") returns integer`

Adds a filter to the list of session-tracing filters. A filter must be passed as a sequence of alternating key-value pairs, where the key is the name of the filter attribute from Table G.81 except `filter_id`. For example:

```
pgpro_stats_trace_insert('pid', 42, 'database_name', 'main', 'explain_analyze',
 true)
```

Key-value pairs are position-independent: they can be provided in any order, independently of the order of attributes in Table G.81. Some of the attributes can be missing from the sequence. Such attributes will be assigned the default values. Returns the unique `filter_id`, which the function assigns to the added filter.

`pgpro_stats_trace_update(filter_id integer, VARIADIC "any") returns boolean`

Updates a session-tracing filter defined by *`filter_id`*. Filter attributes to update must be passed as a sequence of alternating key-value pairs, where the key is the name of the filter attribute from Table G.81 except `filter_id`. Key-value pairs are position-independent: they can be provided in any order, independently of the order of attributes in Table G.81. Filter attributes whose values are not explicitly specified will not be changed. The value of NULL for identification and threshold attributes resets the values of these attributes, which means that a query will match the conditions of the updated filter regardless of the respective characteristics. Returns `true` on success and `false` otherwise.

`pgpro_stats_trace_delete(filter_id integer) returns boolean`

Deletes a session-tracing filter defined by *`filter_id`*. Returns `true` on success and `false` otherwise.

`pgpro_stats_trace_reset() returns integer`

Removes all session-tracing filters. Returns the number of removed filters. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

`pgpro_stats_trace_show() returns setof record`

Displays the contents of the table of filters, whose columns are shown in Table G.81.

G.2.8.2. Session-Tracing Configuration Parameters

The following parameters can be used to configure session-tracing logging. Note that `pgpro_stats.explain_*_default` settings define the logging behavior when the corresponding `explain_*` filter attributes (from Table G.81) are not specified or explicitly set to NULL.

`pgpro_stats.explain_analyze_default` (`boolean`)

If `true`, the `EXPLAIN` output will be logged with the `ANALYZE` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_verbose_default` (`boolean`)

If `true`, the `EXPLAIN` output will be logged with the `VERBOSE` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_costs_default` (`boolean`)

If `true`, the `EXPLAIN` output will be logged with the `COSTS` option and without it if `false`. The default value is `true`. Only superusers can change this setting.

`pgpro_stats.explain_settings_default` (`boolean`)

If `true`, the `EXPLAIN` output will be logged with the `SETTINGS` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_buffers_default` (`boolean`)

If `true`, the `EXPLAIN` output will be logged with the `BUFFERS` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_wal_default` (`boolean`)

If `true`, the `EXPLAIN` output will be logged with the `WAL` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_timing_default` (`boolean`)

If `true`, the `EXPLAIN` output will be logged with the `TIMING` option and without it if `false`. The default value is `true`. Only superusers can change this setting.

`pgpro_stats.trace_log_level` (`enum`)

Defines the log level at which the `EXPLAIN` output will be logged to the system log file (when the trace file is not specified). Valid values are `DEBUG5`, `DEBUG4`, `DEBUG3`, `DEBUG2`, `DEBUG1`, `INFO`, `NOTICE`, `WARNING`, and `LOG`. The default value is `LOG`.

`pgpro_stats.trace_query_text_size` (`int`)

Defines the maximum size of query texts in the session-tracing output, in kilobytes. If the size of the query text in kilobytes is larger, it is trimmed to the maximum size. If this parameter is not specified, the default value of zero is used, which means that the whole query texts are output.

G.2.8.3. Examples Related to Session Tracing

Example G.1. Usage of Session-Tracing Functions

Let's add the filter `first`:

```
SELECT pgpro_stats_trace_insert('alias', 'first', 'pid', pg_backend_pid(),
 'explain_analyze', true);
```

Let's add the filter `second` and specify logging to the trace file `second_tf.trace`:

```
SELECT pgpro_stats_trace_insert('alias', 'second', 'database_name', current_database(),
 'explain_costs', false, 'tracefile', 'second_tf');
```

You can view the table with filters as follows:

```
\x auto
SELECT * from pgpro_stats_trace_show();
```

```
-[ RECORD 1 ]-------+----------
filter_id           | 1
active              | t
alias               | first
tracefile           |
pid                 | 243183
database_name       |
client_addr         |
application_name    |
username            |
queryid             |
planid              |
duration            |
plan_time           |
exec_time           |
user_time           |
system_time         |
rows                |
shared_blks_hit     |
shared_blks_read    |
shared_blks_fetched |
shared_blks_dirtied |
shared_blks_written |
local_blks_hit      |
local_blks_read     |
local_blks_fetched  |
local_blks_dirtied  |
local_blks_written  |
temp_blks_read      |
temp_blks_written   |
wal_bytes           |
total_wait_time     |
total_inval_msgs    |
explain_analyze     | t
explain_verbose     | f
explain_costs       | t
explain_settings    | f
explain_buffers     | f
explain_wal         | f
explain_timing      | t
explain_format      | text
time_info           | f
```

```
-[ RECORD 2 ]-------+----------
filter_id           | 2
active              | t
alias               | second
tracefile           | second_tf
pid                 |
database_name       | postgres
client_addr         |
application_name    |
username            |
queryid             |
planid              |
duration            |
plan_time           |
exec_time           |
user_time           |
system_time         |
rows                |
shared_blks_hit     |
shared_blks_read    |
shared_blks_fetched |
shared_blks_dirtied |
shared_blks_written |
local_blks_hit      |
local_blks_read     |
local_blks_fetched  |
local_blks_dirtied  |
local_blks_written  |
temp_blks_read      |
temp_blks_written   |
wal_bytes           |
total_wait_time     |
total_inval_msgs    |
explain_analyze     | f
explain_verbose     | f
explain_costs       | f
explain_settings    | f
explain_buffers     | f
explain_wal         | f
explain_timing      | f
explain_format      | text
time_info           | f
```

The following query matches the conditions of both filters, so it must be logged in the system log file and in the specified trace file:

```
SELECT 1 as result;
```

The following is the output to the system log file:

```
2023-04-18 04:52:53.242 MSK [63112] LOG:  Filter 1 triggered explain of the plan:
Query Text: SELECT 1 as result;
Result  (cost=0.00..0.01 rows=1 width=4) (actual time=0.003..0.003 rows=1 loops=1)
```

And the following is the output to the `second_tf.trace` trace file:

```
Query Text: SELECT 1 as result;
Result
```

Let's delete the first filter:

```
SELECT pgpro_stats_trace_delete(1);
```

Let's also change `pid` to 2 for the second filter

```
SELECT pgpro_stats_trace_update(2, 'pid', 2);
```

When you execute the query

```
SELECT 2 as result;
```

it does not get logged to `second_tf.trace`.

Now let's remove all filters from the table:

```
SELECT pgpro_stats_trace_reset();
```

Example G.2. Session-Tracing Output with `time_info` = `true`

The following is an example of the session-tracing output in the JSON format when `time_info` = `true`:

```
{
  "Pid": 123456,
  "Duration ms": 0.094691,
  "Start time": "2025-01-12 15:39:27.580447+03",
  "Stop time": "2025-01-12 15:39:27.587802+03",
  "Query Text": "SELECT 2 AS Result;",
  "Plan": {
    "Node Type": "Result",
    "Parallel Aware": false,
    "Async Capable": false,
    "Startup Cost": 0.00,
    "Total Cost": 0.01,
    "Plan Rows": 1,
    "Plan Width": 4
  }
}
```

G.2.9. Cache Invalidation Metrics

Among the rest, pgpro_stats can collect cache invalidation statistics. This section provides some background information needed to better understand related metrics.

Each backend has its local cache, which allows you to minimize accesses for meta information on tables, for example, to the system catalogs. If a backend changes the meta information, this information must be updated in other backends' caches. This is implemented by sending invalidation messages through a queue: the backend that changed the meta information on some object sends an appropriate message to the queue.

All backends get invalidation messages from the queue. Depending on whether the object for which the invalidation message was received is cached, the backend either ignores the message (when the object is not cached) or updates its cache (when the object is cached). In pgpro_stats, most invalidation message counters, unless explicitly stated otherwise for certain counters, are incremented when backends just generate messages, which will only be sent to the queue upon commit of the appropriate transaction. Note that the counters will remain incremented if the transaction is rolled back, although the message will not be sent to the queue.

When a backend that is adding messages to the queue figures out that the queue size reached a certain limit, it starts a cleanup by deleting messages already processed by all backends, and if backends are found that heavily fall behind and thus delay the cleanup, they get a reset signal, which forces them to reset all their caches.

G.2.9.1. The `pgpro_stats_inval_status` View

The `pgpro_stats_inval_status` view shows one row with the current status of the cache invalidation global queue. The columns of the view are shown in Table G.82.

Table G.82. `pgpro_stats_inval_status` Columns

Name	Type	Description
num_inval_messages	int8	Current number of invalidation messages in the queue
num_inval_queue_cleanups	int8	Number of invalidation queue cleanups done to prevent its overflow
num_inval_queue_resets	int4	Number of cache resets for backends that fail to process messages fast enough

In a working system, num_inval_messages usually approximately equals 4000, which means that the queue is pretty full. The speed of the num_inval_queue_cleanups growth is determined by how fast invalidation messages are generated. Growth of num_inval_queue_resets is normally zero, and non-zero growth indicates either too fast generation of messages or delays in processing messages by backends. Monitoring num_inval_queue_cleanups and num_inval_queue_resets may in some cases allow you to detect problematic backend/backeds as described below.

If for a certain time interval, num_inval_queue_cleanups considerably increased, while num_inval_queue_resets did not, this indicates that invalidation messages are generated faster and/or backends process them more slowly, but backends still manage to process messages before the queue overflows.

If for a time interval, num_inval_queue_cleanups did not considerably increase, while num_inval_queue_resets did, this definitely indicates a delay in processing messages by backend(s), and the cache_resets column of the pgpro_stats_totals view allows you to figure out which backend(s) to blame.

If for a time interval, both counters considerably increased, this also indicates that invalidation messages are generated faster and/or backends process them more slowly, but this time backends fail to process messages before the queue overflows. The cache_resets column of the pgpro_stats_totals view allows you detect which backend(s) delay message processing. In this case, it is not possible to definitely conclude whether too fast generation of messages or a delay in message processing accounts for the growth of num_inval_queue_resets. However, the totals counter of the pgpro_stats_inval_msgs view may help here. If the change of this counter for that interval is pretty the same as for a previous interval of the same length, you can definitely conclude that the growth is caused by backend delays.

The pgpro_stats_inval_status view can be defined in terms of a function:

pgpro_stats_inval_status() returns record

Defines the pgpro_stats_inval_status view, which is described in detail in Table G.82.

G.2.9.2. The `pgpro_stats_inval_msgs` Type

The pgpro_stats_statements and pgpro_stats_totals views for each corresponding object, show a record of the pgpro_stats_inval_msgs record type containing counters for cache invalidation messages. The fields of the type are shown in Table G.83.

Table G.83. `pgpro_stats_inval_msgs` Fields

Name	Type	Description
total	bigint	Total number of invalidation messages
catcache	bigint	Number of selective catalog cache invalidation messages
catalog	bigint	Number of whole catalog cache invalidation messages

Name	Type	Description
relcache	bigint	Number of selective relation cache invalidation messages
relcache_all	bigint	Number of whole relation cache invalidation messages
smgr	bigint	Number of invalidation messages of open relation files. Gets incremented when the messages are sent to the queue.
relmap	bigint	Number of relation map cache invalidation messages. Gets incremented when the messages are sent to the queue.
snapshot	bigint	Number of catalog snapshot invalidation messages

G.2.10. Authors

Postgres Professional, Moscow, Russia

Appendix H. Third-Party Modules and Extensions Shipped as Individual Packages

This appendix contains third-party modules and extensions that are made available in Postgres Pro Standard as individual packages. These packages are listed in Section 16.1.4.1, and the documentation for each module explains which package to choose to install it. Appendix F and Appendix G cover more modules and extensions included in the Postgres Pro Standard distribution. Note also the following extensions that are shipped as individual packages: orafce, pldebugger and plv8 (see Table 16.3 for details).

H.1. oracle_fdw

The oracle_fdw module is a Postgres Pro extension that provides a Foreign Data Wrapper for easy and efficient access to Oracle databases, including pushdown of `WHERE` conditions and required columns as well as comprehensive `EXPLAIN` support.

H.1.1. Installation

The oracle_fdw extension is provided with Postgres Pro Standard as a separate pre-built package `oracle-fdw-std-14` (for the detailed installation instructions, see Chapter 16). oracle_fdw requires Oracle Instant Client version 19.5.

For RPM-based systems (RHEL, SUSE, Red OS, ROSA, ALT Linux), download the `oracle-instantclient` RPM and install it using `rpm`. If you use a Debian-based system (Ubuntu, Astra Linux), you have to either convert the RPM package to a Debian package using alien, and then install it using dpkg, or download the ZIP archive of the client and extract the contents of the archive into the `/opt/oracle` directory.

Once you have Postgres Pro Standard installed, create the oracle_fdw extension:

```
CREATE EXTENSION oracle_fdw;
```

That will define the required functions and create a foreign data wrapper.

Note that the extension version as shown by the psql `\dx` command or the system catalog `pg_available_extensions` is *not* the installed version of oracle_fdw. To get the oracle_fdw version, use the `oracle_diag` function.

H.1.2. Internals

oracle_fdw sets the `MODULE` of the Oracle session to `postgres` and the `ACTION` to the backend process number. This can help identifying the Oracle session and allows you to trace it with `DBMS_MONITOR.SERV_MOD_ACT_TRACE_ENABLE`.

oracle_fdw uses Oracle array interface to avoid unnecessary client-server round-trips. The batch size can be configured with the prefetch table option and is set to 50 by default.

Rather than using a `PLAN_TABLE` to explain an Oracle query (which would require such a table to be created in the Oracle database), oracle_fdw uses execution plans stored in the library cache. For that, an Oracle query is *explicitly described*, which forces Oracle to parse the query. The hard part is to find the `SQL_ID` and `CHILD_NUMBER` of the statement in `V$SQL` because the `SQL_TEXT` column contains only the first 1000 bytes of the query. Therefore, oracle_fdw adds a comment to the query that contains a hash of the query text. This is used to search in `V$SQL`. The actual execution plan or cost information is retrieved from `V$SQL_PLAN`.

oracle_fdw uses transaction isolation level `SERIALIZABLE` on the Oracle side, which corresponds to Postgres Pro's `REPEATABLE READ`. This is necessary because a single Postgres Pro statement can lead to multiple Oracle queries (e.g. during a nested loop join) and the results need to be consistent. Unfortunately, the Oracle implementation of `SERIALIZABLE` has certain quirks; see the Problems section for more.

The Oracle transaction is committed immediately before the local transaction commits, so that a completed Postgres Pro transaction guarantees that the Oracle transaction has completed. However, there is a small chance that the Postgres Pro transaction cannot complete even though the Oracle transaction is committed. This cannot be avoided without using two-phase transactions and a transaction manager, which is beyond what a foreign data wrapper can reasonably provide. Prepared statements involving Oracle are not supported for the same reason.

H.1.3. Short Simple Example

This is an example how to use oracle_fdw. More detailed information is provided in the sections Options and Usage. You should also read the documentation on foreign data and the commands referenced there.

For the sake of this example, let's assume you can connect to Oracle as the operating system user `postgres` (or whoever starts the Postgres Pro server) with the following command:

```
sqlplus orauser/orapwd@//dbserver.mydomain.com:1521/ORADB
```

That means that the Oracle client and the environment are set up correctly. It is also assumed that oracle_fdw has been installed (see the Installation section).

We want to access a table defined like this:

```
SQL> DESCRIBE oratab
 Name                           Null?    Type
 ------------------------------ -------- ------------
 ID                             NOT NULL NUMBER(5)
 TEXT                                    VARCHAR2(30)
 FLOATING                       NOT NULL NUMBER(7,2)
```

Then configure oracle_fdw as a Postgres Pro superuser like this:

```
pgdb=# CREATE EXTENSION oracle_fdw;
pgdb=# CREATE SERVER oradb FOREIGN DATA WRAPPER oracle_fdw
          OPTIONS (dbserver '//dbserver.mydomain.com:1521/ORADB');
```

You can use other naming methods or local connections, see the description of dbserver below.

It is a good idea to use a superuser only where really necessary, so let's allow a normal user to use the foreign server (this is not required for the example to work but recommended):

```
pgdb=# GRANT USAGE ON FOREIGN SERVER oradb TO pguser;
```

Then you can connect to Postgres Pro as `pguser` and define the following:

```
pgdb=> CREATE USER MAPPING FOR pguser SERVER oradb
          OPTIONS (user 'orauser', password 'orapwd');
```

You can use external authentication to avoid storing Oracle passwords.

```
pgdb=> CREATE FOREIGN TABLE oratab (
          id        integer           OPTIONS (key 'true')  NOT NULL,
          text      character varying(30),
          floating  double precision  NOT NULL
       ) SERVER oradb OPTIONS (schema 'ORAUSER', table 'ORATAB');
```

Remember that the table and schema name (the latter is optional) must normally be in uppercase.

Now you can use the table like a regular Postgres Pro table.

H.1.4. Usage

H.1.4.1. Oracle Permissions

The Oracle user will need the `CREATE SESSION` privilege and the right to select from the table or view in question. Note that oracle_fdw accesses the Oracle table at query planning time to get its definition. This happens *before* permissions on the foreign table are checked. Consequently, you may receive an Oracle error if you try to access a foreign table on which you have no permissions in Postgres Pro. This is expected and no security problem.

For `EXPLAIN VERBOSE`, the user will also need `SELECT` privileges on `V$SQL` and `V$SQL_PLAN`.

H.1.4.2. Connections

oracle_fdw caches Oracle connections because it is expensive to create an Oracle session for each individual query. All connections are automatically closed when the Postgres Pro session ends.

The `close_connections` function can be used to close all cached Oracle connections. This can be useful for long-running sessions that do not access foreign tables all the time and want to avoid blocking the resources needed by an open Oracle connection. You cannot call this function inside a transaction that modifies Oracle data.

H.1.4.3. Columns

When you define a foreign table, the columns of the Oracle table are mapped to the Postgres Pro columns in the order of their definition.

oracle_fdw will only include those columns in the Oracle query that are actually needed by the Postgres Pro query.

The Postgres Pro table can have more or less columns than the Oracle table. If it has more columns, and these columns are used, you will receive a warning and NULL values will be returned.

If you want to `UPDATE` or `DELETE`, make sure that the `key` option is set on all columns that belong to the table's primary key. Failure to do so will result in errors.

H.1.4.4. Data Types

You must define the Postgres Pro columns with data types that oracle_fdw can translate (see the conversion table below). This restriction is only enforced if the column actually gets used, so you can define "dummy" columns for untranslatable data types as long as you don't access them (this trick only works with `SELECT`, not when modifying foreign data). If an Oracle value exceeds the size of the Postgres Pro column (e.g., the length of a `varchar` column or the maximal `integer` value), you will receive a runtime error.

These conversions are automatically handled by oracle_fdw:

```
Oracle type              | Possible PostgreSQL types
-------------------------+--------------------------------------------------
CHAR                     | char, varchar, text
NCHAR                    | char, varchar, text
VARCHAR                  | char, varchar, text
VARCHAR2                 | char, varchar, text, json
NVARCHAR2                | char, varchar, text
CLOB                     | char, varchar, text, json
LONG                     | char, varchar, text
RAW                      | uuid, bytea
BLOB                     | bytea
```

```
BFILE                     | bytea (read-only)
LONG RAW                  | bytea
NUMBER                    | numeric, float4, float8, char, varchar, text
NUMBER(n,m) with m<=0     | numeric, float4, float8, int2, int4, int8,
                          |    boolean, char, varchar, text
FLOAT                     | numeric, float4, float8, char, varchar, text
BINARY_FLOAT              | numeric, float4, float8, char, varchar, text
BINARY_DOUBLE             | numeric, float4, float8, char, varchar, text
DATE                      | date, timestamp, timestamptz, char, varchar, text
TIMESTAMP                 | date, timestamp, timestamptz, char, varchar, text
TIMESTAMP WITH TIME ZONE  | date, timestamp, timestamptz, char, varchar, text
TIMESTAMP WITH            | date, timestamp, timestamptz, char, varchar, text
   LOCAL TIME ZONE        |
INTERVAL YEAR TO MONTH    | interval, char, varchar, text
INTERVAL DAY TO SECOND    | interval, char, varchar, text
XMLTYPE                   | xml, char, varchar, text
MDSYS.SDO_GEOMETRY        | geometry (see "PostGIS support" below)
```

If a `NUMBER` is converted to a `boolean`, 0 means `false`, everything else `true`.

Inserting or updating `XMLTYPE` only works with values that do not exceed the maximum length of the `VARCHAR2` data type (4000 or 32767, depending on the `MAX_STRING_SIZE` parameter).

`NCLOB` is currently not supported because Oracle cannot automatically convert it to the client encoding.

If you want to convert `TIMESTAMP WITH LOCAL TIME ZONE` to `timestamp`, consider setting the `set_time-zone` option on the foreign server.

If you need conversions exceeding the above, define an appropriate view in Oracle or Postgres Pro.

H.1.4.5. `WHERE` Conditions and `ORDER BY` Clauses

Postgres Pro will use all applicable parts of the `WHERE` clause as a filter for the scan. The Oracle query that oracle_fdw constructs will contain a `WHERE` clause corresponding to these filter criteria whenever such a condition can safely be translated to Oracle SQL. This feature, also known as *push-down* of `WHERE` clauses, can greatly reduce the number of rows retrieved from Oracle and may enable Oracle's optimizer to choose a good plan for accessing the required tables.

Similarly, `ORDER BY` clauses will be pushed down to Oracle wherever possible. Note that no `ORDER BY` condition that sorts by a character string will be pushed down as the sort orders in Postgres Pro and Oracle cannot be guaranteed to be the same.

To make use of that, try to use simple conditions for the foreign table. Choose Postgres Pro column data types that correspond to Oracle's types because otherwise conditions cannot be translated.

The expressions `now()`, `transaction_timestamp()`, `current_timestamp`, `current_date`, and `local-timestamp` will be translated correctly.

The output of `EXPLAIN` will show the Oracle query used so you can see which conditions were translated to Oracle and how.

H.1.4.6. Joins Between Foreign Tables

oracle_fdw can push down joins to the Oracle server, that is, a join between two foreign tables will lead to a single Oracle query that performs the join on the Oracle side.

There are some restrictions when this can happen:

- Both tables must be defined on the same foreign server.
- Joins between three or more tables won't be pushed down.

- The join must be in a SELECT statement.
- oracle_fdw must be able to push down all join conditions and WHERE clauses.
- Cross joins without join conditions are not pushed down.
- If a join is pushed down, ORDER BY clauses will not be pushed down.

It is important that table statistics for both foreign tables have been collected with ANALYZE for Postgres Pro to determine the best join strategy.

H.1.4.7. Modifying Foreign Data

oracle_fdw supports INSERT, UPDATE, and DELETE on foreign tables. This is allowed by default (also in databases upgraded from an earlier Postgres Pro release) and can be disabled by setting the readonly table option.

For UPDATE and DELETE to work, the columns corresponding to the primary key columns of the Oracle table must have the key column option set. These columns are used to identify a foreign table row, so make sure that the option is set on *all* columns that belong to the primary key.

If you omit a foreign table column during INSERT, that column is set to the value defined in the DEFAULT clause on the Postgres Pro foreign table (or NULL if there is no DEFAULT clause). DEFAULT clauses on the corresponding Oracle columns are not used. If the Postgres Pro foreign table does not include all columns of the Oracle table, the Oracle DEFAULT clauses will be used for the columns not included in the foreign table definition.

The RETURNING clause on INSERT, UPDATE and DELETE is supported except for columns with Oracle data types LONG and LONG RAW (Oracle doesn't support these data types in the RETURNING clause).

Triggers on foreign tables are supported. Triggers defined with AFTER and FOR EACH ROW require that the foreign table has no columns with Oracle data type LONG or LONG RAW. This is because such triggers make use of the RETURNING clause mentioned above.

While modifying foreign data works, the performance is not particularly good, specifically when many rows are affected, because (owing to the way foreign data wrappers work) each row has to be treated individually.

Transactions are forwarded to Oracle so BEGIN, COMMIT, ROLLBACK, and SAVEPOINT work as expected. Prepared statements involving Oracle are not supported. See the Internals section for details.

Since oracle_fdw uses serialized transactions by default, it is possible that data modifying statements lead to a serialization failure:

```
ORA-08177: can't serialize access for this transaction
```

This can happen if concurrent transactions modify the table and gets more likely in long running transactions. Such errors can be identified by their SQLSTATE (40001). An application using oracle_fdw should retry transactions that fail with this error.

It is possible to use a different transaction isolation level, see Foreign Server Options for a discussion.

H.1.4.8. EXPLAIN

Postgres Pro's EXPLAIN will show the query that is actually issued to Oracle. EXPLAIN VERBOSE will show Oracle's execution plan (that will not work with Oracle server 9i or older, see Problems).

H.1.4.9. ANALYZE

You can use ANALYZE to gather statistics on a foreign table. This is supported by oracle_fdw.

Without statistics, Postgres Pro has no way to estimate the row count for queries on a foreign table, which can cause bad execution plans to be chosen.

Postgres Pro will *not* automatically gather statistics for foreign tables with the autovacuum daemon like it does for normal tables, so it is particularly important to run `ANALYZE` on foreign tables after creation and whenever the remote table has changed significantly.

Keep in mind that analyzing an Oracle foreign table will result in a full sequential table scan. You can use the table option sample_percent to speed this up by using only a sample of the Oracle table.

H.1.4.10. PostGIS Support

The data type `geometry` is only available when PostGIS is installed.

The only supported geometry types are `POINT`, `LINE`, `POLYGON`, `MULTIPOINT`, `MULTILINE`, and `MULTIPOLYGON` in two and three dimensions. Empty PostGIS geometries are not supported because they have no equivalent in Oracle Spatial.

NULL values for Oracle `SRID` will be converted to 0 and vice versa. For other conversions between Oracle `SRID` and PostGIS `SRID`, create a file `srid.map` in the Postgres Pro `share` directory. Each line of this file shall contain an Oracle `SRID` and the corresponding PostGIS `SRID`, separated by a whitespace. Keep the file small for good performance.

H.1.4.11. Support for `IMPORT FOREIGN SCHEMA`

IMPORT FOREIGN SCHEMA is supported to bulk import table definitions for all tables in an Oracle schema. In addition to the documentation of `IMPORT FOREIGN SCHEMA`, consider the following:

- `IMPORT FOREIGN SCHEMA` will create foreign tables for all objects found in `ALL_TAB_COLUMNS`. That includes tables, views and materialized views, but not synonyms.
- These are the supported options for `IMPORT FOREIGN SCHEMA`:
  - `case` controls case folding for table and column names during import.

    The possible values are:

    - `keep`: leave the names as they are in Oracle, usually in upper case.
    - `lower`: translate all table and column names to lower case.
    - `smart`: only translate names that are all upper case in Oracle (this is the default).
  - `collation` is the collation used for case folding for the `lower` and `smart` options of `case`.

    The default value is `default`, which is the database's default collation. Only collations in the `pg_catalog` schema are supported. See the `collname` values in the `pg_collation` catalog for a list of possible values.
  - `dblink` is the Oracle database link through which the schema is accessed.

    This name must be written exactly as it occurs in Oracle's system catalog so normally consist of uppercase letters only.
  - `readonly` sets the readonly option on all imported tables.
  - `skip_tables` (default `false`): don't import tables.
  - `skip_views` (default `false`): don't import views.
  - `skip_matviews` (default `false`): don't import materialized views.
  - `max_long` sets the max_long option on all imported tables.
  - `sample_percent` sets the sample_percent option on all imported tables.
  - `prefetch` sets the prefetch option on all imported tables.
  - `lob_prefetch` sets the lob_prefetch option on all imported tables.
  - `nchar` sets the nchar option on all imported tables.

- `set_timezone` sets the set_timezone option on all imported tables.

- The Oracle schema name must be written exactly as it is in Oracle, so normally in upper case. Since Postgres Pro translates names to lower case before processing, you must protect the schema name with double quotes (for example, `"SCOTT"`).
- Table names in the `LIMIT TO` or `EXCEPT` clause must be written as they will appear in Postgres Pro after the case folding described above.

Note that `IMPORT FOREIGN SCHEMA` does not work with Oracle server 8i; see the Problems section for details.

H.1.5. Reference

H.1.5.1. Objects Created by the Extension

`oracle_fdw_handler() RETURNS fdw_handler`
`oracle_fdw_validator(text[], oid) RETURNS void`

These functions are the handler and validator functions necessary to create a foreign data wrapper.

```
FOREIGN DATA WRAPPER oracle_fdw
  HANDLER oracle_fdw_handler
  VALIDATOR oracle_fdw_validator
```

The extension automatically creates a foreign data wrapper named `oracle_fdw`. Normally, that's all you need, and you can proceed to define foreign servers. You can create additional Oracle foreign data wrappers, for example, if you need to set the nls_lang option (you can alter the existing `oracle_fdw` wrapper, but all modifications will be lost after a dump/restore).

`oracle_close_connections() RETURNS void`

This function can be used to close all open Oracle connections in this session. See Usage for further description.

`oracle_diag(name DEFAULT NULL) RETURNS text`

This function is useful for diagnostic purposes only. It will return the versions of oracle_fdw, Postgres Pro server, and Oracle client. If called with no argument or NULL, it will additionally return the values of some environment variables used for establishing Oracle connections. If called with the name of a foreign server, it will additionally return the Oracle server version.

`oracle_execute(server name, stmt text) RETURNS void`

This function can be used to execute arbitrary SQL statements on the remote Oracle server. That will only work with statements that do not return results (typically DDL statements).

Be careful when using this function since it might disturb the transaction management of oracle_fdw. Remember that running a DDL statement in Oracle will issue an implicit `COMMIT`. You are best advised to use this function outside of multi-statement transactions.

H.1.5.2. Options

H.1.5.2.1. Foreign Data Wrapper Options

Important

If you modify the default foreign data wrapper `oracle_fdw`, any changes will be lost upon dump/restore. Create a new foreign data wrapper if you want the options to be persistent. The SQL script shipped with the software contains a `CREATE FOREIGN DATA WRAPPER` statement you can use.

`[nls_lang]`

Sets the `NLS_LANG` environment variable for Oracle to this value. `NLS_LANG` is in the form *`language_territory.charset`* (for example, `AMERICAN_AMERICA.AL32UTF8`). This must match your database encoding. When this value is not set, oracle_fdw will automatically do the right thing if it can and issue a warning if it cannot. Set this only if you know what you are doing. See the Problems section.

H.1.5.2.2. Foreign Server Options

`dbserver`

The Oracle database connection string for the remote database. This can be in any of the forms that Oracle supports as long as your Oracle client is configured accordingly. Set this to an empty string for local (`BEQUEATH`) connections.

`[isolation_level]`

The transaction isolation level to use at the Oracle database. The value can be `serializable`, `read_committed`, or `read_only`. The default is `serializable`.

Note that the Oracle table can be queried more than once during a single Postgres Pro statement (for example, during a nested loop join). To make sure that no inconsistencies caused by race conditions with concurrent transactions can occur, the transaction isolation level must guarantee read stability. This is only guaranteed with Oracle's `SERIALIZABLE` or `READ ONLY` isolation levels.

Unfortunately Oracle's implementation of `SERIALIZABLE` is rather bad and causes serialization errors (ORA-08177) in unexpected situations, like inserts into the table. Using `READ COMMITTED` transactions works around this problem, but *there is a risk of inconsistencies*. If you want to use it, check your execution plans if the foreign scan could be executed more than once.

`[nchar]`

Setting this option to `on` chooses a more expensive character conversion on the Oracle side. This is required if Oracle tables have `NCHAR` or `NVARCHAR2` columns that contain characters that cannot be represented in the Oracle database character set. The default is `off`.

Setting `nchar` to `on` has a noticable performance impact, and it causes ORA-01461 errors with `UPDATE` statements that set strings over 2000 bytes (or 16383 if you have `MAX_STRING_SIZE = EXTENDED`). This error seems to be an Oracle bug.

`[set_timezone]`

Setting this option to `on` sets the Oracle session time zone to the current value of the Postgres Pro parameter `timezone` when the connection to Oracle is made. This is only useful if you plan to use Oracle columns of type `TIMESTAMP WITH LOCAL TIME ZONE` and want to translate them to `timestamp without time zone` in Postgres Pro. The default is `off`.

Note that if you change `timezone` after the Oracle connection has been established, oracle_fdw will not change the Oracle session time zone. You can call `oracle_close_connections() RETURNS void` in that case so that a new connection is opened the next time you access a foreign table.

If Oracle does not recognize the time zone, connections will fail with an error like “ORA-01882: timezone region not found”.

In that case, either use a different `timezone` or leave the option set to `off` and set the environment variable `ORA_SDTZ` to an appropriate value in the environment of the Postgres Pro server.

H.1.5.2.3. User Mapping Options

`user`

The Oracle user name for the session. Set this to an empty string for *external authentication* if you don't want to store Oracle credentials in the Postgres Pro database (one simple way is to use an *external password store*).

password

The password for the Oracle user.

H.1.5.2.4. Foreign Table Options

table

The Oracle table name. This name must be written exactly as it occurs in Oracle's system catalog so normally consist of uppercase letters only.

To define a foreign table based on an arbitrary Oracle query, set this option to the query enclosed in parentheses:

```
OPTIONS (table '(SELECT col FROM tab WHERE val = ''string'')')
```

Do not set the schema option in this case. INSERT, UPDATE, and DELETE will work on foreign tables defined on simple queries; if you want to avoid that (or confusing Oracle error messages for more complicated queries), use the table option readonly.

dblink

The Oracle database link through which the table is accessed. This name must be written exactly as it occurs in Oracle's system catalog so normally consist of uppercase letters only.

[schema]

The table's schema (or owner). Useful to access tables that do not belong to the connecting Oracle user. This name must be written exactly as it occurs in Oracle's system catalog so normally consist of uppercase letters only.

[max_long]

The maximal length of any LONG, LONG RAW, and XMLTYPE columns in the Oracle table. Possible values are integers between 1 and 1073741823 (the maximal size of a bytea in Postgres Pro). This amount of memory will be allocated at least twice so large values will consume a lot of memory. If max_long is less than the length of the longest value retrieved, you will receive the error message “ORA-01406: fetched column value was truncated”. The default is 32767.

[readonly]

INSERT, UPDATE, and DELETE are only allowed on tables where this option is not set to yes/on/true. The default is false.

[sample_percent]

This option only influences ANALYZE processing and can be useful to ANALYZE very large tables in a reasonable time.

The value must be between 0.000001 and 100 and defines the percentage of Oracle table blocks that will be randomly selected to calculate Postgres Pro table statistics. This is accomplished using the SAMPLE BLOCK (x) clause in Oracle. The default is 100.

ANALYZE will fail with ORA-00933 for tables defined with Oracle queries and may fail with ORA-01446 for tables defined with complex Oracle views.

[prefetch]

Sets the number of rows that will be fetched with a single round-trip between Postgres Pro and Oracle during a foreign table scan. The value must be between 1 and 1000, where a value of zero disables prefetching. The default is 50.

Higher values can speed up performance but will use more memory on the Postgres Pro server.

Note that there is no prefetching if the Oracle table contains columns of the type MDSYS.SDO_GEOMETRY.

[lob_prefetch]

Sets the number of bytes that are prefetched for BLOB, CLOB, and BFILE values. LOBs that exceed that size will require additional round trips between Postgres Pro and Oracle so setting this value bigger than the size of your typical LOB will be good for performance. Choosing bigger values for this option can allocate more memory on the server side but will boost performance for large LOBs. The default is 1048576.

H.1.5.2.5. Column Options

[key]

If set to yes/on/true, the corresponding column on the foreign Oracle table is considered a primary key column. For UPDATE and DELETE to work, you must set this option on all columns that belong to the table's primary key. The default is false.

[strip_zeros]

If set to yes/on/true, ASCII 0 characters will be removed from the string during transfer. Such characters are valid in Oracle but not in Postgres Pro so they will cause an error when read by oracle_fdw. This option only makes sense for character, character varying, and text columns. The default is false.

H.1.6. Problems

H.1.6.1. Encoding

Characters stored in an Oracle database that cannot be converted to the Postgres Pro database encoding will silently be replaced by replacement characters, typically a normal or inverted question mark, by Oracle. You will get no warning or error messages.

If you use a Postgres Pro database encoding that Oracle does not know (currently these are EUC_CN, EUC_KR, LATIN10, MULE_INTERNAL, WIN874, and SQL_ASCII), non-ASCII characters cannot be translated correctly. You will get a warning in this case, and the characters will be replaced by replacement characters as described above.

You can set the nls_lang option of the foreign data wrapper to force a certain Oracle encoding, but the resulting characters will most likely be incorrect and lead to Postgres Pro error messages. This is probably only useful for SQL_ASCII encoding if you know what you are doing.

H.1.6.2. Limited Functionality in Old Oracle Versions

The definition of the Oracle system catalogs V$SQL and V$SQL_PLAN has changed with Oracle 10.1. Using EXPLAIN VERBOSE with older Oracle server versions will result in errors like:

```
ERROR:  error describing query: OCIStmtExecute failed to execute
        remote query for sql_id
DETAIL:  ORA-00904: "LAST_ACTIVE_TIME": invalid identifier
```

There is no plan to fix this, since Oracle 9i has been out of Extended Support since 2010 and the functionality is not essential.

IMPORT FOREIGN SCHEMA throws the following error with Oracle server 8i:

```
ERROR:  error importing foreign schema: OCIStmtExecute failed to execute
        column query
DETAIL:  ORA-00904: invalid column name
```

This is because the view ALL_TAB_COLUMNS lacks the column CHAR_LENGTH, which was added in Oracle 9i.

H.1.6.3. LDAP Libraries

The Oracle client shared library comes with its own LDAP client implementation conforming to *RFC 1823* so these functions have the same names as OpenLDAP's. This will lead to a name collision when the Postgres Pro server was configured `--with-ldap`.

The name collision will not be detected because oracle_fdw is loaded at runtime, but trouble will happen if anybody calls an LDAP function. Typically, OpenLDAP is loaded first so if Oracle calls an LDAP function (for example, if you use *directory naming* name resolution), the backend will crash. This can lead to messages like the following (seen on Linux) in the Postgres Pro server log:

```
../../../libraries/libldap/getentry.c:29: ldap_first_entry:
 Assertion `( (ld)->ld_options.ldo_valid == 0x2 )' failed.
```

Since Postgres Pro is built `--with-ldap`, it may work as long as you don't use any LDAP client functionality in Oracle. On some platforms, you can force Oracle's client shared library to be loaded before the Postgres Pro server is started (`LD_PRELOAD` on Linux). Then Oracle's LDAP functions should get used. In that case, Oracle may be able to use LDAP functionality, but using LDAP from Postgres Pro will crash the backend.

You cannot use LDAP functionality both in Postgres Pro and in Oracle.

H.1.6.4. Serialization Errors

In Oracle 11.2 or above, inserting the first row into a newly created Oracle table with oracle_fdw will lead to a serialization error.

This is because of an Oracle feature called *deferred segment creation*, which defers allocation of storage space for a new table until the first row is inserted. This causes a serialization failure with serializable transactions.

This is no serious problem; you can work around it by either ignoring that first error or creating the table with `SEGMENT CREATION IMMEDIATE`.

A much nastier problem is that concurrent inserts can sometimes cause serialization errors when an index page is split concurrently with a modifying serializable transaction.

Oracle claims that this is not a bug, and the suggested solution is to retry the transaction that got a serialization error.

H.1.6.5. Oracle Bugs

This is the list of Oracle bugs that affect or have affected oracle_fdw in the past.

Bug 2728408 can cause “ORA-8177 cannot serialize access for this transaction” even if no modification of remote data is attempted. It can occur with Oracle server 8.1.7.4 (install one-off patch 2728408) or Oracle server 9.2 (install Patch Set 9.2.0.4 or better).

Oracle client 21c is known not to work for `CLOB` columns (they appear empty). There is no ultimate proof that that is an Oracle bug, but other versions are working fine.

H.1.7. Authors

Laurenz Albe, with notable contributions from Vincent Mora of Oslandia and Tatsuro Yamada of the NTT OSS Center.

H.2. tds_fdw

The `tds_fdw` module provides the foreign data wrapper tds_fdw, which can connect to databases that use the Tabular Data Stream (TDS) protocol, such as *Sybase* databases and *Microsoft SQL Server*.

This foreign data wrapper requires a library that implements the DB-Library interface, such as FreeTDS. This has been tested with FreeTDS, but not the proprietary implementations of DB-Library.

H.2.1. Limitations

Unlike `WHERE` and column pushdowns, which are supported when `match_column_names` is enabled, `JOIN` pushdown or write operations are not supported.

H.2.2. Installing tds_fdw

tds_fdw is provided with Postgres Pro Standard as a separate pre-built package `tds-fdw` (for the detailed installation instructions, see Chapter 16).

Install the `tds_fdw` extension using CREATE EXTENSION.

H.2.3. Configuring tds_fdw

H.2.3.1. Managing Character Sets/Encoding

Although many newer versions of the TDS protocol will only use USC-2 to communicate with the server, FreeTDS converts the UCS-2 to the client character set of your choice. To set the client character set, you can set `client charset` in `freetds.conf`. See *The `freetds.conf` File* and *Localization and TDS 7.0* for details.

You may need more configuring in case you get an error like this with Microsoft SQL Server when working with Unicode data:

```
NOTICE: DB-Library notice: Msg #: 4004, Msg state: 1, Msg: Unicode data in a Unicode-only
collation or ntext data cannot be sent to clients using DB-Library (such as ISQL) or ODBC
version 3.7 or earlier., Server: PILLIUM\SQLEXPRESS, Process: , Line: 1, Level: 16

ERROR: DB-Library error: DB #: 4004, DB Msg: General SQL Server error: Check messages
from the SQL Server, OS #: -1, OS Msg: (null), Level: 16
```

In this case, you may have to manually set tds version in `freetds.conf` to 7.0 or higher. See *The `freetds.conf` File* and *Choosing a TDS protocol version* for details.

H.2.3.2. Configuring Encrypted Connections to MSSQL

This needs to be configured at the `freetds.conf`. See *The `freetds.conf` File* and under `freetds.conf settings`, look for encryption.

H.2.4. Usage

To prepare for database access using tds_fdw:

1. Create a foreign server object, using CREATE SERVER, to represent each database you want to connect to.
2. Create a user mapping, using CREATE USER MAPPING, for each database user you want to allow to access each foreign server.
3. Create a foreign table, using CREATE FOREIGN TABLE or IMPORT FOREIGN SCHEMA, for each table you want to access.

H.2.4.1. Creating a Foreign Server

To create a foreign server, execute the CREATE SERVER command providing the following options:

`servername`

The servername, address or hostname of the foreign server. This can be a DSN, as specified in `freetds.conf`. See *FreeTDS name lookup* for details. You can set this option to a comma-separated list of server names, then each server is tried until the first connection succeeds. This is useful for automatic failover to a secondary server.

Required: Yes

Default: 127.0.0.1

`port`

The port of the foreign server. Instead of providing a port here, it can be specified in `freetds.conf` (if `servername` is a DSN).

Required: No

`database`

The database to connect to for this server

Required: No

`dbuse`

If `dbuse` is 0, tds_fdw will connect directly to `database`. If `dbuse` is not 0, tds_fdw will connect to the server's default database and then select the database by calling the DB-Library's `dbuse()` function. For Azure, `dbuse` currently needs to be set to 0.

Required: No

Default: 0

`language`

The language to use for messages and the locale to use for date formats. FreeTDS may default to U.S. English on most systems. You can probably also change this in `freetds.conf`. For information related to this for MS SQL Server, see *`SET LANGUAGE` in MS SQL Server*. For information related to Sybase ASE, see *Sybase ASE login options* and *`SET LANGUAGE` in Sybase ASE*.

Required: No

`character_set`

The client character set to use for the connection if you need to set this for some reason. For TDS protocol versions 7.0+, the connection always uses UCS-2, so this parameter does nothing in those cases. See *Localization and TDS 7.0* for details.

Required: No

`tds_version`

The version of the TDS protocol to use for this server. See *Choosing a TDS protocol version* and *History of TDS Versions* for details.

Required: No

`msg_handler`

The function used for the TDS message handler. Can be one of the following values:

- `notice`: TDS messages are turned into PostgreSQL notices
- `blackhole`: TDS messages are ignored

Required: No

Default: `blackhole`

`fdw_startup_cost`

A cost that is used in query planning to represent the overhead of using this foreign data wrapper.

Required: No

`fdw_tuple_cost`

A cost that is used in query planning to represent the overhead of fetching rows from this server.

Required: No

`sqlserver_ansi_mode`

A cost that is used to represent the overhead of fetching rows from this server used in query planning.

This option is supported for SQL Server only. Setting this to `true` will enable the following server-side settings after a successful connection to the foreign server:

- `CONCAT_NULLS_YIELDS_NULL ON`
- `ANSI_NULLS ON`
- `ANSI_WARNINGS ON`
- `QUOTED_IDENTIFIER ON`
- `ANSI_PADDING ON`
- `ANSI_NULL_DFLT_ON ON`

Those parameters in summary are comparable to the SQL Server option `ANSI_DEFAULTS`. In contrast, `sqlserver_ansi_mode` currently does not activate the following options:

- `CURSOR_CLOSE_ON_COMMIT`
- `IMPLICIT_TRANSACTIONS`

This follows the behavior of the native ODBC and OLEDB driver for SQL servers, which explicitly turn them off if not configured otherwise.

Required: No

Default: `false`

Some foreign table options can also be set at the server level. Those include:

- `use_remote_estimate`
- `row_estimate_method`

Example H.1. Create a Foreign Server

```
CREATE SERVER mssql_svr
    FOREIGN DATA WRAPPER tds_fdw
    OPTIONS (servername '127.0.0.1', port '1433', database 'tds_fdw_test', tds_version
 '7.1');
```

H.2.4.2. Creating a User Mapping

To create a user mapping, execute the CREATE USER MAPPING command providing the following options:

`username`

The username of the account on the foreign server

> **Important**
>
> If you are using Azure SQL, then your username for the foreign server will need to be in the format `username@servername`. If you only use the username, the authentication will fail.

Required: Yes

`password`

The password of the account on the foreign server

Required: Yes

Example H.2. Create a User Mapping

```
CREATE USER MAPPING FOR postgres
    SERVER mssql_svr
    OPTIONS (username 'sa', password '');
```

H.2.4.3. Creating a Foreign Table

To create a foreign table, execute the CREATE FOREIGN TABLE command providing the following options:

`query`

The query string to use to query the foreign table

Required: Yes (mutually exclusive with `table_name`)

`schema_name`

The schema that the table is in. The schema name can also be included in `table_name`.

Required: No

`table_name`

The table on the foreign server to query

Aliases: *table*

Required: Yes (mutually exclusive with `query`)

`match_column_names`

Match local columns with remote columns by comparing their table names instead of using the order in which they appear in the result set. Required for `WHERE` and column pushdowns.

Required: No

`use_remote_estimate`

Estimate the size of the table by performing some operation on the remote server, as defined by `row_estimate_method`, instead of using the local estimate, as defined by `local_tuple_estimate`

Required: No

`local_tuple_estimate`

A locally set estimate of the number of tuples that is used when `use_remote_estimate` is disabled

Required: No

`row_estimate_method`

Can be one of the following values:

- `execute`: Execute the query on the remote server and get the actual number of rows in the query
- `showplan_all`: Get the estimated number of rows using *MS SQL Server's* *`SET SHOWPLAN_ALL`*

Required: No

Default: `execute`

Example H.3. Create a Foreign Table

Using a `table_name` definition:

```
CREATE FOREIGN TABLE mssql_table (
    id integer,
    data varchar)
    SERVER mssql_svr
    OPTIONS (table_name 'dbo.mytable', row_estimate_method 'showplan_all');
```

Using a `schema_name` and `table_name` definition:

```
CREATE FOREIGN TABLE mssql_table (
    id integer,
    data varchar)
    SERVER mssql_svr
    OPTIONS (schema_name 'dbo', table_name 'mytable', row_estimate_method
 'showplan_all');
```

Using a `query` definition:

```
CREATE FOREIGN TABLE mssql_table (
    id integer,
    data varchar)
    SERVER mssql_svr
    OPTIONS (query 'SELECT * FROM dbo.mytable', row_estimate_method 'showplan_all');
```

Setting a remote column name:

```
CREATE FOREIGN TABLE mssql_table (
    id integer,
    col2 varchar OPTIONS (column_name 'data'))
    SERVER mssql_svr
    OPTIONS (schema_name 'dbo', table_name 'mytable', row_estimate_method
 'showplan_all');
```

H.2.4.4. Importing a Foreign Schema

To import a foreign schema, execute the IMPORT FOREIGN SCHEMA command providing the following options:

`import_default`

Controls whether column `DEFAULT` expressions are included in the definitions of foreign tables

Required: No

Default: false

`import_not_null`

Controls whether column `NOT NULL` constraints are included in the definitions of foreign tables

Required: No

Default: true

Example H.4. Import a Foreign Schema

```
IMPORT FOREIGN SCHEMA dbo
    EXCEPT (mssql_table)
    FROM SERVER mssql_svr
```

```
    INTO public
    OPTIONS (import_default 'true');
```

H.2.4.5. Setting Variables

To set a variable, execute the SET command.

The following variables are available:

`tds_fdw.show_before_row_memory_stats`

Print memory context stats to the Postgres Pro log before each row is fetched

`tds_fdw.show_after_row_memory_stats`

Print memory context stats to the Postgres Pro log after each row is fetched

`tds_fdw.show_finished_memory_stats`

Print memory context stats to the Postgres Pro log when a query is finished

Example H.5. Set a Variable

```
postgres=# SET tds_fdw.show_finished_memory_stats=1;
SET
```

H.2.4.6. Viewing the Query Issued on the Remote System

To view the query issued on the remote system, execute the EXPLAIN `[ VERBOSE ]` command.

H.2.5. Author

Geoff Montee

Appendix I. Additional Supplied Programs

This appendix, Appendix F, and Appendix G contain information regarding additional modules available in the Postgres Pro Standard distribution. See Appendix F and Appendix G for more information about the server extensions and plug-ins.

This appendix covers the utility programs. Once installed, they are found in the `bin` directory of the Postgres Pro Standard installation and can be used like any other program.

I.1. Additional PostgreSQL/Postgres Pro Client Applications

This section covers PostgreSQL/Postgres Pro additional client applications included in the Postgres Pro Standard distribution. They can be run from anywhere, independent of where the database server resides. See also Postgres Pro Client Applications for information about client applications that are part of the core Postgres Pro Standard distribution.

oid2name

oid2name — resolve OIDs and file nodes in a Postgres Pro data directory

Synopsis

`oid2name` [*option*...]

Description

oid2name is a utility program that helps administrators to examine the file structure used by Postgres Pro. To make use of it, you need to be familiar with the database file structure, which is described in Chapter 67.

> **Note**
>
> The name “oid2name” is historical, and is actually rather misleading, since most of the time when you use it, you will really be concerned with tables' filenode numbers (which are the file names visible in the database directories). Be sure you understand the difference between table OIDs and table filenodes!

oid2name connects to a target database and extracts OID, filenode, and/or table name information. You can also have it show database OIDs or tablespace OIDs.

Options

oid2name accepts the following command-line arguments:

`-f` *`filenode`*
`--filenode=`*`filenode`*

show info for table with filenode *`filenode`*.

`-i`
`--indexes`

include indexes and sequences in the listing.

`-o` *`oid`*
`--oid=`*`oid`*

show info for table with OID *`oid`*.

`-q`
`--quiet`

omit headers (useful for scripting).

`-s`
`--tablespaces`

show tablespace OIDs.

`-S`
`--system-objects`

include system objects (those in `information_schema`, `pg_toast` and `pg_catalog` schemas).

`-t` *`tablename_pattern`*
`--table=`*`tablename_pattern`*

show info for table(s) matching *`tablename_pattern`*.

`-V`
`--version`

Print the oid2name version and exit.

`-x`
`--extended`

display more information about each object shown: tablespace name, schema name, and OID.

`-?`
`--help`

Show help about oid2name command line arguments, and exit.

oid2name also accepts the following command-line arguments for connection parameters:

`-d` *database*
`--dbname=`*database*

database to connect to.

`-h` *host*
`--host=`*host*

database server's host.

`-H` *host*

database server's host. Use of this parameter is *deprecated* as of Postgres Pro 12.

`-p` *port*
`--port=`*port*

database server's port.

`-U` *username*
`--username=`*username*

user name to connect as.

To display specific tables, select which tables to show by using `-o`, `-f` and/or `-t`. `-o` takes an OID, `-f` takes a filenode, and `-t` takes a table name (actually, it's a `LIKE` pattern, so you can use things like `foo%`). You can use as many of these options as you like, and the listing will include all objects matched by any of the options. But note that these options can only show objects in the database given by `-d`.

If you don't give any of `-o`, `-f` or `-t`, but do give `-d`, it will list all tables in the database named by `-d`. In this mode, the `-S` and `-i` options control what gets listed.

If you don't give `-d` either, it will show a listing of database OIDs. Alternatively you can give `-s` to get a tablespace listing.

Environment

`PGHOST`
`PGPORT`
`PGUSER`

Default connection parameters.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see Section 33.15).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

Notes

oid2name requires a running database server with non-corrupt system catalogs. It is therefore of only limited use for recovering from catastrophic database corruption situations.

Examples

```
$ # what's in this database server, anyway?
$ oid2name
All databases:
    Oid  Database Name  Tablespace
----------------------------------
  17228       alvherre  pg_default
  17255     regression  pg_default
  17227      template0  pg_default
      1      template1  pg_default

$ oid2name -s
All tablespaces:
     Oid  Tablespace Name
-------------------------
    1663       pg_default
    1664        pg_global
  155151         fastdisk
  155152          bigdisk

$ # OK, let's look into database alvherre
$ cd $PGDATA/base/17228

$ # get top 10 db objects in the default tablespace, ordered by size
$ ls -lS * | head -10
-rw-------  1 alvherre alvherre 136536064 sep 14 09:51 155173
-rw-------  1 alvherre alvherre  17965056 sep 14 09:51 1155291
-rw-------  1 alvherre alvherre   1204224 sep 14 09:51 16717
-rw-------  1 alvherre alvherre    581632 sep  6 17:51 1255
-rw-------  1 alvherre alvherre    237568 sep 14 09:50 16674
-rw-------  1 alvherre alvherre    212992 sep 14 09:51 1249

Description

pg_probackup is a utility to manage backup and recovery of Postgres Pro database clusters. It is designed to perform periodic backups of the Postgres Pro instance that enable you to restore the server in case of a failure. pg_probackup supports PostgreSQL 11 or higher.

- Overview
- Quick Start
- Installation and Setup
- Command-Line Reference
- Usage

Overview

As compared to other backup solutions, pg_probackup offers the following benefits that can help you implement different backup strategies and deal with large amounts of data:

- Incremental backup: with three different incremental modes, you can plan the backup strategy in accordance with your data flow. Incremental backups allow you to save disk space and speed up backup as compared to taking full backups. It is also faster to restore the cluster by applying incremental backups than by replaying WAL files.
- Incremental restore: speed up restore from a backup by reusing valid unchanged pages available in PGDATA.
- Validation: automatic data consistency checks and on-demand backup validation without actual data recovery.
- Verification: on-demand verification of Postgres Pro instance with the `checkdb` command.
- Retention: managing WAL archive and backups in accordance with retention policy. You can configure retention policy based on recovery time or the number of backups to keep, as well as specify time to live (TTL) for a particular backup. Expired backups can be merged or deleted.
- Parallelization: running `backup`, `restore`, `merge`, `delete`, `validate`, and `checkdb` processes on multiple parallel threads.
- Compression: storing backup data in a compressed state to save disk space.
- Deduplication: saving disk space by excluding non-data files (such as `_vm` or `_fsm`) from incremental backups if these files have not changed since they were copied into one of the previous backups in this incremental chain.
- Remote operations: backing up Postgres Pro instance located on a remote system or restoring a backup remotely.
- Backups from a standby: avoiding extra load on the primary by taking backups from a standby server.
- External directories: backing up files and directories located outside of the Postgres Pro data directory (`PGDATA`), such as scripts, configuration files, logs, or SQL dump files.
- Backup catalog: getting the list of backups and the corresponding meta information in plain text or JSON formats.
- Archive catalog: getting the list of all WAL timelines and the corresponding meta information in plain text or JSON formats.
- Partial restore: restoring only the specified databases.
- Catchup: cloning a Postgres Pro instance for a fallen-behind standby server to “catch up” with the primary.

To manage backup data, pg_probackup creates a *backup catalog*. This is a directory that stores all backup files with additional meta information, as well as WAL archives required for point-in-time recovery. You can store backups for different instances in separate subdirectories of a single backup catalog.

Using pg_probackup, you can take full or incremental backups:

- FULL backups contain all the data files required to restore the database cluster.
- Incremental backups operate at the page level, only storing the data that has changed since the previous backup. It allows you to save disk space and speed up the backup process as compared to taking full backups. It is also faster to restore the cluster by applying incremental backups than by replaying WAL files. pg_probackup supports the following modes of incremental backups:

  - DELTA backup. In this mode, pg_probackup reads all data files in the data directory and copies only those pages that have changed since the previous backup. This mode can impose read-only I/O pressure equal to a full backup.
  - PAGE backup. In this mode, pg_probackup scans all WAL files in the archive from the moment the previous full or incremental backup was taken. Newly created backups contain only the pages that were mentioned in WAL records. This requires all the WAL files since the previous backup to be present in the WAL archive. If the size of these files is comparable to the total size of the database cluster files, speedup is smaller, but the backup still takes less space. You have to configure WAL archiving as explained in Setting up continuous WAL archiving to make PAGE backups.

- PTRACK backup. In this mode, Postgres Pro tracks page changes on the fly. Continuous archiving is not necessary for it to operate. Each time a relation page is updated, this page is marked in a special PTRACK bitmap. Tracking implies some minor overhead on the database server operation, but speeds up incremental backups significantly.

> **Warning**
>
> After promoting a standby server to primary and switching timelines, take the first backup in **either FULL or DELTA mode**. Using other backup modes in this case may result in data corruption.

pg_probackup can take only physical online backups, and online backups require WAL for consistent recovery. So regardless of the chosen backup mode (FULL, PAGE or DELTA), any backup taken with pg_probackup must use one of the following *WAL delivery modes*:

- ARCHIVE. Such backups rely on continuous archiving to ensure consistent recovery. This is the default WAL delivery mode.
- STREAM. Such backups include all the files required to restore the cluster to a consistent state at the time the backup was taken. Regardless of continuous archiving having been set up or not, the WAL segments required for consistent recovery are streamed via replication protocol during backup and included into the backup files. That's why such backups are called *autonomous*, or *standalone*.

Limitations

pg_probackup currently has the following limitations:

- The remote mode is not supported on Windows systems.
- On Unix systems, for Postgres Pro, a backup can be made only by the same OS user that has started the Postgres Pro server. For example, if Postgres Pro server is started by user `postgres`, the `backup` command must also be run by user `postgres`. To satisfy this requirement when taking backups in the remote mode using SSH, you must set `--remote-user` option to `postgres`.
- The Postgres Pro server from which the backup was taken and the restored server must be compatible by the block_size and wal_block_size parameters and have the same major release number. Depending on cluster configuration, Postgres Pro itself may apply additional restrictions, such as CPU architecture or libc/icu versions.

Quick Start

To quickly get started with pg_probackup, complete the steps below. This will set up FULL and DELTA backups in the remote mode and demonstrate some basic pg_probackup operations. In the following, these terms are used:

- `backup` — Postgres Pro role used to connect to the Postgres Pro cluster.
- `backupdb` — database used to connect to the Postgres Pro cluster.
- `backup_host` — host with the backup catalog.
- `backup_user` — user on `backup_host` running all pg_probackup operations.
- `/mnt/backups` — directory on `backup_host` where the backup catalog is stored.
- `postgres_host` — host with the Postgres Pro cluster.
- `postgres` — user on `postgres_host` under which Postgres Pro cluster processes are running.
- `/var/lib/pgpro/std-16/data` — Postgres Pro data directory on `postgres_host`.

Steps to perform:

1. Install pg_probackup on both `backup_host` and `postgres_host`.
2. Set up an SSH connection from `backup_host` to `postgres_host`.
3. Configure your database cluster for STREAM backups.
4. Initialize the backup catalog:

```
backup_user@backup_host:~$ pg_probackup init -B /mnt/backups
INFO: Backup catalog '/mnt/backups' successfully initialized
```

5. Add a backup instance called `mydb` to the backup catalog:

```
backup_user@backup_host:~$ pg_probackup add-instance \
    -B /mnt/backups \
    -D /var/lib/pgpro/std-16/data \
    --instance=node \
    --remote-host=postgres_host \
    --remote-user=postgres
INFO: Instance 'node' successfully initialized
```

6. Make a FULL backup:

```
backup_user@backup_host:~$ pg_probackup backup \
    -B /mnt/backups \
    -b FULL \
    --instance=node \
    --stream \
    --compress-algorithm=zstd \
    --remote-host=postgres_host \
    --remote-user=postgres \
    -U backup \
    -d backupdb
INFO: Backup start, pg_probackup version: 2.7.3, instance: node, backup ID: SBOL6J,
 backup mode: FULL, wal mode: STREAM, remote: true, compress-algorithm: zstd,
 compress-level: 1
WARNING:  pgpro_edition() function is old-style and will be removed in future major
 release, use pgpro_edition GUC variable instead.
INFO: This PostgreSQL instance was initialized with data block checksums. Data
 block corruption will be detected
INFO: Database backup start
INFO: wait for pg_backup_start()
INFO: PGDATA size: 96MB
INFO: Current Start LSN: 0/8000028, TLI: 1
INFO: Start transferring data files
INFO: Data files are transferred, time elapsed: 2s
INFO: wait for pg_stop_backup()
INFO: pg_stop_backup() successfully executed
INFO: stop_stream_lsn 0/9000000 currentpos 0/9000000
INFO: backup->stop_lsn 0/8004E40
INFO: Getting the Recovery Time from WAL
INFO: Syncing backup files to disk
INFO: Backup files are synced, time elapsed: 1s
INFO: Validating backup SBOL6J
INFO: Backup SBOL6J data files are valid
INFO: Backup SBOL6J resident size: 53MB
INFO: Backup SBOL6J completed
```

7. List the backups of the instance:

```
backup_user@backup_host:~$ pg_probackup show \
        -B /mnt/backups \
        --instance=node
================================================================================
 Instance  Version  ID      Recovery Time                  Mode  WAL Mode  TLI
 Time  Data   WAL  Zalg  Zratio  Start LSN  Stop LSN   Status
================================================================================
```

```
 node      17       SBOL6J  2024-04-09 18:18:21.970314+03  FULL  STREAM    1/0
 4s  37MB  16MB  zstd    2.57  0/8000028  0/8004E40  OK
```

8. Make an incremental backup in the DELTA mode:

```
backup_user@backup_host:~$ pg_probackup backup \
    -B /mnt/backups \
    -b DELTA \
    --instance=node \
    --stream \
    --compress-algorithm=zstd \
    --remote-host=postgres_host \
    --remote-user=postgres \
    -U backup \
    -d backupdb
INFO: Backup start, pg_probackup version: 2.7.3, instance: node, backup ID: SBOL6N,
 backup mode: DELTA, wal mode: STREAM, remote: true, compress-algorithm: zstd,
 compress-level: 1
WARNING:  pgpro_edition() function is old-style and will be removed in future major
 release, use pgpro_edition GUC variable instead.
INFO: This PostgreSQL instance was initialized with data block checksums. Data
 block corruption will be detected
INFO: Database backup start
INFO: wait for pg_backup_start()
INFO: Parent backup: SBOL6J
INFO: PGDATA size: 96MB
INFO: Current Start LSN: 0/9000028, TLI: 1
INFO: Parent Start LSN: 0/8000028, TLI: 1
INFO: Start transferring data files
INFO: Data files are transferred, time elapsed: 1s
INFO: wait for pg_stop_backup()
INFO: pg_stop_backup() successfully executed
INFO: stop_stream_lsn 0/A000000 currentpos 0/A000000
INFO: backup->stop_lsn 0/9000190
INFO: Getting the Recovery Time from WAL
INFO: Syncing backup files to disk
INFO: Backup files are synced, time elapsed: 0
INFO: Validating backup SBOL6N
INFO: Backup SBOL6N data files are valid
INFO: Backup SBOL6N resident size: 17MB
INFO: Backup SBOL6N completed
```

9. Add or modify some parameters in the pg_probackup configuration file, so that you do not have to specify them each time on the command line:

```
backup_user@backup_host:~$ pg_probackup set-config \
    -B /mnt/backups \
    --instance=node \
    --remote-host=postgres_host \
    --remote-user=postgres \
    -U backup \
    -d backupdb
```

10. Check the configuration of the instance:

```
backup_user@backup_host:~$ pg_probackup show-config \
    -B /mnt/backups \
    --instance=node
# Backup instance information
pgdata = /var/lib/pgpro/std-16/data
```

```
system-identifier = 7355886958826772732
xlog-seg-size = 16777216
# Connection parameters
pgdatabase = backupdb
pghost = postgres_host
pguser = backup
# Archive parameters
archive-timeout = 5min
# Logging parameters
log-level-console = INFO
log-level-file = OFF
log-format-console = PLAIN
log-format-file = PLAIN
log-filename = pg_probackup.log
log-rotation-size = 0TB
log-rotation-age = 0d
# Retention parameters
retention-redundancy = 0
retention-window = 0
wal-depth = 0
# Compression parameters
compress-algorithm = none
compress-level = 1
# Remote access parameters
remote-proto = ssh
remote-host = postgres_host
remote-user = postgres
```

Note that the parameters not modified via `set-config` retain their default values.

11. Make another incremental backup in the DELTA mode, omitting the parameters stored in the configuration file earlier:

```
backup_user@backup_host:~$ pg_probackup backup \
    -B /mnt/backups \
    -b DELTA \
    --instance=node \
    --stream \
    --compress-algorithm=zstd
INFO: Backup start, pg_probackup version: 2.7.3, instance: node, backup ID: SBOL6P,
 backup mode: DELTA, wal mode: STREAM, remote: true, compress-algorithm: zstd,
 compress-level: 1
WARNING:  pgpro_edition() function is old-style and will be removed in future major
 release, use pgpro_edition GUC variable instead.
INFO: This PostgreSQL instance was initialized with data block checksums. Data
 block corruption will be detected
INFO: Database backup start
INFO: wait for pg_backup_start()
INFO: Parent backup: SBOL6N
INFO: PGDATA size: 96MB
INFO: Current Start LSN: 0/A000028, TLI: 1
INFO: Parent Start LSN: 0/9000028, TLI: 1
INFO: Start transferring data files
INFO: Data files are transferred, time elapsed: 1s
INFO: wait for pg_stop_backup()
INFO: pg_stop_backup() successfully executed
INFO: stop_stream_lsn 0/B000000 currentpos 0/B000000
INFO: backup->stop_lsn 0/A000190
INFO: Getting the Recovery Time from WAL
```

```
INFO: Syncing backup files to disk
INFO: Backup files are synced, time elapsed: 0
INFO: Validating backup SBOL6P
INFO: Backup SBOL6P data files are valid
INFO: Backup SBOL6P resident size: 17MB
INFO: Backup SBOL6P completed
```

12. List the backups of the instance again:

```
backup_user@backup_host:~$ pg_probackup show \
    -B /mnt/backups \
    --instance=node
========================================================================================
 Instance  Version  ID      Recovery Time                  Mode   WAL Mode  TLI
 Time    Data   WAL  Zalg  Zratio  Start LSN  Stop LSN   Status
========================================================================================
 node      17       SBOL6P  2024-04-09 18:18:26.630175+03  DELTA  STREAM    1/1
 1s  1147kB  16MB  zstd    1.00  0/A000028  0/A000190  OK
 node      17       SBOL6N  2024-04-09 18:18:25.015713+03  DELTA  STREAM    1/1
 2s  1160kB  16MB  zstd    1.04  0/9000028  0/9000190  OK
 node      17       SBOL6J  2024-04-09 18:18:21.970314+03  FULL   STREAM    1/0
 4s    37MB  16MB  zstd    2.57  0/8000028  0/8004E40  OK
```

13. Restore the data from the latest available backup to an arbitrary location:

```
backup_user@backup_host:~$ pg_probackup restore \
    -B /mnt/backups \
    -D /var/lib/pgpro/std-16/staging-data \
    --instance=node
INFO: Validating parents for backup SBOL6P
INFO: Validating backup SBOL6J
INFO: Backup SBOL6J data files are valid
INFO: Validating backup SBOL6N
INFO: Backup SBOL6N data files are valid
INFO: Validating backup SBOL6P
INFO: Backup SBOL6P data files are valid
INFO: Backup SBOL6P WAL segments are valid
INFO: Backup SBOL6P is valid.
INFO: Restoring the database from the backup starting at 2024-04-09 18:18:25+03 on
 localhost
INFO: Start restoring backup files. PGDATA size: 112MB
INFO: Backup files are restored. Transferred bytes: 112MB, time elapsed: 2s
INFO: Restore incremental ratio (less is better): 100% (112MB/112MB)
INFO: Syncing restored files to disk
INFO: Restored backup files are synced, time elapsed: 1s
INFO: Restore of backup SBOL6P completed.
```

Installation and Setup

Once you have pg_probackup installed, complete the following setup:

- Initialize the backup catalog.
- Add a new backup instance to the backup catalog.
- Configure the database cluster to enable pg_probackup backups.
- Optionally, configure SSH for running pg_probackup operations in the remote mode.

Initializing the Backup Catalog

pg_probackup stores all WAL and backup files in the corresponding subdirectories of the backup catalog.

To initialize the backup catalog, run the following command:

```
pg_probackup init -B backup_dir
```

where *backup_dir* is the path to the backup catalog. If the *backup_dir* already exists, it must be empty. Otherwise, pg_probackup returns an error.

The user launching pg_probackup must have full access to the *backup_dir* directory.

pg_probackup creates the *backup_dir* backup catalog, with the following subdirectories:

- `wal/` — directory for WAL files.
- `backups/` — directory for backup files.

Once the backup catalog is initialized, you can add a new backup instance.

Adding a New Backup Instance

pg_probackup can store backups for multiple database clusters in a single backup catalog. To set up the required subdirectories, you must add a backup instance to the backup catalog for each database cluster you are going to back up.

To add a new backup instance, run the following command:

```
pg_probackup add-instance -B backup_dir -D data_dir --instance=instance_name
 [remote_options]
```

Where:

- *data_dir* is the data directory of the cluster you are going to back up. To set up and use pg_probackup, write access to this directory is required.
- *instance_name* is the name of the subdirectories that will store WAL and backup files for this cluster.
- remote_options are optional parameters that need to be specified only if *data_dir* is located on a remote system.

pg_probackup creates the *instance_name* subdirectories under the `backups/` and `wal/` directories of the backup catalog. The `backups/`*instance_name* directory contains the `pg_probackup.conf` configuration file that controls pg_probackup settings for this backup instance. If you run this command with the remote_options, the specified parameters will be added to `pg_probackup.conf`.

For details on how to fine-tune pg_probackup configuration, see the section called “Configuring pg_probackup”.

The user launching pg_probackup must have full access to *backup_dir* directory and at least read-only access to *data_dir* directory. If you specify the path to the backup catalog in the `BACKUP_PATH` environment variable, you can omit the corresponding option when running pg_probackup commands.

> **Note**
>
> For Postgres Pro 11 or higher, it is recommended to use the group access feature, so that backups can be done by any OS user in the same group as the cluster owner. In this case, the user should have read permissions for the cluster directory.

Configuring the Database Cluster

Although pg_probackup can be used by a superuser, it is recommended to create a separate role with the minimum permissions required for the chosen backup strategy. In these configuration instructions, the `backup` role is used as an example.

For security reasons, it is recommended to run the configuration SQL queries below in a separate database.

```
postgres=# CREATE DATABASE backupdb;
postgres=# \c backupdb
```

To perform a backup, the following permissions for role `backup` are required only in the database **used for connection** to the Postgres Pro server.

For Postgres Pro versions 11 — 14:

```
BEGIN;
CREATE ROLE backup WITH LOGIN;
GRANT USAGE ON SCHEMA pg_catalog TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_start_backup(text, boolean, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_stop_backup(boolean, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_wal() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_last_wal_replay_lsn() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_control_checkpoint() TO backup;
COMMIT;
```

For Postgres Pro 15 or higher:

```
BEGIN;
CREATE ROLE backup WITH LOGIN;
GRANT USAGE ON SCHEMA pg_catalog TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_backup_start(text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_backup_stop(boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_wal() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_last_wal_replay_lsn() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_control_checkpoint() TO backup;
COMMIT;
```

In the pg_hba.conf file, allow connection to the database cluster on behalf of the `backup` role.

Since pg_probackup needs to read cluster files directly, pg_probackup must be started by (or connected to, if used in the remote mode) the OS user that has read access to all files and directories inside the data directory (`PGDATA`) you are going to back up.

Depending on whether you plan to take standalone or archive backups, Postgres Pro cluster configuration will differ, as specified in the sections below. To back up the database cluster from a standby server, run pg_probackup in the remote mode, or create PTRACK backups, additional setup is required.

For details, see the sections Setting up STREAM Backups, Setting up continuous WAL archiving, Setting up Backup from Standby, Configuring the Remote Mode, Setting up Partial Restore, and Setting up PTRACK Backups.

Setting up STREAM Backups

To set up the cluster for STREAM backups, complete the following steps:

- If the `backup` role does not exist, create it with the `REPLICATION` privilege when Configuring the Database Cluster:

  ```
  CREATE ROLE backup WITH LOGIN REPLICATION;
  ```

- If the `backup` role already exists, grant it with the `REPLICATION` privilege:

  ```
  ALTER ROLE backup WITH REPLICATION;
  ```

- In the pg_hba.conf file, allow replication on behalf of the `backup` role.
- Make sure the parameter max_wal_senders is set high enough to leave at least one session available for the backup process.
- Set the parameter wal_level to be higher than `minimal`.

If you are planning to take PAGE backups in the STREAM mode or perform PITR with STREAM backups, you still have to configure WAL archiving, as explained in the section Setting up continuous WAL archiving.

Once these steps are complete, you can start taking FULL, PAGE, DELTA, and PTRACK backups in the STREAM WAL mode.

> **Note**
>
> If you are planning to rely on .pgpass for authentication when running backup in STREAM mode, then .pgpass must contain credentials for `replication` database, used to establish connection via replication protocol. Example: pghost:5432:replication:backup_user:my_strong_password

Setting up Continuous WAL Archiving

Making backups in the PAGE backup mode, performing PITR and making backups with the ARCHIVE WAL delivery mode require continuous WAL archiving to be enabled. To set up continuous archiving in the cluster, complete the following steps:

- Make sure the wal_level parameter is higher than `minimal`.
- If you are configuring archiving on the primary, archive_mode must be set to `on` or `always`. To perform archiving on a standby, set this parameter to `always`.
- Set the archive_command parameter, as follows:

  ```
  archive_command = '"install_dir/pg_probackup" archive-push -B "backup_dir" --
  instance=instance_name --wal-file-name=%f [remote_options]'
  ```

where *`install_dir`* is the installation directory of the pg_probackup version you are going to use, *`backup_dir`* and *`instance_name`* refer to the already initialized backup catalog instance for this database cluster, and remote_options only need to be specified to archive WAL on a remote host. For details about all possible `archive-push` parameters, see the section archive-push.

Once these steps are complete, you can start making backups in the ARCHIVE WAL mode, backups in the PAGE backup mode, as well as perform PITR.

You can view the current state of the WAL archive using the show command. For details, see the section called “Viewing WAL Archive Information”.

If you are planning to make PAGE backups and/or backups with ARCHIVE WAL mode from a standby server that generates a small amount of WAL traffic, without long waiting for WAL segment to fill up, consider setting the archive_timeout Postgres Pro parameter **on the primary**. The value of this parameter should be slightly lower than the `--archive-timeout` setting (5 minutes by default), so that there is enough time for the rotated segment to be streamed to a standby and sent to WAL archive before the backup is aborted because of `--archive-timeout`.

> **Note**
>
> Instead of using the archive-push command provided by pg_probackup, you can use any other tool to set up continuous archiving as long as it delivers WAL segments into *backup_dir*/wal/*instance_name* directory. If compression is used, it should be gzip, and .gz suffix in filename is mandatory.

> **Note**
>
> Instead of configuring continuous archiving by setting the archive_mode and archive_command parameters, you can opt for using the pg_receivewal utility. In this case, pg_receivewal -D *directory* option should point to *backup_dir*/wal/*instance_name* directory. pg_probackup supports WAL compression that can be done by pg_receivewal. “Zero Data Loss” archive strategy can be achieved only by using pg_receivewal.

Setting up Backups from a Standby

pg_probackup can take backups from a standby server. This requires the following additional setup:

- On the standby server, set the hot_standby parameter to on.
- On the primary server, set the full_page_writes parameter to on.
- To perform standalone backups on a standby, complete all the steps in section Setting up STREAM Backups.
- To perform archive backups on a standby, complete all steps in section Setting up continuous WAL archiving.

Once these steps are complete, you can start taking FULL, PAGE, DELTA, or PTRACK backups with appropriate WAL delivery mode: ARCHIVE or STREAM, from the standby server.

Backups from a standby server have the following limitations:

- If a standby is promoted to a primary during the backup process, the backup fails.
- All WAL records required for the backup must contain sufficient full-page writes. This requires you to enable full_page_writes on the primary, and not to use tools like pg_compresslog as archive_command to remove full-page writes from WAL files.

Setting up Cluster Verification

Logical verification of a database cluster requires the following additional setup. Role backup is used as an example:

- Install the amcheck or *amcheck_next* extension **in every database** of the cluster:

  ```
  CREATE EXTENSION amcheck;
  ```

- Grant the following permissions to the backup role **in every database** of the cluster:

```
GRANT SELECT ON TABLE pg_catalog.pg_am TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_class TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_database TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_namespace TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_extension TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass) TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass, bool) TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass, bool, bool) TO backup;
```

Setting up Partial Restore

If you are planning to use partial restore, complete the following additional step:

- Grant the read-only access to `pg_catalog.pg_database` to the `backup` role only in the database **used for connection** to Postgres Pro server:

  ```
  GRANT SELECT ON TABLE pg_catalog.pg_database TO backup;
  ```

Configuring the Remote Mode

pg_probackup supports the remote mode that allows you to perform backup, restore and WAL archiving operations remotely. In this mode, the backup catalog is stored on a local system, while Postgres Pro instance to backup and/or to restore is located on a remote system. Currently the only supported remote protocol is SSH.

Set up SSH

If you are going to use pg_probackup in remote mode via SSH, complete the following steps:

1. Install pg_probackup on both systems: `backup_host` and `postgres_host`.
2. For communication between the hosts set up a passwordless SSH connection between the `backup_user` user on `backup_host` and the `postgres` user on `postgres_host`:

   ```
   backup_user@backup_host:~$ ssh-copy-id postgres@postgres_host
   ```

   Where:

   - `backup_host` is the system with *backup catalog*.
   - `postgres_host` is the system with the Postgres Pro cluster.
   - `backup_user` is the OS user on `backup_host` used to run pg_probackup.
   - `postgres` is the user on `postgres_host` under which Postgres Pro cluster processes are running. For Postgres Pro 11 or higher a more secure approach can be used thanks to group access feature.
3. If you are going to rely on continuous WAL archiving, set up a passwordless SSH connection between the `postgres` user on `postgres_host` and the `backup` user on `backup_host`:

   ```
   postgres@postgres_host:~$ ssh-copy-id backup_user@backup_host
   ```
4. Make sure pg_probackup on `postgres_host` can be located when a connection via SSH is made. For example, for Bash, you can modify `PATH` in `~/.bashrc` of the `postgres` user (above the line in `bashrc` that exits the script for non-interactive shells). Alternatively, for pg_probackup commands, specify the path to the directory containing the pg_probackup binary on `postgres_host` via the --remote-path option.

pg_probackup in the remote mode via SSH works as follows:

- Only the following commands can be launched in the remote mode: add-instance, backup, restore, delete, catchup, archive-push, and archive-get.
- Operating in remote mode requires pg_probackup binary to be installed on both local and remote systems. The versions of local and remote binary must be the same.
- When started in the remote mode, the main pg_probackup process on the local system connects to the remote system via SSH and launches one or more agent processes on the remote system, which are called *remote agents*. The number of remote agents is equal to the `-j`/`--threads` setting.
- The main pg_probackup process uses remote agents to access remote files and transfer data between local and remote systems.
- Remote agents try to minimize the network traffic and the number of round-trips between hosts.
- The main process is usually started on *`backup_host`* and connects to *`postgres_host`*, but in case of `archive-push` and `archive-get` commands the main process is started on *`postgres_host`* and connects to *`backup_host`*.
- Once data transfer is complete, remote agents are terminated and SSH connections are closed.
- If an error condition is encountered by a remote agent, then all agents are terminated and error details are reported by the main pg_probackup process, which exits with an error.
- Compression is always done on *`postgres_host`*, while decompression is always done on *`backup_host`*.

> **Note**
>
> You can impose *additional restrictions* on SSH settings to protect the system in the event of account compromise.

> **Note**
>
> Setting the number of threads (`-j`/`--threads` option) to a value greater than 10 for pg_probackup working in the remote mode via SSH may result in the actual number of SSH connections exceeding the maximum allowed number of simultaneous SSH connections on the remote server and consequently lead to an “ERROR: Agent error: kex_exchange_identification: Connection closed by remote host” error. To correct the error, either reduce the number of pg_probackup threads or adjust the value of `MaxStartups` configuration parameter of the remote SSH server. If SSH is set up as a xinetd service on the remote server, adjust the value of the xinetd `per_source` configuration parameter rather than `MaxStartups`.

Setting up PTRACK Backups

> **Note**
>
> PTRACK versions lower than 2.0 are deprecated and not supported. Postgres Pro Standard and Postgres Pro Enterprise versions starting with 11.9.1 contain PTRACK 2.0. Upgrade your server to avoid issues in backups that you will take in future and be sure to take fresh backups of your clusters with the upgraded PTRACK since the backups taken with PTRACK 1.x might be corrupt.

If you are going to use PTRACK backups, complete the following additional steps.

> **Note**
>
> The permissions required for the role that will perform PTRACK backups (the `backup` role in the examples below) are listed in the section called “Configuring the Database Cluster”. The role must have permissions only in the database used for connection to the Postgres Pro server.

For Postgres Pro 11 or higher:

1. Create PTRACK extension in the database *used for connection* to the Postgres Pro server:

   ```
   CREATE EXTENSION ptrack;
   ```

2. To enable tracking page updates, set `ptrack.map_size` parameter to a positive integer and restart the server.

   For optimal performance, it is recommended to set `ptrack.map_size` to *`N / 1024`*, where *`N`* is the size of the Postgres Pro cluster, in MB. If you set this parameter to a lower value, PTRACK is more likely to map several blocks together, which leads to false-positive results when tracking changed blocks and increases the incremental backup size as unchanged blocks can also be copied into the incremental backup. Setting `ptrack.map_size` to a higher value does not affect PTRACK operation, but it is not recommended to set this parameter to a value higher than 1024.

   > **Note**
   >
   > If you change the `ptrack.map_size` parameter value, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. Thus, you have to retake a full backup before taking incremental PTRACK backups after changing `ptrack.map_size`.

Usage

Creating a Backup

To create a backup, run the following command:

```
pg_probackup backup -B backup_dir --instance=instance_name -b backup_mode
```

Where *backup_mode* can take one of the following values: FULL, DELTA, PAGE, and PTRACK.

When restoring a cluster from an incremental backup, pg_probackup relies on the parent full backup and all the incremental backups between them, which is called “the backup chain”. Thus, to perform incremental backups, it is necessary to have the last parent full backup with the status OK or DONE in the directory. If the parent full backup has the MERGING or MERGED status, an incremental backup cannot be performed.

For example, if merge has already been launched with a single full backup, an attempt to perform an incremental backup will end with the following messages:

```
WARNING: Valid full backup on current timeline 1 is not found, trying to look up on
 previous timelines
WARNING: Cannot find valid backup on previous timelines
ERROR: Create new full backup before an incremental one
```

ARCHIVE Mode

ARCHIVE is the default WAL delivery mode.

For example, to make a FULL backup in ARCHIVE mode, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL
```

ARCHIVE backups rely on continuous archiving to get WAL segments required to restore the cluster to a consistent state at the time the backup was taken.

When a backup is taken, pg_probackup ensures that WAL files containing WAL records between Start LSN and Stop LSN actually exist in *backup_dir*/wal/*instance_name* directory. pg_probackup also ensures that WAL records between Start LSN and Stop LSN can be parsed. This precaution eliminates the risk of silent WAL corruption.

STREAM Mode

STREAM is the optional WAL delivery mode.

For example, to make a FULL backup in the STREAM mode, add the --stream flag to the command from the previous example:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --stream --temp-slot
```

The optional --temp-slot flag ensures that the required segments remain available if the WAL is rotated before the backup is complete.

Unlike backups in ARCHIVE mode, STREAM backups include all the WAL segments required to restore the cluster to a consistent state at the time the backup was taken.

During backup pg_probackup streams WAL files containing WAL records between Start LSN and Stop LSN to *backup_dir*/backups/*instance_name*/*backup_id*/database/pg_wal directory. To eliminate the risk of silent WAL corruption, pg_probackup also checks that WAL records between Start LSN and Stop LSN can be parsed.

Even if you are using continuous archiving, STREAM backups can still be useful in the following cases:

- STREAM backups can be restored on the server that has no file access to WAL archive.

- STREAM backups enable you to restore the cluster state at the point in time for which WAL files in archive are no longer available.
- Backup in STREAM mode can be taken from a standby of a server that generates small amount of WAL traffic, without long waiting for WAL segment to fill up.

Page Validation

If data_checksums are enabled in the database cluster, pg_probackup uses this information to check correctness of data files during backup. While reading each page, pg_probackup checks whether the calculated checksum coincides with the checksum stored in the page header. This guarantees that the Postgres Pro instance and the backup itself have no corrupt pages. Note that pg_probackup reads database files directly from the filesystem, so under heavy write load during backup it can show false-positive checksum mismatches because of partial writes. If a page checksum mismatch occurs, the page is re-read and checksum comparison is repeated.

A page is considered corrupt if checksum comparison has failed more than 300 times. In this case, the backup is aborted.

Even if data checksums are not enabled, pg_probackup always performs sanity checks for page headers.

External Directories

To back up a directory located outside of the data directory, use the optional `--external-dirs` parameter that specifies the path to this directory. If you would like to add more than one external directory, you can provide several paths separated by colons on Linux systems or semicolons on Windows systems.

For example, to include `/etc/dir1` and `/etc/dir2` directories into the full backup of your *instance_name* instance that will be stored under the *backup_dir* directory on Linux, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --external-dirs=/
etc/dir1:/etc/dir2
```

Similarly, to include `C:\dir1` and `C:\dir2` directories into the full backup on Windows, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --external-dirs=C:
\dir1;C:\dir2
```

pg_probackup recursively copies the contents of each external directory into a separate subdirectory in the backup catalog. Since external directories included into different backups do not have to be the same, when you are restoring the cluster from an incremental backup, only those directories that belong to this particular backup will be restored. Any external directories stored in the previous backups will be ignored.

To include the same directories into each backup of your instance, you can specify them in the `pg_probackup.conf` configuration file using the set-config command with the `--external-dirs` option.

Performing Cluster Verification

To verify that Postgres Pro database cluster is not corrupt, run the following command:

```
pg_probackup checkdb [-B backup_dir [--instance=instance_name]] [-D data_dir]
 [connection_options]
```

This command performs physical verification of all data files located in the specified data directory by running page header sanity checks, as well as block-level checksum verification if checksums are enabled. If a corrupt page is detected, `checkdb` continues cluster verification until all pages in the cluster are validated.

By default, similar page validation is performed automatically while a backup is taken by pg_probackup. The `checkdb` command enables you to perform such page validation on demand, without taking any backup copies, even if the cluster is not backed up using pg_probackup at all.

To perform cluster verification, pg_probackup needs to connect to the cluster to be verified. In general, it is enough to specify the backup instance of this cluster for pg_probackup to determine the required

connection options. However, if `-B` and `--instance` options are omitted, you have to provide connection options and *`data_dir`* via environment variables or command-line options.

Physical verification cannot detect logical inconsistencies, missing or nullified blocks and entire files, or similar anomalies. Extensions amcheck and *amcheck_next* provide a partial solution to these problems.

If you would like, in addition to physical verification, to verify all indexes in all databases using these extensions, you can specify the `--amcheck` flag when running the checkdb command:

```
pg_probackup checkdb -D data_dir --amcheck [connection_options]
```

You can skip physical verification by specifying the `--skip-block-validation` flag. In this case, you can omit *backup_dir* and *data_dir* options, only connection options are mandatory:

```
pg_probackup checkdb --amcheck --skip-block-validation [connection_options]
```

Logical verification can be done more thoroughly with the `--heapallindexed` flag by checking that all heap tuples that should be indexed are actually indexed, but at the higher cost of CPU, memory, and I/O consumption.

Validating a Backup

pg_probackup calculates checksums for each file in a backup during the backup process. The process of checking checksums of backup data files is called *the backup validation*. By default, validation is run immediately after the backup is taken and right before the restore, to detect possible backup corruption.

If you would like to skip backup validation, you can specify the `--no-validate` flag when running backup and restore commands.

To ensure that all the required backup files are present and can be used to restore the database cluster, you can run the validate command with the exact recovery target options you are going to use for recovery.

For example, to check that you can restore the database cluster from a backup copy up to transaction ID 4242, run this command:

```
pg_probackup validate -B backup_dir --instance=instance_name --recovery-target-xid=4242
```

If validation completes successfully, pg_probackup displays the corresponding message. If validation fails, you will receive an error message with the exact time, transaction ID, and LSN up to which the recovery is possible.

If you specify *backup_id* via `-i/--backup-id` option, then only the backup copy with specified backup ID will be validated. If *backup_id* is specified with recovery target options, the `validate` command will check whether it is possible to restore the specified backup to the specified recovery target.

For example, to check that you can restore the database cluster from a backup copy with the `SBOL6P` backup ID up to the specified timestamp, run this command:

```
pg_probackup validate -B backup_dir --instance=instance_name -i SBOL6P --recovery-
target-time="2024-04-10 18:18:26+03"
```

If you specify the *`backup_id`* of an incremental backup, all its parents starting from FULL backup will be validated.

If you omit all the parameters, all backups are validated.

Restoring a Cluster

To restore the database cluster from a backup, run the restore command with at least the following options:

```
pg_probackup restore -B backup_dir --instance=instance_name -i backup_id
```

Where:

- *backup_dir* is the backup catalog that stores all backup files and meta information.
- *instance_name* is the backup instance for the cluster to be restored.
- *backup_id* specifies the backup to restore the cluster from. If you omit this option, pg_probackup uses the latest valid backup available for the specified instance. If you specify an incremental backup to restore, pg_probackup automatically restores the underlying full backup and then sequentially applies all the necessary increments.

Once the `restore` command is complete, start the database service.

If you restore ARCHIVE backups, perform PITR, or specify the `--restore-as-replica` flag with the `restore` command to set up a standby server, pg_probackup creates a recovery configuration file once all data files are copied into the target directory. This file includes the minimal settings required for recovery, except for the password in the primary_conninfo parameter; you have to add the password manually or use the `--primary-conninfo` option, if required. For Postgres Pro 11, recovery settings are written into the `recovery.conf` file. Starting from Postgres Pro 12, pg_probackup writes these settings into the `probackup_recovery.conf` file and then includes it into `postgresql.auto.conf`.

If you are restoring a STREAM backup, the restore is complete at once, with the cluster returned to a self-consistent state at the point when the backup was taken. For ARCHIVE backups, Postgres Pro replays all available archived WAL segments, so the cluster is restored to the latest state possible within the current timeline. You can change this behavior by using the recovery target options with the `restore` command, as explained in the section called “Performing Point-in-Time (PITR) Recovery”.

If the cluster to restore contains tablespaces, pg_probackup restores them to their original location by default. To restore tablespaces to a different location, use the `--tablespace-mapping`/`-T` option. Otherwise, restoring the cluster on the same host will fail if tablespaces are in use, because the backup would have to be written to the same directories.

When using the `--tablespace-mapping`/`-T` option, you must provide absolute paths to the old and new tablespace directories. If a path happens to contain an equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces. For example:

```
pg_probackup restore -B backup_dir --instance=instance_name -D data_dir -j 4 -
i backup_id -T tablespace1_dir=tablespace1_newdir -T tablespace2_dir=tablespace2_newdir
```

To restore the cluster on a remote host, follow the instructions in the section called “Using pg_probackup in the Remote Mode”.

> **Note**
>
> By default, the restore command validates the specified backup before restoring the cluster. If you run regular backup validations and would like to save time when restoring the cluster, you can specify the `--no-validate` flag to skip validation and speed up the recovery.

Incremental Restore

The speed of restore from backup can be significantly improved by replacing only invalid and changed pages in already existing Postgres Pro data directory using incremental restore options with the restore command.

To restore the database cluster from a backup in incremental mode, run the restore command with the following options:

```
pg_probackup restore -B backup_dir --instance=instance_name -D data_dir -
I incremental_mode
```

Where *incremental_mode* can take one of the following values:

- CHECKSUM — read all data files in the data directory, validate header and checksum in every page and replace only invalid pages and those with checksum and LSN not matching with corresponding page in backup. This is the simplest, the most fool-proof incremental mode. Recommended to use by default.
- LSN — read the *pg_control* in the data directory to obtain redo LSN and redo TLI, which allows you to determine a point in history(shiftpoint), where data directory state shifted from target backup chain history. If shiftpoint is not within reach of backup chain history, then restore is aborted. If shiftpoint is within reach of backup chain history, then read all data files in the data directory, validate header and checksum in every page and replace only invalid pages and those with LSN greater than shiftpoint. This mode offers a greater speed up compared to CHECKSUM, but rely on two conditions to be met. First, data_checksums parameter must be enabled in data directory (to avoid corruption due to hint bits). This condition will be checked at the start of incremental restore and the operation will be aborted if checksums are disabled. Second, the *pg_control* file must be synched with state of data directory. This condition cannot checked at the start of restore, so it is a user responsibility to ensure that *pg_control* contain valid information. Therefore it is not recommended to use LSN mode in any situation, where pg_control cannot be trusted or has been tampered with: after *pg_resetxlog* execution, after restore from backup without recovery been run, etc.
- NONE — regular restore without any incremental optimizations.

Regardless of chosen incremental mode, pg_probackup will check, that postmaster in given destination directory is not running and `system-identifier` is the same as in the backup.

Suppose you want to return an old primary as a replica after switchover using incremental restore in LSN mode:

```
================================================================================================

> **Note**
>
> Incremental restore is possible only for backups with `program_version` equal or greater than 2.4.0.

Partial Restore

If you have enabled partial restore before taking backups, you can restore only some of the databases using partial restore options with the restore commands.

To restore the specified databases only, run the restore command with the following options:

```
pg_probackup restore -B backup_dir --instance=instance_name --db-include=database_name
```

The `--db-include` option can be specified multiple times. For example, to restore only databases `db1` and `db2`, run the following command:

```
pg_probackup restore -B backup_dir --instance=instance_name --db-include=db1 --db-include=db2
```

To exclude one or more databases from restore, use the `--db-exclude` option:

```
pg_probackup restore -B backup_dir --instance=instance_name --db-exclude=database_name
```

The `--db-exclude` option can be specified multiple times. For example, to exclude the databases `db1` and `db2` from restore, run the following command:

```
pg_probackup restore -B backup_dir --instance=instance_name --db-exclude=db1 --db-exclude=db2
```

Partial restore relies on lax behavior of Postgres Pro recovery process toward truncated files. For recovery to work properly, files of excluded databases are restored as files of zero size. After the Postgres Pro cluster is successfully started, you must drop the excluded databases using `DROP DATABASE` command.

To decouple a single cluster containing multiple databases into separate clusters with minimal downtime, you can do partial restore of the cluster as a standby using the `--restore-as-replica` option for specific databases.

> **Note**
>
> The `template0` and `template1` databases are always restored.

> **Note**
>
> Due to recovery specifics of Postgres Pro versions earlier than 12, it is advisable that you set the hot_standby parameter to `off` when running partial restore of a Postgres Pro cluster of version earlier than 12. Otherwise the recovery may fail.

Performing Point-in-Time (PITR) Recovery

If you have enabled continuous WAL archiving before taking backups, you can restore the cluster to its state at an arbitrary point in time (recovery target) using recovery target options with the restore command.

You can use both STREAM and ARCHIVE backups for point in time recovery as long as the WAL archive is available at least starting from the time the backup was taken. If `-i`/`--backup-id` option is omitted, pg_probackup automatically chooses the backup that is the closest to the specified recovery target and starts the restore process, otherwise pg_probackup will try to restore the specified backup to the specified recovery target.

- To restore the cluster state at the exact time, specify the `--recovery-target-time` option, in the timestamp format. For example:

  ```
  pg_probackup restore -B backup_dir --instance=instance_name --recovery-target-time="2024-04-10 18:18:26+03"
  ```

- To restore the cluster state up to a specific transaction ID, use the `--recovery-target-xid` option:

  ```
  pg_probackup restore -B backup_dir --instance=instance_name --recovery-target-xid=687
  ```

- To restore the cluster state up to the specific LSN, use `--recovery-target-lsn` option:

  ```
  pg_probackup restore -B backup_dir --instance=instance_name --recovery-target-lsn=16/B374D848
  ```

- To restore the cluster state up to the specific named restore point, use `--recovery-target-name` option:

  ```
  pg_probackup restore -B backup_dir --instance=instance_name --recovery-target-name="before_app_upgrade"
  ```

- To restore the backup to the latest state available in the WAL archive, use `--recovery-target` option with `latest` value:

  ```
  pg_probackup restore -B backup_dir --instance=instance_name --recovery-target="latest"
  ```

- To restore the cluster to the earliest point of consistency, use `--recovery-target` option with the `immediate` value:

  ```
  pg_probackup restore -B backup_dir --instance=instance_name --recovery-target='immediate'
  ```

Using pg_probackup in the Remote Mode

pg_probackup supports the remote mode that allows you to perform `backup` and `restore` operations remotely via SSH. In this mode, the backup catalog is stored on a local system, while Postgres Pro instance to be backed up is located on a remote system. You must have pg_probackup installed on both systems.

> **Note**
>
> pg_probackup relies on passwordless SSH connection for communication between the hosts.

> **Note**
>
> In addition to SSH connection, pg_probackup uses a regular connection to the database to manage the remote operation. See the section Configuring the Database Cluster for details of how to set up a database connection.

The typical workflow is as follows:

- On your backup host, configure pg_probackup as explained in the section Installation and Setup. For the add-instance and set-config commands, make sure to specify remote mode options that point to the database host with the Postgres Pro instance.
- If you would like to take remote backups in PAGE mode, or rely on ARCHIVE WAL delivery mode, or use PITR, configure continuous WAL archiving from the database host to the backup host as explained in the section Setting up continuous WAL archiving. For the archive-push and archive-get commands, you must specify the remote mode options that point to the backup host with the backup catalog.
- Run backup or restore commands with remote mode options **on the backup host**. pg_probackup connects to the remote system via SSH and creates a backup locally or restores the previously taken backup on the remote system, respectively.

For example, to create an archive full backup of a Postgres Pro cluster located on a remote system with host address `192.168.0.2` on behalf of the `postgres` user via SSH connection through port `2302`, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --remote-
user=postgres --remote-host=192.168.0.2 --remote-port=2302
```

To restore the latest available backup on a remote system with host address `192.168.0.2` on behalf of the `postgres` user via SSH connection through port `2302`, run:

```
pg_probackup restore -B backup_dir --instance=instance_name --remote-user=postgres --
remote-host=192.168.0.2 --remote-port=2302
```

Restoring an ARCHIVE backup or performing PITR in the remote mode require additional information: destination address, port and username for establishing an SSH connection **from** the host with database **to** the host with the backup catalog. This information will be used by the `restore_command` to copy WAL segments from the archive to the Postgres Pro `pg_wal` directory.

To solve this problem, you can use Remote WAL Archive Options.

For example, to restore latest backup on remote system using remote mode through SSH connection to user `postgres` on host with address `192.168.0.2` via port `2302` and user `backup` on backup catalog host with address `192.168.0.3` via port `2303`, run:

```
pg_probackup restore -B backup_dir --instance=instance_name --remote-user=postgres
 --remote-host=192.168.0.2 --remote-port=2302 --archive-host=192.168.0.3 --archive-
port=2303 --archive-user=backup
```

Provided arguments will be used to construct the `restore_command`:

```
restore_command = '"install_dir/pg_probackup" archive-get -B "backup_dir" --
instance=instance_name --wal-file-path=%p --wal-file-name=%f --remote-host=192.168.0.3
 --remote-port=2303 --remote-user=backup'
```

Alternatively, you can use the `--restore-command` option to provide the entire *restore_command*:

```
pg_probackup restore -B backup_dir --instance=instance_name --remote-user=postgres
 --remote-host=192.168.0.2 --remote-port=2302 --restore-command='"install_dir/
pg_probackup" archive-get -B "backup_dir" --instance=instance_name --wal-file-path=%p
 --wal-file-name=%f --remote-host=192.168.0.3 --remote-port=2303 --remote-user=backup'
```

> **Note**
>
> The remote mode is currently unavailable for Windows systems.

Running pg_probackup on Parallel Threads

backup, restore, merge, delete, catchup, checkdb, and validate processes can be executed on several parallel threads. This can significantly speed up pg_probackup operation given enough resources (CPU cores, disk, and network bandwidth).

Parallel execution is controlled by the `-j/--threads` command-line option. For example, to create a backup using four parallel threads, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL -j 4
```

> **Note**
>
> Parallel restore applies only to copying data from the backup catalog to the data directory of the cluster. When Postgres Pro server is started, WAL records need to be replayed, and this cannot be done in parallel.

> **Important**
>
> A technique is implemented that prevents repeatable copying of one file when pg_probackup runs on multiple threads. With this technique, however, when disks are slow or the system is overloaded, parallel copying might fail. To handle this situation, resolve issues with your system resources.

Configuring pg_probackup

Once the backup catalog is initialized and a new backup instance is added, you can use the `pg_probackup.conf` configuration file located in the *backup_dir*`/backups/`*instance_name* directory to fine-tune pg_probackup configuration.

For example, backup and checkdb commands use a regular Postgres Pro connection. To avoid specifying connection options each time on the command line, you can set them in the `pg_probackup.conf` configuration file using the set-config command.

> **Note**
>
> It is **not recommended** to edit `pg_probackup.conf` manually.

Initially, `pg_probackup.conf` contains the following settings:

- `PGDATA` — the path to the data directory of the cluster to back up.
- `system-identifier` — the unique identifier of the Postgres Pro instance.

Additionally, you can define remote mode, retention, logging, and compression settings using the `set-config` command:

```
pg_probackup set-config -B backup_dir --instance=instance_name
[--external-dirs=external_directory_path] [remote_options] [connection_options]
 [retention_options] [logging_options]
```

To view the current settings, run the following command:

```
pg_probackup show-config -B backup_dir --instance=instance_name
```

You can override the settings defined in `pg_probackup.conf` when running pg_probackup commands via the corresponding environment variables and/or command line options.

Specifying Connection Settings

If you define connection settings in the `pg_probackup.conf` configuration file, you can omit connection options in all the subsequent pg_probackup commands. However, if the corresponding environment variables are set, they get higher priority. The options provided on the command line overwrite both environment variables and configuration file settings.

If nothing is given, the default values are taken. By default pg_probackup tries to use local connection via Unix domain socket (`localhost` on Windows) and tries to get the database name and the user name from the `PGUSER` environment variable or the current OS user name.

Managing the Backup Catalog

With pg_probackup, you can manage backups from the command line:

- View backup information
- View WAL Archive Information
- Validate backups
- Merge backups
- Delete backups

Viewing Backup Information

To view the list of existing backups for every instance, run the command:

```
pg_probackup show -B backup_dir
```

pg_probackup displays the list of all the available backups. For example:

```
BACKUP INSTANCE 'node'
============================================================================================
 Instance  Version  ID      Recovery Time                  Mode    WAL Mode  TLI  Time
  Data    WAL  Zalg  Zratio  Start LSN    Stop LSN    Status

 144MB  16MB  zstd    2.47  0/22000028   0/220001C8  OK
```

For each backup, the following information is provided:

- `Instance` — the instance name.
- `Version` — Postgres Pro major version.
- `ID` — the backup identifier.
- `Recovery time` — the earliest moment for which you can restore the state of the database cluster.
- `Mode` — the method used to take this backup. Possible values: `FULL`, `PAGE`, `DELTA`, `PTRACK`.
- `WAL Mode` — WAL delivery mode. Possible values: `STREAM` and `ARCHIVE`.
- `TLI` — timeline identifiers of the current backup and its parent.
- `Time` — the time it took to perform the backup.
- `Data` — the size of the data files in this backup. This value does not include the size of WAL files. For STREAM backups, the total size of the backup can be calculated as `Data` + `WAL`.
- `WAL` — the uncompressed size of WAL files that need to be applied during recovery for the backup to reach a consistent state.
- `compress-alg` — compression algorithm used during backup. Possible values: `zlib`, `pglz`, `lz4`, `zstd`, `none`.

- `Zratio` — compression ratio calculated as “uncompressed-bytes” / “data-bytes”.
- `Start LSN` — WAL log sequence number corresponding to the start of the backup process. REDO point for Postgres Pro recovery process to start from.
- `Stop LSN` — WAL log sequence number corresponding to the end of the backup process. Consistency point for Postgres Pro recovery process.
- `Status` — backup status. Possible values:
  - `OK` — the backup is complete and valid.
  - `DONE` — the backup is complete, but was not validated.
  - `RUNNING` — the backup is in progress.
  - `MERGING` — the backup is being merged.
  - `MERGED` — the backup data files were successfully merged, but its metadata is in the process of being updated. Only full backups can have this status.
  - `DELETING` — the backup files are being deleted.
  - `CORRUPT` — some of the backup files are corrupt.
  - `ERROR` — the backup was aborted because of an unexpected error.
  - `ORPHAN` — the backup is invalid because one of its parent backups is corrupt or missing.
  - `HIDDEN_FOR_TEST` — a test script marked the backup as nonexistent. (pg_probackup never sets this status by itself.)

You can restore the cluster from the backup only if the backup status is `OK` or `DONE`.

To get more detailed information about the backup, run the `show` command with the backup ID:

```
pg_probackup show -B backup_dir --instance=instance_name -i backup_id
```

The sample output is as follows:

```
#Configuration
backup-mode = FULL
stream = false
compress-alg = lz4
compress-level = 1
from-replica = false

#Compatibility
block-size = 8192
xlog-block-size = 8192
checksum-version = 1
program-version = 2.7.3
server-version = 17

#Result backup info
timelineid = 1
start-lsn = 0/41000028
stop-lsn = 0/420000C0
start-time = '2024-04-09 18:19:52+03'
end-time = '2024-04-09 18:19:58+03'
end-validation-time = '2024-04-09 18:19:59+03'
recovery-xid = 757
recovery-time = '2024-04-09 18:19:56.603355+03'
data-bytes = 395651278
wal-bytes = 16777216
uncompressed-bytes = 578552566
pgdata-bytes = 578552248
status = OK
primary_conninfo = 'user=backup channel_binding=prefer host=localhost
 port=5432 sslmode=prefer sslcompression=0 sslcertmode=allow sslsni=1
```

```
 ssl_min_protocol_version=TLSv1.2 gssencmode=prefer krbsrvname=postgres gssdelegation=0
 target_session_attrs=any load_balance_hosts=disable'
content-crc = 3862224379
```

Detailed output has additional attributes:

- `compress-alg` — compression algorithm used during backup. Possible values: `zlib`, `pglz`, `lz4`, `zstd`, `none`.
- `compress-level` — compression level used during backup.
- `from-replica` — was this backup taken on a standby? Possible values: `1`, `0`.
- `block-size` — the block_size setting of Postgres Pro cluster at the backup start.
- `checksum-version` — are data_checksums enabled in the backed up Postgres Pro cluster? Possible values: `1`, `0`.
- `program-version` — full version of pg_probackup binary used to create the backup.
- `start-time` — the backup start time.
- `end-time` — the backup end time.
- `end-validation-time` — the backup validation end time.
- `expire-time` — the point in time when a pinned backup can be removed in accordance with retention policy. This attribute is only available for pinned backups.
- `uncompressed-bytes` — the size of data files before adding page headers and applying compression. You can evaluate the effectiveness of compression by comparing `uncompressed-bytes` to `data-bytes` if compression if used.
- `pgdata-bytes` — the size of Postgres Pro cluster data files at the time of backup. You can evaluate the effectiveness of an incremental backup by comparing `pgdata-bytes` to `uncompressed-bytes`.
- `recovery-xid` — transaction ID at the backup end time.
- `parent-backup-id` — ID of the parent backup. Available only for incremental backups.
- `primary_conninfo` — libpq connection parameters used to connect to the Postgres Pro cluster to take this backup. The password is not included.
- `note` — text note attached to backup.
- `content-crc` — CRC32 checksum of `backup_content.control` file. It is used to detect corruption of backup metainformation.

You can also get the detailed information about the backup in the JSON format:

```
pg_probackup show -B backup_dir --instance=instance_name --format=json -i backup_id
```

The sample output is as follows:

```
[
    {
        "instance": "node",
        "backups": [
            {
                "id": "SBOL94",
                "status": "OK",

                "content-crc": 3862224379
            }
        ]
    }
]
```

Viewing WAL Archive Information

To view the information about WAL archive for every instance, run the command:

```
pg_probackup show -B backup_dir [--instance=instance_name] --archive
```

pg_probackup displays the list of all the available WAL files grouped by timelines. For example:

```
ARCHIVE INSTANCE 'node'
================================================================================================================================
 TLI  Parent TLI  Switchpoint  Min Segno                 Max Segno                 N
 segments  Size   Zratio  N backups  Status
================================================================================================================================
 1    0           0/0          000000010000000000000001B  000000010000000000000042  40
        640MB  1.00    5          OK
```

For each timeline, the following information is provided:

- `TLI` — timeline identifier.
- `Parent TLI` — identifier of the timeline from which this timeline branched off.
- `Switchpoint` — LSN of the moment when the timeline branched off from its parent timeline.
- `Min Segno` — the first WAL segment belonging to the timeline.
- `Max Segno` — the last WAL segment belonging to the timeline.
- `N segments` — number of WAL segments belonging to the timeline.
- `Size` — the size that files take on disk.
- `Zalg` — compression algorithm used during backup. Possible values: `zlib`, `pglz`, `lz4`, `zstd`, `none`.
- `Zratio` — compression ratio calculated as `N segments` * *`wal_segment_size`* * *`wal_block_size`* / `Size`.
- `N backups` — number of backups belonging to the timeline. To get the details about backups, use the JSON format.
- `Status` — status of the WAL archive for this timeline. Possible values:
  - `OK` — all WAL segments between `Min Segno` and `Max Segno` are present.
  - `DEGRADED` — some WAL segments between `Min Segno` and `Max Segno` are missing. To find out which files are lost, view this report in the JSON format. This status may appear if several WAL files (in the middle of the sequence) were deleted by the delete command with the `--delete-wal` option according to the retention policy. This status does not affect the restore correctness, but it can be impossible to perform PITR of the cluster to some recovery targets.

To get more detailed information about the WAL archive in the JSON format, run the command:

```
pg_probackup show -B backup_dir [--instance=instance_name] --archive --format=json
```

The sample output is as follows:

```
[
    {
        "instance": "node",
        "timelines": [
            {
                "tli": 1,
                "parent-tli": 0,

            }
        ]
    }
]
```

Most fields are consistent with the plain format, with some exceptions:

- The size is in bytes.
- The `closest-backup-id` attribute contains the ID of the most recent valid backup that belongs to one of the previous timelines. You can use this backup to perform point-in-time recovery to this timeline. If such a backup does not exist, this string is empty.
- The `lost-segments` array provides with information about intervals of missing segments in `DEGRADED` timelines. In `OK` timelines, the `lost-segments` array is empty.
- The `backups` array lists all backups belonging to the timeline. If the timeline has no backups, this array is empty.

Configuring Retention Policy

With pg_probackup, you can configure retention policy to remove redundant backups, clean up unneeded WAL files, as well as pin specific backups to ensure they are kept for the specified time, as explained in the sections below. All these actions can be combined together in any way.

Removing Redundant Backups

By default, all backup copies created with pg_probackup are stored in the specified backup catalog. To save disk space, you can configure retention policy to remove redundant backup copies.

To configure retention policy, set one or more of the following variables in the `pg_probackup.conf` file via set-config:

`--retention-redundancy=`*`redundancy`*

Specifies **the number of full backup copies** to keep in the backup catalog.

`--retention-window=`*`window`*

Defines the earliest point in time for which pg_probackup can complete the recovery. This option is set in **the number of days** from the current moment. For example, if `retention-window=7`, pg_probackup must keep at least one backup copy that is older than seven days, with all the corresponding WAL files, and all the backups that follow.

If both `--retention-redundancy` and `--retention-window` options are set, both these conditions have to be taken into account when purging the backup catalog. For example, if you set `--retention-redundancy=2` and `--retention-window=7`, pg_probackup has to keep two full backup copies, as well as all the backups required to ensure recoverability for the last seven days:

```
pg_probackup set-config -B backup_dir --instance=instance_name --retention-redundancy=2
 --retention-window=7
```

It is recommended to always keep at least two last parent full backups to avoid errors when creating incremental backups.

To clean up the backup catalog in accordance with retention policy, you have to run the delete command with retention flags, as shown below, or use the backup command with these flags to process the outdated backup copies right when the new backup is created.

For example, to remove all backup copies that no longer satisfy the defined retention policy, run the following command with the `--delete-expired` flag:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired
```

If you would like to also remove the WAL files that are no longer required for any of the backups, you should also specify the `--delete-wal` flag:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired --delete-
wal
```

You can also set or override the current retention policy by specifying `--retention-redundancy` and `--retention-window` options directly when running `delete` or `backup` commands:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired --
retention-window=7 --retention-redundancy=2
```

Since incremental backups require that their parent full backup and all the preceding incremental backups are available, if any of such backups expire, they still cannot be removed while at least one incremental backup in this chain satisfies the retention policy. To avoid keeping expired backups that are still required to restore an active incremental one, you can merge them with this backup using the `--merge-expired` flag when running backup or delete commands.

Suppose you have backed up the *node* instance in the *backup_dir* directory, with the `--retention-window` option set to `6` and `--retention-redundancy` option set to `2`, and you have the following backups available on August 01, 2024:

```
BACKUP INSTANCE 'node'
============================================================================================

 16MB  zstd    2,86  0/B000028   0/C0000C0   OK
 node      17       SGWTN3  2024-07-20 09:49:54+03  PAGE   ARCHIVE   1/1    5s  6432kB
 16MB  zstd    1,06  0/8000028   0/90000C0   OK
 node      17       SGUYZ2  2024-07-19 09:49:53+03  DELTA  ARCHIVE   1/1    5s  6442kB
 16MB  zstd    1,07  0/5000028   0/60000C0   OK
 node      17       SGT4B1  2024-07-18 09:49:52+03  FULL   ARCHIVE   1/0    5s    11MB
 16MB  zstd    2,89  0/2000028   0/3003A28   OK
```

If you run the delete command with the `--delete-expired` flag, the backups with IDs `SGT4B1`, `SGUYZ2`, and `SGWTN3` will be removed as they are expired both according to the retention window and due to

redundancy (the required set of full backups has already been retained). SGUYZ2 and SGWTN3 will also be removed since the base full backup is expired.

Running the delete command with the --merge-expired flag will merge backups SH48B3 and SH62Z5 with SH9SB5. The merge will occur with SH9SB5 as it is the first non-expired delta backup, which can be merged with expired delta backups SH62Z5 and expired full backup SH48B3.

```
pg_probackup delete -B backup_dir --instance=node --delete-expired --merge-expired
pg_probackup show -B backup_dir
```

```
BACKUP INSTANCE 'node'

 16MB  zstd    2,84  0/11000028  0/120000C0  OK
```

The Time field for the merged backup displays the time required for the merge.

Pinning Backups

If you need to keep certain backups longer than the established retention policy allows, you can pin them for arbitrary time. For example:

```
pg_probackup set-backup -B backup_dir --instance=instance_name -i backup_id --ttl=30d
```

This command sets the expiration time of the specified backup to 30 days starting from the time indicated in its recovery-time attribute.

You can also explicitly set the expiration time for a backup using the --expire-time option. For example:

```
pg_probackup set-backup -B backup_dir --instance=instance_name -i backup_id --expire-
time="2027-04-09 18:21:32+00"
```

Alternatively, you can use the --ttl and --expire-time options with the backup command to pin the newly created backup:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --ttl=30d
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --expire-
time="2027-04-09 18:21:32+00"
```

To check if the backup is pinned, run the show command:

```
pg_probackup show -B backup_dir --instance=instance_name -i backup_id
```

If the backup is pinned, it has the expire-time attribute that displays its expiration time:

```
...
recovery-time = '2024-04-09 18:21:32+00'
expire-time = '2027-04-09 18:21:32+00'
data-bytes = 22288792
...
```

You can unpin the backup by setting the --ttl option to zero:

```
pg_probackup set-backup -B backup_dir --instance=instance_name -i backup_id --ttl=0
```

> **Note**
>
> A pinned incremental backup implicitly pins all its parent backups. If you unpin such a backup later, its implicitly pinned parents will also be automatically unpinned.

Configuring WAL Archive Retention Policy

When continuous WAL archiving is enabled, archived WAL segments can take a lot of disk space. Even if you delete old backup copies from time to time, the `--delete-wal` flag can purge only those WAL segments that do not apply to any of the remaining backups in the backup catalog. However, if point-in-time recovery is critical only for the most recent backups, you can configure WAL archive retention policy to keep WAL archive of limited depth and win back some more disk space.

To configure WAL archive retention policy, you have to run the set-config command with the `--wal-depth` option that specifies the number of backups that can be used for PITR. This setting applies to all the timelines, so you should be able to perform PITR for the same number of backups on each timeline, if available. Pinned backups are not included into this count: if one of the latest backups is pinned, pg_probackup ensures that PITR is possible for one extra backup.

To remove WAL segments that do not satisfy the defined WAL archive retention policy, you simply have to run the delete or backup command with the `--delete-wal` flag. For archive backups, WAL segments between `Start LSN` and `Stop LSN` are always kept intact, so such backups remain valid regardless of the `--wal-depth` setting and can still be restored, if required.

You can also use the `--wal-depth` option with the delete and backup commands to override the previously defined WAL archive retention policy and purge old WAL segments on the fly.

Suppose you have backed up the `node` instance in the *backup_dir* directory and configured continuous WAL archiving:

```
pg_probackup show -B backup_dir --instance=node
```

```
========================================================================================================

 278MB   96MB  zstd    2.46  0/600060C8  0/64FE6640  OK
 node       17       SBOLBW  2024-04-09 18:21:38.399702+03  FULL   STREAM    1/0   12s
 278MB   96MB  zstd    2.46  0/54001830  0/589E5908  OK
```

You can check the state of the WAL archive by running the show command with the `--archive` flag:

```
pg_probackup show -B backup_dir --instance=node --archive
```

```
ARCHIVE INSTANCE 'node'
========================================================================================================
 TLI  Parent TLI  Switchpoint  Min Segno                Max Segno                 N
 segments  Size   Zratio  N backups  Status
```

```
========================================================================================
 1    0           0/0          000000010000000000000052  000000010000000000000006F  30
        480MB  1.00    6          OK
```

WAL purge without `--wal-depth` cannot achieve much, only one segment is removed:

```
pg_probackup delete -B backup_dir --instance=node --delete-wal
```

```
ARCHIVE INSTANCE 'node'
========================================================================================
 TLI  Parent TLI  Switchpoint  Min Segno                 Max Segno                 N
 segments  Size   Zratio  N backups  Status
========================================================================================
 1    0           0/0          000000010000000000000054  000000010000000000000006F  28
        448MB  1.00    6          OK
```

If you would like, for example, to keep only those WAL segments that can be applied to the latest valid backup, set the `--wal-depth` option to 1:

```
pg_probackup delete -B backup_dir --instance=node --delete-wal --wal-depth=1
```

```
ARCHIVE INSTANCE 'node'
========================================================================================
 TLI  Parent TLI  Switchpoint  Min Segno                 Max Segno                 N
 segments  Size  Zratio  N backups  Status
========================================================================================
 1    0           0/0          000000010000000000000006F  000000010000000000000006F  1
        16MB  1.00    6          OK
```

Alternatively, you can use the `--wal-depth` option with the backup command:

```
pg_probackup backup -B backup_dir --instance=node -b DELTA --wal-depth=1 --delete-wal
```

```
ARCHIVE INSTANCE 'node'
========================================================================================
 TLI  Parent TLI  Switchpoint  Min Segno                 Max Segno                 N
 segments  Size  Zratio  N backups  Status
========================================================================================
 1    0           0/0          000000010000000000000071  000000010000000000000071  1
        16MB  1.00    7          OK
```

Merging Backups

As you take more and more incremental backups, the total size of the backup catalog can substantially grow. To save disk space, you can merge incremental backups to their parent full backup by running the `merge` command, specifying the backup ID of the most recent incremental backup you would like to merge:

```
pg_probackup merge -B backup_dir --instance=instance_name -i backup_id
```

This command merges backups that belong to a common incremental backup chain. If you specify a full backup, it will be merged with its first incremental backup. If you specify an incremental backup, it will be merged to its parent full backup, together with all incremental backups between them. Once the merge is complete, the full backup takes in all the merged data, and the incremental backups are removed as redundant. Thus, the merge operation is virtually equivalent to retaking a full backup and removing all the outdated backups, but it allows you to save much time, especially for large data volumes, as well as I/O and network traffic if you are using pg_probackup in the remote mode.

Before the merge, pg_probackup validates all the affected backups to ensure that they are valid. You can check the current backup status by running the show command with the backup ID:

```
pg_probackup show -B backup_dir --instance=instance_name -i backup_id
```

If the merge is still in progress, the backup status is displayed as `MERGING`. For full backups, it can also be shown as `MERGED` while the metadata is being updated at the final stage of the merge. The merge is idempotent, so you can restart the merge if it was interrupted.

> **Warning**
>
> Avoid force-terminating the merge operation, as it may cause subsequent `merge` commands to fail and disrupt backup validation.

Deleting Backups

To delete a backup that is no longer required, run the following command:

```
pg_probackup delete -B backup_dir --instance=instance_name -i backup_id
```

This command will delete the backup with the specified *backup_id*, together with all the incremental backups that descend from *backup_id*, if any. This way you can delete some recent incremental backups, retaining the underlying full backup and some of the incremental backups that follow it.

To delete obsolete WAL files that are not necessary to restore any of the remaining backups, use the `--delete-wal` flag:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-wal
```

To delete backups that are expired according to the current retention policy, use the `--delete-expired` flag:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired
```

Expired backups cannot be removed while at least one incremental backup that satisfies the retention policy is based on them. If you would like to minimize the number of backups still required to keep incremental backups valid, specify the `--merge-expired` flag when running this command:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired --merge-expired
```

In this case, pg_probackup searches for the oldest incremental backup that satisfies the retention policy and merges this backup with the underlying full and incremental backups that have already expired, thus making it a full backup. Once the merge is complete, the remaining expired backups are deleted.

Before merging or deleting backups, you can run the `delete` command with the `--dry-run` flag, which displays the status of all the available backups according to the current retention policy, without performing any irreversible actions.

To delete all backups with specific status, use the `--status`:

```
pg_probackup delete -B backup_dir --instance=instance_name --status=ERROR
```

Deleting backups by status ignores established retention policies.

Cloning and Synchronizing Postgres Pro Instance

pg_probackup can create a copy of a Postgres Pro instance directly, without using the backup catalog. To do this, you can run the catchup command. It can be useful in the following cases:

- To add a new standby server.

  Usually, pg_basebackup is used to create a copy of a Postgres Pro instance. If the data directory of the destination instance is empty, the `catchup` command works similarly, but it can be faster if run in parallel mode.

- To have a fallen-behind standby server “catch up” with the primary.

  Under write-intensive load, replicas may fail to replay WAL fast enough to keep up with the primary and hence may lag behind. A usual solution to create a new replica and switch to it requires a lot of extra space and data transfer. The `catchup` command allows you to update an existing replica much faster by bringing differences from the primary.

`catchup` is different from other pg_probackup operations:

- The backup catalog is not required.
- STREAM WAL delivery mode is only supported.
- Copying external directories is not supported.
- DDL commands CREATE TABLESPACE/DROP TABLESPACE cannot be run simultaneously with `catchup`.
- `catchup` takes configuration files, such as `postgresql.conf`, `postgresql.auto.conf`, or `pg_hba.conf`, from the source server and overwrites them on the target server. The `--exclude-path` option allows you to keep the configuration files intact.

To prepare for cloning/synchronizing a Postgres Pro instance, set up the source server as follows:

- Configure the database cluster for the instance to copy.
- To copy from a remote server, configure the remote mode.
- To use the PTRACK catchup mode, set up PTRACK backups.

Before cloning/synchronizing a Postgres Pro instance, ensure that the source server is running and accepting connections. To clone/sync a Postgres Pro instance, on the server with the destination instance, you can run the catchup command as follows:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --destination-pgdata=path_to_local_dir --stream [connection_options] [remote_options]
```

Where *`catchup_mode`* can take one of the following values:

- `FULL` — creates a full copy of the Postgres Pro instance. The data directory of the destination instance must be empty for this mode.
- `DELTA` — reads all data files in the data directory and creates an incremental copy for pages that have changed since the destination instance was shut down.
- `PTRACK` — tracking page changes on the fly, only reads and copies pages that have changed since the point of divergence of the source and destination instances.

> **Warning**
>
> PTRACK catchup mode requires PTRACK not earlier than 2.0 and hence, Postgres Pro not earlier than 11.

By specifying the `--stream` option, you can set STREAM WAL delivery mode of copying, which will include all the necessary WAL files by streaming them from the server via replication protocol.

You can use connection_options to specify the connection to the source database cluster. If it is located on a different server, also specify remote_options.

If the source database cluster contains tablespaces that must be located in a different directory, additionally specify the `--tablespace-mapping` option:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --destination-pgdata=path_to_local_dir --stream --tablespace-mapping=OLDDIR=NEWDIR
```

To run the `catchup` command on parallel threads, specify the number of threads with the `--threads` option:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --destination-pgdata=path_to_local_dir --stream --threads=num_threads
```

Before cloning/synchronising a Postgres Pro instance, you can run the `catchup` command with the `--dry-run` flag to estimate the size of data files to be transferred, but make no changes on disk:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --destination-pgdata=path_to_local_dir --stream --dry-run
```

For example, assume that a remote standby server with the Postgres Pro instance having `/replica-pgdata` data directory has fallen behind. To sync this instance with the one in `/master-pgdata` data directory, you can run the `catchup` command in the `PTRACK` mode on four parallel threads as follows:

```
pg_probackup catchup --source-pgdata=/master-pgdata --destination-pgdata=/replica-pgdata -p 5432 -d postgres -U remote-postgres-user --stream --backup-mode=PTRACK  --remote-host=remote-hostname --remote-user=remote-unix-username -j 4 --exclude-path=postgresql.conf --exclude-path=postgresql.auto.conf --exclude-path=pg_hba.conf --exclude-path=pg_ident.conf
```

Note that in this example, the configuration files will not be overwritten during synchronization.

Another example shows how you can add a new remote standby server with the Postgres Pro data directory `/replica-pgdata` by running the `catchup` command in the `FULL` mode on four parallel threads:

```
pg_probackup catchup --source-pgdata=/master-pgdata --destination-pgdata=/replica-pgdata -p 5432 -d postgres -U remote-postgres-user --stream --backup-mode=FULL --remote-host=remote-hostname --remote-user=remote-unix-username -j 4
```

Command-Line Reference

Commands

This section describes pg_probackup commands. Optional parameters are enclosed in square brackets. For detailed parameter descriptions, see the section Options.

version

```
pg_probackup version [--format=json]
```

Prints pg_probackup version and edition, as well as Postgres Pro version and edition.

If `--format=json` is specified, the output is printed in the JSON format. This may be needed for native integration with JSON-based applications, such as PPEM. Example of a JSON output:

```
pg_probackup version --format=json
{
    "pg_probackup":
    {
        "version": "2.8.2",
        "edition": "community"
    },
    "database":
    {
        "type": "Postgres Pro Standard",
        "version": "16.3.1"
    },
    "compressions": [zlib, pglz, lz4, zstd]
}
```

help

```
pg_probackup help [command]
```

Displays the synopsis of pg_probackup commands. If one of the pg_probackup commands is specified, shows detailed information about the options that can be used with this command.

init

```
pg_probackup init -B backup_dir [--skip-if-exists] [--help]
[logging_options]
```

Initializes the backup catalog in *backup_dir* that will store backup copies, WAL archive, and meta information for the backed up database clusters. If the specified *backup_dir* already exists, it must be empty. Otherwise, pg_probackup displays a corresponding error message. You can ignore this error by specifying the `--skip-if-exists` option. Although the backup will not be initialized, the application will return 0 code.

For details, see the section Initializing the Backup Catalog.

add-instance

```
pg_probackup add-instance -B backup_dir -D data_dir --instance=instance_name
[--skip-if-exists] [--help] [--wal-tree] [logging_options]
```

Initializes a new backup instance inside the backup catalog *backup_dir* and generates the `pg_probackup.conf` configuration file that controls pg_probackup settings for the cluster with the specified *data_dir* data directory.

`--skip-if-exists`

Allows skipping initialization without raising an error if an instance already exists.

`--wal-tree`

Sets WAL files to be stored in subdirectories, optimizing disk space. This prevents file system overload, especially NFS (Network File System), which can struggle with excessive files in a single directory.

For more details on the `add-instance` command, see the section Adding a New Backup Instance.

del-instance

```
pg_probackup del-instance -B backup_dir --instance=instance_name [--help]
[logging_options]
```

Deletes all backups and WAL files associated with the specified instance.

set-config

```
pg_probackup set-config -B backup_dir --instance=instance_name
[--help] [--pgdata=pgdata-path]
[--retention-redundancy=redundancy][--retention-window=window][--wal-depth=wal_depth]
[--compress-algorithm=compression_algorithm] [--compress-level=compression_level]
[-d dbname] [-h host] [-p port] [-U username]
[--archive-timeout=timeout] [--external-dirs=external_directory_path]
[--restore-command=cmdline]
[remote_options] [remote_wal_archive_options] [logging_options]
```

Adds the specified connection, compression, retention, logging, and external directory settings into the `pg_probackup.conf` configuration file, or modifies the previously defined values.

For all available settings, see the Options section.

It is **not recommended** to edit `pg_probackup.conf` manually.

set-backup

```
pg_probackup set-backup -B backup_dir --instance=instance_name -i backup_id
{--ttl=ttl | --expire-time=time}
[--note=backup_note] [--help] [logging_options]
```

Sets the provided backup-specific settings into the `backup.control` configuration file, or modifies the previously defined values.

`--note=`*`backup_note`*

Sets the text note for backup copy. If *`backup_note`* contains newline characters, then only the substring before the first newline character will be saved. The maximum size of a text note is 1 KB. The *`'none'`* value removes the current note.

For all available pinning settings, see the section Pinning Options.

show-config

```
pg_probackup show-config -B backup_dir --instance instance_name [--format=plain|json]
[--no-scale-units] [logging_options]
```

Displays all the current pg_probackup configuration settings, including those that are specified in the `pg_probackup.conf` configuration file located in the *`backup_dir`*`/backups/`*`instance_name`* directory and those that were provided on a command line. You can specify the `--format=json` option to get the result in the JSON format. By default, configuration settings are shown as plain text.

You can also specify the `--no-scale-units` option to display time and memory configuration settings in their base (unscaled) units. Otherwise, the values are scaled to larger units for optimal display. For example, if `archive-timeout` is 300, then `5min` is displayed, but if `archive-timeout` is 301, then `301s` is displayed. Also, if the `--no-scale-units` option is specified, configuration settings are displayed without units and for the JSON format, numeric and boolean values are not enclosed in quotes. This facilitates parsing the output.

To edit `pg_probackup.conf`, use the set-config command.

show

```
pg_probackup show -B backup_dir
[--help] [--instance=instance_name [-i backup_id | --archive]] [--format=plain|json]
 [--no-color] [--show-symlinks]
[logging_options]
```

Shows the contents of the backup catalog. If *`instance_name`* and *`backup_id`* are specified, shows detailed information about this backup. If the `--archive` option is specified, shows the contents of WAL archive of the backup catalog.

By default, the contents of the backup catalog is shown as plain text. You can specify the `--format=json` option to get the result in the JSON format. If `--no-color` flag is used, then the output is not colored.

If the `--show-symlinks` option is specified, the command also shows the links between merged backups and the original full backups that incremental backups were merged to.

For details on usage, see the sections Managing the Backup Catalog and Viewing WAL Archive Information.

backup

```
pg_probackup backup -B backup_dir -b backup_mode --instance=instance_name
[--help] [-j num_threads] [--progress]
[--backup-threads num_threads] [--validate-threads num_threads]
[-C] [--stream [-S slot_name] [--temp-slot[=true|false|on|off]]] [--backup-pg-log]
[--no-validate] [--skip-block-validation]
[-w --no-password] [-W --password] [--allow-group-access]
[--write-rate-limit=bitrate]
[--archive-timeout=timeout] [--external-dirs=external_directory_path]
[--no-sync] [--note=backup_note]
[connection_options] [compression_options] [remote_options]
[retention_options] [pinning_options] [logging_options]
```

Creates a backup copy of the Postgres Pro instance.

`-b` *mode*
`--backup-mode=`*mode*

Specifies the backup mode to use. Possible values are: `FULL`, `DELTA`, `PAGE`, and `PTRACK`.

`--backup-threads` *num_threads*

Specifies the number of threads for copying files. Overrides the `j`/`--threads` option for file copying.

`--validate-threads` *num_threads*

Specifies the number of threads for the backup validation. Overrides the `j`/`--threads` option for the backup validation.

`-C`
`--smooth-checkpoint`

Spreads out the checkpoint over a period of time. By default, pg_probackup tries to complete the checkpoint as soon as possible.

`--stream`

Makes a STREAM backup, which includes all the necessary WAL files by streaming them from the database server via replication protocol.

`--temp-slot[=true|false|on|off]`

Creates a *temporary* physical replication slot for streaming WAL from the backed up Postgres Pro instance. `--temp-slot` is enabled by default. It ensures that all the required WAL segments remain available if WAL is rotated while the backup is in progress. This flag can only be used together with the `--stream` flag. The default slot name is `pg_probackup_slot`. To change it, use the `--slot`/`-S` option and explicitly specify `--temp-slot` or `--temp-slot=true|on`.

`-S` *slot_name*
`--slot=`*slot_name*

Specifies the replication slot to connect to for WAL streaming. This option can only be used together with the `--stream` flag.

`--backup-pg-log`

Includes the log directory into the backup. This directory usually contains log messages. By default, log directory is excluded.

`-E` *external_directory_path*
`--external-dirs=`*external_directory_path*

Includes the specified directory into the backup by recursively copying its contents into a separate subdirectory in the backup catalog. This option is useful to back up scripts, SQL dump files, and configuration files located outside of the data directory. If you would like to back up several external directories, separate their paths by a colon on Unix and a semicolon on Windows.

`--allow-group-access`

Provides read access to backups stored on the backup host to any OS user in the same group as the OS user on the backup host who runs pg_probackup operations.

`--write-rate-limit=`*bitrate*

Sets the rate of writing data to disk, in MBps or GBps. The default unit is MBps. For example: `--write-rate-limit=1GBps` or `--write-rate-limit=100` (MBps). The default value is 0 — no limitation.

If this option is specified, the following information is displayed at the end of the backup:

- `written` — the amount of data written, in MB.
- `total time` — the time that elapsed between the first and last writes, in seconds. Note that this is not the total backup time.
- `sleep time` — the amount of forced delay time, in seconds.
- `average rate` — the actual average write rate, in MBps.

For example:

```
INFO: Rate limit: written 14975.445 MB, total time 17.163 s, sleep time 2.370 s,
 average rate 872.560715 MBps
```

`--archive-timeout=`*`wait_time`*

Sets the timeout for WAL segment archiving and streaming, in seconds. By default, pg_probackup waits 300 seconds.

`--skip-block-validation`

Disables block-level checksum verification to speed up the backup process.

`--no-validate`

Skips automatic validation after the backup is taken. You can use this flag if you validate backups regularly and would like to save time when running backup operations.

`--no-sync`

Do not sync backed up files to disk. You can use this flag to speed up the backup process. Using this flag can result in data corruption in case of operating system or hardware crash. If you use this option, it is recommended to run the validate command once the backup is complete to detect possible issues.

`--note=`*`backup_note`*

Sets the text note for backup copy. If *`backup_note`* contain newline characters, then only substring before first newline character will be saved. Max size of text note is 1 KB. The *`'none'`* value removes current note.

For more details of the command settings, see sections Common Options, Connection Options, Retention Options, Pinning Options, Remote Mode Options, Compression Options, and Logging Options.

For details on usage, see the section Creating a Backup.

restore

```
pg_probackup restore -B backup_dir --instance=instance_name
[--help] [--dry-run] [-D data_dir] [-i backup_id]
[-j num_threads] [--progress]
[-T OLDDIR=NEWDIR] [--external-mapping=OLDDIR=NEWDIR] [--skip-external-dirs]
[-R | --restore-as-replica] [--no-validate] [--skip-block-validation]
[--force] [--no-sync] [--allow-group-access]
[--restore-command=cmdline]
[--primary-conninfo=primary_conninfo]
[-S | --primary-slot-name=slot_name]
[-X wal_dir | --waldir=wal_dir]
[recovery_target_options] [logging_options] [remote_options]
[partial_restore_options] [remote_wal_archive_options]
```

Restores the Postgres Pro instance from a backup copy located in the *`backup_dir`* backup catalog. If you specify a recovery target option, pg_probackup finds the closest backup and restores it to the specified recovery target. If neither the backup ID nor recovery target options are provided, pg_probackup uses the most recent backup to perform the recovery.

`-R`
`--restore-as-replica`

Creates a minimal recovery configuration file to facilitate setting up a standby server. If the replication connection requires a password, you must specify the password manually in the primary_conninfo parameter as it is not included. For Postgres Pro 11 or lower, recovery settings are written into the `recovery.conf` file. Starting from Postgres Pro 12, pg_probackup writes these settings into the `probackup_recovery.conf` file in the data directory, and then includes them into the `postgresql.auto.conf` when the cluster is is started.

`--primary-conninfo=`*`primary_conninfo`*

Sets the primary_conninfo parameter to the specified value. This option will be ignored unless the `-R` flag is specified.

Example: `--primary-conninfo="host=192.168.1.50 port=5432 user=foo password=foopass"`

`-S`
`--primary-slot-name=`*`slot_name`*

Sets the primary_slot_name parameter to the specified value. This option will be ignored unless the `-R` flag is specified.

`-T` *`OLDDIR=NEWDIR`*
`--tablespace-mapping=`*`OLDDIR=NEWDIR`*

Relocates the tablespace from the *`OLDDIR`* to the *`NEWDIR`* directory at the time of recovery. Both *`OLDDIR`* and *`NEWDIR`* must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces.

`--external-mapping=`*`OLDDIR=NEWDIR`*

Relocates an external directory included into the backup from the *`OLDDIR`* to the *`NEWDIR`* directory at the time of recovery. Both *`OLDDIR`* and *`NEWDIR`* must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple directories.

`--skip-external-dirs`

Skip external directories included into the backup with the `--external-dirs` option. The contents of these directories will not be restored.

`--skip-block-validation`

Disables block-level checksum verification to speed up validation. During automatic validation before the restore only file-level checksums will be verified.

`--no-validate`

Skips backup validation. You can use this flag if you validate backups regularly and would like to save time when running restore operations.

`--allow-group-access`

Provides any OS user in the same group as the cluster owner with the same access to the `PGDATA` directory on the database server as the cluster owner has. Running `restore` with this option will set the same permissions as when the cluster is created using the command

```
initdb --group access
```

`--restore-command=`*`cmdline`*

Sets the restore_command parameter to the specified command. For example: `--restore-command='cp /mnt/server/archivedir/%f "%p"'`

`--force`

Allows to ignore an invalid status of the backup. You can use this flag if you need to restore the Postgres Pro cluster from a corrupt or an invalid backup. Use with caution. If `PGDATA` contains a non-empty directory with system ID different from that of the backup being restored, incremental restore with this flag overwrites the directory contents (while an error occurs without the flag). If tablespaces are remapped through the `--tablespace-mapping` option into non-empty directories, the contents of such directories will be deleted.

`--no-sync`

Do not sync restored files to disk. You can use this flag to speed up restore process. Using this flag can result in data corruption in case of operating system or hardware crash. If it happens, you have to run the restore command again.

`-X` *`wal_dir`*
`--waldir=`*`wal_dir`*

Sets the directory to write WAL files to. By default WAL files will be placed in the `pg_wal` subdirectory of the target directory, but this option can be used to place them elsewhere. *`wal_dir`* must be an absolute path, which must not already exist, but if it does, it must be empty.

For more details of the command settings, see sections Common Options, Recovery Target Options, Remote Mode Options, Remote WAL Archive Options, Logging Options, and Partial Restore Options.

For details on usage, see the section Restoring a Cluster.

checkdb

```
pg_probackup checkdb
[-B backup_dir] [--instance=instance_name] [-D data_dir]
[--help] [-j num_threads] [--progress]
[--amcheck [--skip-block-validation] [--checkunique] [--heapallindexed]]
[connection_options] [logging_options]
```

Verifies the Postgres Pro database cluster correctness by detecting physical and logical corruption.

`--amcheck`

Performs logical verification of indexes for the specified Postgres Pro instance if no corruption was found while checking data files. You must have the amcheck extension or the amcheck_next extension installed in the database to check its indexes. For databases without amcheck, index verification will be skipped. Additional options `--checkunique` and `--heapallindexed` are effective depending on the version of amcheck installed.

`--checkunique`

Verifies unique constraints during logical verification of indexes. You can use this flag only together with the `--amcheck` flag when the amcheck extension is installed in the database.

The verification of unique constraints is only possible if in the version of the amcheck extension you are using, the `bt_index_check` function takes the *`checkunique`* parameter.

`--heapallindexed`

Checks that all heap tuples that should be indexed are actually indexed. You can use this flag only together with the `--amcheck` flag.

This check is only possible if in the version of the amcheck/amcheck_next extension you are using, the `bt_index_check` function takes the *`heapallindexed`* parameter.

`--skip-block-validation`

Skip validation of data files. You can use this flag only together with the `--amcheck` flag, so that only logical verification of indexes is performed.

For more details of the command settings, see sections Common Options, Connection Options, and Logging Options.

For details on usage, see the section Verifying a Cluster.

validate

```
pg_probackup validate -B backup_dir
[--help] [--instance=instance_name] [-i backup_id]
[-j num_threads] [--progress] [--wal]
[--skip-block-validation]
[recovery_target_options] [logging_options]
```

Verifies that all the files required to restore the cluster are present and are not corrupt. If *instance_name* is not specified, pg_probackup validates all backups available in the backup catalog. If you specify the *instance_name* without any additional options, pg_probackup validates all the backups available for this backup instance. If you specify the *instance_name* with a recovery target option and/or a *backup_id*, pg_probackup checks whether it is possible to restore the cluster using these options. If the `--wal` option is specified, full check of the WAL archive will be performed instead of only checking WAL segments needed to restore the cluster.

For details, see the section Validating a Backup.

merge

```
pg_probackup merge -B backup_dir --instance=instance_name -i backup_id
[--dry-run] [--help] [-j num_threads] [--progress] [--no-validate] [--no-sync]
[logging_options]
```

Merges backups that belong to a common incremental backup chain. If you specify a full backup, it will be merged with its first incremental backup. If you specify an incremental backup, it will be merged to its parent full backup, together with all incremental backups between them. Once the merge is complete, the full backup takes in all the merged data, and the incremental backups are removed as redundant.

`--no-validate`

Skips automatic validation before and after merge.

`--no-sync`

Do not sync merged files to disk. You can use this flag to speed up the merge process. Using this flag can result in data corruption in case of operating system or hardware crash.

For more details of the command settings, see sections Common Options and Merging Backups.

delete

```
pg_probackup delete -B backup_dir --instance=instance_name
[--help] [-j num_threads] [--progress]
[--retention-redundancy=redundancy][--retention-window=window][--wal-depth=wal_depth]
 [--delete-wal]
{-i backup_id | --delete-expired [--merge-expired] | --merge-expired | --
status=backup_status}
[--dry-run] [--no-validate] [--no-sync] [logging_options]
```

Deletes backup with specified *backup_id* or launches the retention purge of backups and archived WAL that do not satisfy the current retention policies.

`--no-validate`

Skips automatic validation before and after retention merge.

`--no-sync`

Do not sync merged files to disk. You can use this flag to speed up the retention merge process. Using this flag can result in data corruption in case of operating system or hardware crash.

For details, see the sections Deleting Backups, Retention Options, and Configuring Retention Policy.

archive-push

```
pg_probackup archive-push -B backup_dir --instance=instance_name
--wal-file-name=wal_file_name [--wal-file-path=wal_file_path]
[--help] [--dry-run] [--no-sync] [--compress] [--no-ready-rename] [--overwrite]
[-j num_threads] [--batch-size=batch_size]
[--archive-timeout=timeout]
[--compress-algorithm=compression_algorithm]
[--compress-level=compression_level]
[remote_options] [logging_options]
```

Copies WAL files into the corresponding subdirectory of the backup catalog and validates the backup instance by *instance_name* and `system-identifier`. If parameters of the backup instance and the cluster do not match, this command fails with the following error message: `Refuse to push WAL segment segment_name into archive. Instance parameters mismatch.`

If the files to be copied already exists in the backup catalog, pg_probackup computes and compares their checksums. If the checksums match, `archive-push` skips the corresponding file and returns a successful execution code. Otherwise, `archive-push` fails with an error. If you would like to replace WAL files in the case of checksum mismatch, run the `archive-push` command with the `--overwrite` flag.

Each file is copied to a temporary file with the `.part` suffix. If the temporary file already exists, pg_probackup will wait `archive_timeout` seconds before discarding it. After the copy is done, atomic rename is performed. This algorithm ensures that a failed `archive-push` will not stall continuous archiving and that concurrent archiving from multiple sources into a single WAL archive has no risk of archive corruption.

The Postgres Pro server requests WAL segments one at a time. To speed up archiving, you can specify the `--batch-size` option to copy WAL segments in batches of the specified size. If `--batch-size` option is used, then you can also specify the `-j` option to copy the batch of WAL segments on multiple threads.

WAL segments copied to the archive are synced to disk unless the `--no-sync` flag is used.

You can use `archive-push` in the archive_command Postgres Pro parameter to set up continuous WAL archiving.

For more details of the command settings, see sections Common Options, Archiving Options, and Compression Options.

archive-get

```
pg_probackup archive-get -B backup_dir --instance=instance_name --wal-file-
path=wal_file_path --wal-file-name=wal_file_name
[-j num_threads] [--batch-size=batch_size]
[--prefetch-dir=prefetch_dir_path] [--no-validate-wal]
[--dry-run] [--help] [remote_options] [logging_options]
```

Copies WAL files from the corresponding subdirectory of the backup catalog to the cluster's write-ahead log location. This command is automatically set by pg_probackup as part of the `restore_command` when restoring backups using a WAL archive. You do not need to set it manually.

The Postgres Pro server requests WAL segments one at a time. To speed up recovery, you can specify the `--batch-size` option to copy WAL segments in batches of the specified size. If `--batch-size` option is used, then you can also specify the `-j` option to copy the batch of WAL segments on multiple threads.

For more details of the command settings, see sections Common Options, Archiving Options, and Compression Options.

catchup

```
pg_probackup catchup -b catchup_mode
```

```
--source-pgdata=path_to_pgdata_on_remote_server
--destination-pgdata=path_to_local_dir
[--help] [-j | --threads=num_threads] [--dry-run]
[--write-rate-limit=bitrate]
[--stream [--temp-slot[=true|false|on|off]] [-P | --perm-slot] [-S | --slot=slot_name]]
[--exclude-path=PATHNAME]
[-T OLDDIR=NEWDIR]
[-X | --waldir=wal_dir]
[connection_options] [remote_options]
[logging_options]
```

Creates a copy of a Postgres Pro instance without using the backup catalog.

`-b catchup_mode`
`--backup-mode=catchup_mode`

Specifies the catchup mode to use. Possible values are: `FULL`, `DELTA`, and `PTRACK`.

`--source-pgdata=path_to_pgdata_on_remote_server`

Specifies the path to the data directory of the instance to be copied. The path can be local or remote.

`--destination-pgdata=path_to_local_dir`

Specifies the path to the local data directory to copy to.

`-j num_threads`
`--threads=num_threads`

Sets the number of parallel threads for `catchup` process.

`--stream`

Copies the instance in STREAM WAL delivery mode, including all the necessary WAL files by streaming them from the server via replication protocol. For `catchup`, it is enabled by default.

`--write-rate-limit=bitrate`

Sets the rate of writing data to disk, in MBps or GBps. The default unit is MBps. For example: `--write-rate-limit=1GBps` or `--write-rate-limit=100` (MBps). The default value is 0 — no limitation.

If this option is specified, the following information is displayed at the end of the `catchup` operation:

- `written` — the amount of data written, in MB.
- `total time` — the time that elapsed between the first and last writes, in seconds. Note that this is not the total duration of the `catchup` operation.
- `sleep time` — the amount of forced delay time, in seconds.
- `average rate` — the actual average write rate, in MBps.

For example:

```
INFO: Rate limit: written 14975.445 MB, total time 17.163 s, sleep time 2.370 s,
 average rate 872.560715 MBps
```

`-x=path_prefix`
`--exclude-path=path_prefix`

Specifies a prefix for files to exclude from the synchronization of Postgres Pro instances during copying. The prefix must contain a path relative to the data directory of an instance. If the prefix specifies a directory, all files in this directory will not be synchronized.

> **Warning**
>
> This option is dangerous since excluding files from synchronization can result in incomplete synchronization; use with care.

`--temp-slot[=true|false|on|off]`

Creates a *temporary* physical replication slot for streaming WAL from the Postgres Pro instance being copied. `--temp-slot` is enabled by default. It ensures that all the required WAL segments remain available if WAL is rotated while the backup is in progress. This flag can only be used together with the `--stream` flag and cannot be used together with the `--perm-slot` flag. The default slot name is `pg_probackup_slot`. To change it, use the `--slot`/`-S` option and explicitly specify `--temp-slot` or `--temp-slot=true|on`.

`-P`
`--perm-slot`

Creates a *permanent* physical replication slot for streaming WAL from the Postgres Pro instance being copied. This flag can only be used together with the `--stream` flag and cannot be used together with the `--temp-slot` flag. The default slot name is `pg_probackup_perm_slot`, which can be changed using the `--slot`/`-S` option.

`-S` *slot_name*
`--slot=`*slot_name*

Specifies the replication slot to connect to for WAL streaming. This option can only be used together with the `--stream` flag.

`-T` *OLDDIR=NEWDIR*
`--tablespace-mapping=`*OLDDIR=NEWDIR*

Relocates the tablespace from the *OLDDIR* to the *NEWDIR* directory at the time of recovery. Both *OLDDIR* and *NEWDIR* must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces.

`-X` *wal_dir*
`--waldir=`*wal_dir*

Sets the directory to write WAL files to. By default WAL files will be placed in the `pg_wal` subdirectory of the target directory, but this option can be used to place them elsewhere. *wal_dir* must be an absolute path, which must not already exist, but if it does, it must be empty to perform `catchup` with `--catchup-mode=FULL`.

For more details of the command settings, see sections Common Options, Connection Options, and Remote Mode Options.

For details on usage, see the section Cloning and Synchronizing Postgres Pro Instance.

maintain

```
pg_probackup maintain --B backup_dir --instance=instance_name
[-i backup_id] --status-sync [--help] [--dry-run]
[--log-level-console=log-level-console] [--log-level-file=log-level-file]
[--log-format-console=log-format-console] [--log-format-file=log-format-file]
[--log-filename=log-filename]
```

Performs a cleanup of the directory with backups of the specified instance after a forced termination of previous pg_probackup commands.

`--status-sync`

Detects expired locks and hanging backups, as well as updates backup statuses.

For more details of the command settings, see sections Common Options and Logging Options.

Options

This section describes command-line options for pg_probackup commands. If the option value can be derived from an environment variable, this variable is specified below the command-line option, in the uppercase. Some values can be taken from the `pg_probackup.conf` configuration file located in the backup catalog.

For details, see the section called “Configuring pg_probackup”.

If an option is specified using more than one method, command-line input has the highest priority, while the `pg_probackup.conf` settings have the lowest priority.

Common Options

The list of general options.

`--dry-run`

Initiates a trial run of the appropriate command, which does not actually do any changes, that is, it does not create, delete or move files on disk. This flag allows you to check that all the command options are correct and the command is ready to run. WAL streaming is skipped with `--dry-run`.

`-B` *directory*
`--backup-path=`*directory*
`BACKUP_PATH`

Specifies the absolute path to the backup catalog. Backup catalog is a directory where all backup files and meta information are stored. Since this option is required for most of the pg_probackup commands, you are recommended to specify it once in the `BACKUP_PATH` environment variable. In this case, you do not need to use this option each time on the command line.

`-D` *directory*
`--pgdata=`*directory*
`PGDATA`

Specifies the absolute path to the data directory of the database cluster. This option is mandatory only for the add-instance command. Other commands can take its value from the `PGDATA` environment variable, or from the `pg_probackup.conf` configuration file.

`-i` *backup_id*
`--backup-id=`*backup_id*

Specifies the unique identifier of the backup.

`--instance` *instance_name*

Specifies the name of the Postgres Pro instance.

`-j` *num_threads*
`--threads=`*num_threads*

Sets the number of parallel threads for `backup`, `restore`, `merge`, `validate`, `checkdb`, and `archive-push` processes.

`--progress`

Shows the progress of operations.

`--help`

Shows detailed information about the options that can be used with this command.

Recovery Target Options

If continuous WAL archiving is configured, you can use one of these options together with restore or validate commands to specify the moment up to which the database cluster must be restored or validated.

`--recovery-target=immediate|latest`

Defines when to stop the recovery:

- The `immediate` value stops the recovery after reaching the consistent state of the specified backup, or the latest available backup if the `-i`/`--backup-id` option is omitted. This is the default behavior for STREAM backups.
- The `latest` value continues the recovery until all WAL segments available in the archive are applied. Setting this value of `--recovery-target` also sets `--recovery-target-timeline` to `latest`.

`--recovery-target-timeline=`*`timeline`*

Specifies a particular timeline to be used for recovery:

- `current` — the timeline of the specified backup, default.
- `latest` — the timeline of the latest available backup.
- A numeric value.

`--recovery-target-lsn=`*`lsn`*

Specifies the LSN of the write-ahead log location up to which recovery will proceed.

`--recovery-target-name=`*`recovery_target_name`*

Specifies a named savepoint up to which to restore the cluster.

`--recovery-target-time=`*`time`*

Specifies the timestamp up to which recovery will proceed. If the time zone offset is not specified, the local time zone is used.

Example: `--recovery-target-time="2027-04-09 18:21:32+00"`

`--recovery-target-xid=`*`xid`*

Specifies the transaction ID up to which recovery will proceed.

`--recovery-target-inclusive=`*`boolean`*

Specifies whether to stop just after the specified recovery target (`true`), or just before the recovery target (`false`). This option can only be used together with `--recovery-target-time`, `--recovery-target-lsn` or `--recovery-target-xid` options. The default depends on the recovery_target_inclusive parameter.

`--recovery-target-action=pause|promote|shutdown`

Specifies recovery_target_action the server should take when the recovery target is reached.

Default: `pause`

Retention Options

You can use these options together with backup and delete commands.

For details on configuring retention policy, see the section Configuring Retention Policy.

`--retention-redundancy=`*`redundancy`*

Specifies the number of full backup copies to keep in the data directory. Must be a non-negative integer. The zero value disables this setting.

Default: `0`

`--retention-window=`*window*

Number of days of recoverability. Must be a non-negative integer. The zero value disables this setting.

Default: `0`

`--wal-depth=`*wal_depth*

Number of latest valid backups on every timeline that must retain the ability to perform PITR. Must be a non-negative integer. The zero value disables this setting.

Default: `0`

`--delete-wal`

Deletes WAL files that are no longer required to restore the cluster from any of the existing backups.

`--delete-expired`

Deletes backups that do not conform to the retention policy defined in the `pg_probackup.conf` configuration file.

`--merge-expired`

Merges the oldest incremental backup that satisfies the requirements of retention policy with its parent backups that have already expired.

`--dry-run`

Displays the current status of all the available backups, without deleting or merging expired backups, if any.

Pinning Options

You can use these options together with backup and set-backup commands.

For details on backup pinning, see the section Backup Pinning.

`--ttl=`*ttl*

Specifies the amount of time the backup should be pinned. Must be a non-negative integer. The zero value unpins the already pinned backup. Supported units: ms, s, min, h, d (s by default).

Example: `--ttl=30d`

`--expire-time=`*time*

Specifies the timestamp up to which the backup will stay pinned. Must be an ISO-8601 complaint timestamp. If the time zone offset is not specified, the local time zone is used.

Example: `--expire-time="2027-04-09 18:21:32+00"`

Logging Options

You can use these options with any command.

`--no-color`

Disable coloring for console log messages of `warning` and `error` levels.

`--log-level-console=`*log_level*

Controls which message levels are sent to the console log. Valid values are `verbose`, `log`, `info`, `warning`, `error` and `off`. Each level includes all the levels that follow it. The later the level, the fewer messages are sent. The `off` level disables console logging.

Default: `info`

> **Note**
>
> All console log messages are going to stderr, so the output of show and show-config commands does not mingle with log messages.

`--log-level-file=`*`log_level`*

Controls which message levels are sent to a log file. Valid values are `verbose`, `log`, `info`, `warning`, `error`, and `off`. Each level includes all the levels that follow it. The later the level, the fewer messages are sent. The `off` level disables file logging.

Default: `off`

`--log-filename=`*`log_filename`*

Defines the filenames of the created log files. The filenames are treated as a `strftime` pattern, so you can use %-escapes to specify time-varying filenames.

Default: `pg_probackup.log`

For example, if you specify the `pg_probackup-%u.log` pattern, pg_probackup generates a separate log file for each day of the week, with `%u` replaced by the corresponding decimal number: `pg_probackup-1.log` for Monday, `pg_probackup-2.log` for Tuesday, and so on.

This option takes effect if file logging is enabled by the `--log-level-file` option.

`--error-log-filename=`*`error_log_filename`*

Defines the filenames of log files for error messages only. The filenames are treated as a `strftime` pattern, so you can use %-escapes to specify time-varying filenames.

Default: none

For example, if you specify the `error-pg_probackup-%u.log` pattern, pg_probackup generates a separate log file for each day of the week, with `%u` replaced by the corresponding decimal number: `error-pg_probackup-1.log` for Monday, `error-pg_probackup-2.log` for Tuesday, and so on.

This option is useful for troubleshooting and monitoring.

`--log-directory=`*`log_directory`*

Defines the directory in which log files will be created. You must specify the absolute path. This directory is created lazily, when the first log message is written.

Default: `$BACKUP_PATH/log/`

`--log-format-console=`*`log_format`*

Defines the format of the console log. Only set from the command line. Note that you cannot specify this option in the `pg_probackup.conf` configuration file through the set-config command and that the backup command also treats this option specified in the configuration file as an error. Possible values are:

- `plain` — sets the plain-text format of the console log.
- `json` — sets the JSON format of the console log.

Default: `plain`

`--log-format-file=`*`log_format`*

Defines the format of log files used. Possible values are:

- `plain` — sets the plain-text format of log files.
- `json` — sets the JSON format of log files.

Default: `plain`

`--log-rotation-size=`*`log_rotation_size`*

Maximum size of an individual log file. If this value is reached, the log file is rotated once a pg_probackup command is launched, except `help` and `version` commands. The zero value disables size-based rotation. Supported units: kB, MB, GB, TB (kB by default).

Default: `0`

`--log-rotation-age=`*`log_rotation_age`*

Maximum lifetime of an individual log file. If this value is reached, the log file is rotated once a pg_probackup command is launched, except `help` and `version` commands. The time of the last log file creation is stored in `$BACKUP_PATH/log/log_rotation`. The zero value disables time-based rotation. Supported units: ms, s, min, h, d (min by default).

Default: `0`

Connection Options

You can use these options together with backup, catchup, and checkdb commands.

All libpq environment variables are supported.

`-d` *`dbname`*
`--pgdatabase=`*`dbname`*
`PGDATABASE`

Specifies the name of the database to connect to. The connection is used only for managing backup process, so you can connect to any existing database. If this option is not provided on the command line, `PGDATABASE` environment variable, or the `pg_probackup.conf` configuration file, pg_probackup tries to take this value from the `PGUSER` environment variable, or from the current user name if `PGUSER` variable is not set.

`-h` *`host`*
`--pghost=`*`host`*
`PGHOST`

Specifies the host name of the system on which the server is running. If the value begins with a slash, it is used as a directory for the Unix domain socket.

Default: `localhost`

`-p` *`port`*
`--pgport=`*`port`*
`PGPORT`

Specifies the TCP port or the local Unix domain socket file extension on which the server is listening for connections.

Default: `5432`

`-U` *`username`*
`--pguser=`*`username`*
`PGUSER`

User name to connect as.

`-w`
`--no-password`

Disables a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file or `PGPASSWORD` environment variable, the connection

attempt will fail. This flag can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`
`--password`

Forces a password prompt. (Deprecated)

Compression Options

You can use these options together with backup and archive-push commands.

`--compress-algorithm=`*`compression_algorithm`*

Defines the algorithm to use for compressing data files. Possible values are `zlib`, `lz4`, `zstd`, `pglz`, and `none`. If set to any value, but `none`, this option enables compression that uses the corresponding algorithm. Both data files and WAL files are compressed. By default, compression is disabled. For the archive-push command, the `pglz` compression algorithm is not supported.

> **Note**
>
> pg_probackup supports compression algorithms included in the Postgres Pro version. In particular:
>
> - lz4 is supported for Postgres Pro 14 and higher.
> - zstd is supported for Postgres Pro 15 and higher.

Default: `none`

`--compress-level=`*`compression_level`*

Defines the compression level. This option can be used together with the `--compress-algorithm` option. Possible values depend on the compression algorithm specified:

- 0 — 9 for `zlib`
- 1 for `pglz`
- 0 — 12 for `lz4`
- -131072 — 22 for `zstd`

The value of 0 sets the default compression level, which is `1`, for all compression algorithms.

> **Note**
>
> The pure lz4 algorithmn has only one compression level — 1. So, if the specified compression algorithm is `lz4` and `--compress-level` is greater than 1, the lz4hc algorithm is actually used, which is much slower although does better compression.

Default: `1`

`--compress`

Specifies the default compression algorithm and `--compress-level=1`. The default algorithm is selected among those supported by Postgres Pro according to the priorities: `zstd` (highest) -> `lz4` -> `zlib` -> `pglz`. The `--compress` option overrides the `--compression-algorithm` and `--compress-level` settings and cannot be specified together with them.

Archiving Options

These options can be used with the archive-push command in the archive_command setting and the archive-get command in the restore_command setting.

Additionally, remote mode options and logging options can be used.

`--wal-file-path=`*`wal_file_path`*

Provides the path to the WAL file in *`archive_command`* and *`restore_command`*. Use the `%p` variable as the value for this option or explicitly specify the path to a file outside of the data directory. If you skip this option, the path specified in `pg_probackup.conf` will be used.

`--wal-file-name=`*`wal_file_name`*

Provides the name of the WAL file in *`archive_command`* and *`restore_command`*. Use the `%f` variable as the value for this option for correct processing. If the value of `--wal-file-path` is a path outside of the data directory, explicitly specify the filename.

`--overwrite`

Overwrites archived WAL file. Use this flag together with the archive-push command if the specified subdirectory of the backup catalog already contains this WAL file and it needs to be replaced with its newer copy. Otherwise, `archive-push` reports that a WAL segment already exists, and aborts the operation. If the file to replace has not changed, `archive-push` skips this file regardless of the `--overwrite` flag.

`--batch-size=`*`batch_size`*

Used to speed up archiving in case of `archive-push` or to speed up recovery in case of `archive-get`. Sets the maximum number of WAL files that can be copied into the archive by a single `archive-push` process, or from the archive by a single `archive-get` process.

`--archive-timeout=`*`wait_time`*

Sets the timeout for considering existing `.part` files to be stale. By default, pg_probackup waits 300 seconds. This option can be used only with archive-push command.

`--no-ready-rename`

Do not rename status files in the `archive_status` directory. This option should be used only if *`archive_command`* contains multiple commands. This option can be used only with archive-push command.

`--no-sync`

Do not sync copied WAL files to disk. You can use this flag to speed up archiving process. Using this flag can result in WAL archive corruption in case of operating system or hardware crash. This option can be used only with archive-push command.

`--prefetch-dir=`*`path`*

Directory used to store prefetched WAL segments if `--batch-size` option is used. Directory must be located on the same filesystem and on the same mountpoint the `PGDATA/pg_wal` is located. By default files are stored in `PGDATA/pg_wal/pbk_prefetch` directory. This option can be used only with archive-get command.

`--no-validate-wal`

Do not validate prefetched WAL file before using it. Use this option if you want to increase the speed of recovery. This option can be used only with archive-get command.

Remote Mode Options

This section describes the options related to running pg_probackup operations remotely via SSH. These options can be used with add-instance, set-config, backup, catchup, restore, archive-push, and archive-get commands.

For details on configuring and using the remote mode, see the section called “Configuring the Remote Mode” and the section called “Using pg_probackup in the Remote Mode”.

`--remote-proto=`*`proto`*

Specifies the protocol to use for remote operations. Currently only the SSH protocol is supported. Possible values are:

- `ssh` enables the remote mode via SSH. This is the default value.
- `none` explicitly disables the remote mode.

You can omit this option if the `--remote-host` option is specified.

`--remote-host=`*`destination`*

Specifies the remote host IP address or hostname to connect to.

`--remote-port=`*`port`*

Specifies the remote host port to connect to.

Default: `22`

`--remote-user=`*`username`*

Specifies remote host user for SSH connection. If you omit this option, the current user initiating the SSH connection is used.

`--remote-path=`*`path`*

Specifies pg_probackup installation directory on the remote system.

`--ssh-options=`*`ssh_options`*

Provides a string of SSH command-line options. For example, the following options can be used to set *`keep-alive`* for SSH connections opened by pg_probackup: `--ssh-options="-o ServerAliveCountMax=5 -o ServerAliveInterval=60"`. For the full list of possible options, see *ssh_config manual page*.

Remote WAL Archive Options

This section describes the options used to provide the arguments for remote mode options in archive-get used in the restore_command command when restoring ARCHIVE backups or performing PITR.

`--archive-host=`*`destination`*

Provides the argument for the `--remote-host` option in the `archive-get` command.

`--archive-port=`*`port`*

Provides the argument for the `--remote-port` option in the `archive-get` command.

Default: `22`

`--archive-user=`*`username`*

Provides the argument for the `--remote-user` option in the `archive-get` command. If you omit this option, the user that has started the Postgres Pro cluster is used.

Default: Postgres Pro user

Incremental Restore Options

This section describes the options for incremental cluster restore. These options can be used with the restore command.

`-I` *`incremental_mode`*
`--incremental-mode=`*`incremental_mode`*

Specifies the incremental mode to be used. Possible values are:

- `CHECKSUM` — replace only pages with mismatched checksum and LSN.
- `LSN` — replace only pages with LSN greater than point of divergence.
- `NONE` — regular restore.

Partial Restore Options

This section describes the options for partial cluster restore. These options can be used with the restore command.

`--db-exclude=`*dbname*

Specifies the name of the database to exclude from restore. All other databases in the cluster will be restored as usual, including `template0` and `template1`. This option can be specified multiple times for multiple databases.

`--db-include=`*dbname*

Specifies the name of the database to restore from a backup. All other databases in the cluster will not be restored, with the exception of `template0` and `template1`. This option can be specified multiple times for multiple databases.

Testing and Debugging Options

This section describes options useful only in a test or development environment.

`PGPROBACKUP_TESTS_SKIP_HIDDEN`

Instructs pg_probackup to ignore backups marked as hidden. Note that pg_probackup can never mark a backup as hidden. It can only be done by directly editing the `backup.control` file. This option can only be set with environment variables.

`--destroy-all-other-dbs`

By default, pg_probackup exits with an error if an attempt is made to perform a partial incremental restore since this destroys databases not included in the restore set. This flag allows you to suppress the error and proceed with the partial incremental restore (e.g., to keep a development database snapshot up-to-date with a production one). This option can be used with the restore command.

> **Important**
>
> Never use this flag in a production cluster.

`--lock-lifetime`

Specifies the lifetime for locks taken when performing a backup, in seconds. The default value is 300. The minimum value is 60.

`PGPROBACKUP_TESTS_SKIP_EMPTY_COMMIT`

Instructs pg_probackup to skip empty commits after pg_backup_stop.

Versioning

pg_probackup follows *semantic* versioning.

Authors

Postgres Professional, Moscow, Russia.

Credits

pg_probackup utility is based on pg_arman, which was originally written by NTT and then developed and maintained by Michael Paquier.

vacuumlo

vacuumlo — remove orphaned large objects from a Postgres Pro database

Synopsis

`vacuumlo` [*option*...] *dbname*...

Description

vacuumlo is a simple utility program that will remove any “orphaned” large objects from a Postgres Pro database. An orphaned large object (LO) is considered to be any LO whose OID does not appear in any `oid` or `lo` data column of the database.

If you use this, you may also be interested in the `lo_manage` trigger in the lo module. `lo_manage` is useful to try to avoid creating orphaned LOs in the first place.

All databases named on the command line are processed.

Options

vacuumlo accepts the following command-line arguments:

`-l` *limit*
`--limit=`*limit*

Remove no more than *limit* large objects per transaction (default 1000). Since the server acquires a lock per LO removed, removing too many LOs in one transaction risks exceeding max_locks_per_transaction. Set the limit to zero if you want all removals done in a single transaction.

`-n`
`--dry-run`

Don't remove anything, just show what would be done.

`-v`
`--verbose`

Write a lot of progress messages.

`-V`
`--version`

Print the vacuumlo version and exit.

`-?`
`--help`

Show help about vacuumlo command line arguments, and exit.

vacuumlo also accepts the following command-line arguments for connection parameters:

`-h` *host*
`--host=`*host*

Database server's host.

`-p` *port*
`--port=`*port*

Database server's port.

`-U` *username*
`--username=`*username*

User name to connect as.

`-w`
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`
`--password`

Force vacuumlo to prompt for a password before connecting to a database.

This option is never essential, since vacuumlo will automatically prompt for a password if the server demands password authentication. However, vacuumlo will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

Environment

`PGHOST`
`PGPORT`
`PGUSER`

Default connection parameters.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see Section 33.15).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

Notes

vacuumlo works by the following method: First, vacuumlo builds a temporary table which contains all of the OIDs of the large objects in the selected database. It then scans through all columns in the database that are of type `oid` or `lo`, and removes matching entries from the temporary table. (Note: Only types with these names are considered; in particular, domains over them are not considered.) The remaining entries in the temporary table identify orphaned LOs. These are removed.

Author

Peter Mount `<peter@retep.org.uk>`

I.2. Third-Party Client Applications

This section covers third-party client applications included in the Postgres Pro Standard distribution. They can be run from anywhere, independent of where the database server resides.

pgbadger

pgbadger — rapidly analyze Postgres Pro logs, producing detailed reports and graphs

Synopsis

`pgbadger` [*`connection-option`*...] [*`option`*...] [*`logfile`*...]

Description

pgbadger is a Postgres Pro/PostgreSQL log analyzer, which rapidly provides detailed reports based on your log files. pgbadger is provided with Postgres Pro as a standalone Perl script.

`logfile` can be a single log file, a list of files or a shell command that returns a list of files. To get log content from the standard input, pass "-" as *`logfile`*.

pgbadger can parse huge log files and compressed files. It can autodetect your log file format (syslog, stderr, csvlog or jsonlog) if the file is long enough. Supported compressed formats are gzip, bzip2, lz4, xz, zip and zstd. For the xz format, you must have an xz version higher than 5.05, which supports the `--robot` option. For pgbadger to determine the uncompressed file size for the lz4 format, the file must be compressed with the `--content-size` option.

pgbadger supports any format of log-line prefixes that can be specified through the log_line_prefix configuration setting of your `postgresql.conf` configuration file, provided that at least `%t` and `%p` are specified.

pgbouncer log files can also be parsed.

To speed up log parsing, you can use any of these multiprocessing modes: one core per log file and multiple cores per file. These modes can be combined.

pgbadger can also parse remote log files fetched using a passwordless SSH connection. This mode can be used with compressed files and even supports multiprocessing with multiple cores per file.

Examples of reports can be found at *https://pgbadger.darold.net/#reports*.

Limitations

pgbadger currently has the following limitations:

- Multiprocessing is not supported for compressed log files and CSV files, as well as on Windows.
- CSV format of log files cannot be parsed remotely.
- csvlog logs cannot be passed from the standard input.

Setup and Configuring

pgbadger is provided with Postgres Pro Standard as a separate pre-built package `pgbadger` (for the detailed installation instructions, see Chapter 16). Once you have pgbadger installed, complete the setup described in sections below.

[Optional] Set up Parsing Specific Log Formats

If you plan to parse CSV log files, install `Text::CSV_XS` Perl module.

[Optional] Set up Export of Statistics

If you want to export statistics as a JSON file, install `JSON::XS` Perl module:

To install this optional module:

- On a Debian-based system, run:

```
sudo apt-get install libjson-xs-perl
```

- On an RPM system, run:

  ```
  sudo yum install perl-JSON-XS
  ```

[Optional] Set up Parsing Compressed Log Files

By default, pgbadger autodetects the compressed log file format from the file extension and uses decompression utilities accordingly:

- zcat for `gz`
- bzcat for `bz2`
- lz4cat for `lz4`
- zstdcat for `zst`
- unzip or xz for `zip` or `xz`

If the needed utility is outside of your `PATH` directories, use the `--zcat` command-line option to specify the path to the decompression utility. For example:

```
--zcat="/usr/local/bin/gunzip -c" or --zcat="/usr/local/bin/bzip2 -dc"
--zcat="C:\tools\unzip -p"
```

> **Note**
>
> With the default autodetection of the compressed file format, you can mix gz, bz2, lz4, xz, zip and zstd log files. Once you specified a custom value of `--zcat`, mixing compressed files of different formats is longer possible.

Configure Your Postgres Pro Server

Set the values of certain configuration parameters in your `postgresql.conf`:

- Set up logging SQL queries.

  To enable SQL query logging and have the query statistics include actual query strings, set

  ```
  log_min_duration_statement = 0
  ```

  On a busy server you may want to increase this value to only log queries with a longer duration.

  If you just want to report the duration and number of queries and do not want details of queries, set log_min_duration_statement to -1, which disables logging statement durations, and enable log_duration.

  Enabling `log_min_duration_statement` will add reports about slowest queries and queries that took the most time. Note that if you set log_statement to `all`, the setting of `log_min_duration_statement` will have no effect.

  > **Warning**
  >
  > Avoid setting `log_min_duration_statement` to a non-positive value together with enabling `log_duration` and `log_statement` as this will result in wrong counter values and drastically increase the size of your log. Always prefer setting `log_min_duration_statement`.

- Set the log line prefix string in log_line_prefix.

  It must at least include a time escape sequence (`%t`, `%m` or `%n`) and the process-related escape sequence (`%p` or `%c`). For example, for stderr logs, the setting must be at least

```
log_line_prefix = '%t [%p]: '
```

The log line prefix could also specify the user, database name, application name and client IP address. For example,

for stderr logs:

```
log_line_prefix = '%t [%p]: user=%u,db=%d,app=%a,client=%h '
```

or

```
log_line_prefix = '%t [%p]: db=%d,user=%u,app=%a,client=%h '
```

and for syslog logs:

```
log_line_prefix = 'user=%u,db=%d,app=%a,client=%h '
```

or

```
log_line_prefix = 'db=%d,user=%u,app=%a,client=%h '
```

- To get more information from your log files, set certain configuration parameters as follows:

```
log_checkpoints = on
log_connections = on
log_disconnections = on
log_lock_waits = on
log_temp_files = 0
log_autovacuum_min_duration = 0
log_error_verbosity = default
```

To benefit from these settings, do not enable log_statement as pgbadger does not parse the corresponding log format.

- Set the language in which messages are displayed; messages must be in English with or without locale support:

```
lc_messages='C'
```

or

```
lc_messages='en_US.UTF-8'
```

Locales for other languages, such as `ru_RU.utf8`, are not supported.

Usage

The following are simple examples to illustrate miscellaneous pgbadger usage details.

```
pgbadger /var/lib/pgpro/std-14/data/log/postgresql-2022-01-14_000000.log
pgbadger /var/lib/pgpro/std-14/data/log/postgres.log.2.gz /var/lib/pgpro/std-14/data/
log/postgres.log.1.gz /var/lib/pgpro/std-14/data/log/postgresql-2022-01-14_000000.log
pgbadger /var/lib/pgpro/std-14/data/log/postgresql/postgresql-2022-01-*
pgbadger --exclude-query="^(COPY|COMMIT)" /var/lib/pgpro/std-14/data/log/
postgresql-2022-01-14_000000.log
pgbadger -b "2022-01-25 10:56:11" -e "2022-01-25 10:59:11" /var/lib/pgpro/std-14/data/
log/postgresql-2022-01-25-0000.log
cat /var/lib/pgpro/std-14/data/log/postgresql-2022-01-14_000000.log | pgbadger -
# Log line prefix with stderr log output
pgbadger --prefix '%t [%p]: user=%u,db=%d,client=%h' /var/lib/pgpro/std-14/data/log/
postgresql-2022-08-21*
pgbadger --prefix '%m %u@%d %p %r %a : ' /var/lib/pgpro/std-14/data/log/
postgresql-2022-08-21-0000.log
# Log line prefix with syslog log output
pgbadger --prefix 'user=%u,db=%d,client=%h,appname=%a' /var/lib/pgpro/std-14/data/log/
postgresql-2022-08-21*
# Use 8 CPUs to parse 10GB file faster
```

```
pgbadger -j 8 /var/lib/pgpro/std-14/data/log/postgresql-2022-08-21-0000.log
# Use a cron job to report errors weekly
30 23 * * 1 /usr/bin/pgbadger -q -w /var/lib/pgpro/std-14/data/log/
postgresql-2022-01*.log -o /var/www/pg_reports/pg_errors.html
```

Specifying Remote Log Files

Specify remote log files to parse using a URI. Supported protocols are HTTP[S] and [S]FTP. The `curl` command will be used to download the file, and the file will be parsed during download. The SSH protocol is also supported and will use the `ssh` command to get log files, as when the `--remote-host` option is used.

Use these URI notations for the remote log file:

```
pgbadger http://172.12.110.1//var/lib/pgpro/std-14/data/log/
postgresql-2022-01-14_000000.log
pgbadger ftp://username@172.12.110.14/postgresql-2022-01-14_000000.log
pgbadger ssh://username@172.12.110.14:2222//var/lib/pgpro/std-14/data/log/
postgresql-2022-01-14_000000.log*
```

You can parse a local Postgres Pro log and a remote pgbouncer log file together:

```
pgbadger /var/lib/pgpro/std-14/data/log/postgresql-2022-01-14_000000.log ssh://
username@172.12.110.14/pgbouncer.log
```

Parallel Processing

To enable parallel processing, specify the `-j N` option, where *N* is the number of cores to use.

Parallel processing in pgbadger follows the algorithm below:

```
For each log file
  chunk size = int(file size / N)
  look at start/end offsets of these chunks
  fork N processes and seek to the start offset of each chunk
    each process will terminate when the parser reaches the end offset of its chunk
    each process writes stats into a binary temporary file
  wait for all child processes to terminate
All binary temporary files generated will then be read and loaded into
memory to build the html output.
```

With this method, at start/end of chunks pgbadger may truncate or omit a maximum of *N* queries per log file, which is an insignificant gap if you have millions of queries in your log file. The chance that the query that you were looking for is lost is near zero, so this gap can be considered suitable. Most of the time the query is counted twice, but truncated.

When you have many small log files and many CPUs, it is faster to dedicate one core to one log file at a time. To enable this behavior, specify the `-J N` option instead. Using this method, you can be sure not to lose any queries in the reports. With 200 log files of 10 MB each, the `-J` option starts being really efficient with 8 cores.

Here is a benchmark done on a server with 8 CPUs and a single file of 9.5 GB.

```
 Option |  1 CPU  | 2 CPU | 4 CPU | 8 CPU
--------+---------+-------+-------+------
   -j   | 1h41m18 | 50m25 | 25m39 | 15m58
   -J   | 1h41m18 | 54m28 | 41m16 | 34m45
```

With 200 log files of 10 MB each, which is 2 GB in total, the results are slightly different:

```
 Option | 1 CPU | 2 CPU | 4 CPU | 8 CPU
--------+-------+-------+-------+------
```

```
-j    | 20m15 |  9m56 |  5m20 | 4m20
-J    | 20m15 |  9m49 |  5m00 | 2m40
```

So it is recommended to use the `-j` option unless you have hundreds of small log files and can use at least 8 CPUs.

> **Important**
>
> During parallel parsing, pgbadger generates a lot of temporary files named `tmp_pgbadgerXXXX.bin` in the `/tmp` directory and removes them at the end.

Building Incremental Reports

The following sample cron job builds a report every week with the incremental behavior assuming that your log file and HTML report are also rotated every week:

```
0 4 * * 1 /usr/bin/pgbadger -q `find /var/lib/pgpro/std-14/data/log/ -mtime -7 -name
 "postgresql.log*"` -o /var/www/pg_reports/pg_errors-`date +\%F`.html -l /var/reports/
pgbadger_incremental_file.dat
```

But better turn on pgbadger's automatic building incremental reports by specifyng the `-I`/`--incremental` option. In this mode, pgbadger builds one report per day and a cumulative report per week. The output is first built in the binary format and saved to the output directory, specified by the `-O`/`--outdir` option, and then daily and weekly reports are built in the HTML format with the main index file. The main index file shows a dropdown menu per week with a link to the week's report and links to daily reports for that week. For example, run pgbadger as follows with the file rotated daily:

```
0 4 * * * /usr/bin/pgbadger -I -q /var/lib/pgpro/std-14/data/log/postgresql/
postgresql.log.1 -O /var/www/pg_reports/
```

You will have all daily and weekly reports. In this mode pgbadger will automatically create an incremental file in the output directory, so you do not have to use the `-l` option unless you want to change the path of that file. This means that you can run pgbadger in this mode every day on a log file rotated every week and it will not count the log entries twice. To save disk space, you may want to use the `-X`/`--extra-files` command-line option to force pgbadger to write CSS and JavaScript files to the output directory as separate files. The resources will then be loaded using script and link tags.

In the incremental mode, you can also specify the number of weeks to keep in the report by using the `-O`/`--retention` option:

```
/usr/bin/pgbadger --retention 2 -I -q /var/lib/pgpro/std-14/data/log/postgresql/
postgresql.log.1 -O /var/www/pg_reports/
```

If pg_dump is scheduled to run at 23:00 and 13:00 every day, you can exclude these periods from the report as follows:

```
pgbadger --exclude-time "2013-09-.* (23|13):.*" postgresql.log
```

This will help avoid having `COPY` statements generated by pg_dump on top of the list of slowest queries. Alternatively, you can use `--exclude-appname "pg_dump"` to solve this problem in a simpler way.

Rebuilding Reports

To update all HTML reports after fixing a pgbadger report or adding a new feature to it, you can rebuild incremental reports. To rebuild all reports in the case a binary file is still available, run:

```
rm /path/to/reports/*.js
rm /path/to/reports/*.css
pgbadger -X -I -O /var/www/pg_reports/ --rebuild
```

This will also update all the resource files (JavaScript and CSS). Use the `-E`/`--explode` option if the reports were built with this option.

Building Monthly Reports

By default, in the incremental mode pgbadger only computes daily and weekly reports. To have monthly cumulative reports, you will need to use a separate command to specify the report to build. For example, to build a report for August 2021, run:

```
pgbadger -X --month-report 2021-08 /var/www/pg_reports/
```

This will add a link to the month name to the calendar view of incremental reports to look at the monthly report. The report for a current month can be run every day, and it is entirely rebuilt each time. The monthly report is not built by default because it could take too long. Like when rebuilding reports, if reports were built with the per-database option (`-E`/`--explode`), it must be used to build the monthly report:

```
pgbadger -E -X --month-report 2021-08 /var/www/pg_reports/
```

Choosing the Report File Format

The pgbadger report file format is determined by the extension of the file passed to the `-o`/`--outfile` option.

Use the binary format (`-o *.bin`) to create custom incremental and cumulative reports.

For example, to refresh a pgbadger report every hour from a daily log file, you can run the following commands every hour:

```
# Generate incremental data files in the binary format
pgbadger --last-parsed .pgbadger_last_state_file -o sunday/hourX.bin /var/lib/pgpro/
std-14/data/log/postgresql-Sun.log
# Build a fresh HTML report from the generated binary file
pgbadger sunday/*.bin
```

For another example, assume that you generate one log file per hour. To have reports rebuilt each time the log file is rotated, run:

```
pgbadger -o day1/hour01.bin /var/lib/pgpro/std-14/data/log/postgresql-2022-01-23_10.log
pgbadger -o day1/hour02.bin /var/lib/pgpro/std-14/data/log/postgresql-2022-01-23_11.log
pgbadger -o day1/hour03.bin /var/lib/pgpro/std-14/data/log/postgresql-2022-01-23_12.log
...
```

And to refresh the HTML report, for example, each time after a new binary file is generated, just run:

```
pgbadger -o day1_report.html day1/*.bin
```

Adjust the commands to your particular needs.

Use the JSON format (`-o *.json`) to share data with other languages and to facilitate integration of pgbadger output with other monitoring tools, such as Cacti or Graphite.

Select other output formats to meet your particular needs. For example, this command will generate *Tsung* sessions XML file for `SELECT` queries only:

```
  pgbadger -S -o sessions.tsung --prefix '%t [%p]: user=%u,db=%d ' /var/lib/pgpro/
std-14/data/log/postgresql-2022-01-14_000000.log
```

Return Codes

pgbadger return codes depend on how it terminated as follows:

- `0`: was a success
- `1`: died on error
- `2`: has been interrupted using `Ctrl+C`, for example
- `3`: the PID file already exists or cannot be created

- `4`: no log file was specified on the command line

Options

This section describes pgbadger command-line options.

`-a` *minutes*
`--average` *minutes*

Specifies the number of minutes for which to build average graphs of queries and connections.

Default: 5.

`-A` *minutes*
`--histo-average` *minutes*

Specifies the number of minutes for which to build histogram graphs of queries.

Default: 60.

`-b` *datetime*
`--begin` *datetime*

Timestamp or time that specifies the start date/time for the data to be parsed in logs.

`-c` *host*
`--dbclient` *host*

Only report on log entries for the specified client host.

`-C`
`--nocomment`

Remove /* ... */ comments from queries.

`-d` *name*
`--dbname` *name*

Only report on log entries for the specified database.

`-D`
`--dns-resolv`

Replace client IP addresses with their DNS names.

> **Warning**
>
> This can considerably slow down pgbadger.

`-e` *datetime*
`--end` *datetime*

Timestamp or time that specifies the end date/time for the data to be parsed in logs.

`-E`
`--explode`

Build one report per each database. Global information not related to any database gets added to the `postgres` database report.

`-f` *logtype*
`--format` *logtype*

Specifies the log type.

Possible values: `syslog`, `syslog2`, `stderr`, `jsonlog`, `csv`, `pgbouncer`, `logplex`, `rds` and `redshift`. Use when pgbadger cannot detect the log format.

`-G`
`--nograph`

Disables graphs in HTML output.

`-h`
`--help`

Show detailed information about pbadger options and exit.

`-H` *path*
`--html-outdir` *path*

Specifies the path to the directory where the HTML report must be written in the incremental mode. Note that binary files remain in the directory specified by `-O`/`--outdir`.

`-i` *name*
`--ident` *name*

Specifies the program name used to identify Postgres Pro messages in syslog logs.

Default: `postgres`.

`-I`
`--incremental`

Use the incremental mode, where reports will be generated by days in a separate directory specified by the `-O`/`--outdir` option.

`-j` *number*
`--jobs` *number*

Specifies the number of jobs to run at the same time. When working with csvlog logs, pgbadger always runs as single job.

Default: 1.

`-J` *number*
`--Jobs` *number*

Specifies the number of log files to parse in parallel.

Default: 1.

`-l` *filename*
`--last-parsed` *filename*

Specifies the file where the last datetime and line parsed are registered to allow incremental log parsing. Useful to watch errors since the last run or to get one report per day with the log rotated weekly.

`-L` *filename*
`--logfile-list` *filename*

Specifies the file containing the list of log files to parse.

`-m` *size*
`--maxlength` *size*

Specifies the maximum length of a query in reports. Longer queries will be truncated.

Default: 100000.

`-M`
`--no-multiline`

Turns off collecting multiline statements to avoid reporting excessive information, especially on errors that generate a huge report.

`-N` *name*
`--appname` *name*

Only report on log entries for the specified application.

`-o` *filename*
`--outfile` *filename*

Specifies the filename for the output and determines the report file format: `out.html`, `out.txt`, `out.bin` or `out.json`. Can be used multiple times to output several formats. For the `json` output, ensure that the Perl module `JSON::XS` is installed. To dump the output to stdout, use the value of "-" as filename.

Default: `out.html`, `out.txt`, `out.bin`, `out.json` or `out.tsung`,

for the respective output format.

`-O` *path*
`--outdir` *path*

Specifies the directory where out files must be saved.

`-p` *string*
`--prefix` *string*

Specifies the value of your custom log_line_prefix string, as defined in your `postgresql.conf`. Only use if your log line prefix is different from the standard `log_line_prefix` strings, for example, if your prefix includes additional variables, such as client IP or application name. The string must contain escape sequences for time (%t, %m or %n) and processes (%p or %c).

`-P`
`--no-prettify`

Disables SQL query code prettifier.

`-q`
`--quiet`

Disables printing anything to stdout, even the progress bar.

`-Q`
`--query-numbering`

Add numbering of queries to the output when used together with `--dump-all-queries` or `--normalized-only`.

`-r` *address*
`--remote-host` *address*

Specifies the host to execute the `cat` command on a remote log file to parse the file locally.

`-R` *number*
`--retention` *number*

Specifies the number of weeks for which to keep reports in the output directory in the incremental mode. The directories for older weeks and days are automatically removed.

Default: 0 (no reports are removed).

`-s` *number*
`--sample` *number*

Specifies the number of query samples to store.

Default: 3.

`-S`
`--select-only`

Only report on SELECT queries.

`-t` *number*
`--top` *number*

Specifies the number of queries to store/display.

Default: 20.

`-T` *string*
`--title` *string*

Specifies the title of the HTML report page.

`-u` *username*
`--dbuser` *username*

Only report on log entries for the specified username.

`-U` *username*
`--exclude-user` *username*

Specifies the username to exclude log entries for from the report. Can be used multiple times.

`-v`
`--verbose`

Enables the verbose or debug mode.

Default: off.

`-V`
`--version`

Show pgbadger version and exit.

`-w`
`--watch-mode`

Only report errors, just like *Logwatch* can do.

`-W`
`--wide-char`

Encode HTML output of queries in UTF8 to avoid Perl messages “Wide character in print”.

`-x` *format*
`--extension` *format*

Specfies the output format. Possible values: `text`, `html`, `bin` or `json`.

Default: `html`.

`-X`
`--extra-files`

In the incremental mode, write CSS and JavaScript resources to the output directory as separate files.

`-z` *command*
`--zcat` *command*

Specifies the full command to run the zcat program. Use if zcat, bzcat or unzip is outside of your `PATH` directories.

`-Z` *+/-XX*
`--timezone` *+/-XX*

Specifies the number of hours from GMT for the timezone. Use to adjust date/time in JavaScript graphs. The value can be an integer (e.g., 2), or a float, (e.g., 2.5).

`--pie-limit` *number*

Specifies the number such that instead of lower pie data the sum will be shown.

`--exclude-query` *regexp*

Specifies the regular expression such that matching queries will be excluded from the report. For example: "^(VACUUM|COMMIT)". Can be used multiple times.

`--exclude-file` *filename*

Specifies the path to the file that contains each regular expression to use to exclude matching queries from the report, one expression per line.

`--include-query` *regexp*

Specifies the regular expression such that only matching queries will be included in the report. Can be used multiple times. For example: "(tbl1|tbl2)".

`--include-file` *filename*

Specifies the path to the file that contains each regular expression to use to include matching queries in the report, one expression per line.

`--disable-error`

Turns off generation of an error report.

`--disable-hourly`

Turns off generation of an hourly report.

`--disable-type`

Turns off generation of a report on queries by type, database and user.

`--disable-query`

Turns off generation of query reports, such as slowest or most frequent queries, queries by users, by database and so on.

`--disable-session`

Turns off generation of a session report.

`--disable-connection`

Turns off generation of a connection report.

`--disable-lock`

Turns off generation of a lock report.

`--disable-temporary`

Turns off generation of a report on temporary files.

`--disable-checkpoint`

Turns off generation of checkpoint/restartpoint reports.

`--disable-autovacuum`

Turns off generation of an autovacuum report.

`--charset` *name*

Specifies the HTML charset to be used.

Default: utf-8.

`--csv-separator` *char*

Specifies the CSV field separator.

Default: “,”.

`--exclude-time` *regexp*

Specifies the regular expression such that log entries for any matching timestamp will be excluded from the report. For example: “2013-04-12 .*”. Can be used multiple times.

`--include-time` *regexp*

Specifies the regular expression such that log entries for any matching timestamp will be included in the report. For example: “2013-04-12 .*”. Can be used multiple times.

`--exclude-db` *name*

Specifies the name of the database to exclude related log entries from the report. For example: “outdated_db”. Can be used multiple times.

`--exclude-appname` *name*

Specifies the name of the application to exclude related log entries from the report. For example: “pg_dump”. Can be used multiple time.

`--exclude-line` *regexp*

Specifies the regular expression such that any matching log entry will be excluded from the report. Can be used multiple times.

`--exclude-client` *name*

Specifies the client IP/name to exclude related log entries from the report. Can be used multiple times.

`--anonymize`

Obscure all literals in queries. Useful to hide confidential data.

`--noreport`

Prevents generation of reports in the incremental mode.

`--log-duration`

Associate log entries generated by `log_duration = on` and `log_statement = all`.

`--enable-checksum`

Add the MD5 sum under each query report.

`--journalctl` *command*

Specifies the command to produce the information similar to what the Postgres Pro log file contains. Usually, like this: `journalctl -u postgrespro-std-14`.

`--pid-dir` *path*

Specifies the path to store the PID file.

Default: `/tmp`.

`--pid-file` *filename*

Specifies the name of the PID file to manage concurrent execution of pgbadger.

Default: `pgbadger.pid`.

`--rebuild`

Rebuild all HTML reports in incremental output directories that contain binary data files.

`--pgbouncer-only`

Only show pgbouncer-related menus in the header.

`--start-monday`

In the incremental mode, start calendar weeks on Monday. By default, they start on Sunday.

`--iso-week-number`

In the incremental mode, start calendar weeks on Monday (by default, they start on Sunday) with ISO 8601 week numbering: 01 to 53, where week 1 is the first week of a year that has at least 4 days.

`--normalized-only`

Only dump all normalized queries to `out.txt`.

`--log-timezone` *+/-XX*

Specifies the number of hours from GMT for the timezone to adjust date/time read from the log file before parsing. The use of this option makes log search with date/time more complicated. The value can be an integer (e.g., 2), or a float, (e.g., 2.5).

`--prettify-json`

Prettify JSON output.

`--month-report` *YYYY-MM*

Specifies the month (YYYY-MM) to create a cumulative HTML report for. Requires incremental output directories to be set and all the necessary binary data files available.

`--day-report` *YYYY-MM-DD*

Specifies the day (YYYY-MM-DD) to create an HTML report for. Requires incremental output directories to be set and all the necessary binary data files available.

`--noexplain`

Avoid processing log lines generated by auto_explain.

`--command` *cmd*

Specifies the command to run to retrieve log entries on stdin. pgbadger will open a pipe to this command and parse log entries that it generates.

`--no-week`

Avoid building weekly reports in the incremental mode. Use if building weekly reports takes too long.

`--explain-url` *URL*

Specifes the URL to override the URL of the graphical explain tool.

Default: *http://explain.depesz.com/*

`--tempdir` *path*

Specifies the directory for temporary files.

Default: `File::Spec->tmpdir() || '/tmp'`.

`--no-process-info`

Disables changing the pgbadger process title to help identify this process. Useful for systems where changing process titles is not supported.

`--dump-all-queries`

Dump all queries found in the log file to a text file, replacing bind parameters in the queries at their respective placeholder positions.

`--keep-comments`

Retains comments in normalized queries. Useful to distinguish between same normalized queries.

`--no-progressbar`

Disables displaying the progress bar.

`--dump-raw-csv`

Parse the log and dump the information into CSV format. No further processing is done, no report.

`--include-pid` *PID*

Only report events related to the session PID (%p). Can be used multiple times.

`--include-session` *ID*

Only report events related to the session ID (%c). Can be used multiple times.

`--histogram-query` *VAL*

Use custom inbound for query time histogram. Default inbound in milliseconds: 0,1,5,10,25,50,100,500,1000,10000.

`--histogram-session` *VAL*

Use custom inbound for session time histogram. Default inbound in milliseconds: 0,500,1000,30000,60000,600000,1800000,3600000,28800000.

Remote Log Connection Options

pgbadger can parse a remote log file fetched using passwordless SSH connection. Use the `-r`/`--remote-host` option to set the IP address or name of the target host. More options to define SSH connection parameters are as follows:

`--ssh-program` *ssh*

Specifies the path to the SSH program to use.

Default: ssh.

`--ssh-port` *port*

Specifies the SSH port for the connection.

Default: 22.

`--ssh-user` *username*

Specifies the username for the connection.

Default: user running pgbadger.

`--ssh-identity` *filename*

Specifies the path to the identity file.

`--ssh-timeout` *seconds*

Specifies the timeout in seconds in case of the SSH connection failure.

Default: 10.

`--ssh-option` *options*

Specifies the list of options to define SSH connection parameters. The following options are always used:

```
-o ConnectTimeout=$ssh_timeout -o PreferredAuthentications=hostbased,publickey
```

```
-o PreferredAuthentications=hostbased,publickey
```

pg_repack

pg_repack — utility and Postgres Pro Standard extension to reorganize tables

Synopsis

`pg_repack` [*option*...] [*dbname*]

Description

pg_repack is a Postgres Pro Standard extension which lets you remove bloat from tables and indexes, and optionally restore the physical order of clustered indexes. Unlike CLUSTER and `VACUUM FULL` it works online, without holding an exclusive lock on the processed tables during processing. pg_repack is efficient to boot, with performance comparable to using `CLUSTER` directly.

pg_repack is a fork of the previous *https://github.com/reorg/pg_reorg* project.

You can choose one of the following methods to reorganize data:

- Online `CLUSTER` (ordered by cluster index)
- Ordering by specified columns
- Online `VACUUM FULL` (packing rows only)
- Rebuild or relocate only the indexes of a table

> **Note**
>
> Only superusers can use the utility.

> **Note**
>
> Target table must have a PRIMARY KEY, or at least a UNIQUE total index on a NOT NULL column.

Installation

On Linux systems, pg_repack is provided together with Postgres Pro Standard as a separate pre-built package `pg-repack-std-14` and requires the `postgrespro-std-14-server` package to be installed with all the dependencies. For the list of available packages and detailed installation instructions, see Chapter 16. On Windows systems, pg_repack is automatically installed as part of Postgres Pro.

Once you have pg_repack installed, load the `pg_repack` extension in the database you want to process, as follows:

```
$ psql -c "CREATE EXTENSION pg_repack" -d your_database
```

You can later remove `pg_repack` from a Postgres Pro installation using `DROP EXTENSION pg_repack`.

If you are upgrading from a previous version of pg_repack, just drop the old version from the database as explained above and install the new version.

Options

Reorganization Options

`-a`
`--all`

Attempt to repack all the databases of the cluster. Databases where the `pg_repack` extension is not installed will be skipped.

`-t` *table*
`--table=`*table*

Reorganize the specified table(s) only. Multiple tables may be reorganized by writing multiple `-t` switches. By default, all eligible tables in the target databases are reorganized.

`-I` *table*
`--parent-table=`*table*

Reorganize both the specified table(s) and its inheritors. Multiple table hierarchies may be reorganized by writing multiple `-I` switches.

`-c` *schema*
`--schema=`*schema*

Repack the tables in the specified schema(s) only. Multiple schemas may be repacked by writing multiple `-c` switches. Can be used in conjunction with `--tablespace` to move tables to a different tablespace.

`-o` *column*`[, ...]`
`--order-by=`*column*`[, ...]`

Perform an online `CLUSTER` ordered by the specified columns.

`-n`
`--no-order`

Perform an online `VACUUM FULL`. Since version 1.2 this is the default for non-clustered tables.

`-N`
`--dry-run`

Show what would be repacked and exit.

`-j` *num_jobs*
`--jobs=`*num_jobs*

Create the specified number of extra connections to Postgres Pro, and use these extra connections to parallelize the rebuild of indexes on each table. Parallel index builds are only supported for full-table repacks, not with `--index` or `--only-indexes` options. If your server has extra cores and disk I/O available, this can be a useful way to speed up pg_repack.

`-s` *tablespace*
`--tablespace=`*tablespace*

Move the repacked tables to the specified tablespace: essentially an online version of `ALTER TABLE ... SET TABLESPACE`. The tables' indexes are left in the original tablespace unless `--moveidx` is specified too.

`-S`
`--moveidx`

Also move the indexes of the repacked tables to the tablespace specified by the `--tablespace` option.

`-i` *index*
`--index=`*index*

Repack the specified index(es) only. Multiple indexes may be repacked by writing multiple `-i` switches. May be used in conjunction with `--tablespace` to move the index(es) to a different tablespace.

`-x`
`--only-indexes`

Repack only the indexes of the specified table(s), which must be specified with the `--table` option.

`-T` *secs*
`--wait-timeout=`*secs*

pg_repack needs to take an exclusive lock at the end of the reorganization. This setting controls how many seconds pg_repack will wait to acquire this lock. If the lock cannot be taken after this duration and `--no-kill-backend` option is not specified, pg_repack will forcibly cancel the conflicting queries. If you are using Postgres Pro or PostgreSQL version 8.4 or newer, pg_repack will fall back to using `pg_terminate_backend()` to disconnect any remaining backends after this timeout has passed twice. The default is 60 seconds.

`-D`
`--no-kill-backend`

Skip repacking a table if the lock cannot be taken for duration specified in `--wait-timeout`, instead of cancelling conflicting queries. The default is `false`.

`-Z`
`--no-analyze`

Disable `ANALYZE` after a full-table reorganization. If not specified, `ANALYZE` is executed after the reorganization.

`-k`
`--no-superuser-check`

Skip the superuser checks in the client. This setting is useful for using pg_repack on platforms that support running it as non-superusers.

`-C`
`--exclude-extension`

Skip tables that belong to the specified extension(s). Some extensions may heavily depend on such tables at planning time etc.

`--switch-threshold`

Switch tables when that many tuples are left in the log table. This setting can be used to avoid the inability to catch up with write-heavy tables.

Connection Options

Options to connect to servers. You cannot use `--all` and `--dbname` or `--table` or `--parent-table` together.

`-a`
`--all`

Reorganize all databases.

`[-d]` *dbname*
`[--dbname=]`*dbname*

Specifies the name of the database to be reorganized. If this is not specified and `-a` (or `--all`) is not used, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used.

`-h` *host*
`--host=`*host*

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p` *port*
`--port=`*port*

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

`-U` *username*
`--username=`*username*

User name to connect as.

`-w`
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`
`--password`

Force pg_repack to prompt for a password before connecting to a database.

This option is never essential, since pg_repack will automatically prompt for a password if the server demands password authentication. However, pg_repack will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

Generic Options

`-e`
`--echo`

Echo the commands that pg_repack generates and sends to the server.

`-E` *level*
`--elevel=`*level*

Choose the output message level from `DEBUG`, `INFO`, `NOTICE`, `WARNING`, `ERROR`, `LOG`, `FATAL`, and `PANIC`. The default is `INFO`.

`--help`

Show help about pg_repack command line arguments, and exit.

`-V`
`--version`

Print the pg_repack version and exit.

Environment

`PGDATABASE`
`PGHOST`
`PGPORT`
`PGUSER`

Default connection parameters

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see Section 33.15).

Examples

Perform an online `CLUSTER` of all the clustered tables in the database `test`, and perform an online `VACUUM FULL` of all the non-clustered tables:

```
$ pg_repack test
```

Perform an online `VACUUM FULL` on the tables `foo` and `bar` in the database `test` (an eventual cluster index is ignored):

```
$ pg_repack --no-order --table foo --table bar test
```

Move all indexes of table `foo` to tablespace `tbs`:

```
$ pg_repack -d test --table foo --only-indexes --tablespace tbs
```

Move the specified index to tablespace `tbs`:

```
$ pg_repack -d test --index idx --tablespace tbs
```

Diagnostics

Error messages are reported when pg_repack fails. The following list shows the cause of errors.

You need to cleanup by hand after fatal errors. To cleanup, just remove `pg_repack` from the database and install it again.

For Postgres Pro or PostgreSQL 9.1 and newer execute:

```
DROP EXTENSION pg_repack CASCADE
```

in the database where the error occurred, followed by

```
CREATE EXTENSION pg_repack
```

For previous versions load the script `$SHAREDIR/contrib/uninstall_pg_repack.sql` into the database where the error occurred and then load `$SHAREDIR/contrib/pg_repack.sql` again.

```
INFO: database "db" skipped:
pg_repack VER is not installed in the database:
pg_repack is not installed in the database when the --all option is specified.
```

Create the `pg_repack` extension in the database.

```
ERROR: pg_repack VER is not installed in the database:
pg_repack is not installed in the database specified by --dbname
```

Create the `pg_repack` extension in the database.

```
ERROR: program 'pg_repack V1' does not match database library 'pg_repack V2':
There is a mismatch between the pg_repack binary and the database library
(.so or .dll).
```

The mismatch could be due to the wrong binary in the `PATH` or the wrong database being addressed. Check the program directory and the database; if they are what expected you may need to repeat `pg_repack` installation.

```
ERROR: extension 'pg_repack V1' required, found 'pg_repack V2':
The SQL extension found in the database does not match the version required by the
 pg_repack program.
```

You should drop the extension from the database and reload it as described in the section called “Installation”.

```
ERROR: relation "table" must have a primary key or not-null unique keys:
```

```
The target table doesn't have a PRIMARY KEY or any UNIQUE constraints defined.
```

Define a PRIMARY KEY or a UNIQUE constraint on the table.

```
ERROR: query failed: ERROR: column "col" does not exist:
The target table doesn't have columns specified by --order-by option.
```

Specify existing columns.

```
WARNING: the table "tbl" already has a trigger called z_repack_trigger:
The trigger was probably installed during a previous attempt
to run pg_repack on the table which was interrupted
and for some reason failed to clean up the temporary objects.
```

You can remove all the temporary objects by dropping and re-creating the extension: see the section called “Installation” for the details.

```
WARNING: trigger "trg" conflicting on table "tbl":
The target table has a trigger whose name follows z_repack_trigger
in alphabetical order.
```

The `z_repack_trigger` should be the last BEFORE trigger to fire. Please rename your trigger so that it sorts alphabetically before `pg_repack` one; you can use:

```
ALTER TRIGGER zzz_my_trigger
 ON sometable RENAME TO yyy_my_trigger;
```

```
ERROR: Another pg_repack command may be running on the table. Please try again later.
```

There is a chance of deadlock when two concurrent `pg_repack` commands are run on the same table. So, try to run the command after some time.

```
WARNING: Cannot create index "schema"."index_xxxxx", already exists
DETAIL: An invalid index may have been left behind by a previous
pg_repack on the table which was interrupted. Please use DROP INDEX
"schema"."index_xxxxx" to remove this index and try again.
```

A temporary index apparently created by pg_repack has been left behind, and we do not want to risk dropping this index ourselves. If the index was in fact created by an old pg_repack job which didn't get cleaned up, you should just use `DROP INDEX` and try the `repack` command again.

Restrictions

pg_repack comes with the following restrictions.

Temporary tables

pg_repack cannot reorganize temporary tables.

GiST indexes

pg_repack cannot cluster tables by `GiST` indexes.

DDL commands

You will not be able to perform DDL commands of the target table(s) *except* `VACUUM` or `ANALYZE` while pg_repack is working. pg_repack will hold an `ACCESS SHARE` lock on the target table during a full-table repack, to enforce this restriction.

If you are using version 1.1.8 or earlier, you must not attempt to perform any DDL commands on the target table(s) while pg_repack is running. In many cases pg_repack would fail and rollback correctly, but there were some cases in these earlier versions which could result in data corruption.

I.3. Additional Postgres Pro Server Applications

This section covers Postgres Pro Standard server-related applications. They are typically run on the host where the database server resides. See also Postgres Pro Server Applications for information about server applications that are part of the core Postgres Pro Standard distribution.

mamonsu

mamonsu — a monitoring agent for collecting Postgres Pro and system metrics

Synopsis

`mamonsu agent` [*agent_action*]

`mamonsu bootstrap -M` *mamonsu_user* [`-c` | `--config`] [`-x` | `--create-extensions`] [*connection_options*]

`mamonsu export` {`template` | `config`} *filename* [*export_options*]

`mamonsu report` [*report_options*] [*connection_options*]

`mamonsu tune` [*tuning_options*] [*connection_options*]

`mamonsu upload` [*upload_options*]

`mamonsu zabbix dashboard upload` *template_name*

`mamonsu zabbix` {`template` | `host` | `hostgroup`} *server_action*

`mamonsu zabbix item` {`error` | `lastvalue` | `lastclock`} *host_id*

`mamonsu zabbix version`

`mamonsu` [`-c` | `--config`] [`-d` | `--daemonize`]

`mamonsu --version`

`mamonsu --help`

Description

mamonsu is a monitoring agent for collecting Postgres Pro and system metrics that can be visualized on the Zabbix server. Unlike the native Zabbix Agent configured to collect Postgres Pro metrics, mamonsu uses a single database connection, which allows to minimize performance impact on the monitored system.

The mamonsu agent includes the following components:

- A supervisor process that monitors database and system activity.
- Plugins that specify which Postgres Pro and system metrics to collect.
- Customizable configuration and template files that define which plugins to use and how to visualize the collected data.

mamonsu is an active agent, which means that it sends the data to the Zabbix server once it is collected. Pre-configured to monitor multiple Postgres Pro and system metrics out of the box, mamonsu can be extended with your own custom plugins to track other metrics critical for your system.

mamonsu also provides the command-line interface for updating some Zabbix server settings, as well as getting an overview of the monitored system configuration and tuning Postgres Pro and system settings on the fly. You can find the list of all mamonsu commands in the section called “Command-Line Reference”.

Installation and Setup

> **Important**
>
> Before you start installation, attentively read Compatibility Considerations.

To use mamonsu, you must create a Zabbix account and set up a Zabbix server as explained in *Zabbix documentation*. Naturally, you must also have a Postgres Pro instance up and running if you are going to monitor Postgres Pro metrics. If you are configuring your Postgres Pro cluster from scratch, see Chapter 16 and Section 17.2 for Postgres Pro installation and setup instructions, respectively.

> **Note**
>
> While mamonsu can collect Postgres Pro metrics from a remote cluster, system metrics are only collected locally. If you choose to collect Postgres Pro metrics remotely, make sure to disable collection of system metrics to avoid confusion, as they will be displayed under the same host in Zabbix.

mamonsu is provided with Postgres Pro Standard as a separate pre-built package `mamonsu` (for the detailed installation instructions, see Chapter 16). Once you have installed mamonsu, complete the following steps to set up metrics collection:

1. **Optionally, bootstrap mamonsu**

   If you omit this step, metrics can only be collected on behalf of a superuser, which is not recommended.

   In this step, the `bootstrap` command sets the mamonsu user, creates `mamonsu` schema in the specified or implied database, as well as extensions and objects needed for monitoring.

   `bootstrap` has no mandatory options. When run without options, it takes the values needed from the configuration file (`/etc/mamonsu/agent.conf` by default). Below is a simple example of bootstrap:

   1. In the `[postgres]` section of `agent.conf`, specify connection parameters for the Postgres Pro cluster you are going to monitor. For more details, see Connection Parameters.
   2. Run the following command to bootstrap mamonsu:

      ```
      mamonsu bootstrap
      ```

      This command will create the user `mamonsu` with the password `mamonsu`, create monitoring functions in the database specified in `agent.conf` and grant the right to execute them to the `mamonsu` user.

   In the following example, `bootstrap` options are passed explicitly.

   1. Create a non-privileged database user for mamonsu. For example:

      ```
      CREATE USER mamonsu_user WITH PASSWORD 'mamonsu_password';
      GRANT pg_monitor TO mamonsu_user;
      ```

   2. Create a database that will be used for connection to Postgres Pro. For example:

      ```
      CREATE DATABASE mamonsu_database OWNER mamonsu_user;
      ```

   3. Run the following command to bootstrap mamonsu:

      ```
      mamonsu bootstrap -M mamonsu_user -x -c /etc/mamonsu/agent.conf -d
       mamonsu_database -U postgres --host myhost --port 5432
      ```

      For details of the options `-M`, `-x` and `-c`, see `bootstrap`. For details of other options, see Connection Options. This command will create monitoring functions in the *`mamonsu_database`* and grant the right to execute them to *`mamonsu_user`*. The pg_buffercache extension will also be created to ensure collection of metrics on the shared buffer cache, and the path to the configuration file will be changed.

   As a result, a superuser connection is no longer required. Note that mamonsu also creates several tables in the `mamonsu` schema in the specified database. Do not delete these tables as they are required for mamonsu to work.

2. **Configure mamonsu**

   Edit the `agent.conf` configuration file, which is located in the `/etc/mamonsu/` directory by default.

   - Configure Zabbix-related settings. The `address` field must point to the running Zabbix server, while the `client` field must provide the name of the Zabbix host. You can find the list of hosts available for your account in the Zabbix web interface under **Configuration > Hosts**.

     ```
     [zabbix]
     ; enabled by default
     enabled = True
     client = zabbix_host_name
     address = zabbix_server
     ```

   - By default, mamonsu will collect both Postgres Pro and system metrics. If required, you can disable metrics collection of either type by setting the `enabled` parameter to `False` in the `[postgres]` or `[system]` section of the `agent.conf` file, respectively.

     ```
     [system]
     ; enabled by default
     enabled = True
     ```

     > **Note**
     >
     > While mamonsu can collect Postgres Pro metrics from a remote cluster, system metrics are only collected locally. If you choose to collect Postgres Pro metrics remotely, make sure to disable collection of system metrics to avoid confusion, as they will be displayed under the same host in Zabbix.

   - If you are going to collect Postgres Pro metrics, specify connection parameters for the Postgres Pro cluster you are going to monitor. In the `user`, `password`, and `database` fields, you must specify the *`mamonsu_user`*, *`mamonsu_password`*, and the *`mamonsu_database`* used for bootstrap, respectively. If you skipped the bootstrap, specify superuser credentials and the database to connect to.

     ```
     [postgres]
     ; enabled by default
     enabled = True
     user = mamonsu_user
     database = mamonsu_database
     password = mamonsu_password
     port = 5432
     ```

   These are the main mamonsu settings to get started. You can also fine-tune other mamonsu settings as explained in the section called “Configuration Parameters”.

3. **Configure how to display metrics on the Zabbix server**

   1. Generate a template that defines how to visualize the collected metrics on the Zabbix server:

      ```
      mamonsu export template template.xml
      ```

      mamonsu generates the `template.xml` file in your current directory. By default, the name of the template that will be displayed in the Zabbix account is `PostgresPro-`*`OS`*, where *`OS`* is the name of your operating system. To get a template with a different display name, you can run the above command with the `--template-name` option.

   2. Optionally, specify your Zabbix account settings in the following environment variables on your monitoring system:

- Set the `ZABBIX_USER` and `ZABBIX_PASSWD` variables to the login and password of your Zabbix account, respectively.
- Set the `ZABBIX_URL` to `http://zabbix/`

If you skip this step, you will have to add the following options to all `mamonsu zabbix` commands that you run:

```
--url=http://zabbix/ --user=zabbix_login --password=zabbix_password
```

3. Upload `template.xml` to the Zabbix server.

   ```
   mamonsu zabbix template export template.xml
   ```

   Alternatively, you can upload the template through the Zabbix web interface: log in to your Zabbix account and select **Templates > Import**.

4. Link the generated template to the host to be monitored.

   In the Zabbix web interface, select your host, go to **Templates > Add**, select your template, and click **Update**.

> **Tip**
>
> If you would like to link a template with a new Zabbix host, you can do it from the command line using `mamonsu zabbix` commands. See the section called “Managing Zabbix Server Settings from the Command Line” for details.

When the setup is complete, start mamonsu. For example, on Linux systems, you can start mamonsu as a service with the following command:

```
service mamonsu start
```

mamonsu picks up all the parameters from the mamonsu configuration file and starts monitoring your system.

Command-Line Reference

agent

Syntax:

```
mamonsu agent { metric-list | metric-get metric_name | version }
```

Provide information on the collected metrics from the command line. You can specify one of the following parameters:

`metric-list`

Show the list of metrics that mamonsu is collecting. The output of this command provides the item key of each metric, its latest value, and the time when this value was received.

`metric-get` *`metric_name`*

Check the latest value for the specified metric. You can get the list of available metrics using the `metric-list` option.

`version`

Display mamonsu version.

bootstrap

Syntax:

```
mamonsu bootstrap -M mamonsu_user
        [-c[ config_file] | --config[=config_file]]
        [-x | --create-extensions] [connection_options]
```

Bootstrap mamonsu. This command can take the following options:

`-M`

Specify a non-privileged user that will own all mamonsu processes.

`-c config_file`
`--config=config_file`

Specify the `agent.conf` file where the `[postgres]` section contains the database name to be used if `--dbname` is not specified through *connection_options*.

Default: `/etc/mamonsu/agent.conf`

`-x`
`--create-extensions`

Create auxiliary extensions. The pg_buffercache extension will be created, which is no longer created by default. For Postgres Pro 12 or higher, the `bootstrap -x` command will also create functions to work with the pgpro_stats extension and grant the right to execute them to the `mamonsu` user.

connection_options

Provide optional *command-line connection parameters*.

export

Syntax:

```
mamonsu export config filename.conf  [--add-plugins=plugin_directory]
mamonsu export template filename.xml [--add-plugins=plugin_directory]
                                     [--template-name=template_name]
                                     [--application=application_name]
                                     [--old-zabbix]
```

Generate a template or configuration file for metrics collection. The optional parameters to customize metrics collection are as follows:

`--add-plugins=plugin_directory`

Collect metrics that are defined in custom plugins located in the specified *plugin_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

`--template-name=template_name`

Specify the name of the template that will be displayed on the Zabbix server.

Default: `PostgresPro-OS`, where *OS* is the name of your operating system

`--application=application_name`

Specify an identifier under which the collected metrics will be displayed on the Zabbix server.

Default: `App-PostgresPro-OS`, where *OS* is the name of your operating system

`--old-zabbix`

Export a template for Zabbix server version 4.2 or lower. By default, the template is generated in a format compatible with Zabbix 4.4 or higher.

export zabbix-parameters

Syntax:

```
mamonsu export zabbix-parameters filename.conf [--add-plugins=plugin_directory]
                                       [--plugin-type={pg | sys | all}]
                                       [--pg-version=version]
                                       [--config=config_file]
```

Export metrics configuration for use with the native *Zabbix agent*. The optional parameters to customize metrics collection are as follows:

`--add-plugins=`*`plugin_directory`*

Collect metrics that are defined in custom plugins located in the specified *`plugin_directory`*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

`--plugin-type={pg | sys | all}`

Specify the type of metrics to collect:

- `pg` for Postgres Pro metrics.
- `sys` for system metrics.
- `all` for both Postgres Pro and system metrics.

Default: `all`

`--pg-version=`*`version`*

Specify the major version of the server for which to configure metrics collection. `mamonsu` can collect metrics for all supported Postgres Pro versions, as well as PostgreSQL versions starting from 9.5.

Default: `10`

`--config=`*`config_file`*

Specify the `agent.conf` file to be used as the source for metrics definitions.

Default: `/etc/mamonsu/agent.conf`

export zabbix-template

Syntax:

```
mamonsu export zabbix-template filename.conf [--add-plugins=plugin_directory]
                                       [--plugin-type={pg | sys | all}]
                                       [--template-name=template_name]
                                       [--application=application_name]
                                       [--config=config_file]
                                       [--old-zabbix]
```

Export a template for use with the native Zabbix agent. The optional parameters to customize metrics collection are as follows:

`--add-plugins=`*`plugin_directory`*

Collect metrics that are defined in custom plugins located in the specified *`plugin_directory`*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

`--plugin-type={pg | sys | all}`

Specify the type of metrics to collect:

- `pg` configures Postgres Pro metrics.
- `sys` configures system metrics.
- `all` configures both Postgres Pro and system metrics.

Default: `all`

`--template-name=`*`template_name`*

Specify the name of the template that will be displayed on the Zabbix server.

Default: `PostgresPro-`*`OS`*, where *`OS`* is the name of your operating system

`--application=`*`application_name`*

Specify an identifier under which the collected metrics will be displayed on the Zabbix server.

Default: `App-PostgresPro-`*`OS`*, where *`OS`* is the name of your operating system

`--config=`*`config_file`*

Specify the `agent.conf` file to be used as the source for metrics definitions.

Default: `/etc/mamonsu/agent.conf`

`--old-zabbix`

Export a template for Zabbix server version 4.2 or lower. By default, the template is generated in a format compatible with Zabbix 4.4 or higher.

report

Syntax:

```
mamonsu report [--run-system=Boolean] [--run-postgres=Boolean]
               [--print-report=Boolean] [--report-path=report_file]
               [--disable-sudo] [connection_options]
```

Generate a detailed report on the hardware, operating system, memory usage and other parameters of the monitored system, as well as Postgres Pro configuration.

The following optional parameters customize the report:

`--run-system=`*`Boolean`*

Include system information into the generated report.

Default: `True`

`--run-postgres=`*`Boolean`*

Include information on Postgres Pro into the generated report.

Default: `True`

`--print-report=`*`Boolean`*

Print the report to stdout.

Default: `True`

`--report-path=`*`report_file`*

Save the report into the specified file.

Default: `/tmp/report.txt`

`--disable-sudo`

Do not report data that can only be received with superuser rights. This option is only available for Linux systems.

`connection_options`

Provide optional *command-line connection parameters*.

tune

Syntax:

```
mamonsu tune [--dry-run] [--disable-sudo] [--log-level {INFO|DEBUG|WARN}]
             [--dont-tune-pgbadger] [--dont-reload-postgresql]
             [connection_options]
```

Optimize Postgres Pro and system configuration based on the collected statistics. You can use the following options:

`--dry-run`

Display the settings to be tuned without changing the actual system and Postgres Pro configuration.

`--disable-sudo`

Do not tune the settings that can only be changed by a superuser. This option is only available for Linux systems.

`--dont-tune-pgbadger`

Do not tune pgbadger parameters.

`--log-level { INFO | DEBUG | WARN}`

Change the logging level.

Default: `INFO`

`--dont-reload-postgresql`

Forbid mamonsu to run the `pg_reload_conf()` function. If you specify this option, the modified settings that require reloading Postgres Pro configuration do not take effect immediately.

`connection_options`

Provide optional *command-line connection parameters*.

upload

Syntax:

```
mamonsu upload [--zabbix-file=metrics_file]
               [--zabbix-address=zabbix_address] [--zabbix-port=port_number]
               [--zabbix-client=zabbix_host_name] [--zabbix-log-level={INFO|DEBUG|
WARN}]
```

Upload metrics data previously saved into a file onto a Zabbix server for visualization. For details on how to save metrics into a file, see the section called “Logging Parameters”.

This command can take the following options:

`--zabbix-address=`*`zabbix_address`*

The address of the Zabbix server.

Default: `localhost`

`--zabbix-port=`*`port_number`*

The port of the Zabbix server.

Default: 10051

`--zabbix-file=`*`metrics_file`*

A text file that stores the collected metrics data to be visualized, such as `localhost.log`.

`--zabbix-client=`*`zabbix_host_name`*

The name of the Zabbix host.

Default: `localhost`

`--zabbix-log-level={INFO|DEBUG|WARN}`

Change the logging level.

Default: `INFO`

zabbix dashboard upload

Syntax:

```
mamonsu dashboard upload template_name
```

Upload a Zabbix dashboard with the mamonsu metrics to a template on the Zabbix server version 6.0 or higher.

zabbix item

Syntax:

```
mamonsu zabbix item {error | lastvalue | lastclock } host_name
```

View the specified property of the latest metrics data received by Zabbix for the specified host.

zabbix version

Syntax:

```
mamonsu zabbix version
```

Get the version of the Zabbix server that mamonsu is connected to.

zabbix host

Syntax:

```
mamonsu zabbix host list
mamonsu zabbix host show host_name
mamonsu zabbix host id host_name
mamonsu zabbix host delete host_id
mamonsu zabbix host create host_name hostgroup_id template_id mamonsu_address
mamonsu zabbix host info {templates | hostgroups | graphs | items} host_id
```

Manage Zabbix hosts using one of the actions described in the section called “Zabbix Server Actions”.

zabbix hostgroup

Syntax:

```
mamonsu zabbix hostgroup list
mamonsu zabbix hostgroup show hostgroup_name
mamonsu zabbix hostgroup id hostgroup_name
```

```
mamonsu zabbix hostgroup delete hostgroup_id
mamonsu zabbix hostgroup create hostgroup_name
```

Manage Zabbix host groups using one of the actions described in the section called "Zabbix Server Actions".

zabbix template

Syntax:

```
mamonsu zabbix template list
mamonsu zabbix template show template_name
mamonsu zabbix template id template_name
mamonsu zabbix template delete template_id
mamonsu zabbix template export file
```

Manage Zabbix templates using one of the actions described in the section called "Zabbix Server Actions".

[--config] [--daemonize]

Syntax:

```
mamonsu [-c config_file | --config=config_file]
        [-d | --daemonize]
```

Start working as a monitoring agent in the foreground or in the background using configuration parameters loaded from the configuration file. If the specified or default configuration file does not exist, exit with an error. Useful for debugging. You can specify the following options:

`-c config_file`
`--config=config_file`

Specify the `agent.conf` file where to load the configuration parameters from.

Default: `/etc/mamonsu/agent.conf`

`-d`
`--daemonize`

Run in the background. Without it, mamonsu will run in the foreground.

--version

Syntax:

```
mamonsu --version
```

Display `mamonsu` version.

--help

Syntax:

```
mamonsu --help
```

Display `mamonsu` command-line help.

Connection Options

connection_options provide command-line connection parameters for the target Postgres Pro cluster. *connection_options* can be `--host`, `--port`, `--dbname` (`-d`), `--username` (`-U`), and `--password` (`-W`). The `--dbname` option should specify the *mamonsu_database* created for monitoring purposes. Note that the `--username` (`-U`) option must specify a superuser that can access the cluster.

If you omit *connection_options*, mamonsu checks the configuration file for the needed settings.

Zabbix Server Actions

Using mamonsu, you can control some of the Zabbix server functionality from the command line. Specifically, you can create or delete Zabbix hosts and host groups, as well as generate, import, and delete Zabbix templates using one of the following commands. The *object_name* to use must correspond to the type of the Zabbix object specified in the command: `template`, `host`, or `hostgroup`.

`list`

Display the list of available templates, hosts, or host groups.

`show` *object_name*

Display the details about the specified template, host, or host group.

`id` *object_name*

Show the ID of the specified object, which is assigned automatically by the Zabbix server.

`delete` *object_id*

Delete the object with the specified ID.

`create` *hostgroup_name*
`create` *host_name hostgroup_id template_id mamonsu_address*

Create a new host or a host group.

`export` *template_name*

Generate a Zabbix template.

`info {templates | hostgroups | graphs | items}` *host_id*

Display detailed information about the templates, host groups, graphs, and metrics available on the host with the specified ID.

Configuration Parameters

The `agent.conf` configuration file is located in the `/etc/mamonsu` directory by default. It provides several groups of parameters that control which metrics to collect and how to log the collected data:

- connection parameters
- logging parameters
- plugin parameters

All parameters must be specified in the *parameter = value* format.

Connection Parameters

[postgres]

The `[postgres]` section controls Postgres Pro metrics collection and can contain the following parameters:

`enabled`

Enables/disables Postgres Pro metrics collection if set to `True` or `False`, respectively.

Default: `True`

`user`

The user on behalf of which the cluster will be monitored. It must be the mamonsu user set in bootstrap, or a superuser if `bootstrap` was not run.

Default: `postgres`

`password`

The password for the specified user.

`database`

The database to connect to for metrics collection.

Default: `postgres`

`host`

The server address to connect to.

Default: `localhost`

`port`

The port to connect to.

Default: 5432

`application_name`

Application name that identifies mamonsu connected to the Postgres Pro cluster.

Default: `mamonsu`

`query_timeout`

statement_timeout for the mamonsu session, in seconds. If a Postgres Pro metric query does not complete within this time interval, it gets terminated.

Default: 10

Alternatively you can specify environment variables rather than the configuration parameters. The following environment variables can be used: `PGUSER`, `PGPASSWORD`, `PGHOST`, `PGDATABASE`, `PGPORT`, and `PGAPPNAME`. See Section 33.15 for their meaning.

[system]

The `[system]` section controls system metrics collection and can contain the following parameters:

`enabled`

Enables/disables system metrics collection if set to `True` or `False`, respectively.

Default: `True`

[zabbix]

The `[zabbix]` section provides connection settings for the Zabbix server and can contain the following parameters:

`enabled`

Enables/disables sending the collected metrics data to the Zabbix server if set to `True` or `False`, respectively.

Default: `True`

`client`

The name of the Zabbix host.

`address`

The address of the Zabbix server.

Default: 127.0.0.1

`port`

The port of the Zabbix server.

Default: 10051

`timeout`

Maximum time to wait while connecting to the Zabbix server, in seconds.

Default: 15

[agent]

The `[agent]` section specifies the location of mamonsu and whether it is allowed to access metrics from the command line:

`enabled`

Enables/disables metrics collection from the command line using the `agent` command.

Default: `True`

`host`

The address of the system on which mamonsu is running.

Default: 127.0.0.1

`port`

The port on which mamonsu is running.

Default: 10052

[sender]

The `[sender]` section controls the queue size of the data to be sent to the Zabbix server:

`queue`

The maximum number of collected metric values that can be accumulated locally before mamonsu sends them to the Zabbix server. Once the accumulated data is sent, the queue is cleared.

Default: 2048

Logging Parameters

[metric_log]

The `[metric_log]` section enables storing the collected metrics data in text files locally. This section can contain the following parameters:

`enabled`

Enables/disables storing the collected metrics data in a text file. If this option is set to `True`, mamonsu creates the `localhost.log` file for storing metric values.

Default: `False`

`directory`

Specifies the directory where log files with metrics data will be stored.

Default: `/var/log/mamonsu`

`max_size_mb`

The maximum size of a log file, in MB. When the specified size is reached, it is renamed to `localhost.log.archive`, and an empty `localhost.log` file is created.

Default: 1024

[log]

The `[log]` section specifies logging settings for mamonsu and can contain the following parameters:

`file`

Specifies the log filename, which can be preceded by the full path.

`level`

Specifies the debug level. This option can take `DEBUG`, `ERROR`, or `INFO` values.

Default: `INFO`

`format`

The format of the logged data.

Default: `[%(levelname)s] %(asctime)s - %(name)s - %(message)s`

where `levelname` is the debug level, `asctime` returns the current time, `name` specifies the plugin that emitted this log entry or `root` otherwise, and `message` provides the actual log message.

Plugin Parameters

[plugins]

The `[plugins]` section specifies custom plugins to be added for metrics collection and can contain the following parameters:

`enabled`

Enables/disables using custom plugins for metrics collection if set to `True` or `False`, respectively.

Default: `False`

`directory`

Specifies the directory that contains custom plugins for metrics collection. Setting this parameter to `None` forbids using custom plugins.

Default: `/etc/mamonsu/plugins`

If you need to configure any of the plugins you add to mamonsu after installation, you have to add this plugin section to the `agent.conf` file.

The syntax of this section should follow the syntax used with the examples shown below in the section called “Individual Plugin Sections”.

Individual Plugin Sections

All built-in plugins are installed along with mamonsu. To configure a built-in plugin you should find a corresponding section below the `Individual Plugin Sections` heading and edit its parameter values:

`enabled`

Enables/disables using built-in plugins if set to `True` or `False`, respectively. These values are case-sensitive.

Default: `False`

`interval`

Specifies the plugin operation interval, in seconds. The parameter is set with an integer specifying the plugin operation interval in seconds. You can set different intervals for different plugins. For plugins that collect PostgreSQL/ Postgres Pro metrics, for example, autovacuum, checkpoint, etc., this is the interval within which mamonsu accesses the Postgres Pro instance for metrics collection. For system plugins, for example, diskstats, memory, etc., this is the interval within which the operating system is accessed. For service plugins, for example, agentapi, logsender, zbxsender, this is the interval within which their functions are called. Note that the `interval` parameter of the zbxsender plugin is associated with the `timeout` parameter of the `[zabbix]` section. The maximum Zabbix server response timeout greater than the plugin operation interval may cause misbehavior of the zbxsender plugin: the plugin restarts with an error message if the connection or data transfer require longer time than the value specified in the `interval` parameter.

Default: 60

The example below shows individual plugin sections corresponding to the `preparedtransaction` and the `pgprobackup` built-in plugins:

```
[preparedtransaction]
max_prepared_transaction_time = 60
interval = 60

[pgprobackup]
enabled = false
interval = 300
backup_dirs = /backup_dir1,/backup_dir2
pg_probackup_path = /usr/bin/pg_probackup-11
```

[preparedtransaction]

This plugin gets age in seconds of the oldest prepared transaction and number of all transactions prepared for a two-phase commit. For additional information refer to PREPARE TRANSACTION and Section 51.80.

The `max_prepared_transaction_time` parameter specifies the threshold in seconds for the age of the prepared transaction.

The plugin collects two metrics: `pgsql.prepared.count` (number of prepared transactions) and `pgsql.prepared.oldest` (oldest prepared transaction age in seconds).

If `pgsql.prepared.oldest` value exceeds the threshold specified by the `max_prepared_transaction_time` parameter, a trigger with the following message is fired: "PostgreSQL prepared transaction is too old on {host}".

[pgprobackup]

This plugin uses pg_probackup to track its backups' state and gets size of backup directories which store all backup files.

Please note that this plugin counts the total size of all files in the target directory. Make sure that extraneous files are not stored in this directory.

The `backup_dirs` parameter specifies a comma-separated list of paths to directories for which metrics should be collected.

The `pg_probackup_path` parameter specifies the path to pg_probackup.

By default this plugin is disabled. To enable it set the `enabled` parameter to `True`.

This plugin collects two metrics: `pg_probackup.dir.size[#backup_directory]` (the size of the target directory) and `pg_probackup.dir.error[#backup_directory]` (backup errors) for each specified *`backup_directory`*.

If any generated backup has bad status, like `ERROR`, `CORRUPT`, `ORPHAN`, a trigger is fired.

Usage

Collecting and Viewing Metrics Data

Once started, mamonsu begins collecting system and Postgres Pro metrics. The `agent` command enables you to get an overview of the collected metrics from the command line in real time.

To view the list of available metrics, use the `agent metric-list` command:

```
mamonsu agent metric-list
```

The output of this command provides the item key of each metric, its latest value, and the time when this value was received. For example:

```
system.memory[active]       7921004544    1564570818
system.memory[swap_cache]       868352    1564570818
pgsql.connections[idle]            6.0    1564570818
pgsql.archive_command[failed_trying_to_archive]    0    1564570818
```

To view the current value for a specific metric, you can use the `agent metric-get` command:

```
mamonsu agent metric-get metric_name
```

where *`metric_name`* is the item key of the metric to monitor, as returned by the `metric-list` command. For example, `pgsql.connections[idle]`.

You can view graphs for the collected metrics in the Zabbix web interface under the **Graphs** menu. For details on working with Zabbix, see its official documentation at *https://www.zabbix.com/documentation/current/manual*.

If you have chosen to save all the collected metrics data into a file, as explained in the section called “Logging Parameters”, you can later upload these metrics onto a Zabbix server for visualization using the upload command.

Adding Custom Plugins

You can extend mamonsu with your own custom plugins, as follows:

1. Save all custom plugins in a single directory, such as `/etc/mamonsu/plugins`.
2. Make sure this directory is specified in your configuration file under the `[plugins]` section:

   ```
   [plugins]
   directory = /etc/mamonsu/plugins
   ```
3. Generate a new Zabbix template to include custom plugins:

   ```
   mamonsu export template template.xml --add-plugins=/etc/mamonsu/plugins
   ```
4. Upload the generated `template.xml` to the Zabbix server as explained in the section called “Installation and Setup”.

Tuning Postgres Pro and System Configuration

Based on the collected metrics data, mamonsu can tune your Postgres Pro and system configuration for optimal performance.

You can get detailed information about the hardware, operating system, memory usage and other parameters of the monitored system, as well as Postgres Pro configuration, as follows:

```
mamonsu report
```

To view the suggested optimizations without applying them, run the `tune` command with the `--dry-run` option:

```
mamonsu tune --dry-run
```

To apply all the suggested changes, run the `tune` command without any parameters:

```
mamonsu tune
```

You can exclude some settings from the report or disable some of the optimizations by passing optional parameters. See the section called “Command-Line Reference” for the full list of parameters available for `report` and `tune` commands.

Managing Zabbix Server Settings from the Command Line

mamonsu enables you to work with the Zabbix server from the command line. You can upload template files to Zabbix, create and delete Zabbix hosts and host groups, link templates with hosts and check the latest metric values.

To set up your Zabbix host from scratch, you can follow these steps:

1. Optionally, specify your Zabbix account settings in the following environment variables on your monitoring system:

   - Set the `ZABBIX_USER` and `ZABBIX_PASSWD` variables to the login and password of your Zabbix account, respectively.
   - Set the `ZABBIX_URL` to `http://zabbix/`

   If you skip this step, you will have to add the following options to all `mamonsu zabbix` commands that you run:

   ```
   --url=http://zabbix/ --user=zabbix_login --password=zabbix_password
   ```

2. Generate a new template file and upload it to the Zabbix server:

   ```
   mamonsu export template template.xml
   mamonsu zabbix template export template.xml
   ```

3. Create a new host group:

   ```
   mamonsu zabbix hostgroup create hostgroup_name
   ```

4. Check the IDs for this host group and the uploaded template, which are assigned automatically by the Zabbix server:

   ```
   mamonsu zabbix hostgroup id hostgroup_name
   mamonsu zabbix template id template_name
   ```

5. Create a host associated with this group and link it with the uploaded template using a single command:

   ```
   mamonsu zabbix host create host_name hostgroup_id template_id mamonsu_address
   ```

   where *`host_name`* is the name of the host, *`hostgroup_id`* and *`template_id`* are the unique IDs returned in the previous step, and *`mamonsu_address`* is the IP address of the system on which mamonsu runs.

Once your Zabbix host is configured, complete the setup of your monitoring system as explained in the section called “Installation and Setup”.

Exporting Metrics for Native Zabbix Agent

Using mamonsu, you can convert system and Postgres Pro metrics definitions to the format supported by the native *Zabbix agent*.

This feature currently has the following limitations:

- You cannot export metrics if you run `mamonsu` on Windows systems.
- Metrics definitions for `pg_wait_sampling` and CFS features available in Postgres Pro Enterprise are not converted.

> **Important**
>
> To work with Zabbix proxy, you must export settings to the format supported by the native Zabbix agent.

To collect metrics provided by mamonsu using the native Zabbix agent, do the following:

1. Generate a configuration file that is compatible with the native Zabbix agent and place it under `/etc/zabbix/zabbix_agent.d/`. You can prepend the filename with the required path:

   ```
   mamonsu export zabbix-parameters /etc/zabbix/zabbix_agent.d/zabbix_agent.conf
   ```

   For all possible options of the `export zabbix-parameters` command, see the section called “Command-Line Reference”.

2. Generate a template for the native Zabbix agent:

   ```
   mamonsu export zabbix-template template.xml
   ```

   For all possible options of the `export zabbix-template` command, see the section called “Command-Line Reference”.

3. Upload the generated template to the Zabbix server, as explained in the section called “Installation and Setup”.

4. If you are going to collect Postgres Pro metrics, change the following macros in the template after the upload:

   - For `{$PG_CONNINFO}`, provide connection parameters for the Postgres Pro server to be monitored.
   - For `{$PG_PATH}`, specify psql installation directory.

Compatibility Considerations

If you want to upgrade mamonsu to a version that is not compatible with the previous one, what you must do to continue using the application depends on whether you need to retain the metrics data collected.

- If you need to retain the collected data, do the following:

  1. Install the new version of mamonsu.
  2. Generate a new template for the Zabbix server.
  3. If you performed a bootstrap using the previous version of mamonsu, run the `bootstrap` command again.
  4. Upload the new template to the Zabbix server.
  5. Rename the host for which you want to retain the collected data and leave the old template linked to that host.
  6. Create a new host for the same system and link the new template to it.
  7. Restart mamonsu. It will collect data for the new host. The old host will no longer be used, but the data collected will be available.

- If you do not need to retain the collected data, do the following:

  1. Install the new version of mamonsu.
  2. Generate a new template for the Zabbix server.

3. If you performed a bootstrap using the previous version of mamonsu, run the `bootstrap` command again.
4. Upload the new template to the Zabbix server.
5. In the settings of the Zabbix host, link the new template to the host instead of the old one.
6. Restart mamonsu. It will start collecting data. All the data collected earlier will be lost.

pgpro_controldata

pgpro_controldata — display control information of a PostgreSQL/Postgres Pro database cluster and compatibility information for a cluster and/or server

Synopsis

`pgpro_controldata` [*option*...]

Description

`pgpro_controldata` prints control information, such as the catalog version, initialized by `initdb` command of any PostgreSQL/Postgres Pro server. It also shows information about write-ahead logging and checkpoint processing. This information is cluster-wide and not specific to any database.

`pgpro_controldata` also helps to check compatibility between PostgreSQL/Postgres Pro database servers and clusters. It can print server or cluster parameters that can affect the compatibility and check whether a cluster and server are compatible by comparing those parameters.

pgpro_controldata is provided with Postgres Pro Standard as a separate pre-built package `pgpro-controldata` (for the detailed installation instructions, see Chapter 16).

Options

`pgpro_controldata` accepts the following command-line arguments. If no arguments are specified, `pgpro_controldata` just prints the control information like pg_controldata does. Note that compatibility-related command-line arguments `-P` and `-S` specified together work the same way as `-C`.

General-Purpose

`-B`
`--bindir`

Specifies the PostgreSQL/Postgres Pro executable directory, needed to get server compatibility parameters.

`-D` *datadir*
`--pgdata=`*datadir*

Specifies the file system location of the database configuration files. If this option is omitted, the environment variable `PGDATA` is used.

`-V`
`--version`

Print the pgpro_controldata version, then exit.

`-?`
`--help`

Show help about pgpro_controldata command-line arguments, then exit.

Compatibility-Related

`-C`
`--compatibility-check`

Display all parameters that can affect compatibility between the specified server and cluster and check whether they are compatible.

Use the `-D` option or the environment variable `PGDATA` to provide the path to the data directory, where read access is required.

If the `-B` option is omitted, the current server is assumed.

The cluster data and the server must have the same byte order and architecture type for this option to work correctly.

`-P`
`--cluster-compatibility-params`

Display all parameters of the specified cluster that can affect the compatibility.

Use the `-D` option or the environment variable `PGDATA` to provide the path to the data directory, where read access is required.

The cluster data and the server must have the same byte order and architecture type for this option to work correctly.

`-S`
`--server-compatibility-params`

Display all parameters of the specified or current server that can affect the compatibility.

If the `-B` option is omitted, the current server is assumed.

Environment

`PGDATA`

Default data directory location

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

See Also

pg_controldata

pg_integrity_check

pg_integrity_check — calculate and validate checksums for controlled files (certified edition only)

Synopsis

`pg_integrity_check` [*connection-option*...] [-s | --system] [-u | --user] [-c | --catalog] [-o | --output] [-l *filename* | --log=*filename*] [--syslog] [-D *datadir*] [-C *filename*] [-v | --verbose] [-? | --help]

Description

`pg_integrity_check` is a utility provided with Postgres Pro Standard that can calculate and validate checksums for the objects you would like to control. When running `pg_integrity_check`, you must specify at least one of the options that define the type of the controlled objects: `-s`, `-u`, or `-c` for read-only files, additional files, or system catalog tables, respectively.

If you use the `-o` option, `pg_integrity_check` calculates checksums and writes them into configuration files under the `share/security/` directory. You must have write access to the corresponding files to perform this command. You cannot use the `-o` option together with the `-s` option, since a checksum for read-only files cannot be overwritten.

If you omit the `-o` option, `pg_integrity_check` compares the calculated checksums with the corresponding checksums in the configuration files. If the checksums differ for any of the controlled objects, `pg_integrity_check` displays a message indicating the difference.

For details on using `pg_integrity_check`, see Section 31.2.

Options

connection-options

Standard options for connecting to a database: `-d`, `-h`, `-p`, `-U`. You must specify `-d` and `-U` options when validating checksums for catalog tables with the `-c` option. For detailed description of connection options, see psql.

`-s`
`--system`

Validate checksums for read-only files. Checksums for read-only files control both file contents and file attributes.

`-u`
`--user`

Validate checksums for additional files. Checksums for additional files control both file contents and file attributes.

`-c`
`--catalog`

Validate checksums for system catalog tables. For the `-c` option to work correctly, you must also specify connection parameters for the database. The database server must be started and accept connections.

`-o`
`--output`

Recalculate checksums and write it into a file.

`-l` *filename*
`--log=`*filename*

Write checksum validation results into a log file.

`--syslog`

Write checksum validation results into the syslog.

`-D` *`datadir`*

Data directory of the database cluster. This option is required to define the filenames for the generated configuration files when using `-u` option.

`-C` *`filename`*

The absolute path to the configuration file used for integrity checks of system catalog tables of the selected database. If used with the `-o` option, `pg_integrity_check` writes into the specified file. If no other option is used, `pg_integrity_check` checks data against the specified file.

`-v`
`--verbose`

Print debugging information, including checksum values.

`-?`
`--help`

Print command-line help.

Return Values

0 — checksums are calculated or validated successfully.

1 — an error occurred during the initial checksum calculation for read-only files.

2 — checksum validation revealed changes in one or more of the controlled objects.

3 — an unexpected error occurred during checksum validation.

Examples

Compute checksums for additional files and write them into the `share/security/_var_lib_pgpro_std-14_data.user.conf` configuration file:

```
pg_integrity_check -u -o -D /var/lib/pgpro/std-14/data
```

Check integrity of all controlled objects in the `postgres` database on behalf of the `postgres` user:

```
pg_integrity_check -s -u -c -D /var/lib/pgpro/std-14/data -d postgres -h localhost -p
 5432 -U postgres
```

I.4. Third-Party Server Applications

This section covers third-party server-related applications. They are typically run on the host where the database server resides.

pgbouncer

pgbouncer — a Postgres Pro connection pooler

Synopsis

On Linux systems:

`pgbouncer` [-d] [-R] [-v] [-u *`user`*] pgbouncer.ini

`pgbouncer` -V | -h

On Windows:

`pgbouncer` [-v] [-u *`user`*] pgbouncer.ini

`pgbouncer` -V | -h

To use pgbouncer as a Windows service:

`pgbouncer.exe` --regservice pgbouncer.ini

`pgbouncer.exe` --unregservice pgbouncer.ini

Description

pgbouncer is a Postgres Pro connection pooler. Any target application can be connected to pgbouncer as if it were a Postgres Pro server, and pgbouncer will create a connection to the actual server, or it will reuse one of its existing connections.

The aim of pgbouncer is to lower the performance impact of opening new connections to Postgres Pro.

In order not to compromise transaction semantics for connection pooling, pgbouncer supports several types of pooling when rotating connections:

Session pooling

Most polite method. When a client connects, a server connection will be assigned to it for the whole duration the client stays connected. When the client disconnects, the server connection will be put back into the pool. This is the default method.

Transaction pooling

A server connection is assigned to a client only during a transaction. When pgbouncer notices that transaction is over, the server connection will be put back into the pool.

Statement pooling

Most aggressive method. The server connection will be put back into the pool immediately after a query completes. Multi-statement transactions are disallowed in this mode as they would break.

The administration interface of pgbouncer consists of some new `SHOW` commands available when connected to a special “virtual” database `pgbouncer`.

Quick Start

pgbouncer is provided with Postgres Pro Standard as a separate pre-built package `pgbouncer` (for the detailed installation instructions, see Chapter 16). Basic setup and usage is as follows.

1. Create a `pgbouncer.ini` file. Details in the `pgbouncer(5)` man page. Simple example:

```
[databases]
template1 = host=localhost dbname=template1 auth_user=someuser
```

```
[pgbouncer]
listen_port = 6432
listen_addr = localhost
auth_type = md5
auth_file = userlist.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
```

2. Create a `userlist.txt` file that contains the users allowed in:

```
"someuser" "same_password_as_in_server"
```

3. Launch pgbouncer:

```
$ pgbouncer -d pgbouncer.ini
```

> **Note**
>
> The above command does not work on Windows systems. Instead, pgbouncer must be launched as a service that first needs to be registered, as follows:
>
> ```
> pgbouncer --regservice
> ```

4. Have your application (or the `psql` client) connect to pgbouncer instead of directly to the Postgres Pro server:

```
$ psql -p 6432 -U someuser template1
```

5. Manage pgbouncer by connecting to the special administration database pgbouncer and issuing `SHOW HELP;` to begin:

```
$ psql -p 6432 -U someuser pgbouncer
pgbouncer=# SHOW HELP;
NOTICE:  Console usage
DETAIL:
  SHOW [HELP|CONFIG|DATABASES|FDS|POOLS|CLIENTS|SERVERS|SOCKETS|LISTS|VERSION|...]
  SET key = arg
  RELOAD
  PAUSE
  SUSPEND
  RESUME
  SHUTDOWN
  [...]
```

6. If you made changes to the `pgbouncer.ini` file, you can reload it with:

```
pgbouncer=# RELOAD;
```

Options

`-d, --daemon`

Run in the background. Without it, the process will run in the foreground. In daemon mode, setting `pidfile` as well as `logfile` or `syslog` is required. No log messages will be written to stderr after going into the background.

> **Note**
>
> Does not work on Windows, pgbouncer needs to run as service there.

`-R, --reboot`

> **Note**
>
> This option is deprecated. Instead of this option use a rolling restart with multiple pgbouncer processes listening on the same port using `so_reuseport` instead.

Do an online restart. That means connecting to the running process, loading the open sockets from it, and then using them. If there is no active process, boot normally.

> **Note**
>
> Works only if OS supports Unix sockets and the `unix_socket_dir` is not disabled in configuration. Does not work on Windows. Does not work with TLS connections, they are dropped.

`-u` *user*`, --user` *user*

Switch to the given user on startup.

`-v, --verbose`

Increase verbosity. Can be used multiple times.

`-q, --quiet`

Be quiet: do not log to stderr. This does not affect logging verbosity, only that stderr is not to be used. For use in `init.d` scripts.

`-V, --version`

Show version.

`-h, --help`

Show short help.

`--regservice`

Win32: Register to run as Windows service. The `service_name` configuration parameter value is used as the name to register under.

`--unregservice`

Win32: Unregister Windows service.

Admin Console

The console is available by connecting as normal to the database pgbouncer:

```
$ psql -p 6432 pgbouncer
```

Only users listed in the configuration parameters `admin_users` or `stats_users` are allowed to log in to the console. (Except when `auth_mode=any`, then any user is allowed in as a `stats_user`.)

Additionally, the user name `pgbouncer` is allowed to log in without password, if the login comes via the Unix socket and the client has same Unix user uid as the running process.

The admin console currently only supports the simple query protocol. Some drivers use the extended query protocol for all commands; these drivers will not work for this.

Show Commands

The `SHOW` commands output information. Each command is described below.

SHOW STATS

Shows statistics. In this and related commands, the total figures are since process start, the averages are updated every `stats_period`.

`database`

Statistics are presented per database.

`total_xact_count`

Total number of SQL transactions pooled by pgbouncer.

`total_query_count`

Total number of SQL queries pooled by pgbouncer.

`total_received`

Total volume in bytes of network traffic received by pgbouncer.

`total_sent`

Total volume in bytes of network traffic sent by pgbouncer.

`total_xact_time`

Total number of microseconds spent by pgbouncer when connected to Postgres Pro in a transaction, either idle in transaction or executing queries.

`total_query_time`

Total number of microseconds spent by pgbouncer when actively connected to Postgres Pro, executing queries.

`total_wait_time`

Time spent by clients waiting for a server, in microseconds. Updated when a client connection is assigned a backend connection.

`avg_xact_count`

Average transactions per second in last stat period.

`avg_query_count`

Average queries per second in last stat period.

`avg_recv`

Average received (from clients) bytes per second.

`avg_sent`

Average sent (to clients) bytes per second.

`avg_xact_time`

Average transaction duration, in microseconds.

`avg_query_time`

Average query duration, in microseconds.

`avg_wait_time`

Average time spent by clients waiting for a server that were assigned a backend connection within the current `stats_period`, in microseconds (average per second within that period).

SHOW STATS_TOTALS

Subset of `SHOW STATS` showing the total values (`total_`).

SHOW STATS_AVERAGES

Subset of `SHOW STATS` showing the average values (`avg_`).

SHOW TOTALS

Like `SHOW STATS` but aggregated across all databases.

SHOW SERVERS

`type`

S, for server.

`user`

User name pgbouncer uses to connect to server.

`database`

Database name.

`state`

State of the pgbouncer server connection, one of `active`, `idle`, `used`, `tested`, `new`, `active_cancel`, or `being_canceled`.

`addr`

IP address of Postgres Pro server.

`port`

Port of Postgres Pro server.

`local_addr`

Connection start address on local machine.

`local_port`

Connection start port on local machine.

`connect_time`

When the connection was made.

`request_time`

When last request was issued.

`wait`

Not used for server connections.

`wait_us`

Not used for server connections.

`close_needed`

1 if the connection will be closed as soon as possible, because a configuration file reload or DNS update changed the connection information or `RECONNECT` was issued.

`ptr`

Address of internal object for this connection. Used as unique ID.

`link`

Address of client connection the server is paired with.

`remote_pid`

PID of backend server process. In case connection is made over Unix socket and OS supports getting process ID info, its OS PID. Otherwise it's extracted from cancel packet the server sent, which should be the PID in case the server is Postgres Pro, but it's a random number in case the server is another pgbouncer.

`tls`

A string with TLS connection information, or empty if not using TLS.

`application_name`

A string containing the `application_name` set on the linked client connection, or empty if this is not set, or if there is no linked connection.

SHOW CLIENTS

`type`

C, for client.

`user`

Client connected user.

`database`

Database name.

`state`

State of the client connection, one of `active`, `waiting`, `active_cancel_req`, or `waiting_cancel_req`.

`addr`

IP address of the client.

`port`

Source port of the client.

`local_addr`

Connection end address on local machine.

`local_port`

Connection end port on local machine.

`connect_time`

Timestamp of connect time.

`request_time`

Timestamp of latest client request.

`wait`

Current waiting time in seconds.

`wait_us`

Microsecond part of the current waiting time.

`close_needed`

Not used for clients.

`ptr`

Address of internal object for this connection. Used as unique ID.

`link`

Address of server connection the client is paired with.

`remote_pid`

Process ID, in case client connects over Unix socket and OS supports getting it.

`tls`

A string with TLS connection information, or empty if not using TLS.

`application_name`

A string containing the `application_name` set by the client for this connection, or empty if this is not set.

SHOW POOLS

A new pool entry is made for each couple of (database, user).

`database`

Database name.

`user`

User name.

`cl_active`

Client connections that are either linked to server connections or are idle with no queries waiting to be processed.

`cl_waiting`

Client connections that have sent queries but have not yet got a server connection.

`cl_active_cancel_req`

Client connections that have forwarded query cancellations to the server and are waiting for the server response.

`cl_waiting_cancel_req`

Client connections that have not forwarded query cancellations to the server yet.

`sv_active`

Server connections that are linked to a client.

`sv_active_cancel`

Server connections that are currently forwarding a cancel request.

`sv_being_canceled`

Servers that normally could become idle but are waiting to do so until all in-flight cancel requests have completed that were sent to cancel a query on this server.

`sv_idle`

Server connections that are unused and immediately usable for client queries.

`sv_used`

Server connections that have been idle for more than `server_check_delay`, so they need `server_check_query` to run on them before they can be used again.

`sv_tested`

Server connections that are currently running either `server_reset_query` or `server_check_query`.

`sv_login`

Server connections currently in the process of logging in.

`maxwait`

How long the first (oldest) client in the queue has waited, in seconds. If this starts increasing, then the current pool of servers does not handle requests quickly enough. The reason may be either an overloaded server or just too small of a `pool_size` setting.

`maxwait_us`

Microsecond part of the maximum waiting time.

`pool_mode`

The pooling mode in use.

SHOW PEER_POOLS

A new `peer_pool` entry is made for each configured peer.

`database`

ID of the configured peer entry.

`cl_active_cancel_req`

Client connections that have forwarded query cancellations to the server and are waiting for the server response.

`cl_waiting_cancel_req`

Client connections that have not forwarded query cancellations to the server yet.

`sv_active_cancel`

Server connections that are currently forwarding a cancel request.

`sv_login`

Server connections currently in the process of logging in.

SHOW LISTS

Show following internal information, in columns (not rows):

`databases`

Count of databases.

`users`

Count of users.

`pools`

Count of pools.

`free_clients`

Count of free clients.

`used_clients`

Count of used clients.

`login_clients`

Count of clients in `login` state.

`free_servers`

Count of free servers.

`used_servers`

Count of used servers.

`dns_names`

Count of DNS names in the cache.

`dns_zones`

Count of DNS zones in the cache.

`dns_queries`

Count of in-flight DNS queries.

`dns_pending`

Not used.

SHOW USERS

`name`

The user name.

`pool_mode`

The user's override `pool_mode`, or `NULL` if the default will be used instead.

SHOW DATABASES

`name`

Name of configured database entry.

`host`

Host pgbouncer connects to.

`port`

Port pgbouncer connects to.

`database`

Actual database name pgbouncer connects to.

`force_user`

When the user is part of the connection string, the connection between pgbouncer and Postgres Pro is forced to the given user, whatever the client user.

`pool_size`

Maximum number of server connections.

`min_pool_size`

Minimum number of server connections.

`reserve_pool`

Maximum number of additional connections for this database.

`pool_mode`

The database's override pool_mode, or `NULL` if the default will be used instead.

`max_connections`

Maximum number of allowed connections for this database, as set by `max_db_connections`, either globally or per database.

`current_connections`

Current number of connections for this database.

`paused`

1 if this database is currently paused, else 0.

`disabled`

1 if this database is currently disabled, else 0.

SHOW PEERS

`peer_id`

ID of the configured peer entry.

`host`

Host pgbouncer connects to.

`port`

Port pgbouncer connects to.

`pool_size`

Maximum number of server connections that can be made to this peer.

SHOW FDS

Internal command — shows list of file descriptors (FDs) in use with internal state attached to them.

When the connected user has the user name `pgbouncer`, connects through the Unix socket and has the same UID as the running process, the actual FDs are passed over the connection. This mechanism is used to do an online restart.

> **Note**
>
> This does not work on Windows.

This command also blocks the internal event loop, so it should not be used while pgbouncer is in use.

`fd`

File descriptor numeric value.

`task`

One of `pooler`, `client` or `server`.

`user`

User of the connection using the FD.

`database`

Database of the connection using the FD.

`addr`

IP address of the connection using the FD, `unix` if a Unix socket is used.

`port`

Port used by the connection using the FD.

`cancel`

Cancel key for this connection.

`link`

File descriptor for corresponding server/client. `NULL` if idle.

SHOW SOCKETS, SHOW ACTIVE_SOCKETS

Shows low-level information about sockets or only active sockets. This includes the information shown under `SHOW CLIENTS` and `SHOW SERVERS` as well as other more low-level information.

SHOW CONFIG

Show the current configuration settings, one per row, with the following columns:

`key`

Configuration variable name.

`value`

Configuration value.

`default`

Configuration default value.

`changeable`

Either `yes` or `no`, shows if the variable can be changed while running. If `no`, the variable can be changed only at boot-time. Use `SET` to change a variable at run time.

SHOW MEM

Shows low-level information about the current sizes of various internal memory allocations. The information presented is subject to change.

SHOW DNS_HOSTS

Show host names in DNS cache.

`hostname`

Host name.

`ttl`

How many seconds until next lookup.

`addrs`

Comma separated list of addresses.

SHOW DNS_ZONES

Show DNS zones in cache.

`zonename`

Zone name.

`serial`

Current serial.

`count`

Host names belonging to this zone.

SHOW VERSION

Show the pgbouncer version string.

SHOW STATE

Show the pgbouncer state settings. Current states are active, paused and suspended.

Process Controlling Commands

PAUSE [*db*]

pgbouncer tries to disconnect from all servers. Disconnecting each server connection waits for that server connection to be released according to the server pool's pooling mode (in transaction pooling mode, the transaction must complete, in statement mode, the statement must complete, and in session pooling mode the client must disconnect). The command will not return before all server connections have been disconnected. To be used at the time of database restart.

If database name is given, only that database will be paused.

New client connections to a paused database will wait until `RESUME` is called.

DISABLE *db*

Reject all new client connections on the given database.

ENABLE *db*

Allow new client connections after a previous `DISABLE` command.

RECONNECT *db*

Close each open server connection for the given database, or all databases, after it is released (according to the pooling mode), even if its lifetime is not up yet. New server connections can be made immediately and will connect as necessary according to the pool size settings.

This command is useful when the server connection setup has changed, for example to perform a gradual switchover to a new server. It is not necessary to run this command when the connection string in `pgbouncer.ini` has been changed and reloaded (see `RELOAD`) or when DNS resolution has changed,

because then the equivalent of this command will be run automatically. This command is only necessary if something downstream of pgbouncer routes the connections.

After this command is run, there could be an extended period where some server connections go to an old destination and some server connections go to a new destination. This is likely only sensible when switching read-only traffic between read-only replicas, or when switching between nodes of a multimaster replication setup. If all connections need to be switched at the same time, `PAUSE` is recommended instead. To close server connections without waiting (for example, in emergency failover rather than gradual switchover scenarios), also consider `KILL`.

KILL *db*

Immediately drop all client and server connections on given database.

New client connections to a killed database will wait until `RESUME` is called.

SUSPEND

All socket buffers are flushed and pgbouncer stops listening for data on them. The command will not return before all buffers are empty. To be used at the time of pgbouncer online reboot.

New client connections to a suspended database will wait until `RESUME` is called.

RESUME [*db*]

Resume work from previous `KILL`, `PAUSE`, or `SUSPEND` command.

SHUTDOWN

The pgbouncer process will exit.

RELOAD

The pgbouncer process will reload its configuration files and update changeable settings. This includes the main configuration file as well as the files specified by the settings `auth_file` and `auth_hba_file`.

pgbouncer notices when a configuration file reload changes the connection parameters of a database definition. An existing server connection to the old destination will be closed when the server connection is next released (according to the pooling mode), and new server connections will immediately use the updated connection parameters.

WAIT_CLOSE [*db*]

Wait until all server connections, either of the specified database or of all databases, have cleared the `close_needed` state (see the section called “SHOW SERVERS”). This can be called after a `RECONNECT` or `RELOAD` to wait until the respective configuration change has been fully activated, for example in switchover scripts.

Other Commands

SET *key* = *arg*

Changes a configuration setting (see also the section called “SHOW CONFIG”). For example:

```
SET log_connections = 1;
SET server_check_query = 'select 2';
```

(Note that this command is run on the pgbouncer admin console and sets pgbouncer settings. A `SET` command run on another database will be passed to the Postgres Pro backend like any other SQL command.)

Signals

`SIGHUP`

Reload config. Same as issuing the command `RELOAD` on the console.

`SIGINT`

Safe shutdown. Same as issuing `PAUSE` and `SHUTDOWN` on the console.

`SIGTERM`

Immediate shutdown. Same as issuing `SHUTDOWN` on the console.

`SIGUSR1`

Same as issuing `PAUSE` on the console.

`SIGUSR2`

Same as issuing `RESUME` on the console.

Libevent Settings

From the libevent documentation:

> It is possible to disable support for `epoll`, `kqueue`, `devpoll`, `poll`, or `select` by setting the environment variable `EVENT_NOEPOLL`, `EVENT_NOKQUEUE`, `EVENT_NODEVPOLL`, `EVENT_NOPOLL` or `EVENT_NOSELECT`, respectively.
>
> By setting the environment variable `EVENT_SHOW_METHOD`, `libevent` displays the kernel notification method that it uses.

`pgbouncer.ini` Configuration File

The configuration file is in the `.ini` format. Section names are between `[` and `]`. Lines starting with `;` or `#` are taken as comments and ignored. The characters `;` and `#` are not recognized as special when they appear later in the line.

Generic Settings

`logfile`

Specifies the log file. For daemonization (`-d`), either this or `syslog` has to be set. The log file is kept open, so after rotation, `kill -HUP` or on console `RELOAD;` should be done. On Windows, the service must be stopped and started.

Note that setting `logfile` does not by itself turn off logging to stderr. Use the command-line option `-q` or `-d` for that.

Default: not set

`pidfile`

Specifies the PID file. Without `pidfile` set, daemonization (`-d`) is not allowed.

Default: not set

`listen_addr`

Specifies a list (comma-separated) of addresses where to listen for TCP connections. You may also use `*` meaning "listen on all addresses". When not set, only Unix socket connections are accepted.

Addresses can be specified numerically (IPv4/IPv6) or by name.

Default: not set

`listen_port`

Which port to listen on. Applies to both TCP and Unix sockets.

Default: 6432

`unix_socket_dir`

Specifies the location for Unix sockets. Applies to both the listening socket and server connections. If set to an empty string, Unix sockets are disabled. A value that starts with `@` specifies that a Unix socket in the abstract namespace should be created (currently supported on Linux and Windows).

For online reboot (`-R`) to work, a Unix socket needs to be configured, and it needs to be in the file-system namespace.

Default: `/tmp` (empty on Windows)

`unix_socket_mode`

File system mode for Unix socket. Ignored for sockets in the abstract namespace. Not supported on Windows.

Default: 0777

`unix_socket_group`

Group name to use for Unix socket. Ignored for sockets in the abstract namespace. Not supported on Windows.

Default: not set

`user`

If set, specifies the Unix user to change to after startup. Works only if pgbouncer is started as root or if it's already running as the given user.

Not supported on Windows.

Default: not set

`pool_mode`

Specifies when a server connection can be reused by other clients.

`session`

Server is released back to pool after client disconnects. Default.

`transaction`

Server is released back to pool after transaction finishes.

`statement`

Server is released back to pool after query finishes. Transactions spanning multiple statements are disallowed in this mode.

`max_client_conn`

Maximum number of client connections allowed.

When this setting is increased, then the file descriptor limits in the operating system might also have to be increased. Note that the number of file descriptors potentially used is more than `max_client_conn`. If each user connects under its own username to the server, the theoretical maximum used is:

```
max_client_conn + (max pool_size * total databases * total users)
```

If a database user is specified in the connection string (all users connect under the same user name), the theoretical maximum is:

```
max_client_conn + (max pool_size * total databases)
```

The theoretical maximum should never be reached, unless somebody deliberately crafts a special load for it. Still, it means you should set the number of file descriptors to a safely high number.

Search for `ulimit` in your favorite shell man page. Note: `ulimit` does not apply in a Windows environment.

Default: 100

`default_pool_size`

How many server connections to allow per user/database pair. Can be overridden in the per-database configuration.

Default: 20

`min_pool_size`

Add more server connections to pool if below this number. Improves the behavior when the normal load suddenly comes back after a period of total inactivity. The value is effectively capped at the pool size.

Default: 0 (disabled)

`reserve_pool_size`

How many additional connections to allow to a pool (see `reserve_pool_timeout`). The 0 value disables this parameter.

Default: 0 (disabled)

`reserve_pool_timeout`

If a client has not been serviced in this time, pgbouncer enables use of additional connections from the reserve pool. The 0 value disables this parameter. [seconds]

Default: 5.0

`max_db_connections`

Do not allow more than this many server connections per database (regardless of user). This considers the pgbouncer database that the client has connected to, not the Postgres Pro database of the outgoing connection. This can also be set per database in the `[databases]` section.

Note that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: 0 (unlimited)

`max_user_connections`

Do not allow more than this many server connections per user (regardless of database). This considers the pgbouncer user that is associated with a pool, which is either the user specified for the server connection or in absence of that the user the client has connected as. This can also be set per user in the `[users]` section.

Note that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: 0 (unlimited)

`server_round_robin`

By default, pgbouncer reuses server connections in LIFO (last-in, first-out) manner, so that few connections get the most load. This gives best performance if you have a single server serving a database. But if there is a round-robin system behind a database address (TCP, DNS, or host list), then it is better if pgbouncer also uses connections in that manner, thus achieving uniform load.

Default: 0

`track_extra_parameters`

By default, pgbouncer tracks `client_encoding`, `datestyle`, `timezone`, `standard_conforming_strings` and `application_name` parameters per client. To allow other parameters to be tracked, they can be specified here, so that pgbouncer knows that they should be maintained in the client variable cache and restored in the server whenever the client becomes active.

If you need to specify multiple values, use a comma-separated list (e.g. `default_transaction_read-only, IntervalStyle`)

> **Note**
>
> Most parameters cannot be tracked this way. The only parameters that can be tracked are ones that Postgres Pro reports to the client. Postgres Pro has an official list of parameters that it reports to the client. Postgres Pro extensions can change this list though, they can add parameters themselves that they also report, and they can start reporting already existing paremeters that Postgres Pro does not report. Notably Citus 12.0+ causes PostgreSQL to also report `search_path`.

The `postgres` protocol allows specifying parameter settings, both directly as a parameter in the startup packet, or inside the `options` startup packet. Parameters specified using both of these methods are supported by `track_extra_parameters`. However, it's not possible to include `options` itself in `track_extra_parameters`, only the parameters contained in `options`.

Default: `IntervalStyle`

`ignore_startup_parameters`

By default, pgbouncer allows only parameters it can keep track of in startup packets: `client_encoding`, `datestyle`, `timezone` and `standard_conforming_strings`.

All other parameters will raise an error. To allow other parameters, they can be specified here, so that pgbouncer knows that they are handled by the admin and it can ignore them.

If you need to specify multiple values, use a comma-separated list (e.g. `options,extra_float_digits`).

The `postgres` protocol allows specifying parameter settings, both directly as a parameter in the startup packet, or inside the `options` startup packet. Parameters specified using both of these methods are supported by `ignore_startup_parameters`. It's even possible to include `options` itself in `ignore_startup_parameters`, which results in any unknown parameters contained inside `options` to be ignored.

Default: empty

`peer_id`

The peer ID used to identify this pgbouncer process in a group of pgbouncer processes that are peered together. The `peer_id` value should be unique within a group of peered pgbouncer processes. When set to 0, pgbouncer peering is disabled. See also [peers] Section for more information. The maximum value that can be used for the `peer_id` is 16383.

Default: 0

`disable_pqexec`

Disable the Simple Query protocol (PQexec). Unlike the Extended Query protocol, Simple Query allows multiple queries in one packet, which allows some classes of SQL-injection attacks. Disabling it can improve security. Obviously, this means only clients that exclusively use the Extended Query protocol will stay working.

Default: 0

`application_name_add_host`

Add the client host address and port to the application name setting set on connection start. This helps in identifying the source of bad queries, etc. This logic applies only at the start of a connection. If `application_name` is later changed with `SET`, pgbouncer does not change it again.

Default: 0

`conffile`

Show location of current configuration file. Changing it will make pgbouncer use another configuration file for next `RELOAD` / `SIGHUP`.

Default: file from command line

`service_name`

Used on win32 service registration.

Default: `pgbouncer`

`job_name`

Alias for `service_name`.

`stats_period`

Sets how often the averages shown in various `SHOW` commands are updated and how often aggregated statistics are written to the log (but see `log_stats`). [seconds]

Default: 60

Authentication Settings

pgbouncer handles its own client authentication and has its own database of users. These settings control this.

`auth_type`

How to authenticate users.

`cert`

The client must connect over TLS connection with a valid client certificate. The user name is then taken from the `CommonName` field from the certificate.

`md5`

Use MD5-based password check. This is the default authentication method. `auth_file` may contain both MD5-encrypted and plain-text passwords. If `md5` is configured and a user has a SCRAM secret, then SCRAM authentication is used automatically instead.

`scram-sha-256`

Use password check with SCRAM-SHA-256. `auth_file` has to contain SCRAM secrets or plain-text passwords. Note that SCRAM secrets can only be used for verifying the password of a client

but not for logging into a server. To be able to use SCRAM on server connections, use plain-text passwords.

`plain`

The clear-text password is sent over the wire. Deprecated.

`trust`

No authentication is done. The user name must still exist in `auth_file`.

`any`

Like the `trust` method, but the user name given is ignored. Requires that all databases are configured to log in as a specific user. Additionally, the console database allows any user to log in as admin.

`hba`

The actual authentication type is loaded from `auth_hba_file`. This allows different authentication methods for different access paths, for example: connections over Unix socket use `peer` authentication method, connections over TCP must use TLS.

`pam`

Pluggable Authentication Modules (PAM) method is used to authenticate users, `auth_file` is ignored. This method is not compatible with databases using the `auth_user` option. The service name reported to PAM is `pgbouncer`. `pam` is not supported in the HBA configuration file.

`auth_hba_file`

HBA configuration file to use when `auth_type` is `hba`.

Default: not set

`auth_file`

The name of the file to load user names and passwords from. See the section called “Authentication File Format” for details.

Most authentication types (see `auth_type`) require that either `auth_file` or `auth_user` be set; otherwise there would be no users defined.

Default: not set

`auth_user`

If `auth_user` is set, then any user not specified in `auth_file` will be queried through the `auth_query` query from `pg_shadow` in the database, using `auth_user`. The password of `auth_user` will be taken from `auth_file`. (If `auth_user` does not require a password, then it does not need to be defined in `auth_file`.)

Direct access to `pg_shadow` requires admin rights. It's preferable to use a non-superuser that calls a `SECURITY DEFINER` function instead.

Default: not set

`auth_query`

Query to load user's password from database.

Direct access to `pg_shadow` requires admin rights. It's preferable to use a non-superuser that calls a `SECURITY DEFINER` function instead.

Note that the query is run inside the target database. So if a function is used, it needs to be installed into each database.

Default: `SELECT usename, passwd FROM pg_shadow WHERE usename=$1`

`auth_dbname`

Database name in the [databases] section to be used for authentication purposes. This option can be either global or overriden in the connection string if this parameter is specified.

Log Settings

`syslog`

Toggles syslog on/off. On Windows, the event log is used instead.

Default: 0

`syslog_ident`

Under what name to send logs to syslog.

Default: `pgbouncer` (program name)

`syslog_facility`

Under what facility to send logs to syslog. Possibilities: `auth`, `authpriv`, `daemon`, `user`, `local0-7`.

Default: `daemon`

`log_connections`

Log successful logins.

Default: 1

`log_disconnections`

Log disconnections with reasons.

Default: 1

`log_pooler_errors`

Log error messages the pooler sends to clients.

Default: 1

`log_stats`

Write aggregated statistics into the log, every `stats_period`. This can be disabled if external monitoring tools are used to grab the same data from `SHOW` commands.

Default: 1

`verbose`

Increase verbosity. Mirrors the `-v` switch on the command line. For example, using `-v -v` on the command line is the same as `verbose=2`.

Default: 0

Console Access Control

`admin_users`

Comma-separated list of database users that are allowed to connect and run all commands on the console. Ignored when `auth_type` is `any`, in which case any user name is allowed in as admin.

Default: empty

`stats_users`

Comma-separated list of database users that are allowed to connect and run read-only queries on the console. That means all `SHOW` commands except `SHOW FDS`.

Default: empty

Connection Sanity Checks, Timeouts

`server_reset_query`

Query sent to server on connection release, before making it available to other clients. At that moment no transaction is in progress, so the value should not include `ABORT` or `ROLLBACK`.

The query is supposed to clean any changes made to the database session so that the next client gets the connection in a well-defined state. The default is `DISCARD ALL`, which cleans everything, but that leaves the next client no pre-cached state. It can be made lighter, e.g. `DEALLOCATE ALL` to just drop prepared statements, if the application does not break when some state is kept around.

When transaction pooling is used, the `server_reset_query` is not used, because in that mode, clients must not use any session-based features, since each transaction ends up in a different connection and thus gets a different session state.

Default: `DISCARD ALL`

`server_reset_query_always`

Whether `server_reset_query` should be run in all pooling modes. When this setting is off (default), the `server_reset_query` will be run only in pools that are in sessions-pooling mode. Connections in transaction-pooling mode should not have any need for a reset query.

This setting is for working around broken setups that run applications that use session features over a transaction-pooled pgbouncer. It changes non-deterministic breakage to deterministic breakage: clients always lose their state after each transaction.

Default: 0

`server_check_delay`

How long to keep released connections available for immediate re-use, without running `server_check_query` on it. If 0 then the query is always run.

Default: 30.0

`server_check_query`

Simple do-nothing query to check if the server connection is alive.

If an empty string, then sanity checking is disabled.

Default: `select 1`

`server_fast_close`

Disconnect a server in session pooling mode immediately or after the end of the current transaction if it is in `close_needed` mode (set by `RECONNECT`, `RELOAD` that changes connection settings, or DNS change), rather than waiting for the session end. In statement or transaction pooling mode, this has no effect since that is the default behavior there.

If because of this setting a server connection is closed before the end of the client session, the client connection is also closed. This ensures that the client notices that the session has been interrupted.

This setting makes connection configuration changes take effect sooner if session pooling and long-running sessions are used. The downside is that client sessions are liable to be interrupted by a

configuration change, so client applications will need logic to reconnect and reestablish session state. But note that no transactions will be lost, because running transactions are not interrupted, only idle sessions.

Default: 0

`server_lifetime`

The pooler will close an unused (not currently linked to any client connection) server connection that has been connected longer than this. Setting it to 0 means the connection is to be used only once, then closed. [seconds]

Default: 3600.0

`server_idle_timeout`

If a server connection has been idle more than this many seconds it will be closed. If 0 then timeout is disabled. [seconds]

Default: 600.0

`server_connect_timeout`

If connection and login don't finish in this amount of time, the connection will be closed. [seconds]

Default: 15.0

`server_login_retry`

If login to the server failed, because of failure to connect or from authentication, the pooler waits this much before retrying to connect. During the waiting interval, new clients trying to connect to the failing server will get an error immediately without another connection attempt. [seconds]

The purpose of this behavior is that clients don't unnecessarily queue up waiting for a server connection to become available if the server is not working. However, it also means that if a server is momentarily failing, for example during a restart or if the configuration was erroneous, then it will take at least this long until the pooler will consider connecting to it again. Planned events such as restarts should normally be managed using the `PAUSE` command to avoid this.

Default: 15.0

`client_login_timeout`

If a client connects but does not manage to log in in this amount of time, it will be disconnected. Mainly needed to avoid dead connections stalling `SUSPEND` and thus online restart. [seconds]

Default: 60.0

`autodb_idle_timeout`

If the automatically created (via "*") database pools have been unused this many seconds, they are freed. The negative aspect of that is that their statistics are also forgotten. [seconds]

Default: 3600.0

`dns_max_ttl`

How long DNS lookups can be cached. The actual DNS TTL is ignored. [seconds]

Default: 15.0

`dns_nxdomain_ttl`

How long DNS errors and `NXDOMAIN` DNS lookups can be cached. [seconds]

Default: 15.0

`dns_zone_check_period`

Period to check if a zone serial has changed.

pgbouncer can collect DNS zones from host names (everything after first dot) and then periodically check if the zone serial changes. If it notices changes, all host names under that zone are looked up again. If any host IP changes, its connections are invalidated.

Default: 0.0 (disabled)

`resolv_conf`

The location of a custom `resolv.conf` file. This is to allow specifying custom DNS servers and perhaps other name resolution options, independent of the global operating system configuration.

The parsing of the file is done by the DNS backend library, not pgbouncer, so see the library's documentation for details on allowed syntax and directives.

Default: empty (use operating system defaults)

TLS Settings

`client_tls_sslmode`

TLS mode to use for connections from clients. TLS connections are disabled by default. When enabled, `client_tls_key_file` and `client_tls_cert_file` must be also configured to set up the key and certificate pgbouncer uses to accept client connections.

`disable`

Plain TCP. If client requests TLS, it's ignored. Default.

`allow`

If client requests TLS, it is used. If not, plain TCP is used. If the client presents a client certificate, it is not validated.

`prefer`

Same as `allow`.

`require`

The client must use TLS. If not, the client connection is rejected. If the client presents a client certificate, it is not validated.

`verify-ca`

Client must use TLS with valid client certificate.

`verify-full`

Same as `verify-ca`.

`client_tls_key_file`

Private key for pgbouncer to accept client connections.

Default: not set

`client_tls_cert_file`

Certificate for private key. Clients can validate it.

Default: not set

`client_tls_ca_file`

Root certificate file to validate client certificates.

Default: not set

`client_tls_protocols`

Which TLS protocol versions are allowed. Allowed values: `tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`. Shortcuts: `all` (tlsv1.0,tlsv1.1,tlsv1.2,tlsv1.3), `secure` (tlsv1.2,tlsv1.3), `legacy` (all).

Default: `secure`

`client_tls_ciphers`

Allowed TLS ciphers, in OpenSSL syntax. Shortcuts: `default`/`secure`, `compat`/`legacy`, `insecure`/`all`, `normal`, `fast`.

Only connections using TLS version 1.2 and lower are affected. There is currently no setting that controls the cipher choices used by TLS version 1.3 connections.

Default: `fast`

`client_tls_ecdhcurve`

Elliptic Curve name to use for ECDH key exchanges.

Allowed values: `none` (DH is disabled), `auto` (256-bit ECDH), curve name.

Default: `auto`

`client_tls_dheparams`

DHE key exchange type.

Allowed values: `none` (DH is disabled), `auto` (2048-bit DH), `legacy` (1024-bit DH).

Default: `auto`

`server_tls_sslmode`

TLS mode to use for connections to Postgres Pro servers. The default mode is `prefer`.

`disable`

Plain TCP. TLS is not even requested from the server.

`prefer`

TLS connection is always requested first from Postgres Pro. If refused, the connection will be established over plain TCP. Server certificate is not validated. Default.

`require`

Connection must go over TLS. If server rejects it, plain TCP is not attempted. Server certificate is not validated.

`verify-ca`

Connection must go over TLS and server certificate must be valid according to `server_tls_ca_file`. Server host name is not checked against certificate.

`verify-full`

Connection must go over TLS and server certificate must be valid according to `server_tls_ca_file`. Server host name must match certificate information.

`server_tls_ca_file`

Root certificate file to validate Postgres Pro server certificates.

Default: not set

`server_tls_key_file`

Private key for pgbouncer to authenticate against Postgres Pro server.

Default: not set

`server_tls_cert_file`

Certificate for private key. Postgres Pro server can validate it.

Default: not set

`server_tls_protocols`

Which TLS protocol versions are allowed. Allowed values: `tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`. Shortcuts: `all` (tlsv1.0,tlsv1.1,tlsv1.2,tlsv1.3), `secure` (tlsv1.2,tlsv1.3), `legacy` (all).

Default: `secure`

`server_tls_ciphers`

Allowed TLS ciphers, in OpenSSL syntax. Shortcuts: `default`/`secure`, `compat`/`legacy`, `insecure`/`all`, `normal`, `fast`.

Only connections using TLS version 1.2 and lower are affected. There is currently no setting that controls the cipher choices used by TLS version 1.3 connections.

Default: `fast`

Dangerous Timeouts

Setting the following timeouts can cause unexpected errors.

`query_timeout`

Queries running longer than that are canceled. This should be used only with a slightly smaller server-side `statement_timeout`, to apply only for network problems. [seconds]

Default: 0.0 (disabled)

`query_wait_timeout`

Maximum time queries are allowed to spend waiting for execution. If the query is not assigned to a server during that time, the client is disconnected. The 0 value disables this parameter. If this is disabled, clients will be queued indefinitely. [seconds]

This setting is used to prevent unresponsive servers from grabbing up connections. It also helps when the server is down or rejects connections for any reason.

Default: 120.0

`cancel_wait_timeout`

Maximum time cancellation requests are allowed to spend waiting for execution. If the cancel request is not assigned to a server during that time, the client is disconnected. 0 disables. If this is disabled, cancel requests will be queued indefinitely. [seconds]

This setting is used to prevent a client locking up when a cancel cannot be forwarded due to the server being down.

Default: 10.0

`client_idle_timeout`

Client connections idling longer than this many seconds are closed. This should be larger than the client-side connection lifetime settings, and only used for network problems. [seconds]

Default: 0.0 (disabled)

`idle_transaction_timeout`

If a client has been in the “idle in transaction” state longer, it will be disconnected. [seconds]

Default: 0.0 (disabled)

`suspend_timeout`

How long to wait for buffer flush during `SUSPEND` or reboot (`-R`). A connection is dropped if the flush does not succeed. [seconds]

Default: 10

Low-Level Network Settings

`pkt_buf`

Internal buffer size for packets. Affects size of TCP packets sent and general memory usage. Actual libpq packets can be larger than this, so no need to set it large.

Default: 4096

`max_packet_size`

Maximum size for Postgres Pro packets that pgbouncer allows through. One packet is either one query or one result set row. The full result set can be larger.

Default: 2147483647

`listen_backlog`

The value of the `backlog` argument for `listen()`. Determines how many new unanswered connection attempts are kept in the queue. When the queue is full, further new connections are dropped.

Default: 128

`sbuf_loopcnt`

How many times to process data on one connection, before proceeding. Without this limit, one connection with a big result set can stall pgbouncer for a long time. One loop processes one `pkt_buf` amount of data. 0 means no limit.

Default: 5

`so_reuseport`

Specifies whether to set the socket option `SO_REUSEPORT` on TCP listening sockets. On some operating systems, this allows running multiple pgbouncer instances on the same host listening on the same port and having the kernel distribute the connections automatically. This option is a way to get pgbouncer to use more CPU cores. (pgbouncer is single-threaded and uses one CPU core per instance.)

This setting has the desired effect on Linux. On systems that don't support the socket option at all, turning this setting on will result in an error.

Each pgbouncer instance on the same host needs different settings for at least `unix_socket_dir` and `pidfile`, as well as `logfile` if that is used. Also note that if you make use of this option, you can no longer connect to a specific pgbouncer instance via TCP/IP, which might have implications for monitoring and metrics collection.

To make sure query cancellations keep working, you should set up pgbouncer peering between the different pgbouncer processes. For details see the `peer_id` configuration option and the `[peers]` configuration section. There's also an example that uses peering and `so_reuseport` in the Examples section.

Default: 0

`tcp_defer_accept`

Sets the `TCP_DEFER_ACCEPT` socket option; see `man 7 tcp` for details. (This is a Boolean option: 1 means enabled. The actual value set if enabled is currently hardcoded to 45 seconds.)

This is currently only supported on Linux.

Default: 1 on Linux, otherwise 0

`tcp_socket_buffer`

Default: not set

`tcp_keepalive`

Turns on basic keepalive with OS defaults.

On Linux, the system defaults are **tcp_keepidle=7200**, **tcp_keepintvl=75**, **tcp_keepcnt=9**. They are probably similar on other operating systems.

Default: 1

`tcp_keepcnt`

Default: not set

`tcp_keepidle`

Default: not set

`tcp_keepintvl`

Default: not set

`tcp_user_timeout`

Sets the `TCP_USER_TIMEOUT` socket option. This specifies the maximum amount of time in milliseconds that transmitted data may remain unacknowledged before the TCP connection is forcibly closed. If set to 0, then operating system's default is used.

This is currently only supported on Linux.

Default: 0

Section [databases]

The section `[databases]` defines the names of the databases that clients of pgbouncer can connect to and specifies where those connections will be routed. The section contains key=value lines like

```
dbname = connection string
```

where the key will be taken as a database name and the value as a connection string, consisting of key=value pairs of connection parameters, described below (similar to libpq, but the actual libpq is not used and the set of available features is different).

Example:

```
foodb = host=host1.example.com port=5432
```

```
bardb = host=localhost dbname=bazdb
```

The database name can contain characters `_0-9A-Za-z` without quoting. Names that contain other chars need to be quoted with standard SQL ident quoting: double quotes where "" is taken as single quote.

The database name `pgbouncer` is reserved for the admin console and cannot be used as a key here.

`*` acts as fallback database: if the exact name does not exist, its value is taken as connection string for the requested database. For example, if there is the following entry (and no other overriding entries):

```
* = host=foo
```

In this case, a connection to pgbouncer specifying a database `bar` will effectively behave as if the following entry exists (taking advantage of the default for `dbname` being the client-side database name):

```
bar = host=foo dbname=bar
```

Such automatically created database entries are cleaned up if they stay idle longer than the time specified by the `autodb_idle_timeout` parameter.

`dbname`

Destination database name.

Default: same as client-side database name

`host`

Host name or IP address to connect to. Host names are resolved at connection time, the result is cached per `dns_max_ttl` parameter. When a host name's resolution changes, existing server connections are automatically closed when they are released (according to the pooling mode), and new server connections immediately use the new resolution. If DNS returns several results, they are used in a round-robin manner.

If the value begins with `/`, then a Unix socket in the file-system namespace is used. If the value begins with `@`, then a Unix socket in the abstract namespace is used.

A comma-separated list of host names or addresses can be specified. In that case, connections are made in a round-robin manner. (If a host list contains host names that in turn resolve via DNS to multiple addresses, the round-robin systems operate independently. This is an implementation dependency that is subject to change.) Note that in a list, all hosts must be available at all times: there are no mechanisms to skip unreachable hosts or to select only available hosts from a list or similar. (This is different from what a host list in libpq means.) Also note that this only affects how the destinations of new connections are chosen. See also the setting `server_round_robin` for how clients are assigned to already established server connections.

Examples:

```
host=localhost
host=127.0.0.1
host=2001:0db8:85a3:0000:0000:8a2e:0370:7334
host=/var/run/postgresql
host=192.168.0.1,192.168.0.2,192.168.0.3
```

Default: not set, meaning to use a Unix socket

`port`

Default: 5432

`user`

If `user=` is set, all connections to the destination database will be done with the specified user, meaning that there will be only one pool for this database.

Otherwise pgbouncer logs into the destination database with the client user name, meaning that there will be one pool per user.

`password`

If no password is specified here, the password from the `auth_file` or `auth_query` will be used.

`auth_user`

Override of the global `auth_user` setting, if specified.

`pool_size`

Set the maximum size of pools for this database. If not set, the `default_pool_size` is used.

`min_pool_size`

Set the minimum pool size for this database. If not set, the global `min_pool_size` is used.

`reserve_pool`

Set additional connections for this database. If not set, `reserve_pool_size` is used.

`connect_query`

Query to be executed after a connection is established, but before allowing the connection to be used by any clients. If the query raises errors, they are logged but ignored otherwise.

`pool_mode`

Set the pool mode specific to this database. If not set, the default `pool_mode` is used.

`max_db_connections`

Configure a database-wide maximum (i.e. all pools within the database will not have more than this many server connections).

`client_encoding`

Ask specific `client_encoding` from server.

`datestyle`

Ask specific `datestyle` from server.

`timezone`

Ask specific `timezone` from server.

Section [users]

This section contains key=value lines like

```
user1 = settings
```

where the key will be taken as a user name and the value as a list of configuration settings specific for this user.

Example:

```
user1 = pool_mode=session
```

Only a few settings are available here.

`pool_mode`

Set the pool mode to be used for all connections from this user. If not set, the database or default `pool_mode` is used.

`max_user_connections`

Configure a maximum for the user (i.e. all pools with the user will not have more than this many server connections).

Section [peers]

This section defines the peers that pgbouncer can forward cancellation requests to and where those cancellation requests will be routed.

pgbouncer processes can be peered together in a group by defining a `peer_id` value and a `[peers]` section in the configs of all the pgbouncer processes. These pgbouncer processes can then forward cancellation requests to the process that it originated from. This is needed to make cancellations work when multiple pgbouncer processes (possibly on different servers) are behind the same TCP load balancer. Cancellation requests are sent over different TCP connections than the query they are cancelling, so a TCP load balancer might send the cancellation request connection to a different process than the one that it was meant for. By peering them these cancellation requests eventually end up at the right process.

The section contains key=value lines like

```
peer_id = connection string
```

where the key will be taken as a `peer_id` and the value as a connection string, consisting of key=value pairs of connection parameters, described below (similar to libpq, but the actual libpq is not used and the set of available features is different).

Example:

```
1 = host=host1.example.com
2 = host=/tmp/pgbouncer-2  port=5555
```

> **Note**
>
> For peering to work, the `peer_id` of each pgbouncer process in the group must be unique within the peered group. And the `[peers]` section should contain entries for each of those peer IDs. An example can be found in the Examples section. It is allowed, but not necessary, for the `[peers]` section to contain the `peer_id` of the pgbouncer that the config is for. Such an entry will be ignored, but it is allowed to make config management easier. Because it allows using the exact same `[peers]` section for multiple configs.

`host`

Host name or IP address to connect to. Host names are resolved at connection time, the result is cached per `dns_max_ttl` parameter. If DNS returns several results, they are used in a round-robin manner. But in general it's not recommended to use a hostname that resolves to multiple IPs, because then the cancel request might still be forwarded to the wrong node and it would need to be forwarded again (which is only allowed up to three times).

If the value begins with `/`, then a Unix socket in the file-system namespace is used. If the value begins with `@`, then a Unix socket in the abstract namespace is used.

Examples:

```
host=localhost
host=127.0.0.1
host=2001:0db8:85a3:0000:0000:8a2e:0370:7334
host=/var/run/pgbouncer-1
```

`port`

Default: 6432

`pool_size`

If not set, the `default_pool_size` is used.

Include Directive

The pgbouncer configuration file can contain include directives, which specify another configuration file to read and process. This allows splitting the configuration file into physically separate parts. The include directives look like this:

```
%include filename
```

If the filename is not an absolute path, it is taken as relative to the current working directory.

Authentication File Format

This section describes the format of the file specified by the `auth_file` setting. It is a text file in the following format:

```
"username1" "password" ...
"username2" "md5abcdef012342345" ...
"username2" "SCRAM-SHA-256$iterations:salt$storedkey:serverkey"
```

There should be at least two fields, surrounded by double quotes. The first field is the user name and the second is either a plain-text, a MD5-hashed password, or a SCRAM secret. pgbouncer ignores the rest of the line. Double quotes in a field value can be escaped by writing two double quotes.

Postgres Pro MD5-hashed password format:

```
"md5" + md5(password + username)
```

So user `admin` with password `1234` will have MD5-hashed password `md545f2603610af569b6155c45067268c6b`.

Postgres Pro SCRAM secret format:

```
SCRAM-SHA-256$iterations:salt$storedkey:serverkey
```

The passwords or secrets stored in the authentication file serve two purposes. First, they are used to verify the passwords of incoming client connections, if a password-based authentication method is configured. Second, they are used as the passwords for outgoing connections to the backend server, if the backend server requires password-based authentication (unless the password is specified directly in the database's connection string). The latter works if the password is stored in plain text or MD5-hashed. SCRAM secrets can only be used for logging into a server if the client authentication also uses SCRAM, the pgbouncer database definition does not specify a user name, and the SCRAM secrets are identical in pgbouncer and the Postgres Pro server (same salt and iterations, not merely the same password). This is due to an inherent security property of SCRAM: the stored SCRAM secret cannot by itself be used for deriving login credentials.

The authentication file can be written by hand, but it's also useful to generate it from some other list of users and passwords. See `./etc/mkauth.py` for a sample script to generate the authentication file from the `pg_shadow` system table.

Alternatively, use `auth_query` instead of `auth_file` to avoid having to maintain a separate authentication file.

HBA File Format

The location of the HBA file is specified by the setting `auth_hba_file`. It is only used if `auth_type` is set to `hba`.

The file follows the format of the Postgres Pro `pg_hba.conf` file described in Section 19.1.

- Supported record types: `local`, `host`, `hostssl`, `hostnossl`.

- Database field: Supports `all`, `sameuser`, @*`file`*, multiple names. Not supported: `replication`, `samerole`, `samegroup`.
- User name field: Supports `all`, @*`file`*, multiple names. Not supported: `+groupname`.
- Address field: Supports `IPv4`, `IPv6`. Not supported: DNS names, domain prefixes.
- Auth-method field: Only methods supported by pgbouncer's `auth_type` are supported, plus `peer` and `reject`, but except `any` and `pam`, which only work globally. User name map (`map=`) parameter is not supported.

Examples

Small example configuration:

```
[databases]
template1 = host=localhost dbname=template1 auth_user=someuser

[pgbouncer]
pool_mode = session
listen_port = 6432
listen_addr = localhost
auth_type = md5
auth_file = users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
stats_users = stat_collector
```

Database examples:

```
[databases]

; foodb over Unix socket
foodb =

; redirect bardb to bazdb on localhost
bardb = host=localhost dbname=bazdb

; access to destination database will go with single user
forcedb = host=localhost port=300 user=baz password=foo client_encoding=UNICODE
 datestyle=ISO
```

Example of a secure function for `auth_query`:

```
CREATE OR REPLACE FUNCTION pgbouncer.user_lookup(in i_username text, out uname text,
 out phash text)
RETURNS record AS $$
BEGIN
    SELECT usename, passwd FROM pg_catalog.pg_shadow
    WHERE usename = i_username INTO uname, phash;
    RETURN;
END;$$ LANGUAGE plpgsql SECURITY DEFINER;
REVOKE ALL ON FUNCTION pgbouncer.user_lookup(text) FROM public, pgbouncer;
GRANT EXECUTE ON FUNCTION pgbouncer.user_lookup(text) TO pgbouncer;
```

Example configs for 2 peered pgbouncer processes to create a multi-core pgbouncer setup using `so_reuseport`.

The config for the first process:

```
[databases]
postgres = host=localhost dbname=postgres
```

```
[peers]
1 = host=/tmp/pgbouncer1
2 = host=/tmp/pgbouncer2

[pgbouncer]
listen_addr=127.0.0.1
auth_file=auth_file.conf
so_reuseport=1
unix_socket_dir=/tmp/pgbouncer1
peer_id=1
```

The config for the second process:

```
[databases]
postgres = host=localhost dbname=postgres

[peers]
1 = host=/tmp/pgbouncer1
2 = host=/tmp/pgbouncer2

[pgbouncer]
listen_addr=127.0.0.1
auth_file=auth_file.conf
so_reuseport=1
; only unix_socket_dir and peer_id are different
unix_socket_dir=/tmp/pgbouncer2
peer_id=2
```

pg_filedump

pg_filedump — display formatted contents of a Postgres Pro heap, index, or control file

Synopsis

`pg_filedump` [*option*...] [*file*]

Description

pg_filedump is a utility to format Postgres Pro heap/index/control files into a human-readable form. You can format/dump the files several ways, as listed in the Options section, as well as dump a straight binary. The type of file (heap/index) can usually be determined automatically by the content of the blocks within the file. However, to format a `pg_control` file you must use the `-c` option. The default is to format the entire file using the block size listed in block 0 and display block relative addresses. These defaults can be modified using run-time options. Some options may seem strange but they are there for a reason. For example, block size. It is there because if the header of block 0 is corrupt, you need a method of forcing a block size.

Installation

pg_filedump is provided with Postgres Pro Standard as a separate pre-built package `pg-filedump-std-14` (for the detailed installation instructions, see Chapter 16).

Options

Defaults are: relative addressing, range of the entire file, block size as listed on block 0 in the file.

The following options are valid for heap and index files:

`-a`

Display absolute addresses when formatting. Block header information is always block-relative.

`-b`

Display binary block images within a range. The option will turn off all formatting options.

`-d`

Display formatted block content dump. The option will turn off all other formatting options.

`-D` *attrlist*

Decode tuples using given comma-separated list of types. The list of supported types:

`bigint`
`bigserial`
`bool`
`char`
`charN` — char(n)
`date`
`float`
`float4`
`float8`
`int`
`json`
`macaddr`
`name`
`numeric`
`oid`
`real`

`serial`
`smallint`
`smallserial`
`text`
`time`
`timestamp`
`timetz`
`uuid`
`varchar`
`varcharN` — varchar(n)
`xid`
`xml`
`~` — ignore all attributes left in a tuple

`-f`

Display formatted block content dump along with interpretation.

`-h`

Display help.

`-i`

Display interpreted item details.

`-k`

Verify block checksums.

`-o`

Do not dump old values.

`-R` *`startblock`* `[`*`endblock`*`]`

Display specific block ranges within the file. Blocks are indexed from 0. *`startblock`*: block to start at. *`endblock`*: block to end at. A *`startblock`* without an *`endblock`* will format a single block.

`-s` *`segsize`*

Force segment size to *`segsize`*.

`-t`

Dump TOAST files.

`-v`

Output additional information about TOAST relations.

`-n` *`segnumber`*

Force segment number to *`segnumber`*.

`-S` *`blocksize`*

Force block size to *`blocksize`*.

`-x`

Force interpreted formatting of block items as index items.

`-y`

Force interpreted formatting of block items as heap items.

The following options are valid for control files:

`-c`

Interpret the file listed as a control file.

`-f`

Display formatted content dump along with interpretation.

`-S` *`blocksize`*

Force block size to *`blocksize`*.

Additional parameters:

`-m`

Interpret file as `pg_filenode.map` file and print contents. All other options will be ignored.

In most cases, it is recommended to use the `-i` and `-f` options to get the most useful dump output.

Appendix J. External Projects

Postgres Pro is a complex software project, and managing the project is difficult. We have found that many enhancements to Postgres Pro can be more efficiently developed separately from the core project.

J.1. Client Interfaces

There are only two client interfaces included in the base Postgres Pro Standard distribution:

- libpq is included because it is the primary C language interface, and because many other client interfaces are built on top of it.
- ECPG is included because it depends on the server-side SQL grammar, and is therefore sensitive to changes in Postgres Pro itself.

All other language interfaces are external projects and are distributed separately. A *list of language interfaces* is maintained on the PostgreSQL wiki. Note that some of these packages are not released under the same license as Postgres Pro. For more information on each language interface, including licensing terms, refer to its website and documentation.

https://wiki.postgresql.org/wiki/List_of_drivers

J.2. Administration Tools

There are several administration tools available for Postgres Pro. One of them is *Postgres Pro Enterprise Manager*, an integrated administration panel for Postgres Pro management. It provides centralized privilege-based access to a unified management and monitoring interface with embedded command line. There are other solutions, e.g. an open-source platform *pgAdmin*.

J.3. Procedural Languages

Postgres Pro includes several procedural languages with the base distribution: PL/pgSQL, PL/Tcl, PL/Perl, and PL/Python.

In addition, there are a number of procedural languages that are developed and maintained outside the core Postgres Pro distribution. A list of *procedural languages* is maintained on the PostgreSQL wiki. Note that some of these projects are not released under the same license as Postgres Pro. For more information on each procedural language, including licensing information, refer to its website and documentation.

https://wiki.postgresql.org/wiki/PL_Matrix

J.4. Extensions

Postgres Pro is designed to be easily extensible. For this reason, extensions loaded into the database can function just like features that are built in. The extensions shipped with Postgres Pro are described in Appendix F. Other extensions are developed independently, like *PostGIS*. Even Postgres Pro replication solutions can be developed externally. For example, *Slony-I* is a popular primary/standby replication solution that is developed independently from the core project.

Appendix K. Configuring Postgres Pro for 1C Solutions

This section describes how to configure Postgres Pro for work with 1C solutions to get the maximum performance and stability.

K.1. Configuring the Locale

Before configuring Postgres Pro for 1C solutions, make sure that the Russian locale is installed on the system and that it is the active locale of the user who creates the database cluster. The following example shows how to set up the `ru_RU.UTF-8` locale for Debian systems:

```
sudo dpkg-reconfigure locales
export LANG="ru_RU.UTF-8"
/opt/pgpro/std-14/bin/pg-setup initdb
```

For more details, see related documentation sections for your operating system and for 1C.

K.2. Basic Server Requirements and Configuration

To provide high performance for 1C solutions, the Postgres Pro server must have at least the following hardware characteristics:

- 8 - 512 GB of RAM
- 4 - 256 CPU cores
- RAID 0-1 or SSD

The exact recommended characteristics depend on your system's specifics and the load on it.

It is recommended to configure the Postgres Pro server as follows:

- Disable the hyper-threading technology.
- Disable energy saving. Otherwise, delays of database responses may increase unpredictably.
- Disable swapping for POSIX/System V shared memory.

K.3. Configuring Server Parameters

This document describes how to specify configuration parameters of the Postgres Pro server for the maximum performance and stability when working with 1C solutions. Edit these parameters in the `postgresql.conf` configuration file. Note that all given parameter values are approximate. They can be considered as a starting point for further fine-tuning.

For fast automatic tuning of Postgres Pro, you can also use the pgpro_tune utility. It provides the `1c.tune` preset that specifies optimal values for 1C-specific configuration parameters. For detailed information about the usage of this utility, see its documentation.

K.3.1. Connection Parameters

Increase the maximum number of allowed concurrent connections to the database server using the max_connections configuration parameter. 1C solutions can open a large number of connections even if not all of them are used. Therefore, it is recommended to allow not less than 500 connections. The higher the number of client sessions, the higher the parameter value should be.

```
-- max_connections = 500..10000
```

K.3.2. Memory Consumption Parameters

1. Increase the amount of memory allocated by the database for data caching. To do this, use the shared_buffers configuration parameter. For good performance, it is recommended to set this parameter to at least 25% of the available system RAM.

   ```
   -- shared_buffers = RAM/4
   ```

2. Increase the maximum amount of memory used for temporary buffers within each database session to ensure that all temporary tables are handled correctly. To do this, use the temp_buffers configuration parameter.

   The recommended value should be between `32MB` and `256MB`. The exact value depends on the amount of memory on the server and the number of concurrent connections. The more connections and the smaller the amount of memory, the smaller the parameter value should be.

   ```
   -- temp_buffers = 32..256MB
   ```

3. Increase the maximum amount of memory to be used by a single query operation before writing to temporary disk files. To do this, use the work_mem configuration parameter.

   When choosing the parameter value, note that a complex query might perform several sort and hash operations at the same time, and each of them can use the specified amount of memory. Also, several running sessions can perform such operations concurrently. Therefore, the total used memory can be many times greater than the specified value. You can fine-tune the parameter value by monitoring the number of temporary files created in the system.

   ```
   -- work_mem = RAM/32..64 or 32MB..256MB
   ```

4. Increase the maximum amount of memory to be used by maintenance database operations, such as `VACUUM` or `CREATE INDEX`. To do this, use the maintenance_work_mem configuration parameter.

   Note that only one of these operations can be executed at a time by a database session. Therefore, you can set this value significantly larger than `work_mem`. Larger values can improve performance for vacuuming and restoring database dumps.

   ```
   -- maintenance_work_mem = RAM/16..32 or work_mem * 4 or 256MB..4GB
   ```

5. In the case of significant memory fragmentation, specify the following environment variable in the `/etc/systemd/system/postgresql.service` file:

   ```
   -- Environment = MALLOC_MMAP_THRESHOLD_= 8192
   ```

K.3.3. Kernel Resource Usage Parameters

Increase the maximum number of simultaneously open files allowed to each server subprocess. To do this, use the max_files_per_process configuration parameter.

The recommended value is `10000` but it can be increased depending on the load. The maximum allowed value depends on the operating system. If the server reaches the specified limit, it starts to open and close files, which affects the performance. You can monitor open files using the `lsof` command.

```
-- max_files_per_process = 10000
```

K.3.4. Background Writer Parameters

1. Decrease the delay between activity rounds for the background writer using the bgwriter_delay configuration parameter. Note that a too high parameter value will increase the load on the checkpoint process and the backend processes, while a too low value will result in the full load of one of the cores.

   ```
   -- bgwriter_delay = 20ms
   ```

2. Increase values for the bgwriter_lru_multiplier and bgwriter_lru_maxpages configuration parameters that control the number of dirty buffers written by the background writer in each round.

```
-- bgwriter_lru_multiplier = 4.0
-- bgwriter_lru_maxpages = 400
```

K.3.5. Asynchronous Behavior Parameters

1. Specify the number of concurrent disk I/O operations that any individual Postgres Pro session attempts to initiate in parallel. To do this, use the effective_io_concurrency configuration parameter. Currently, this parameter affects bitmap heap scans only.

   For magnetic drives, a good starting point for this parameter is the number of separate drives comprising a RAID 0 stripe or RAID 1 mirror used for the database. However, too high parameter values will keep the disk array busy, which results in extra CPU overhead.

   SSD disks can often process many concurrent requests, so the best value might be in the hundreds.

   ```
   -- effective_io_concurrency = 2
   ```

2. Set the max_parallel_workers_per_gather configuration parameter to 0. This disables parallel queries that can be started by `Gather` and `Gather Merge` nodes. Parallel queries may consume very significantly more resources than non-parallel queries.

   ```
   -- max_parallel_workers_per_gather = 0
   ```

K.3.6. WAL Parameters

1. Leave the fsync configuration parameter set to `on` (default). In this case, the Postgres Pro server tries to make sure that updates are physically written to disk by issuing the `fsync()` system calls. This ensures that the database cluster can recover to a consistent state after an operating system or hardware crash.

   Although disabling the `fsync` parameter often leads to a performance benefit, this can result in unrecoverable data corruption in case of a power failure or system crash.

   ```
   -- fsync = on
   ```

   Important note: if your RAID has a cache and works in the write-back mode, make sure that the disk controller cache has a valid battery. Otherwise, data written to the cache will be lost in the case of a power failure, and the Postgres Pro server will be unable to recover the data.

2. Set the synchronous_commit configuration parameter to `off`. This means that the Postgres Pro server does not wait for writing WAL records to disk but returns a success indication to the client.

   Unlike fsync, setting this parameter to `off` does not create any risk of database inconsistency. An operating system or database crash might only result in some recent transactions being lost. Thus, disabling the `synchronous_commit` parameter is useful when high performance is very important.

   ```
   -- synchronous_commit = off
   ```

3. Increase values for the checkpoint_timeout, min_wal_size, and max_wal_size configuration parameters to reduce the frequency of checkpoints. Too frequent checkpoints lead to the significant load on the disk system.

   ```
   -- checkpoint_timeout = 15min
   -- min_wal_size = 512MB..4G
   -- max_wal_size = 2 * min_wal_size
   ```

4. Specify the commit_delay configuration parameter if the average number of transactions per second (TPS) exceeds 1000. This parameter adds a time delay before a WAL flush is initiated and can improve the group commit throughput.

   ```
   -- commit_delay = 1000
   ```

K.3.7. Query Planning Parameters

1. Specify the effective_cache_size configuration parameter to define the planner's assumption about the effective size of the disk cache that is available to a single query.

   The query optimizer's performance depends on the amount of allocated RAM. A higher value makes it more likely index scans will be used, while a lower value results in using sequential scans.

   ```
   -- effective_cache_size = RAM - shared_buffers
   ```

2. Specify the random_page_cost configuration parameter to define the planner's estimate of the cost of a non-sequentially-fetched disk page.

   The parameter value is specified relative to the seq_page_cost parameter, which is set to `1.0` by default. Reducing the `random_page_cost` value will cause the system to prefer index scans to sequential scans. The recommended value depends on the seek time of the disk system. The smaller the seek time, the smaller the parameter value should be (but not less than `1.0`).

   ```
   -- random_page_cost = 1.5-2.0 (for RAID) or 1.1-1.3 (for SSD)
   ```

3. Increase the value for the from_collapse_limit configuration parameter. The planner will merge subqueries into upper queries if the resulting `FROM` list would have no more than this many items. Note that smaller parameter values reduce planning time but can lead to less efficient query plans.

   ```
   -- from_collapse_limit = 20
   ```

4. Increase the value of the join_collapse_limit configuration parameter. The planner will rewrite explicit `JOIN` constructs (except `FULL JOIN`s) into lists of `FROM` items whenever a list contains no more than this many items. Note that smaller parameter values reduce planning time but can lead to less efficient query plans.

   ```
   -- join_collapse_limit = 20
   ```

5. Leave the geqo configuration parameter set to `on` (default). This enables the genetic query optimizer (GEQO) that does query planning using the heuristic search. GEQO reduces planning time for complex queries joining many relations but sometimes may produce plans that are less efficient than plans chosen by the regular exhaustive-search algorithm.

   To manage the use of GEQO, specify the geqo_threshold configuration parameter. GEQO will be used to plan queries that involve at least the specified number of `FROM` items.

   ```
   -- geqo = on
   -- geqo_threshold = 12
   ```

6. Set the jit configuration parameter to `off` to disable Just-in-Time (JIT) compilation. This compilation is beneficial primarily for long-running CPU-bound queries, such as analytical queries. For short queries, the added overhead will be higher than the time that JIT compilation can save.

   ```
   -- jit = off
   ```

K.3.8. Automatic Vacuuming Parameters

1. Leave the autovacuum configuration parameter set to `on` (default) to run the autovacuum launcher daemon. Note that disabling the autovacuum launcher daemon will lead to increasing the database size and significant performance degradation.

   ```
   -- autovacuum = on
   ```

2. Increase the maximum number of autovacuum processes that may be running at the same time using the autovacuum_max_workers configuration parameter. The more write requests are executed in the system, the more autovacuum processes are required.

   ```
   -- autovacuum_max_workers = CPU cores/4..2 (but no less than 4)
   ```

3. Decrease the minimum delay between autovacuum rounds using the autovacuum_naptime configuration parameter. If a parameter value is too high, there can be not enough time to clean the required tables. This will lead to increasing the database size and significant performance degradation. However, a too low parameter value leads to the useless load.

   ```
   -- autovacuum_naptime = 20s
   ```

K.3.9. Client Connection Parameters

1. Specify the directory in which to create temporary tables and indexes on temporary tables using the temp_tablespaces configuration parameter. Typically, 1C solutions use a lot of temporary tables. To increase the performance when working with these tables, locate this directory on separate fast disks.

   Before this, you should first create the tablespace using the `CREATE TABLESPACE` command. If characteristics of the target disks differ from the main disks, specify the corresponding value for the `random_page_cost` parameter in this command.

   ```
   -- temp_tablespaces = 'tablespace_name'
   ```

2. Set the row_security configuration parameter to `off` to raise an error if a query's results are filtered by a row-level security policy.

   ```
   -- row_security = off
   ```

K.3.10. Lock Management Parameters

Increase the value for the max_locks_per_transaction configuration parameter up to `256`. It specifies how many objects per server process or prepared transaction can be locked at the same time.

Typically, 1C solutions use a lot of temporary tables. Every backend process usually contains multiple temporary tables. When closing a connection, Postgres Pro tries to drop all temporary tables in a single transaction, so this transaction may use a lot of locks. If the number of locks exceeds the `max_locks_per_transaction` value, the transaction will fail leaving multiple orphaned temporary tables.

```
-- max_locks_per_transaction = 256
```

K.3.11. Parameters for 1C Compatibility

1. Set the standard_conforming_strings configuration parameter to `off` to enable backslash escapes (`\`) in all strings.

   ```
   -- standard_conforming_strings = off
   ```

2. Set the escape_string_warning configuration parameter to `off` to switch off the warning about using the backslash escape symbol.

   ```
   -- escape_string_warning = off
   ```

K.3.12. Path to `pg_stat_tmp` Subdirectory

Change the default path to the `PGDATA/pg_stat_tmp` subdirectory to locate it separately from the cluster directory. This subdirectory contains temporary files for the statistics subsystem. These files are changed intensively, which creates the significant load on the disk system. It is recommended to locate this subdirectory in `tmpfs` (temporary file storage).

K.4. Additional Modules

K.4.1. Built-In Default Modules

To provide support for 1C solutions, the Postgres Pro distribution includes the following built-in modules that are enabled by default and do not require additional configuration:

- fasttrun — provides a transaction-unsafe function to truncate temporary tables without growing the size of `pg_class`.
- fulleq — provides an additional equivalence operator for compatibility with Microsoft SQL Server.
- mchar — provides additional `MCHAR` and `MVARCHAR` data types for compatibility with Microsoft SQL Server.

K.4.2. plantuner

The plantuner module allows optimizing query execution plans. To configure it for 1C solutions, do the following:

1. Add the library name to the `shared_preload_libraries` variable in the `postgresql.conf` file.

   ```
   shared_preload_libraries = 'plantuner'
   ```

2. Set the `plantuner.fix_empty_table` parameter to `on` to improve planning for recently created empty tables.

   ```
   plantuner.fix_empty_table = on
   ```

K.4.3. online_analyze

The online_analyze module provides a set of features that immediately update statistics after `INSERT`, `UPDATE`, `DELETE`, `SELECT INTO`, or `COPY` operations for the affected tables.

To configure this module, follow the steps below.

1. Add the library name to the `shared_preload_libraries` variable in the `postgresql.conf` file.

   ```
   shared_preload_libraries = 'online_analyze'
   ```

2. Enable this module.

   ```
   online_analyze.enable = on
   ```

3. Specify the minimum number of row updates before starting online analysis.

   ```
   online_analyze.threshold = 50
   ```

4. Specify the fraction of the table size to start online analysis.

   ```
   online_analyze.scale_factor = 0.1
   ```

5. Execute the `ANALYZE` command without `VERBOSE`.

   ```
   online_analyze.verbose = off
   ```

6. Enable online analysis for temporary tables.

   ```
   online_analyze.table_type = 'temporary'
   ```

7. Specify the minimum time interval between `ANALYZE` calls per table, in milliseconds.

   ```
   online_analyze.min_interval = 10000
   ```

Appendix L. Postgres Pro Limits

Table L.1 describes various hard limits of Postgres Pro. However, practical limits, such as performance limitations or available disk space may apply before absolute hard limits are reached.

Table L.1. Postgres Pro Limitations

Item	Upper Limit	Comment
database size	unlimited	
number of databases	4,294,950,911	
relations per database	1,431,650,303	
relation size	32 TB	with the default `BLCKSZ` of 8192 bytes
rows per table	limited by the number of tuples that can fit onto 4,294,967,295 pages	
columns per table	1,600	further limited by tuple size fitting on a single page; see note below
columns in a result set	1,664	
field size	1 GB	
indexes per table	unlimited	constrained by maximum relations per database
columns per index	32	can be increased by recompiling Postgres Pro
partition keys	32	can be increased by recompiling Postgres Pro
identifier length	63 bytes	can be increased by recompiling Postgres Pro
function arguments	100	can be increased by recompiling Postgres Pro
query parameters	65,535	

The maximum number of columns for a table is further reduced as the tuple being stored must fit in a single 8192-byte heap page. For example, excluding the tuple header, a tuple made up of 1,600 `int` columns would consume 6400 bytes and could be stored in a heap page, but a tuple of 1,600 `bigint` columns would consume 12800 bytes and would therefore not fit inside a heap page. Variable-length fields of types such as `text`, `varchar`, and `char` can have their values stored out of line in the table's TOAST table when the values are large enough to require it. Only an 18-byte pointer must remain inside the tuple in the table's heap. For shorter length variable-length fields, either a 4-byte or 1-byte field header is used and the value is stored inside the heap tuple.

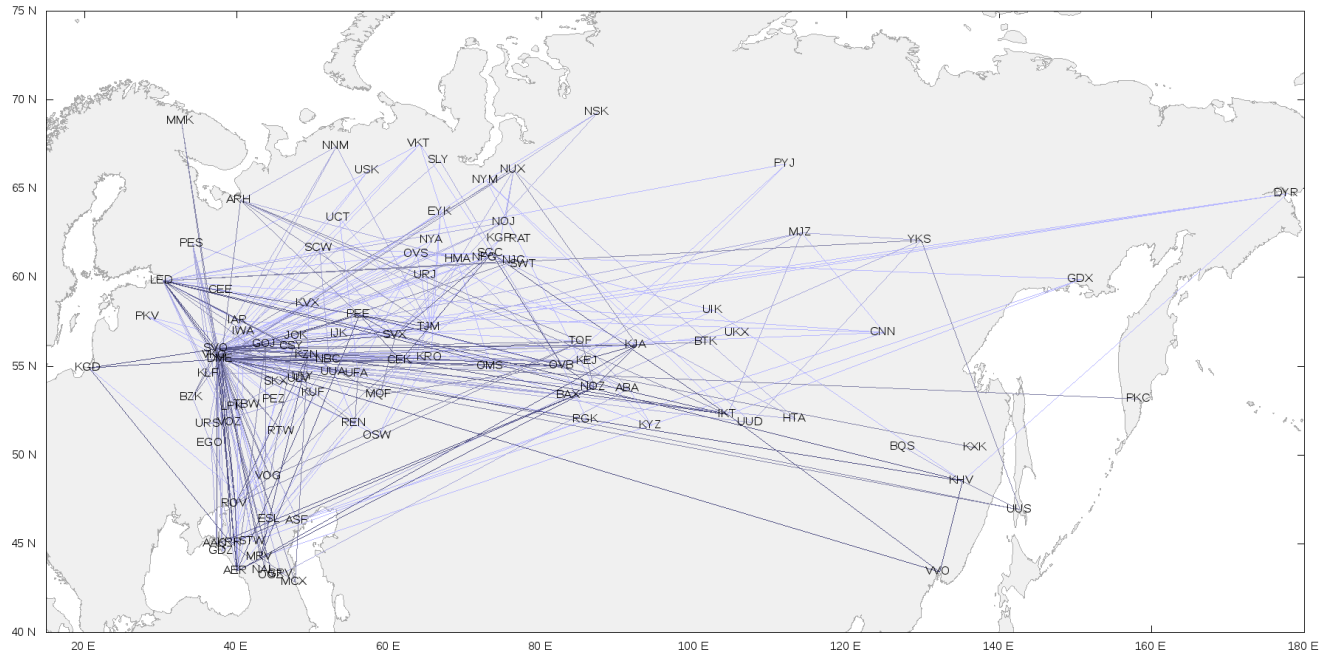
Columns that have been dropped from the table also contribute to the maximum column limit. Moreover, although the dropped column values for newly created tuples are internally marked as null in the tuple's null bitmap, the null bitmap also occupies space.

Each table can store a theoretical maximum of 2^32 out-of-line values; see Section 67.2 for a detailed discussion of out-of-line storage. This limit arises from the use of a 32-bit OID to identify each such value. The practical limit is significantly less than the theoretical limit, because as the OID space fills up, finding an OID that is still free can become expensive, in turn slowing down INSERT/UPDATE statements. Typically, this is only an issue for tables containing many terabytes of data; partitioning is a possible workaround.

Appendix M. Demo Database “Airlines”

This is an overview of a demo database for Postgres Pro. This appendix describes the database schema, which consists of eight tables and several views. The subject field of this database is airline flights in Russia. You can download the database from *our website*. See Section M.1 for details.

Figure M.1. Airlines in Russia



You can use this database for various purposes, such as:

- learning SQL language on your own
- preparing books, manuals, and courses on SQL
- showing Postgres Pro features in stories and articles

When developing this demo database, we pursued several goals:

- Database schema must be simple enough to be understood without extra explanations.
- At the same time, database schema must be complex enough to allow writing meaningful queries.
- The database must contain true-to-life data that will be interesting to work with.

This demo database is distributed under the *PostgreSQL license*.

You can send us your feedback to *edu@postgrespro.ru*.

M.1. Installation

The demo database is available at *edu.postgrespro.com* in three flavors, which differ only in the data size:

- *demo-small-en.zip* (21 MB) — flight data for one month (DB size is about 300 MB)
- *demo-medium-en.zip* (62 MB) — flight data for three months (DB size is about 700 MB)
- *demo-big-en.zip* (232 MB) — flight data for one year (DB size is about 2.5 GB)

The small database is good for writing queries, and it will not take up much disk space. The large database can help you understand the query behavior on large data volumes and consider query optimization.

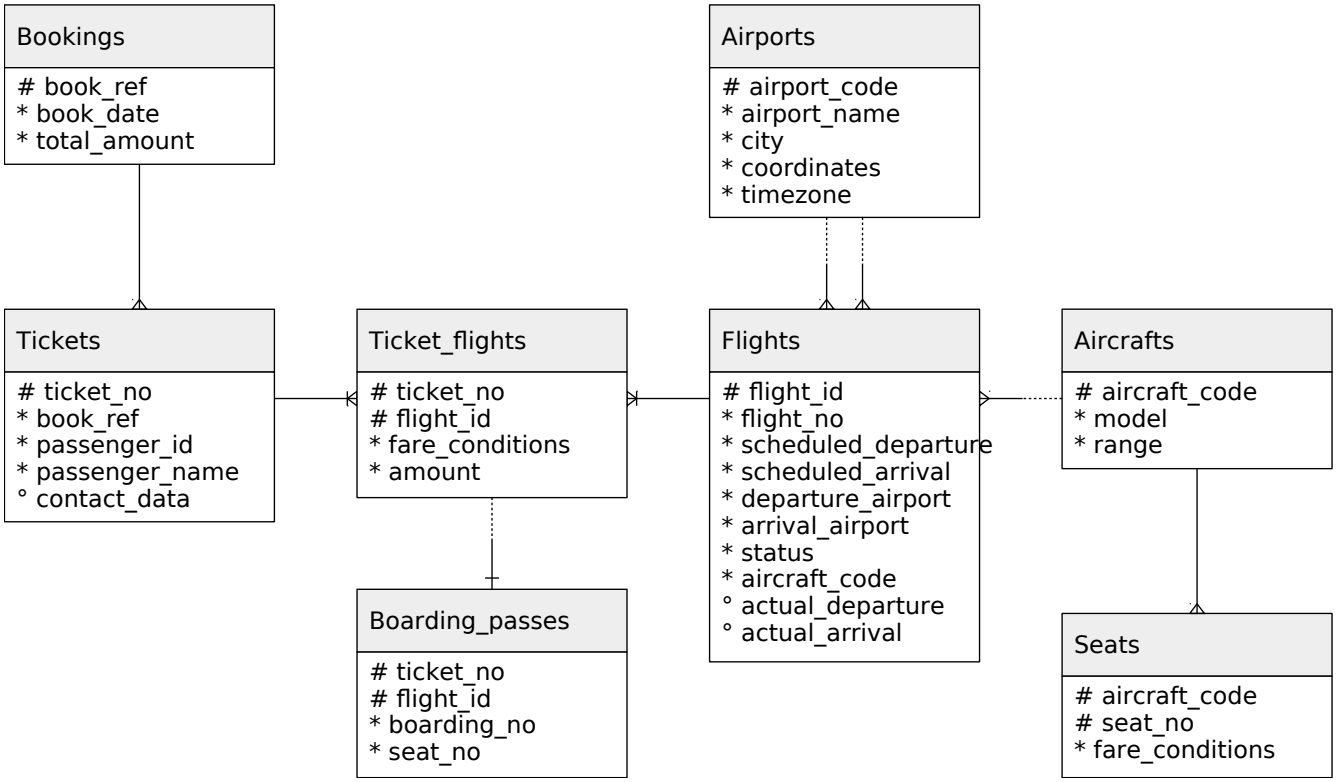
The files include an SQL script that creates the `demo` database and fills it with data (virtually, it is a backup copy created with the pg_dump utility). The owner of the `demo` database will be the DBMS user who runs the script. For example, to create the small database, run the script as the user `postgres` by means of psql:

```
psql -f demo_small_YYYYMMDD.sql -U postgres
```

Note that if the `demo` database already exists, it will be deleted and recreated!

M.2. Schema Diagram

Figure M.2. Bookings Schema Diagram



M.3. Schema Description

The main entity is a booking (`bookings`).

One booking can include several passengers, with a separate ticket (`tickets`) issued to each passenger. A ticket has a unique number and includes information about the passenger. As such, the passenger is not a separate entity. Both the passenger's name and identity document number can change over time, so it is impossible to uniquely identify all the tickets of a particular person; for simplicity, we can assume that all passengers are unique.

The ticket includes one or more flight segments (`ticket_flights`). Several flight segments can be included into a single ticket if there are no non-stop flights between the points of departure and destination (connecting flights), or if it is a round-trip ticket. Although there is no constraint in the schema, it is assumed that all tickets in the booking have the same flight segments.

Each flight (`flights`) goes from one airport (`airports`) to another. Flights with the same flight number have the same points of departure and destination, but differ in departure date.

At flight check-in, the passenger is issued a boarding pass (`boarding_passes`), where the seat number is specified. The passenger can check in for the flight only if this flight is included into the ticket. The flight-seat combination must be unique to avoid issuing two boarding passes for the same seat.

The number of seats (`seats`) in the aircraft and their distribution between different travel classes depends on the model of the aircraft (`aircrafts`) performing the flight. It is assumed that every aircraft model has only one cabin configuration. Database schema does not check that seat numbers in boarding passes have the corresponding seats in the aircraft (such verification can be done using table triggers, or at the application level).

M.4. Schema Objects

M.4.1. List of Relations

```
       Name       |     Type      |  Small  | Medium |   Big   |       Description
------------------+---------------+---------+--------+---------+-------------------------
 aircrafts        | view          |         |        |         | Aircraft
 aircrafts_data   | table         |  16 kB  |  16 kB |  16 kB  | Aircraft (translations)
 airports         | view          |         |        |         | Airports
 airports_data    | table         |  56 kB  |  56 kB |  56 kB  | Airports (translations)
 boarding_passes  | table         |  31 MB  | 102 MB | 427 MB  | Boarding passes
 bookings         | table         |  13 MB  |  30 MB | 105 MB  | Bookings
 flights          | table         |   3 MB  |   6 MB |  19 MB  | Flights
 flights_v        | view          |         |        |         | Flights
 routes           | view          |         |        |         | Routes
 seats            | table         |  88 kB  |  88 kB |  88 kB  | Seats
 ticket_flights   | table         |  64 MB  | 145 MB | 516 MB  | Flight segments
 tickets          | table         |  47 MB  | 107 MB | 381 MB  | Tickets
```

M.4.2. View `bookings.aircrafts`

Each aircraft model is identified by its three-digit code (`aircraft_code`). The view also includes the name of the aircraft model (`model`) and the maximal flying distance, in kilometers (`range`).

The value of the `model` field is selected according to the chosen language. See Section M.4.15 for details.

```
    Column     |  Type   | Modifiers |             Description
---------------+---------+-----------+-------------------------------------
 aircraft_code | char(3) | not null  | Aircraft code, IATA
 model         | text    | not null  | Aircraft model
 range         | integer | not null  | Maximal flying distance, km
View definition:
 SELECT ml.aircraft_code,
    ml.model ->> lang() AS model,
    ml.range
   FROM aircrafts_data ml;
```

M.4.3. Table `bookings.aircrafts_data`

This is the base table for the `aircrafts` view. The `model` field of this table contains translations of aircraft models to different languages, in the JSONB format. In most cases, this table is not supposed to be used directly.

```
    Column     |  Type   | Modifiers |             Description
---------------+---------+-----------+-------------------------------------
 aircraft_code | char(3) | not null  | Aircraft code, IATA
```

```
 model         | jsonb   | not null     | Aircraft model
 range         | integer | not null     | Maximal flying distance, km
Indexes:
    PRIMARY KEY, btree (aircraft_code)
Check constraints:
    CHECK (range > 0)
Referenced by:
    TABLE "flights" FOREIGN KEY (aircraft_code)
        REFERENCES aircrafts_data(aircraft_code)
    TABLE "seats" FOREIGN KEY (aircraft_code)
        REFERENCES aircrafts_data(aircraft_code) ON DELETE CASCADE
```

M.4.4. View `bookings.airports`

An airport is identified by a three-letter code (`airport_code`) and has a name (`airport_name`).

There is no separate entity for the city, but there is a city name (`city`) to identify the airports of the same city. The view also includes coordinates (`coordinates`) and the time zone (`timezone`).

The values of the `airport_name` and `city` fields are selected according to the chosen language. See Section M.4.15 for details.

```
   Column     |  Type   | Modifiers    |                 Description
--------------+---------+--------------+---------------------------------------------
 airport_code | char(3) | not null     | Airport code
 airport_name | text    | not null     | Airport name
 city         | text    | not null     | City
 coordinates  | point   | not null     | Airport coordinates (longitude and latitude)
 timezone     | text    | not null     | Airport time zone
View definition:
 SELECT ml.airport_code,
    ml.airport_name ->> lang() AS airport_name,
    ml.city ->> lang() AS city,
    ml.coordinates,
    ml.timezone
   FROM airports_data ml;
```

M.4.5. Table `bookings.airports_data`

This is the base table for the `airports` view. This table contains translations of `airport_name` and `city` values to different languages, in the JSONB format. In most cases, this table is not supposed to be used directly.

```
   Column     |  Type   | Modifiers    |                 Description
--------------+---------+--------------+---------------------------------------------
 airport_code | char(3) | not null     | Airport code
 airport_name | jsonb   | not null     | Airport name
 city         | jsonb   | not null     | City
 coordinates  | point   | not null     | Airport coordinates (longitude and latitude)
 timezone     | text    | not null     | Airport time zone
Indexes:
    PRIMARY KEY, btree (airport_code)
Referenced by:
    TABLE "flights" FOREIGN KEY (arrival_airport)
        REFERENCES airports_data(airport_code)
    TABLE "flights" FOREIGN KEY (departure_airport)
        REFERENCES airports_data(airport_code)
```

M.4.6. Table bookings.boarding_passes

At the time of check-in, which opens twenty-four hours before the scheduled departure, the passenger is issued a boarding pass. Like the flight segment, the boarding pass is identified by the ticket number and the flight number.

Boarding passes are assigned sequential numbers (boarding_no), in the order of check-ins for the flight (this number is unique only within the context of a particular flight). The boarding pass specifies the seat number (seat_no).

```
   Column    |    Type    | Modifiers    |         Description
-------------+------------+--------------+-------------------------
 ticket_no   | char(13)   | not null     | Ticket number
 flight_id   | integer    | not null     | Flight ID
 boarding_no | integer    | not null     | Boarding pass number
 seat_no     | varchar(4) | not null     | Seat number
Indexes:
    PRIMARY KEY, btree (ticket_no, flight_id)
    UNIQUE CONSTRAINT, btree (flight_id, boarding_no)
    UNIQUE CONSTRAINT, btree (flight_id, seat_no)
Foreign-key constraints:
    FOREIGN KEY (ticket_no, flight_id)
        REFERENCES ticket_flights(ticket_no, flight_id)
```

M.4.7. Table bookings.bookings

Passengers book tickets for themselves, and, possibly, for several other passengers, in advance (book_date, not earlier than one month before the flight). The booking is identified by its number (book_ref, a six-position combination of letters and digits).

The total_amount field stores the total cost of all tickets included into the booking, for all passengers.

```
   Column     |      Type     | Modifiers    |         Description
--------------+---------------+--------------+-------------------------
 book_ref     | char(6)       | not null     | Booking number
 book_date    | timestamptz   | not null     | Booking date
 total_amount | numeric(10,2) | not null     | Total booking cost
Indexes:
    PRIMARY KEY, btree (book_ref)
Referenced by:
    TABLE "tickets" FOREIGN KEY (book_ref) REFERENCES bookings(book_ref)
```

M.4.8. Table bookings.flights

The natural key of the bookings.flights table consists of two fields — flight_no and scheduled_departure. To make foreign keys for this table more compact, a surrogate key is used as the primary key (flight_id).

A flight always connects two points — the airport of departure (departure_airport) and arrival (arrival_airport). There is no such entity as a “connecting flight”: if there are no non-stop flights from one airport to another, the ticket simply includes several required flight segments.

Each flight has a scheduled date and time of departure (scheduled_departure) and arrival (scheduled_arrival). The actual departure time (actual_departure) and arrival time (actual_arrival) can differ: the difference is usually not very big, but sometimes can be up to several hours if the flight is delayed.

Flight status (`status`) can take one of the following values:

`Scheduled`

The flight is available for booking. It happens one month before the planned departure date; before that time, there is no entry for this flight in the database.

`On Time`

The flight is open for check-in (in twenty-four hours before the scheduled departure) and is not delayed.

`Delayed`

The flight is open for check-in (in twenty-four hours before the scheduled departure) but is delayed.

`Departed`

The aircraft has already departed and is airborne.

`Arrived`

The aircraft has reached the point of destination.

`Cancelled`

The flight is canceled.

```
        Column       |     Type    | Modifiers    |         Description
---------------------+-------------+--------------+-----------------------------
 flight_id           | serial      | not null     | Flight ID
 flight_no           | char(6)     | not null     | Flight number
 scheduled_departure | timestamptz | not null     | Scheduled departure time
 scheduled_arrival   | timestamptz | not null     | Scheduled arrival time
 departure_airport   | char(3)     | not null     | Airport of departure
 arrival_airport     | char(3)     | not null     | Airport of arrival
 status              | varchar(20) | not null     | Flight status
 aircraft_code       | char(3)     | not null     | Aircraft code, IATA
 actual_departure    | timestamptz |              | Actual departure time
 actual_arrival      | timestamptz |              | Actual arrival time
Indexes:
    PRIMARY KEY, btree (flight_id)
    UNIQUE CONSTRAINT, btree (flight_no, scheduled_departure)
Check constraints:
    CHECK (scheduled_arrival > scheduled_departure)
    CHECK ((actual_arrival IS NULL)
       OR  ((actual_departure IS NOT NULL AND actual_arrival IS NOT NULL)
            AND (actual_arrival > actual_departure)))
    CHECK (status IN ('On Time', 'Delayed', 'Departed',
                      'Arrived', 'Scheduled', 'Cancelled'))
Foreign-key constraints:
    FOREIGN KEY (aircraft_code)
        REFERENCES aircrafts(aircraft_code)
    FOREIGN KEY (arrival_airport)
        REFERENCES airports(airport_code)
    FOREIGN KEY (departure_airport)
        REFERENCES airports(airport_code)
Referenced by:
    TABLE "ticket_flights" FOREIGN KEY (flight_id)
        REFERENCES flights(flight_id)
```

M.4.9. Table `bookings.seats`

Seats define the cabin configuration of each aircraft model. Each seat is defined by its number (`seat_no`) and has an assigned travel class (`fare_conditions`): `Economy`, `Comfort` or `Business`.

```
      Column     |     Type    | Modifiers    |      Description
-----------------+-------------+--------------+--------------------
 aircraft_code   | char(3)     | not null     | Aircraft code, IATA
 seat_no         | varchar(4)  | not null     | Seat number
 fare_conditions | varchar(10) | not null     | Travel class
Indexes:
    PRIMARY KEY, btree (aircraft_code, seat_no)
Check constraints:
    CHECK (fare_conditions IN ('Economy', 'Comfort', 'Business'))
Foreign-key constraints:
    FOREIGN KEY (aircraft_code)
        REFERENCES aircrafts(aircraft_code) ON DELETE CASCADE
```

M.4.10. Table `bookings.ticket_flights`

A flight segment connects a ticket with a flight and is identified by their numbers.

Each flight has its cost (`amount`) and travel class (`fare_conditions`).

```
     Column      |     Type      | Modifiers    |    Description
-----------------+---------------+--------------+--------------------
 ticket_no       | char(13)      | not null     | Ticket number
 flight_id       | integer       | not null     | Flight ID
 fare_conditions | varchar(10)   | not null     | Travel class
 amount          | numeric(10,2) | not null     | Travel cost
Indexes:
    PRIMARY KEY, btree (ticket_no, flight_id)
Check constraints:
    CHECK (amount >= 0)
    CHECK (fare_conditions IN ('Economy', 'Comfort', 'Business'))
Foreign-key constraints:
    FOREIGN KEY (flight_id) REFERENCES flights(flight_id)
    FOREIGN KEY (ticket_no) REFERENCES tickets(ticket_no)
Referenced by:
    TABLE "boarding_passes" FOREIGN KEY (ticket_no, flight_id)
        REFERENCES ticket_flights(ticket_no, flight_id)
```

M.4.11. Table `bookings.tickets`

A ticket has a unique number (`ticket_no`) that consists of 13 digits.

The ticket includes a passenger ID (`passenger_id`) — the identity document number, — their first and last names (`passenger_name`), and contact information (`contact_data`).

Neither the passenger ID, nor the name is permanent (for example, one can change the last name or passport), so it is impossible to uniquely identify all tickets of a particular passenger.

```
     Column     |     Type    | Modifiers    |          Description
----------------+-------------+--------------+---------------------------
 ticket_no      | char(13)    | not null     | Ticket number
 book_ref       | char(6)     | not null     | Booking number
 passenger_id   | varchar(20) | not null     | Passenger ID
 passenger_name | text        | not null     | Passenger name
```

```
 contact_data   | jsonb       |              | Passenger contact information
Indexes:
    PRIMARY KEY, btree (ticket_no)
Foreign-key constraints:
    FOREIGN KEY (book_ref) REFERENCES bookings(book_ref)
Referenced by:
    TABLE "ticket_flights" FOREIGN KEY (ticket_no) REFERENCES tickets(ticket_no)
```

M.4.12. View `bookings.flights_v`

There is a `flights_v` view over the `flights` table that provides additional information:

- Details about the airport of departure — `departure_airport`, `departure_airport_name`, `departure_city`
- Details about the airport of arrival — `arrival_airport`, `arrival_airport_name`, `arrival_city`
- Local departure time — `scheduled_departure_local`, `actual_departure_local`
- Local arrival time — `scheduled_arrival_local`, `actual_arrival_local`
- Flight duration — `scheduled_duration`, `actual_duration`.

```
          Column           |    Type     |              Description
---------------------------+-------------+---------------------------------------
 flight_id                 | integer     | Flight ID
 flight_no                 | char(6)     | Flight number
 scheduled_departure       | timestamptz | Scheduled departure time
 scheduled_departure_local | timestamp   | Scheduled departure time,
                           |             | local time at the point of departure
 scheduled_arrival         | timestamptz | Scheduled arrival time
 scheduled_arrival_local   | timestamp   | Scheduled arrival time,
                           |             | local time at the point of destination
 scheduled_duration        | interval    | Scheduled flight duration
 departure_airport         | char(3)     | Departure airport code
 departure_airport_name    | text        | Departure airport name
 departure_city            | text        | City of departure
 arrival_airport           | char(3)     | Arrival airport code
 arrival_airport_name      | text        | Arrival airport name
 arrival_city              | text        | City of arrival
 status                    | varchar(20) | Flight status
 aircraft_code             | char(3)     | Aircraft code, IATA
 actual_departure          | timestamptz | Actual departure time
 actual_departure_local    | timestamp   | Actual departure time,
                           |             | local time at the point of departure
 actual_arrival            | timestamptz | Actual arrival time
 actual_arrival_local      | timestamp   | Actual arrival time,
                           |             | local time at the point of destination
 actual_duration           | interval    | Actual flight duration
```

M.4.13. View `bookings.routes`

The `bookings.flights` table contains some redundancies, which you can use to single out route information (flight number, airports of departure and destination) that does not depend on the exact flight dates.

Such information is shown in the `routes` view.

```
        Column          |   Type    |             Description
```

```
------------------------+-----------+--------------------------------------
 flight_no              | char(6)   | Flight number
 departure_airport      | char(3)   | Departure airport code
 departure_airport_name | text      | Departure airport name
 departure_city         | text      | City of departure
 arrival_airport        | char(3)   | Arrival airport code
 arrival_airport_name   | text      | Arrival airport name
 arrival_city           | text      | City of arrival
 aircraft_code          | char(3)   | Aircraft code, IATA
 duration               | interval  | Flight duration
 days_of_week           | integer[] | Days of the week on which flights are performed
```

M.4.14. Function `bookings.now`

The demo database contains “snapshots” of data — similar to a backup copy of a real system captured at some point in time. For example, if a flight has the `Departed` status, it means that the aircraft had already departed and was airborne at the time of the backup copy.

The “snapshot” time is saved in the `bookings.now()` function. You can use this function in demo queries for cases where you would use the `now()` function in a real database.

In addition, the return value of this function determines the version of the demo database. The latest version available is of August 15, 2017.

M.4.15. Function `bookings.lang`

Some fields in the demo database are available in English and Russian. Translations to other languages are not provided, but are easy to add. The `bookings.lang` returns the value of the *`bookings.lang`* parameter, that is, the language in which these fields will be displayed.

This function is used in the `aircrafts` and `airports` views and is not intended to be used directly in queries.

M.5. Usage

M.5.1. Schema `bookings`

The `bookings` schema contains all objects of the demo database. When you connect to the database, `search_path` configuration parameter is automatically set to `bookings, public`, so you do not need to specify the schema name explicitly.

However, for the `bookings.now` function, you always have to specify the schema to distinguish this function from the standard `now` function.

M.5.2. Translations

By default, values of several translatable fields are shown in Russian. These are `airport_name` and `city` of the `airports` view, as well as `model` of the `aircrafts` view.

You can choose to display these fields in another language (although only the English translation is provided in the demo database). To switch to English, set the *`bookings.lang`* parameter to `en`. It may be convenient to choose the language at the database level:

```
ALTER DATABASE demo SET bookings.lang = en;
```

You have to reconnect to the database for this command to take effect. For other methods of settings configuration parameters, see Section 18.1.

In the examples below, the English language is selected for translatable fields.

M.5.3. Sample Queries

To better understand the contents of the demo database, let's take a look at the results of several simple queries.

The results displayed below were received on a small database version (demo-small) of August 15, 2017. If the same queries return different data on your system, check your demo database version (using the `bookings.now` function). Some minor deviations may be caused by the difference between your local time and Moscow time, or your locale settings.

All flights are operated by several types of aircraft:

```
SELECT * FROM aircrafts;
```

```
 aircraft_code |        model         | range
---------------+----------------------+-------
 773           | Boeing 777-300       | 11100
 763           | Boeing 767-300       |  7900
 SU9           | Sukhoi SuperJet-100  |  3000
 320           | Airbus A320-200      |  5700
 321           | Airbus A321-200      |  5600
 319           | Airbus A319-100      |  6700
 733           | Boeing 737-300       |  4200
 CN1           | Cessna 208 Caravan   |  1200
 CR2           | Bombardier CRJ-200   |  2700
(9 rows)
```

For each aircraft type, a separate list of seats is supported. For example, in a small Cessna 208 Caravan, one can select the following seats:

```
SELECT   a.aircraft_code,
         a.model,
         s.seat_no,
         s.fare_conditions
FROM     aircrafts a
         JOIN seats s ON a.aircraft_code = s.aircraft_code
WHERE    a.model = 'Cessna 208 Caravan'
ORDER BY s.seat_no;
```

```
 aircraft_code |       model        | seat_no | fare_conditions
---------------+--------------------+---------+-----------------
 CN1           | Cessna 208 Caravan | 1A      | Economy
 CN1           | Cessna 208 Caravan | 1B      | Economy
 CN1           | Cessna 208 Caravan | 2A      | Economy
 CN1           | Cessna 208 Caravan | 2B      | Economy
 CN1           | Cessna 208 Caravan | 3A      | Economy
 CN1           | Cessna 208 Caravan | 3B      | Economy
 CN1           | Cessna 208 Caravan | 4A      | Economy
 CN1           | Cessna 208 Caravan | 4B      | Economy
 CN1           | Cessna 208 Caravan | 5A      | Economy
 CN1           | Cessna 208 Caravan | 5B      | Economy
 CN1           | Cessna 208 Caravan | 6A      | Economy
 CN1           | Cessna 208 Caravan | 6B      | Economy
(12 rows)
```

Bigger aircraft have more seats of various travel classes:

```
SELECT   s2.aircraft_code,
```

```
         string_agg (s2.fare_conditions || '(' || s2.num::text || ')',
                     ', ') as fare_conditions
FROM     (
          SELECT   s.aircraft_code, s.fare_conditions, count(*) as num
          FROM     seats s
          GROUP BY s.aircraft_code, s.fare_conditions
          ORDER BY s.aircraft_code, s.fare_conditions
         ) s2
GROUP BY s2.aircraft_code
ORDER BY s2.aircraft_code;
```

```
 aircraft_code |             fare_conditions
---------------+-----------------------------------------
 319           | Business(20), Economy(96)
 320           | Business(20), Economy(120)
 321           | Business(28), Economy(142)
 733           | Business(12), Economy(118)
 763           | Business(30), Economy(192)
 773           | Business(30), Comfort(48), Economy(324)
 CN1           | Economy(12)
 CR2           | Economy(50)
 SU9           | Business(12), Economy(85)
(9 rows)
```

The demo database contains the list of airports of almost all major Russian cities. Most cities have only one airport. The exceptions are:

```
SELECT   a.airport_code as code,
         a.airport_name,
         a.city,
         a.coordinates
FROM     airports a
WHERE    a.city IN (
            SELECT   aa.city
            FROM     airports aa
            GROUP BY aa.city
            HAVING   COUNT(*) > 1
         )
ORDER BY a.city, a.airport_code;
```

```
 code |      airport_name      |   city    |           coordinates
------+------------------------+-----------+-------------------------
 DME  | Domodedovo             | Moscow    | (37.9062995910645,55.4087982177734)
      | International Airport  |           |
 SVO  | Sheremetyevo           | Moscow    | (37.4146,55.972599)
      | International Airport  |           |
 VKO  | Vnukovo                | Moscow    | (37.2615013123,55.5914993286)
      | International Airport  |           |
 ULV  | Ulyanovsk              | Ulyanovsk | (48.2266998291,54.2682991028)
      | Baratayevka Airport    |           |
 ULY  | Ulyanovsk East Airport | Ulyanovsk | (48.8027000427246,54.4010009765625)
(5 rows)
```

To learn about your flying options from one point to another, it is convenient to use the `routes` materialized view that aggregates information on all flights. For example, here are the destinations where you can get from Volgograd on specific days of the week, with flight duration:

```
SELECT r.arrival_city as city,
       r.arrival_airport as code,
       r.arrival_airport_name as airport_name,
       r.days_of_week,
       r.duration
FROM   routes r
WHERE  r.departure_city = 'Volgograd';
```

```
    city     | code |            airport_name             |  days_of_week   | duration
-------------+------+-------------------------------------+-----------------+----------
 Moscow      | SVO  | Sheremetyevo International Airport | {1,2,3,4,5,6,7} | 01:15:00
 Chelyabinsk | CEK  | Chelyabinsk Balandino Airport      | {1,2,3,4,5,6,7} | 01:50:00
 Rostov      | ROV  | Rostov-on-Don Airport              | {1,2,3,4,5,6,7} | 00:30:00
 Moscow      | VKO  | Vnukovo International Airport      | {1,2,3,4,5,6,7} | 01:10:00
 Cheboksary  | CSY  | Cheboksary Airport                 | {1,2,3,4,5,6,7} | 02:45:00
 Tomsk       | TOF  | Bogashevo Airport                  | {1}             | 03:50:00
(6 rows)
```

The database was formed at the moment returned by the `bookings.now()` function:

```
SELECT bookings.now() as now;
```

```
          now
------------------------
 2017-08-15 18:00:00+03
```

In relation to this moment, all flights are classified as past and future flights:

```
SELECT   status,
         count(*) as count,
         min(scheduled_departure) as min_scheduled_departure,
         max(scheduled_departure) as max_scheduled_departure
FROM     flights
GROUP BY status
ORDER BY min_scheduled_departure;
```

```
  status   | count | min_scheduled_departure | max_scheduled_departure
-----------+-------+-------------------------+-------------------------
 Arrived   | 16707 | 2017-07-16 01:50:00+03  | 2017-08-15 17:25:00+03
 Cancelled |   414 | 2017-07-19 11:35:00+03  | 2017-09-14 20:55:00+03
 Departed  |    58 | 2017-08-15 09:55:00+03  | 2017-08-15 17:50:00+03
 Delayed   |    41 | 2017-08-15 15:15:00+03  | 2017-08-16 17:25:00+03
 On Time   |   518 | 2017-08-15 17:55:00+03  | 2017-08-16 18:00:00+03
 Scheduled | 15383 | 2017-08-16 18:05:00+03  | 2017-09-14 20:40:00+03
(6 rows)
```

Let's find the next flight from Yekaterinburg to Moscow. The `flight` table is not very convenient for such queries, as it does not include information on the cities of departure and arrival. That is why we will use the `flights_v` view:

```
\x
SELECT   f.*
FROM     flights_v f
WHERE    f.departure_city = 'Yekaterinburg'
AND      f.arrival_city = 'Moscow'
```

```
AND      f.scheduled_departure > bookings.now()
ORDER BY f.scheduled_departure
LIMIT    1;
```

```
-[ RECORD 1 ]-------------+---------------------------------
flight_id                 | 10927
flight_no                 | PG0226
scheduled_departure       | 2017-08-16 08:10:00+03
scheduled_departure_local | 2017-08-16 10:10:00
scheduled_arrival         | 2017-08-16 09:55:00+03
scheduled_arrival_local   | 2017-08-16 09:55:00
scheduled_duration        | 01:45:00
departure_airport         | SVX
departure_airport_name    | Koltsovo Airport
departure_city            | Yekaterinburg
arrival_airport           | SVO
arrival_airport_name      | Sheremetyevo International Airport
arrival_city              | Moscow
status                    | On Time
aircraft_code             | 773
actual_departure          |
actual_departure_local    |
actual_arrival            |
actual_arrival_local      |
actual_duration           |
```

Note that the `flights_v` view shows both Moscow time and local time at the airports of departure and arrival.

M.5.4. Bookings

Each booking can include several tickets, one for each passenger. The ticket, in its turn, can include several flight segments. The complete information about the booking is stored in three tables: `bookings`, `tickets`, and `ticket_flights`.

Let's find several most expensive bookings:

```
SELECT   *
FROM     bookings
ORDER BY total_amount desc
LIMIT    10;
```

```
 book_ref |       book_date        | total_amount
----------+------------------------+--------------
 3B54BB   | 2017-07-05 17:08:00+03 |   1204500.00
 3AC131   | 2017-07-31 01:06:00+03 |   1087100.00
 65A6EA   | 2017-07-03 06:28:00+03 |   1065600.00
 D7E9AA   | 2017-08-08 05:29:00+03 |   1062800.00
 EF479E   | 2017-08-02 15:58:00+03 |   1035100.00
 521C53   | 2017-07-08 09:25:00+03 |    985500.00
 514CA6   | 2017-07-27 05:07:00+03 |    955000.00
 D70BD9   | 2017-07-05 12:47:00+03 |    947500.00
 EC7EDA   | 2017-07-02 16:13:00+03 |    946800.00
 8E4370   | 2017-07-28 02:04:00+03 |    945700.00
(10 rows)
```

Let's take a look at the tickets included into the booking with code `521C53`:

```
SELECT ticket_no,
       passenger_id,
       passenger_name
FROM   tickets
WHERE  book_ref = '521C53';
```

```
   ticket_no   | passenger_id |   passenger_name
---------------+--------------+--------------------
 0005432661914 | 8234 547529  | IVAN IVANOV
 0005432661915 | 2034 201228  | ANTONINA KUZNECOVA
(2 rows)
```

If we would like to know, which flight segments are included into Antonina Kuznecova's ticket, we can use the following query:

```
SELECT   to_char(f.scheduled_departure, 'DD.MM.YYYY') AS when,
         f.departure_city || ' (' || f.departure_airport || ')' AS departure,
         f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
         tf.fare_conditions AS class,
         tf.amount
FROM     ticket_flights tf
         JOIN flights_v f ON tf.flight_id = f.flight_id
WHERE    tf.ticket_no = '0005432661915'
ORDER BY f.scheduled_departure;
```

```
    when    |      departure       |       arrival        |  class   |  amount
------------+----------------------+----------------------+----------+-----------
 29.07.2017 | Moscow (SVO)         | Anadyr (DYR)         | Business | 185300.00
 02.08.2017 | Anadyr (DYR)         | Khabarovsk (KHV)     | Business |  92200.00
 03.08.2017 | Khabarovsk (KHV)     | Blagoveshchensk (BQS)| Business |  18000.00
 08.08.2017 | Blagoveshchensk (BQS)| Khabarovsk (KHV)     | Business |  18000.00
 12.08.2017 | Khabarovsk (KHV)     | Anadyr (DYR)         | Economy  |  30700.00
 17.08.2017 | Anadyr (DYR)         | Moscow (SVO)         | Business | 185300.00
(6 rows)
```

As we can see, high booking cost is explained by multiple long-haul flights in business class.

Some of the flight segments in this ticket have earlier dates than the `bookings.now()` return value: it means that these flights had already happened. The last flight had not happened yet at the time of the database creation. After the check-in, a boarding pass with the allocated seat number is issued. We can check the exact seats occupied by Antonina (note the outer left join with table `boarding_passes`):

```
SELECT   to_char(f.scheduled_departure, 'DD.MM.YYYY') AS when,
         f.departure_city || ' (' || f.departure_airport || ')' AS departure,
         f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
         f.status,
         bp.seat_no
FROM     ticket_flights tf
         JOIN flights_v f ON tf.flight_id = f.flight_id
         LEFT JOIN boarding_passes bp ON tf.flight_id = bp.flight_id
                                     AND tf.ticket_no = bp.ticket_no
WHERE    tf.ticket_no = '0005432661915'
ORDER BY f.scheduled_departure;
```

```
    when    |      departure       |       arrival        |  status   | seat_no
------------+----------------------+----------------------+-----------+---------
```

```
 29.07.2017 | Moscow (SVO)          | Anadyr (DYR)          | Arrived   | 5C
 02.08.2017 | Anadyr (DYR)          | Khabarovsk (KHV)      | Arrived   | 1D
 03.08.2017 | Khabarovsk (KHV)      | Blagoveshchensk (BQS)| Arrived   | 2C
 08.08.2017 | Blagoveshchensk (BQS)| Khabarovsk (KHV)      | Arrived   | 2D
 12.08.2017 | Khabarovsk (KHV)      | Anadyr (DYR)          | Arrived   | 20B
 17.08.2017 | Anadyr (DYR)          | Moscow (SVO)          | Scheduled |
(6 rows)
```

M.5.5. New Booking

Let's try to send Aleksandr Radishchev from Saint Petersburg to Moscow — the route that made him famous. Naturally, he will travel for free and in business class. We have already found a flight for tomorrow, and a return flight a week later.

```
BEGIN;

INSERT INTO bookings (book_ref, book_date, total_amount)
VALUES      ('_QWE12', bookings.now(), 0);

INSERT INTO tickets (ticket_no, book_ref, passenger_id, passenger_name)
VALUES      ('_000000000001', '_QWE12', '1749 051790', 'ALEKSANDR RADISHCHEV');

INSERT INTO ticket_flights (ticket_no, flight_id, fare_conditions, amount)
VALUES      ('_000000000001', 8525, 'Business', 0),
            ('_000000000001', 4967, 'Business', 0);

COMMIT;
```

To avoid conflicts with the range of values present in the database, identifiers are started with an underscore.

We will check in Aleksandr for tomorrow's flight right away:

```
INSERT INTO boarding_passes (ticket_no, flight_id, boarding_no, seat_no)
VALUES      ('_000000000001', 8525, 1, '1A');
```

Now let's check the booking information:

```
SELECT   b.book_ref,
         t.ticket_no,
         t.passenger_id,
         t.passenger_name,
         tf.fare_conditions,
         tf.amount,
         f.scheduled_departure_local,
         f.scheduled_arrival_local,
         f.departure_city || ' (' || f.departure_airport || ')' AS departure,
         f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
         f.status,
         bp.seat_no
FROM     bookings b
         JOIN tickets t ON b.book_ref = t.book_ref
         JOIN ticket_flights tf ON tf.ticket_no = t.ticket_no
         JOIN flights_v f ON tf.flight_id = f.flight_id
         LEFT JOIN boarding_passes bp ON tf.flight_id = bp.flight_id
                                     AND tf.ticket_no = bp.ticket_no
WHERE    b.book_ref = '_QWE12'
```

```
ORDER BY t.ticket_no, f.scheduled_departure;

-[ RECORD 1 ]-------------+--------------------
book_ref                  | _QWE12
ticket_no                 | _000000000001

Appendix O. Glossary

This is a list of terms and their meaning in the context of PostgreSQL and relational database systems in general.

ACID
: *Atomicity*, *Consistency*, *Isolation*, and *Durability*. This set of properties of database transactions is intended to guarantee validity in concurrent operation and even in event of errors, power failures, etc.

Aggregate function (routine)
: A *function* that combines (*aggregates*) multiple input values, for example by counting, averaging or adding, yielding a single output value.

  For more information, see Section 9.21.

  See Also Window function (routine).

Analytic function
: See Window function (routine).

Analyze (operation)
: The process of collecting statistics from data in *tables* and other *relations* to help the *query planner* to make decisions about how to execute *queries*.

  (Don't confuse this term with the `ANALYZE` option to the EXPLAIN command.)

  For more information, see ANALYZE.

Atomic
: In reference to a *datum*: the fact that its value cannot be broken down into smaller components.

  In reference to a *database transaction*: see *atomicity*.

Atomicity
: The property of a *transaction* that either all its operations complete as a single unit or none do. In addition, if a system failure occurs during the execution of a transaction, no partial results are visible after recovery. This is one of the ACID properties.

Attribute
: An element with a certain name and data type found within a *tuple*.

Autovacuum (process)
: A set of background processes that routinely perform *vacuum* and *analyze* operations.

  For more information, see Section 23.1.6.

Backend (process)
: Process of an *instance* which acts on behalf of a *client session* and handles its requests.

  (Don't confuse this term with the similar terms *Background Worker* or *Background Writer*).

Background worker (process)
: Process within an *instance*, which runs system- or user-supplied code. Serves as infrastructure for several features in PostgreSQL, such as *logical replication* and *parallel queries*. In addition, *Extensions* can add custom background worker processes.

  For more information, see Chapter 47.

Background writer (process)
: A process that writes dirty *data pages* from *shared memory* to the file system. It wakes up periodically, but works only for a short period in order to distribute its expensive I/O activity over time to avoid generating larger I/O peaks which could block other processes.

  For more information, see Section 18.4.5.

Base Backup	A binary copy of all *database cluster* files. It is generated by the tool pg_basebackup. In combination with WAL files it can be used as the starting point for recovery, log shipping, or streaming replication.
Bloat	Space in data pages which does not contain current row versions, such as unused (free) space or outdated row versions.
Cast	A conversion of a *datum* from its current data type to another data type. For more information, see CREATE CAST.
Catalog	The SQL standard uses this term to indicate what is called a *database* in PostgreSQL's terminology. (Don't confuse this term with *system catalog*). For more information, see Section 21.1.
Check constraint	A type of *constraint* defined on a *relation* which restricts the values allowed in one or more *attributes*. The check constraint can make reference to any attribute of the same row in the relation, but cannot reference other rows of the same relation or other relations. For more information, see Section 5.4.
Checkpoint	A point in the *WAL* sequence at which it is guaranteed that the heap and index data files have been updated with all information from *shared memory* modified before that checkpoint; a *checkpoint record* is written and flushed to WAL to mark that point. A checkpoint is also the act of carrying out all the actions that are necessary to reach a checkpoint as defined above. This process is initiated when predefined conditions are met, such as a specified amount of time has passed, or a certain volume of records has been written; or it can be invoked by the user with the command `CHECKPOINT`. For more information, see Section 28.5.
Checkpointer (process)	A specialized process responsible for executing checkpoints.
Class (archaic)	See Relation.
Client (process)	Any process, possibly remote, that establishes a *session* by *connecting* to an *instance* to interact with a *database*.
Column	An *attribute* found in a *table* or *view*.
Commit	The act of finalizing a *transaction* within the *database*, which makes it visible to other transactions and assures its *durability*. For more information, see COMMIT.
Concurrency	The concept that multiple independent operations happen within the *database* at the same time. In PostgreSQL, concurrency is controlled by the *multiversion concurrency control* mechanism.
Connection	An established line of communication between a client process and a *backend* process, usually over a network, supporting a *session*. This term is sometimes used as a synonym for session. For more information, see Section 18.3.

Consistency	The property that the data in the *database* is always in compliance with *integrity constraints*. Transactions may be allowed to violate some of the constraints transiently before it commits, but if such violations are not resolved by the time it commits, such a transaction is automatically *rolled back*. This is one of the ACID properties.
Constraint	A restriction on the values of data allowed within a *table*, or in attributes of a *domain*. For more information, see Section 5.4.
Data area	See Data directory.
Database	A named collection of *local SQL objects*. For more information, see Section 21.1.
Database cluster	A collection of databases and global SQL objects, and their common static and dynamic metadata. Sometimes referred to as a *cluster*. In PostgreSQL, the term *cluster* is also sometimes used to refer to an instance. (Don't confuse this term with the SQL command `CLUSTER`.)
Database server	See Instance.
Data directory	The base directory on the file system of a *server* that contains all data files and subdirectories associated with a *database cluster* (with the exception of *tablespaces*, and optionally *WAL*). The environment variable `PGDATA` is commonly used to refer to the data directory. A *cluster*'s storage space comprises the data directory plus any additional tablespaces. For more information, see Section 67.1.
Data page	The basic structure used to store relation data. All pages are of the same size. Data pages are typically stored on disk, each in a specific file, and can be read to *shared buffers* where they can be modified, becoming *dirty*. They become clean when written to disk. New pages, which initially exist in memory only, are also dirty until written.
Datum	The internal representation of one value of an SQL data type.
Delete	An SQL command which removes *rows* from a given *table* or *relation*. For more information, see DELETE.
Durability	The assurance that once a *transaction* has been *committed*, the changes remain even after a system failure or crash. This is one of the ACID properties.
Epoch	See Transaction ID.
Extension	A software add-on package that can be installed on an *instance* to get extra features. For more information, see Section 37.17.
File segment	A physical file which stores data for a given *relation*. File segments are limited in size by a configuration value (typically 1 gigabyte), so if a relation exceeds that size, it is split into multiple segments.

	For more information, see Section 67.1. (Don't confuse this term with the similar term *WAL segment*).
Foreign data wrapper	A means of representing data that is not contained in the local *database* so that it appears as if were in local *table(s)*. With a foreign data wrapper it is possible to define a *foreign server* and *foreign tables*. For more information, see CREATE FOREIGN DATA WRAPPER.
Foreign key	A type of *constraint* defined on one or more *columns* in a *table* which requires the value(s) in those *columns* to identify zero or one *row* in another (or, infrequently, the same) *table*.
Foreign server	A named collection of *foreign tables* which all use the same *foreign data wrapper* and have other configuration values in common. For more information, see CREATE SERVER.
Foreign table (relation)	A *relation* which appears to have *rows* and *columns* similar to a regular *table*, but will forward requests for data through its *foreign data wrapper*, which will return *result sets* structured according to the definition of the *foreign table*. For more information, see CREATE FOREIGN TABLE.
Fork	Each of the separate segmented file sets in which a relation is stored. The *main fork* is where the actual data resides. There also exist two secondary forks for metadata: the *free space map* and the *visibility map*. *Unlogged relations* also have an *init fork*.
Free space map (fork)	A storage structure that keeps metadata about each data page of a table's main fork. The free space map entry for each page stores the amount of free space that's available for future tuples, and is structured to be efficiently searched for available space for a new tuple of a given size. For more information, see Section 67.3.
Function (routine)	A type of routine that receives zero or more arguments, returns zero or more output values, and is constrained to run within one transaction. Functions are invoked as part of a query, for example via `SELECT`. Certain functions can return *sets*; those are called *set-returning functions*. Functions can also be used for *triggers* to invoke. For more information, see CREATE FUNCTION.
GMT	See UTC.
Grant	An SQL command that is used to allow a *user* or *role* to access specific objects within the *database*. For more information, see GRANT.
Heap	Contains the values of *row* attributes (i.e., the data) for a *relation*. The heap is realized within one or more *file segments* in the relation's *main fork*.
Host	A computer that communicates with other computers over a network. This is sometimes used as a synonym for *server*. It is also used to refer to a computer where *client processes* run.

Index (relation)

A *relation* that contains data derived from a *table* or *materialized view*. Its internal structure supports fast retrieval of and access to the original data.

For more information, see CREATE INDEX.

Insert

An SQL command used to add new data into a *table*.

For more information, see INSERT.

Instance

A group of backend and auxiliary processes that communicate using a common shared memory area. One *postmaster process* manages the instance; one instance manages exactly one *database cluster* with all its databases. Many instances can run on the same *server* as long as their TCP ports do not conflict.

The instance handles all key features of a DBMS: read and write access to files and shared memory, assurance of the ACID properties, *connections* to *client processes*, privilege verification, crash recovery, replication, etc.

Isolation

The property that the effects of a transaction are not visible to *concurrent transactions* before it commits. This is one of the ACID properties.

For more information, see Section 13.2.

Join

An operation and SQL keyword used in *queries* for combining data from multiple *relations*.

Key

A means of identifying a *row* within a *table* or other *relation* by values contained within one or more *attributes* in that relation.

Lock

A mechanism that allows a process to limit or prevent simultaneous access to a resource.

Log file

Log files contain human-readable text lines about events. Examples include login failures, long-running queries, etc.

For more information, see Section 23.3.

Logged

A *table* is considered *logged* if changes to it are sent to the *WAL*. By default, all regular tables are logged. A table can be specified as *unlogged* either at creation time or via the `ALTER TABLE` command.

Logger (process)

If activated, the process writes information about database events into the current *log file*. When reaching certain time- or volume-dependent criteria, a new log file is created. Also called *syslogger*.

For more information, see Section 18.8.

Log record

Archaic term for a *WAL record*.

Master (server)

See Primary (server).

Materialized

The property that some information has been pre-computed and stored for later use, rather than computing it on-the-fly.

This term is used in *materialized view*, to mean that the data derived from the view's query is stored on disk separately from the sources of that data.

This term is also used to refer to some multi-step queries to mean that the data resulting from executing a given step is stored in memory (with the possibility of spilling to disk), so that it can be read multiple times by another step.

Materialized view (relation)	A *relation* that is defined by a `SELECT` statement (just like a *view*), but stores data in the same way that a *table* does. It cannot be modified via `INSERT`, `UPDATE`, or `DELETE` operations. For more information, see CREATE MATERIALIZED VIEW.
Multi-version concurrency control (MVCC)	A mechanism designed to allow several *transactions* to be reading and writing the same rows without one process causing other processes to stall. In PostgreSQL, MVCC is implemented by creating copies (*versions*) of *tuples* as they are modified; after transactions that can see the old versions terminate, those old versions need to be removed.
Null	A concept of non-existence that is a central tenet of relational database theory. It represents the absence of a definite value.
Optimizer	See Query planner.
Parallel query	The ability to handle parts of executing a *query* to take advantage of parallel processes on servers with multiple CPUs.
Partition	One of several disjoint (not overlapping) subsets of a larger set. In reference to a *partitioned table*: One of the tables that each contain part of the data of the partitioned table, which is said to be the *parent*. The partition is itself a table, so it can also be queried directly; at the same time, a partition can sometimes be a partitioned table, allowing hierarchies to be created. In reference to a *window function* in a *query*, a partition is a user-defined criterion that identifies which neighboring *rows* of the *query's result set* can be considered by the function.
Partitioned table (relation)	A *relation* that is in semantic terms the same as a *table*, but whose storage is distributed across several *partitions*.
Postmaster (process)	The very first process of an *instance*. It starts and manages the other auxiliary processes and creates *backend processes* on demand. For more information, see Section 17.3.
Primary key	A special case of a *unique constraint* defined on a *table* or other *relation* that also guarantees that all of the *attributes* within the *primary key* do not have *null* values. As the name implies, there can be only one primary key per table, though it is possible to have multiple unique constraints that also have no null-capable attributes.
Primary (server)	When two or more *databases* are linked via *replication*, the *server* that is considered the authoritative source of information is called the *primary*, also known as a *master*.
Procedure (routine)	A type of routine. Their distinctive qualities are that they do not return values, and that they are allowed to make transactional statements such as `COMMIT` and `ROLLBACK`. They are invoked via the `CALL` command. For more information, see CREATE PROCEDURE.
Query	A request sent by a client to a *backend*, usually to return results or to modify data on the database.
Query planner	The part of PostgreSQL that is devoted to determining (*planning*) the most efficient way to execute *queries*. Also known as *query optimizer*, *optimizer*, or simply *planner*.

Record	See Tuple.
Recycling	See WAL file.
Referential integrity	A means of restricting data in one *relation* by a *foreign key* so that it must have matching data in another *relation*.
Relation	The generic term for all objects in a *database* that have a name and a list of *attributes* defined in a specific order. *Tables*, *sequences*, *views*, *foreign tables*, *materialized views*, composite types, and *indexes* are all relations. More generically, a relation is a set of tuples; for example, the result of a query is also a relation. In PostgreSQL, *Class* is an archaic synonym for *relation*.
Replica (server)	A *database* that is paired with a *primary* database and is maintaining a copy of some or all of the primary database's data. The foremost reasons for doing this are to allow for greater access to that data, and to maintain availability of the data in the event that the *primary* becomes unavailable.
Replication	The act of reproducing data on one *server* onto another server called a *replica*. This can take the form of *physical replication*, where all file changes from one server are copied verbatim, or *logical replication* where a defined subset of data changes are conveyed using a higher-level representation.
Result set	A *relation* transmitted from a *backend process* to a *client* upon the completion of an SQL command, usually a `SELECT` but it can be an `INSERT`, `UPDATE`, or `DELETE` command if the `RETURNING` clause is specified. The fact that a result set is a relation means that a query can be used in the definition of another query, becoming a *subquery*.
Revoke	A command to prevent access to a named set of *database* objects for a named list of *roles*. For more information, see REVOKE.
Role	A collection of access privileges to the *instance*. Roles are themselves a privilege that can be granted to other roles. This is often done for convenience or to ensure completeness when multiple *users* need the same privileges. For more information, see CREATE ROLE.
Rollback	A command to undo all of the operations performed since the beginning of a *transaction*. For more information, see ROLLBACK.
Routine	A defined set of instructions stored in the database system that can be invoked for execution. A routine can be written in a variety of programming languages. Routines can be *functions* (including set-returning functions and *trigger functions*), *aggregate functions*, and *procedures*. Many routines are already defined within PostgreSQL itself, but user-defined ones can also be added.
Row	See Tuple.
Savepoint	A special mark in the sequence of steps in a *transaction*. Data modifications after this point in time may be reverted to the time of the savepoint.

For more information, see SAVEPOINT.

Schema

A schema is a namespace for *SQL objects*, which all reside in the same *database*. Each SQL object must reside in exactly one schema.

All system-defined SQL objects reside in schema `pg_catalog`.

More generically, the term *schema* is used to mean all data descriptions (*table* definitions, *constraints*, comments, etc) for a given *database* or subset thereof.

For more information, see Section 5.9.

Segment

See File segment.

Select

The SQL command used to request data from a *database*. Normally, `SELECT` commands are not expected to modify the *database* in any way, but it is possible that *functions* invoked within the query could have side effects that do modify data.

For more information, see SELECT.

Sequence (relation)

A type of relation that is used to generate values. Typically the generated values are sequential non-repeating numbers. They are commonly used to generate surrogate *primary key* values.

Server

A computer on which PostgreSQL *instances* run. The term *server* denotes real hardware, a container, or a *virtual machine*.

This term is sometimes used to refer to an instance or to a host.

Session

A state that allows a client and a backend to interact, communicating over a *connection*.

Shared memory

RAM which is used by the processes common to an *instance*. It mirrors parts of *database* files, provides a transient area for *WAL records*, and stores additional common information. Note that shared memory belongs to the complete instance, not to a single database.

The largest part of shared memory is known as *shared buffers* and is used to mirror part of data files, organized into pages. When a page is modified, it is called a dirty page until it is written back to the file system.

For more information, see Section 18.4.1.

SQL object

Any object that can be created with a `CREATE` command. Most objects are specific to one database, and are commonly known as *local objects*.

Most local objects reside in a specific *schema* in their containing database, such as *relations* (all types), *routines* (all types), data types, etc. The names of such objects of the same type in the same schema are enforced to be unique.

There also exist local objects that do not reside in schemas; some examples are *extensions*, *data type casts*, and *foreign data wrappers*. The names of such objects of the same type are enforced to be unique within the database.

Other object types, such as *roles*, *tablespaces*, replication origins, subscriptions for logical replication, and databases themselves are not local SQL objects since they exist entirely outside of any specific database; they are

called *global objects*. The names of such objects are enforced to be unique within the whole database cluster.

For more information, see Section 21.1.

SQL standard

A series of documents that define the SQL language.

Standby (server)

See Replica (server).

Stats collector (process)

This process collects statistical information about the *instance*'s activities.

For more information, see Section 26.2.

System catalog

A collection of *tables* which describe the structure of all *SQL objects* of the instance. The system catalog resides in the schema `pg_catalog`. These tables contain data in internal representation and are not typically considered useful for user examination; a number of user-friendlier *views*, also in schema `pg_catalog`, offer more convenient access to some of that information, while additional tables and views exist in schema `information_schema` (see Chapter 36) that expose some of the same and additional information as mandated by the *SQL standard*.

For more information, see Section 5.9.

Table

A collection of *tuples* having a common data structure (the same number of *attributes*, in the same order, having the same name and type per position). A table is the most common form of *relation* in PostgreSQL.

For more information, see CREATE TABLE.

Tablespace

A named location on the server file system. All *SQL objects* which require storage beyond their definition in the *system catalog* must belong to a single tablespace. Initially, a database cluster contains a single usable tablespace which is used as the default for all SQL objects, called `pg_default`.

For more information, see Section 21.6.

Temporary table

Tables that exist either for the lifetime of a *session* or a *transaction*, as specified at the time of creation. The data in them is not visible to other sessions, and is not *logged*. Temporary tables are often used to store intermediate data for a multi-step operation.

For more information, see CREATE TABLE.

TOAST

A mechanism by which large attributes of table rows are split and stored in a secondary table, called the *TOAST table*. Each relation with large attributes has its own TOAST table.

For more information, see Section 67.2.

Transaction

A combination of commands that must act as a single *atomic* command: they all succeed or all fail as a single unit, and their effects are not visible to other *sessions* until the transaction is complete, and possibly even later, depending on the isolation level.

For more information, see Section 13.2.

Transaction ID

The numerical, unique, sequentially-assigned identifier that each transaction receives when it first causes a database modification. Frequently abbreviated as *xid*. When stored on disk, xids are only 32-bits wide, so only approximately four billion write transaction IDs can be generated; to per-

	mit the system to run for longer than that, *epochs* are used, also 32 bits wide. When the counter reaches the maximum xid value, it starts over at `3` (values under that are reserved) and the epoch value is incremented by one. In some contexts, the epoch and xid values are considered together as a single 64-bit value. For more information, see Section 8.19.
Transactions per second (TPS)	Average number of transactions that are executed per second, totaled across all sessions active for a measured run. This is used as a measure of the performance characteristics of an instance.
Trigger	A *function* which can be defined to execute whenever a certain operation (`INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`) is applied to a *relation*. A trigger executes within the same *transaction* as the statement which invoked it, and if the function fails, then the invoking statement also fails. For more information, see CREATE TRIGGER.
Tuple	A collection of *attributes* in a fixed order. That order may be defined by the *table* (or other *relation*) where the tuple is contained, in which case the tuple is often called a *row*. It may also be defined by the structure of a result set, in which case it is sometimes called a *record*.
Unique constraint	A type of *constraint* defined on a *relation* which restricts the values allowed in one or a combination of columns so that each value or combination of values can only appear once in the relation — that is, no other row in the relation contains values that are equal to those. Because *null values* are not considered equal to each other, multiple rows with null values are allowed to exist without violating the unique constraint.
Unlogged	The property of certain *relations* that the changes to them are not reflected in the *WAL*. This disables replication and crash recovery for these relations. The primary use of unlogged tables is for storing transient work data that must be shared across processes. *Temporary tables* are always unlogged.
Update	An SQL command used to modify *rows* that may already exist in a specified *table*. It cannot create or remove rows. For more information, see UPDATE.
User	A *role* that has the `LOGIN` privilege.
User mapping	The translation of login credentials in the local *database* to credentials in a remote data system defined by a *foreign data wrapper*. For more information, see CREATE USER MAPPING.
UTC	Universal Coordinated Time, the primary global time reference, approximately the time prevailing at the zero meridian of longitude. Often but inaccurately referred to as GMT (Greenwich Mean Time).
Vacuum	The process of removing outdated *tuple versions* from tables or materialized views, and other closely related processing required by PostgreSQL's implementation of *MVCC*. This can be initiated through the use of the `VACUUM` command, but can also be handled automatically via *autovacuum* processes. For more information, see Section 23.1 .

View

A *relation* that is defined by a `SELECT` statement, but has no storage of its own. Any time a query references a view, the definition of the view is substituted into the query as if the user had typed it as a subquery instead of the name of the view.

For more information, see CREATE VIEW.

Visibility map (fork)

A storage structure that keeps metadata about each data page of a table's main fork. The visibility map entry for each page stores two bits: the first one (`all-visible`) indicates that all tuples in the page are visible to all transactions. The second one (`all-frozen`) indicates that all tuples in the page are marked frozen.

WAL

See Write-ahead log.

WAL archiver (process)

A process that saves copies of *WAL files* for the purpose of creating backups or keeping *replicas* current.

For more information, see Section 24.3.

WAL file

Also known as *WAL segment* or *WAL segment file*. Each of the sequentially-numbered files that provide storage space for *WAL*. The files are all of the same predefined size and are written in sequential order, interspersing changes as they occur in multiple simultaneous sessions. If the system crashes, the files are read in order, and each of the changes is replayed to restore the system to the state it was in before the crash.

Each WAL file can be released after a *checkpoint* writes all the changes in it to the corresponding data files. Releasing the file can be done either by deleting it, or by changing its name so that it will be used in the future, which is called *recycling*.

For more information, see Section 28.6.

WAL record

A low-level description of an individual data change. It contains sufficient information for the data change to be re-executed (*replayed*) in case a system failure causes the change to be lost. WAL records use a non-printable binary format.

For more information, see Section 28.6.

WAL segment

See WAL file.

WAL writer (process)

A process that writes *WAL records* from *shared memory* to *WAL files*.

For more information, see Section 18.5.

Window function (routine)

A type of *function* used in a *query* that applies to a *partition* of the query's *result set*; the function's result is based on values found in *rows* of the same partition or frame.

All *aggregate functions* can be used as window functions, but window functions can also be used to, for example, give ranks to each of the rows in the partition. Also known as *analytic functions*.

For more information, see Section 3.5.

Write-ahead log

The journal that keeps track of the changes in the *database cluster* as user- and system-invoked operations take place. It comprises many individual *WAL records* written sequentially to *WAL files*.

Appendix P. Color Support

Most programs in the PostgreSQL package can produce colorized console output. This appendix describes how that is configured.

P.1. When Color is Used

To use colorized output, set the environment variable `PG_COLOR` as follows:

1. If the value is `always`, then color is used.
2. If the value is `auto` and the standard error stream is associated with a terminal device, then color is used.
3. Otherwise, color is not used.

P.2. Configuring the Colors

The actual colors to be used are configured using the environment variable `PG_COLORS` (note plural). The value is a colon-separated list of *`key=value`* pairs. The keys specify what the color is to be used for. The values are SGR (Select Graphic Rendition) specifications, which are interpreted by the terminal.

The following keys are currently in use:

`error`

used to highlight the text "error" in error messages

`warning`

used to highlight the text "warning" in warning messages

`locus`

used to highlight location information (e.g., program name and file name) in messages

The default value is `error=01;31:warning=01;35:locus=01` (`01;31` = bold red, `01;35` = bold magenta, `01` = bold default color).

> **Tip**
>
> This color specification format is also used by other software packages such as GCC, GNU coreutils, and GNU grep.

Appendix Q. Obsolete or Renamed Features

Functionality is sometimes removed from PostgreSQL, feature, setting and file names sometimes change, or documentation moves to different places. This section directs users coming from old versions of the documentation or from external links to the appropriate new location for the information they need.

Q.1. `recovery.conf` file merged into `postgresql.conf`

Postgres Pro 11 and below used a configuration file named `recovery.conf` to manage replicas and standbys. Support for this file was removed in Postgres Pro 12. See the release notes for PostgreSQL 12 for details on this change.

On Postgres Pro 12 and above, archive recovery, streaming replication, and PITR are configured using normal server configuration parameters. These are set in `postgresql.conf` or via ALTER SYSTEM like any other parameter.

The server will not start if a `recovery.conf` exists.

The `trigger_file` setting has been renamed to promote_trigger_file.

The `standby_mode` setting has been removed. A `standby.signal` file in the data directory is used instead. See Standby Server Operation for details.

Q.2. Default Roles Renamed to Predefined Roles

PostgreSQL 13 and below used the term “Default Roles”. However, as these roles are not able to actually be changed and are installed as part of the system at initialization time, the more appropriate term to use is “Predefined Roles”. See Section 20.5 for current documentation regarding Predefined Roles, and the release notes for PostgreSQL 14 for details on this change.

Q.3. `pg_xlogdump` renamed to `pg_waldump`

Postgres Pro 9.6 and below provided a command named `pg_xlogdump` to read write-ahead-log (WAL) files. This command was renamed to `pg_waldump`, see pg_waldump for documentation of `pg_waldump` and see the release notes for PostgreSQL 10 for details on this change.

Q.4. `pg_resetxlog` renamed to `pg_resetwal`

Postgres Pro 9.6 and below provided a command named `pg_resetxlog` to reset the write-ahead-log (WAL) files. This command was renamed to `pg_resetwal`, see pg_resetwal for documentation of `pg_resetwal` and see the release notes for PostgreSQL 10 for details on this change.

Q.5. `pg_receivexlog` renamed to `pg_receivewal`

Postgres Pro 9.6 and below provided a command named `pg_receivexlog` to fetch write-ahead-log (WAL) files. This command was renamed to `pg_receivewal`, see pg_receivewal for documentation of `pg_receivewal` and see the release notes for PostgreSQL 10 for details on this change.

Bibliography

Selected references and readings for SQL and PostgreSQL.

Some white papers and technical reports from the original POSTGRES development team are available at the University of California, Berkeley, Computer Science Department *web site*.
