Begin execution of a sampling scan. This is called just before the first attempt to fetch a tuple, and may be called again if the scan needs to be restarted. Information about the table to scan is accessible through fields of the `SampleScanState` node (but note that the `node->ss.ss_currentScanDesc` scan descriptor is not set up yet). The `params` array, of length `nparams`, contains the values of the parameters supplied in the `TABLESAMPLE` clause. These will have the number and types specified in the sampling method's `parameterTypes` list, and have been checked to not be null. `seed` contains a seed to use for any random numbers generated within the sampling method; it is either a hash derived from the `REPEATABLE` value if one was given, or the result of `random()` if not.

This function may adjust the fields `node->use_bulkread` and `node->use_pagemode`. If `node->use_bulkread` is true, which it is by default, the scan will use a buffer access strategy that encourages recycling buffers after use. It might be reasonable to set this to false if the scan will visit only a small fraction of the table's pages. If `node->use_pagemode` is true, which it is by default, the scan will perform visibility checking in a single pass for all tuples on each visited page. It might be reasonable to set this to false if the scan will select only a small fraction of the tuples on each visited page. That will result in fewer tuple visibility checks being performed, though each one will be more expensive because it will require more locking.

If the sampling method is marked `repeatable_across_scans`, it must be able to select the same set of tuples during a rescan as it did originally, that is a fresh call of `BeginSampleScan` must lead to selecting the same tuples as before (if the `TABLESAMPLE` parameters and seed don't change).

```
BlockNumber
NextSampleBlock (SampleScanState *node, BlockNumber nblocks);
```

Returns the block number of the next page to be scanned, or `InvalidBlockNumber` if no pages remain to be scanned.

This function can be omitted (set the pointer to NULL), in which case the core code will perform a sequential scan of the entire relation. Such a scan can use synchronized scanning, so that the sampling method cannot assume that the relation pages are visited in the same order on each scan.

```
OffsetNumber  
NextSampleTuple (SampleScanState *node,  
                 BlockNumber blockno,  
                 OffsetNumber maxoffset);
```

Returns the offset number of the next tuple to be sampled on the specified page, or `InvalidOffsetNumber` if no tuples remain to be sampled. `maxoffset` is the largest offset number in use on the page.

Note

`NextSampleTuple` is not explicitly told which of the offset numbers in the range `1 .. maxoffset` actually contain valid tuples. This is not normally a problem since the core code ignores requests to sample missing or invisible tuples; that should not result in any bias in the sample. However, if necessary, the function can use `node->donetuples` to examine how many of the tuples it returned were valid and visible.

Note

`NextSampleTuple` must *not* assume that `blockno` is the same page number returned by the most recent `NextSampleBlock` call. It was returned by some previous `NextSampleBlock` call, but the core code is allowed to call `NextSampleBlock` in advance of actually scanning pages, so as to support prefetching. It is OK to assume that once sampling of a given page begins, successive `NextSampleTuple` calls all refer to the same page until `InvalidOffsetNumber` is returned.

```
void  
EndSampleScan (SampleScanState *node);
```

End the scan and release resources. It is normally not important to release palloc'd memory, but any externally-visible resources should be cleaned up. This function can be omitted (set the pointer to NULL) in the common case where no such resources exist.

Chapter 58. Writing a Custom Scan Provider

Postgres Pro supports a set of experimental facilities which are intended to allow extension modules to add new scan types to the system. Unlike a [foreign data wrapper](#), which is only responsible for knowing how to scan its own foreign tables, a custom scan provider can provide an alternative method of scanning any relation in the system. Typically, the motivation for writing a custom scan provider will be to allow the use of some optimization not supported by the core system, such as caching or some form of hardware acceleration. This chapter outlines how to write a new custom scan provider.

Implementing a new type of custom scan is a three-step process. First, during planning, it is necessary to generate access paths representing a scan using the proposed strategy. Second, if one of those access paths is selected by the planner as the optimal strategy for scanning a particular relation, the access path must be converted to a plan. Finally, it must be possible to execute the plan and generate the same results that would have been generated for any other access path targeting the same relation.

58.1. Creating Custom Scan Paths

A custom scan provider will typically add paths for a base relation by setting the following hook, which is called after the core code has generated all the access paths it can for the relation (except for Gather and Gather Merge paths, which are made after this call so that they can use partial paths added by the hook):

```
typedef void (*set_rel_pathlist_hook_type) (PlannerInfo *root,
                                           RelOptInfo *rel,
                                           Index rti,
                                           RangeTblEntry *rte);

extern PGDLLIMPORT set_rel_pathlist_hook_type set_rel_pathlist_hook;
```

Although this hook function can be used to examine, modify, or remove paths generated by the core system, a custom scan provider will typically confine itself to generating `CustomPath` objects and adding them to `rel` using `add_path`, or `add_partial_path` if they are partial paths. The custom scan provider is responsible for initializing the `CustomPath` object, which is declared like this:

```
typedef struct CustomPath
{
    Path      path;
    uint32    flags;
    List      *custom_paths;
    List      *custom_restrictinfo;
    List      *custom_private;
    const CustomPathMethods *methods;
} CustomPath;
```

`path` must be initialized as for any other path, including the row-count estimate, start and total cost, and sort ordering provided by this path. `flags` is a bit mask, which specifies whether the scan provider can support certain optional capabilities. `flags` should include `CUSTOMPATH_SUPPORT_BACKWARD_SCAN` if the custom path can support a backward scan, `CUSTOMPATH_SUPPORT_MARK_RESTORE` if it can support mark and restore, and `CUSTOMPATH_SUPPORT_PROJECTION` if it can perform projections. (If `CUSTOMPATH_SUPPORT_PROJECTION` is not set, the scan node will only be asked to produce Vars of the scanned relation; while if that flag is set, the scan node must be able to evaluate scalar expressions over these Vars.) An optional `custom_paths` is a list of `Path` nodes used by this custom-path node; these will be transformed into `Plan` nodes by planner. As described below, custom paths can be created for join relations as well. In such a case, `custom_restrictinfo` should be used to store the set of join clauses to apply to the join the custom path replaces. Otherwise it should be `NIL`. `custom_private` can be used to store the custom path's private data. Private data should be stored in a form that can be handled by `nodeToString`, so that debugging routines that attempt to print the custom path will work as designed. `methods` must point to a (usually statically allocated) object implementing the required custom path methods, which are further detailed below.

A custom scan provider can also provide join paths. Just as for base relations, such a path must produce the same output as would normally be produced by the join it replaces. To do this, the join provider should set the following hook, and then within the hook function, create `CustomPath` path(s) for the join relation.

```
typedef void (*set_join_pathlist_hook_type) (PlannerInfo *root,
                                             RelOptInfo *joinrel,
                                             RelOptInfo *outerrel,
                                             RelOptInfo *innerrel,
                                             JoinType jointype,
                                             JoinPathExtraData *extra);

extern PGDLLIMPORT set_join_pathlist_hook_type set_join_pathlist_hook;
```

This hook will be invoked repeatedly for the same join relation, with different combinations of inner and outer relations; it is the responsibility of the hook to minimize duplicated work.

Note also that the set of join clauses to apply to the join, which is passed as `extra->restrictlist`, varies depending on the combination of inner and outer relations. A `CustomPath` path generated for the `joinrel` must contain the set of join clauses it uses, which will be used by the planner to convert the `CustomPath` path into a plan, if it is selected by the planner as the best path for the `joinrel`.

58.1.1. Custom Scan Path Callbacks

```
Plan *(*PlanCustomPath) (PlannerInfo *root,
                          RelOptInfo *rel,
                          CustomPath *best_path,
                          List *tlist,
                          List *clauses,
                          List *custom_plans);
```

Convert a custom path to a finished plan. The return value will generally be a `CustomScan` object, which the callback must allocate and initialize. See [Section 58.2](#) for more details.

```
List *(*ReparameterizeCustomPathByChild) (PlannerInfo *root,
                                           List *custom_private,
                                           RelOptInfo *child_rel);
```

This callback is called while converting a path parameterized by the top-most parent of the given child relation `child_rel` to be parameterized by the child relation. The callback is used to reparameterize any paths or translate any expression nodes saved in the given `custom_private` member of a `CustomPath`. The callback may use `reparameterize_path_by_child`, `adjust_appendrel_attrs` or `adjust_appendrel_attrs_multilevel` as required.

58.2. Creating Custom Scan Plans

A custom scan is represented in a finished plan tree using the following structure:

```
typedef struct CustomScan
{
    Scan        scan;
    uint32      flags;
    List        *custom_plans;
    List        *custom_exprs;
    List        *custom_private;
    List        *custom_scan_tlist;
    Bitmapset   *custom_relids;
    const CustomScanMethods *methods;
} CustomScan;
```

`scan` must be initialized as for any other scan, including estimated costs, target lists, qualifications, and so on. `flags` is a bit mask with the same meaning as in `CustomPath`. `custom_plans` can be used to store child `Plan` nodes. `custom_exprs` should be used to store expression trees that will need to be fixed up

by `setrefs.c` and `subselect.c`, while `custom_private` should be used to store other private data that is only used by the custom scan provider itself. `custom_scan_tlist` can be `NIL` when scanning a base relation, indicating that the custom scan returns scan tuples that match the base relation's row type. Otherwise it is a target list describing the actual scan tuples. `custom_scan_tlist` must be provided for joins, and could be provided for scans if the custom scan provider can compute some non-Var expressions. `custom_relids` is set by the core code to the set of relations (range table indexes) that this scan node handles; except when this scan is replacing a join, it will have only one member. `methods` must point to a (usually statically allocated) object implementing the required custom scan methods, which are further detailed below.

When a `CustomScan` scans a single relation, `scan.scanrelid` must be the range table index of the table to be scanned. When it replaces a join, `scan.scanrelid` should be zero.

Plan trees must be able to be duplicated using `copyObject`, so all the data stored within the “custom” fields must consist of nodes that that function can handle. Furthermore, custom scan providers cannot substitute a larger structure that embeds a `CustomScan` for the structure itself, as would be possible for a `CustomPath` or `CustomScanState`.

58.2.1. Custom Scan Plan Callbacks

```
Node *(*CreateCustomScanState) (CustomScan *cscan);
```

Allocate a `CustomScanState` for this `CustomScan`. The actual allocation will often be larger than required for an ordinary `CustomScanState`, because many providers will wish to embed that as the first field of a larger structure. The value returned must have the node tag and `methods` set appropriately, but other fields should be left as zeroes at this stage; after `ExecInitCustomScan` performs basic initialization, the `BeginCustomScan` callback will be invoked to give the custom scan provider a chance to do whatever else is needed.

58.3. Executing Custom Scans

When a `CustomScan` is executed, its execution state is represented by a `CustomScanState`, which is declared as follows:

```
typedef struct CustomScanState
{
    ScanState ss;
    uint32    flags;
    const CustomExecMethods *methods;
} CustomScanState;
```

`ss` is initialized as for any other scan state, except that if the scan is for a join rather than a base relation, `ss.ss_currentRelation` is left `NULL`. `flags` is a bit mask with the same meaning as in `CustomPath` and `CustomScan`. `methods` must point to a (usually statically allocated) object implementing the required custom scan state methods, which are further detailed below. Typically, a `CustomScanState`, which need not support `copyObject`, will actually be a larger structure embedding the above as its first member.

58.3.1. Custom Scan Execution Callbacks

```
void (*BeginCustomScan) (CustomScanState *node,
                        EState *estate,
                        int eflags);
```

Complete initialization of the supplied `CustomScanState`. Standard fields have been initialized by `ExecInitCustomScan`, but any private fields should be initialized here.

```
TupleTableSlot *(*ExecCustomScan) (CustomScanState *node);
```

Fetch the next scan tuple. If any tuples remain, it should fill `ps_ResultTupleSlot` with the next tuple in the current scan direction, and then return the tuple slot. If not, `NULL` or an empty slot should be returned.

```
void (*EndCustomScan) (CustomScanState *node);
```

Clean up any private data associated with the `CustomScanState`. This method is required, but it does not need to do anything if there is no associated data or it will be cleaned up automatically.

```
void (*ReScanCustomScan) (CustomScanState *node);
```

Rewind the current scan to the beginning and prepare to rescan the relation.

```
void (*MarkPosCustomScan) (CustomScanState *node);
```

Save the current scan position so that it can subsequently be restored by the `RestrPosCustomScan` callback. This callback is optional, and need only be supplied if the `CUSTOMPATH_SUPPORT_MARK_RESTORE` flag is set.

```
void (*RestrPosCustomScan) (CustomScanState *node);
```

Restore the previous scan position as saved by the `MarkPosCustomScan` callback. This callback is optional, and need only be supplied if the `CUSTOMPATH_SUPPORT_MARK_RESTORE` flag is set.

```
Size (*EstimateDSMCustomScan) (CustomScanState *node,  
                               ParallelContext *pcxt);
```

Estimate the amount of dynamic shared memory that will be required for parallel operation. This may be higher than the amount that will actually be used, but it must not be lower. The return value is in bytes. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution.

```
void (*InitializeDSMCustomScan) (CustomScanState *node,  
                                ParallelContext *pcxt,  
                                void *coordinate);
```

Initialize the dynamic shared memory that will be required for parallel operation. `coordinate` points to a shared memory area of size equal to the return value of `EstimateDSMCustomScan`. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution.

```
void (*ReInitializeDSMCustomScan) (CustomScanState *node,  
                                  ParallelContext *pcxt,  
                                  void *coordinate);
```

Re-initialize the dynamic shared memory required for parallel operation when the custom-scan plan node is about to be re-scanned. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution. Recommended practice is that this callback reset only shared state, while the `ReScanCustomScan` callback resets only local state. Currently, this callback will be called before `ReScanCustomScan`, but it's best not to rely on that ordering.

```
void (*InitializeWorkerCustomScan) (CustomScanState *node,  
                                    shm_toc *toc,  
                                    void *coordinate);
```

Initialize a parallel worker's local state based on the shared state set up by the leader during `InitializeDSMCustomScan`. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution.

```
void (*ShutdownCustomScan) (CustomScanState *node);
```

Release resources when it is anticipated the node will not be executed to completion. This is not called in all cases; sometimes, `EndCustomScan` may be called without this function having been called first. Since the DSM segment used by parallel query is destroyed just after this callback is invoked, custom scan providers that wish to take some action before the DSM segment goes away should implement this method.

```
void (*ExplainCustomScan) (CustomScanState *node,  
                           List *ancestors,
```

```
ExplainState *es);
```

Output additional information for `EXPLAIN` of a custom-scan plan node. This callback is optional. Common data stored in the `ScanState`, such as the target list and scan relation, will be shown even without this callback, but the callback allows the display of additional, private state.

Chapter 59. Genetic Query Optimizer

Author

Written by Martin Utesch (<utesch@aut.tu-freiberg.de>) for the Institute of Automatic Control at the University of Mining and Technology in Freiberg, Germany.

59.1. Query Handling as a Complex Optimization Problem

Among all relational operators the most difficult one to process and optimize is the *join*. The number of possible query plans grows exponentially with the number of joins in the query. Further optimization effort is caused by the support of a variety of *join methods* (e.g., nested loop, hash join, merge join in Postgres Pro) to process individual joins and a diversity of *indexes* (e.g., B-tree, hash, GiST and GIN in Postgres Pro) as access paths for relations.

The normal Postgres Pro query optimizer performs a *near-exhaustive search* over the space of alternative strategies. This algorithm, first introduced in IBM's System R database, produces a near-optimal join order, but can take an enormous amount of time and memory space when the number of joins in the query grows large. This makes the ordinary Postgres Pro query optimizer inappropriate for queries that join a large number of tables.

The Institute of Automatic Control at the University of Mining and Technology, in Freiberg, Germany, encountered some problems when it wanted to use PostgreSQL as the backend for a decision support knowledge based system for the maintenance of an electrical power grid. The DBMS needed to handle large join queries for the inference machine of the knowledge based system. The number of joins in these queries made using the normal query optimizer infeasible.

In the following we describe the implementation of a *genetic algorithm* to solve the join ordering problem in a manner that is efficient for queries involving large numbers of joins.

59.2. Genetic Algorithms

The genetic algorithm (GA) is a heuristic optimization method which operates through randomized search. The set of possible solutions for the optimization problem is considered as a *population of individuals*. The degree of adaptation of an individual to its environment is specified by its *fitness*.

The coordinates of an individual in the search space are represented by *chromosomes*, in essence a set of character strings. A *gene* is a subsection of a chromosome which encodes the value of a single parameter being optimized. Typical encodings for a gene could be *binary* or *integer*.

Through simulation of the evolutionary operations *recombination*, *mutation*, and *selection* new generations of search points are found that show a higher average fitness than their ancestors. [Figure 59.1](#) illustrates these steps.

Figure 59.1. Structure of a Genetic Algorithm

According to the comp.ai.genetic FAQ it cannot be stressed too strongly that a GA is not a pure random search for a solution to a problem. A GA uses stochastic processes, but the result is distinctly non-random (better than random).

59.3. Genetic Query Optimization (GEQO) in Postgres Pro

The GEQO module approaches the query optimization problem as though it were the well-known traveling salesman problem (TSP). Possible query plans are encoded as integer strings. Each string represents the join order from one relation of the query to the next. For example, the join tree

```

  /\
 /\ 2
 /\ 3

```

4 1

is encoded by the integer string '4-1-3-2', which means, first join relation '4' and '1', then '3', and then '2', where 1, 2, 3, 4 are relation IDs within the Postgres Pro optimizer.

Specific characteristics of the GEQO implementation in Postgres Pro are:

- Usage of a *steady state* GA (replacement of the least fit individuals in a population, not whole-generational replacement) allows fast convergence towards improved query plans. This is essential for query handling with reasonable time;
- Usage of *edge recombination crossover* which is especially suited to keep edge losses low for the solution of the TSP by means of a GA;
- Mutation as genetic operator is deprecated so that no repair mechanisms are needed to generate legal TSP tours.

Parts of the GEQO module are adapted from D. Whitley's Genitor algorithm.

The GEQO module allows the Postgres Pro query optimizer to support large join queries effectively through non-exhaustive search.

59.3.1. Generating Possible Plans with GEQO

The GEQO planning process uses the standard planner code to generate plans for scans of individual relations. Then join plans are developed using the genetic approach. As shown above, each candidate join plan is represented by a sequence in which to join the base relations. In the initial stage, the GEQO code simply generates some possible join sequences at random. For each join sequence considered, the standard planner code is invoked to estimate the cost of performing the query using that join sequence. (For each step of the join sequence, all three possible join strategies are considered; and all the initially-determined relation scan plans are available. The estimated cost is the cheapest of these possibilities.) Join sequences with lower estimated cost are considered “more fit” than those with higher cost. The genetic algorithm discards the least fit candidates. Then new candidates are generated by combining genes of more-fit candidates — that is, by using randomly-chosen portions of known low-cost join sequences to create new sequences for consideration. This process is repeated until a preset number of join sequences have been considered; then the best one found at any time during the search is used to generate the finished plan.

This process is inherently nondeterministic, because of the randomized choices made during both the initial population selection and subsequent “mutation” of the best candidates. To avoid surprising changes of the selected plan, each run of the GEQO algorithm restarts its random number generator with the current `geqo_seed` parameter setting. As long as `geqo_seed` and the other GEQO parameters are kept fixed, the same plan will be generated for a given query (and other planner inputs such as statistics). To experiment with different search paths, try changing `geqo_seed`.

59.3.2. Future Implementation Tasks for PostgreSQL GEQO

Work is still needed to improve the genetic algorithm parameter settings. We have to find a compromise for the parameter settings to satisfy two competing demands:

- Optimality of the query plan
- Computing time

In the current implementation, the fitness of each candidate join sequence is estimated by running the standard planner's join selection and cost estimation code from scratch. To the extent that different candidates use similar sub-sequences of joins, a great deal of work will be repeated. This could be made significantly faster by retaining cost estimates for sub-joins. The problem is to avoid expending unreasonable amounts of memory on retaining that state.

At a more basic level, it is not clear that solving query optimization with a GA algorithm designed for TSP is appropriate. In the TSP case, the cost associated with any substring (partial tour) is independent of the rest of the tour, but this is certainly not true for query optimization. Thus it is questionable whether edge recombination crossover is the most effective mutation procedure.

Chapter 60. Table Access Method Interface Definition

This chapter explains the interface between the core Postgres Pro system and *table access methods*, which manage the storage for tables. The core system knows little about these access methods beyond what is specified here, so it is possible to develop entirely new access method types by writing add-on code.

Each table access method is described by a row in the `pg_am` system catalog. The `pg_am` entry specifies a name and a *handler function* for the table access method. These entries can be created and deleted using the `CREATE ACCESS METHOD` and `DROP ACCESS METHOD` SQL commands.

A table access method handler function must be declared to accept a single argument of type `internal` and to return the pseudo-type `table_am_handler`. The argument is a dummy value that simply serves to prevent handler functions from being called directly from SQL commands.

Here is how an extension SQL script file might create a table access method handler:

```
CREATE OR REPLACE FUNCTION my_tableam_handler(internal)
  RETURNS table_am_handler AS 'my_extension', 'my_tableam_handler'
  LANGUAGE C STRICT;
```

```
CREATE ACCESS METHOD myam TYPE TABLE HANDLER my_tableam_handler;
```

The result of the function must be a pointer to a struct of type `TableAmRoutine`, which contains everything that the core code needs to know to make use of the table access method. The return value needs to be of server lifetime, which is typically achieved by defining it as a `static const` variable in global scope.

Here is how a source file with the table access method handler might look like:

```
#include "postgres.h"

#include "access/tableam.h"
#include "fmgr.h"

PG_MODULE_MAGIC;

static const TableAmRoutine my_tableam_methods = {
    .type = T_TableAmRoutine,

    /* Methods of TableAmRoutine omitted from example, add them here. */
};

PG_FUNCTION_INFO_V1(my_tableam_handler);

Datum
my_tableam_handler(PG_FUNCTION_ARGS)
{
    PG_RETURN_POINTER(&my_tableam_methods);
}
```

The `TableAmRoutine` struct, also called the access method's *API struct*, defines the behavior of the access method using callbacks. These callbacks are pointers to plain C functions and are not visible or callable at the SQL level. All the callbacks and their behavior is defined in the `TableAmRoutine` structure (with comments inside the struct defining the requirements for callbacks). Most callbacks have wrapper functions, which are documented from the point of view of a user (rather than an implementor) of the table access method. For details, please refer to the `src/include/access/tableam.h` file.

To implement an access method, an implementor will typically need to implement an AM-specific type of tuple table slot (see [src/include/executor/tuptable.h](#)), which allows code outside the access method to hold references to tuples of the AM, and to access the columns of the tuple.

Currently, the way an AM actually stores data is fairly unconstrained. For example, it's possible, but not required, to use postgres' shared buffer cache. In case it is used, it likely makes sense to use Postgres Pro's standard page layout as described in [Section 64.6](#).

One fairly large constraint of the table access method API is that, currently, if the AM wants to support modifications and/or indexes, it is necessary for each tuple to have a tuple identifier (TID) consisting of a block number and an item number (see also [Section 64.6](#)). It is not strictly necessary that the sub-parts of TIDs have the same meaning they e.g., have for `heap`, but if bitmap scan support is desired (it is optional), the block number needs to provide locality.

For crash safety, an AM can use postgres' [WAL](#), or a custom implementation. If WAL is chosen, either [Generic WAL Records](#) can be used, or a [Custom WAL Resource Manager](#) can be implemented.

To implement transactional support in a manner that allows different table access methods be accessed within a single transaction, it likely is necessary to closely integrate with the machinery in [src/backend/access/transam/xlog.c](#).

Chapter 61. Index Access Method Interface Definition

This chapter defines the interface between the core Postgres Pro system and *index access methods*, which manage individual index types. The core system knows nothing about indexes beyond what is specified here, so it is possible to develop entirely new index types by writing add-on code.

All indexes in Postgres Pro are what are known technically as *secondary indexes*; that is, the index is physically separate from the table file that it describes. Each index is stored as its own physical *relation* and so is described by an entry in the `pg_class` catalog. The contents of an index are entirely under the control of its index access method. In practice, all index access methods divide indexes into standard-size pages so that they can use the regular storage manager and buffer manager to access the index contents. (All the existing index access methods furthermore use the standard page layout described in [Section 64.6](#), and most use the same format for index tuple headers; but these decisions are not forced on an access method.)

An index is effectively a mapping from some data key values to *tuple identifiers*, or TIDs, of row versions (tuples) in the index's parent table. A TID consists of a block number and an item number within that block (see [Section 64.6](#)). This is sufficient information to fetch a particular row version from the table. Indexes are not directly aware that under MVCC, there might be multiple extant versions of the same logical row; to an index, each tuple is an independent object that needs its own index entry. Thus, an update of a row always creates all-new index entries for the row, even if the key values did not change. ([HOT tuples](#) are an exception to this statement; but indexes do not deal with those, either.) Index entries for dead tuples are reclaimed (by vacuuming) when the dead tuples themselves are reclaimed.

61.1. Basic API Structure for Indexes

Each index access method is described by a row in the `pg_am` system catalog. The `pg_am` entry specifies a name and a *handler function* for the index access method. These entries can be created and deleted using the [CREATE ACCESS METHOD](#) and [DROP ACCESS METHOD](#) SQL commands.

An index access method handler function must be declared to accept a single argument of type `internal` and to return the pseudo-type `index_am_handler`. The argument is a dummy value that simply serves to prevent handler functions from being called directly from SQL commands. The result of the function must be a palloc'd struct of type `IndexAmRoutine`, which contains everything that the core code needs to know to make use of the index access method. The `IndexAmRoutine` struct, also called the access method's *API struct*, includes fields specifying assorted fixed properties of the access method, such as whether it can support multicolumn indexes. More importantly, it contains pointers to support functions for the access method, which do all of the real work to access indexes. These support functions are plain C functions and are not visible or callable at the SQL level. The support functions are described in [Section 61.2](#).

The structure `IndexAmRoutine` is defined thus:

```
typedef struct IndexAmRoutine
{
    NodeTag      type;

    /*
     * Total number of strategies (operators) by which we can traverse/search
     * this AM. Zero if AM does not have a fixed set of strategy assignments.
     */
    uint16       amstrategies;
    /* total number of support functions that this AM uses */
    uint16       amsupport;
    /* opclass options support function number or 0 */
    uint16       amoptsprocnum;
    /* does AM support ORDER BY indexed column's value? */

```

Index Access Method Interface Definition

```
bool            amcanorder;
/* does AM support ORDER BY result of an operator on indexed column? */
bool            amcanorderbyop;
/* does AM support hashing using API consistent with the hash AM? */
bool            amcanhash;
/* do operators within an opfamily have consistent equality semantics? */
bool            amconsistentequality;
/* do operators within an opfamily have consistent ordering semantics? */
bool            amconsistentordering;
/* does AM support backward scanning? */
bool            amcanbackward;
/* does AM support UNIQUE indexes? */
bool            amcanunique;
/* does AM support multi-column indexes? */
bool            amcanmulticol;
/* does AM require scans to have a constraint on the first index column? */
bool            amoptionalkey;
/* does AM handle ScalarArrayOpExpr quals? */
bool            amsearcharray;
/* does AM handle IS NULL/IS NOT NULL quals? */
bool            amsearchnulls;
/* can index storage data type differ from column data type? */
bool            amstorage;
/* can an index of this type be clustered on? */
bool            amclusterable;
/* does AM handle predicate locks? */
bool            ampredlocks;
/* does AM support parallel scan? */
bool            amcanparallel;
/* does AM support parallel build? */
bool            amcanbuildparallel;
/* does AM support columns included with clause INCLUDE? */
bool            amcaninclude;
/* does AM use maintenance_work_mem? */
bool            amusemaintenanceworkmem;
/* does AM summarize tuples, with at least all tuples in the block
 * summarized in one summary */
bool            amsummarizing;
/* OR of parallel vacuum flags */
uint8           amparallelvacuumoptions;
/* type of data stored in index, or InvalidOid if variable */
Oid             amkeytype;

/* interface functions */
ambuild_function ambuild;
ambuildempty_function ambuildempty;
aminert_function aminert;
aminertcleanup_function aminertcleanup; /* can be NULL */
ambulkdelete_function ambulkdelete;

/* interface functions to support planning */
amtranslate_strategy_function amtranslatestrategy; /* can be NULL */
amtranslate_cmptype_function amtranslatexcmptype;  /* can be NULL */
} IndexAmRoutine;

```

To be useful, an index access method must also have one or more *operator families* and *operator classes* defined in [pg_opfamily](#), [pg_opclass](#), [pg_amop](#), and [pg_amproc](#). These entries allow the planner to determine what kinds of query qualifications can be used with indexes of this access method. Operator families and classes are described in [Section 36.16](#), which is prerequisite material for reading this chapter.

An individual index is defined by a [pg_class](#) entry that describes it as a physical relation, plus a [pg_index](#) entry that shows the logical content of the index — that is, the set of index columns it has and the semantics of those columns, as captured by the associated operator classes. The index columns (key values) can be either simple columns of the underlying table or expressions over the table rows. The index access method normally has no interest in where the index key values come from (it is always handed precomputed key values) but it will be very interested in the operator class information in [pg_index](#). Both of these catalog entries can be accessed as part of the `Relation` data structure that is passed to all operations on the index.

Some of the flag fields of `IndexAmRoutine` have nonobvious implications. The requirements of `amcanunique` are discussed in [Section 61.5](#). The `amcanmulticol` flag asserts that the access method supports multi-key-column indexes, while `amoptionalkey` asserts that it allows scans where no indexable restriction clause is given for the first index column. When `amcanmulticol` is false, `amoptionalkey` essentially says whether the access method supports full-index scans without any restriction clause. Access methods that support multiple index columns *must* support scans that omit restrictions on any or all of the columns after the first; however they are permitted to require some restriction to appear for the first index column, and this is signaled by setting `amoptionalkey` false. One reason that an index AM might set `amoptionalkey` false is if it doesn't index null values. Since most indexable operators are strict and hence cannot return true for null inputs, it is at first sight attractive to not store index entries for null values: they could never be returned by an index scan anyway. However, this argument fails when an index scan has no restriction clause for a given index column. In practice this means that indexes that have `amoptionalkey` true must index nulls, since the planner might decide to use such an index with no scan keys at all. A related restriction is that an index access method that supports multiple index columns *must* support indexing null values in columns after the first, because the planner will assume the index can be used for queries that do not restrict these columns. For example, consider an index on (a,b) and a query with `WHERE a = 4`. The system will assume the index can be used to scan for rows with `a = 4`, which is wrong if the index omits rows where `b` is null. It is, however, OK to omit rows where the first indexed column is null. An index access method that does index nulls may also set `amsearchnulls`, indicating that it supports `IS NULL` and `IS NOT NULL` clauses as search conditions.

The `amcaninclude` flag indicates whether the access method supports “included” columns, that is it can store (without processing) additional columns beyond the key column(s). The requirements of the preceding paragraph apply only to the key columns. In particular, the combination of `amcanmulticol=false` and `amcaninclude=true` is sensible: it means that there can only be one key column, but there can also

be included column(s). Also, included columns must be allowed to be null, independently of `amoption-alkey`.

The `amsummarizing` flag indicates whether the access method summarizes the indexed tuples, with summarizing granularity of at least per block. Access methods that do not point to individual tuples, but to block ranges (like BRIN), may allow the HOT optimization to continue. This does not apply to attributes referenced in index predicates, an update of such an attribute always disables HOT.

61.2. Index Access Method Functions

The index construction and maintenance functions that an index access method must provide in `Index-AmRoutine` are:

```
IndexBuildResult *
ambuild (Relation heapRelation,
         Relation indexRelation,
         IndexInfo *indexInfo);
```

Build a new index. The index relation has been physically created, but is empty. It must be filled in with whatever fixed data the access method requires, plus entries for all tuples already existing in the table. Ordinarily the `ambuild` function will call `table_index_build_scan()` to scan the table for existing tuples and compute the keys that need to be inserted into the index. The function must return a palloc'd struct containing statistics about the new index. The `amcanbuildparallel` flag indicates whether the access method supports parallel index builds. When set to `true`, the system will attempt to allocate parallel workers for the build. Access methods supporting only non-parallel index builds should leave this flag set to `false`.

```
void
ambuildempty (Relation indexRelation);
```

Build an empty index, and write it to the initialization fork (`INIT_FORKNUM`) of the given relation. This method is called only for unlogged indexes; the empty index written to the initialization fork will be copied over the main relation fork on each server restart.

```
bool
aminert (Relation indexRelation,
         Datum *values,
         bool *isnull,
         ItemPointer heap_tid,
         Relation heapRelation,
         IndexUniqueCheck checkUnique,
         bool indexUnchanged,
         IndexInfo *indexInfo);
```

Insert a new tuple into an existing index. The `values` and `isnull` arrays give the key values to be indexed, and `heap_tid` is the TID to be indexed. If the access method supports unique indexes (its `amcanunique` flag is `true`) then `checkUnique` indicates the type of uniqueness check to perform. This varies depending on whether the unique constraint is deferrable; see [Section 61.5](#) for details. Normally the access method only needs the `heapRelation` parameter when performing uniqueness checking (since then it will have to look into the heap to verify tuple liveness).

The `indexUnchanged` Boolean value gives a hint about the nature of the tuple to be indexed. When it is `true`, the tuple is a duplicate of some existing tuple in the index. The new tuple is a logically unchanged successor MVCC tuple version. This happens when an `UPDATE` takes place that does not modify any columns covered by the index, but nevertheless requires a new version in the index. The index AM may use this hint to decide to apply bottom-up index deletion in parts of the index where many versions of the same logical row accumulate. Note that updating a non-key column or a column that only appears in a partial index predicate does not affect the value of `indexUnchanged`. The core code determines each tuple's `indexUnchanged` value using a low overhead approach that allows both false positives and false

negatives. Index AMs must not treat `indexUnchanged` as an authoritative source of information about tuple visibility or versioning.

The function's Boolean result value is significant only when `checkUnique` is `UNIQUE_CHECK_PARTIAL`. In this case a true result means the new entry is known unique, whereas false means it might be non-unique (and a deferred uniqueness check must be scheduled). For other cases a constant false result is recommended.

Some indexes might not index all tuples. If the tuple is not to be indexed, `amininsert` should just return without doing anything.

If the index AM wishes to cache data across successive index insertions within an SQL statement, it can allocate space in `indexInfo->ii_Context` and store a pointer to the data in `indexInfo->ii_AmCache` (which will be NULL initially). If resources other than memory have to be released after index insertions, `amininsertcleanup` may be provided, which will be called before the memory is released.

```
void  
amininsertcleanup (Relation indexRelation,  
                  IndexInfo *indexInfo);
```

Clean up state that was maintained across successive inserts in `indexInfo->ii_AmCache`. This is useful if the data requires additional cleanup steps (e.g., releasing pinned buffers), and simply releasing the memory is not sufficient.

```
IndexBulkDeleteResult *  
ambulkdelete (IndexVacuumInfo *info,  
              IndexBulkDeleteResult *stats,  
              IndexBulkDeleteCallback callback,  
              void *callback_state);
```

Delete tuple(s) from the index. This is a “bulk delete” operation that is intended to be implemented by scanning the whole index and checking each entry to see if it should be deleted. The passed-in `callback` function must be called, in the style `callback(TID, callback_state)` returns `bool`, to determine whether any particular index entry, as identified by its referenced TID, is to be deleted. Must return either NULL or a palloc'd struct containing statistics about the effects of the deletion operation. It is OK to return NULL if no information needs to be passed on to `amvacuumcleanup`.

Because of limited `maintenance_work_mem`, `ambulkdelete` might need to be called more than once when many tuples are to be deleted. The `stats` argument is the result of the previous call for this index (it is NULL for the first call within a `VACUUM` operation). This allows the AM to accumulate statistics across the whole operation. Typically, `ambulkdelete` will modify and return the same struct if the passed `stats` is not null.

```
IndexBulkDeleteResult *  
amvacuumcleanup (IndexVacuumInfo *info,  
                 IndexBulkDeleteResult *stats);
```

Clean up after a `VACUUM` operation (zero or more `ambulkdelete` calls). This does not have to do anything beyond returning index statistics, but it might perform bulk cleanup such as reclaiming empty index pages. `stats` is whatever the last `ambulkdelete` call returned, or NULL if `ambulkdelete` was not called because no tuples needed to be deleted. If the result is not NULL it must be a palloc'd struct. The statistics it contains will be used to update `pg_class`, and will be reported by `VACUUM` if `VERBOSE` is given. It is OK to return NULL if the index was not changed at all during the `VACUUM` operation, but otherwise correct stats should be returned.

`amvacuumcleanup` will also be called at completion of an `ANALYZE` operation. In this case `stats` is always NULL and any return value will be ignored. This case can be distinguished by checking `info->analyze_only`. It is recommended that the access method do nothing except post-insert cleanup in such a call, and that only in an autovacuum worker process.

```
bool
```

```
amcanreturn (Relation indexRelation, int attno);
```

Check whether the index can support *index-only scans* on the given column, by returning the column's original indexed value. The attribute number is 1-based, i.e., the first column's `attno` is 1. Returns true if supported, else false. This function should always return true for included columns (if those are supported), since there's little point in an included column that can't be retrieved. If the access method does not support index-only scans at all, the `amcanreturn` field in its `IndexAmRoutine` struct can be set to NULL.

```
void
amcostestimate (PlannerInfo *root,
                IndexPath *path,
                double loop_count,
                Cost *indexStartupCost,
                Cost *indexTotalCost,
                Selectivity *indexSelectivity,
                double *indexCorrelation,
                double *indexPages);
```

Estimate the costs of an index scan. This function is described fully in [Section 61.6](#), below.

```
int
amgettreeheight (Relation rel);
```

Compute the height of a tree-shaped index. This information is supplied to the `amcostestimate` function in `path->indexinfo->tree_height` and can be used to support the cost estimation. The result is not used anywhere else, so this function can actually be used to compute any kind of data (that fits into an integer) about the index that the cost estimation function might want to know. If the computation is expensive, it could be useful to cache the result as part of `RelationData.rd_amcache`.

```
bytea *
amoptions (ArrayType *reloptions,
           bool validate);
```

Parse and validate the reloptions array for an index. This is called only when a non-null reloptions array exists for the index. *reloptions* is a text array containing entries of the form *name=value*. The function should construct a `bytea` value, which will be copied into the `rd_options` field of the index's relcache entry. The data contents of the `bytea` value are open for the access method to define; most of the standard access methods use struct `StdRdOptions`. When *validate* is true, the function should report a suitable error message if any of the options are unrecognized or have invalid values; when *validate* is false, invalid entries should be silently ignored. (*validate* is false when loading options already stored in `pg_catalog`; an invalid entry could only be found if the access method has changed its rules for options, and in that case ignoring obsolete entries is appropriate.) It is OK to return NULL if default behavior is wanted.

```
bool
amproperty (Oid index_oid, int attno,
            IndexAMProperty prop, const char *propname,
            bool *res, bool *isnull);
```

The `amproperty` method allows index access methods to override the default behavior of `pg_index_column_has_property` and related functions. If the access method does not have any special behavior for index property inquiries, the `amproperty` field in its `IndexAmRoutine` struct can be set to NULL. Otherwise, the `amproperty` method will be called with *index_oid* and *attno* both zero for `pg_indexam_has_property` calls, or with *index_oid* valid and *attno* zero for `pg_index_has_property` calls, or with *index_oid* valid and *attno* greater than zero for `pg_index_column_has_property` calls. *prop* is an enum value identifying the property being tested, while *propname* is the original property name string. If the core code does not recognize the property name then *prop* is `AMPROP_UNKNOWN`. Access methods can define custom property names by checking *propname* for a match (use `pg_strcasecmp` to match, for consistency with the core code); for names known to the core code, it's better to inspect *prop*. If the `amproperty` method returns true then it has determined the property test result: it must set **res* to the Boolean value to return, or set **isnull* to true to return a NULL. (Both of the referenced variables are initialized

to false before the call.) If the `amproperty` method returns false then the core code will proceed with its normal logic for determining the property test result.

Access methods that support ordering operators should implement `AMPROP_DISTANCE_ORDERABLE` property testing, as the core code does not know how to do that and will return NULL. It may also be advantageous to implement `AMPROP_RETURNABLE` testing, if that can be done more cheaply than by opening the index and calling `amcanreturn`, which is the core code's default behavior. The default behavior should be satisfactory for all other standard properties.

```
char *
ambuildphasename (int64 phasenum);
```

Return the textual name of the given build phase number. The phase numbers are those reported during an index build via the `pgstat_progress_update_param` interface. The phase names are then exposed in the `pg_stat_progress_create_index` view.

```
bool
amvalidate (Oid opclassoid);
```

Validate the catalog entries for the specified operator class, so far as the access method can reasonably do that. For example, this might include testing that all required support functions are provided. The `amvalidate` function must return false if the opclass is invalid. Problems should be reported with `ereport` messages, typically at `INFO` level.

```
void
amadjustmembers (Oid opfamilyoid,
                  Oid opclassoid,
                  List *operators,
                  List *functions);
```

Validate proposed new operator and function members of an operator family, so far as the access method can reasonably do that, and set their dependency types if the default is not satisfactory. This is called during `CREATE OPERATOR CLASS` and during `ALTER OPERATOR FAMILY ADD`; in the latter case `opclassoid` is `InvalidOid`. The `List` arguments are lists of `OpFamilyMember` structs. Tests done by this function will typically be a subset of those performed by `amvalidate`, since `amadjustmembers` cannot assume that it is seeing a complete set of members. For example, it would be reasonable to check the signature of a support function, but not to check whether all required support functions are provided. Any problems can be reported by throwing an error. The dependency-related fields of the `OpFamilyMember` structs are initialized by the core code to create hard dependencies on the opclass if this is `CREATE OPERATOR CLASS`, or soft dependencies on the opfamily if this is `ALTER OPERATOR FAMILY ADD`. `amadjustmembers` can adjust these fields if some other behavior is more appropriate. For example, GIN, GiST, and SP-GiST always set operator members to have soft dependencies on the opfamily, since the connection between an operator and an opclass is relatively weak in these index types; so it is reasonable to allow operator members to be added and removed freely. Optional support functions are typically also given soft dependencies, so that they can be removed if necessary.

The purpose of an index, of course, is to support scans for tuples matching an indexable `WHERE` condition, often called a *qualifier* or *scan key*. The semantics of index scanning are described more fully in [Section 61.3](#), below. An index access method can support “plain” index scans, “bitmap” index scans, or both. The scan-related functions that an index access method must or may provide are:

```
IndexScanDesc
ambeginscan (Relation indexRelation,
             int nkeys,
             int norderbys);
```

Prepare for an index scan. The `nkeys` and `norderbys` parameters indicate the number of quals and ordering operators that will be used in the scan; these may be useful for space allocation purposes. Note that the actual values of the scan keys aren't provided yet. The result must be a palloc'd struct. For implementation reasons the index access method *must* create this struct by calling `RelationGetIndexS-`

`can()`. In most cases `ambeginscan` does little beyond making that call and perhaps acquiring locks; the interesting parts of index-scan startup are in `amrescan`.

```
void
amrescan (IndexScanDesc scan,
          ScanKey keys,
          int nkeys,
          ScanKey orderbys,
          int norderbys);
```

Start or restart an index scan, possibly with new scan keys. (To restart using previously-passed keys, NULL is passed for `keys` and/or `orderbys`.) Note that it is not allowed for the number of keys or order-by operators to be larger than what was passed to `ambeginscan`. In practice the restart feature is used when a new outer tuple is selected by a nested-loop join and so a new key comparison value is needed, but the scan key structure remains the same.

```
bool
amgettupple (IndexScanDesc scan,
             ScanDirection direction);
```

Fetch the next tuple in the given scan, moving in the given direction (forward or backward in the index). Returns true if a tuple was obtained, false if no matching tuples remain. In the true case the tuple TID is stored into the `scan` structure. Note that “success” means only that the index contains an entry that matches the scan keys, not that the tuple necessarily still exists in the heap or will pass the caller's snapshot test. On success, `amgettupple` must also set `scan->xs_recheck` to true or false. False means it is certain that the index entry matches the scan keys. True means this is not certain, and the conditions represented by the scan keys must be rechecked against the heap tuple after fetching it. This provision supports “lossy” index operators. Note that rechecking will extend only to the scan conditions; a partial index predicate (if any) is never rechecked by `amgettupple` callers.

If the index supports [index-only scans](#) (i.e., `amcanreturn` returns true for any of its columns), then on success the AM must also check `scan->xs_want_itup`, and if that is true it must return the originally indexed data for the index entry. Columns for which `amcanreturn` returns false can be returned as nulls. The data can be returned in the form of an `IndexTuple` pointer stored at `scan->xs_itup`, with tuple descriptor `scan->xs_itupdesc`; or in the form of a `HeapTuple` pointer stored at `scan->xs_hitup`, with tuple descriptor `scan->xs_hitupdesc`. (The latter format should be used when reconstructing data that might possibly not fit into an `IndexTuple`.) In either case, management of the data referenced by the pointer is the access method's responsibility. The data must remain good at least until the next `amgettupple`, `amrescan`, or `amendscan` call for the scan.

The `amgettupple` function need only be provided if the access method supports “plain” index scans. If it doesn't, the `amgettupple` field in its `IndexAmRoutine` struct must be set to NULL.

```
int64
amgetbitmap (IndexScanDesc scan,
             TIDBitmap *tbm);
```

Fetch all tuples in the given scan and add them to the caller-supplied `TIDBitmap` (that is, OR the set of tuple IDs into whatever set is already in the bitmap). The number of tuples fetched is returned (this might be just an approximate count, for instance some AMs do not detect duplicates). While inserting tuple IDs into the bitmap, `amgetbitmap` can indicate that rechecking of the scan conditions is required for specific tuple IDs. This is analogous to the `xs_recheck` output parameter of `amgettupple`. Note: in the current implementation, support for this feature is conflated with support for lossy storage of the bitmap itself, and therefore callers recheck both the scan conditions and the partial index predicate (if any) for recheckable tuples. That might not always be true, however. `amgetbitmap` and `amgettupple` cannot be used in the same index scan; there are other restrictions too when using `amgetbitmap`, as explained in [Section 61.3](#).

The `amgetbitmap` function need only be provided if the access method supports “bitmap” index scans. If it doesn't, the `amgetbitmap` field in its `IndexAmRoutine` struct must be set to NULL.

```
void  
amendscan (IndexScanDesc scan);
```

End a scan and release resources. The `scan` struct itself should not be freed, but any locks or pins taken internally by the access method must be released, as well as any other memory allocated by `ambeginscan` and other scan-related functions.

```
void  
ammarkpos (IndexScanDesc scan);
```

Mark current scan position. The access method need only support one remembered scan position per scan.

The `ammarkpos` function need only be provided if the access method supports ordered scans. If it doesn't, the `ammarkpos` field in its `IndexAmRoutine` struct may be set to `NULL`.

```
void  
amrestrpos (IndexScanDesc scan);
```

Restore the scan to the most recently marked position.

The `amrestrpos` function need only be provided if the access method supports ordered scans. If it doesn't, the `amrestrpos` field in its `IndexAmRoutine` struct may be set to `NULL`.

In addition to supporting ordinary index scans, some types of index may wish to support *parallel index scans*, which allow multiple backends to cooperate in performing an index scan. The index access method should arrange things so that each cooperating process returns a subset of the tuples that would be performed by an ordinary, non-parallel index scan, but in such a way that the union of those subsets is equal to the set of tuples that would be returned by an ordinary, non-parallel index scan. Furthermore, while there need not be any global ordering of tuples returned by a parallel scan, the ordering of that subset of tuples returned within each cooperating backend must match the requested ordering. The following functions may be implemented to support parallel index scans:

```
Size  
amestimateparallelscale (Relation indexRelation,  
                          int nkeys,  
                          int norderbys);
```

Estimate and return the number of bytes of dynamic shared memory which the access method will be needed to perform a parallel scan. (This number is in addition to, not in lieu of, the amount of space needed for AM-independent data in `ParallelIndexScanDescData`.)

The `nkeys` and `norderbys` parameters indicate the number of quals and ordering operators that will be used in the scan; the same values will be passed to `amrescan`. Note that the actual values of the scan keys aren't provided yet.

It is not necessary to implement this function for access methods which do not support parallel scans or for which the number of additional bytes of storage required is zero.

```
void  
aminitparallelscale (void *target);
```

This function will be called to initialize dynamic shared memory at the beginning of a parallel scan. `target` will point to at least the number of bytes previously returned by `amestimateparallelscale`, and this function may use that amount of space to store whatever data it wishes.

It is not necessary to implement this function for access methods which do not support parallel scans or in cases where the shared memory space required needs no initialization.

```
void  
amparallelscale (IndexScanDesc scan);
```

This function, if implemented, will be called when a parallel index scan must be restarted. It should reset any shared state set up by `aminitparallelscale` such that the scan will be restarted from the beginning.

```
CompareType
amtranslatestrategy (StrategyNumber strategy, Oid opfamily, Oid opcintype);
```

```
StrategyNumber
amtranslatexcmptype (CompareType cmptype, Oid opfamily, Oid opcintype);
```

These functions, if implemented, will be called by the planner and executor to convert between fixed `CompareType` values and the specific strategy numbers used by the access method. These functions can be implemented by access methods that implement functionality similar to the built-in btree or hash access methods, and by implementing these translations, the system can learn about the semantics of the access method's operations and can use them in place of btree or hash indexes in various places. If the functionality of the access method is not similar to those built-in access methods, these functions do not need to be implemented. If the functions are not implemented, the access method will be ignored for certain planner and executor decisions, but is otherwise fully functional.

61.3. Index Scanning

In an index scan, the index access method is responsible for regurgitating the TIDs of all the tuples it has been told about that match the *scan keys*. The access method is *not* involved in actually fetching those tuples from the index's parent table, nor in determining whether they pass the scan's visibility test or other conditions.

A scan key is the internal representation of a `WHERE` clause of the form *index_key operator constant*, where the index key is one of the columns of the index and the operator is one of the members of the operator family associated with that index column. An index scan has zero or more scan keys, which are implicitly ANDed — the returned tuples are expected to satisfy all the indicated conditions.

The access method can report that the index is *lossy*, or requires rechecks, for a particular query. This implies that the index scan will return all the entries that pass the scan key, plus possibly additional entries that do not. The core system's index-scan machinery will then apply the index conditions again to the heap tuple to verify whether or not it really should be selected. If the recheck option is not specified, the index scan must return exactly the set of matching entries.

Note that it is entirely up to the access method to ensure that it correctly finds all and only the entries passing all the given scan keys. Also, the core system will simply hand off all the `WHERE` clauses that match the index keys and operator families, without any semantic analysis to determine whether they are redundant or contradictory. As an example, given `WHERE x > 4 AND x > 14` where `x` is a b-tree indexed column, it is left to the b-tree `amrescan` function to realize that the first scan key is redundant and can be discarded. The extent of preprocessing needed during `amrescan` will depend on the extent to which the index access method needs to reduce the scan keys to a “normalized” form.

Some access methods return index entries in a well-defined order, others do not. There are actually two different ways that an access method can support sorted output:

- Access methods that always return entries in the natural ordering of their data (such as btree) should set `amcanorder` to true. Currently, such access methods must use btree-compatible strategy numbers for their equality and ordering operators.
- Access methods that support ordering operators should set `amcanorderbyop` to true. This indicates that the index is capable of returning entries in an order satisfying `ORDER BY index_key operator constant`. Scan modifiers of that form can be passed to `amrescan` as described previously.

The `amgettupple` function has a `direction` argument, which can be either `ForwardScanDirection` (the normal case) or `BackwardScanDirection`. If the first call after `amrescan` specifies `BackwardScanDirection`, then the set of matching index entries is to be scanned back-to-front rather than in the normal front-to-back direction, so `amgettupple` must return the last matching tuple in the index, rather than the first one as it normally would. (This will only occur for access methods that set `amcanorder` to true.) After the first call, `amgettupple` must be prepared to advance the scan in either direction from the most recently returned entry. (But if `amcanbackward` is false, all subsequent calls will have the same direction as the first one.)

Access methods that support ordered scans must support “marking” a position in a scan and later returning to the marked position. The same position might be restored multiple times. However, only one position need be remembered per scan; a new `ammarkpos` call overrides the previously marked position. An access method that does not support ordered scans need not provide `ammarkpos` and `amrestrpos` functions in `IndexAmRoutine`; set those pointers to NULL instead.

Both the scan position and the mark position (if any) must be maintained consistently in the face of concurrent insertions or deletions in the index. It is OK if a freshly-inserted entry is not returned by a scan that would have found the entry if it had existed when the scan started, or for the scan to return such an entry upon rescanning or backing up even though it had not been returned the first time through. Similarly, a concurrent delete might or might not be reflected in the results of a scan. What is important is that insertions or deletions not cause the scan to miss or multiply return entries that were not themselves being inserted or deleted.

If the index stores the original indexed data values (and not some lossy representation of them), it is useful to support [index-only scans](#), in which the index returns the actual data not just the TID of the heap tuple. This will only avoid I/O if the visibility map shows that the TID is on an all-visible page; else the heap tuple must be visited anyway to check MVCC visibility. But that is no concern of the access method's.

Instead of using `amgettupple`, an index scan can be done with `amgetbitmap` to fetch all tuples in one call. This can be noticeably more efficient than `amgettupple` because it allows avoiding lock/unlock cycles within the access method. In principle `amgetbitmap` should have the same effects as repeated `amgettupple` calls, but we impose several restrictions to simplify matters. First of all, `amgetbitmap` returns all tuples at once and marking or restoring scan positions isn't supported. Secondly, the tuples are returned in a bitmap which doesn't have any specific ordering, which is why `amgetbitmap` doesn't take a `direction` argument. (Ordering operators will never be supplied for such a scan, either.) Also, there is no provision for index-only scans with `amgetbitmap`, since there is no way to return the contents of index tuples. Finally, `amgetbitmap` does not guarantee any locking of the returned tuples, with implications spelled out in [Section 61.4](#).

Note that it is permitted for an access method to implement only `amgetbitmap` and not `amgettupple`, or vice versa, if its internal implementation is unsuited to one API or the other.

61.4. Index Locking Considerations

Index access methods must handle concurrent updates of the index by multiple processes. The core Postgres Pro system obtains `AccessShareLock` on the index during an index scan, and `RowExclusiveLock` when updating the index (including plain `VACUUM`). Since these lock types do not conflict, the access method is responsible for handling any fine-grained locking it might need. An `ACCESS EXCLUSIVE` lock on the index as a whole will be taken only during index creation, destruction, or `REINDEX (SHARE UPDATE EXCLUSIVE)` is taken instead with `CONCURRENTLY`).

Building an index type that supports concurrent updates usually requires extensive and subtle analysis of the required behavior.

Aside from the index's own internal consistency requirements, concurrent updates create issues about consistency between the parent table (the *heap*) and the index. Because Postgres Pro separates accesses and updates of the heap from those of the index, there are windows in which the index might be inconsistent with the heap. We handle this problem with the following rules:

- A new heap entry is made before making its index entries. (Therefore a concurrent index scan is likely to fail to see the heap entry. This is okay because the index reader would be uninterested in an uncommitted row anyway. But see [Section 61.5](#).)
- When a heap entry is to be deleted (by `VACUUM`), all its index entries must be removed first.
- An index scan must maintain a pin on the index page holding the item last returned by `amgettupple`, and `ambulkdelete` cannot delete entries from pages that are pinned by other backends. The need for this rule is explained below.

Without the third rule, it is possible for an index reader to see an index entry just before it is removed by `VACUUM`, and then to arrive at the corresponding heap entry after that was removed by `VACUUM`. This creates no serious problems if that item number is still unused when the reader reaches it, since an empty item slot will be ignored by `heap_fetch()`. But what if a third backend has already re-used the item slot for something else? When using an MVCC-compliant snapshot, there is no problem because the new occupant of the slot is certain to be too new to pass the snapshot test. However, with a non-MVCC-compliant snapshot (such as `SnapshotAny`), it would be possible to accept and return a row that does not in fact match the scan keys. We could defend against this scenario by requiring the scan keys to be rechecked against the heap row in all cases, but that is too expensive. Instead, we use a pin on an index page as a proxy to indicate that the reader might still be “in flight” from the index entry to the matching heap entry. Making `ambulkdelete` block on such a pin ensures that `VACUUM` cannot delete the heap entry before the reader is done with it. This solution costs little in run time, and adds blocking overhead only in the rare cases where there actually is a conflict.

This solution requires that index scans be “synchronous”: we have to fetch each heap tuple immediately after scanning the corresponding index entry. This is expensive for a number of reasons. An “asynchronous” scan in which we collect many TIDs from the index, and only visit the heap tuples sometime later, requires much less index locking overhead and can allow a more efficient heap access pattern. Per the above analysis, we must use the synchronous approach for non-MVCC-compliant snapshots, but an asynchronous scan is workable for a query using an MVCC snapshot.

In an `amgetbitmap` index scan, the access method does not keep an index pin on any of the returned tuples. Therefore it is only safe to use such scans with MVCC-compliant snapshots.

When the `ampredlocks` flag is not set, any scan using that index access method within a serializable transaction will acquire a nonblocking predicate lock on the full index. This will generate a read-write conflict with the insert of any tuple into that index by a concurrent serializable transaction. If certain patterns of read-write conflicts are detected among a set of concurrent serializable transactions, one of those transactions may be canceled to protect data integrity. When the flag is set, it indicates that the index access method implements finer-grained predicate locking, which will tend to reduce the frequency of such transaction cancellations.

61.5. Index Uniqueness Checks

Postgres Pro enforces SQL uniqueness constraints using *unique indexes*, which are indexes that disallow multiple entries with identical keys. An access method that supports this feature sets `amcanunique` true. (At present, only b-tree supports it.) Columns listed in the `INCLUDE` clause are not considered when enforcing uniqueness.

Because of MVCC, it is always necessary to allow duplicate entries to exist physically in an index: the entries might refer to successive versions of a single logical row. The behavior we actually want to enforce is that no MVCC snapshot could include two rows with equal index keys. This breaks down into the following cases that must be checked when inserting a new row into a unique index:

- If a conflicting valid row has been deleted by the current transaction, it's okay. (In particular, since an `UPDATE` always deletes the old row version before inserting the new version, this will allow an `UPDATE` on a row without changing the key.)
- If a conflicting row has been inserted by an as-yet-uncommitted transaction, the would-be inserter must wait to see if that transaction commits. If it rolls back then there is no conflict. If it commits without deleting the conflicting row again, there is a uniqueness violation. (In practice we just wait for the other transaction to end and then redo the visibility check in toto.)
- Similarly, if a conflicting valid row has been deleted by an as-yet-uncommitted transaction, the would-be inserter must wait for that transaction to commit or abort, and then repeat the test.

Furthermore, immediately before reporting a uniqueness violation according to the above rules, the access method must recheck the liveness of the row being inserted. If it is committed dead then no violation should be reported. (This case cannot occur during the ordinary scenario of inserting a row that's just been created by the current transaction. It can happen during `CREATE UNIQUE INDEX CONCURRENTLY`, however.)

We require the index access method to apply these tests itself, which means that it must reach into the heap to check the commit status of any row that is shown to have a duplicate key according to the index contents. This is without a doubt ugly and non-modular, but it saves redundant work: if we did a separate probe then the index lookup for a conflicting row would be essentially repeated while finding the place to insert the new row's index entry. What's more, there is no obvious way to avoid race conditions unless the conflict check is an integral part of insertion of the new index entry.

If the unique constraint is deferrable, there is additional complexity: we need to be able to insert an index entry for a new row, but defer any uniqueness-violation error until end of statement or even later. To avoid unnecessary repeat searches of the index, the index access method should do a preliminary uniqueness check during the initial insertion. If this shows that there is definitely no conflicting live tuple, we are done. Otherwise, we schedule a recheck to occur when it is time to enforce the constraint. If, at the time of the recheck, both the inserted tuple and some other tuple with the same key are live, then the error must be reported. (Note that for this purpose, “live” actually means “any tuple in the index entry's HOT chain is live”.) To implement this, the `amininsert` function is passed a `checkUnique` parameter having one of the following values:

- `UNIQUE_CHECK_NO` indicates that no uniqueness checking should be done (this is not a unique index).
- `UNIQUE_CHECK_YES` indicates that this is a non-deferrable unique index, and the uniqueness check must be done immediately, as described above.
- `UNIQUE_CHECK_PARTIAL` indicates that the unique constraint is deferrable. Postgres Pro will use this mode to insert each row's index entry. The access method must allow duplicate entries into the index, and report any potential duplicates by returning false from `amininsert`. For each row for which false is returned, a deferred recheck will be scheduled.

The access method must identify any rows which might violate the unique constraint, but it is not an error for it to report false positives. This allows the check to be done without waiting for other transactions to finish; conflicts reported here are not treated as errors and will be rechecked later, by which time they may no longer be conflicts.

- `UNIQUE_CHECK_EXISTING` indicates that this is a deferred recheck of a row that was reported as a potential uniqueness violation. Although this is implemented by calling `amininsert`, the access method must *not* insert a new index entry in this case. The index entry is already present. Rather, the access method must check to see if there is another live index entry. If so, and if the target row is also still live, report error.

It is recommended that in a `UNIQUE_CHECK_EXISTING` call, the access method further verify that the target row actually does have an existing entry in the index, and report error if not. This is a good idea because the index tuple values passed to `amininsert` will have been recomputed. If the index definition involves functions that are not really immutable, we might be checking the wrong area of the index. Checking that the target row is found in the recheck verifies that we are scanning for the same tuple values as were used in the original insertion.

61.6. Index Cost Estimation Functions

The `amcostestimate` function is given information describing a possible index scan, including lists of WHERE and ORDER BY clauses that have been determined to be usable with the index. It must return estimates of the cost of accessing the index and the selectivity of the WHERE clauses (that is, the fraction of parent-table rows that will be retrieved during the index scan). For simple cases, nearly all the work of the cost estimator can be done by calling standard routines in the optimizer; the point of having an `amcostestimate` function is to allow index access methods to provide index-type-specific knowledge, in case it is possible to improve on the standard estimates.

Each `amcostestimate` function must have the signature:

```
void
amcostestimate (PlannerInfo *root,
               IndexPath *path,
```

```
double loop_count,  
Cost *indexStartupCost,  
Cost *indexTotalCost,  
Selectivity *indexSelectivity,  
double *indexCorrelation,  
double *indexPages);
```

The first three parameters are inputs:

root

The planner's information about the query being processed.

path

The index access path being considered. All fields except cost and selectivity values are valid.

loop_count

The number of repetitions of the index scan that should be factored into the cost estimates. This will typically be greater than one when considering a parameterized scan for use in the inside of a nestloop join. Note that the cost estimates should still be for just one scan; a larger *loop_count* means that it may be appropriate to allow for some caching effects across multiple scans.

The last five parameters are pass-by-reference outputs:

**indexStartupCost*

Set to cost of index start-up processing

**indexTotalCost*

Set to total cost of index processing

**indexSelectivity*

Set to index selectivity

**indexCorrelation*

Set to correlation coefficient between index scan order and underlying table's order

**indexPages*

Set to number of index leaf pages

Note that cost estimate functions must be written in C, not in SQL or any available procedural language, because they must access internal data structures of the planner/optimizer.

The index access costs should be computed using the parameters: a sequential disk block fetch has cost *seq_page_cost*, a nonsequential fetch has cost *random_page_cost*, and the cost of processing one index row should usually be taken as *cpu_index_tuple_cost*. In addition, an appropriate multiple of *cpu_operator_cost* should be charged for any comparison operators invoked during index processing (especially evaluation of the *indexquals* themselves).

The “start-up cost” is the part of the total scan cost that must be expended before we can begin to fetch the first row. For most indexes this can be taken as zero, but an index type with a high start-up cost might want to set it nonzero.

The *indexSelectivity* should be set to the estimated fraction of the parent table rows that will be retrieved during the index scan. In the case of a lossy query, this will typically be higher than the fraction of rows that actually pass the given qual conditions.

The *indexCorrelation* should be set to the correlation (ranging between -1.0 and 1.0) between the index order and the table order. This is used to adjust the estimate for the cost of fetching rows from the parent table.

The *indexPages* should be set to the number of leaf pages. This is used to estimate the number of workers for parallel index scan.

When *loop_count* is greater than one, the returned numbers should be averages expected for any one scan of the index.

Cost Estimation

A typical cost estimator will proceed as follows:

1. Estimate and return the fraction of parent-table rows that will be visited based on the given qual conditions. In the absence of any index-type-specific knowledge, use the standard optimizer function `clauselist_selectivity()`:

```
*indexSelectivity = clauselist_selectivity(root, path->indexquals,
                                           path->indexinfo->rel->relid,
                                           JOIN_INNER, NULL);
```

2. Estimate the number of index rows that will be visited during the scan. For many index types this is the same as *indexSelectivity* times the number of rows in the index, but it might be more. (Note that the index's size in pages and rows is available from the `path->indexinfo` struct.)
3. Estimate the number of index pages that will be retrieved during the scan. This might be just *indexSelectivity* times the index's size in pages.
4. Compute the index access cost. A generic estimator might do this:

```
/*
 * Our generic assumption is that the index pages will be read
 * sequentially, so they cost seq_page_cost each, not random_page_cost.
 * Also, we charge for evaluation of the indexquals at each index row.
 * All the costs are assumed to be paid incrementally during the scan.
 */
cost_qual_eval(&index_qual_cost, path->indexquals, root);
*indexStartupCost = index_qual_cost.startup;
*indexTotalCost = seq_page_cost * numIndexPages +
    (cpu_index_tuple_cost + index_qual_cost.per_tuple) * numIndexTuples;
```

However, the above does not account for amortization of index reads across repeated index scans.

5. Estimate the index correlation. For a simple ordered index on a single field, this can be retrieved from `pg_statistic`. If the correlation is not known, the conservative estimate is zero (no correlation).

Chapter 62. Write Ahead Logging for Extensions

Certain extensions, principally extensions that implement custom access methods, may need to perform write-ahead logging in order to ensure crash-safety. Postgres Pro provides two ways for extensions to achieve this goal.

First, extensions can choose to use [generic WAL](#), a special type of WAL record which describes changes to pages in a generic way. This method is simple to implement and does not require that an extension library be loaded in order to apply the records. However, generic WAL records will be ignored when performing logical decoding.

Second, extensions can choose to use a [custom resource manager](#). This method is more flexible, supports logical decoding, and can sometimes generate much smaller write-ahead log records than would be possible with generic WAL. However, it is more complex for an extension to implement.

62.1. Generic WAL Records

Although all built-in WAL-logged modules have their own types of WAL records, there is also a generic WAL record type, which describes changes to pages in a generic way.

Note

Generic WAL records are ignored during [Logical Decoding](#). If logical decoding is required for your extension, consider a Custom WAL Resource Manager.

The API for constructing generic WAL records is defined in `access/generic_xlog.h` and implemented in `access/transam/generic_xlog.c`.

To perform a WAL-logged data update using the generic WAL record facility, follow these steps:

1. `state = GenericXLogStart(relation)` — start construction of a generic WAL record for the given relation.
2. `page = GenericXLogRegisterBuffer(state, buffer, flags)` — register a buffer to be modified within the current generic WAL record. This function returns a pointer to a temporary copy of the buffer's page, where modifications should be made. (Do not modify the buffer's contents directly.) The third argument is a bit mask of flags applicable to the operation. Currently the only such flag is `GENERIC_XLOG_FULL_IMAGE`, which indicates that a full-page image rather than a delta update should be included in the WAL record. Typically this flag would be set if the page is new or has been rewritten completely. `GenericXLogRegisterBuffer` can be repeated if the WAL-logged action needs to modify multiple pages.
3. Apply modifications to the page images obtained in the previous step.
4. `GenericXLogFinish(state)` — apply the changes to the buffers and emit the generic WAL record.

WAL record construction can be canceled between any of the above steps by calling `GenericXLogAbort(state)`. This will discard all changes to the page image copies.

Please note the following points when using the generic WAL record facility:

- No direct modifications of buffers are allowed! All modifications must be done in copies acquired from `GenericXLogRegisterBuffer()`. In other words, code that makes generic WAL records should never call `BufferGetPage()` for itself. However, it remains the caller's responsibility to pin/unpin and lock/unlock the buffers at appropriate times. Exclusive lock must be held on each target buffer from before `GenericXLogRegisterBuffer()` until after `GenericXLogFinish()`.

- Registrations of buffers (step 2) and modifications of page images (step 3) can be mixed freely, i.e., both steps may be repeated in any sequence. Keep in mind that buffers should be registered in the same order in which locks are to be obtained on them during replay.
- The maximum number of buffers that can be registered for a generic WAL record is `MAX_GENERIC_XLOG_PAGES`. An error will be thrown if this limit is exceeded.
- Generic WAL assumes that the pages to be modified have standard layout, and in particular that there is no useful data between `pd_lower` and `pd_upper`.
- Since you are modifying copies of buffer pages, `GenericXLogStart()` does not start a critical section. Thus, you can safely do memory allocation, error throwing, etc. between `GenericXLogStart()` and `GenericXLogFinish()`. The only actual critical section is present inside `GenericXLogFinish()`. There is no need to worry about calling `GenericXLogAbort()` during an error exit, either.
- `GenericXLogFinish()` takes care of marking buffers dirty and setting their LSNs. You do not need to do this explicitly.
- For unlogged relations, everything works the same except that no actual WAL record is emitted. Thus, you typically do not need to do any explicit checks for unlogged relations.
- The generic WAL redo function will acquire exclusive locks to buffers in the same order as they were registered. After redoing all changes, the locks will be released in the same order.
- If `GENERIC_XLOG_FULL_IMAGE` is not specified for a registered buffer, the generic WAL record contains a delta between the old and the new page images. This delta is based on byte-by-byte comparison. This is not very compact for the case of moving data within a page, and might be improved in the future.

62.2. Custom WAL Resource Managers

This section explains the interface between the core Postgres Pro system and custom WAL resource managers, which enable extensions to integrate directly with the [WAL](#).

An extension, especially a [Table Access Method](#) or [Index Access Method](#), may need to use WAL for recovery, replication, and/or [Logical Decoding](#).

To create a new custom WAL resource manager, first define an `RmgrData` structure with implementations for the resource manager methods.

```
/*
 * Method table for resource managers.
 *
 * This struct must be kept in sync with the PG_RMGR definition in
 * rmgr.c.
 *
 * rm_identify must return a name for the record based on xl_info (without
 * reference to the rmid). For example, XLOG_BTREE_VACUUM would be named
 * "VACUUM". rm_desc can then be called to obtain additional detail for the
 * record, if available (e.g. the last block).
 *
 * rm_mask takes as input a page modified by the resource manager and masks
 * out bits that shouldn't be flagged by wal_consistency_checking.
 *
 * RmgrTable[] is indexed by RmgrId values (see rmgrlist.h). If rm_name is
 * NULL, the corresponding RmgrTable entry is considered invalid.
 */
typedef struct RmgrData
{
    const char *rm_name;
    void (*rm_redo) (XLogReaderState *record);
    void (*rm_desc) (StringInfo buf, XLogReaderState *record);
```

```
const char *(*rm_identify) (uint8 info);
void        (*rm_startup) (void);
void        (*rm_cleanup) (void);
void        (*rm_mask) (char *pagedata, BlockNumber blkno);
void        (*rm_decode) (struct LogicalDecodingContext *ctx,
                          struct XLogRecordBuffer *buf);

} RmgrData;
```

Then, register your new resource manager.

```
/*
 * Register a new custom WAL resource manager.
 *
 * Resource manager IDs must be globally unique across all extensions. Refer
 * to https://wiki.postgresql.org/wiki/CustomWALResourceManagers to reserve a
 * unique RmgrId for your extension, to avoid conflicts with other extension
 * developers. During development, use RM_EXPERIMENTAL_ID to avoid needlessly
 * reserving a new ID.
 */
extern void RegisterCustomRmgr(RmgrId rmid, const RmgrData *rmgr);
```

`RegisterCustomRmgr` must be called from the extension module's `_PG_init` function. While developing a new extension, use `RM_EXPERIMENTAL_ID` for `rmid`. When you are ready to release the extension to users, reserve a new resource manager ID at the [Custom WAL Resource Manager](#) page.

Place the extension module implementing the custom resource manager in [shared_preload_libraries](#) so that it will be loaded early during Postgres Pro startup.

Note

The extension must remain in `shared_preload_libraries` as long as any custom WAL records may exist in the system. Otherwise Postgres Pro will not be able to apply or decode the custom WAL records, which may prevent the server from starting.

Chapter 63. Built-in Index Access Methods

63.1. B-Tree Indexes

63.1.1. Introduction

Postgres Pro includes an implementation of the standard btree (multi-way balanced tree) index data structure. Any data type that can be sorted into a well-defined linear order can be indexed by a btree index. The only limitation is that an index entry cannot exceed approximately one-third of a page (after TOAST compression, if applicable).

Because each btree operator class imposes a sort order on its data type, btree operator classes (or, really, operator families) have come to be used as Postgres Pro's general representation and understanding of sorting semantics. Therefore, they've acquired some features that go beyond what would be needed just to support btree indexes, and parts of the system that are quite distant from the btree AM make use of them.

63.1.2. Behavior of B-Tree Operator Classes

As shown in [Table 36.3](#), a btree operator class must provide five comparison operators, `<`, `<=`, `=`, `>=` and `>`. One might expect that `<>` should also be part of the operator class, but it is not, because it would almost never be useful to use a `<>` WHERE clause in an index search. (For some purposes, the planner treats `<>` as associated with a btree operator class; but it finds that operator via the `=` operator's negator link, rather than from `pg_amop`.)

When several data types share near-identical sorting semantics, their operator classes can be grouped into an operator family. Doing so is advantageous because it allows the planner to make deductions about cross-type comparisons. Each operator class within the family should contain the single-type operators (and associated support functions) for its input data type, while cross-type comparison operators and support functions are “loose” in the family. It is recommendable that a complete set of cross-type operators be included in the family, thus ensuring that the planner can represent any comparison conditions that it deduces from transitivity.

There are some basic assumptions that a btree operator family must satisfy:

- An `=` operator must be an equivalence relation; that is, for all non-null values *A*, *B*, *C* of the data type:
 - *A* = *A* is true (*reflexive law*)
 - if *A* = *B*, then *B* = *A* (*symmetric law*)
 - if *A* = *B* and *B* = *C*, then *A* = *C* (*transitive law*)
- A `<` operator must be a strong ordering relation; that is, for all non-null values *A*, *B*, *C*:
 - *A* < *A* is false (*irreflexive law*)
 - if *A* < *B* and *B* < *C*, then *A* < *C* (*transitive law*)
- Furthermore, the ordering is total; that is, for all non-null values *A*, *B*:
 - exactly one of *A* < *B*, *A* = *B*, and *B* < *A* is true (*trichotomy law*)

(The trichotomy law justifies the definition of the comparison support function, of course.)

The other three operators are defined in terms of `=` and `<` in the obvious way, and must act consistently with them.

For an operator family supporting multiple data types, the above laws must hold when *A*, *B*, *C* are taken from any data types in the family. The transitive laws are the trickiest to ensure, as in cross-type situations they represent statements that the behaviors of two or three different operators are consistent. As an example, it would not work to put `float8` and `numeric` into the same operator family, at least not with the current semantics that `numeric` values are converted to `float8` for comparison to a `float8`. Because

of the limited accuracy of `float8`, this means there are distinct `numeric` values that will compare equal to the same `float8` value, and thus the transitive law would fail.

Another requirement for a multiple-data-type family is that any implicit or binary-coercion casts that are defined between data types included in the operator family must not change the associated sort ordering.

It should be fairly clear why a btree index requires these laws to hold within a single data type: without them there is no ordering to arrange the keys with. Also, index searches using a comparison key of a different data type require comparisons to behave sanely across two data types. The extensions to three or more data types within a family are not strictly required by the btree index mechanism itself, but the planner relies on them for optimization purposes.

63.1.3. B-Tree Support Functions

As shown in [Table 36.9](#), btree defines one required and five optional support functions. The six user-defined methods are:

`order`

For each combination of data types that a btree operator family provides comparison operators for, it must provide a comparison support function, registered in `pg_amproc` with support function number 1 and `amproclefttype/amprocrighttype` equal to the left and right data types for the comparison (i.e., the same data types that the matching operators are registered with in `pg_amop`). The comparison function must take two non-null values *A* and *B* and return an `int32` value that is `< 0`, `0`, or `> 0` when *A* `<` *B*, *A* `=` *B*, or *A* `>` *B*, respectively. A null result is disallowed: all values of the data type must be comparable.

If the compared values are of a collatable data type, the appropriate collation OID will be passed to the comparison support function, using the standard `PG_GET_COLLATION()` mechanism.

`sortsupport`

Optionally, a btree operator family may provide *sort support* function(s), registered under support function number 2. These functions allow implementing comparisons for sorting purposes in a more efficient way than naively calling the comparison support function. The APIs involved in this are defined in [src/include/utils/sortsupport.h](#).

`in_range`

Optionally, a btree operator family may provide *in_range* support function(s), registered under support function number 3. These are not used during btree index operations; rather, they extend the semantics of the operator family so that it can support window clauses containing the `RANGE offset PRECEDING` and `RANGE offset FOLLOWING` frame bound types (see [Section 4.2.8](#)). Fundamentally, the extra information provided is how to add or subtract an *offset* value in a way that is compatible with the family's data ordering.

An *in_range* function must have the signature

```
in_range(val type1, base type1, offset type2, sub bool, less bool)
returns bool
```

val and *base* must be of the same type, which is one of the types supported by the operator family (i.e., a type for which it provides an ordering). However, *offset* could be of a different type, which might be one otherwise unsupported by the family. An example is that the built-in `time_ops` family provides an *in_range* function that has *offset* of type `interval`. A family can provide *in_range* functions for any of its supported types and one or more *offset* types. Each *in_range* function should be entered in `pg_amproc` with `amproclefttype` equal to *type1* and `amprocrighttype` equal to *type2*.

The essential semantics of an *in_range* function depend on the two Boolean flag parameters. It should add or subtract *base* and *offset*, then compare *val* to the result, as follows:

- if `!sub` and `!less`, return `val >= (base + offset)`
- if `!sub` and `less`, return `val <= (base + offset)`

- if *sub* and *!less*, return *val* \geq (*base* - *offset*)
- if *sub* and *less*, return *val* \leq (*base* - *offset*)

Before doing so, the function should check the sign of *offset*: if it is less than zero, raise error `ERRCODE_INVALID_PRECEDING_OR_FOLLOWING_SIZE` (22013) with error text like “invalid preceding or following size in window function”. (This is required by the SQL standard, although nonstandard operator families might perhaps choose to ignore this restriction, since there seems to be little semantic necessity for it.) This requirement is delegated to the `in_range` function so that the core code needn't understand what “less than zero” means for a particular data type.

An additional expectation is that `in_range` functions should, if practical, avoid throwing an error if *base* + *offset* or *base* - *offset* would overflow. The correct comparison result can be determined even if that value would be out of the data type's range. Note that if the data type includes concepts such as “infinity” or “NaN”, extra care may be needed to ensure that `in_range`'s results agree with the normal sort order of the operator family.

The results of the `in_range` function must be consistent with the sort ordering imposed by the operator family. To be precise, given any fixed values of *offset* and *sub*, then:

- If `in_range` with *less* = true is true for some *val1* and *base*, it must be true for every *val2* \leq *val1* with the same *base*.
- If `in_range` with *less* = true is false for some *val1* and *base*, it must be false for every *val2* \geq *val1* with the same *base*.
- If `in_range` with *less* = true is true for some *val* and *base1*, it must be true for every *base2* \geq *base1* with the same *val*.
- If `in_range` with *less* = true is false for some *val* and *base1*, it must be false for every *base2* \leq *base1* with the same *val*.

Analogous statements with inverted conditions hold when *less* = false.

If the type being ordered (*type1*) is collatable, the appropriate collation OID will be passed to the `in_range` function, using the standard `PG_GET_COLLATION()` mechanism.

`in_range` functions need not handle NULL inputs, and typically will be marked strict.

`equalimage`

Optionally, a btree operator family may provide `equalimage` (“equality implies image equality”) support functions, registered under support function number 4. These functions allow the core code to determine when it is safe to apply the btree deduplication optimization. Currently, `equalimage` functions are only called when building or rebuilding an index.

An `equalimage` function must have the signature

```
equalimage(opcintype oid) returns bool
```

The return value is static information about an operator class and collation. Returning `true` indicates that the `order` function for the operator class is guaranteed to only return 0 (“arguments are equal”) when its *A* and *B* arguments are also interchangeable without any loss of semantic information. Not registering an `equalimage` function or returning `false` indicates that this condition cannot be assumed to hold.

The *opcintype* argument is the `pg_type.oid` of the data type that the operator class indexes. This is a convenience that allows reuse of the same underlying `equalimage` function across operator classes. If *opcintype* is a collatable data type, the appropriate collation OID will be passed to the `equalimage` function, using the standard `PG_GET_COLLATION()` mechanism.

As far as the operator class is concerned, returning `true` indicates that deduplication is safe (or safe for the collation whose OID was passed to its `equalimage` function). However, the core code will only deem deduplication safe for an index when *every* indexed column uses an operator class that registers an `equalimage` function, and each function actually returns `true` when called.

Image equality is *almost* the same condition as simple bitwise equality. There is one subtle difference: When indexing a varlena data type, the on-disk representation of two image equal datums may not be bitwise equal due to inconsistent application of TOAST compression on input. Formally, when an operator class's `equalimage` function returns `true`, it is safe to assume that the `datum_image_eq()` C function will always agree with the operator class's `order` function (provided that the same collation OID is passed to both the `equalimage` and `order` functions).

The core code is fundamentally unable to deduce anything about the “equality implies image equality” status of an operator class within a multiple-data-type family based on details from other operator classes in the same family. Also, it is not sensible for an operator family to register a cross-type `equalimage` function, and attempting to do so will result in an error. This is because “equality implies image equality” status does not just depend on sorting/equality semantics, which are more or less defined at the operator family level. In general, the semantics that one particular data type implements must be considered separately.

The convention followed by the operator classes included with the core Postgres Pro distribution is to register a stock, generic `equalimage` function. Most operator classes register `btequalimage()`, which indicates that deduplication is safe unconditionally. Operator classes for collatable data types such as `text` register `btvarstrequalimage()`, which indicates that deduplication is safe with deterministic collations. Best practice for third-party extensions is to register their own custom function to retain control.

`options`

Optionally, a B-tree operator family may provide `options` (“operator class specific options”) support functions, registered under support function number 5. These functions define a set of user-visible parameters that control operator class behavior.

An `options` support function must have the signature

```
options(relopts local_relopts *) returns void
```

The function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

Currently, no B-Tree operator class has an `options` support function. B-tree doesn't allow flexible representation of keys like GiST, SP-GiST, GIN and BRIN do. So, `options` probably doesn't have much application in the current B-tree index access method. Nevertheless, this support function was added to B-tree for uniformity, and will probably find uses during further evolution of B-tree in Postgres Pro.

`skipsupport`

Optionally, a btree operator family may provide a *skip support* function, registered under support function number 6. These functions give the B-tree code a way to iterate through every possible value that can be represented by an operator class's underlying input type, in key space order. This is used by the core code when it applies the skip scan optimization. The APIs involved in this are defined in [src/include/utils/skipsupport.h](#).

Operator classes that do not provide a skip support function are still eligible to use skip scan. The core code can still use its fallback strategy, though that might be suboptimal for some discrete types. It usually doesn't make sense (and may not even be feasible) for operator classes on continuous types to provide a skip support function.

It is not sensible for an operator family to register a cross-type `skipsupport` function, and attempting to do so will result in an error. This is because determining the next indexable value must happen by incrementing a value copied from an index tuple. The values generated must all be of the same underlying data type (the “skipped” index column's opclass input type).

63.1.4. Implementation

This section covers B-Tree index implementation details that may be of use to advanced users.

63.1.4.1. B-Tree Structure

Postgres Pro B-Tree indexes are multi-level tree structures, where each level of the tree can be used as a doubly-linked list of pages. A single metapage is stored in a fixed position at the start of the first segment file of the index. All other pages are either leaf pages or internal pages. Leaf pages are the pages on the lowest level of the tree. All other levels consist of internal pages. Each leaf page contains tuples that point to table rows. Each internal page contains tuples that point to the next level down in the tree. Typically, over 99% of all pages are leaf pages. Both internal pages and leaf pages use the standard page format described in [Section 64.6](#).

New leaf pages are added to a B-Tree index when an existing leaf page cannot fit an incoming tuple. A *page split* operation makes room for items that originally belonged on the overflowing page by moving a portion of the items to a new page. Page splits must also insert a new *downlink* to the new page in the parent page, which may cause the parent to split in turn. Page splits “cascade upwards” in a recursive fashion. When the root page finally cannot fit a new downlink, a *root page split* operation takes place. This adds a new level to the tree structure by creating a new root page that is one level above the original root page.

63.1.4.2. Bottom-up Index Deletion

B-Tree indexes are not directly aware that under MVCC, there might be multiple extant versions of the same logical table row; to an index, each tuple is an independent object that needs its own index entry. “Version churn” tuples may sometimes accumulate and adversely affect query latency and throughput. This typically occurs with `UPDATE`-heavy workloads where most individual updates cannot apply the [HOT optimization](#). Changing the value of only one column covered by one index during an `UPDATE` *always* necessitates a new set of index tuples — one for *each and every* index on the table. Note in particular that this includes indexes that were not “logically modified” by the `UPDATE`. All indexes will need a successor physical index tuple that points to the latest version in the table. Each new tuple within each index will generally need to coexist with the original “updated” tuple for a short period of time (typically until shortly after the `UPDATE` transaction commits).

B-Tree indexes incrementally delete version churn index tuples by performing *bottom-up index deletion* passes. Each deletion pass is triggered in reaction to an anticipated “version churn page split”. This only happens with indexes that are not logically modified by `UPDATE` statements, where concentrated build up of obsolete versions in particular pages would occur otherwise. A page split will usually be avoided, though it's possible that certain implementation-level heuristics will fail to identify and delete even one garbage index tuple (in which case a page split or deduplication pass resolves the issue of an incoming new tuple not fitting on a leaf page). The worst-case number of versions that any index scan must traverse (for any single logical row) is an important contributor to overall system responsiveness and throughput. A bottom-up index deletion pass targets suspected garbage tuples in a single leaf page based on *qualitative* distinctions involving logical rows and versions. This contrasts with the “top-down” index cleanup performed by autovacuum workers, which is triggered when certain *quantitative* table-level thresholds are exceeded (see [Section 23.1.6](#)).

Note

Not all deletion operations that are performed within B-Tree indexes are bottom-up deletion operations. There is a distinct category of index tuple deletion: *simple index tuple deletion*. This is a deferred maintenance operation that deletes index tuples that are known to be safe to delete (those whose item identifier's `LP_DEAD` bit is already set). Like bottom-up index deletion, simple index deletion takes place at the point that a page split is anticipated as a way of avoiding the split.

Simple deletion is opportunistic in the sense that it can only take place when recent index scans set the `LP_DEAD` bits of affected items in passing. Prior to Postgres Pro 14, the only category of B-Tree deletion was simple deletion. The main differences between it and bottom-up deletion are that only the former is opportunistically driven by the activity of passing index scans, while only the latter specifically targets version churn from `UPDATES` that do not logically modify indexed columns.

Bottom-up index deletion performs the vast majority of all garbage index tuple cleanup for particular indexes with certain workloads. This is expected with any B-Tree index that is subject to significant version churn from `UPDATES` that rarely or never logically modify the columns that the index covers. The average and worst-case number of versions per logical row can be kept low purely through targeted incremental deletion passes. It's quite possible that the on-disk size of certain indexes will never increase by even one single page/block despite *constant* version churn from `UPDATES`. Even then, an exhaustive “clean sweep” by a `VACUUM` operation (typically run in an autovacuum worker process) will eventually be required as a part of *collective* cleanup of the table and each of its indexes.

Unlike `VACUUM`, bottom-up index deletion does not provide any strong guarantees about how old the oldest garbage index tuple may be. No index can be permitted to retain “floating garbage” index tuples that became dead prior to a conservative cutoff point shared by the table and all of its indexes collectively. This fundamental table-level invariant makes it safe to recycle table TIDs. This is how it is possible for distinct logical rows to reuse the same table TID over time (though this can never happen with two logical rows whose lifetimes span the same `VACUUM` cycle).

63.1.4.3. Deduplication

A duplicate is a leaf page tuple (a tuple that points to a table row) where *all* indexed key columns have values that match corresponding column values from at least one other leaf page tuple in the same index. Duplicate tuples are quite common in practice. B-Tree indexes can use a special, space-efficient representation for duplicates when an optional technique is enabled: *deduplication*.

Deduplication works by periodically merging groups of duplicate tuples together, forming a single *posting list* tuple for each group. The column key value(s) only appear once in this representation. This is followed by a sorted array of TIDs that point to rows in the table. This significantly reduces the storage size of indexes where each value (or each distinct combination of column values) appears several times on average. The latency of queries can be reduced significantly. Overall query throughput may increase significantly. The overhead of routine index vacuuming may also be reduced significantly.

Note

B-Tree deduplication is just as effective with “duplicates” that contain a `NULL` value, even though `NULL` values are never equal to each other according to the `=` member of any B-Tree operator class. As far as any part of the implementation that understands the on-disk B-Tree structure is concerned, `NULL` is just another value from the domain of indexed values.

The deduplication process occurs lazily, when a new item is inserted that cannot fit on an existing leaf page, though only when index tuple deletion could not free sufficient space for the new item (typically deletion is briefly considered and then skipped over). Unlike GIN posting list tuples, B-Tree posting list tuples do not need to expand every time a new duplicate is inserted; they are merely an alternative physical representation of the original logical contents of the leaf page. This design prioritizes consistent performance with mixed read-write workloads. Most client applications will at least see a moderate performance benefit from using deduplication. Deduplication is enabled by default.

`CREATE INDEX` and `REINDEX` apply deduplication to create posting list tuples, though the strategy they use is slightly different. Each group of duplicate ordinary tuples encountered in the sorted input taken from the table is merged into a posting list tuple *before* being added to the current pending leaf page. Individual posting list tuples are packed with as many TIDs as possible. Leaf pages are written out in the usual way, without any separate deduplication pass. This strategy is well-suited to `CREATE INDEX` and `REINDEX` because they are once-off batch operations.

Write-heavy workloads that don't benefit from deduplication due to having few or no duplicate values in indexes will incur a small, fixed performance penalty (unless deduplication is explicitly disabled). The `deduplicate_items` storage parameter can be used to disable deduplication within individual indexes. There is never any performance penalty with read-only workloads, since reading posting list tuples is at least as efficient as reading the standard tuple representation. Disabling deduplication isn't usually helpful.

It is sometimes possible for unique indexes (as well as unique constraints) to use deduplication. This allows leaf pages to temporarily “absorb” extra version churn duplicates. Deduplication in unique indexes augments bottom-up index deletion, especially in cases where a long-running transaction holds a snapshot that blocks garbage collection. The goal is to buy time for the bottom-up index deletion strategy to become effective again. Delaying page splits until a single long-running transaction naturally goes away can allow a bottom-up deletion pass to succeed where an earlier deletion pass failed.

Tip

A special heuristic is applied to determine whether a deduplication pass in a unique index should take place. It can often skip straight to splitting a leaf page, avoiding a performance penalty from wasting cycles on unhelpful deduplication passes. If you're concerned about the overhead of deduplication, consider setting `deduplicate_items = off` selectively. Leaving deduplication enabled in unique indexes has little downside.

Deduplication cannot be used in all cases due to implementation-level restrictions. Deduplication safety is determined when `CREATE INDEX` or `REINDEX` is run.

Note that deduplication is deemed unsafe and cannot be used in the following cases involving semantically significant differences among equal datums:

- `text`, `varchar`, and `char` cannot use deduplication when a *nondeterministic* collation is used. Case and accent differences must be preserved among equal datums.
- `numeric` cannot use deduplication. Numeric display scale must be preserved among equal datums.
- `jsonb` cannot use deduplication, since the `jsonb` B-Tree operator class uses `numeric` internally.
- `float4` and `float8` cannot use deduplication. These types have distinct representations for `-0` and `0`, which are nevertheless considered equal. This difference must be preserved.

There is one further implementation-level restriction that may be lifted in a future version of Postgres Pro:

- Container types (such as composite types, arrays, or range types) cannot use deduplication.

There is one further implementation-level restriction that applies regardless of the operator class or collation used:

- `INCLUDE` indexes can never use deduplication.

63.2. GiST Indexes

63.2.1. Introduction

GiST stands for Generalized Search Tree. It is a balanced, tree-structured access method, that acts as a base template in which to implement arbitrary indexing schemes. B-trees, R-trees and many other indexing schemes can be implemented in GiST.

One advantage of GiST is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from the University of California at Berkeley's GiST Indexing Project [web site](#) and Marcel Kornacker's thesis, *Access Methods for Next-Generation Database Systems*. The GiST implementation in Postgres Pro is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their [web site](#).

63.2.2. Built-in Operator Classes

The core Postgres Pro distribution includes the GiST operator classes shown in [Table 63.1](#). (Some of the optional modules described in [Appendix F](#) provide additional GiST operator classes.)

Table 63.1. Built-in GiST Operator Classes

Name	Indexable Operators	Ordering Operators

	- - (anyrange, anymultirange)	
tsquery_ops	<@ (tsquery, tsquery)	
	@> (tsquery, tsquery)	
tsvector_ops	@@ (tsvector, tsquery)	

For historical reasons, the `inet_ops` operator class is not the default class for types `inet` and `cidr`. To use it, mention the class name in `CREATE INDEX`, for example

```
CREATE INDEX ON my_table USING GIST (my_inet_column inet_ops);
```

63.2.3. Extensibility

Traditionally, implementing a new index access method meant a lot of difficult work. It was necessary to understand the inner workings of the database, such as the lock manager and Write-Ahead Log. The GiST interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GiST layer itself takes care of concurrency, logging and searching the tree structure.

This extensibility should not be confused with the extensibility of the other standard search trees in terms of the data they can handle. For example, Postgres Pro supports extensible B-trees and hash indexes. That means that you can use Postgres Pro to build a B-tree or hash over any data type you want. But B-trees only support range predicates (`<`, `=`, `>`), and hash indexes only support equality queries.

So if you index, say, an image collection with a Postgres Pro B-tree, you can only issue queries such as “is `imagex` equal to `imagey`”, “is `imagex` less than `imagey`” and “is `imagex` greater than `imagey`”. Depending on how you define “equals”, “less than” and “greater than” in this context, this could be useful. However, by using a GiST based index, you could create ways to ask domain-specific questions, perhaps “find all images of horses” or “find all over-exposed images”.

All it takes to get a GiST access method up and running is to implement several user-defined methods, which define the behavior of keys in the tree. Of course these methods have to be pretty fancy to support fancy queries, but for all the standard queries (B-trees, R-trees, etc.) they're relatively straightforward. In short, GiST combines extensibility along with generality, code reuse, and a clean interface.

There are five methods that an index operator class for GiST must provide, and seven that are optional. Correctness of the index is ensured by proper implementation of the `same`, `consistent` and `union` methods, while efficiency (size and speed) of the index will depend on the `penalty` and `picksplit` methods. Two optional methods are `compress` and `decompress`, which allow an index to have internal tree data of a different type than the data it indexes. The leaves are to be of the indexed data type, while the other tree nodes can be of any C struct (but you still have to follow Postgres Pro data type rules here, see about `varlena` for variable sized data). If the tree's internal data type exists at the SQL level, the `STORAGE` option of the `CREATE OPERATOR CLASS` command can be used. The optional eighth method

is `distance`, which is needed if the operator class wishes to support ordered scans (nearest-neighbor searches). The optional ninth method `fetch` is needed if the operator class wishes to support index-only scans, except when the `compress` method is omitted. The optional tenth method `options` is needed if the operator class has user-specified parameters. The optional eleventh method `sortsupport` is used to speed up building a GiST index. The optional twelfth method `stratnum` is used to translate compare types into strategy numbers used by the operator class. This lets the core code look up operators for temporal constraint indexes.

`consistent`

Given an index entry `p` and a query value `q`, this function determines whether the index entry is “consistent” with the query; that is, could the predicate “*indexed_column indexable_operator q*” be true for any row represented by the index entry? For a leaf index entry this is equivalent to testing the indexable condition, while for an internal tree node this determines whether it is necessary to scan the subtree of the index represented by the tree node. When the result is `true`, a `recheck` flag must also be returned. This indicates whether the predicate is certainly true or only possibly true. If `recheck = false` then the index has tested the predicate condition exactly, whereas if `recheck = true` the row is only a candidate match. In that case the system will automatically evaluate the *indexable_operator* against the actual row value to see if it is really a match. This convention allows GiST to support both lossless and lossy index structures.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_consistent(internal, data_type, smallint, oid,
internal)
RETURNS bool
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_consistent);

Datum
my_consistent(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    data_type *query = PG_GETARG_DATA_TYPE_P(1);
    StrategyNumber strategy = (StrategyNumber) PG_GETARG_UINT16(2);
    /* Oid subtype = PG_GETARG_OID(3); */
    bool *recheck = (bool *) PG_GETARG_POINTER(4);
    data_type *key = DatumGetDataTypes(entry->key);
    bool retval;

    /*
     * determine return value as a function of strategy, key and query.
     *
     * Use GIST_LEAF(entry) to know where you're called in the index tree,
     * which comes handy when supporting the = operator for example (you could
     * check for non empty union() in non-leaf nodes and equality in leaf
     * nodes).
     */

    *recheck = true; /* or false if check is exact */

    PG_RETURN_BOOL(retval);
}
```

Here, `key` is an element in the index and `query` the value being looked up in the index. The `StrategyNumber` parameter indicates which operator of your operator class is being applied — it matches one of the operator numbers in the `CREATE OPERATOR CLASS` command.

Depending on which operators you have included in the class, the data type of `query` could vary with the operator, since it will be whatever type is on the right-hand side of the operator, which might be different from the indexed data type appearing on the left-hand side. (The above code skeleton assumes that only one type is possible; if not, fetching the `query` argument value would have to depend on the operator.) It is recommended that the SQL declaration of the `consistent` function use the opclass's indexed data type for the `query` argument, even though the actual type might be something else depending on the operator.

`union`

This method consolidates information in the tree. Given a set of entries, this function generates a new index entry that represents all the given entries.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_union(internal, internal)
RETURNS storage_type
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_union);

Datum
my_union(PG_FUNCTION_ARGS)
{
    GistEntryVector *entryvec = (GistEntryVector *) PG_GETARG_POINTER(0);
    GISTENTRY *ent = entryvec->vector;
    data_type *out,
                *tmp,
                *old;
    int numranges,
        i = 0;

    numranges = entryvec->n;
    tmp = DatumGetDataTypes(ent[0].key);
    out = tmp;

    if (numranges == 1)
    {
        out = data_type_deep_copy(tmp);

        PG_RETURN_DATA_TYPE_P(out);
    }

    for (i = 1; i < numranges; i++)
    {
        old = out;
        tmp = DatumGetDataTypes(ent[i].key);
        out = my_union_implementation(out, tmp);
    }

    PG_RETURN_DATA_TYPE_P(out);
}
```

As you can see, in this skeleton we're dealing with a data type where `union(X, Y, Z) = union(union(X, Y), Z)`. It's easy enough to support data types where this is not the case, by implementing the proper union algorithm in this GiST support method.

The result of the `union` function must be a value of the index's storage type, whatever that is (it might or might not be different from the indexed column's type). The `union` function should return a pointer to newly `palloc()`ed memory. You can't just return the input value as-is, even if there is no type change.

As shown above, the `union` function's first internal argument is actually a `GistEntryVector` pointer. The second argument is a pointer to an integer variable, which can be ignored. (It used to be required that the `union` function store the size of its result value into that variable, but this is no longer necessary.)

`compress`

Converts a data item into a format suitable for physical storage in an index page. If the `compress` method is omitted, data items are stored in the index without modification.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_compress(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_compress);
```

```
Datum
```

```
my_compress(PG_FUNCTION_ARGS)
```

```
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY *retval;

    if (entry->leafkey)
    {
        /* replace entry->key with a compressed version */
        compressed_data_type *compressed_data =
        palloc(sizeof(compressed_data_type));

        /* fill *compressed_data from entry->key ... */

        retval = palloc(sizeof(GISTENTRY));
        gistentryinit(*retval, PointerGetDatum(compressed_data),
                      entry->rel, entry->page, entry->offset, FALSE);
    }
    else
    {
        /* typically we needn't do anything with non-leaf entries */
        retval = entry;
    }

    PG_RETURN_POINTER(retval);
}
```

You have to adapt `compressed_data_type` to the specific type you're converting to in order to compress your leaf nodes, of course.

`decompress`

Converts the stored representation of a data item into a format that can be manipulated by the other GiST methods in the operator class. If the `decompress` method is omitted, it is assumed that the other

GiST methods can work directly on the stored data format. (`decompress` is not necessarily the reverse of the `compress` method; in particular, if `compress` is lossy then it's impossible for `decompress` to exactly reconstruct the original data. `decompress` is not necessarily equivalent to `fetch`, either, since the other GiST methods might not require full reconstruction of the data.)

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_decompress(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_decompress);

Datum
my_decompress(PG_FUNCTION_ARGS)
{
    PG_RETURN_POINTER(PG_GETARG_POINTER(0));
}
```

The above skeleton is suitable for the case where no decompression is needed. (But, of course, omitting the method altogether is even easier, and is recommended in such cases.)

`penalty`

Returns a value indicating the “cost” of inserting the new entry into a particular branch of the tree. Items will be inserted down the path of least `penalty` in the tree. Values returned by `penalty` should be non-negative. If a negative value is returned, it will be treated as zero.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_penalty(internal, internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT; -- in some cases penalty functions need not be strict
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_penalty);

Datum
my_penalty(PG_FUNCTION_ARGS)
{
    GISTENTRY *origentry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY *newentry = (GISTENTRY *) PG_GETARG_POINTER(1);
    float *penalty = (float *) PG_GETARG_POINTER(2);
    data_type *orig = DatumGetDataType(origentry->key);
    data_type *new = DatumGetDataType(newentry->key);

    *penalty = my_penalty_implementation(orig, new);
    PG_RETURN_POINTER(penalty);
}
```

For historical reasons, the `penalty` function doesn't just return a `float` result; instead it has to store the value at the location indicated by the third argument. The return value per se is ignored, though it's conventional to pass back the address of that argument.

The `penalty` function is crucial to good performance of the index. It'll get used at insertion time to determine which branch to follow when choosing where to add the new entry in the tree. At query time, the more balanced the index, the quicker the lookup.

picksplit

When an index page split is necessary, this function decides which entries on the page are to stay on the old page, and which are to move to the new page.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_picksplit(internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_picksplit);

Datum
my_picksplit(PG_FUNCTION_ARGS)
{
    GistEntryVector *entryvec = (GistEntryVector *) PG_GETARG_POINTER(0);
    GIST_SPLITVEC *v = (GIST_SPLITVEC *) PG_GETARG_POINTER(1);
    OffsetNumber maxoff = entryvec->n - 1;
    GISTENTRY *ent = entryvec->vector;
    int i,
        nbytes;
    OffsetNumber *left,
        *right;
    data_type *tmp_union;
    data_type *unionL;
    data_type *unionR;
    GISTENTRY **raw_entryvec;

    maxoff = entryvec->n - 1;
    nbytes = (maxoff + 1) * sizeof(OffsetNumber);

    v->spl_left = (OffsetNumber *) palloc(nbytes);
    left = v->spl_left;
    v->spl_nleft = 0;

    v->spl_right = (OffsetNumber *) palloc(nbytes);
    right = v->spl_right;
    v->spl_nright = 0;

    unionL = NULL;
    unionR = NULL;

    /* Initialize the raw entry vector. */
    raw_entryvec = (GISTENTRY **) malloc(entryvec->n * sizeof(void *));
    for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
        raw_entryvec[i] = &(entryvec->vector[i]);

    for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
    {
        int real_index = raw_entryvec[i] - entryvec->vector;

        tmp_union = DatumGetDataTypes(entryvec->vector[real_index].key);
        Assert(tmp_union != NULL);

        /*
         * Choose where to put the index entries and update unionL and unionR
        */
    }
}
```

```
* accordingly. Append the entries to either v->spl_left or
* v->spl_right, and care about the counters.
*/

if (my_choice_is_left(unionL, curl, unionR, curr))
{
    if (unionL == NULL)
        unionL = tmp_union;
    else
        unionL = my_union_implementation(unionL, tmp_union);

    *left = real_index;
    ++left;
    ++(v->spl_nleft);
}
else
{
    /*
     * Same on the right
     */
}

v->spl_ldatum = DataTypeGetDatum(unionL);
v->spl_rdatum = DataTypeGetDatum(unionR);
PG_RETURN_POINTER(v);
}
```

Notice that the `picksplit` function's result is delivered by modifying the passed-in `v` structure. The return value per se is ignored, though it's conventional to pass back the address of `v`.

Like `penalty`, the `picksplit` function is crucial to good performance of the index. Designing suitable `penalty` and `picksplit` implementations is where the challenge of implementing well-performing GiST indexes lies.

same

Returns true if two index entries are identical, false otherwise. (An “index entry” is a value of the index's storage type, not necessarily the original indexed column's type.)

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_same(storage_type, storage_type, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_same);

Datum
my_same(PG_FUNCTION_ARGS)
{
    prefix_range *v1 = PG_GETARG_PREFIX_RANGE_P(0);
    prefix_range *v2 = PG_GETARG_PREFIX_RANGE_P(1);
    bool          *result = (bool *) PG_GETARG_POINTER(2);

    *result = my_eq(v1, v2);
    PG_RETURN_POINTER(result);
}
```

```
}
```

For historical reasons, the `same` function doesn't just return a Boolean result; instead it has to store the flag at the location indicated by the third argument. The return value per se is ignored, though it's conventional to pass back the address of that argument.

`distance`

Given an index entry `p` and a query value `q`, this function determines the index entry's “distance” from the query value. This function must be supplied if the operator class contains any ordering operators. A query using the ordering operator will be implemented by returning index entries with the smallest “distance” values first, so the results must be consistent with the operator's semantics. For a leaf index entry the result just represents the distance to the index entry; for an internal tree node, the result must be the smallest distance that any child entry could have.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_distance(internal, data_type, smallint, oid, internal)
RETURNS float8
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_distance);

Datum
my_distance(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    data_type *query = PG_GETARG_DATA_TYPE_P(1);
    StrategyNumber strategy = (StrategyNumber) PG_GETARG_UINT16(2);
    /* Oid subtype = PG_GETARG_OID(3); */
    /* bool *recheck = (bool *) PG_GETARG_POINTER(4); */
    data_type *key = DatumGetDataTypes(entry->key);
    double      retval;

    /*
     * determine return value as a function of strategy, key and query.
     */

    PG_RETURN_FLOAT8(retval);
}
```

The arguments to the `distance` function are identical to the arguments of the `consistent` function.

Some approximation is allowed when determining the distance, so long as the result is never greater than the entry's actual distance. Thus, for example, distance to a bounding box is usually sufficient in geometric applications. For an internal tree node, the distance returned must not be greater than the distance to any of the child nodes. If the returned distance is not exact, the function must set `*recheck` to true. (This is not necessary for internal tree nodes; for them, the calculation is always assumed to be inexact.) In this case the executor will calculate the accurate distance after fetching the tuple from the heap, and reorder the tuples if necessary.

If the distance function returns `*recheck = true` for any leaf node, the original ordering operator's return type must be `float8` or `float4`, and the distance function's result values must be comparable to those of the original ordering operator, since the executor will sort using both distance function results and recalculated ordering-operator results. Otherwise, the distance function's result values can be any finite `float8` values, so long as the relative order of the result values matches the order returned by the ordering operator. (Infinity and minus infinity are used internally to handle cases such as nulls, so it is not recommended that `distance` functions return these values.)

fetch

Converts the compressed index representation of a data item into the original data type, for index-only scans. The returned data must be an exact, non-lossy copy of the originally indexed value.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_fetch(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

The argument is a pointer to a `GISTENTRY` struct. On entry, its `key` field contains a non-NULL leaf datum in compressed form. The return value is another `GISTENTRY` struct, whose `key` field contains the same datum in its original, uncompressed form. If the opclass's compress function does nothing for leaf entries, the `fetch` method can return the argument as-is. Or, if the opclass does not have a compress function, the `fetch` method can be omitted as well, since it would necessarily be a no-op.

The matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_fetch);

Datum
my_fetch(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    input_data_type *in = DatumGetPointer(entry->key);
    fetched_data_type *fetched_data;
    GISTENTRY *retval;

    retval = palloc(sizeof(GISTENTRY));
    fetched_data = palloc(sizeof(fetched_data_type));

    /*
     * Convert 'fetched_data' into the a Datum of the original datatype.
     */

    /* fill *retval from fetched_data. */
    gistentryinit(retval, PointerGetDatum(converted_datum),
                  entry->rel, entry->page, entry->offset, FALSE);

    PG_RETURN_POINTER(retval);
}
```

If the compress method is lossy for leaf entries, the operator class cannot support index-only scans, and must not define a `fetch` function.

options

Allows definition of user-visible parameters that control operator class behavior.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_options(internal)
RETURNS void
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

The function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

An example implementation of `my_options()` and parameters use from other support functions are given below:

```
typedef enum MyEnumType
{
    MY_ENUM_ON,
    MY_ENUM_OFF,
    MY_ENUM_AUTO
} MyEnumType;

typedef struct
{
    int32    vl_len_;    /* varlena header (do not touch directly!) */
    int      int_param; /* integer parameter */
    double   real_param; /* real parameter */
    MyEnumType enum_param; /* enum parameter */
    int      str_param; /* string parameter */
} MyOptionsStruct;

/* String representation of enum values */
static relopt_enum_elt_def myEnumValues[] =
{
    {"on", MY_ENUM_ON},
    {"off", MY_ENUM_OFF},
    {"auto", MY_ENUM_AUTO},
    {(const char *) NULL} /* list terminator */
};

static char *str_param_default = "default";

/*
 * Sample validator: checks that string is not longer than 8 bytes.
 */
static void
validate_my_string_relopt(const char *value)
{
    if (strlen(value) > 8)
        ereport(ERROR,
                (errcode(ERRCODE_INVALID_PARAMETER_VALUE),
                 errmsg("str_param must be at most 8 bytes")));
}

/*
 * Sample filler: switches characters to lower case.
 */
static Size
fill_my_string_relopt(const char *value, void *ptr)
{
    char    *tmp = str_tolower(value, strlen(value), DEFAULT_COLLATION_OID);
    int      len = strlen(tmp);

    if (ptr)
        strcpy(ptr, tmp);

    pfree(tmp);
    return len + 1;
}
```

```
PG_FUNCTION_INFO_V1(my_options);

Datum
my_options(PG_FUNCTION_ARGS)
{
    local_relopts *relopts = (local_relopts *) PG_GETARG_POINTER(0);

    init_local_reloptions(relopts, sizeof(MyOptionsStruct));
    add_local_int_reloption(relopts, "int_param", "integer parameter",
                           100, 0, 1000000,
                           offsetof(MyOptionsStruct, int_param));
    add_local_real_reloption(relopts, "real_param", "real parameter",
                             1.0, 0.0, 1000000.0,
                             offsetof(MyOptionsStruct, real_param));
    add_local_enum_reloption(relopts, "enum_param", "enum parameter",
                             myEnumValues, MY_ENUM_ON,
                             "Valid values are: \"on\", \"off\" and \"auto\".",
                             offsetof(MyOptionsStruct, enum_param));
    add_local_string_reloption(relopts, "str_param", "string parameter",
                               str_param_default,
                               &validate_my_string_relopt,
                               &fill_my_string_relopt,
                               offsetof(MyOptionsStruct, str_param));

    PG_RETURN_VOID();
}

PG_FUNCTION_INFO_V1(my_compress);

Datum
my_compress(PG_FUNCTION_ARGS)
{
    int      int_param = 100;
    double   real_param = 1.0;
    MyEnumType enum_param = MY_ENUM_ON;
    char     *str_param = str_param_default;

    /*
     * Normally, when opclass contains 'options' method, then options are always
     * passed to support functions. However, if you add 'options' method to
     * existing opclass, previously defined indexes have no options, so the
     * check is required.
     */
    if (PG_HAS_OPCLASS_OPTIONS())
    {
        MyOptionsStruct *options = (MyOptionsStruct *) PG_GET_OPCLASS_OPTIONS();

        int_param = options->int_param;
        real_param = options->real_param;
        enum_param = options->enum_param;
        str_param = GET_STRING_RELOPTION(options, str_param);
    }

    /* the rest implementation of support function */
}
```

Since the representation of the key in GiST is flexible, it may depend on user-specified parameters. For instance, the length of key signature may be specified. See `gtsvector_options()` for example.

`sortsupport`

Returns a comparator function to sort data in a way that preserves locality. It is used by `CREATE INDEX` and `REINDEX` commands. The quality of the created index depends on how well the sort order determined by the comparator function preserves locality of the inputs.

The `sortsupport` method is optional. If it is not provided, `CREATE INDEX` builds the index by inserting each tuple to the tree using the `penalty` and `picksplit` functions, which is much slower.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_sortsupport(internal)
RETURNS void
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

The argument is a pointer to a `SortSupport` struct. At a minimum, the function must fill in its `comparator` field. The comparator takes three arguments: two `Datums` to compare, and a pointer to the `SortSupport` struct. The `Datums` are the two indexed values in the format that they are stored in the index; that is, in the format returned by the `compress` method. The full API is defined in [src/include/utils/sortsupport.h](#).

The matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_sortsupport);

static int
my_fastcmp(Datum x, Datum y, SortSupport ssup)
{
    /* establish order between x and y by computing some sorting value z */

    int z1 = ComputeSpatialCode(x);
    int z2 = ComputeSpatialCode(y);

    return z1 == z2 ? 0 : z1 > z2 ? 1 : -1;
}

Datum
my_sortsupport(PG_FUNCTION_ARGS)
{
    SortSupport ssup = (SortSupport) PG_GETARG_POINTER(0);

    ssup->comparator = my_fastcmp;
    PG_RETURN_VOID();
}
```

`translate_cmptype`

Given a `CompareType` value, returns a strategy number used by this operator class for matching functionality. The function should return `InvalidStrategy` if the operator class has no matching strategy.

This is used for temporal index constraints (i.e., `PRIMARY KEY` and `UNIQUE`). If the operator class provides this function and it returns results for `COMPARE_EQ`, it can be used in the non-WITHOUT `OVERLAPS` part(s) of an index constraint.

This support function corresponds to the index access method callback function `amtranslatecmptype` (see [Section 61.2](#)). The `amtranslatecmptype` callback function for GiST indexes merely calls down

to the `translate_cmptype` support function of the respective operator family, since the GiST index access method has no fixed strategy numbers itself.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_translate_cmptype(integer)
RETURNS smallint
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the operator family registration must look like this:

```
ALTER OPERATOR FAMILY my_opfamily USING gist ADD
    FUNCTION 12 ("any", "any") my_translate_cmptype(int);
```

The matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_translate_cmptype);

Datum
my_translate_cmptype(PG_FUNCTION_ARGS)
{
    CompareType cmptype = PG_GETARG_INT32(0);
    StrategyNumber ret = InvalidStrategy;

    switch (cmptype)
    {
        case COMPARE_EQ:
            ret = BTEqualStrategyNumber;
    }

    PG_RETURN_UINT16(ret);
}
```

One translation function is provided by Postgres Pro: `gist_translate_cmptype_common` is for operator classes that use the `RT*StrategyNumber` constants. The `btree_gist` extension defines a second translation function, `gist_translate_cmptype_btree`, for operator classes that use the `BT*StrategyNumber` constants.

All the GiST support methods are normally called in short-lived memory contexts; that is, `CurrentMemoryContext` will get reset after each tuple is processed. It is therefore not very important to worry about `pfree`'ing everything you `palloc`. However, in some cases it's useful for a support method to cache data across repeated calls. To do that, allocate the longer-lived data in `fcinfo->flinfo->fn_mcxt`, and keep a pointer to it in `fcinfo->flinfo->fn_extra`. Such data will survive for the life of the index operation (e.g., a single GiST index scan, index build, or index tuple insertion). Be careful to `pfree` the previous value when replacing a `fn_extra` value, or the leak will accumulate for the duration of the operation.

63.2.4. Implementation

63.2.4.1. GiST Index Build Methods

The simplest way to build a GiST index is just to insert all the entries, one by one. This tends to be slow for large indexes, because if the index tuples are scattered across the index and the index is large enough to not fit in cache, a lot of random I/O will be needed. Postgres Pro supports two alternative methods for initial build of a GiST index: *sorted* and *buffered* modes.

The sorted method is only available if each of the opclasses used by the index provides a `sortsupport` function, as described in [Section 63.2.3](#). If they do, this method is usually the best, so it is used by default.

The buffered method works by not inserting tuples directly into the index right away. It can dramatically reduce the amount of random I/O needed for non-ordered data sets. For well-ordered data sets the

benefit is smaller or non-existent, because only a small number of pages receive new tuples at a time, and those pages fit in cache even if the index as a whole does not.

The buffered method needs to call the `penalty` function more often than the simple method does, which consumes some extra CPU resources. Also, the buffers need temporary disk space, up to the size of the resulting index. Buffering can also influence the quality of the resulting index, in both positive and negative directions. That influence depends on various factors, like the distribution of the input data and the operator class implementation.

If sorting is not possible, then by default a GiST index build switches to the buffering method when the index size reaches `effective_cache_size`. Buffering can be manually forced or prevented by the `buffering` parameter to the `CREATE INDEX` command. The default behavior is good for most cases, but turning buffering off might speed up the build somewhat if the input data is ordered.

63.2.5. Examples

The Postgres Pro core system currently provides text search support (indexing for `tsvector` and `tsquery`) as well as R-Tree equivalent functionality for some of the built-in geometric data types. The following `contrib` modules also contain GiST operator classes:

`btree_gist`

B-tree equivalent functionality for several data types

`cube`

Indexing for multidimensional cubes

`hstore`

Module for storing (key, value) pairs

`intarray`

RD-Tree for one-dimensional array of `int4` values

`ltree`

Indexing for tree-like structures

`pg_trgm`

Text similarity using trigram matching

`seg`

Indexing for “float ranges”

63.3. SP-GiST Indexes

63.3.1. Introduction

SP-GiST is an abbreviation for space-partitioned GiST. SP-GiST supports partitioned search trees, which facilitate development of a wide range of different non-balanced data structures, such as quad-trees, k-d trees, and radix trees (tries). The common feature of these structures is that they repeatedly divide the search space into partitions that need not be of equal size. Searches that are well matched to the partitioning rule can be very fast.

These popular data structures were originally developed for in-memory usage. In main memory, they are usually designed as a set of dynamically allocated nodes linked by pointers. This is not suitable for direct storing on disk, since these chains of pointers can be rather long which would require too many disk accesses. In contrast, disk-based data structures should have a high fanout to minimize I/O. The challenge addressed by SP-GiST is to map search tree nodes to disk pages in such a way that a search need access only a few disk pages, even if it traverses many nodes.

Like GiST, SP-GiST is meant to allow the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from Purdue University's SP-GiST Indexing Project [web site](#). The SP-GiST implementation in Postgres Pro is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their [web site](#).

63.3.2. Built-in Operator Classes

The core Postgres Pro distribution includes the SP-GiST operator classes shown in [Table 63.2](#).

Table 63.2. Built-in SP-GiST Operator Classes

Name	Indexable Operators	Ordering Operators
box_ops	<< (box,box)	<-> (box,point)
	&< (box,box)	
	&> (box,box)	
	>> (box,box)	
	<@ (box,box)	
	@> (box,box)	
	~= (box,box)	
	&& (box,box)	
	<< (box,box)	
	&< (box,box)	
	&> (box,box)	
	>> (box,box)	
inet_ops	<< (inet,inet)	
	<<= (inet,inet)	
	>> (inet,inet)	
	>>= (inet,inet)	
	= (inet,inet)	
	<> (inet,inet)	
	< (inet,inet)	
	<= (inet,inet)	
	> (inet,inet)	
	>= (inet,inet)	
	&& (inet,inet)	
kd_point_ops	>> (point,point)	<-> (point,point)
	<< (point,point)	
	>> (point,point)	
	<< (point,point)	
	~= (point,point)	
	<@ (point,box)	
poly_ops	<< (polygon,polygon)	<-> (polygon,point)
	&< (polygon,polygon)	
	&> (polygon,polygon)	

Name	Indexable Operators	Ordering Operators
	>> (polygon,polygon) <@ (polygon,polygon) @> (polygon,polygon) ~= (polygon,polygon) && (polygon,polygon) << (polygon,polygon) &< (polygon,polygon) >> (polygon,polygon) &> (polygon,polygon)	
quad_point_ops	>> (point,point) << (point,point) >> (point,point) << (point,point) ~= (point,point) <@ (point,box)	<-> (point,point)
range_ops	= (anyrange,anyrange) && (anyrange,anyrange) @> (anyrange,anyelement) @> (anyrange,anyrange) <@ (anyrange,anyrange) << (anyrange,anyrange) >> (anyrange,anyrange) &< (anyrange,anyrange) &> (anyrange,anyrange) - - (anyrange,anyrange)	
text_ops	= (text,text) < (text,text) <= (text,text) > (text,text) >= (text,text) ~<~ (text,text) ~<=~ (text,text) ~>=~ (text,text) ~>~ (text,text) ^@ (text,text)	

Of the two operator classes for type `point`, `quad_point_ops` is the default. `kd_point_ops` supports the same operators but uses a different index data structure that may offer better performance in some applications.

The `quad_point_ops`, `kd_point_ops` and `poly_ops` operator classes support the `<->` ordering operator, which enables the k-nearest neighbor (k-NN) search over indexed point or polygon data sets.

63.3.3. Extensibility

SP-GiST offers an interface with a high level of abstraction, requiring the access method developer to implement only methods specific to a given data type. The SP-GiST core is responsible for efficient disk mapping and searching the tree structure. It also takes care of concurrency and logging considerations.

Leaf tuples of an SP-GiST tree usually contain values of the same data type as the indexed column, although it is also possible for them to contain lossy representations of the indexed column. Leaf tuples stored at the root level will directly represent the original indexed data value, but leaf tuples at lower levels might contain only a partial value, such as a suffix. In that case the operator class support functions must be able to reconstruct the original value using information accumulated from the inner tuples that are passed through to reach the leaf level.

When an SP-GiST index is created with `INCLUDE` columns, the values of those columns are also stored in leaf tuples. The `INCLUDE` columns are of no concern to the SP-GiST operator class, so they are not discussed further here.

Inner tuples are more complex, since they are branching points in the search tree. Each inner tuple contains a set of one or more *nodes*, which represent groups of similar leaf values. A node contains a downlink that leads either to another, lower-level inner tuple, or to a short list of leaf tuples that all lie on the same index page. Each node normally has a *label* that describes it; for example, in a radix tree the node label could be the next character of the string value. (Alternatively, an operator class can omit the node labels, if it works with a fixed set of nodes for all inner tuples; see [Section 63.3.4.2](#).) Optionally, an inner tuple can have a *prefix* value that describes all its members. In a radix tree this could be the common prefix of the represented strings. The prefix value is not necessarily really a prefix, but can be any data needed by the operator class; for example, in a quad-tree it can store the central point that the four quadrants are measured with respect to. A quad-tree inner tuple would then also contain four nodes corresponding to the quadrants around this central point.

Some tree algorithms require knowledge of level (or depth) of the current tuple, so the SP-GiST core provides the possibility for operator classes to manage level counting while descending the tree. There is also support for incrementally reconstructing the represented value when that is needed, and for passing down additional data (called *traverse values*) during a tree descent.

Note

The SP-GiST core code takes care of null entries. Although SP-GiST indexes do store entries for nulls in indexed columns, this is hidden from the index operator class code: no null index entries or search conditions will ever be passed to the operator class methods. (It is assumed that SP-GiST operators are strict and so cannot succeed for null values.) Null values are therefore not discussed further here.

There are five user-defined methods that an index operator class for SP-GiST must provide, and two are optional. All five mandatory methods follow the convention of accepting two `internal` arguments, the first of which is a pointer to a C struct containing input values for the support method, while the second argument is a pointer to a C struct where output values must be placed. Four of the mandatory methods just return `void`, since all their results appear in the output struct; but `leaf_consistent` returns a `boolean` result. The methods must not modify any fields of their input structs. In all cases, the output struct is initialized to zeroes before calling the user-defined method. The optional sixth method `compress` accepts a `datum` to be indexed as the only argument and returns a value suitable for physical storage in a leaf tuple. The optional seventh method `options` accepts an `internal` pointer to a C struct, where opclass-specific parameters should be placed, and returns `void`.

The five mandatory user-defined methods are:

`config`

Returns static information about the index implementation, including the data type OIDs of the prefix and node label data types.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_config(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgConfigIn` C struct, containing input data for the function. The second argument is a pointer to a `spgConfigOut` C struct, which the function must fill with result data.

```
typedef struct spgConfigIn
{
    Oid          attType;          /* Data type to be indexed */
} spgConfigIn;

typedef struct spgConfigOut
{
    Oid          prefixType;       /* Data type of inner-tuple prefixes */
    Oid          labelType;       /* Data type of inner-tuple node labels */
    Oid          leafType;        /* Data type of leaf-tuple values */
    bool         canReturnData;    /* Opclass can reconstruct original data */
    bool         longValuesOK;    /* Opclass can cope with values > 1 page */
} spgConfigOut;
```

`attType` is passed in order to support polymorphic index operator classes; for ordinary fixed-data-type operator classes, it will always have the same value and so can be ignored.

For operator classes that do not use prefixes, `prefixType` can be set to `VOIDOID`. Likewise, for operator classes that do not use node labels, `labelType` can be set to `VOIDOID`. `canReturnData` should be set true if the operator class is capable of reconstructing the originally-supplied index value. `longValuesOK` should be set true only when the `attType` is of variable length and the operator class is capable of segmenting long values by repeated suffixing (see [Section 63.3.4.1](#)).

`leafType` should match the index storage type defined by the operator class's `opkeytype` catalog entry. (Note that `opkeytype` can be zero, implying the storage type is the same as the operator class's input type, which is the most common situation.) For reasons of backward compatibility, the `config` method can set `leafType` to some other value, and that value will be used; but this is deprecated since the index contents are then incorrectly identified in the catalogs. Also, it's permissible to leave `leafType` uninitialized (zero); that is interpreted as meaning the index storage type derived from `opkeytype`.

When `attType` and `leafType` are different, the optional method `compress` must be provided. Method `compress` is responsible for transformation of datums to be indexed from `attType` to `leafType`.

`choose`

Chooses a method for inserting a new value into an inner tuple.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_choose(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgChooseIn` C struct, containing input data for the function. The second argument is a pointer to a `spgChooseOut` C struct, which the function must fill with result data.

```
typedef struct spgChooseIn
{
    Datum        datum;          /* original datum to be indexed */
    Datum        leafDatum;      /* current datum to be stored at leaf */
    int          level;          /* current level (counting from zero) */

    /* Data from current inner tuple */
    bool         allTheSame;     /* tuple is marked all-the-same? */
    bool         hasPrefix;      /* tuple has a prefix? */
    Datum        prefixDatum;    /* if so, the prefix value */
    int          nNodes;         /* number of nodes in the inner tuple */
    Datum        *nodeLabels;    /* node label values (NULL if none) */
}
```

```

} spgChooseIn;

typedef enum spgChooseResultType
{
    spgMatchNode = 1,          /* descend into existing node */
    spgAddNode,                /* add a node to the inner tuple */
    spgSplitTuple              /* split inner tuple (change its prefix) */
} spgChooseResultType;

typedef struct spgChooseOut
{
    spgChooseResultType resultType; /* action code, see above */
    union
    {
        struct /* results for spgMatchNode */
        {
            int      nodeN; /* descend to this node (index from 0) */
            int      levelAdd; /* increment level by this much */
            Datum     restDatum; /* new leaf datum */
        } matchNode;
        struct /* results for spgAddNode */
        {
            Datum     nodeLabel; /* new node's label */
            int      nodeN; /* where to insert it (index from 0) */
        } addNode;
        struct /* results for spgSplitTuple */
        {
            /* Info to form new upper-level inner tuple with one child tuple */
            bool      prefixHasPrefix; /* tuple should have a prefix? */
            Datum     prefixPrefixDatum; /* if so, its value */
            int      prefixNNodes; /* number of nodes */
            Datum     *prefixNodeLabels; /* their labels (or NULL for
                                         * no labels) */
            int      childNodeN; /* which node gets child tuple */

            /* Info to form new lower-level inner tuple with all old nodes */
            bool      postfixHasPrefix; /* tuple should have a prefix? */
            Datum     postfixPrefixDatum; /* if so, its value */
        } splitTuple;
    } result;
} spgChooseOut;

```

`datum` is the original datum of `spgConfigIn.attType` type that was to be inserted into the index. `leafDatum` is a value of `spgConfigOut.leafType` type, which is initially a result of method `compress` applied to `datum` when method `compress` is provided, or the same value as `datum` otherwise. `leafDatum` can change at lower levels of the tree if the `choose` or `picksplit` methods change it. When the insertion search reaches a leaf page, the current value of `leafDatum` is what will be stored in the newly created leaf tuple. `level` is the current inner tuple's level, starting at zero for the root level. `allTheSame` is true if the current inner tuple is marked as containing multiple equivalent nodes (see [Section 63.3.4.3](#)). `hasPrefix` is true if the current inner tuple contains a prefix; if so, `prefixDatum` is its value. `nNodes` is the number of child nodes contained in the inner tuple, and `nodeLabels` is an array of their label values, or NULL if there are no labels.

The `choose` function can determine either that the new value matches one of the existing child nodes, or that a new child node must be added, or that the new value is inconsistent with the tuple prefix and so the inner tuple must be split to create a less restrictive prefix.

If the new value matches one of the existing child nodes, set `resultType` to `spgMatchNode`. Set `nodeN` to the index (from zero) of that node in the node array. Set `levelAdd` to the increment in `level`

caused by descending through that node, or leave it as zero if the operator class does not use levels. Set `restDatum` to equal `leafDatum` if the operator class does not modify datums from one level to the next, or otherwise set it to the modified value to be used as `leafDatum` at the next level.

If a new child node must be added, set `resultType` to `spgAddNode`. Set `nodeLabel` to the label to be used for the new node, and set `nodeN` to the index (from zero) at which to insert the node in the node array. After the node has been added, the `choose` function will be called again with the modified inner tuple; that call should result in an `spgMatchNode` result.

If the new value is inconsistent with the tuple prefix, set `resultType` to `spgSplitTuple`. This action moves all the existing nodes into a new lower-level inner tuple, and replaces the existing inner tuple with a tuple having a single downlink pointing to the new lower-level inner tuple. Set `prefixHasPrefix` to indicate whether the new upper tuple should have a prefix, and if so set `prefixPrefixDatum` to the prefix value. This new prefix value must be sufficiently less restrictive than the original to accept the new value to be indexed. Set `prefixNNodes` to the number of nodes needed in the new tuple, and set `prefixNodeLabels` to a palloc'd array holding their labels, or to NULL if node labels are not required. Note that the total size of the new upper tuple must be no more than the total size of the tuple it is replacing; this constrains the lengths of the new prefix and new labels. Set `childNodeN` to the index (from zero) of the node that will downlink to the new lower-level inner tuple. Set `postfixHasPrefix` to indicate whether the new lower-level inner tuple should have a prefix, and if so set `postfixPrefixDatum` to the prefix value. The combination of these two prefixes and the downlink node's label (if any) must have the same meaning as the original prefix, because there is no opportunity to alter the node labels that are moved to the new lower-level tuple, nor to change any child index entries. After the node has been split, the `choose` function will be called again with the replacement inner tuple. That call may return an `spgAddNode` result, if no suitable node was created by the `spgSplitTuple` action. Eventually `choose` must return `spgMatchNode` to allow the insertion to descend to the next level.

`picksplit`

Decides how to create a new inner tuple over a set of leaf tuples.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_picksplit(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgPickSplitIn` C struct, containing input data for the function. The second argument is a pointer to a `spgPickSplitOut` C struct, which the function must fill with result data.

```
typedef struct spgPickSplitIn
{
    int          nTuples;          /* number of leaf tuples */
    Datum        *datums;          /* their datums (array of length nTuples) */
    int          level;           /* current level (counting from zero) */
} spgPickSplitIn;

typedef struct spgPickSplitOut
{
    bool         hasPrefix;        /* new inner tuple should have a prefix? */
    Datum        prefixDatum;      /* if so, its value */

    int          nNodes;           /* number of nodes for new inner tuple */
    Datum        *nodeLabels;      /* their labels (or NULL for no labels) */

    int          *mapTuplesToNodes; /* node index for each leaf tuple */
    Datum        *leafTupleDatums; /* datum to store in each new leaf tuple */
} spgPickSplitOut;
```

`nTuples` is the number of leaf tuples provided. `datums` is an array of their datum values of `spgConfigOut.leafType` type. `level` is the current level that all the leaf tuples share, which will become the level of the new inner tuple.

Set `hasPrefix` to indicate whether the new inner tuple should have a prefix, and if so set `prefixDatum` to the prefix value. Set `nNodes` to indicate the number of nodes that the new inner tuple will contain, and set `nodeLabels` to an array of their label values, or to NULL if node labels are not required. Set `mapTuplesToNodes` to an array that gives the index (from zero) of the node that each leaf tuple should be assigned to. Set `leafTupleDatums` to an array of the values to be stored in the new leaf tuples (these will be the same as the input `datums` if the operator class does not modify datums from one level to the next). Note that the `picksplit` function is responsible for `palloc`'ing the `nodeLabels`, `mapTuplesToNodes` and `leafTupleDatums` arrays.

If more than one leaf tuple is supplied, it is expected that the `picksplit` function will classify them into more than one node; otherwise it is not possible to split the leaf tuples across multiple pages, which is the ultimate purpose of this operation. Therefore, if the `picksplit` function ends up placing all the leaf tuples in the same node, the core SP-GiST code will override that decision and generate an inner tuple in which the leaf tuples are assigned at random to several identically-labeled nodes. Such a tuple is marked `allTheSame` to signify that this has happened. The `choose` and `inner_consistent` functions must take suitable care with such inner tuples. See [Section 63.3.4.3](#) for more information.

`picksplit` can be applied to a single leaf tuple only in the case that the `config` function set `long-ValuesOK` to true and a larger-than-a-page input value has been supplied. In this case the point of the operation is to strip off a prefix and produce a new, shorter leaf datum value. The call will be repeated until a leaf datum short enough to fit on a page has been produced. See [Section 63.3.4.1](#) for more information.

`inner_consistent`

Returns set of nodes (branches) to follow during tree search.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_inner_consistent(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgInnerConsistentIn` C struct, containing input data for the function. The second argument is a pointer to a `spgInnerConsistentOut` C struct, which the function must fill with result data.

```
typedef struct spgInnerConsistentIn
{
    ScanKey      scankeys;          /* array of operators and comparison values */
    ScanKey      orderbys;          /* array of ordering operators and comparison
                                     * values */
    int          nkeys;             /* length of scankeys array */
    int          norderbys;         /* length of orderbys array */

    Datum        reconstructedValue; /* value reconstructed at parent */
    void         *traversalValue;    /* opclass-specific traverse value */
    MemoryContext traversalMemoryContext; /* put new traverse values here */
    int          level;             /* current level (counting from zero) */
    bool         returnData;        /* original data must be returned? */

    /* Data from current inner tuple */
    bool         allTheSame;        /* tuple is marked all-the-same? */
    bool         hasPrefix;         /* tuple has a prefix? */
    Datum        prefixDatum;       /* if so, the prefix value */
    int          nNodes;            /* number of nodes in the inner tuple */
    Datum        *nodeLabels;       /* node label values (NULL if none) */
} spgInnerConsistentIn;

typedef struct spgInnerConsistentOut
{
    int          nNodes;            /* number of child nodes to be visited */
    int          *nodeNumbers;      /* their indexes in the node array */
}
```

```

int          *levelAdds;          /* increment level by this much for each */
Datum        *reconstructedValues; /* associated reconstructed values */
void         **traversalValues;   /* opclass-specific traverse values */
double       **distances;         /* associated distances */
} spgInnerConsistentOut;

```

The array `scankeys`, of length `nkeys`, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them are interesting. (Note that `nkeys = 0` implies that all index entries satisfy the query.) Usually the consistent function only cares about the `sk_strategy` and `sk_argument` fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check `sk_flags` to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions. The array `orderbys`, of length `norderbys`, describes ordering operators (if any) in the same manner. `reconstructedValue` is the value reconstructed for the parent tuple; it is (Datum) 0 at the root level or if the `inner_consistent` function did not provide a value at the parent level. `traversalValue` is a pointer to any traverse data passed down from the previous call of `inner_consistent` on the parent index tuple, or NULL at the root level. `traversalMemoryContext` is the memory context in which to store output traverse values (see below). `level` is the current inner tuple's level, starting at zero for the root level. `returnData` is true if reconstructed data is required for this query; this will only be so if the `config` function asserted `canReturnData`. `allTheSame` is true if the current inner tuple is marked “all-the-same”; in this case all the nodes have the same label (if any) and so either all or none of them match the query (see [Section 63.3.4.3](#)). `hasPrefix` is true if the current inner tuple contains a prefix; if so, `prefixDatum` is its value. `nNodes` is the number of child nodes contained in the inner tuple, and `nodeLabels` is an array of their label values, or NULL if the nodes do not have labels.

`nNodes` must be set to the number of child nodes that need to be visited by the search, and `nodeNumbers` must be set to an array of their indexes. If the operator class keeps track of levels, set `levelAdds` to an array of the level increments required when descending to each node to be visited. (Often these increments will be the same for all the nodes, but that's not necessarily so, so an array is used.) If value reconstruction is needed, set `reconstructedValues` to an array of the values reconstructed for each child node to be visited; otherwise, leave `reconstructedValues` as NULL. The reconstructed values are assumed to be of type `spgConfigOut.leafType`. (However, since the core system will do nothing with them except possibly copy them, it is sufficient for them to have the same `typlen` and `typbyval` properties as `leafType`.) If ordered search is performed, set `distances` to an array of distance values according to `orderbys` array (nodes with lowest distances will be processed first). Leave it NULL otherwise. If it is desired to pass down additional out-of-band information (“traverse values”) to lower levels of the tree search, set `traversalValues` to an array of the appropriate traverse values, one for each child node to be visited; otherwise, leave `traversalValues` as NULL. Note that the `inner_consistent` function is responsible for `palloc`'ing the `nodeNumbers`, `levelAdds`, `distances`, `reconstructedValues`, and `traversalValues` arrays in the current memory context. However, any output traverse values pointed to by the `traversalValues` array should be allocated in `traversalMemoryContext`. Each traverse value must be a single `palloc`'d chunk.

`leaf_consistent`

Returns true if a leaf tuple satisfies a query.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_leaf_consistent(internal, internal) RETURNS bool ...
```

The first argument is a pointer to a `spgLeafConsistentIn` C struct, containing input data for the function. The second argument is a pointer to a `spgLeafConsistentOut` C struct, which the function must fill with result data.

```

typedef struct spgLeafConsistentIn
{
    ScanKey      scankeys;          /* array of operators and comparison values */
    ScanKey      orderbys;          /* array of ordering operators and comparison
                                   * values */
    int          nkeys;             /* length of scankeys array */

```

```
int            norderbys;        /* length of orderbys array */

Datum          reconstructedValue; /* value reconstructed at parent */
void          *traversalValue; /* opclass-specific traverse value */
int            level;           /* current level (counting from zero) */
bool           returnData;      /* original data must be returned? */

Datum          leafDatum;        /* datum in leaf tuple */
} spgLeafConsistentIn;

typedef struct spgLeafConsistentOut
{
    Datum          leafValue;      /* reconstructed original data, if any */
    bool           recheck;        /* set true if operator must be rechecked */
    bool           recheckDistances; /* set true if distances must be rechecked */
    double         *distances;     /* associated distances */
} spgLeafConsistentOut;
```

The array `scankeys`, of length `nkeys`, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them satisfy the query. (Note that `nkeys = 0` implies that all index entries satisfy the query.) Usually the consistent function only cares about the `sk_strategy` and `sk_argument` fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check `sk_flags` to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions. The array `orderbys`, of length `norderbys`, describes the ordering operators in the same manner. `reconstructedValue` is the value reconstructed for the parent tuple; it is (Datum) 0 at the root level or if the `inner_consistent` function did not provide a value at the parent level. `traversalValue` is a pointer to any traverse data passed down from the previous call of `inner_consistent` on the parent index tuple, or NULL at the root level. `level` is the current leaf tuple's level, starting at zero for the root level. `returnData` is true if reconstructed data is required for this query; this will only be so if the `config` function asserted `canReturnData`. `leafDatum` is the key value of `spgConfigOut.leafType` stored in the current leaf tuple.

The function must return `true` if the leaf tuple matches the query, or `false` if not. In the `true` case, if `returnData` is `true` then `leafValue` must be set to the value (of type `spgConfigIn.attType`) originally supplied to be indexed for this leaf tuple. Also, `recheck` may be set to `true` if the match is uncertain and so the operator(s) must be re-applied to the actual heap tuple to verify the match. If ordered search is performed, set `distances` to an array of distance values according to `orderbys` array. Leave it NULL otherwise. If at least one of returned distances is not exact, set `recheckDistances` to `true`. In this case, the executor will calculate the exact distances after fetching the tuple from the heap, and will reorder the tuples if needed.

The optional user-defined methods are:

`Datum compress(Datum in)`

Converts a data item into a format suitable for physical storage in a leaf tuple of the index. It accepts a value of type `spgConfigIn.attType` and returns a value of type `spgConfigOut.leafType`. The output value must not contain an out-of-line TOAST pointer.

Note: the `compress` method is only applied to values to be stored. The consistent methods receive query `scankeys` unchanged, without transformation using `compress`.

`options`

Defines a set of user-visible parameters that control operator class behavior.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_options(internal)
RETURNS void
```

```
AS 'MODULE_PATHNAME'  
LANGUAGE C STRICT;
```

The function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

Since the representation of the key in SP-GiST is flexible, it may depend on user-specified parameters.

All the SP-GiST support methods are normally called in a short-lived memory context; that is, `CurrentMemoryContext` will be reset after processing of each tuple. It is therefore not very important to worry about pfree'ing everything you palloc. (The `config` method is an exception: it should try to avoid leaking memory. But usually the `config` method need do nothing but assign constants into the passed parameter struct.)

If the indexed column is of a collatable data type, the index collation will be passed to all the support methods, using the standard `PG_GET_COLLATION()` mechanism.

63.3.4. Implementation

This section covers implementation details and other tricks that are useful for implementers of SP-GiST operator classes to know.

63.3.4.1. SP-GiST Limits

Individual leaf tuples and inner tuples must fit on a single index page (8kB by default). Therefore, when indexing values of variable-length data types, long values can only be supported by methods such as radix trees, in which each level of the tree includes a prefix that is short enough to fit on a page, and the final leaf level includes a suffix also short enough to fit on a page. The operator class should set `longValuesOK` to true only if it is prepared to arrange for this to happen. Otherwise, the SP-GiST core will reject any request to index a value that is too large to fit on an index page.

Likewise, it is the operator class's responsibility that inner tuples do not grow too large to fit on an index page; this limits the number of child nodes that can be used in one inner tuple, as well as the maximum size of a prefix value.

Another limitation is that when an inner tuple's node points to a set of leaf tuples, those tuples must all be in the same index page. (This is a design decision to reduce seeking and save space in the links that chain such tuples together.) If the set of leaf tuples grows too large for a page, a split is performed and an intermediate inner tuple is inserted. For this to fix the problem, the new inner tuple *must* divide the set of leaf values into more than one node group. If the operator class's `picksplit` function fails to do that, the SP-GiST core resorts to extraordinary measures described in [Section 63.3.4.3](#).

When `longValuesOK` is true, it is expected that successive levels of the SP-GiST tree will absorb more and more information into the prefixes and node labels of the inner tuples, making the required leaf datum smaller and smaller, so that eventually it will fit on a page. To prevent bugs in operator classes from causing infinite insertion loops, the SP-GiST core will raise an error if the leaf datum does not become any smaller within ten cycles of `choose` method calls.

63.3.4.2. SP-GiST Without Node Labels

Some tree algorithms use a fixed set of nodes for each inner tuple; for example, in a quad-tree there are always exactly four nodes corresponding to the four quadrants around the inner tuple's centroid point. In such a case the code typically works with the nodes by number, and there is no need for explicit node labels. To suppress node labels (and thereby save some space), the `picksplit` function can return NULL for the `nodeLabels` array, and likewise the `choose` function can return NULL for the `prefixNodeLabels` array during a `spgSplitTuple` action. This will in turn result in `nodeLabels` being NULL during subsequent calls to `choose` and `inner_consistent`. In principle, node labels could be used for some inner tuples and omitted for others in the same index.

When working with an inner tuple having unlabeled nodes, it is an error for `choose` to return `spgAddNode`, since the set of nodes is supposed to be fixed in such cases.

63.3.4.3. “All-the-Same” Inner Tuples

The SP-GiST core can override the results of the operator class's `picksplit` function when `picksplit` fails to divide the supplied leaf values into at least two node categories. When this happens, the new inner tuple is created with multiple nodes that each have the same label (if any) that `picksplit` gave to the one node it did use, and the leaf values are divided at random among these equivalent nodes. The `allTheSame` flag is set on the inner tuple to warn the `choose` and `inner_consistent` functions that the tuple does not have the node set that they might otherwise expect.

When dealing with an `allTheSame` tuple, a `choose` result of `spgMatchNode` is interpreted to mean that the new value can be assigned to any of the equivalent nodes; the core code will ignore the supplied `nodeN` value and descend into one of the nodes at random (so as to keep the tree balanced). It is an error for `choose` to return `spgAddNode`, since that would make the nodes not all equivalent; the `spgSplitTuple` action must be used if the value to be inserted doesn't match the existing nodes.

When dealing with an `allTheSame` tuple, the `inner_consistent` function should return either all or none of the nodes as targets for continuing the index search, since they are all equivalent. This may or may not require any special-case code, depending on how much the `inner_consistent` function normally assumes about the meaning of the nodes.

63.4. GIN Indexes

63.4.1. Introduction

GIN stands for Generalized Inverted Index. GIN is designed for handling cases where the items to be indexed are composite values, and the queries to be handled by the index need to search for element values that appear within the composite items. For example, the items could be documents, and the queries could be searches for documents containing specific words.

We use the word *item* to refer to a composite value that is to be indexed, and the word *key* to refer to an element value. GIN always stores and searches for keys, not item values per se.

A GIN index stores a set of (key, posting list) pairs, where a *posting list* is a set of row IDs in which the key occurs. The same row ID can appear in multiple posting lists, since an item can contain more than one key. Each key value is stored only once, so a GIN index is very compact for cases where the same key appears many times.

GIN is generalized in the sense that the GIN access method code does not need to know the specific operations that it accelerates. Instead, it uses custom strategies defined for particular data types. The strategy defines how keys are extracted from indexed items and query conditions, and how to determine whether a row that contains some of the key values in a query actually satisfies the query.

One advantage of GIN is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert. This is much the same advantage as using GiST.

The GIN implementation in Postgres Pro is primarily maintained by Teodor Sigaev and Oleg Bartunov. There is more information about GIN on their [website](#).

63.4.2. Built-in Operator Classes

The core Postgres Pro distribution includes the GIN operator classes shown in [Table 63.3](#). (Some of the optional modules described in [Appendix F](#) provide additional GIN operator classes.)

Table 63.3. Built-in GIN Operator Classes

Name	Indexable Operators
array_ops	&& (anyarray, anyarray)
	@> (anyarray, anyarray)
	<@ (anyarray, anyarray)

Name	Indexable Operators
	= (anyarray, anyarray)
jsonb_ops	@> (jsonb, jsonb)
	@? (jsonb, jsonpath)
	@@ (jsonb, jsonpath)
	? (jsonb, text)
	? (jsonb, text[])
	?& (jsonb, text[])
jsonb_path_ops	@> (jsonb, jsonb)
	@? (jsonb, jsonpath)
	@@ (jsonb, jsonpath)
tsvector_ops	@@ (tsvector, tsquery)

Of the two operator classes for type `jsonb`, `jsonb_ops` is the default. `jsonb_path_ops` supports fewer operators but offers better performance for those operators. See [Section 8.14.4](#) for details.

63.4.3. Extensibility

The GIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GIN layer itself takes care of concurrency, logging and searching the tree structure.

All it takes to get a GIN access method working is to implement a few user-defined methods, which define the behavior of keys in the tree and the relationships between keys, indexed items, and indexable queries. In short, GIN combines extensibility with generality, code reuse, and a clean interface.

There are two methods that an operator class for GIN must provide:

```
Datum *extractValue(Datum itemValue, int32 *nkeys, bool **nullFlags)
```

Returns a palloc'd array of keys given an item to be indexed. The number of returned keys must be stored into `*nkeys`. If any of the keys can be null, also palloc an array of `*nkeys` `bool` fields, store its address at `*nullFlags`, and set these null flags as needed. `*nullFlags` can be left `NULL` (its initial value) if all keys are non-null. The return value can be `NULL` if the item contains no keys.

```
Datum *extractQuery(Datum query, int32 *nkeys, StrategyNumber n, bool **pmatch, Pointer
**extra_data, bool **nullFlags, int32 *searchMode)
```

Returns a palloc'd array of keys given a value to be queried; that is, `query` is the value on the right-hand side of an indexable operator whose left-hand side is the indexed column. `n` is the strategy number of the operator within the operator class (see [Section 36.16.2](#)). Often, `extractQuery` will need to consult `n` to determine the data type of `query` and the method it should use to extract key values. The number of returned keys must be stored into `*nkeys`. If any of the keys can be null, also palloc an array of `*nkeys` `bool` fields, store its address at `*nullFlags`, and set these null flags as needed. `*nullFlags` can be left `NULL` (its initial value) if all keys are non-null. The return value can be `NULL` if the query contains no keys.

`searchMode` is an output argument that allows `extractQuery` to specify details about how the search will be done. If `*searchMode` is set to `GIN_SEARCH_MODE_DEFAULT` (which is the value it is initialized to before call), only items that match at least one of the returned keys are considered candidate matches. If `*searchMode` is set to `GIN_SEARCH_MODE_INCLUDE_EMPTY`, then in addition to items containing at least one matching key, items that contain no keys at all are considered candidate matches. (This mode is useful for implementing is-subset-of operators, for example.) If `*searchMode` is set to `GIN_SEARCH_MODE_ALL`, then all non-null items in the index are considered candidate matches, whether they match any of the returned keys or not. (This mode is much slower than the other two choices, since it requires scanning essentially the entire index, but it may be necessary to implement

corner cases correctly. An operator that needs this mode in most cases is probably not a good candidate for a GIN operator class.) The symbols to use for setting this mode are defined in `access/gin.h`.

`pmatch` is an output argument for use when partial match is supported. To use it, `extractQuery` must allocate an array of `*nkeys` `bools` and store its address at `*pmatch`. Each element of the array should be set to `true` if the corresponding key requires partial match, `false` if not. If `*pmatch` is set to `NULL` then GIN assumes partial match is not required. The variable is initialized to `NULL` before call, so this argument can simply be ignored by operator classes that do not support partial match.

`extra_data` is an output argument that allows `extractQuery` to pass additional data to the `consistent` and `comparePartial` methods. To use it, `extractQuery` must allocate an array of `*nkeys` `pointers` and store its address at `*extra_data`, then store whatever it wants to into the individual pointers. The variable is initialized to `NULL` before call, so this argument can simply be ignored by operator classes that do not require extra data. If `*extra_data` is set, the whole array is passed to the `consistent` method, and the appropriate element to the `comparePartial` method.

An operator class must also provide a function to check if an indexed item matches the query. It comes in two flavors, a Boolean `consistent` function, and a ternary `triConsistent` function. `triConsistent` covers the functionality of both, so providing `triConsistent` alone is sufficient. However, if the Boolean variant is significantly cheaper to calculate, it can be advantageous to provide both. If only the Boolean variant is provided, some optimizations that depend on refuting index items before fetching all the keys are disabled.

```
bool consistent(bool check[], StrategyNumber n, Datum query, int32 nkeys, Pointer extra_data[], bool *recheck, Datum queryKeys[], bool nullFlags[])
```

Returns `true` if an indexed item satisfies the query operator with strategy number `n` (or might satisfy it, if the `recheck` indication is returned). This function does not have direct access to the indexed item's value, since GIN does not store items explicitly. Rather, what is available is knowledge about which key values extracted from the query appear in a given indexed item. The `check` array has length `nkeys`, which is the same as the number of keys previously returned by `extractQuery` for this query datum. Each element of the `check` array is `true` if the indexed item contains the corresponding query key, i.e., if `(check[i] == true)` the `i`-th key of the `extractQuery` result array is present in the indexed item. The original query datum is passed in case the `consistent` method needs to consult it, and so are the `queryKeys[]` and `nullFlags[]` arrays previously returned by `extractQuery`. `extra_data` is the extra-data array returned by `extractQuery`, or `NULL` if none.

When `extractQuery` returns a null key in `queryKeys[]`, the corresponding `check[]` element is `true` if the indexed item contains a null key; that is, the semantics of `check[]` are like `IS NOT DISTINCT FROM`. The `consistent` function can examine the corresponding `nullFlags[]` element if it needs to tell the difference between a regular value match and a null match.

On success, `*recheck` should be set to `true` if the heap tuple needs to be rechecked against the query operator, or `false` if the index test is exact. That is, a false return value guarantees that the heap tuple does not match the query; a true return value with `*recheck` set to `false` guarantees that the heap tuple does match the query; and a true return value with `*recheck` set to `true` means that the heap tuple might match the query, so it needs to be fetched and rechecked by evaluating the query operator directly against the originally indexed item.

```
GinTernaryValue triConsistent(GinTernaryValue check[], StrategyNumber n, Datum query, int32 nkeys, Pointer extra_data[], Datum queryKeys[], bool nullFlags[])
```

`triConsistent` is similar to `consistent`, but instead of Booleans in the `check` vector, there are three possible values for each key: `GIN_TRUE`, `GIN_FALSE` and `GIN_MAYBE`. `GIN_FALSE` and `GIN_TRUE` have the same meaning as regular Boolean values, while `GIN_MAYBE` means that the presence of that key is not known. When `GIN_MAYBE` values are present, the function should only return `GIN_TRUE` if the item certainly matches whether or not the index item contains the corresponding query keys. Likewise, the function must return `GIN_FALSE` only if the item certainly does not match, whether or not it contains the `GIN_MAYBE` keys. If the result depends on the `GIN_MAYBE` entries, i.e., the match cannot be confirmed or refuted based on the known query keys, the function must return `GIN_MAYBE`.

When there are no `GIN_MAYBE` values in the `check` vector, a `GIN_MAYBE` return value is the equivalent of setting the `recheck` flag in the Boolean `consistent` function.

In addition, GIN must have a way to sort the key values stored in the index. The operator class can define the sort ordering by specifying a comparison method:

```
int compare(Datum a, Datum b)
```

Compares two keys (not indexed items!) and returns an integer less than zero, zero, or greater than zero, indicating whether the first key is less than, equal to, or greater than the second. Null keys are never passed to this function.

Alternatively, if the operator class does not provide a `compare` method, GIN will look up the default btree operator class for the index key data type, and use its comparison function. It is recommended to specify the comparison function in a GIN operator class that is meant for just one data type, as looking up the btree operator class costs a few cycles. However, polymorphic GIN operator classes (such as `array_ops`) typically cannot specify a single comparison function.

An operator class for GIN can optionally supply the following methods:

```
int comparePartial(Datum partial_key, Datum key, StrategyNumber n, Pointer extra_data)
```

Compare a partial-match query key to an index key. Returns an integer whose sign indicates the result: less than zero means the index key does not match the query, but the index scan should continue; zero means that the index key does match the query; greater than zero indicates that the index scan should stop because no more matches are possible. The strategy number `n` of the operator that generated the partial match query is provided, in case its semantics are needed to determine when to end the scan. Also, `extra_data` is the corresponding element of the extra-data array made by `extractQuery`, or `NULL` if none. Null keys are never passed to this function.

```
void options(local_relopts *relopts)
```

Defines a set of user-visible parameters that control operator class behavior.

The `options` function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

Since both key extraction of indexed values and representation of the key in GIN are flexible, they may depend on user-specified parameters.

To support “partial match” queries, an operator class must provide the `comparePartial` method, and its `extractQuery` method must set the `pmatch` parameter when a partial-match query is encountered. See [Section 63.4.4.2](#) for details.

The actual data types of the various `Datum` values mentioned above vary depending on the operator class. The item values passed to `extractValue` are always of the operator class's input type, and all key values must be of the class's `STORAGE` type. The type of the `query` argument passed to `extractQuery`, `consistent` and `triConsistent` is whatever is the right-hand input type of the class member operator identified by the strategy number. This need not be the same as the indexed type, so long as key values of the correct type can be extracted from it. However, it is recommended that the SQL declarations of these three support functions use the opclass's indexed data type for the `query` argument, even though the actual type might be something else depending on the operator.

63.4.4. Implementation

Internally, a GIN index contains a B-tree index constructed over keys, where each key is an element of one or more indexed items (a member of an array, for example) and where each tuple in a leaf page contains either a pointer to a B-tree of heap pointers (a “posting tree”), or a simple list of heap pointers (a “posting list”) when the list is small enough to fit into a single index tuple along with the key value. [Figure 63.1](#) illustrates these components of a GIN index.

As of PostgreSQL 9.1, null key values can be included in the index. Also, placeholder nulls are included in the index for indexed items that are null or contain no keys according to `extractValue`. This allows searches that should find empty items to do so.

Multicolumn GIN indexes are implemented by building a single B-tree over composite values (column number, key value). The key values for different columns can be of different types.

Figure 63.1. GIN Internals

63.4.4.1. GIN Fast Update Technique

Updating a GIN index tends to be slow because of the intrinsic nature of inverted indexes: inserting or updating one heap row can cause many inserts into the index (one for each key extracted from the indexed item). GIN is capable of postponing much of this work by inserting new tuples into a temporary, unsorted list of pending entries. When the table is vacuumed or autoanalyzed, or when `gin_clean_pending_list` function is called, or if the pending list becomes larger than `gin_pending_list_limit`, the entries are moved to the main GIN data structure using the same bulk insert techniques used during initial index creation. This greatly improves GIN index update speed, even counting the additional vacuum overhead. Moreover the overhead work can be done by a background process instead of in foreground query processing.

The main disadvantage of this approach is that searches must scan the list of pending entries in addition to searching the regular index, and so a large list of pending entries will slow searches significantly. Another disadvantage is that, while most updates are fast, an update that causes the pending list to become “too large” will incur an immediate cleanup cycle and thus be much slower than other updates. Proper use of autovacuum can minimize both of these problems.

If consistent response time is more important than update speed, use of pending entries can be disabled by turning off the `fastupdate` storage parameter for a GIN index. See [CREATE INDEX](#) for details.

63.4.4.2. Partial Match Algorithm

GIN can support “partial match” queries, in which the query does not determine an exact match for one or more keys, but the possible matches fall within a reasonably narrow range of key values (within the key sorting order determined by the `compare` support method). The `extractQuery` method, instead of returning a key value to be matched exactly, returns a key value that is the lower bound of the range to be searched, and sets the `pmatch` flag true. The key range is then scanned using the `comparePartial`

method. `comparePartial` must return zero for a matching index key, less than zero for a non-match that is still within the range to be searched, or greater than zero if the index key is past the range that could match.

63.4.5. GIN Tips and Tricks

Create vs. insert

Insertion into a GIN index can be slow due to the likelihood of many keys being inserted for each item. So, for bulk insertions into a table it is advisable to drop the GIN index and recreate it after finishing bulk insertion.

When `fastupdate` is enabled for GIN (see [Section 63.4.4.1](#) for details), the penalty is less than when it is not. But for very large updates it may still be best to drop and recreate the index.

`maintenance_work_mem`

Build time for a GIN index is very sensitive to the `maintenance_work_mem` setting; it doesn't pay to skimp on work memory during index creation.

`gin_pending_list_limit`

During a series of insertions into an existing GIN index that has `fastupdate` enabled, the system will clean up the pending-entry list whenever the list grows larger than `gin_pending_list_limit`. To avoid fluctuations in observed response time, it's desirable to have pending-list cleanup occur in the background (i.e., via autovacuum). Foreground cleanup operations can be avoided by increasing `gin_pending_list_limit` or making autovacuum more aggressive. However, enlarging the threshold of the cleanup operation means that if a foreground cleanup does occur, it will take even longer.

`gin_pending_list_limit` can be overridden for individual GIN indexes by changing storage parameters, which allows each GIN index to have its own cleanup threshold. For example, it's possible to increase the threshold only for the GIN index which can be updated heavily, and decrease it otherwise.

`gin_fuzzy_search_limit`

The primary goal of developing GIN indexes was to create support for highly scalable full-text search in Postgres Pro, and there are often situations when a full-text search returns a very large set of results. Moreover, this often happens when the query contains very frequent words, so that the large result set is not even useful. Since reading many tuples from the disk and sorting them could take a lot of time, this is unacceptable for production. (Note that the index search itself is very fast.)

To facilitate controlled execution of such queries, GIN has a configurable soft upper limit on the number of rows returned: the `gin_fuzzy_search_limit` configuration parameter. It is set to 0 (meaning no limit) by default. If a non-zero limit is set, then the returned set is a subset of the whole result set, chosen at random.

“Soft” means that the actual number of returned results could differ somewhat from the specified limit, depending on the query and the quality of the system's random number generator.

From experience, values in the thousands (e.g., 5000 — 20000) work well.

63.4.6. Limitations

GIN assumes that indexable operators are strict. This means that `extractValue` will not be called at all on a null item value (instead, a placeholder index entry is created automatically), and `extractQuery` will not be called on a null query value either (instead, the query is presumed to be unsatisfiable). Note however that null key values contained within a non-null composite item or query value are supported.

63.4.7. Examples

The core Postgres Pro distribution includes the GIN operator classes previously shown in [Table 63.3](#). The following `contrib` modules also contain GIN operator classes:

`btree_gin`

B-tree equivalent functionality for several data types

`hstore`

Module for storing (key, value) pairs

`intarray`

Enhanced support for `int[]`

`pg_trgm`

Text similarity using trigram matching

63.5. BRIN Indexes

63.5.1. Introduction

BRIN stands for Block Range Index. BRIN is designed for handling very large tables in which certain columns have some natural correlation with their physical location within the table.

BRIN works in terms of *block ranges* (or “page ranges”). A block range is a group of pages that are physically adjacent in the table; for each block range, some summary info is stored by the index. For example, a table storing a store's sale orders might have a date column on which each order was placed, and most of the time the entries for earlier orders will appear earlier in the table as well; a table storing a ZIP code column might have all codes for a city grouped together naturally.

BRIN indexes can satisfy queries via regular bitmap index scans, and will return all tuples in all pages within each range if the summary info stored by the index is *consistent* with the query conditions. The query executor is in charge of rechecking these tuples and discarding those that do not match the query conditions — in other words, these indexes are lossy. Because a BRIN index is very small, scanning the index adds little overhead compared to a sequential scan, but may avoid scanning large parts of the table that are known not to contain matching tuples.

The specific data that a BRIN index will store, as well as the specific queries that the index will be able to satisfy, depend on the operator class selected for each column of the index. Data types having a linear sort order can have operator classes that store the minimum and maximum value within each block range, for instance; geometrical types might store the bounding box for all the objects in the block range.

The size of the block range is determined at index creation time by the `pages_per_range` storage parameter. The number of index entries will be equal to the size of the relation in pages divided by the selected value for `pages_per_range`. Therefore, the smaller the number, the larger the index becomes (because of the need to store more index entries), but at the same time the summary data stored can be more precise and more data blocks can be skipped during an index scan.

63.5.1.1. Index Maintenance

At the time of creation, all existing heap pages are scanned and a summary index tuple is created for each range, including the possibly-incomplete range at the end. As new pages are filled with data, page ranges that are already summarized will cause the summary information to be updated with data from the new tuples. When a new page is created that does not fall within the last summarized range, the range that the new page belongs to does not automatically acquire a summary tuple; those tuples remain unsummarized until a summarization run is invoked later, creating the initial summary for that range.

There are several ways to trigger the initial summarization of a page range. If the table is vacuumed, either manually or by [autovacuum](#), all existing unsummarized page ranges are summarized. Also, if the index's [autosummarize](#) parameter is enabled, which it isn't by default, whenever [autovacuum](#) runs in that database, summarization will occur for all unsummarized page ranges that have been filled, regardless of whether the table itself is processed by [autovacuum](#); see below.

Lastly, the following functions can be used (while these functions run, [search_path](#) is temporarily changed to `pg_catalog`, `pg_temp`):

`brin_summarize_new_values(regclass)` which summarizes all unsummarized ranges;
`brin_summarize_range(regclass, bigint)` which summarizes only the range containing the given page, if it is unsummarized.

When autosummarization is enabled, a request is sent to `autovacuum` to execute a targeted summarization for a block range when an insertion is detected for the first item of the first page of the next block range, to be fulfilled the next time an `autovacuum` worker finishes running in the same database. If the request queue is full, the request is not recorded and a message is sent to the server log:

LOG: request for BRIN range summarization for index "brin_wi_idx" page 128 was not recorded

When this happens, the range will remain unsummarized until the next regular vacuum run on the table, or one of the functions mentioned above are invoked.

Conversely, a range can be de-summarized using the `brin_desummarize_range(regclass, bigint)` function, which is useful when the index tuple is no longer a very good representation because the existing values have changed. See [Section 9.28.8](#) for details.

63.5.2. Built-in Operator Classes

The core Postgres Pro distribution includes the BRIN operator classes shown in [Table 63.4](#).

The *minmax* operator classes store the minimum and the maximum values appearing in the indexed column within the range. The *inclusion* operator classes store a value which includes the values in the indexed column within the range. The *bloom* operator classes build a Bloom filter for all values in the range. The *minmax-multi* operator classes store multiple minimum and maximum values, representing values appearing in the indexed column within the range.

Table 63.4. Built-in BRIN Operator Classes

63.5.2.1. Operator Class Parameters

Some of the built-in operator classes allow specifying parameters affecting behavior of the operator class. Each operator class has its own set of allowed parameters. Only the `bloom` and `minmax-multi` operator classes allow specifying parameters:

`bloom` operator classes accept these parameters:

`n_distinct_per_range`

Defines the estimated number of distinct non-null values in the block range, used by BRIN bloom indexes for sizing of the Bloom filter. It behaves similarly to `n_distinct` option for [ALTER TABLE](#). When set to a positive value, each block range is assumed to contain this number of distinct non-null values. When set to a negative value, which must be greater than or equal to -1, the number of distinct non-null values is assumed to grow linearly with the maximum possible number of tuples in the block range (about 290 rows per block). The default value is `-0.1`, and the minimum number of distinct non-null values is 16.

`false_positive_rate`

Defines the desired false positive rate used by BRIN bloom indexes for sizing of the Bloom filter. The values must be between 0.0001 and 0.25. The default value is 0.01, which is 1% false positive rate.

`minmax-multi` operator classes accept these parameters:

`values_per_range`

Defines the maximum number of values stored by BRIN minmax indexes to summarize a block range. Each value may represent either a point, or a boundary of an interval. Values must be between 8 and 256, and the default value is 32.

63.5.3. Extensibility

The BRIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The BRIN layer itself takes care of concurrency, logging and searching the index structure.

All it takes to get a BRIN access method working is to implement a few user-defined methods, which define the behavior of summary values stored in the index and the way they interact with scan keys. In short, BRIN combines extensibility with generality, code reuse, and a clean interface.

There are four methods that an operator class for BRIN must provide:

```
BrinOpcInfo *opcInfo(Oid type_oid)
```

Returns internal information about the indexed columns' summary data. The return value must point to a `palloc'd` `BrinOpcInfo`, which has this definition:

```
typedef struct BrinOpcInfo
{
    /* Number of columns stored in an index column of this opclass */
    uint16      oi_nstored;

    /* Opaque pointer for the opclass' private use */
    void        *oi_opaque;

    /* Type cache entries of the stored columns */
    TypeCacheEntry *oi_tpcache[FLEXIBLE_ARRAY_MEMBER];
} BrinOpcInfo;
```

`BrinOpcInfo.oi_opaque` can be used by the operator class routines to pass information between support functions during an index scan.

```
bool consistent(BrinDesc *bdesc, BrinValues *column, ScanKey *keys, int nkeys)
```

Returns whether all the `ScanKey` entries are consistent with the given indexed values for a range. The attribute number to use is passed as part of the scan key. Multiple scan keys for the same attribute may be passed at once; the number of entries is determined by the `nkeys` parameter.

```
bool consistent(BrinDesc *bdesc, BrinValues *column, ScanKey key)
```

Returns whether the `ScanKey` is consistent with the given indexed values for a range. The attribute number to use is passed as part of the scan key. This is an older backward-compatible variant of the `consistent` function.

```
bool addValue(BrinDesc *bdesc, BrinValues *column, Datum newval, bool isnull)
```

Given an index tuple and an indexed value, modifies the indicated attribute of the tuple so that it additionally represents the new value. If any modification was done to the tuple, `true` is returned.

```
bool unionTuples(BrinDesc *bdesc, BrinValues *a, BrinValues *b)
```

Consolidates two index tuples. Given two index tuples, modifies the indicated attribute of the first of them so that it represents both tuples. The second tuple is not modified.

An operator class for BRIN can optionally specify the following method:

```
void options(local_relopts *relopts)
```

Defines a set of user-visible parameters that control operator class behavior.

The `options` function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

Since both key extraction of indexed values and representation of the key in BRIN are flexible, they may depend on user-specified parameters.

The core distribution includes support for four types of operator classes: minmax, minmax-multi, inclusion and bloom. Operator class definitions using them are shipped for in-core data types as appropriate. Additional operator classes can be defined by the user for other data types using equivalent definitions, without having to write any source code; appropriate catalog entries being declared is enough. Note that assumptions about the semantics of operator strategies are embedded in the support functions' source code.

Operator classes that implement completely different semantics are also possible, provided implementations of the four main support functions described above are written. Note that backwards compatibility across major releases is not guaranteed: for example, additional support functions might be required in later releases.

To write an operator class for a data type that implements a totally ordered set, it is possible to use the minmax support functions alongside the corresponding operators, as shown in [Table 63.5](#). All operator class members (functions and operators) are mandatory.

Table 63.5. Function and Support Numbers for Minmax Operator Classes

Operator class member	Object
Support Function 1	internal function <code>brin_minmax_opcinfo()</code>
Support Function 2	internal function <code>brin_minmax_add_value()</code>
Support Function 3	internal function <code>brin_minmax_consistent()</code>
Support Function 4	internal function <code>brin_minmax_union()</code>
Operator Strategy 1	operator less-than
Operator Strategy 2	operator less-than-or-equal-to
Operator Strategy 3	operator equal-to
Operator Strategy 4	operator greater-than-or-equal-to
Operator Strategy 5	operator greater-than

To write an operator class for a complex data type which has values included within another type, it's possible to use the inclusion support functions alongside the corresponding operators, as shown in [Table 63.6](#). It requires only a single additional function, which can be written in any language. More functions can be defined for additional functionality. All operators are optional. Some operators require other operators, as shown as dependencies on the table.

Table 63.6. Function and Support Numbers for Inclusion Operator Classes

Operator class member	Object	Dependency
Support Function 1	internal function <code>brin_inclusion_opcinfo()</code>	
Support Function 2	internal function <code>brin_inclusion_add_value()</code>	
Support Function 3	internal function <code>brin_inclusion_consistent()</code>	
Support Function 4	internal function <code>brin_inclusion_union()</code>	
Support Function 11	function to merge two elements	
Support Function 12	optional function to check whether two elements are mergeable	
Support Function 13	optional function to check if an element is contained within another	

Operator class member	Object	Dependency
Support Function 14	optional function to check whether an element is empty	
Operator Strategy 1	operator left-of	Operator Strategy 4
Operator Strategy 2	operator does-not-extend-to-the-right-of	Operator Strategy 5
Operator Strategy 3	operator overlaps	
Operator Strategy 4	operator does-not-extend-to-the-left-of	Operator Strategy 1
Operator Strategy 5	operator right-of	Operator Strategy 2
Operator Strategy 6, 18	operator same-as-or-equal-to	Operator Strategy 7
Operator Strategy 7, 16, 24, 25	operator contains-or-equal-to	
Operator Strategy 8, 26, 27	operator is-contained-by-or-equal-to	Operator Strategy 3
Operator Strategy 9	operator does-not-extend-above	Operator Strategy 11
Operator Strategy 10	operator is-below	Operator Strategy 12
Operator Strategy 11	operator is-above	Operator Strategy 9
Operator Strategy 12	operator does-not-extend-below	Operator Strategy 10
Operator Strategy 20	operator less-than	Operator Strategy 5
Operator Strategy 21	operator less-than-or-equal-to	Operator Strategy 5
Operator Strategy 22	operator greater-than	Operator Strategy 1
Operator Strategy 23	operator greater-than-or-equal-to	Operator Strategy 1

Support function numbers 1 through 10 are reserved for the BRIN internal functions, so the SQL level functions start with number 11. Support function number 11 is the main function required to build the index. It should accept two arguments with the same data type as the operator class, and return the union of them. The inclusion operator class can store union values with different data types if it is defined with the `STORAGE` parameter. The return value of the union function should match the `STORAGE` data type.

Support function numbers 12 and 14 are provided to support irregularities of built-in data types. Function number 12 is used to support network addresses from different families which are not mergeable. Function number 14 is used to support empty ranges. Function number 13 is an optional but recommended one, which allows the new value to be checked before it is passed to the union function. As the BRIN framework can shortcut some operations when the union is not changed, using this function can improve index performance.

To write an operator class for a data type that implements only an equality operator and supports hashing, it is possible to use the bloom support procedures alongside the corresponding operators, as shown in [Table 63.7](#). All operator class members (procedures and operators) are mandatory.

Table 63.7. Procedure and Support Numbers for Bloom Operator Classes

Operator class member	Object
Support Procedure 1	internal function <code>brin_bloom_opcinfo()</code>
Support Procedure 2	internal function <code>brin_bloom_add_value()</code>
Support Procedure 3	internal function <code>brin_bloom_consistent()</code>
Support Procedure 4	internal function <code>brin_bloom_union()</code>
Support Procedure 5	internal function <code>brin_bloom_options()</code>
Support Procedure 11	function to compute hash of an element
Operator Strategy 1	operator equal-to

Support procedure numbers 1-10 are reserved for the BRIN internal functions, so the SQL level functions start with number 11. Support function number 11 is the main function required to build the index. It should accept one argument with the same data type as the operator class, and return a hash of the value.

The minmax-multi operator class is also intended for data types implementing a totally ordered set, and may be seen as a simple extension of the minmax operator class. While minmax operator class summarizes values from each block range into a single contiguous interval, minmax-multi allows summarization into multiple smaller intervals to improve handling of outlier values. It is possible to use the minmax-multi support procedures alongside the corresponding operators, as shown in [Table 63.8](#). All operator class members (procedures and operators) are mandatory.

Table 63.8. Procedure and Support Numbers for minmax-multi Operator Classes

Operator class member	Object
Support Procedure 1	internal function <code>brin_minmax_multi_opcinfo()</code>
Support Procedure 2	internal function <code>brin_minmax_multi_add_value()</code>
Support Procedure 3	internal function <code>brin_minmax_multi_consistent()</code>
Support Procedure 4	internal function <code>brin_minmax_multi_union()</code>
Support Procedure 5	internal function <code>brin_minmax_multi_options()</code>
Support Procedure 11	function to compute distance between two values (length of a range)
Operator Strategy 1	operator less-than
Operator Strategy 2	operator less-than-or-equal-to
Operator Strategy 3	operator equal-to
Operator Strategy 4	operator greater-than-or-equal-to
Operator Strategy 5	operator greater-than

Both minmax and inclusion operator classes support cross-data-type operators, though with these the dependencies become more complicated. The minmax operator class requires a full set of operators to be defined with both arguments having the same data type. It allows additional data types to be supported by defining extra sets of operators. Inclusion operator class operator strategies are dependent on another operator strategy as shown in [Table 63.6](#), or the same operator strategy as themselves. They require the dependency operator to be defined with the `STORAGE` data type as the left-hand-side argument and the other supported data type to be the right-hand-side argument of the supported operator. See `float4_minmax_ops` as an example of minmax, and `box_inclusion_ops` as an example of inclusion.

63.6. Hash Indexes

63.6.1. Overview

Postgres Pro includes an implementation of persistent on-disk hash indexes, which are fully crash recoverable. Any data type can be indexed by a hash index, including data types that do not have a well-defined linear ordering. Hash indexes store only the hash value of the data being indexed, thus there are no restrictions on the size of the data column being indexed.

Hash indexes support only single-column indexes and do not allow uniqueness checking.

Hash indexes support only the `=` operator, so `WHERE` clauses that specify range operations will not be able to take advantage of hash indexes.

Each hash index tuple stores just the 4-byte hash value, not the actual column value. As a result, hash indexes may be much smaller than B-trees when indexing longer data items such as UUIDs, URLs, etc. The absence of the column value also makes all hash index scans lossy. Hash indexes may take part in bitmap index scans and backward scans.

Hash indexes are best optimized for SELECT and UPDATE-heavy workloads that use equality scans on larger tables. In a B-tree index, searches must descend through the tree until the leaf page is found. In tables with millions of rows, this descent can increase access time to data. The equivalent of a leaf page in a hash index is referred to as a bucket page. In contrast, a hash index allows accessing the bucket pages directly, thereby potentially reducing index access time in larger tables. This reduction in "logical I/O" becomes even more pronounced on indexes/data larger than shared_buffers/RAM.

Hash indexes have been designed to cope with uneven distributions of hash values. Direct access to the bucket pages works well if the hash values are evenly distributed. When inserts mean that the bucket page becomes full, additional overflow pages are chained to that specific bucket page, locally expanding the storage for index tuples that match that hash value. When scanning a hash bucket during queries, we need to scan through all of the overflow pages. Thus an unbalanced hash index might actually be worse than a B-tree in terms of number of block accesses required, for some data.

As a result of the overflow cases, we can say that hash indexes are most suitable for unique, nearly unique data or data with a low number of rows per hash bucket. One possible way to avoid problems is to exclude highly non-unique values from the index using a partial index condition, but this may not be suitable in many cases.

Like B-Trees, hash indexes perform simple index tuple deletion. This is a deferred maintenance operation that deletes index tuples that are known to be safe to delete (those whose item identifier's LP_DEAD bit is already set). If an insert finds no space is available on a page we try to avoid creating a new overflow page by attempting to remove dead index tuples. Removal cannot occur if the page is pinned at that time. Deletion of dead index pointers also occurs during VACUUM.

If it can, VACUUM will also try to squeeze the index tuples onto as few overflow pages as possible, minimizing the overflow chain. If an overflow page becomes empty, overflow pages can be recycled for reuse in other buckets, though we never return them to the operating system. There is currently no provision to shrink a hash index, other than by rebuilding it with REINDEX. There is no provision for reducing the number of buckets, either.

Hash indexes may expand the number of bucket pages as the number of rows indexed grows. The hash key-to-bucket-number mapping is chosen so that the index can be incrementally expanded. When a new bucket is to be added to the index, exactly one existing bucket will need to be "split", with some of its tuples being transferred to the new bucket according to the updated key-to-bucket-number mapping.

The expansion occurs in the foreground, which could increase execution time for user inserts. Thus, hash indexes may not be suitable for tables with rapidly increasing number of rows.

63.6.2. Implementation

There are four kinds of pages in a hash index: the meta page (page zero), which contains statically allocated control information; primary bucket pages; overflow pages; and bitmap pages, which keep track of overflow pages that have been freed and are available for re-use. For addressing purposes, bitmap pages are regarded as a subset of the overflow pages.

Both scanning the index and inserting tuples require locating the bucket where a given tuple ought to be located. To do this, we need the bucket count, highmask, and lowmask from the metapage; however, it's undesirable for performance reasons to have to lock and pin the metapage for every such operation. Instead, we retain a cached copy of the metapage in each backend's relcache entry. This will produce the correct bucket mapping as long as the target bucket hasn't been split since the last cache refresh.

Primary bucket pages and overflow pages are allocated independently since any given index might need more or fewer overflow pages relative to its number of buckets. The hash code uses an interesting set

of addressing rules to support a variable number of overflow pages while not having to move primary bucket pages around after they are created.

Each row in the table indexed is represented by a single index tuple in the hash index. Hash index tuples are stored in bucket pages, and if they exist, overflow pages. We speed up searches by keeping the index entries in any one index page sorted by hash code, thus allowing binary search to be used within an index page. Note however that there is **no** assumption about the relative ordering of hash codes across different index pages of a bucket.

The bucket splitting algorithms to expand the hash index are too complex to be worthy of mention here. The split algorithm is crash safe and can be restarted if not completed successfully.

Chapter 64. Database Physical Storage

This chapter provides an overview of the physical storage format used by Postgres Pro databases.

64.1. Database File Layout

This section describes the storage format at the level of files and directories.

Traditionally, the configuration and data files used by a database cluster are stored together within the cluster's data directory, commonly referred to as `PGDATA` (after the name of the environment variable that can be used to define it). A common location for `PGDATA` is `/var/lib/pgpro/std-18/data`. Multiple clusters, managed by different server instances, can exist on the same machine.

The `PGDATA` directory contains several subdirectories and control files, as shown in [Table 64.1](#). In addition to these required items, the cluster configuration files `postgresql.conf`, `pg_hba.conf`, and `pg_ident.conf` are traditionally stored in `PGDATA`, although it is possible to place them elsewhere.

Table 64.1. Contents of `PGDATA`

Item	Description
<code>PG_VERSION</code>	A file containing the major version number of Postgres Pro
<code>base</code>	Subdirectory containing per-database subdirectories
<code>current_logfiles</code>	File recording the log file(s) currently written to by the logging collector
<code>global</code>	Subdirectory containing cluster-wide tables, such as <code>pg_database</code>
<code>pg_commit_ts</code>	Subdirectory containing transaction commit timestamp data
<code>pg_dynshmem</code>	Subdirectory containing files used by the dynamic shared memory subsystem
<code>pg_logical</code>	Subdirectory containing status data for logical decoding
<code>pg_multixact</code>	Subdirectory containing multitransaction status data (used for shared row locks)
<code>pg_notify</code>	Subdirectory containing LISTEN/NOTIFY status data
<code>pg_replslot</code>	Subdirectory containing replication slot data
<code>pg_serial</code>	Subdirectory containing information about committed serializable transactions
<code>pg_snapshots</code>	Subdirectory containing exported snapshots
<code>pg_stat</code>	Subdirectory containing permanent files for the statistics subsystem
<code>pg_stat_tmp</code>	Subdirectory containing temporary files for the statistics subsystem
<code>pg_subtrans</code>	Subdirectory containing subtransaction status data
<code>pg_tblspc</code>	Subdirectory containing symbolic links to tablespaces
<code>pg_twophase</code>	Subdirectory containing state files for prepared transactions

Item	Description
<code>pg_wal</code>	Subdirectory containing WAL (Write Ahead Log) files
<code>pg_xact</code>	Subdirectory containing transaction commit status data
<code>postgresql.auto.conf</code>	A file used for storing configuration parameters that are set by <code>ALTER SYSTEM</code>
<code>postmaster.opts</code>	A file recording the command-line options the server was last started with
<code>postmaster.pid</code>	A lock file recording the current postmaster process ID (PID), cluster data directory path, postmaster start timestamp, port number, Unix-domain socket directory path (could be empty), first valid listen_address (IP address or *, or empty if not listening on TCP), and shared memory segment ID (this file is not present after server shutdown)

For each database in the cluster there is a subdirectory within `PGDATA/base`, named after the database's OID in `pg_database`. This subdirectory is the default location for the database's files; in particular, its system catalogs are stored there.

Note that the following sections describe the behavior of the builtin heap [table access method](#), and the builtin [index access methods](#). Due to the extensible nature of Postgres Pro, other access methods might work differently.

Each table and index is stored in a separate file. For ordinary relations, these files are named after the table or index's *filenode* number, which can be found in `pg_class.relfilenode`. But for temporary relations, the file name is of the form `tBBB_FFF`, where *BBB* is the process number of the backend which created the file, and *FFF* is the filenode number. In either case, in addition to the main file (a/k/a main fork), each table and index has a *free space map* (see [Section 64.3](#)), which stores information about free space available in the relation. The free space map is stored in a file named with the filenode number plus the suffix `_fsm`. Tables also have a *visibility map*, stored in a fork with the suffix `_vm`, to track which pages are known to have no dead tuples. The visibility map is described further in [Section 64.4](#). Unlogged tables and indexes have a third fork, known as the initialization fork, which is stored in a fork with the suffix `_init` (see [Section 64.5](#)).

Caution

Note that while a table's filenode often matches its OID, this is *not* necessarily the case; some operations, like `TRUNCATE`, `REINDEX`, `CLUSTER` and some forms of `ALTER TABLE`, can change the filenode while preserving the OID. Avoid assuming that filenode and table OID are the same. Also, for certain system catalogs including `pg_class` itself, `pg_class.relfilenode` contains zero. The actual filenode number of these catalogs is stored in a lower-level data structure, and can be obtained using the `pg_relation_filenode()` function.

When a table or index exceeds 1 GB, it is divided into gigabyte-sized *segments*. The first segment's file name is the same as the filenode; subsequent segments are named `filenode.1`, `filenode.2`, etc. This arrangement avoids problems on platforms that have file size limitations. (Actually, 1 GB is just the default segment size. The segment size can be adjusted using the configuration option `--with-segsize` when building Postgres Pro.) In principle, free space map and visibility map forks could require multiple segments as well, though this is unlikely to happen in practice.

A table that has columns with potentially large entries will have an associated *TOAST* table, which is used for out-of-line storage of field values that are too large to keep in the table rows proper. `pg_class.reltoastrelid` links from a table to its TOAST table, if any. See [Section 64.2](#) for more information.

The contents of tables and indexes are discussed further in [Section 64.6](#).

Tablespaces make the scenario more complicated. Each user-defined tablespace has a symbolic link inside the `PGDATA/pg_tblspc` directory, which points to the physical tablespace directory (i.e., the location specified in the tablespace's `CREATE TABLESPACE` command). This symbolic link is named after the tablespace's OID. Inside the physical tablespace directory there is a subdirectory with a name that depends on the Postgres Pro server version, such as `PG_9.0_201008051`. (The reason for using this subdirectory is so that successive versions of the database can use the same `CREATE TABLESPACE` location value without conflicts.) Within the version-specific subdirectory, there is a subdirectory for each database that has elements in the tablespace, named after the database's OID. Tables and indexes are stored within that directory, using the filenode naming scheme. The `pg_default` tablespace is not accessed through `pg_tblspc`, but corresponds to `PGDATA/base`. Similarly, the `pg_global` tablespace is not accessed through `pg_tblspc`, but corresponds to `PGDATA/global`.

The `pg_relation_filepath()` function shows the entire path (relative to `PGDATA`) of any relation. It is often useful as a substitute for remembering many of the above rules. But keep in mind that this function just gives the name of the first segment of the main fork of the relation — you may need to append a segment number and/or `_fsm`, `_vm`, or `_init` to find all the files associated with the relation.

Temporary files (for operations such as sorting more data than can fit in memory) are created within `PGDATA/base/pgsql_tmp`, or within a `pgsql_tmp` subdirectory of a tablespace directory if a tablespace other than `pg_default` is specified for them. The name of a temporary file has the form `pgsql_tmpPPP-P.NNN`, where `PPP` is the PID of the owning backend and `NNN` distinguishes different temporary files of that backend.

64.2. TOAST

This section provides an overview of TOAST (The Oversized-Attribute Storage Technique).

Postgres Pro uses a fixed page size (commonly 8 kB), and does not allow tuples to span multiple pages. Therefore, it is not possible to store very large field values directly. To overcome this limitation, large field values are compressed and/or broken up into multiple physical rows. This happens transparently to the user, with only small impact on most of the backend code. The technique is affectionately known as TOAST (or “the best thing since sliced bread”). The TOAST infrastructure is also used to improve handling of large data values in-memory.

Only certain data types support TOAST — there is no need to impose the overhead on data types that cannot produce large field values. To support TOAST, a data type must have a variable-length (*varlena*) representation, in which, ordinarily, the first four-byte word of any stored value contains the total length of the value in bytes (including itself). TOAST does not constrain the rest of the data type's representation. The special representations collectively called *TOASTed values* work by modifying or reinterpreting this initial length word. Therefore, the C-level functions supporting a TOAST-able data type must be careful about how they handle potentially TOASTed input values: an input might not actually consist of a four-byte length word and contents until after it's been *detoasted*. (This is normally done by invoking `PG_DETOAST_DATUM` before doing anything with an input value, but in some cases more efficient approaches are possible. See [Section 36.13.1](#) for more detail.)

TOAST usurps two bits of the *varlena* length word (the high-order bits on big-endian machines, the low-order bits on little-endian machines), thereby limiting the logical size of any value of a TOAST-able data type to 1 GB (2^{30} - 1 bytes). When both bits are zero, the value is an ordinary un-TOASTed value of the data type, and the remaining bits of the length word give the total datum size (including length word) in bytes. When the highest-order or lowest-order bit is set, the value has only a single-byte header instead of the normal four-byte header, and the remaining bits of that byte give the total datum size (including length byte) in bytes. This alternative supports space-efficient storage of values shorter than 127 bytes, while still allowing the data type to grow to 1 GB at need. Values with single-byte headers aren't aligned on any particular boundary, whereas values with four-byte headers are aligned on at least a four-byte boundary; this omission of alignment padding provides additional space savings that is significant compared to short values. As a special case, if the remaining bits of a single-byte header are all zero (which would be impossible for a self-inclusive length), the value is a pointer to out-of-line

data, with several possible alternatives as described below. The type and size of such a *TOAST pointer* are determined by a code stored in the second byte of the datum. Lastly, when the highest-order or lowest-order bit is clear but the adjacent bit is set, the content of the datum has been compressed and must be decompressed before use. In this case the remaining bits of the four-byte length word give the total size of the compressed datum, not the original data. Note that compression is also possible for out-of-line data but the varlena header does not tell whether it has occurred — the content of the TOAST pointer tells that, instead.

The compression technique used for either in-line or out-of-line compressed data can be selected for each column by setting the `COMPRESSION` column option in `CREATE TABLE` or `ALTER TABLE`. The default for columns with no explicit setting is to consult the `default_toast_compression` parameter at the time data is inserted.

As mentioned, there are multiple types of TOAST pointer datums. The oldest and most common type is a pointer to out-of-line data stored in a *TOAST table* that is separate from, but associated with, the table containing the TOAST pointer datum itself. These *on-disk* pointer datums are created by the TOAST management code when a tuple to be stored on disk is too large to be stored as-is. Further details appear in [Section 64.2.1](#). Alternatively, a TOAST pointer datum can contain a pointer to out-of-line data that appears elsewhere in memory. Such datums are necessarily short-lived, and will never appear on-disk, but they are very useful for avoiding copying and redundant processing of large data values. Further details appear in [Section 64.2.2](#).

64.2.1. Out-of-Line, On-Disk TOAST Storage

If any of the columns of a table are TOAST-able, the table will have an associated TOAST table, whose OID is stored in the table's `pg_class.reltoastrelid` entry. On-disk TOASTed values are kept in the TOAST table, as described in more detail below.

Out-of-line values are divided (after compression if used) into chunks of at most `TOAST_MAX_CHUNK_SIZE` bytes (by default this value is chosen so that four chunk rows will fit on a page, making it about 2000 bytes). Each chunk is stored as a separate row in the TOAST table belonging to the owning table. Every TOAST table has the columns `chunk_id` (an OID identifying the particular TOASTed value), `chunk_seq` (a sequence number for the chunk within its value), and `chunk_data` (the actual data of the chunk). A unique index on `chunk_id` and `chunk_seq` provides fast retrieval of the values. A pointer datum representing an out-of-line on-disk TOASTed value therefore needs to store the OID of the TOAST table in which to look and the OID of the specific value (its `chunk_id`). For convenience, pointer datums also store the logical datum size (original uncompressed data length), physical stored size (different if compression was applied), and the compression method used, if any. Allowing for the varlena header bytes, the total size of an on-disk TOAST pointer datum is therefore 18 bytes regardless of the actual size of the represented value.

The TOAST management code is triggered only when a row value to be stored in a table is wider than `TOAST_TUPLE_THRESHOLD` bytes (normally 2 kB). The TOAST code will compress and/or move field values out-of-line until the row value is shorter than `TOAST_TUPLE_TARGET` bytes (also normally 2 kB, adjustable) or no more gains can be had. During an `UPDATE` operation, values of unchanged fields are normally preserved as-is; so an `UPDATE` of a row with out-of-line values incurs no TOAST costs if none of the out-of-line values change.

The TOAST management code recognizes four different strategies for storing TOAST-able columns on disk:

- `PLAIN` prevents either compression or out-of-line storage. This is the only possible strategy for columns of non-TOAST-able data types.
- `EXTENDED` allows both compression and out-of-line storage. This is the default for most TOAST-able data types. Compression will be attempted first, then out-of-line storage if the row is still too big.
- `EXTERNAL` allows out-of-line storage but not compression. Use of `EXTERNAL` will make substring operations on wide `text` and `bytea` columns faster (at the penalty of increased storage space) because these operations are optimized to fetch only the required parts of the out-of-line value when it is not compressed.

- `MAIN` allows compression but not out-of-line storage. (Actually, out-of-line storage will still be performed for such columns, but only as a last resort when there is no other way to make the row small enough to fit on a page.)

Each TOAST-able data type specifies a default strategy for columns of that data type, but the strategy for a given table column can be altered with `ALTER TABLE ... SET STORAGE`.

`TOAST_TUPLE_TARGET` can be adjusted for each table using `ALTER TABLE ... SET (toast_tuple_target = N)`

This scheme has a number of advantages compared to a more straightforward approach such as allowing row values to span pages. Assuming that queries are usually qualified by comparisons against relatively small key values, most of the work of the executor will be done using the main row entry. The big values of TOASTed attributes will only be pulled out (if selected at all) at the time the result set is sent to the client. Thus, the main table is much smaller and more of its rows fit in the shared buffer cache than would be the case without any out-of-line storage. Sort sets shrink also, and sorts will more often be done entirely in memory. A little test showed that a table containing typical HTML pages and their URLs was stored in about half of the raw data size including the TOAST table, and that the main table contained only about 10% of the entire data (the URLs and some small HTML pages). There was no run time difference compared to an un-TOASTed comparison table, in which all the HTML pages were cut down to 7 kB to fit.

64.2.2. Out-of-Line, In-Memory TOAST Storage

TOAST pointers can point to data that is not on disk, but is elsewhere in the memory of the current server process. Such pointers obviously cannot be long-lived, but they are nonetheless useful. There are currently two sub-cases: pointers to *indirect* data and pointers to *expanded* data.

Indirect TOAST pointers simply point at a non-indirect varlena value stored somewhere in memory. This case was originally created merely as a proof of concept, but it is currently used during logical decoding to avoid possibly having to create physical tuples exceeding 1 GB (as pulling all out-of-line field values into the tuple might do). The case is of limited use since the creator of the pointer datum is entirely responsible that the referenced data survives for as long as the pointer could exist, and there is no infrastructure to help with this.

Expanded TOAST pointers are useful for complex data types whose on-disk representation is not especially suited for computational purposes. As an example, the standard varlena representation of a PostgreSQL array includes dimensionality information, a nulls bitmap if there are any null elements, then the values of all the elements in order. When the element type itself is variable-length, the only way to find the *N*th element is to scan through all the preceding elements. This representation is appropriate for on-disk storage because of its compactness, but for computations with the array it's much nicer to have an "expanded" or "deconstructed" representation in which all the element starting locations have been identified. The TOAST pointer mechanism supports this need by allowing a pass-by-reference Datum to point to either a standard varlena value (the on-disk representation) or a TOAST pointer that points to an expanded representation somewhere in memory. The details of this expanded representation are up to the data type, though it must have a standard header and meet the other API requirements given in `src/include/utils/expandeddatum.h`. C-level functions working with the data type can choose to handle either representation. Functions that do not know about the expanded representation, but simply apply `PG_DETOAST_DATUM` to their inputs, will automatically receive the traditional varlena representation; so support for an expanded representation can be introduced incrementally, one function at a time.

TOAST pointers to expanded values are further broken down into *read-write* and *read-only* pointers. The pointed-to representation is the same either way, but a function that receives a read-write pointer is allowed to modify the referenced value in-place, whereas one that receives a read-only pointer must not; it must first create a copy if it wants to make a modified version of the value. This distinction and some associated conventions make it possible to avoid unnecessary copying of expanded values during query execution.

For all types of in-memory TOAST pointer, the TOAST management code ensures that no such pointer datum can accidentally get stored on disk. In-memory TOAST pointers are automatically expanded to

normal in-line varlena values before storage — and then possibly converted to on-disk TOAST pointers, if the containing tuple would otherwise be too big.

64.2.3. Pluggable TOAST

TOAST is a part of Postgres Pro core. TOAST is not extensible, has the same strategy for all data types and is not effective for structured data (JSON) or data that requires a special workflow (`bytea`).

Experimental pluggable TOAST provides an open API allowing you to develop and plug in custom TOAST implementations for table columns and data types in addition to the default one. These implementations are called TOASTers. A TOASTER can process TOASTed data using the knowledge about the internal data structure and workflow.

TOASTers can use any storage, advanced compression, encryption and other functionalities internally, without being aware of the table access method that calls the TOASTER.

The pluggable TOAST consists of the core, that is, the TOAST API, and custom TOASTers plugged in to Postgres Pro with this API.

This API does not possess any logic regarding the TOAST functionality, it is just a wraparound that allows registering, calling and dropping plugged TOASTers.

To enable using custom TOAST implementations, the TOAST API defines a new `Custom` type of TOAST pointer in addition to `External` and `Extended` (corresponding to `EXTERNAL` and `EXTENDED` TOAST-able column storing strategies).

Currently the pluggable TOAST has several limitations:

- Custom TOASTers must only be assigned to a column with the `EXTERNAL` storing strategy.
- Currently the pluggable TOAST does not support logical replication. A custom TOAST pointer is skipped by the logical replication engine and is not replicated. This is because support of custom pointers requires heavy modifications in the Postgres Pro core (the logical replication engine) and even architecture changes as now custom pointers allow updating TOASTed values, while default pointers do not.
- Custom TOASTers are not restored from dumps and require manual actions for restoring. The TOASTER extension is not restored from dump, thus the data processed with it are not available. Another point is that the same TOASTER extension has different IDs in different systems, so restoring a TOASTed value from dump would require determining the TOASTER used for processing data.
- When a custom TOASTER is assigned to a table column, in all the transactions after the TOASTER assignment, data being stored in the TOAST tables is processed with the TOASTER assigned to the column.
- When a custom TOASTER is assigned to a table column, old data values are left as-is and are not re-TOASTed although while being updated, an old data value is TOASTed with the assigned TOASTER because of the workflow of the default TOAST mechanics.
- If the TOASTER is somehow dropped, the data TOASTed with it will not be accessible with any standard techniques and is considered to be lost. To protect TOASTed values, the API creates some dependencies in the system (`PG_DEPEND` table):
 - When the TOASTER is added to a system, a TOASTER-extension dependency is created.
 - When the TOASTER is assigned to a column, a TOASTER-relation dependency is created.
 - When the TOASTER is unassigned from a column, the TOASTER-relation dependency is deleted.
 - When the TOASTER is dropped from a system, the TOASTER-extension dependency is deleted.

Custom TOASTers are added as extensions implementing some mandatory functions. Pluggable TOAST provides a set of SQL functions to control custom TOASTers. These functions are called with SQL `SELECT` command:

`add_toaster(toaster_name text, toaster_handler_func text) → integer`

Plug in a new TOASTER (added before as an extension). This function also creates a dependency in `PG_DEPEND` for the TOASTER OID to its extension OID, which is used to protect the TOASTER from being dropped when dropping the TOASTER extension.

Arguments:

- `toaster_name` — TOASTER name to be stored in `PG_TOASTER`. Must be unique.
- `toaster_handler_func` — TOASTER handler function name (automatically added as a `regproc` when the TOASTER extension is installed).

Returns OID assigned to the new TOASTER.

`set_toaster(toaster_name text, tab_name text, col_name text) → integer`

Assign a TOASTER to a table column. This function also creates a dependency in `PG_DEPEND` for the TOASTER OID to the relation OID. This dependency is used to protect TOASTed data by restricting dropping the TOASTER that is assigned to a column.

Arguments:

- `toaster_name` — name of the TOASTER assigned to a table column.
- `tab_name` — table name.
- `col_name` — column name.

Returns OID of the TOASTER assigned to the column.

`reset_toaster(tab_name text, col_name text) → integer`

Reset the TOAST mechanism to a default one for a table column. This function drops the TOASTER-relation dependency, which allows dropping the TOASTER later, when all dependencies are dropped.

Arguments:

- `tab_name` — table name.
- `col_name` — table column name.

Returns always 0.

`drop_toaster(toaster_name text)`

Drop a TOASTER from the system. Only unused TOASTers, which do not have any data TOASTed with them can be dropped. Dropping is protected by the dependencies created by `add_toaster` and `set_toaster` functions. If a dependency still exists, the TOASTER would not be dropped. If the TOASTER was dropped successfully, the extension with its implementation can be dropped by the `DROP EXTENSION` command.

Arguments:

- `toaster_name` — name of the TOASTER to be dropped.

Returns the TOASTER OID on success or 0 if the TOASTER is used.

`get_toaster(tab_name text, col_name text) → integer`

Get the OID of the TOASTER assigned to a table column.

Arguments:

- `tab_name` — table name.
- `col_name` — table column name.

Returns the OID of the TOASTER assigned to a column or 0 if none.

The following example illustrates the use of the pluggable TOAST API:

```
CREATE EXTENSION toastapi;

CREATE EXTENSION bytea_toaster;

SELECT add_toaster('bytea_toaster');

CREATE TABLE test_bytea_append (id int, a bytea);

ALTER TABLE test_bytea_append ALTER a SET STORAGE external;

SELECT set_toaster('bytea_toaster', 'test_bytea_append', 'a');
       test_set_toaster
-----
(1 row)

...

SELECT get_toaster('test_bytea_append', 'a') AS bytea_toaster_oid;
       get_toaster
-----
              16348
(1 row)

SELECT pgpro_toast.reset_toaster('test_bytea_append', 'a');
       reset_toaster
-----
                  0
(1 row)

DROP TABLE test_bytea_append;
SELECT pgpro_toast.drop_toaster('bytea_toaster');
       drop_toaster
-----
              16348
(1 row)

64.3. Free Space Map

Each heap and index relation, except for hash indexes, has a Free Space Map (FSM) to keep track of available space in the relation. It's stored alongside the main relation data in a separate relation fork, named after the filenode number of the relation, plus a `_fsm` suffix. For example, if the filenode of a relation is 12345, the FSM is stored in a file called `12345_fsm`, in the same directory as the main relation file.

The Free Space Map is organized as a tree of FSM pages. The bottom level FSM pages store the free space available on each heap (or index) page, using one byte to represent each such page. The upper levels aggregate information from the lower levels.

Within each FSM page is a binary tree, stored in an array with one byte per node. Each leaf node represents a heap page, or a lower level FSM page. In each non-leaf node, the higher of its children's values is stored. The maximum value in the leaf nodes is therefore stored at the root.

The [pg_freespacemap](#) module can be used to examine the information stored in free space maps.

64.4. Visibility Map

Each heap relation has a Visibility Map (VM) to keep track of which pages contain only tuples that are known to be visible to all active transactions; it also keeps track of which pages contain only frozen tuples. It's stored alongside the main relation data in a separate relation fork, named after the filenode number of the relation, plus a `_vm` suffix. For example, if the filenode of a relation is 12345, the VM is stored in a file called `12345_vm`, in the same directory as the main relation file. Note that indexes do not have VMs.

The visibility map stores two bits per heap page. The first bit, if set, indicates that the page is all-visible, or in other words that the page does not contain any tuples that need to be vacuumed. This information can also be used by *index-only scans* to answer queries using only the index tuple. The second bit, if set, means that all tuples on the page have been frozen. That means that even an anti-wraparound vacuum need not revisit the page.

The map is conservative in the sense that we make sure that whenever a bit is set, we know the condition is true, but if a bit is not set, it might or might not be true. Visibility map bits are only set by vacuum, but are cleared by any data-modifying operations on a page.

The `pg_visibility` module can be used to examine the information stored in the visibility map.

64.5. The Initialization Fork

Each unlogged table, and each index on an unlogged table, has an initialization fork. The initialization fork is an empty table or index of the appropriate type. When an unlogged table must be reset to empty due to a crash, the initialization fork is copied over the main fork, and any other forks are erased (they will be recreated automatically as needed).

64.6. Database Page Layout

This section provides an overview of the page format used within Postgres Pro tables and indexes.¹ Sequences and TOAST tables are formatted just like a regular table.

In the following explanation, a *byte* is assumed to contain 8 bits. In addition, the term *item* refers to an individual data value that is stored on a page. In a table, an item is a row; in an index, an item is an index entry.

Every table and index is stored as an array of *pages* of a fixed size (usually 8 kB, although a different page size can be selected when compiling the server). In a table, all the pages are logically equivalent, so a particular item (row) can be stored in any page. In indexes, the first page is generally reserved as a *metapage* holding control information, and there can be different types of pages within the index, depending on the index access method.

Table 64.2 shows the overall layout of a page. There are five parts to each page.

Table 64.2. Overall Page Layout

Item	Description
PageHeaderData	24 bytes long. Contains general information about the page, including free space pointers.
ItemIdData	Array of item identifiers pointing to the actual items. Each entry is an (offset,length) pair. 4 bytes per item.
Free space	The unallocated space. New item identifiers are allocated from the start of this area, new items from the end.

¹ Actually, use of this page format is not required for either table or index access methods. The `heap` table access method always uses this format. All the existing index methods also use the basic format, but the data kept on index metapages usually doesn't follow the item layout rules.

Item	Description
Items	The actual items themselves.
Special space	Index access method specific data. Different methods store different data. Empty in ordinary tables.

The first 24 bytes of each page consists of a page header (`PageHeaderData`). Its format is detailed in [Table 64.3](#). The first field tracks the most recent WAL entry related to this page. The second field contains the page checksum if `-k` are enabled. Next is a 2-byte field containing flag bits. This is followed by three 2-byte integer fields (`pd_lower`, `pd_upper`, and `pd_special`). These contain byte offsets from the page start to the start of unallocated space, to the end of unallocated space, and to the start of the special space. The next 2 bytes of the page header, `pd_pagesize_version`, store both the page size and a version indicator. Beginning with PostgreSQL 8.3 the version number is 4; PostgreSQL 8.1 and 8.2 used version number 3; PostgreSQL 8.0 used version number 2; PostgreSQL 7.3 and 7.4 used version number 1; prior releases used version number 0. (The basic page layout and header format has not changed in most of these versions, but the layout of heap row headers has.) The page size is basically only present as a cross-check; there is no support for having more than one page size in an installation. The last field is a hint that shows whether pruning the page is likely to be profitable: it tracks the oldest un-pruned XMAX on the page.

Table 64.3. PageHeaderData Layout

Field	Type	Length	Description
<code>pd_lsn</code>	<code>PageXLogRecPtr</code>	8 bytes	LSN: next byte after last byte of WAL record for last change to this page
<code>pd_checksum</code>	<code>uint16</code>	2 bytes	Page checksum
<code>pd_flags</code>	<code>uint16</code>	2 bytes	Flag bits
<code>pd_lower</code>	<code>LocationIndex</code>	2 bytes	Offset to start of free space
<code>pd_upper</code>	<code>LocationIndex</code>	2 bytes	Offset to end of free space
<code>pd_special</code>	<code>LocationIndex</code>	2 bytes	Offset to start of special space
<code>pd_pagesize_version</code>	<code>uint16</code>	2 bytes	Page size and layout version number information
<code>pd_prune_xid</code>	<code>TransactionId</code>	4 bytes	Oldest unpruned XMAX on page, or zero if none

Following the page header are item identifiers (`ItemIdData`), each requiring four bytes. An item identifier contains a byte-offset to the start of an item, its length in bytes, and a few attribute bits which affect its interpretation. New item identifiers are allocated as needed from the beginning of the unallocated space. The number of item identifiers present can be determined by looking at `pd_lower`, which is increased to allocate a new identifier. Because an item identifier is never moved until it is freed, its index can be used on a long-term basis to reference an item, even when the item itself is moved around on the page to compact free space. In fact, every pointer to an item (`ItemPointer`, also known as `CTID`) created by Postgres Pro consists of a page number and the index of an item identifier.

The items themselves are stored in space allocated backwards from the end of unallocated space. The exact structure varies depending on what the table is to contain. Tables and sequences both use a structure named `HeapTupleHeaderData`, described below.

The final section is the “special section” which can contain anything the access method wishes to store. For example, b-tree indexes store links to the page's left and right siblings, as well as some other data

relevant to the index structure. Ordinary tables do not use a special section at all (indicated by setting `pd_special` to equal the page size).

Figure 64.1 illustrates how these parts are laid out in a page.

Figure 64.1. Page Layout

64.6.1. Table Row Layout

All table rows are structured in the same way. There is a fixed-size header (occupying 23 bytes on most machines), followed by an optional null bitmap, an optional object ID field, and the user data. The header is detailed in Table 64.4. The actual user data (columns of the row) begins at the offset indicated by `t_hoff`, which must always be a multiple of the `MAXALIGN` distance for the platform. The null bitmap is only present if the `HEAP_HASNULL` bit is set in `t_infomask`. If it is present it begins just after the fixed header and occupies enough bytes to have one bit per data column (that is, the number of bits that equals the attribute count in `t_infomask2`). In this list of bits, a 1 bit indicates not-null, a 0 bit is a null. When the bitmap is not present, all columns are assumed not-null. The object ID is only present if the `HEAP_HASOID_OLD` bit is set in `t_infomask`. If present, it appears just before the `t_hoff` boundary. Any padding needed to make `t_hoff` a `MAXALIGN` multiple will appear between the null bitmap and the object ID. (This in turn ensures that the object ID is suitably aligned.)

Table 64.4. HeapTupleHeaderData Layout

Field	Type	Length	Description
<code>t_xmin</code>	TransactionId	4 bytes	insert XID stamp
<code>t_xmax</code>	TransactionId	4 bytes	delete XID stamp
<code>t_cid</code>	CommandId	4 bytes	insert and/or delete CID stamp (overlays with <code>t_xvac</code>)
<code>t_xvac</code>	TransactionId	4 bytes	XID for VACUUM operation moving a row version
<code>t_ctid</code>	ItemPointerData	6 bytes	current TID of this or newer row version
<code>t_infomask2</code>	uint16	2 bytes	number of attributes, plus various flag bits
<code>t_infomask</code>	uint16	2 bytes	various flag bits
<code>t_hoff</code>	uint8	1 byte	offset to user data

Interpreting the actual data can only be done with information obtained from other tables, mostly `pg_attribute`. The key values needed to identify field locations are `attlen` and `attalign`. There is no way to

directly get a particular attribute, except when there are only fixed width fields and no null values. All this trickery is wrapped up in the functions *heap_getattr*, *fastgetattr* and *heap_getsysattr*.

To read the data you need to examine each attribute in turn. First check whether the field is NULL according to the null bitmap. If it is, go to the next. Then make sure you have the right alignment. If the field is a fixed width field, then all the bytes are simply placed. If it's a variable length field (*attlen* = -1) then it's a bit more complicated. All variable-length data types share the common header structure `struct varlena`, which includes the total length of the stored value and some flag bits. Depending on the flags, the data can be either inline or in a TOAST table; it might be compressed, too (see [Section 64.2](#)).

64.7. Heap-Only Tuples (HOT)

To allow for high concurrency, Postgres Pro uses [multiversion concurrency control](#) (MVCC) to store rows. However, MVCC has some downsides for update queries. Specifically, updates require new versions of rows to be added to tables. This can also require new index entries for each updated row, and removal of old versions of rows and their index entries can be expensive.

To help reduce the overhead of updates, Postgres Pro has an optimization called heap-only tuples (HOT). This optimization is possible when:

- The update does not modify any columns referenced by the table's indexes, not including summarizing indexes. The only summarizing index method in the core Postgres Pro distribution is [BRIN](#).
- There is sufficient free space on the page containing the old row for the updated row.

In such cases, heap-only tuples provide two optimizations:

- New index entries are not needed to represent updated rows, however, summary indexes may still need to be updated.
- When a row is updated multiple times, row versions other than the oldest and the newest can be completely removed during normal operation, including `SELECTs`, instead of requiring periodic vacuum operations. (Indexes always refer to the [page item identifier](#) of the original row version. The tuple data associated with that row version is removed, and its item identifier is converted to a redirect that points to the oldest version that may still be visible to some concurrent transaction. Intermediate row versions that are no longer visible to anyone are completely removed, and the associated page item identifiers are made available for reuse.)

You can increase the likelihood of sufficient page space for HOT updates by decreasing a table's [fill-factor](#). If you don't, HOT updates will still happen because new rows will naturally migrate to new pages and existing pages with sufficient free space for new row versions. The system view [pg_stat_all_tables](#) allows monitoring of the occurrence of HOT and non-HOT updates.

Chapter 65. Transaction Processing

This chapter provides an overview of the internals of Postgres Pro's transaction management system. The word transaction is often abbreviated as *xact*.

65.1. Transactions and Identifiers

Transactions can be created explicitly using `BEGIN` or `START TRANSACTION` and ended using `COMMIT` or `ROLLBACK`. SQL statements outside of explicit transactions automatically use single-statement transactions.

Every transaction is identified by a unique `VirtualTransactionId` (also called `virtualXID` or `vxid`), which is comprised of a backend's process number (or `procNumber`) and a sequentially-assigned number local to each backend, known as `localXID`. For example, the virtual transaction ID 4/12532 has a `procNumber` of 4 and a `localXID` of 12532.

Non-virtual `TransactionIds` (or `xid`), e.g., 278394, are assigned sequentially to transactions from a global counter used by all databases within the Postgres Pro cluster. This assignment happens when a transaction first writes to the database. This means lower-numbered `xids` started writing before higher-numbered `xids`. Note that the order in which transactions perform their first database write might be different from the order in which the transactions started, particularly if the transaction started with statements that only performed database reads.

The internal transaction ID type `xid` is 32 bits wide and **wraps around** every 4 billion transactions. A 32-bit epoch is incremented during each wraparound. There is also a 64-bit type `xid8` which includes this epoch and therefore does not wrap around during the life of an installation; it can be converted to `xid` by casting. The functions in [Table 9.84](#) return `xid8` values. `Xids` are used as the basis for Postgres Pro's **MVCC** concurrency mechanism and streaming replication.

When a top-level transaction with a (non-virtual) `xid` commits, it is marked as committed in the `pg_xact` directory. Additional information is recorded in the `pg_commit_ts` directory if **track_commit_timestamp** is enabled.

In addition to `vxid` and `xid`, prepared transactions are also assigned Global Transaction Identifiers (GID). GIDs are string literals up to 200 bytes long, which must be unique amongst other currently prepared transactions. The mapping of GID to `xid` is shown in [pg_prepared_xacts](#).

65.2. Transactions and Locking

The transaction IDs of currently executing transactions are shown in [pg_locks](#) in columns `virtualxid` and `transactionid`. Read-only transactions will have `virtualxids` but NULL `transactionids`, while both columns will be set in read-write transactions.

Some lock types wait on `virtualxid`, while other types wait on `transactionid`. Row-level read and write locks are recorded directly in the locked rows and can be inspected using the [pgrowlocks](#) extension. Row-level read locks might also require the assignment of multixact IDs (`mxid`; see [Section 23.1.5.1](#)).

65.3. Subtransactions

Subtransactions are started inside transactions, allowing large transactions to be broken into smaller units. Subtransactions can commit or abort without affecting their parent transactions, allowing parent transactions to continue. This allows errors to be handled more easily, which is a common application development pattern. The word subtransaction is often abbreviated as *subxact*.

Subtransactions can be started explicitly using the `SAVEPOINT` command, but can also be started in other ways, such as PL/pgSQL's `EXCEPTION` clause. PL/Python and PL/Tcl also support explicit subtransactions. Subtransactions can also be started from other subtransactions. The top-level transaction and its child subtransactions form a hierarchy or tree, which is why we refer to the main transaction as the top-level transaction.

If a subtransaction is assigned a non-virtual transaction ID, its transaction ID is referred to as a “subxid”. Read-only subtransactions are not assigned subxids, but once they attempt to write, they will be assigned one. This also causes all of a subxid's parents, up to and including the top-level transaction, to be assigned non-virtual transaction ids. We ensure that a parent xid is always lower than any of its child subxids.

The immediate parent xid of each subxid is recorded in the `pg_subtrans` directory. No entry is made for top-level xids since they do not have a parent, nor is an entry made for read-only subtransactions.

When a subtransaction commits, all of its committed child subtransactions with subxids will also be considered subcommitted in that transaction. When a subtransaction aborts, all of its child subtransactions will also be considered aborted.

When a top-level transaction with an xid commits, all of its subcommitted child subtransactions are also persistently recorded as committed in the `pg_xact` subdirectory. If the top-level transaction aborts, all its subtransactions are also aborted, even if they were subcommitted.

The more subtransactions each transaction keeps open (not rolled back or released), the greater the transaction management overhead. Up to 64 open subxids are cached in shared memory for each back-end; after that point, the storage I/O overhead increases significantly due to additional lookups of subxid entries in `pg_subtrans`.

65.4. Two-Phase Transactions

Postgres Pro supports a two-phase commit (2PC) protocol that allows multiple distributed systems to work together in a transactional manner. The commands are `PREPARE TRANSACTION`, `COMMIT PREPARED` and `ROLLBACK PREPARED`. Two-phase transactions are intended for use by external transaction management systems. Postgres Pro follows the features and model proposed by the X/Open XA standard, but does not implement some less often used aspects.

When the user executes `PREPARE TRANSACTION`, the only possible next commands are `COMMIT PREPARED` or `ROLLBACK PREPARED`. In general, this prepared state is intended to be of very short duration, but external availability issues might mean transactions stay in this state for an extended interval. Short-lived prepared transactions are stored only in shared memory and WAL. Transactions that span checkpoints are recorded in the `pg_twophase` directory. Transactions that are currently prepared can be inspected using `pg_prepared_xacts`.

Chapter 66. How the Planner Uses Statistics

This chapter builds on the material covered in [Section 14.1](#) and [Section 14.2](#) to show some additional details about how the planner uses the system statistics to estimate the number of rows each part of a query might return. This is a significant part of the planning process, providing much of the raw material for cost calculation.

The intent of this chapter is not to document the code in detail, but to present an overview of how it works. This will perhaps ease the learning curve for someone who subsequently wishes to read the code.

66.1. Row Estimation Examples

The examples shown below use tables in the Postgres Pro regression test database. Note also that since `ANALYZE` uses random sampling while producing statistics, the results will change slightly after any new `ANALYZE`.

Let's start with a very simple query:

```
EXPLAIN SELECT * FROM tenk1;
```

QUERY PLAN

```
-----  
Seq Scan on tenk1  (cost=0.00..458.00 rows=10000 width=244)
```

How the planner determines the cardinality of `tenk1` is covered in [Section 14.2](#), but is repeated here for completeness. The number of pages and rows is looked up in `pg_class`:

```
SELECT relpages, reltuples FROM pg_class WHERE relname = 'tenk1';
```

```
relpages | reltuples  
-----+-----  
    358 |    10000
```

These numbers are current as of the last `VACUUM` or `ANALYZE` on the table. The planner then fetches the actual current number of pages in the table (this is a cheap operation, not requiring a table scan). If that is different from `relpages` then `reltuples` is scaled accordingly to arrive at a current number-of-rows estimate. In the example above, the value of `relpages` is up-to-date so the rows estimate is the same as `reltuples`.

Let's move on to an example with a range condition in its `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000;
```

QUERY PLAN

```
-----  
Bitmap Heap Scan on tenk1  (cost=24.06..394.64 rows=1007 width=244)  
  Recheck Cond: (unique1 < 1000)  
    -> Bitmap Index Scan on tenk1_unique1  (cost=0.00..23.80 rows=1007 width=0)  
        Index Cond: (unique1 < 1000)
```

The planner examines the `WHERE` clause condition and looks up the selectivity function for the operator `<` in `pg_operator`. This is held in the column `oprrest`, and the entry in this case is `scalarlttsel`. The `scalarlttsel` function retrieves the histogram for `unique1` from `pg_statistic`. For manual queries it is more convenient to look in the simpler `pg_stats` view:

```
SELECT histogram_bounds FROM pg_stats  
WHERE tablename='tenk1' AND attname='unique1';
```

histogram_bounds

```
-----  
{0, 993, 1997, 3050, 4040, 5036, 5957, 7057, 8029, 9016, 9995}
```

Next the fraction of the histogram occupied by “< 1000” is worked out. This is the selectivity. The histogram divides the range into equal frequency buckets, so all we have to do is locate the bucket that our value is in and count *part* of it and *all* of the ones before. The value 1000 is clearly in the second bucket (993–1997). Assuming a linear distribution of values inside each bucket, we can calculate the selectivity as:

```
selectivity = (1 + (1000 - bucket[2].min)/(bucket[2].max - bucket[2].min))/num_buckets
            = (1 + (1000 - 993)/(1997 - 993))/10
            = 0.100697
```

that is, one whole bucket plus a linear fraction of the second, divided by the number of buckets. The estimated number of rows can now be calculated as the product of the selectivity and the cardinality of `tenk1`:

```
rows = rel_cardinality * selectivity
      = 10000 * 0.100697
      = 1007 (rounding off)
```

Next let's consider an example with an equality condition in its `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'CRAAAA';
```

QUERY PLAN

```
-----
Seq Scan on tenk1 (cost=0.00..483.00 rows=30 width=244)
  Filter: (stringu1 = 'CRAAAA'::name)
```

Again the planner examines the `WHERE` clause condition and looks up the selectivity function for `=`, which is `eqsel`. For equality estimation the histogram is not useful; instead the list of *most common values* (MCVs) is used to determine the selectivity. Let's have a look at the MCVs, with some additional columns that will be useful later:

```
SELECT null_frac, n_distinct, most_common_vals, most_common_freqs FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';
```

```
null_frac          | 0
n_distinct         | 676
most_common_vals   | {EJAAAA,BBAAAA,CRAAAA,FCAAAA,FEAAAA,GSAAAA,
JOAAAA,MCAAAA,NAAAAA,WGAAAA}
most_common_freqs  | {0.00333333,0.003,0.003,0.003,0.003,0.003,0.003,0.003,0.003,0.003}
```

Since `CRAAAA` appears in the list of MCVs, the selectivity is merely the corresponding entry in the list of most common frequencies (MCFs):

```
selectivity = mcf[3]
            = 0.003
```

As before, the estimated number of rows is just the product of this with the cardinality of `tenk1`:

```
rows = 10000 * 0.003
      = 30
```

Now consider the same query, but with a constant that is not in the MCV list:

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'xxx';
```

QUERY PLAN

```
-----
Seq Scan on tenk1 (cost=0.00..483.00 rows=15 width=244)
  Filter: (stringu1 = 'xxx'::name)
```

This is quite a different problem: how to estimate the selectivity when the value is *not* in the MCV list. The approach is to use the fact that the value is not in the list, combined with the knowledge of the frequencies for all of the MCVs:

```
selectivity = (1 - sum(mcv_freqs)) / (num_distinct - num_mcv)
            = (1 - (0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 +
                    0.003 + 0.003 + 0.003 + 0.003)) / (676 - 10)
            = 0.0014559
```

That is, add up all the frequencies for the MCVs and subtract them from one, then divide by the number of *other* distinct values. This amounts to assuming that the fraction of the column that is not any of the MCVs is evenly distributed among all the other distinct values. Notice that there are no null values so we don't have to worry about those (otherwise we'd subtract the null fraction from the numerator as well). The estimated number of rows is then calculated as usual:

```
rows = 10000 * 0.0014559
      = 15   (rounding off)
```

The previous example with `unique1 < 1000` was an oversimplification of what `scalarltsel` really does; now that we have seen an example of the use of MCVs, we can fill in some more detail. The example was correct as far as it went, because since `unique1` is a unique column it has no MCVs (obviously, no value is any more common than any other value). For a non-unique column, there will normally be both a histogram and an MCV list, and *the histogram does not include the portion of the column population represented by the MCVs*. We do things this way because it allows more precise estimation. In this situation `scalarltsel` directly applies the condition (e.g., “< 1000”) to each value of the MCV list, and adds up the frequencies of the MCVs for which the condition is true. This gives an exact estimate of the selectivity within the portion of the table that is MCVs. The histogram is then used in the same way as above to estimate the selectivity in the portion of the table that is not MCVs, and then the two numbers are combined to estimate the overall selectivity. For example, consider

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 < 'IAAAAA';
```

QUERY PLAN

```
-----
Seq Scan on tenk1   (cost=0.00..483.00 rows=3077 width=244)
  Filter: (stringu1 < 'IAAAAA'::name)
```

We already saw the MCV information for `stringu1`, and here is its histogram:

```
SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';
```

histogram_bounds

```
-----
{AAAAAA,CQAAAA,FRAAAA,IBAAAA,KRAAAA,NFAAAA,PSAAAA,SGAAAA,VAAAAA,XLAAAA,ZZAAAA}
```

Checking the MCV list, we find that the condition `stringu1 < 'IAAAAA'` is satisfied by the first six entries and not the last four, so the selectivity within the MCV part of the population is

```
selectivity = sum(relevant mvfs)
            = 0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003
            = 0.01833333
```

Summing all the MCFs also tells us that the total fraction of the population represented by MCVs is 0.03033333, and therefore the fraction represented by the histogram is 0.96966667 (again, there are no nulls, else we'd have to exclude them here). We can see that the value `IAAAAA` falls nearly at the end of the third histogram bucket. Using some rather cheesy assumptions about the frequency of different characters, the planner arrives at the estimate 0.298387 for the portion of the histogram population that is less than `IAAAAA`. We then combine the estimates for the MCV and non-MCV populations:

```
selectivity = mcv_selectivity + histogram_selectivity * histogram_fraction
            = 0.01833333 + 0.298387 * 0.96966667
            = 0.307669

rows       = 10000 * 0.307669
            = 3077   (rounding off)
```

In this particular example, the correction from the MCV list is fairly small, because the column distribution is actually quite flat (the statistics showing these particular values as being more common than others are mostly due to sampling error). In a more typical case where some values are significantly more common than others, this complicated process gives a useful improvement in accuracy because the selectivity for the most common values is found exactly.

Now let's consider a case with more than one condition in the `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000 AND stringu1 = 'xxx';
```

QUERY PLAN

```
Bitmap Heap Scan on tenk1  (cost=23.80..396.91 rows=1 width=244)
  Recheck Cond: (unique1 < 1000)
  Filter: (stringu1 = 'xxx'::name)
    -> Bitmap Index Scan on tenk1_unique1  (cost=0.00..23.80 rows=1007 width=0)
        Index Cond: (unique1 < 1000)
```

The planner assumes that the two conditions are independent, so that the individual selectivities of the clauses can be multiplied together:

```
selectivity = selectivity(unique1 < 1000) * selectivity(stringu1 = 'xxx')
              = 0.100697 * 0.0014559
              = 0.0001466

rows        = 10000 * 0.0001466
              = 1   (rounding off)
```

Notice that the number of rows estimated to be returned from the bitmap index scan reflects only the condition used with the index; this is important since it affects the cost estimate for the subsequent heap fetches.

Finally we will examine a query that involves a join:

```
EXPLAIN SELECT * FROM tenk1 t1, tenk2 t2
WHERE t1.unique1 < 50 AND t1.unique2 = t2.unique2;
```

QUERY PLAN

```
Nested Loop  (cost=4.64..456.23 rows=50 width=488)
  -> Bitmap Heap Scan on tenk1 t1  (cost=4.64..142.17 rows=50 width=244)
      Recheck Cond: (unique1 < 50)
      -> Bitmap Index Scan on tenk1_unique1  (cost=0.00..4.63 rows=50 width=0)
          Index Cond: (unique1 < 50)
  -> Index Scan using tenk2_unique2 on tenk2 t2  (cost=0.00..6.27 rows=1 width=244)
      Index Cond: (unique2 = t1.unique2)
```

The restriction on `tenk1, unique1 < 50`, is evaluated before the nested-loop join. This is handled analogously to the previous range example. This time the value 50 falls into the first bucket of the `unique1` histogram:

```
selectivity = (0 + (50 - bucket[1].min)/(bucket[1].max - bucket[1].min))/num_buckets
              = (0 + (50 - 0)/(993 - 0))/10
              = 0.005035

rows        = 10000 * 0.005035
              = 50   (rounding off)
```

The restriction for the join is `t2.unique2 = t1.unique2`. The operator is just our familiar `=`, however the selectivity function is obtained from the `oprjoin` column of `pg_operator`, and is `eqjoinsel`. `eqjoinsel` looks up the statistical information for both `tenk2` and `tenk1`:

```
SELECT tablename, null_frac,n_distinct, most_common_vals FROM pg_stats
```

```
WHERE tablename IN ('tenk1', 'tenk2') AND attname='unique2';
```

tablename	null_frac	n_distinct	most_common_vals
tenk1	0	-1	
tenk2	0	-1	

In this case there is no MCV information for `unique2` and all the values appear to be unique (`n_distinct = -1`), so we use an algorithm that relies on the row count estimates for both relations (`num_rows`, not shown, but "tenk") together with the column null fractions (zero for both):

```
selectivity = (1 - null_frac1) * (1 - null_frac2) / max(num_rows1, num_rows2)
             = (1 - 0) * (1 - 0) / max(10000, 10000)
             = 0.0001
```

This is, subtract the null fraction from one for each of the relations, and divide by the row count of the larger relation (this value does get scaled in the non-unique case). The number of rows that the join is likely to emit is calculated as the cardinality of the Cartesian product of the two inputs, multiplied by the selectivity:

```
rows = (outer_cardinality * inner_cardinality) * selectivity
      = (50 * 10000) * 0.0001
      = 50
```

Had there been MCV lists for the two columns, `eqjoinsel` would have used direct comparison of the MCV lists to determine the join selectivity within the part of the column populations represented by the MCVs. The estimate for the remainder of the populations follows the same approach shown here.

Notice that we showed `inner_cardinality` as 10000, that is, the unmodified size of `tenk2`. It might appear from inspection of the `EXPLAIN` output that the estimate of join rows comes from `50 * 1`, that is, the number of outer rows times the estimated number of rows obtained by each inner index scan on `tenk2`. But this is not the case: the join relation size is estimated before any particular join plan has been considered. If everything is working well then the two ways of estimating the join size will produce about the same answer, but due to round-off error and other factors they sometimes diverge significantly.

66.2. Multivariate Statistics Examples

66.2.1. Functional Dependencies

Multivariate correlation can be demonstrated with a very simple data set — a table with two columns, both containing the same values:

```
CREATE TABLE t (a INT, b INT);
INSERT INTO t SELECT i % 100, i % 100 FROM generate_series(1, 10000) s(i);
ANALYZE t;
```

As explained in [Section 14.2](#), the planner can determine cardinality of `t` using the number of pages and rows obtained from `pg_class`:

```
SELECT relpages, reltuples FROM pg_class WHERE relname = 't';
```

relpages	reltuples
45	10000

The data distribution is very simple; there are only 100 distinct values in each column, uniformly distributed.

The following example shows the result of estimating a `WHERE` condition on the `a` column:

```
EXPLAIN (ANALYZE, TIMING OFF, BUFFERS OFF) SELECT * FROM t WHERE a = 1;
QUERY PLAN
```

```
Seq Scan on t (cost=0.00..170.00 rows=100 width=8) (actual rows=100.00 loops=1)
  Filter: (a = 1)
  Rows Removed by Filter: 9900
```

The planner examines the condition and determines the selectivity of this clause to be 1%. By comparing this estimate and the actual number of rows, we see that the estimate is very accurate (in fact exact, as the table is very small). Changing the `WHERE` condition to use the `b` column, an identical plan is generated. But observe what happens if we apply the same condition on both columns, combining them with `AND`:

```
EXPLAIN (ANALYZE, TIMING OFF, BUFFERS OFF) SELECT * FROM t WHERE a = 1 AND b = 1;
      QUERY PLAN
```

```
-----
Seq Scan on t (cost=0.00..195.00 rows=1 width=8) (actual rows=100.00 loops=1)
  Filter: ((a = 1) AND (b = 1))
  Rows Removed by Filter: 9900
```

The planner estimates the selectivity for each condition individually, arriving at the same 1% estimates as above. Then it assumes that the conditions are independent, and so it multiplies their selectivities, producing a final selectivity estimate of just 0.01%. This is a significant underestimate, as the actual number of rows matching the conditions (100) is two orders of magnitude higher.

This problem can be fixed by creating a statistics object that directs `ANALYZE` to calculate functional-dependency multivariate statistics on the two columns:

```
CREATE STATISTICS stts (dependencies) ON a, b FROM t;
ANALYZE t;
EXPLAIN (ANALYZE, TIMING OFF, BUFFERS OFF) SELECT * FROM t WHERE a = 1 AND b = 1;
      QUERY PLAN
```

```
-----
Seq Scan on t (cost=0.00..195.00 rows=100 width=8) (actual rows=100.00 loops=1)
  Filter: ((a = 1) AND (b = 1))
  Rows Removed by Filter: 9900
```

66.2.2. Multivariate N-Distinct Counts

A similar problem occurs with estimation of the cardinality of sets of multiple columns, such as the number of groups that would be generated by a `GROUP BY` clause. When `GROUP BY` lists a single column, the `n-distinct` estimate (which is visible as the estimated number of rows returned by the `HashAggregate` node) is very accurate:

```
EXPLAIN (ANALYZE, TIMING OFF, BUFFERS OFF) SELECT COUNT(*) FROM t GROUP BY a;
      QUERY PLAN
```

```
-----
HashAggregate (cost=195.00..196.00 rows=100 width=12) (actual rows=100.00 loops=1)
  Group Key: a
    -> Seq Scan on t (cost=0.00..145.00 rows=10000 width=4) (actual rows=10000.00
        loops=1)
```

But without multivariate statistics, the estimate for the number of groups in a query with two columns in `GROUP BY`, as in the following example, is off by an order of magnitude:

```
EXPLAIN (ANALYZE, TIMING OFF, BUFFERS OFF) SELECT COUNT(*) FROM t GROUP BY a, b;
      QUERY PLAN
```

```
-----
HashAggregate (cost=220.00..230.00 rows=1000 width=16) (actual rows=100.00 loops=1)
  Group Key: a, b
    -> Seq Scan on t (cost=0.00..145.00 rows=10000 width=8) (actual rows=10000.00
        loops=1)
```

By redefining the statistics object to include `n-distinct` counts for the two columns, the estimate is much improved:

```
DROP STATISTICS stts;
CREATE STATISTICS stts (dependencies, ndistinct) ON a, b FROM t;
ANALYZE t;
EXPLAIN (ANALYZE, TIMING OFF, BUFFERS OFF) SELECT COUNT(*) FROM t GROUP BY a, b;
                                QUERY PLAN
-----
HashAggregate  (cost=220.00..221.00 rows=100 width=16) (actual rows=100.00 loops=1)
  Group Key: a, b
    -> Seq Scan on t  (cost=0.00..145.00 rows=10000 width=8) (actual rows=10000.00
        loops=1)
```

66.2.3. MCV Lists

As explained in [Section 66.2.1](#), functional dependencies are very cheap and efficient type of statistics, but their main limitation is their global nature (only tracking dependencies at the column level, not between individual column values).

This section introduces multivariate variant of MCV (most-common values) lists, a straightforward extension of the per-column statistics described in [Section 66.1](#). These statistics address the limitation by storing individual values, but it is naturally more expensive, both in terms of building the statistics in `ANALYZE`, storage and planning time.

Let's look at the query from [Section 66.2.1](#) again, but this time with a MCV list created on the same set of columns (be sure to drop the functional dependencies, to make sure the planner uses the newly created statistics).

```
DROP STATISTICS stts;
CREATE STATISTICS stts2 (mcv) ON a, b FROM t;
ANALYZE t;
EXPLAIN (ANALYZE, TIMING OFF, BUFFERS OFF) SELECT * FROM t WHERE a = 1 AND b = 1;
                                QUERY PLAN
-----
Seq Scan on t  (cost=0.00..195.00 rows=100 width=8) (actual rows=100.00 loops=1)
  Filter: ((a = 1) AND (b = 1))
  Rows Removed by Filter: 9900
```

The estimate is as accurate as with the functional dependencies, mostly thanks to the table being fairly small and having a simple distribution with a low number of distinct values. Before looking at the second query, which was not handled by functional dependencies particularly well, let's inspect the MCV list a bit.

Inspecting the MCV list is possible using `pg_mcv_list_items` set-returning function.

```
SELECT m.* FROM pg_statistic_ext join pg_statistic_ext_data on (oid = stxoid),
        pg_mcv_list_items(stxmcv) m WHERE stxname = 'stts2';
```

index	values	nulls	frequency	base_frequency
0	{0, 0}	{f,f}	0.01	0.0001
1	{1, 1}	{f,f}	0.01	0.0001
...				
49	{49, 49}	{f,f}	0.01	0.0001
50	{50, 50}	{f,f}	0.01	0.0001
...				
97	{97, 97}	{f,f}	0.01	0.0001
98	{98, 98}	{f,f}	0.01	0.0001
99	{99, 99}	{f,f}	0.01	0.0001

(100 rows)

This confirms there are 100 distinct combinations in the two columns, and all of them are about equally likely (1% frequency for each one). The base frequency is the frequency computed from per-column

statistics, as if there were no multi-column statistics. Had there been any null values in either of the columns, this would be identified in the `nulls` column.

When estimating the selectivity, the planner applies all the conditions on items in the MCV list, and then sums the frequencies of the matching ones.

Compared to functional dependencies, MCV lists have two major advantages. Firstly, the list stores actual values, making it possible to decide which combinations are compatible.

```
EXPLAIN (ANALYZE, TIMING OFF, BUFFERS OFF) SELECT * FROM t WHERE a = 1 AND b = 10;
                                QUERY PLAN
```

```
-----
Seq Scan on t   (cost=0.00..195.00 rows=1 width=8) (actual rows=0.00 loops=1)
  Filter: ((a = 1) AND (b = 10))
  Rows Removed by Filter: 10000
```

Secondly, MCV lists handle a wider range of clause types, not just equality clauses like functional dependencies. For example, consider the following range query for the same table:

```
EXPLAIN (ANALYZE, TIMING OFF, BUFFERS OFF) SELECT * FROM t WHERE a <= 49 AND b > 49;
                                QUERY PLAN
```

```
-----
Seq Scan on t   (cost=0.00..195.00 rows=1 width=8) (actual rows=0.00 loops=1)
  Filter: ((a <= 49) AND (b > 49))
  Rows Removed by Filter: 10000
```

66.3. Planner Statistics and Security

Access to the table `pg_statistic` is restricted to superusers, so that ordinary users cannot learn about the contents of the tables of other users from it. Some selectivity estimation functions will use a user-provided operator (either the operator appearing in the query or a related operator) to analyze the stored statistics. For example, in order to determine whether a stored most common value is applicable, the selectivity estimator will have to run the appropriate `=` operator to compare the constant in the query to the stored value. Thus the data in `pg_statistic` is potentially passed to user-defined operators. An appropriately crafted operator can intentionally leak the passed operands (for example, by logging them or writing them to a different table), or accidentally leak them by showing their values in error messages, in either case possibly exposing data from `pg_statistic` to a user who should not be able to see it.

In order to prevent this, the following applies to all built-in selectivity estimation functions. When planning a query, in order to be able to use stored statistics, the current user must either have `SELECT` privilege on the table or the involved columns, or the operator used must be `LEAKPROOF` (more accurately, the function that the operator is based on). If not, then the selectivity estimator will behave as if no statistics are available, and the planner will proceed with default or fall-back assumptions. The `psql` program's `\do+` meta-command is useful to determine which operators are marked as leakproof.

If a user does not have the required privilege on the table or columns, then in many cases the query will ultimately receive a permission-denied error, in which case this mechanism is invisible in practice. But if the user is reading from a security-barrier view, then the planner might wish to check the statistics of an underlying table that is otherwise inaccessible to the user. In that case, the operator should be leakproof or the statistics will not be used. There is no direct feedback about that, except that the plan might be suboptimal. If one suspects that this is the case, one could try running the query as a more privileged user, to see if a different plan results.

This restriction applies only to cases where the planner would need to execute a user-defined operator on one or more values from `pg_statistic`. Thus the planner is permitted to use generic statistical information, such as the fraction of null values or the number of distinct values in a column, regardless of access privileges.

Selectivity estimation functions contained in third-party extensions that potentially operate on statistics with user-defined operators should follow the same security rules.

Chapter 67. Backup Manifest Format

The backup manifest generated by `pg_basebackup` is primarily intended to permit the backup to be verified using `pg_verifybackup`. However, it is also possible for other tools to read the backup manifest file and use the information contained therein for their own purposes. To that end, this chapter describes the format of the backup manifest file.

A backup manifest is a JSON document encoded as UTF-8. (Although in general JSON documents are required to be Unicode, Postgres Pro permits the `json` and `jsonb` data types to be used with any supported server encoding. There is no similar exception for backup manifests.) The JSON document is always an object; the keys that are present in this object are described in the next section.

67.1. Backup Manifest Top-level Object

The backup manifest JSON document contains the following keys.

`PostgreSQL-Backup-Manifest-Version`

The associated value is an integer. Beginning in Postgres Pro 17, it is 2; in older versions, it is 1.

`System-Identifier`

The database system identifier of the Postgres Pro instance where the backup was taken. This field is present only when `PostgreSQL-Backup-Manifest-Version` is 2.

`Files`

The associated value is always a list of objects, each describing one file that is present in the backup. No entries are present in this list for the WAL files that are needed in order to use the backup, or for the backup manifest itself. The structure of each object in the list is described in [Section 67.2](#).

`WAL-Ranges`

The associated value is always a list of objects, each describing a range of WAL records that must be readable from a particular timeline in order to make use of the backup. The structure of these objects is further described in [Section 67.3](#).

`Manifest-Checksum`

This key is always present on the last line of the backup manifest file. The associated value is a SHA-256 checksum of all the preceding lines. We use a fixed checksum method here to make it possible for clients to do incremental parsing of the manifest. While a SHA-256 checksum is significantly more expensive than a CRC-32C checksum, the manifest should normally be small enough that the extra computation won't matter very much.

67.2. Backup Manifest File Object

The object which describes a single file contains either a `Path` key or an `Encoded-Path` key. Normally, the `Path` key will be present. The associated string value is the path of the file relative to the root of the backup directory. Files located in a user-defined tablespace will have paths whose first two components are `pg_tblspc` and the OID of the tablespace. If the path is not a string that is legal in UTF-8, or if the user requests that encoded paths be used for all files, then the `Encoded-Path` key will be present instead. This stores the same data, but it is encoded as a string of hexadecimal digits. Each pair of hexadecimal digits in the string represents a single octet.

The following two keys are always present:

`Size`

The expected size of this file, as an integer.

Last-Modified

The last modification time of the file as reported by the server at the time of the backup. Unlike the other fields stored in the backup, this field is not used by [pg_verifybackup](#). It is included only for informational purposes.

If the backup was taken with file checksums enabled, the following keys will be present:

Checksum-Algorithm

The checksum algorithm used to compute a checksum for this file. Currently, this will be the same for every file in the backup manifest, but this may change in future releases. At present, the supported checksum algorithms are CRC32C, SHA224, SHA256, SHA384, and SHA512.

Checksum

The checksum computed for this file, stored as a series of hexadecimal characters, two for each byte of the checksum.

67.3. Backup Manifest WAL Range Object

The object which describes a WAL range always has three keys:

Timeline

The timeline for this range of WAL records, as an integer.

Start-LSN

The LSN at which replay must begin on the indicated timeline in order to make use of this backup. The LSN is stored in the format normally used by Postgres Pro; that is, it is a string consisting of two strings of hexadecimal characters, each with a length of between 1 and 8, separated by a slash.

End-LSN

The earliest LSN at which replay on the indicated timeline may end when making use of this backup. This is stored in the same format as `Start-LSN`.

Ordinarily, there will be only a single WAL range. However, if a backup is taken from a standby which switches timelines during the backup due to an upstream promotion, it is possible for multiple ranges to be present, each with a different timeline. There will never be multiple WAL ranges present for the same timeline.

Part VIII. Appendixes

Appendix A. Postgres Pro Error Codes

All messages emitted by the Postgres Pro server are assigned five-character error codes that follow the SQL standard's conventions for "SQLSTATE" codes. Applications that need to know which error condition has occurred should usually test the error code, rather than looking at the textual error message. The error codes are less likely to change across Postgres Pro releases, and also are not subject to change due to localization of error messages. Note that some, but not all, of the error codes produced by Postgres Pro are defined by the SQL standard; some additional error codes for conditions not defined by the standard have been invented or borrowed from other databases.

According to the standard, the first two characters of an error code denote a class of errors, while the last three characters indicate a specific condition within that class. Thus, an application that does not recognize the specific error code might still be able to infer what to do from the error class.

[Table A.1](#) lists all the error codes defined in Postgres Pro Standard 18.0.1. (Some are not actually used at present, but are defined by the SQL standard.) The error classes are also shown. For each error class there is a "standard" error code having the last three characters 000. This code is used only for error conditions that fall within the class but do not have any more-specific code assigned.

The symbol shown in the column "Condition Name" is the condition name to use in PL/pgSQL. Condition names can be written in either upper or lower case. (Note that PL/pgSQL does not recognize warning, as opposed to error, condition names; those are classes 00, 01, and 02.)

For some types of errors, the server reports the name of a database object (a table, table column, data type, or constraint) associated with the error; for example, the name of the unique constraint that caused a `unique_violation` error. Such names are supplied in separate fields of the error report message so that applications need not try to extract them from the possibly-localized human-readable text of the message. As of PostgreSQL 9.3, complete coverage for this feature exists only for errors in SQLSTATE class 23 (integrity constraint violation), but this is likely to be expanded in future.

Table A.1. Postgres Pro Error Codes

Error Code	Condition Name
Class 00 — Successful Completion	
00000	successful_completion
Class 01 — Warning	
01000	warning
0100C	dynamic_result_sets_returned
01008	implicit_zero_bit_padding
01003	null_value_eliminated_in_set_function
01007	privilege_not_granted
01006	privilege_not_revoked
01004	string_data_right_truncation
01P01	deprecated_feature
Class 02 — No Data (this is also a warning class per the SQL standard)	
02000	no_data
02001	no_additional_dynamic_result_sets_returned
Class 03 — SQL Statement Not Yet Complete	
03000	sql_statement_not_yet_complete
Class 08 — Connection Exception	
08000	connection_exception

Error Code	Condition Name
08003	connection_does_not_exist
08006	connection_failure
08001	sqlclient_unable_to_establish_sqlconnection
08004	sqlserver_rejected_establishment_of_sqlconnection
08007	transaction_resolution_unknown
08P01	protocol_violation
Class 09 — Triggered Action Exception	
09000	triggered_action_exception
Class 0A — Feature Not Supported	
0A000	feature_not_supported
Class 0B — Invalid Transaction Initiation	
0B000	invalid_transaction_initiation
Class 0F — Locator Exception	
0F000	locator_exception
0F001	invalid_locator_specification
Class 0L — Invalid Grantor	
0L000	invalid_grantor
0LP01	invalid_grant_operation
Class 0P — Invalid Role Specification	
0P000	invalid_role_specification
Class 0Z — Diagnostics Exception	
0Z000	diagnostics_exception
0Z002	stacked_diagnostics_accessed_without_active_handler
Class 10 — XQuery Error	
10608	invalid_argument_for_xquery
Class 20 — Case Not Found	
20000	case_not_found
Class 21 — Cardinality Violation	
21000	cardinality_violation
Class 22 — Data Exception	
22000	data_exception
2202E	array_subscript_error
22021	character_not_in_repertoire
22008	datetime_field_overflow
22012	division_by_zero
22005	error_in_assignment
2200B	escape_character_conflict
22022	indicator_overflow
22015	interval_field_overflow

Postgres Pro Error Codes

Error Code	Condition Name
2201E	invalid_argument_for_logarithm
22014	invalid_argument_for_ntile_function
22016	invalid_argument_for_nth_value_function
2201F	invalid_argument_for_power_function
2201G	invalid_argument_for_width_bucket_function
22018	invalid_character_value_for_cast
22007	invalid_datetime_format
22019	invalid_escape_character
2200D	invalid_escape_octet
22025	invalid_escape_sequence
22P06	nonstandard_use_of_escape_character
22010	invalid_indicator_parameter_value
22023	invalid_parameter_value
22013	invalid_preceding_or_following_size
2201B	invalid_regular_expression
2201W	invalid_row_count_in_limit_clause
2201X	invalid_row_count_in_result_offset_clause
2202H	invalid_tablesample_argument
2202G	invalid_tablesample_repeat
22009	invalid_time_zone_displacement_value
2200C	invalid_use_of_escape_character
2200G	most_specific_type_mismatch
22004	null_value_not_allowed
22002	null_value_no_indicator_parameter
22003	numeric_value_out_of_range
2200H	sequence_generator_limit_exceeded
22026	string_data_length_mismatch
22001	string_data_right_truncation
22011	substring_error
22027	trim_error
22024	unterminated_c_string
2200F	zero_length_character_string
22P01	floating_point_exception
22P02	invalid_text_representation
22P03	invalid_binary_representation
22P04	bad_copy_file_format
22P05	untranslatable_character
2200L	not_an_xml_document
2200M	invalid_xml_document

Error Code	Condition Name
2200N	invalid_xml_content
2200S	invalid_xml_comment
2200T	invalid_xml_processing_instruction
22030	duplicate_json_object_key_value
22031	invalid_argument_for_sql_json_datetime_function
22032	invalid_json_text
22033	invalid_sql_json_subscript

Appendix B. Date/Time Support

Postgres Pro uses an internal heuristic parser for all date/time input support. Dates and times are input as strings, and are broken up into distinct fields with a preliminary determination of what kind of information can be in the field. Each field is interpreted and either assigned a numeric value, ignored, or rejected. The parser contains internal lookup tables for all textual fields, including months, days of the week, and time zones.

This appendix includes information on the content of these lookup tables and describes the steps used by the parser to decode dates and times.

B.1. Date/Time Input Interpretation

Date/time input strings are decoded using the following procedure.

1. Break the input string into tokens and categorize each token as a string, time, time zone, or number.
 - a. If the numeric token contains a colon (:), this is a time string. Include all subsequent digits and colons.
 - b. If the numeric token contains a dash (-), slash (/), or two or more dots (.), this is a date string which might have a text month. If a date token has already been seen, it is instead interpreted as a time zone name (e.g., `America/New_York`).
 - c. If the token is numeric only, then it is either a single field or an ISO 8601 concatenated date (e.g., `19990113` for January 13, 1999) or time (e.g., `141516` for 14:15:16).
 - d. If the token starts with a plus (+) or minus (-), then it is either a numeric time zone or a special field.
2. If the token is an alphabetic string, match up with possible strings:
 - a. See if the token matches any known time zone abbreviation. These abbreviations are determined by the configuration settings described in [Section B.4](#).
 - b. If not found, search an internal table to match the token as either a special string (e.g., `today`), day (e.g., `Thursday`), month (e.g., `January`), or noise word (e.g., `at`, `on`).
 - c. If still not found, throw an error.
3. When the token is a number or number field:
 - a. If there are eight or six digits, and if no other date fields have been previously read, then interpret as a “concatenated date” (e.g., `19990118` or `990118`). The interpretation is `YYYYMMDD` or `YYMMDD`.
 - b. If the token is three digits and a year has already been read, then interpret as day of year.
 - c. If four or six digits and a year has already been read, then interpret as a time (`HHMM` or `HHMMSS`).
 - d. If three or more digits and no date fields have yet been found, interpret as a year (this forces `yy-mm-dd` ordering of the remaining date fields).
 - e. Otherwise the date field ordering is assumed to follow the `DateStyle` setting: `mm-dd-yy`, `dd-mm-yy`, or `yy-mm-dd`. Throw an error if a month or day field is found to be out of range.
4. If BC has been specified, negate the year and add one for internal storage. (There is no year zero in the Gregorian calendar, so numerically 1 BC becomes year zero.)
5. If BC was not specified, and if the year field was two digits in length, then adjust the year to four digits. If the field is less than 70, then add 2000, otherwise add 1900.

Tip

Gregorian years AD 1-99 can be entered by using 4 digits with leading zeros (e.g., 0099 is AD 99).

B.2. Handling of Invalid or Ambiguous Timestamps

Ordinarily, if a date/time string is syntactically valid but contains out-of-range field values, an error will be thrown. For example, input specifying the 31st of February will be rejected.

During a daylight-savings-time transition, it is possible for a seemingly valid timestamp string to represent a nonexistent or ambiguous timestamp. Such cases are not rejected; the ambiguity is resolved by determining which UTC offset to apply. For example, supposing that the [TimeZone](#) parameter is set to `America/New_York`, consider

```
=> SELECT '2018-03-11 02:30'::timestampz;
       timestampz
-----
2018-03-11 03:30:00-04
(1 row)
```

Because that day was a spring-forward transition date in that time zone, there was no civil time instant 2:30AM; clocks jumped forward from 2AM EST to 3AM EDT. Postgres Pro interprets the given time as if it were standard time (UTC-5), which then renders as 3:30AM EDT (UTC-4).

Conversely, consider the behavior during a fall-back transition:

```
=> SELECT '2018-11-04 01:30'::timestampz;
       timestampz
-----
2018-11-04 01:30:00-05
(1 row)
```

On that date, there were two possible interpretations of 1:30AM; there was 1:30AM EDT, and then an hour later after clocks jumped back from 2AM EDT to 1AM EST, there was 1:30AM EST. Again, Postgres Pro interprets the given time as if it were standard time (UTC-5). We can force the other interpretation by specifying daylight-savings time:

```
=> SELECT '2018-11-04 01:30 EDT'::timestampz;
       timestampz
-----
2018-11-04 01:30:00-04
(1 row)
```

The precise rule that is applied in such cases is that an invalid timestamp that appears to fall within a jump-forward daylight savings transition is assigned the UTC offset that prevailed in the time zone just before the transition, while an ambiguous timestamp that could fall on either side of a jump-back transition is assigned the UTC offset that prevailed just after the transition. In most time zones this is equivalent to saying that “the standard-time interpretation is preferred when in doubt”.

In all cases, the UTC offset associated with a timestamp can be specified explicitly, using either a numeric UTC offset or a time zone abbreviation that corresponds to a fixed UTC offset. The rule just given applies only when it is necessary to infer a UTC offset for a time zone in which the offset varies.

B.3. Date/Time Key Words

[Table B.1](#) shows the tokens that are recognized as names of months.

Table B.1. Month Names

Month	Abbreviations
January	Jan
February	Feb
March	Mar
April	Apr
May	
June	Jun
July	Jul
August	Aug
September	Sep, Sept
October	Oct
November	Nov
December	Dec

[Table B.2](#) shows the tokens that are recognized as names of days of the week.

Table B.2. Day of the Week Names

Day	Abbreviations
Sunday	Sun
Monday	Mon
Tuesday	Tue, Tues
Wednesday	Wed, Weds
Thursday	Thu, Thur, Thurs
Friday	Fri
Saturday	Sat

[Table B.3](#) shows the tokens that serve various modifier purposes.

Table B.3. Date/Time Field Modifiers

Identifier	Description
AM	Time is before 12:00
AT	Ignored
JULIAN, JD, J	Next field is Julian Date
ON	Ignored
PM	Time is on or after 12:00
T	Next field is time

B.4. Date/Time Configuration Files

Since timezone abbreviations are not well standardized, Postgres Pro provides a means to customize the set of abbreviations accepted in datetime input. There are two sources for these abbreviations:

1. The [TimeZone](#) run-time parameter is usually set to the name of an entry in the IANA time zone database. If that zone has widely-used zone abbreviations, they will appear in the IANA data, and Postgres Pro will preferentially recognize those abbreviations with the meanings given in the IANA

data. For example, if `timezone` is set to `America/New_York` then `EST` will be understood as UTC-5 and `EDT` will be understood as UTC-4. (These IANA abbreviations will also be used in datetime output, if `DateStyle` is set to a style that prefers non-numeric zone abbreviations.)

2. If an abbreviation is not found in the current IANA time zone, it is sought in the list specified by the `timezone_abbreviations` run-time parameter. The `timezone_abbreviations` list is primarily useful for allowing datetime input to recognize abbreviations for time zones other than the current zone. (These abbreviations will not be used in datetime output.)

While the `timezone_abbreviations` parameter can be altered by any database user, the possible values for it are under the control of the database administrator — they are in fact names of configuration files stored in `.../share/timezonesets/` of the installation directory. By adding or altering files in that directory, the administrator can set local policy for timezone abbreviations.

`timezone_abbreviations` can be set to any file name found in `.../share/timezonesets/`, if the file's name is entirely alphabetic. (The prohibition against non-alphabetic characters in `timezone_abbreviations` prevents reading files outside the intended directory, as well as reading editor backup files and other extraneous files.)

A timezone abbreviation file can contain blank lines and comments beginning with `#`. Non-comment lines must have one of these formats:

```
zone_abbreviation offset
zone_abbreviation offset D
zone_abbreviation time_zone_name
@INCLUDE file_name
@OVERRIDE
```

A *zone_abbreviation* is just the abbreviation being defined. An *offset* is an integer giving the equivalent offset in seconds from UTC, positive being east from Greenwich and negative being west. For example, `-18000` would be five hours west of Greenwich, or North American east coast standard time. `D` indicates that the zone name represents local daylight-savings time rather than standard time.

Alternatively, a *time_zone_name* can be given, referencing a zone name defined in the IANA timezone database. The zone's definition is consulted to see whether the abbreviation is or has been in use in that zone, and if so, the appropriate meaning is used — that is, the meaning that was currently in use at the timestamp whose value is being determined, or the meaning in use immediately before that if it wasn't current at that time, or the oldest meaning if it was used only after that time. This behavior is essential for dealing with abbreviations whose meaning has historically varied. It is also allowed to define an abbreviation in terms of a zone name in which that abbreviation does not appear; then using the abbreviation is just equivalent to writing out the zone name.

Tip

Using a simple integer *offset* is preferred when defining an abbreviation whose offset from UTC has never changed, as such abbreviations are much cheaper to process than those that require consulting a time zone definition.

The `@INCLUDE` syntax allows inclusion of another file in the `.../share/timezonesets/` directory. Inclusion can be nested, to a limited depth.

The `@OVERRIDE` syntax indicates that subsequent entries in the file can override previous entries (typically, entries obtained from included files). Without this, conflicting definitions of the same timezone abbreviation are considered an error.

In an unmodified installation, the file `Default` contains all the non-conflicting time zone abbreviations for most of the world. Additional files `Australia` and `India` are provided for those regions: these files first include the `Default` file and then add or modify abbreviations as needed.

For reference purposes, a standard installation also contains files `Africa.txt`, `America.txt`, etc., containing information about every time zone abbreviation known to be in use according to the IANA time-zone database. The zone name definitions found in these files can be copied and pasted into a custom configuration file as needed. Note that these files cannot be directly referenced as `timezone_abbreviations` settings, because of the dot embedded in their names.

Note

If an error occurs while reading the time zone abbreviation set, no new value is applied and the old set is kept. If the error occurs while starting the database, startup fails.

Caution

Time zone abbreviations defined in the configuration file override non-timezone meanings built into Postgres Pro. For example, the `Australia` configuration file defines `SAT` (for South Australian Standard Time). When this file is active, `SAT` will not be recognized as an abbreviation for Saturday.

Caution

If you modify files in `.../share/timezonesets/`, it is up to you to make backups — a normal database dump will not include this directory.

B.5. POSIX Time Zone Specifications

Postgres Pro can accept time zone specifications that are written according to the POSIX standard's rules for the `TZ` environment variable. POSIX time zone specifications are inadequate to deal with the complexity of real-world time zone history, but there are sometimes reasons to use them.

A POSIX time zone specification has the form

```
STD offset [ DST [ dstoffset ] [ , rule ] ]
```

(For readability, we show spaces between the fields, but spaces should not be used in practice.) The fields are:

- *STD* is the zone abbreviation to be used for standard time.
- *offset* is the zone's standard-time offset from UTC.
- *DST* is the zone abbreviation to be used for daylight-savings time. If this field and the following ones are omitted, the zone uses a fixed UTC offset with no daylight-savings rule.
- *dstoffset* is the daylight-savings offset from UTC. This field is typically omitted, since it defaults to one hour less than the standard-time *offset*, which is usually the right thing.
- *rule* defines the rule for when daylight savings is in effect, as described below.

In this syntax, a zone abbreviation can be a string of letters, such as `EST`, or an arbitrary string surrounded by angle brackets, such as `<UTC-05>`. Note that the zone abbreviations given here are only used for output, and even then only in some timestamp output formats. The zone abbreviations recognized in timestamp input are determined as explained in [Section B.4](#).

The offset fields specify the hours, and optionally minutes and seconds, difference from UTC. They have the format `hh[:mm[:ss]]` optionally with a leading sign (+ or -). The positive sign is used for zones west of Greenwich. (Note that this is the opposite of the ISO-8601 sign convention used elsewhere in Postgres Pro.) *hh* can have one or two digits; *mm* and *ss* (if used) must have two.

The daylight-savings transition *rule* has the format

dstdate [/ *dsttime*] , *stddate* [/ *stdtime*]

(As before, spaces should not be included in practice.) The *dstdate* and *dsttime* fields define when daylight-savings time starts, while *stddate* and *stdtime* define when standard time starts. (In some cases, notably in zones south of the equator, the former might be later in the year than the latter.) The date fields have one of these formats:

n

A plain integer denotes a day of the year, counting from zero to 364, or to 365 in leap years.

Jn

In this form, *n* counts from 1 to 365, and February 29 is not counted even if it is present. (Thus, a transition occurring on February 29 could not be specified this way. However, days after February have the same numbers whether it's a leap year or not, so that this form is usually more useful than the plain-integer form for transitions on fixed dates.)

Mm.n.d

This form specifies a transition that always happens during the same month and on the same day of the week. *m* identifies the month, from 1 to 12. *n* specifies the *n*'th occurrence of the weekday identified by *d*. *n* is a number between 1 and 4, or 5 meaning the last occurrence of that weekday in the month (which could be the fourth or the fifth). *d* is a number between 0 and 6, with 0 indicating Sunday. For example, *M3.2.0* means “the second Sunday in March”.

Note

The *M* format is sufficient to describe many common daylight-savings transition laws. But note that none of these variants can deal with daylight-savings law changes, so in practice the historical data stored for named time zones (in the IANA time zone database) is necessary to interpret past time stamps correctly.

The time fields in a transition rule have the same format as the offset fields described previously, except that they cannot contain signs. They define the current local time at which the change to the other time occurs. If omitted, they default to 02:00:00.

If a daylight-savings abbreviation is given but the transition *rule* field is omitted, the fallback behavior is to use the rule *M3.2.0,M11.1.0*, which corresponds to USA practice as of 2020 (that is, spring forward on the second Sunday of March, fall back on the first Sunday of November, both transitions occurring at 2AM prevailing time). Note that this rule does not give correct USA transition dates for years before 2007.

As an example, *CET-1CEST,M3.5.0,M10.5.0/3* describes the current (as of 2020) timekeeping practice in Paris. This specification says that standard time has the abbreviation *CET* and is one hour ahead (east) of UTC; daylight savings time has the abbreviation *CEST* and is implicitly two hours ahead of UTC; daylight savings time begins on the last Sunday in March at 2AM CET and ends on the last Sunday in October at 3AM CEST.

The four timezone names *EST5EDT*, *CST6CDT*, *MST7MDT*, and *PST8PDT* look like they are POSIX zone specifications. However, they actually are treated as named time zones because (for historical reasons) there are files by those names in the IANA time zone database. The practical implication of this is that these zone names will produce valid historical USA daylight-savings transitions, even when a plain POSIX specification would not.

One should be wary that it is easy to misspell a POSIX-style time zone specification, since there is no check on the reasonableness of the zone abbreviation(s). For example, *SET TIMEZONE TO FOOBAR0* will work, leaving the system effectively using a rather peculiar abbreviation for UTC.

B.6. History of Units

The SQL standard states that “Within the definition of a ‘datetime literal’, the ‘datetime values’ are constrained by the natural rules for dates and times according to the Gregorian calendar”. Postgres Pro follows the SQL standard's lead by counting dates exclusively in the Gregorian calendar, even for years before that calendar was in use. This rule is known as the *proleptic Gregorian calendar*.

The Julian calendar was introduced by Julius Caesar in 45 BC. It was in common use in the Western world until the year 1582, when countries started changing to the Gregorian calendar. In the Julian calendar, the tropical year is approximated as $365 \frac{1}{4}$ days = 365.25 days. This gives an error of about 1 day in 128 years.

The accumulating calendar error prompted Pope Gregory XIII to reform the calendar in accordance with instructions from the Council of Trent. In the Gregorian calendar, the tropical year is approximated as $365 + 97 / 400$ days = 365.2425 days. Thus it takes approximately 3300 years for the tropical year to shift one day with respect to the Gregorian calendar.

The approximation $365 + 97 / 400$ is achieved by having 97 leap years every 400 years, using the following rules:

Every year divisible by 4 is a leap year.

However, every year divisible by 100 is not a leap year.

However, every year divisible by 400 is a leap year after all.

So, 1700, 1800, 1900, 2100, and 2200 are not leap years. But 1600, 2000, and 2400 are leap years. By contrast, in the older Julian calendar all years divisible by 4 are leap years.

The papal bull of February 1582 decreed that 10 days should be dropped from October 1582 so that 15 October should follow immediately after 4 October. This was observed in Italy, Poland, Portugal, and Spain. Other Catholic countries followed shortly after, but Protestant countries were reluctant to change, and the Greek Orthodox countries didn't change until the start of the 20th century. The reform was observed by Great Britain and its dominions (including what is now the USA) in 1752. Thus 2 September 1752 was followed by 14 September 1752. This is why Unix systems that have the `cal` program produce the following:

```
$ cal 9 1752
    September 1752
S  M Tu  W Th  F  S
      1  2 14 15 16
17 18 19 20 21 22 23
24 25 26 27 28 29 30
```

But, of course, this calendar is only valid for Great Britain and dominions, not other places. Since it would be difficult and confusing to try to track the actual calendars that were in use in various places at various times, Postgres Pro does not try, but rather follows the Gregorian calendar rules for all dates, even though this method is not historically accurate.

Different calendars have been developed in various parts of the world, many predating the Gregorian system. For example, the beginnings of the Chinese calendar can be traced back to the 14th century BC. Legend has it that the Emperor Huangdi invented that calendar in 2637 BC. The People's Republic of China uses the Gregorian calendar for civil purposes. The Chinese calendar is used for determining festivals.

B.7. Julian Dates

The *Julian Date* system is a method for numbering days. It is unrelated to the Julian calendar, though it is confusingly named similarly to that calendar. The Julian Date system was invented by the French scholar Joseph Justus Scaliger (1540-1609) and probably takes its name from Scaliger's father, the Italian scholar Julius Caesar Scaliger (1484-1558).

In the Julian Date system, each day has a sequential number, starting from JD 0 (which is sometimes called *the* Julian Date). JD 0 corresponds to 1 January 4713 BC in the Julian calendar, or 24 November 4714 BC in the Gregorian calendar. Julian Date counting is most often used by astronomers for labeling

their nightly observations, and therefore a date runs from noon UTC to the next noon UTC, rather than from midnight to midnight: JD 0 designates the 24 hours from noon UTC on 24 November 4714 BC to noon UTC on 25 November 4714 BC.

Although Postgres Pro supports Julian Date notation for input and output of dates (and also uses Julian dates for some internal datetime calculations), it does not observe the nicety of having dates run from noon to noon. Postgres Pro treats a Julian Date as running from local midnight to local midnight, the same as a normal date.

This definition does, however, provide a way to obtain the astronomical definition when you need it: do the arithmetic in time zone `UTC+12`. For example,

```
=> SELECT extract(julian from '2021-06-23 7:00:00-04'::timestampz at time zone 'UTC
+12');
```

extract.

2459388.9583333333333333333333

```
(1 row)
```

```
=> SELECT extract(julian from '2021-06-23 8:00:00-04'::timestampz at time zone 'UTC
+12');
```

extract

2459389.0000000000000000000000000000000000

```
(1 row)
```

```
=> SELECT extract(julian from date '2021-06-23');
```

extract.

2459389

(1 row)

Appendix C. SQL Key Words

[Table C.1](#) lists all tokens that are key words in the SQL standard and in Postgres Pro Standard 18.0.1. Background information can be found in [Section 4.1.1](#). (For space reasons, only the latest two versions of the SQL standard, and SQL-92 for historical comparison, are included. The differences between those and the other intermediate standard versions are small.)

SQL distinguishes between *reserved* and *non-reserved* key words. According to the standard, reserved key words are the only real key words; they are never allowed as identifiers. Non-reserved key words only have a special meaning in particular contexts and can be used as identifiers in other contexts. Most non-reserved key words are actually the names of built-in tables and functions specified by SQL. The concept of non-reserved key words essentially only exists to declare that some predefined meaning is attached to a word in some contexts.

In the Postgres Pro parser, life is a bit more complicated. There are several different classes of tokens ranging from those that can never be used as an identifier to those that have absolutely no special status in the parser, but are considered ordinary identifiers. (The latter is usually the case for functions specified by SQL.) Even reserved key words are not completely reserved in Postgres Pro, but can be used as column labels (for example, `SELECT 55 AS CHECK`, even though `CHECK` is a reserved key word).

In [Table C.1](#) in the column for Postgres Pro we classify as “non-reserved” those key words that are explicitly known to the parser but are allowed as column or table names. Some key words that are otherwise non-reserved cannot be used as function or data type names and are marked accordingly. (Most of these words represent built-in functions or data types with special syntax. The function or type is still available but it cannot be redefined by the user.) Labeled “reserved” are those tokens that are not allowed as column or table names. Some reserved key words are allowable as names for functions or data types; this is also shown in the table. If not so marked, a reserved key word is only allowed as a column label. A blank entry in this column means that the word is treated as an ordinary identifier by Postgres Pro.

Furthermore, while most key words can be used as “bare” column labels without writing `AS` before them (as described in [Section 7.3.2](#)), there are a few that require a leading `AS` to avoid ambiguity. These are marked in the table as “requires `AS`”.

As a general rule, if you get spurious parser errors for commands that use any of the listed key words as an identifier, you should try quoting the identifier to see if the problem goes away.

It is important to understand before studying [Table C.1](#) that the fact that a key word is not reserved in Postgres Pro does not mean that the feature related to the word is not implemented. Conversely, the presence of a key word does not indicate the existence of a feature.

Appendix D. SQL Conformance

This section attempts to outline to what extent Postgres Pro conforms to the current SQL standard. The following information is not a full statement of conformance, but it presents the main topics in as much detail as is both reasonable and useful for users.

The formal name of the SQL standard is ISO/IEC 9075 “Database Language SQL”. A revised version of the standard is released from time to time; the most recent update appearing in 2023. The 2023 version is referred to as ISO/IEC 9075:2023, or simply as SQL:2023. The versions prior to that were SQL:2016, SQL:2011, SQL:2008, SQL:2006, SQL:2003, SQL:1999, and SQL-92. Each version replaces the previous one, so claims of conformance to earlier versions have no official merit. Postgres Pro development aims for conformance with the latest official version of the standard where such conformance does not contradict traditional features or common sense. Many of the features required by the SQL standard are supported, though sometimes with slightly differing syntax or function. Further moves towards conformance can be expected over time.

SQL-92 defined three feature sets for conformance: Entry, Intermediate, and Full. Most database management systems claiming SQL standard conformance were conforming at only the Entry level, since the entire set of features in the Intermediate and Full levels was either too voluminous or in conflict with legacy behaviors.

Starting with SQL:1999, the SQL standard defines a large set of individual features rather than the ineffectively broad three levels found in SQL-92. A large subset of these features represents the “Core” features, which every conforming SQL implementation must supply. The rest of the features are purely optional.

The standard is split into a number of parts, each also known by a shorthand name:

- ISO/IEC 9075-1 Framework (SQL/Framework)
- ISO/IEC 9075-2 Foundation (SQL/Foundation)
- ISO/IEC 9075-3 Call Level Interface (SQL/CLI)
- ISO/IEC 9075-4 Persistent Stored Modules (SQL/PSM)
- ISO/IEC 9075-9 Management of External Data (SQL/MED)
- ISO/IEC 9075-10 Object Language Bindings (SQL/OLB)
- ISO/IEC 9075-11 Information and Definition Schemas (SQL/Schemata)
- ISO/IEC 9075-13 Routines and Types using the Java Language (SQL/JRT)
- ISO/IEC 9075-14 XML-related specifications (SQL/XML)
- ISO/IEC 9075-15 Multi-dimensional arrays (SQL/MDA)
- ISO/IEC 9075-16 Property Graph Queries (SQL/PGQ)

Note that some part numbers are not (or no longer) used.

The Postgres Pro core covers parts 1, 2, 9, 11, and 14. Part 3 is covered by the ODBC driver, and part 13 is covered by the PL/Java plug-in, but exact conformance is currently not being verified for these components. There are currently no implementations of parts 4, 10, 15, and 16 for Postgres Pro.

Postgres Pro supports most of the major features of SQL:2023. Out of 177 mandatory features required for full Core conformance, Postgres Pro conforms to at least 170. In addition, there is a long list of

supported optional features. It might be worth noting that at the time of writing, no current version of any database management system claims full conformance to Core SQL:2023.

In the following two sections, we provide a list of those features that Postgres Pro supports, followed by a list of the features defined in SQL:2023 which are not yet supported in Postgres Pro. Both of these lists are approximate: There might be minor details that are nonconforming for a feature that is listed as supported, and large parts of an unsupported feature might in fact be implemented. The main body of the documentation always contains the most accurate information about what does and does not work.

Note

Feature codes containing a hyphen are subfeatures. Therefore, if a particular subfeature is not supported, the main feature is listed as unsupported even if some other subfeatures are supported.

D.1. Supported Features

Identifier	Core?	Description	Comment
B012		Embedded C

T662		Underscores in numeric literals	
T670		Schema and data statement mixing	
T803		String-based JSON	
T811		Basic SQL/JSON constructor functions	
T812		SQL/JSON: JSON_OBJECTAGG	

Identifier	Core?	Description	Comment
T813		SQL/JSON: JSON_ARRAYAGG with ORDER BY	
T814		Colon in JSON_OBJECT or JSON_OBJECTAGG	
T821		Basic SQL/JSON query operators	
T822		SQL/JSON: IS JSON WITH UNIQUE KEYS predicate	
T823		SQL/JSON: PASSING clause	
T824		JSON_TABLE: specific PLAN clause	
T825		SQL/JSON: ON EMPTY and ON ERROR clauses	
T826		General value expression in ON ERROR or ON EMPTY clauses	
T827		JSON_TABLE: sibling NESTED COLUMNS clauses	
T828		JSON_QUERY	
T829		JSON_QUERY: array wrapper options	
T830		Enforcing unique keys in SQL/JSON constructor functions	
T831		SQL/JSON path language: strict mode	
T832		SQL/JSON path language: item method	
T833		SQL/JSON path language: multiple subscripts	
T834		SQL/JSON path language: wildcard member accessor	
T835		SQL/JSON path language: filter expressions	
T836		SQL/JSON path language: starts with predicate	
T837		SQL/JSON path language: regex_like predicate	
T838		JSON_TABLE: PLAN DEFAULT clause	
T840		Hex integer literals in SQL/JSON path language	
T851		SQL/JSON: optional keywords for default syntax	
T865		SQL/JSON item method: bigint()	
T866		SQL/JSON item method: boolean()	
T867		SQL/JSON item method: date()	
T868		SQL/JSON item method: decimal()	
T869		SQL/JSON item method: decimal() with precision and scale	
T870		SQL/JSON item method: integer()	
T871		SQL/JSON item method: number()	
T872		SQL/JSON item method: string()	
T873		SQL/JSON item method: time()	
T874		SQL/JSON item method: time_tz()	
T875		SQL/JSON item method: time precision	
T876		SQL/JSON item method: timestamp()	
T877		SQL/JSON item method: timestamp_tz()	
T878		SQL/JSON item method: timestamp precision	
T879		JSON in equality operations	with jsonb
T880		JSON in grouping operations	with jsonb
X010		XML type	

Identifier	Core?	Description	Comment
X011		Arrays of XML type	
X014		Attributes of XML type	
X016		Persistent XML values	
X020		XMLConcat	
X031		XMLElement	
X032		XMLForest	
X034		XMLAgg	
X035		XMLAgg: ORDER BY option	
X036		XMLComment	
X037		XMLPI	
X038		XMLText	supported except for RETURNING
X040		Basic table mapping	
X041		Basic table mapping: null absent	
X042		Basic table mapping: null as nil	
X043		Basic table mapping: table as forest	
X044		Basic table mapping: table as element	
X045		Basic table mapping: with target namespace	
X046		Basic table mapping: data mapping	
X047		Basic table mapping: metadata mapping	
X048		Basic table mapping: base64 encoding of binary strings	
X049		Basic table mapping: hex encoding of binary strings	
X050		Advanced table mapping	
X051		Advanced table mapping: null absent	
X052		Advanced table mapping: null as nil	
X053		Advanced table mapping: table as forest	
X054		Advanced table mapping: table as element	
X055		Advanced table mapping: with target namespace	
X056		Advanced table mapping: data mapping	
X057		Advanced table mapping: metadata mapping	
X058		Advanced table mapping: base64 encoding of binary strings	
X059		Advanced table mapping: hex encoding of binary strings	
X060		XMLParse: character string input and CONTENT option	
X061		XMLParse: character string input and DOCUMENT option	
X069		XMLSerialize: INDENT	
X070		XMLSerialize: character string serialization and CONTENT option	
X071		XMLSerialize: character string serialization and DOCUMENT option	
X072		XMLSerialize: character string serialization	

Identifier	Core?	Description	Comment
X090		XML document predicate	
X120		XML parameters in SQL routines	
X121		XML parameters in external routines	
X221		XML passing mechanism BY VALUE	
X301		XMLTable: derived column list option	
X302		XMLTable: ordinality column option	
X303		XMLTable: column default option	
X304		XMLTable: passing a context item	must be XML DOCUMENT
X400		Name and identifier mapping	
X410		Alter column data type: XML type	

D.2. Unsupported Features

The following features defined in SQL:2023 are not implemented in this release of Postgres Pro. In a few cases, equivalent functionality is available.

Identifier	Core?	Description	Comment
B011		Embedded Ada	
B013		Embedded COBOL	
B014		Embedded Fortran	
B015		Embedded MUMPS	
B016		Embedded Pascal	
B017		Embedded PL/I	
B030		Enhanced dynamic SQL	
B031		Basic dynamic SQL	
B032		Extended dynamic SQL	
B033		Untyped SQL-invoked function arguments	
B034		Dynamic specification of cursor attributes	
B035		Non-extended descriptor names	
B036		Describe input statement	
B041		Extensions to embedded SQL exception declarations	
B051		Enhanced execution rights	
B111		Module language Ada	
B112		Module language C	
B113		Module language COBOL	
B114		Module language Fortran	
B115		Module language MUMPS	
B116		Module language Pascal	
B117		Module language PL/I	
B121		Routine language Ada	
B122		Routine language C	
B123		Routine language COBOL	

Identifier	Core?	Description	Comment
B124		Routine language Fortran	
B125		Routine language MUMPS	
B126		Routine language Pascal	
B127		Routine language PL/I	
B200		Polymorphic table functions	
B201		More than one PTF generic table parameter	
B202		PTF copartitioning	
B203		More than one copartition specification	
B204		PRUNE WHEN EMPTY	
B205		Pass-through columns	
B206		PTF descriptor parameters	
B207		Cross products of partitionings	
B208		PTF component procedure interface	
B209		PTF extended names	
B211		Module language Ada: VARCHAR and NUMERIC support	
B221		Routine language Ada: VARCHAR and NUMERIC support	
F054		TIMESTAMP in DATE type precedence list	
F120		Get diagnostics statement	
F121		Basic diagnostics management	
F122		Enhanced diagnostics management	
F123		All diagnostics	
F124		SET TRANSACTION statement: DIAGNOSTICS SIZE clause	
F263		Comma-separated predicates in simple CASE expression	
F291		UNIQUE predicate	
F301		CORRESPONDING in query expressions	
F403		Partitioned join tables	
F451		Character set definition	
F461		Named character sets	
F521		Assertions	
F671		Subqueries in CHECK constraints	intentionally omitted
F673		Reads SQL-data routine invocations in CHECK constraints	
F693		SQL-session and client module collations	
F695		Translation support	
F696		Additional translation documentation	
F721		Deferrable constraints	foreign and unique keys only
F741		Referential MATCH types	no partial match yet
F812		Basic flagging	

Identifier	Core?	Description	Comment
F813		Extended flagging	
F821		Local table references	
F831		Full cursor update	
F832		Updatable scrollable cursors	
F833		Updatable ordered cursors	
F841		LIKE_REGEX predicate	consider regexp_like()
F842		OCCURRENCES_REGEX function	consider regexp_matches()
F843		POSITION_REGEX function	consider regexp_instr()
F844		SUBSTRING_REGEX function	consider regexp_substr()
F845		TRANSLATE_REGEX function	consider regexp_replace()
F846		Octet support in regular expression operators	
F847		Non-constant regular expressions	
F866		FETCH FIRST clause: PERCENT option	
R010		Row pattern recognition: FROM clause	
R020		Row pattern recognition: WINDOW clause	
R030		Row pattern recognition: full aggregate support	
S011	Core	Distinct data types	
S011-01	Core	USER_DEFINED_TYPES view	
S023		Basic structured types	
S024		Enhanced structured types	
S025		Final structured types	
S026		Self-referencing structured types	
S027		Create method by specific method name	
S028		Permutable UDT options list	
S041		Basic reference types	
S043		Enhanced reference types	
S051		Create table of type	partially supported
S081		Subtables	
S091		Basic array support	partially supported
S093		Arrays of distinct types	
S094		Arrays of reference types	
S097		Array element assignment	
S151		Type predicate	see pg_typeof()
S161		Subtype treatment	
S162		Subtype treatment for references	
S202		SQL-invoked routines on multisets	
S231		Structured type locators	
S232		Array locators	
S233		Multiset locators	

Identifier	Core?	Description	Comment
S241		Transform functions	
S242		Alter transform statement	
S251		User-defined orderings	
S261		Specific type method	
S271		Basic multiset support	
S272		Multisets of user-defined types	
S274		Multisets of reference types	
S275		Advanced multiset support	
S281		Nested collection types	
S291		Unique constraint on entire row	
S401		Distinct types based on array types	
S402		Distinct types based on multiset types	
S403		ARRAY_MAX_CARDINALITY	
T011		Timestamp in Information Schema	
T021		BINARY and VARBINARY data types	
T022		Advanced support for BINARY and VARBINARY data types	
T023		Compound binary literals	
T024		Spaces in binary literals	
T039		CLOB locator: non-holdable	
T040		Concatenation of CLOBs	
T041		Basic LOB data type support	
T042		Extended LOB data type support	
T043		Multiplier T	
T044		Multiplier P	
T045		BLOB data type	
T046		CLOB data type	
T047		POSITION, OCTET_LENGTH, TRIM, and SUBSTRING for BLOBs	
T048		Concatenation of BLOBs	
T049		BLOB locator: non-holdable	
T050		POSITION, CHAR_LENGTH, OCTET_LENGTH, LOWER, TRIM, UPPER, and SUBSTRING for CLOBs	
T051		Row types	
T053		Explicit aliases for all-fields reference	
T062		Character length units	
T076		DECFLOAT data type	
T101		Enhanced nullability determination	
T111		Updatable joins, unions, and columns	
T175		Generated columns	mostly supported
T176		Sequence generator support	supported except for NEXT VALUE FOR

Identifier	Core?	Description	Comment
T180		System-versioned tables	
T181		Application-time period tables	
T200		Trigger DDL	similar but not fully compatible
T211		Basic trigger capability	
T218		Multiple triggers for the same event executed in the order created	intentionally omitted
T231		Sensitive cursors	
T251		SET TRANSACTION statement: LOCAL option	
T262		Multiple server transactions	
T272		Enhanced savepoint management	
T301		Functional dependencies	partially supported
T321	Core	Basic SQL-invoked routines	partially supported
T322		Declared data type attributes	
T324		Explicit security for SQL routines	
T326		Table functions	
T471		Result sets return value	
T472		DESCRIBE CURSOR	
T495		Combined data change and retrieval	different syntax
T502		Period predicates	
T511		Transaction counts	
T522		Default values for IN parameters of SQL-invoked procedures	supported except DEFAULT key word in invocation
T561		Holdable locators	
T571		Array-returning external SQL-invoked functions	
T572		Multiset-returning external SQL-invoked functions	
T601		Local cursor references	
T616		Null treatment option for LEAD and LAG functions	
T618		NTH_VALUE function	function exists, but some options missing
T619		Nested window functions	
T625		LISTAGG	
T641		Multiple column assignment	only some syntax variants supported
T652		SQL-dynamic statements in SQL routines	
T654		SQL-dynamic statements in external routines	
T801		JSON data type	
T802		Enhanced JSON data type	
T839		Formatted cast of datetimes to/from character strings	
T860		SQL/JSON simplified accessor: column reference only	
T861		SQL/JSON simplified accessor: case-sensitive JSON member accessor	

Identifier	Core?	Description	Comment
T862		SQL/JSON simplified accessor: wildcard member accessor	
T863		SQL/JSON simplified accessor: single-quoted string literal as member accessor	
T864		SQL/JSON simplified accessor	
T881		JSON in ordering operations	with jsonb, partially supported
T882		JSON in multiset element grouping operations	
M001		Datalinks	
M002		Datalinks via SQL/CLI	
M003		Datalinks via Embedded SQL	
M004		Foreign data support	partially supported
M005		Foreign schema support	
M006		GetSQLString routine	
M007		TransmitRequest	
M009		GetOpts and GetStatistics routines	
M010		Foreign-data wrapper support	different API
M011		Datalinks via Ada	
M012		Datalinks via C	
M013		Datalinks via COBOL	
M014		Datalinks via Fortran	
M015		Datalinks via M	
M016		Datalinks via Pascal	
M017		Datalinks via PL/I	
M018		Foreign-data wrapper interface routines in Ada	
M019		Foreign-data wrapper interface routines in C	different API
M020		Foreign-data wrapper interface routines in COBOL	
M021		Foreign-data wrapper interface routines in Fortran	
M022		Foreign-data wrapper interface routines in MUMPS	
M023		Foreign-data wrapper interface routines in Pascal	
M024		Foreign-data wrapper interface routines in PL/I	
M030		SQL-server foreign data support	
M031		Foreign-data wrapper general routines	
X012		Multisets of XML type	
X013		Distinct types of XML type	
X015		Fields of XML type	
X025		XMLCast	
X030		XMLDocument	
X065		XMLParse: binary string input and CONTENT option	
X066		XMLParse: binary string input and DOCUMENT option	
X068		XMLSerialize: BOM	

Identifier	Core?	Description	Comment
X073		XMLSerialize: binary string serialization and CONTENT option	
X074		XMLSerialize: binary string serialization and DOCUMENT option	
X075		XMLSerialize: binary string serialization

D.3. XML Limits and Conformance to SQL/XML

Significant revisions to the XML-related specifications in ISO/IEC 9075-14 (SQL/XML) were introduced with SQL:2006. Postgres Pro's implementation of the XML data type and related functions largely follows the earlier 2003 edition, with some borrowing from later editions. In particular:

- Where the current standard provides a family of XML data types to hold “document” or “content” in untyped or XML Schema-typed variants, and a type `XML(SEQUENCE)` to hold arbitrary pieces of XML content, Postgres Pro provides the single `xml` type, which can hold “document” or “content”. There is no equivalent of the standard's “sequence” type.
- Postgres Pro provides two functions introduced in SQL:2006, but in variants that use the XPath 1.0 language, rather than XML Query as specified for them in the standard.
- Postgres Pro does not support the `RETURNING CONTENT` or `RETURNING SEQUENCE` clauses, functions which are defined to have these in the specification are implicitly returning content.

This section presents some of the resulting differences you may encounter.

D.3.1. Queries Are Restricted to XPath 1.0

The Postgres Pro-specific functions `xpath()` and `xpath_exists()` query XML documents using the XPath language. Postgres Pro also provides XPath-only variants of the standard functions `XMLEXISTS` and `XMLTABLE`, which officially use the XQuery language. For all of these functions, Postgres Pro relies on the libxml2 library, which provides only XPath 1.0.

There is a strong connection between the XQuery language and XPath versions 2.0 and later: any expression that is syntactically valid and executes successfully in both produces the same result (with a minor exception for expressions containing numeric character references or predefined entity references, which XQuery replaces with the corresponding character while XPath leaves them alone). But there is no such connection between these languages and XPath 1.0; it was an earlier language and differs in many respects.

There are two categories of limitation to keep in mind: the restriction from XQuery to XPath for the functions specified in the SQL standard, and the restriction of XPath to version 1.0 for both the standard and the Postgres Pro-specific functions.

D.3.1.1. Restriction of XQuery to XPath

Features of XQuery beyond those of XPath include:

- XQuery expressions can construct and return new XML nodes, in addition to all possible XPath values. XPath can create and return values of the atomic types (numbers, strings, and so on) but can only return XML nodes that were already present in documents supplied as input to the expression.
- XQuery has control constructs for iteration, sorting, and grouping.

- XQuery allows declaration and use of local functions.

Recent XPath versions begin to offer capabilities overlapping with these (such as functional-style `for-each` and `sort`, anonymous functions, and `parse-xml` to create a node from a string), but such features were not available before XPath 3.0.

D.3.1.2. Restriction of XPath to 1.0

For developers familiar with XQuery and XPath 2.0 or later, XPath 1.0 presents a number of differences to contend with:

- The fundamental type of an XQuery/XPath expression, the *sequence*, which can contain XML nodes, atomic values, or both, does not exist in XPath 1.0. A 1.0 expression can only produce a node-set (containing zero or more XML nodes), or a single atomic value.
- Unlike an XQuery/XPath sequence, which can contain any desired items in any desired order, an XPath 1.0 node-set has no guaranteed order and, like any set, does not allow multiple appearances of the same item.

Note

The libxml2 library does seem to always return node-sets to Postgres Pro with their members in the same relative order they had in the input document. Its documentation does not commit to this behavior, and an XPath 1.0 expression cannot control it.

- While XQuery/XPath provides all of the types defined in XML Schema and many operators and functions over those types, XPath 1.0 has only node-sets and the three atomic types `boolean`, `double`, and `string`.
- XPath 1.0 has no conditional operator. An XQuery/XPath expression such as `if (hat) then hat/@size else "no hat"` has no XPath 1.0 equivalent.
- XPath 1.0 has no ordering comparison operator for strings. Both `"cat" < "dog"` and `"cat" > "dog"` are false, because each is a numeric comparison of two NaNs. In contrast, `=` and `!=` do compare the strings as strings.
- XPath 1.0 blurs the distinction between *value comparisons* and *general comparisons* as XQuery/XPath define them. Both `sale/@hatsize = 7` and `sale/@customer = "alice"` are existentially quantified comparisons, true if there is any `sale` with the given value for the attribute, but `sale/@taxable = false()` is a value comparison to the *effective boolean value* of a whole node-set. It is true only if no `sale` has a `taxable` attribute at all.
- In the XQuery/XPath data model, a *document node* can have either document form (i.e., exactly one top-level element, with only comments and processing instructions outside of it) or content form (with those constraints relaxed). Its equivalent in XPath 1.0, the *root node*, can only be in document form. This is part of the reason an `xml` value passed as the context item to any Postgres Pro XPath-based function must be in document form.

The differences highlighted here are not all of them. In XQuery and the 2.0 and later versions of XPath, there is an XPath 1.0 compatibility mode, and the W3C lists of [function library changes](#) and [language changes](#) applied in that mode offer a more complete (but still not exhaustive) account of the differences. The compatibility mode cannot make the later languages exactly equivalent to XPath 1.0.

D.3.1.3. Mappings between SQL and XML Data Types and Values

In SQL:2006 and later, both directions of conversion between standard SQL data types and the XML Schema types are specified precisely. However, the rules are expressed using the types and semantics of XQuery/XPath, and have no direct application to the different data model of XPath 1.0.

When Postgres Pro maps SQL data values to XML (as in `xmlelement`), or XML to SQL (as in the output columns of `xmltable`), except for a few cases treated specially, Postgres Pro simply assumes that the

XML data type's XPath 1.0 string form will be valid as the text-input form of the SQL datatype, and conversely. This rule has the virtue of simplicity while producing, for many data types, results similar to the mappings specified in the standard.

Where interoperability with other systems is a concern, for some data types, it may be necessary to use data type formatting functions (such as those in [Section 9.8](#)) explicitly to produce the standard mappings.

D.3.2. Incidental Limits of the Implementation

This section concerns limits that are not inherent in the libxml2 library, but apply to the current implementation in Postgres Pro.

D.3.2.1. Only `BY VALUE` Passing Mechanism Is Supported

The SQL standard defines two *passing mechanisms* that apply when passing an XML argument from SQL to an XML function or receiving a result: `BY REF`, in which a particular XML value retains its node identity, and `BY VALUE`, in which the content of the XML is passed but node identity is not preserved. A mechanism can be specified before a list of parameters, as the default mechanism for all of them, or after any parameter, to override the default.

To illustrate the difference, if `x` is an XML value, these two queries in an SQL:2006 environment would produce true and false, respectively:

```
SELECT XMLQUERY('$a is $b' PASSING BY REF x AS a, x AS b NULL ON EMPTY);
SELECT XMLQUERY('$a is $b' PASSING BY VALUE x AS a, x AS b NULL ON EMPTY);
```

Postgres Pro will accept `BY VALUE` or `BY REF` in an `XML EXISTS` or `XMLTABLE` construct, but it ignores them. The `xml` data type holds a character-string serialized representation, so there is no node identity to preserve, and passing is always effectively `BY VALUE`.

D.3.2.2. Cannot Pass Named Parameters to Queries

The XPath-based functions support passing one parameter to serve as the XPath expression's context item, but do not support passing additional values to be available to the expression as named parameters.

D.3.2.3. No `XML (SEQUENCE)` Type

The Postgres Pro `xml` data type can only hold a value in `DOCUMENT` or `CONTENT` form. An XQuery/XPath expression context item must be a single XML node or atomic value, but XPath 1.0 further restricts it to be only an XML node, and has no node type allowing `CONTENT`. The upshot is that a well-formed `DOCUMENT` is the only form of XML value that Postgres Pro can supply as an XPath context item.

Appendix E. Release Notes

The release notes contain the significant changes in each Postgres Pro Standard release, with major features and migration issues listed at the top. The release notes do not contain changes that affect only a few users or changes that are internal and therefore not user-visible. For example, the optimizer is improved in almost every release, but the improvements are usually observed by users as simply faster queries.

E.1. Postgres Pro Standard 18.0.1

Release Date: 2025-11-12

E.1.1. Overview

This release is based on PostgreSQL 18 and includes all the new features introduced in PostgreSQL 18. For their detailed description, see [PostgreSQL 18 Release Notes](#). Other major changes and enhancements are as follows:

- Added the new `OLD_PASSWORD_TIME` and `OLD_PASSWORD_MAX` parameters for the `CREATE PROFILE` and `ALTER PROFILE` commands. These parameters are required to enable authentication with the previous password. `OLD_PASSWORD_TIME` specifies for how long the previous password can be used for authentication alongside the new one. `OLD_PASSWORD_MAX` specifies the number of attempts to authenticate with the previous password before it is locked. The `oid` and `passloginattempts` fields were added to the `pg_role_password` catalog, and the `pfloldpasswordtime` and `pfloldpasswordmax` fields were added to the `pg_profile` catalog to display information related to previous passwords.
- Implemented password masking in the server log by default to protect sensitive data from being revealed.
- Added the new `compute_plan_id` configuration parameter that allows enabling and disabling in-core computation of query plan identifiers. Also added the `plan_id` field to the `pg_stat_activity` view to display plan identifiers.
- Added the new `extra_query_transformations` configuration parameter that controls additional transformations of ANY correlated subqueries into LATERAL joins. This parameter replaces the `enable_any_to_lateral_transformation` and `enable_extra_transformations` parameters that were removed.
- Added new values of the `PGPRO_TUNE` environment variable used by initdb.
- Inherited the vanilla implementation of automatic removal of some unnecessary table self-joins. The corresponding `enable_self_join_removal` configuration parameter is removed; use `enable_self_join_elimination` instead.
- Removed the deprecated `pgpro_version`, `pgpro_edition`, and `pgpro_build` functions. Use the `pgpro_version`, `pgpro_edition`, and `pgpro_build` configuration parameters instead.
- Ended support for Ubuntu 25.04 and Debian 11.
- Upgraded `aqo` to version 4.0 to implement optimizations that improve performance and significantly reduce overhead of query planning.
- Upgraded `pg_proaudit` to provide the following enhancements:
 - Added support for logging of the following event types: `ANALYZE`, `DISCARD ALL`, `DISCARD PLANS`, `DISCARD SEQUENCES`, `DISCARD TEMP` (for temporary tables), `CHECKPOINT`, `FETCH`, and `MOVE`.
 - Added the new event class `MISC`. This class allows logging of all events (including those mentioned above) not related to other event classes.
 - Added a new event log field: application name. `AUTHENTICATE` events now contain the name of the initiating application alongside the connection parameters.

- Upgraded [pgpro_pwr](#) to version 4.11, which provides optimizations and bug fixes. Notable changes are as follows:
 - Improved `take_sample` time tracking.
 - Added a possibility to exclude server connection strings from dumps.
 - Added statistics on restartpoints to the reports when it is available.
- Improved the behavior of [pgpro_stats](#) similarly to [pro_stat_statements](#). The changes are:
 - Allow the parameterization of [SET](#) values.

This reduces the bloat caused by `SET` statements with differing constants.
 - Allow the parameterization of constant lists.
- Upgraded [orafce](#) to version 4.16.2.
- Upgraded [pg_filedump](#) to version 18.0.
- Upgraded [pg_probackup](#) to version 2.8.11.
- Upgraded [pgpro_controldata](#) to version 18.1.0.
- Upgraded [pgvector](#) to version 0.8.1.
- Upgraded [tds_fdw](#) to version 2.0.5.
- Disabled [online_analyze](#). This module is not recommended for use with modern versions of 1C. However, it can be enabled if needed.

For the list of extension modules and utilities specific to Postgres Pro Standard, as well as the main user-visible core changes as compared to vanilla PostgreSQL, see [Section 2](#).

E.1.2. Migration to Version 18

You can migrate to Postgres Pro Standard 18 from the same or a previous version of PostgreSQL (that is supported by the upgrade method chosen) and from a previous version of Postgres Pro Standard or Postgres Pro Standard Certified. The same holds for migration to Postgres Pro Standard Certified 18. See [Section 17.6](#) for the methods to upgrade your database cluster. Consult the Postgres Pro Standard support team if you experience issues during migration. Backward migration is not supported. Note that migration from Postgres Pro Standard to Postgres Pro Standard Certified of the same major version (or vice versa) is an update between Postgres Pro compatible versions (see [Section 17.6](#) for more details).

To migrate from PostgreSQL or a Postgres Pro Standard release based on a previous PostgreSQL major version, make sure to install its latest available minor version and then perform a dump/restore using [pg_dumpall](#) or use the [pg_upgrade](#) utility.

If you choose to run `pg_upgrade`, make sure to initialize the new database cluster with compatible parameters. In particular, pay attention to the [checksum](#) settings in the cluster you are migrating from. If `pg_upgrade` creates any SQL files in its current directory, run these files to complete the upgrade.

When upgrading the installation from version 10 or lower, a dump/restore is recommended. In this case, you may have to resolve constraint violations manually. If this option is infeasible, you can still use `pg_upgrade`, but consult the Postgres Pro Standard support team since the integrity of indexes and constraints might be violated in some cases.

Note

To avoid conflicts, do not use the `postgrespro-std-18` package to install the new Postgres Pro binaries. Use the individual packages instead. In this case, server autostart needs to be enabled manually, if required. For details on the available packages, see [Chapter 16](#).

For upgrade requirements imposed by vanilla PostgreSQL, see [Section E.2](#).

E.2. Release 18

Release date: 2025-09-25

E.2.1. Overview

PostgreSQL 18 contains many new features and enhancements, including:

- An asynchronous I/O (AIO) subsystem that can improve performance of sequential scans, bitmap heap scans, vacuums, and other operations.
- [pg_upgrade](#) now retains optimizer statistics.
- Support for "skip scan" lookups that allow using [multicolumn B-tree indexes](#) in more cases.
- [uuidv7\(\)](#) function for generating timestamp-ordered [UUIDs](#).
- Virtual [generated columns](#) that compute their values during read operations. This is now the default for generated columns.
- [OAuth authentication](#) support.
- `OLD` and `NEW` support for [RETURNING](#) clauses in [INSERT](#), [UPDATE](#), [DELETE](#), and [MERGE](#) commands.
- Temporal constraints, or constraints over ranges, for [PRIMARY KEY](#), [UNIQUE](#), and [FOREIGN KEY](#) constraints.

The above items and other new features of PostgreSQL 18 are explained in more detail in the sections below.

E.2.2. Migration to Version 18

A dump/restore using [pg_dumpall](#) or use of [pg_upgrade](#) or logical replication is required for those wishing to migrate data from any previous release. See [Section 17.6](#) for general information on migrating to new major releases.

Version 18 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

- Change [initdb](#) default to enable data checksums (Greg Sabino Mullane)

Checksums can be disabled with the new `initdb` option `--no-data-checksums`. [pg_upgrade](#) requires matching cluster checksum settings, so this new option can be useful to upgrade non-checksum old clusters.

- Change time zone abbreviation handling (Tom Lane)

The system will now favor the current session's time zone abbreviations before checking the server variable [timezone_abbreviations](#). Previously `timezone_abbreviations` was checked first.

- Deprecate [MD5 password](#) authentication (Nathan Bossart)

Support for MD5 passwords will be removed in a future major version release. [CREATE ROLE](#) and [ALTER ROLE](#) now emit deprecation warnings when setting MD5 passwords. These warnings can be disabled by setting the [md5_password_warnings](#) parameter to `off`.

- Change [VACUUM](#) and [ANALYZE](#) to process the inheritance children of a parent (Michael Harris)

The previous behavior can be performed by using the new `ONLY` option.

- Prevent [COPY FROM](#) from treating `\.` as an end-of-file marker when reading CSV files (Daniel Vérité, Tom Lane)

`psql` will still treat `\.` as an end-of-file marker when reading CSV files from `STDIN`. Older `psql` clients connecting to PostgreSQL 18 servers might experience `\copy` problems. This release also enforces that `\.` must appear alone on a line.

- Disallow unlogged partitioned tables (Michael Paquier)

Previously `ALTER TABLE SET [UN]LOGGED` did nothing, and the creation of an unlogged partitioned table did not cause its children to be unlogged.

- Execute `AFTER` `triggers` as the role that was active when trigger events were queued (Laurenz Albe)

Previously such triggers were run as the role that was active at trigger execution time (e.g., at `COMMIT`). This is significant for cases where the role is changed between queue time and transaction commit.

- Remove non-functional support for rule privileges in `GRANT/REVOKE` (Fujii Masao)

These have been non-functional since PostgreSQL 8.2.

- Remove column `pg_backend_memory_contexts.parent` (Melih Mutlu)

This is no longer needed since `pg_backend_memory_contexts.path` was added.

- Change `pg_backend_memory_contexts.level` and `pg_log_backend_memory_contexts()` to be one-based (Melih Mutlu, Atsushi Torikoshi, David Rowley, Fujii Masao)

These were previously zero-based.

- Change `full text search` to use the default collation provider of the cluster to read configuration files and dictionaries, rather than always using `libc` (Peter Eisentraut)

Clusters that default to non-`libc` collation providers (e.g., ICU, builtin) that behave differently than `libc` for characters processed by `LC_CTYPE` could observe changes in behavior of some full-text search functions, as well as the `pg_trgm` extension. When upgrading such clusters using `pg_upgrade`, it is recommended to reindex all indexes related to full-text search and `pg_trgm` after the upgrade.

E.2.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 18 and the previous major release.

E.2.3.1. Server

E.2.3.1.1. Optimizer

- Automatically remove some unnecessary table self-joins (Andrey Lepikhov, Alexander Kuzmenkov, Alexander Korotkov, Alena Rybakina)

This optimization can be disabled using server variable `enable_self_join_elimination`.

- Convert some `IN (VALUES ...)` to `x = ANY ...` for better optimizer statistics (Alena Rybakina, Andrei Lepikhov)
- Allow transforming `OR`-clauses to arrays for faster index processing (Alexander Korotkov, Andrey Lepikhov)
- Speed up the processing of `INTERSECT`, `EXCEPT`, `window aggregates`, and `view column aliases` (Tom Lane, David Rowley)
- Allow the keys of `SELECT DISTINCT` to be internally reordered to avoid sorting (Richard Guo)

This optimization can be disabled using `enable_distinct_reordering`.

- Ignore `GROUP BY` columns that are functionally dependent on other columns (Zhang Mingli, Jian He, David Rowley)

If a `GROUP BY` clause includes all columns of a unique index, as well as other columns of the same table, those other columns are redundant and can be dropped from the grouping. This was already true for non-deferred primary keys.

- Allow some `HAVING` clauses on `GROUPING SETS` to be pushed to `WHERE` clauses (Richard Guo)

This allows earlier row filtering. This release also fixes some `GROUPING SETS` queries that used to return incorrect results.

- Improve row estimates for `generate_series()` using `numeric` and `timestamp` values (David Rowley, Song Jinzhou)
- Allow the optimizer to use `Right Semi Join` plans (Richard Guo)

Semi-joins are used when needing to find if there is at least one match.

- Allow merge joins to use `incremental sorts` (Richard Guo)
- Improve the efficiency of planning queries accessing many partitions (Ashutosh Bapat, Yuya Watari, David Rowley)
- Allow `partitionwise joins` in more cases, and reduce its memory usage (Richard Guo, Tom Lane, Ashutosh Bapat)
- Improve cost estimates of partition queries (Nikita Malakhov, Andrei Lepikhov)
- Improve `SQL-language function` plan caching (Alexander Pyhalov, Tom Lane)
- Improve handling of disabled optimizer features (Robert Haas)

E.2.3.1.2. Indexes

- Allow skip scans of `btree` indexes (Peter Geoghegan)

This allows multi-column `btree` indexes to be used in more cases such as when there are no restrictions on the first or early indexed columns (or there are non-equality ones), and there are useful restrictions on later indexed columns.

- Allow non-`btree` unique indexes to be used as partition keys and in materialized views (Mark Dilger)

The index type must still support equality.

- Allow `GIN` indexes to be created in parallel (Tomas Vondra, Matthias van de Meent)
- Allow values to be sorted to speed range-type `GiST` and `btree` index builds (Bernd Helmle)

E.2.3.1.3. General Performance

- Add an asynchronous I/O subsystem (Andres Freund, Thomas Munro, Nazir Bilal Yavuz, Melanie Plageman)

This feature allows backends to queue multiple read requests, which allows for more efficient sequential scans, bitmap heap scans, vacuums, etc. This is enabled by server variable `io_method`, with server variables `io_combine_limit` and `io_max_combine_limit` added to control it. This also enables `effective_io_concurrency` and `maintenance_io_concurrency` values greater than zero for systems without `fadvise()` support. The new system view `pg_aios` shows the file handles being used for asynchronous I/O.

- Improve the locking performance of queries that access many relations (Tomas Vondra)
- Improve the performance and reduce memory usage of hash joins and `GROUP BY` (David Rowley, Jeff Davis)

This also improves hash set operations used by `EXCEPT`, and hash lookups of subplan values.

- Allow normal vacuums to freeze some pages, even though they are all-visible (Melanie Plageman)

This reduces the overhead of later full-relation freezing. The aggressiveness of this can be controlled by server variable and per-table setting `vacuum_max_eager_freeze_failure_rate`. Previously vacuum never processed all-visible pages until freezing was required.

- Add server variable `vacuum_truncate` to control file truncation during `VACUUM` (Nathan Bossart, Gurjeet Singh)

A storage-level parameter with the same name and behavior already existed.

- Increase server variables `effective_io_concurrency`'s and `maintenance_io_concurrency`'s default values to 16 (Melanie Plageman)

This more accurately reflects modern hardware.

E.2.3.1.4. Monitoring

- Increase the logging granularity of server variable `log_connections` (Melanie Plageman)

This server variable was previously only boolean, which is still supported.

- Add `log_connections` option to report the duration of connection stages (Melanie Plageman)
- Add `log_line_prefix` escape `%L` to output the client IP address (Greg Sabino Mullane)
- Add server variable `log_lock_failures` to log lock acquisition failures (Yuki Seino, Fujii Masao)

Specifically it reports `SELECT ... NOWAIT` lock failures.

- Modify `pg_stat_all_tables` and its variants to report the time spent in `VACUUM`, `ANALYZE`, and their `automatic` variants (Sami Imseih)

The new columns are `total_vacuum_time`, `total_autovacuum_time`, `total_analyze_time`, and `total_autoanalyze_time`.

- Add delay time reporting to `VACUUM` and `ANALYZE` (Bertrand Drouvot, Nathan Bossart)

This information appears in the server log, the system views `pg_stat_progress_vacuum` and `pg_stat_progress_analyze`, and the output of `VACUUM` and `ANALYZE` when in `VERBOSE` mode; tracking must be enabled with the server variable `track_cost_delay_timing`.

- Add WAL, CPU, and average read statistics output to `ANALYZE VERBOSE` (Anthonin Bonnefoy)
- Add full WAL buffer count to `VACUUM/ANALYZE (VERBOSE)` and autovacuum log output (Bertrand Drouvot)
- Add per-backend I/O statistics reporting (Bertrand Drouvot)

The statistics are accessed via `pg_stat_get_backend_io()`. Per-backend I/O statistics can be cleared via `pg_stat_reset_backend_stats()`.

- Add `pg_stat_io` columns to report I/O activity in bytes (Nazir Bilal Yavuz)

The new columns are `read_bytes`, `write_bytes`, and `extend_bytes`. The `op_bytes` column, which always equaled `BLCKSZ`, has been removed.

- Add WAL I/O activity rows to `pg_stat_io` (Nazir Bilal Yavuz, Bertrand Drouvot, Michael Paquier)

This includes WAL receiver activity and a wait event for such writes.

- Change server variable `track_wal_io_timing` to control tracking WAL timing in `pg_stat_io` instead of `pg_stat_wal` (Bertrand Drouvot)
- Remove read/sync columns from `pg_stat_wal` (Bertrand Drouvot)

This removes columns `wal_write`, `wal_sync`, `wal_write_time`, and `wal_sync_time`.

- Add function `pg_stat_get_backend_wal()` to return per-backend WAL statistics (Bertrand Drouvot)

Per-backend WAL statistics can be cleared via `pg_stat_reset_backend_stats()`.

- Add function `pg_ls_summariesdir()` to specifically list the contents of `PGDATA/pg_wal/summaries` (Yushi Ogiwara)
- Add column `pg_stat_checkpointed.num_done` to report the number of completed checkpoints (Anton A. Melnikov)

Columns `num_timed` and `num_requested` count both completed and skipped checkpoints.

- Add column `pg_stat_checkpointed.slru_written` to report SLRU buffers written (Nitin Jadhav)

Also, modify the checkpoint server log message to report separate shared buffer and SLRU buffer values.

- Add columns to `pg_stat_database` to report parallel worker activity (Benoit Lobréau)

The new columns are `parallel_workers_to_launch` and `parallel_workers_launched`.

- Have `query id` computation of constant lists consider only the first and last constants (Dmitry Dolgov, Sami Imseih)

Jumbling is used by `pg_stat_statements`.

- Adjust query id computations to group together queries using the same relation name (Michael Paquier, Sami Imseih)

This is true even if the tables in different schemas have different column names.

- Add column `pg_backend_memory_contexts.type` to report the type of memory context (David Rowley)
- Add column `pg_backend_memory_contexts.path` to show memory context parents (Melih Mutlu)

E.2.3.1.5. Privileges

- Add function `pg_get_acl()` to retrieve database access control details (Joel Jacobson)
- Add function `has_largeobject_privilege()` to check large object privileges (Yugo Nagata)
- Allow `ALTER DEFAULT PRIVILEGES` to define large object default privileges (Takatsuka Haruka, Yugo Nagata, Laurenz Albe)
- Add predefined role `pg_signal_autovacuum_worker` (Kirill Reshke)

This allows sending signals to autovacuum workers.

E.2.3.1.6. Server Configuration

- Add support for the `OAuth authentication method` (Jacob Champion, Daniel Gustafsson, Thomas Munro)

This adds an `oauth` authentication method to `pg_hba.conf`, libpq OAuth options, a server variable `oauth_validator_libraries` to load token validation libraries, and a configure flag `--with-libcurl` to add the required compile-time libraries.

- Add server variable `ssl_tls13_ciphers` to allow specification of multiple colon-separated TLSv1.3 cipher suites (Erica Zhang, Daniel Gustafsson)
- Change server variable `ssl_groups`'s default to include elliptic curve X25519 (Daniel Gustafsson, Jacob Champion)

- Rename server variable `ssl_ecdh_curve` to `ssl_groups` and allow multiple colon-separated ECDH curves to be specified (Erica Zhang, Daniel Gustafsson)

The previous name still works.

- Make `cancel_request_keys` 256 bits (Heikki Linnakangas, Jelte Fennema-Nio)

This is only possible when the server and client support wire protocol version 3.2, introduced in this release.

- Add server variable `autovacuum_worker_slots` to specify the maximum number of background workers (Nathan Bossart)

With this variable set, `autovacuum_max_workers` can be adjusted at runtime up to this maximum without a server restart.

- Allow specification of the fixed number of dead tuples that will trigger an `autovacuum` (Nathan Bossart, Frédéric Yhuel)

The server variable is `autovacuum_vacuum_max_threshold`. Percentages are still used for triggering.

- Change server variable `max_files_per_process` to limit only files opened by a backend (Andres Freund)

Previously files opened by the postmaster were also counted toward this limit.

- Add server variable `num_os_semaphores` to report the required number of semaphores (Nathan Bossart)

This is useful for operating system configuration.

- Add server variable `extension_control_path` to specify the location of extension control files (Peter Eisentraut, Matheus Alcantara)

E.2.3.1.7. Streaming Replication and Recovery

- Allow inactive replication slots to be automatically invalidated using server variable `idle_replication_slot_timeout` (Nisha Moond, Bharath Rupireddy)
- Add server variable `max_active_replication_origins` to control the maximum active replication origins (Euler Taveira)

This was previously controlled by `max_replication_slots`, but this new setting allows a higher origin count in cases where fewer slots are required.

E.2.3.1.8. Logical Replication

- Allow the values of `generated columns` to be logically replicated (Shubham Khanna, Vignesh C, Zhijie Hou, Shlok Kyal, Peter Smith)

If the publication specifies a column list, all specified columns, generated and non-generated, are published. Without a specified column list, publication option `publish_generated_columns` controls whether generated columns are published. Previously generated columns were not replicated and the subscriber had to compute the values if possible; this is particularly useful for non-PostgreSQL subscribers which lack such a capability.

- Change the default `CREATE SUBSCRIPTION` streaming option from `off` to `parallel` (Vignesh C)
- Allow `ALTER SUBSCRIPTION` to change the replication slot's two-phase commit behavior (Hayato Kuroda, Ajin Cherian, Amit Kapila, Zhijie Hou)
- Log `conflicts` while applying logical replication changes (Zhijie Hou, Nisha Moond)

Also report in new columns of `pg_stat_subscription_stats`.

E.2.3.2. Utility Commands

- Allow [generated columns](#) to be virtual, and make them the default (Peter Eisentraut, Jian He, Richard Guo, Dean Rasheed)

Virtual generated columns generate their values when the columns are read, not written. The write behavior can still be specified via the `STORED` option.

- Add `OLD/NEW` support to [RETURNING](#) in DML queries (Dean Rasheed)

Previously `RETURNING` only returned new values for [INSERT](#) and [UPDATE](#), and old values for [DELETE](#); [MERGE](#) would return the appropriate value for the internal query executed. This new syntax allows the `RETURNING` list of `INSERT/UPDATE/DELETE/MERGE` to explicitly return old and new values by using the special aliases `old` and `new`. These aliases can be renamed to avoid identifier conflicts.

- Allow foreign tables to be created like existing local tables (Zhang Mingli)

The syntax is `CREATE FOREIGN TABLE ... LIKE`.

- Allow [LIKE](#) with [nondeterministic collations](#) (Peter Eisentraut)
- Allow text position search functions with nondeterministic collations (Peter Eisentraut)

These used to generate an error.

- Add builtin collation provider [PG_UNICODE_FAST](#) (Jeff Davis)

This locale supports case mapping, but sorts in code point order, not natural language order.

- Allow [VACUUM](#) and [ANALYZE](#) to process partitioned tables without processing their children (Michael Harris)

This is enabled with the new `ONLY` option. This is useful since autovacuum does not process partitioned tables, just its children.

- Add functions to modify per-relation and per-column optimizer statistics (Corey Huinker)

The functions are `pg_restore_relation_stats()`, `pg_restore_attribute_stats()`, `pg_clear_relation_stats()`, and `pg_clear_attribute_stats()`.

- Add server variable [file_copy_method](#) to control the file copying method (Nazir Bilal Yavuz)

This controls whether `CREATE DATABASE ... STRATEGY=FILE_COPY` and `ALTER DATABASE ... SET TABLESPACE` uses file copy or clone.

E.2.3.2.1. Constraints

- Allow the specification of non-overlapping [PRIMARY KEY](#), [UNIQUE](#), and [foreign key](#) constraints (Paul A. Jungwirth)

This is specified by `WITHOUT OVERLAPS` for `PRIMARY KEY` and `UNIQUE`, and by `PERIOD` for foreign keys, all applied to the last specified column.

- Allow [CHECK](#) and [foreign key](#) constraints to be specified as `NOT ENFORCED` (Amul Sul)

This also adds column `pg_constraint.conenforced`.

- Require [primary/foreign key](#) relationships to use either deterministic collations or the the same nondeterministic collations (Peter Eisentraut)

The restore of a [pg_dump](#), also used by [pg_upgrade](#), will fail if these requirements are not met; schema changes must be made for these upgrade methods to succeed.

- Store column `NOT NULL` specifications in `pg_constraint` (Álvaro Herrera, Bernd Helmle)

This allows names to be specified for `NOT NULL` constraint. This also adds `NOT NULL` constraints to foreign tables and `NOT NULL` inheritance control to local tables.

- Allow `ALTER TABLE` to set the `NOT VALID` attribute of `NOT NULL` constraints (Rushabh Lathia, Jian He)
- Allow modification of the inheritability of `NOT NULL` constraints (Suraj Kharage, Álvaro Herrera)

The syntax is `ALTER TABLE ... ALTER CONSTRAINT ... [NO] INHERIT`.

- Allow `NOT VALID` foreign key constraints on partitioned tables (Amul Sul)
- Allow `dropping` of constraints `ONLY` on partitioned tables (Álvaro Herrera)

This was previously erroneously prohibited.

- Add `REJECT_LIMIT` to control the number of invalid rows `COPY FROM` can ignore (Atsushi Torikoshi)

This is available when `ON_ERROR = 'ignore'`.

- Allow `COPY TO` to copy rows from populated materialized views (Jian He)
- Add `COPY LOG_VERBOSITY` level `silent` to suppress log output of ignored rows (Atsushi Torikoshi)

This new level suppresses output for discarded input rows when `on_error = 'ignore'`.

- Disallow `COPY FREEZE` on foreign tables (Nathan Bossart)

Previously, the `COPY` worked but the `FREEZE` was ignored, so disallow this command.

- Automatically include `BUFFERS` output in `EXPLAIN ANALYZE` (Guillaume Lelarge, David Rowley)
- Add full WAL buffer count to `EXPLAIN (WAL)` output (Bertrand Drouvot)
- In `EXPLAIN ANALYZE`, report the number of index lookups used per index scan node (Peter Geoghegan)
- Modify `EXPLAIN` to output fractional row counts (Ibrar Ahmed, Ilia Evdokimov, Robert Haas)
- Add memory and disk usage details to `Material`, `Window Aggregate`, and common table expression nodes to `EXPLAIN` output (David Rowley, Tatsuo Ishii)
- Add details about window function arguments to `EXPLAIN` output (Tom Lane)
- Add `Parallel Bitmap Heap Scan` worker cache statistics to `EXPLAIN ANALYZE` (David Geier, Heikki Linnakangas, Donghang Lin, Alena Rybakina, David Rowley)
- Indicate disabled nodes in `EXPLAIN ANALYZE` output (Robert Haas, David Rowley, Laurenz Albe)

E.2.3.3. Data Types

- Improve `Unicode` full case mapping and conversion (Jeff Davis)

This adds the ability to do conditional and title case mapping, and case map single characters to multiple characters.

- Allow `jsonb` null values to be cast to scalar types as `NULL` (Tom Lane)

Previously such casts generated an error.

- Add optional parameter to `json{b}_strip_nulls` to allow removal of null array elements (Florents Tselai)
- Add function `array_sort()` which sorts an array's first dimension (Junwang Zhao, Jian He)

- Add function `array_reverse()` which reverses an array's first dimension (Aleksander Alekseev)
- Add function `reverse()` to reverse bytea bytes (Aleksander Alekseev)
- Allow casting between integer types and `bytea` (Aleksander Alekseev)

The integer values are stored as `bytea` two's complement values.

- Update Unicode data to `Unicode` 16.0.0 (Peter Eisentraut)
- Add full text search `stemming` for Estonian (Tom Lane)
- Improve the `XML` error codes to more closely match the SQL standard (Tom Lane)

These errors are reported via `SQLSTATE`.

E.2.3.4. Functions

- Add function `casefold()` to allow for more sophisticated case-insensitive matching (Jeff Davis)

This allows more accurate comparisons, i.e., a character can have multiple upper or lower case equivalents, or upper or lower case conversion changes the number of characters.

- Allow `MIN()`/`MAX()` aggregates on arrays and composite types (Aleksander Alekseev, Marat Buharov)
- Add a `WEEK` option to `EXTRACT()` (Tom Lane)
- Improve the output `EXTRACT(QUARTER ...)` for negative values (Tom Lane)
- Add roman numeral support to `to_number()` (Hunaid Sohail)

This is accessed via the `RN` pattern.

- Add `UUID` version 7 generation function `uuidv7()` (Andrey Borodin)

This `UUID` value is temporally sortable. Function alias `uuidv4()` has been added to explicitly generate version 4 UUIDs.

- Add functions `crc32()` and `crc32c()` to compute CRC values (Aleksander Alekseev)
- Add math functions `gamma()` and `lgamma()` (Dean Rasheed)
- Allow `=>` syntax for named cursor arguments in `PL/pgSQL` (Pavel Stehule)

We previously only accepted `:=`.

- Allow `regexp_match(es)()/regexp_like()/regexp_replace()/regexp_count()/regexp_instr()/regexp_substr()/regexp_split_to_table()/regexp_split_to_array()` to use named arguments (Jian He)
- Add function `PQfullProtocolVersion()` to report the full, including minor, protocol version number (Jacob Champion, Jelte Fennema-Nio)
- Add libpq connection `parameters` and `environment variables` to specify the minimum and maximum acceptable protocol version for connections (Jelte Fennema-Nio)
- Report `search_path` changes to the client (Alexander Kukushkin, Jelte Fennema-Nio, Tomas Vondra)
- Add `PQtrace()` output for all message types, including authentication (Jelte Fennema-Nio)
- Add libpq connection parameter `sslkeylogfile` which dumps out SSL key material (Abhishek Chanda, Daniel Gustafsson)

This is useful for debugging.

- Modify some libpq function signatures to use `int64_t` (Thomas Munro)

These previously used `pg_int64`, which is now deprecated.

- Allow `psql` to parse, bind, and close named prepared statements (Anthonin Bonnefoy, Michael Paquier)

This is accomplished with new commands `\parse`, `\bind_named`, and `\close_prepared`.

- Add `psql` backslash commands to allowing issuance of pipeline queries (Anthonin Bonnefoy)

The new commands are `\startpipeline`, `\syncpipeline`, `\sendpipeline`, `\endpipeline`, `\flushrequest`, `\flush`, and `\getresults`.

- Allow adding pipeline status to the `psql` prompt and add related state variables (Anthonin Bonnefoy)

The new prompt character is `%P` and the new `psql` variables are `PIPELINE_SYNC_COUNT`, `PIPELINE_COMMAND_COUNT`, and `PIPELINE_RESULT_COUNT`.

- Allow adding the connection service name to the `psql` prompt or access it via `psql` variable (Michael Banck)
- Add `psql` option to use expanded mode on all list commands (Dean Rasheed)

Adding backslash suffix `x` enables this.

- Change `psql`'s `\conninfo` to use tabular format and include more information (Álvaro Herrera, Maiquel Grassi, Hunaid Sohail)
- Add function's leakproof indicator to `psql`'s `\df+`, `\do+`, `\dAo+`, and `\dC+` outputs (Yugo Nagata)
- Add access method details for partitioned relations in `\dP+` (Justin Pryzby)
- Add `default_version` to the `psql \dx` extension output (Magnus Hagander)
- Add `psql` variable `WATCH_INTERVAL` to set the default `\watch` wait time (Daniel Gustafsson)

E.2.3.7. Server Applications

- Change `initdb` to default to enabling checksums (Greg Sabino Mullane)

The new `initdb` option `--no-data-checksums` disables checksums.

- Add `initdb` option `--no-sync-data-files` to avoid syncing heap/index files (Nathan Bossart)

`initdb` option `--no-sync` is still available to avoid syncing any files.

- Add `vacuumdb` option `--missing-stats-only` to compute only missing optimizer statistics (Corey Huinker, Nathan Bossart)

This option can only be run by superusers and can only be used with options `--analyze-only` and `--analyze-in-stages`.

- Add `pg_combinebackup` option `-k/--link` to enable hard linking (Israel Barth Rubio, Robert Haas)

Only some files can be hard linked. This should not be used if the backups will be used independently.

- Allow `pg_verifybackup` to verify tar-format backups (Amul Sul)
- If `pg_rewind`'s `--source-server` specifies a database name, use it in `--write-recovery-conf` output (Masahiko Sawada)
- Add `pg_resetwal` option `--char-signedness` to change the default `char` signedness (Masahiko Sawada)

E.2.3.7.1. `pg_dump/pg_dumpall/pg_restore`

- Add `pg_dump` option `--statistics` (Jeff Davis)
- Add `pg_dump` and `pg_dumpall` option `--sequence-data` to dump sequence data that would normally be excluded (Nathan Bossart)
- Add `pg_dump`, `pg_dumpall`, and `pg_restore` options `--statistics-only`, `--no-statistics`, `--no-data`, and `--no-schema` (Corey Huinker, Jeff Davis)
- Add option `--no-policies` to disable row level security policy processing in `pg_dump`, `pg_dumpall`, `pg_restore` (Nikolay Samokhvalov)

This is useful for migrating to systems with different policies.

- Allow `pg_upgrade` to preserve optimizer statistics (Corey Huinker, Jeff Davis, Nathan Bossart)

Extended statistics are not preserved. Also add `pg_upgrade` option `--no-statistics` to disable statistics preservation.

- Allow `pg_upgrade` to process database checks in parallel (Nathan Bossart)

This is controlled by the existing `--jobs` option.

- Add `pg_upgrade` option `--swap` to swap directories rather than copy, clone, or link files (Nathan Bossart)

This mode is potentially the fastest.

- Add `pg_upgrade` option `--set-char-signedness` to set the default `char` signedness of new cluster (Masahiko Sawada)

This is to handle cases where a pre-PostgreSQL 18 cluster's default CPU signedness does not match the new cluster.

E.2.3.7.3. Logical Replication Applications

- Add `pg_createsubscriber` option `--all` to create logical replicas for all databases (Shubham Khanna)
- Add `pg_createsubscriber` option `--clean` to remove publications (Shubham Khanna)
- Add `pg_createsubscriber` option `--enable-two-phase` to enable prepared transactions (Shubham Khanna)
- Add `pg_recvlogical` option `--enable-failover` to specify failover slots (Hayato Kuroda)

Also add option `--enable-two-phase` as a synonym for `--two-phase`, and deprecate the latter.

- Allow `pg_recvlogical` `--drop-slot` to work without `--dbname` (Hayato Kuroda)

E.2.3.8. Source Code

- Separate the loading and running of `injection points` (Michael Paquier, Heikki Linnakangas)

Injection points can now be created, but not run, via `INJECTION_POINT_LOAD()`, and such injection points can be run via `INJECTION_POINT_CACHED()`.

- Support runtime arguments in injection points (Michael Paquier)
- Allow inline injection point test code with `IS_INJECTION_POINT_ATTACHED()` (Heikki Linnakangas)
- Improve the performance of processing long `JSON` strings using SIMD (Single Instruction Multiple Data) (David Rowley)
- Speed up CRC32C calculations using x86 AVX-512 instructions (Raghuveer Devulapalli, Paul Amonson)

- Add ARM Neon and SVE CPU intrinsics for popcount (integer bit counting) (Chiranmoy Bhattacharya, Devanga Susmitha, Rama Malladi)
- Improve the speed of numeric multiplication and division (Joel Jacobson, Dean Rasheed)
- Add configure option `--with-libnuma` to enable NUMA awareness (Jakub Wartak, Bertrand Drouvot)

The function `pg_numa_available()` reports on NUMA awareness, and system views `pg_shmem_al-locations_numa` and `pg_buffercache_numa` which report on shared memory distribution across NUMA nodes.

- Add `TOAST` table to `pg_index` to allow for very large expression indexes (Nathan Bossart)
- Remove column `pg_attribute.attcacheoff` (David Rowley)
- Add column `pg_class.relallfrozen` (Melanie Plageman)
- Add `amgettreeheight`, `amconsistentequality`, and `amconsistentordering` to the index access method API (Mark Dilger)
- Add GiST support function `stratnum()` (Paul A. Jungwirth)
- Record the default CPU signedness of `char` in `pg_controldata` (Masahiko Sawada)
- Add support for Python "Limited API" in `PL/Python` (Peter Eisentraut)

This helps prevent problems caused by Python 3.x version mismatches.

- Change the minimum supported Python version to 3.6.8 (Jacob Champion)
- Remove support for OpenSSL versions older than 1.1.1 (Daniel Gustafsson)
- If LLVM is enabled, require version 14 or later (Thomas Munro)
- Add macro `PG_MODULE_MAGIC_EXT` to allow extensions to report their name and version (Andrei Lepikhov)

This information can be access via the new function `pg_get_loaded_modules()`.

- Document that `SPI_connect()/SPI_connect_ext()` always returns success (`SPI_OK_CONNECT`) (Stepan Neretin)

Errors are always reported via `ereport()`.

- Add [documentation section](#) about API and ABI compatibility (David Wheeler, Peter Eisentraut)
- Remove the experimental designation of Meson builds on Windows (Aleksander Alekseev)
- Remove configure options `--disable-spinlocks` and `--disable-atomics` (Thomas Munro)

Thirty-two-bit atomic operations are now required.

- Remove support for the HPPA/PA-RISC architecture (Tom Lane)

E.2.3.9. Additional Modules

- Add extension `pg_logicalinspect` to inspect logical snapshots (Bertrand Drouvot)
- Add extension `pg_overexplain` which adds debug details to `EXPLAIN` output (Robert Haas)
- Add output columns to `postgres_fdw_get_connections()` (Hayato Kuroda, Sagar Dilip Shedge)

New output column `used_in_xact` indicates if the foreign data wrapper is being used by a current transaction, `closed` indicates if it is closed, `user_name` indicates the user name, and `remote_backend_pid` indicates the remote backend process identifier.

- Allow `SCRAM` authentication from the client to be passed to `postgres_fdw` servers (Matheus Alcantara, Peter Eisentraut)

This avoids storing `postgres_fdw` authentication information in the database, and is enabled with the `postgres_fdw` `use_scram_passthrough` connection option. `libpq` uses new connection parameters `scram_client_key` and `scram_server_key`.

- Allow SCRAM authentication from the client to be passed to `dblink` servers (Matheus Alcantara)
- Add `on_error` and `log_verbosity` options to `file_fdw` (Atsushi Torikoshi)

These control how `file_fdw` handles and reports invalid file rows.

- Add `reject_limit` to control the number of invalid rows `file_fdw` can ignore (Atsushi Torikoshi)

This is active when `ON_ERROR = 'ignore'`.

- Add configurable variable `min_password_length` to `passwordcheck` (Emanuele Musella, Maurizio Boriani)

This controls the minimum password length.

- Have `pgbench` report the number of failed, retried, or skipped transactions in per-script reports (Yugo Nagata)
- Add `isn` server variable `weak` to control invalid check digit acceptance (Viktor Holmberg)

This was previously only controlled by function `isn_weak()`.

- Allow values to be sorted to speed `btree_gist` index builds (Bernd Helmle, Andrey Borodin)
- Add `amcheck` check function `gin_index_check()` to verify GIN indexes (Grigory Kryachko, Heikki Linnakangas, Andrey Borodin)
- Add functions `pg_buffercache_evict_relation()` and `pg_buffercache_evict_all()` to evict unpinned shared buffers (Nazir Bilal Yavuz)

The existing function `pg_buffercache_evict()` now returns the buffer flush status.

- Allow extensions to install custom `EXPLAIN` options (Robert Haas, Sami Imseih)
- Allow extensions to use the server's cumulative statistics API (Michael Paquier)
- Allow the queries of `CREATE TABLE AS` and `DECLARE` to be tracked by `pg_stat_statements` (Anthony Bonnet)

They are also now assigned query ids.

- Allow the parameterization of `SET` values in `pg_stat_statements` (Greg Sabino Mullane, Michael Paquier)

This reduces the bloat caused by `SET` statements with differing constants.

- Add `pg_stat_statements` columns to report parallel activity (Guillaume Lelarge)

The new columns are `parallel_workers_to_launch` and `parallel_workers_launched`.

- Add `pg_stat_statements.wal_buffers_full` to report full WAL buffers (Bertrand Drouvot)
- Add pgcrypto algorithms `sha256crypt` and `sha512crypt` (Bernd Helmle)
- Add `CFB` mode to pgcrypto encryption and decryption (Umar Hayat)
- Add function `fips_mode()` to report the server's FIPS mode (Daniel Gustafsson)
- Add pgcrypto server variable `builtin_crypto_enabled` to allow disabling builtin non-FIPS mode cryptographic functions (Daniel Gustafsson, Joe Conway)

This is useful for guaranteeing FIPS mode behavior.

E.2.4. Acknowledgments

The following individuals (in alphabetical order) have contributed to this release as patch authors, committers, reviewers, testers, or reporters of issues.

E.3. Prior Releases

Release notes for prior versions can be found online. At the time of Postgres Pro Standard 18 release, these prior versions were supported:

- Postgres Pro Standard 16: <https://postgrespro.com/docs/postgrespro/16/release.html>
- Postgres Pro Standard 15: <https://postgrespro.com/docs/postgrespro/15/release.html>
- Postgres Pro Standard 14: <https://postgrespro.com/docs/postgrespro/14/release.html>

- Postgres Pro Standard 13: <https://postgrespro.com/docs/postgrespro/13/release.html>
- Postgres Pro Standard 12: <https://postgrespro.com/docs/postgrespro/12/release.html>

Appendix F. Additional Supplied Modules and Extensions Shipped in postgrespro-std-18-contrib

This appendix, [Appendix G](#), and [Appendix I](#) contain information on the optional components available in the Postgres Pro Standard distribution. These include porting tools, analysis utilities, and plug-in features that are not part of the core Postgres Pro system. They are separate mainly because they address a limited audience or are too experimental to be part of the main source tree. This does not preclude their usefulness.

This appendix and [Appendix G](#) cover the extensions and other server plug-in modules. [Appendix I](#) covers the utility programs.

Many components supply new user-defined functions, operators, or types, packaged as *extensions*. To make use of one of these extensions, after you have installed the code you need to register the new SQL objects in the database system. This is done by executing a [CREATE EXTENSION](#) command. In a fresh database, you can simply do

```
CREATE EXTENSION extension_name;
```

This command registers the new SQL objects in the current database only, so you need to run it in every database in which you want the extension's facilities to be available. Alternatively, run it in database `template1` so that the extension will be copied into subsequently-created databases by default.

For all extensions, the `CREATE EXTENSION` command must be run by a database superuser, unless the extension is considered “trusted”. Trusted extensions can be run by any user who has `CREATE` privilege on the current database. Extensions that are trusted are identified as such in the sections that follow. Generally, trusted extensions are ones that cannot provide access to outside-the-database functionality.

The following extensions are trusted in a default installation:

btree_gin	fuzzystrmatch	ltree	tcn
btree_gist	hstore	pgcrypto	tsm_system_rows
citext	intarray	pg_trgm	tsm_system_time
cube	isn	seg	unaccent
dict_int	lo	tablefunc	uuid-oss

Many extensions allow you to install their objects in a schema of your choice. To do that, add `SCHEMA schema_name` to the `CREATE EXTENSION` command. By default, the objects will be placed in your current creation target schema, which in turn defaults to `public`.

Note, however, that some of these components are not “extensions” in this sense, but are loaded into the server in some other way, for instance by way of [shared_preload_libraries](#). See the documentation of each component for details.

This appendix contains modules and extensions that are made available in Postgres Pro Standard as a separate subpackage `postgrespro-std-18-contrib`. Note that the `toastapi` extension to add custom TOASTers is also available in `postgrespro-std-18-contrib` (see [Section 64.2.3](#) for details).

F.1. amcheck — tools to verify table and index consistency

The `amcheck` module provides functions that allow you to verify the logical consistency of the structure of relations.

The B-Tree checking functions verify various *invariants* in the structure of the representation of particular relations. The correctness of the access method functions behind index scans and other important operations relies on these invariants always holding. For example, certain functions verify, among other things, that all B-Tree pages have items in “logical” order (e.g., for B-Tree indexes on `text`, index tuples should be in collated lexical order). If that particular invariant somehow fails to hold, we can expect binary searches on the affected page to incorrectly guide index scans, resulting in wrong answers to SQL queries. If the structure appears to be valid, no error is raised. While these checking functions are run, the `search_path` is temporarily changed to `pg_catalog, pg_temp`.

Verification is performed using the same procedures as those used by index scans themselves, which may be user-defined operator class code. For example, B-Tree index verification relies on comparisons made with one or more B-Tree support function 1 routines. See [Section 36.16.3](#) for details of operator class support functions.

Unlike the B-Tree checking functions which report corruption by raising errors, the heap checking function `verify_heapam` checks a table and attempts to return a set of rows, one row per corruption detected. Despite this, if facilities that `verify_heapam` relies upon are themselves corrupted, the function may be unable to continue and may instead raise an error.

Permission to execute `amcheck` functions may be granted to non-superusers, but before granting such permissions careful consideration should be given to data security and privacy concerns. Although the corruption reports generated by these functions do not focus on the contents of the corrupted data so much as on the structure of that data and the nature of the corruptions found, an attacker who gains permission to execute these functions, particularly if the attacker can also induce corruption, might be able to infer something of the data itself from such messages.

F.1.1. Functions

`bt_index_check(index regclass, heapallindexed boolean, checkunique boolean)` returns void

`bt_index_check` tests that its target, a B-Tree index, respects a variety of invariants. Example usage:

```
test=# SELECT bt_index_check(index => c.oid, heapallindexed => i.indisunique),
        c.relname,
        c.relpages
```

```
FROM pg_index i
JOIN pg_opclass op ON i.indclass[0] = op.oid
JOIN pg_am am ON op.opcmethod = am.oid
JOIN pg_class c ON i.indexrelid = c.oid
JOIN pg_namespace n ON c.relnamespace = n.oid
WHERE am.amname = 'btree' AND n.nspname = 'pg_catalog'
-- Don't check temp tables, which may be from another session:
AND c.relpersistence != 't'
-- Function may throw an error when this is omitted:
AND c.relkind = 'i' AND i.indisready AND i.indisvalid
ORDER BY c.relpages DESC LIMIT 10;
```

bt_index_check	relname	relpages
	pg_depend_reference_index	43
	pg_depend_depender_index	40
	pg_proc_proname_args_nsp_index	31
	pg_description_o_c_o_index	21
	pg_attribute_relid_attnam_index	14

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

pg_proc_oid_index		10
pg_attribute_relid_attnum_index		9
pg_amproc_fam_proc_index		5
pg_amop_opr_fam_index		5
pg_amop_fam_strat_index		5

(10 rows)

This example shows a session that performs verification of the 10 largest catalog indexes in the database “test”. Verification of the presence of heap tuples as index tuples is requested for the subset that are unique indexes. Since no error is raised, all indexes tested appear to be logically consistent. Naturally, this query could easily be changed to call `bt_index_check` for every index in the database where verification is supported.

`bt_index_check` acquires an `AccessShareLock` on the target index and the heap relation it belongs to. This lock mode is the same lock mode acquired on relations by simple `SELECT` statements. `bt_index_check` does not verify invariants that span child/parent relationships, but will verify the presence of all heap tuples as index tuples within the index when *heapallindexed* is `true`. When *checkunique* is `true` `bt_index_check` will check that no more than one among duplicate entries in unique index is visible. When a routine, lightweight test for corruption is required in a live production environment, using `bt_index_check` often provides the best trade-off between thoroughness of verification and limiting the impact on application performance and availability.

`bt_index_parent_check(index regclass, heapallindexed boolean, rootdescend boolean, checkunique boolean)` returns void

`bt_index_parent_check` tests that its target, a B-Tree index, respects a variety of invariants. Optionally, when the *heapallindexed* argument is `true`, the function verifies the presence of all heap tuples that should be found within the index. When *checkunique* is `true` `bt_index_parent_check` will check that no more than one among duplicate entries in unique index is visible. When the optional *rootdescend* argument is `true`, verification re-finds tuples on the leaf level by performing a new search from the root page for each tuple. The checks that can be performed by `bt_index_parent_check` are a superset of the checks that can be performed by `bt_index_check`. `bt_index_parent_check` can be thought of as a more thorough variant of `bt_index_check`: unlike `bt_index_check`, `bt_index_parent_check` also checks invariants that span parent/child relationships, including checking that there are no missing downlinks in the index structure. `bt_index_parent_check` follows the general convention of raising an error if it finds a logical inconsistency or other problem.

A `ShareLock` is required on the target index by `bt_index_parent_check` (a `ShareLock` is also acquired on the heap relation). These locks prevent concurrent data modification from `INSERT`, `UPDATE`, and `DELETE` commands. The locks also prevent the underlying relation from being concurrently processed by `VACUUM`, as well as all other utility commands. Note that the function holds locks only while running, not for the entire transaction.

`bt_index_parent_check`'s additional verification is more likely to detect various pathological cases. These cases may involve an incorrectly implemented B-Tree operator class used by the index that is checked, or, hypothetically, undiscovered bugs in the underlying B-Tree index access method code. Note that `bt_index_parent_check` cannot be used when hot standby mode is enabled (i.e., on read-only physical replicas), unlike `bt_index_check`.

`gin_index_check(index regclass)` returns void

`gin_index_check` tests that its target GIN index has consistent parent-child tuples relations (no parent tuples require tuple adjustment) and page graph respects balanced-tree invariants (internal pages reference only leaf page or only internal pages).

Tip

`bt_index_check` and `bt_index_parent_check` both output log messages about the verification process at `DEBUG1` and `DEBUG2` severity levels. These messages provide detailed information about

the verification process that may be of interest to PostgreSQL developers. Advanced users may also find this information helpful, since it provides additional context should verification actually detect an inconsistency. Running:

```
SET client_min_messages = DEBUG1;
```

in an interactive psql session before running a verification query will display messages about the progress of verification with a manageable level of detail.

```
verify_heapam(relation regclass, on_error_stop boolean, check_toast boolean, skip text,  
startblock bigint, endblock bigint, blkno OUT bigint, offnum OUT integer, attnum OUT  
integer, msg OUT text) returns setof record
```

Checks a table, sequence, or materialized view for structural corruption, where pages in the relation contain data that is invalidly formatted, and for logical corruption, where pages are structurally valid but inconsistent with the rest of the database cluster.

The following optional arguments are recognized:

`on_error_stop`

If true, corruption checking stops at the end of the first block in which any corruptions are found.

Defaults to false.

`check_toast`

If true, toasted values are checked against the target relation's TOAST table.

This option is known to be slow. Also, if the toast table or its index is corrupt, checking it against toast values could conceivably crash the server, although in many cases this would just produce an error.

Defaults to false.

`skip`

If not `none`, corruption checking skips blocks that are marked as all-visible or all-frozen, as specified. Valid options are `all-visible`, `all-frozen` and `none`.

Defaults to `none`.

`startblock`

If specified, corruption checking begins at the specified block, skipping all previous blocks. It is an error to specify a `startblock` outside the range of blocks in the target table.

By default, checking begins at the first block.

`endblock`

If specified, corruption checking ends at the specified block, skipping all remaining blocks. It is an error to specify an `endblock` outside the range of blocks in the target table.

By default, all blocks are checked.

For each corruption detected, `verify_heapam` returns a row with the following columns:

`blkno`

The number of the block containing the corrupt page.

`offnum`

The OffsetNumber of the corrupt tuple.

`attnum`

The attribute number of the corrupt column in the tuple, if the corruption is specific to a column and not the tuple as a whole.

`msg`

A message describing the problem detected.

F.1.2. Optional *heapallindexed* Verification

When the *heapallindexed* argument to B-Tree verification functions is `true`, an additional phase of verification is performed against the table associated with the target index relation. This consists of a “dummy” `CREATE INDEX` operation, which checks for the presence of all hypothetical new index tuples against a temporary, in-memory summarizing structure (this is built when needed during the basic first phase of verification). The summarizing structure “fingerprints” every tuple found within the target index. The high level principle behind *heapallindexed* verification is that a new index that is equivalent to the existing, target index must only have entries that can be found in the existing structure.

The additional *heapallindexed* phase adds significant overhead: verification will typically take several times longer. However, there is no change to the relation-level locks acquired when *heapallindexed* verification is performed.

The summarizing structure is bound in size by `maintenance_work_mem`. In order to ensure that there is no more than a 2% probability of failure to detect an inconsistency for each heap tuple that should be represented in the index, approximately 2 bytes of memory are needed per tuple. As less memory is made available per tuple, the probability of missing an inconsistency slowly increases. This approach limits the overhead of verification significantly, while only slightly reducing the probability of detecting a problem, especially for installations where verification is treated as a routine maintenance task. Any single absent or malformed tuple has a new opportunity to be detected with each new verification attempt.

F.1.3. Using *amcheck* Effectively

amcheck can be effective at detecting various types of failure modes that [data checksums](#) will fail to catch. These include:

- Structural inconsistencies caused by incorrect operator class implementations.

This includes issues caused by the comparison rules of operating system collations changing. Comparisons of datums of a collatable type like `text` must be immutable (just as all comparisons used for B-Tree index scans must be immutable), which implies that operating system collation rules must never change. Though rare, updates to operating system collation rules can cause these issues. More commonly, an inconsistency in the collation order between a primary server and a standby server is implicated, possibly because the *major* operating system version in use is inconsistent. Such inconsistencies will generally only arise on standby servers, and so can generally only be detected on standby servers.

If a problem like this arises, it may not affect each individual index that is ordered using an affected collation, simply because *indexed* values might happen to have the same absolute ordering regardless of the behavioral inconsistency. See [Section 22.1](#) and [Section 22.2](#) for further details about how Postgres Pro uses operating system locales and collations.

- Structural inconsistencies between indexes and the heap relations that are indexed (when *heapallindexed* verification is performed).

There is no cross-checking of indexes against their heap relation during normal operation. Symptoms of heap corruption can be subtle.

- Corruption caused by hypothetical undiscovered bugs in the underlying Postgres Pro access method code, sort code, or transaction management code.

Automatic verification of the structural integrity of indexes plays a role in the general testing of new or proposed Postgres Pro features that could plausibly allow a logical inconsistency to be in-

troduced. Verification of table structure and associated visibility and transaction status information plays a similar role. One obvious testing strategy is to call `amcheck` functions continuously when running the standard regression tests.

- File system or storage subsystem faults when data checksums are disabled.

Note that `amcheck` examines a page as represented in some shared memory buffer at the time of verification if there is only a shared buffer hit when accessing the block. Consequently, `amcheck` does not necessarily examine data read from the file system at the time of verification. Note that when checksums are enabled, `amcheck` may raise an error due to a checksum failure when a corrupt block is read into a buffer.

- Corruption caused by faulty RAM, or the broader memory subsystem.

Postgres Pro does not protect against correctable memory errors and it is assumed you will operate using RAM that uses industry standard Error Correcting Codes (ECC) or better protection. However, ECC memory is typically only immune to single-bit errors, and should not be assumed to provide *absolute* protection against failures that result in memory corruption.

When `heapallindexed` verification is performed, there is generally a greatly increased chance of detecting single-bit errors, since strict binary equality is tested, and the indexed attributes within the heap are tested.

Structural corruption can happen due to faulty storage hardware, or relation files being overwritten or modified by unrelated software. This kind of corruption can also be detected with [data page checksums](#).

Relation pages which are correctly formatted, internally consistent, and correct relative to their own internal checksums may still contain logical corruption. As such, this kind of corruption cannot be detected with checksums. Examples include toasted values in the main table which lack a corresponding entry in the toast table, and tuples in the main table with a Transaction ID that is older than the oldest valid Transaction ID in the database or cluster.

Multiple causes of logical corruption have been observed in production systems, including bugs in the PostgreSQL server software, faulty and ill-conceived backup and restore tools, and user error.

Corrupt relations are most concerning in live production environments, precisely the same environments where high risk activities are least welcome. For this reason, `verify_heapam` has been designed to diagnose corruption without undue risk. It cannot guard against all causes of backend crashes, as even executing the calling query could be unsafe on a badly corrupted system. Access to [catalog tables](#) is performed and could be problematic if the catalogs themselves are corrupted.

In general, `amcheck` can only prove the presence of corruption; it cannot prove its absence.

F.1.4. Repairing Corruption

No error concerning corruption raised by `amcheck` should ever be a false positive. `amcheck` raises errors in the event of conditions that, by definition, should never happen, and so careful analysis of `amcheck` errors is often required.

There is no general method of repairing problems that `amcheck` detects. An explanation for the root cause of an invariant violation should be sought. [pageinspect](#) may play a useful role in diagnosing corruption that `amcheck` detects. A `REINDEX` may not be effective in repairing corruption.

F.2. aqo — cost-based query optimization

The aqo module is a Postgres Pro Standard extension for cost-based query optimization. Using machine learning methods, more precisely, a modification of the k-NN algorithm, aqo improves cardinality estimation, which can optimize execution plans and, consequently, speed up query execution.

F.2.1. Description

The aqo module can collect statistics on all the executed queries, excluding the queries that access system relations. The collected statistics is classified by query class. If the queries differ in their constants only, they belong to the same class. For each query class, aqo stores the cardinality quality, planning time, execution time, and execution statistics for machine learning. Based on this data, aqo builds a new query plan and uses it for the next query of the same class. aqo test runs have shown significant performance improvements for complex queries.

aqo saves all the learning data ([aqo_data](#)), queries ([aqo_query_texts](#)), query settings ([aqo_queries](#)), and query execution statistics ([aqo_query_stat](#)) to files. When aqo starts, it loads this data to shared memory. You can access aqo data through functions and views.

When [aqo.advanced](#) is on, and aqo is run in the `intelligent` or `learn` mode, a unique hash value, which is computed from the query tree, is assigned to each query class to identify it and separate the collected statistics. If [aqo.advanced](#) is off, the statistics for all untracked query classes is stored in a common query class with hash 0.

Each query class has an associated separate space, called *feature space*, in which the statistics for this query class is collected. This feature space is identified by a hash value (`fs`), called a *basic hash*, which is the same for queries that only differ in table names, so the learning data is aggregated for such queries. Each feature space has associated *feature subspaces*, where the information about selectivity and cardinality for each query plan node is collected. Each subspace is also identified by a hash value (`fss`).

Query-specific optimization settings are stored in the [aqo_queries](#) view.

F.2.1.1. Limitations

aqo currently has the following limitations:

- Query optimization using the aqo module is not supported on standby.
- Query optimization with aqo does not work with queries that only have temporary objects.
- Query optimization with aqo does not work for queries that contain `IMMUTABLE` functions.
- aqo does not collect statistics on replicas because replicas are read-only. However, aqo may use query execution statistics from the primary if the replica is physical.
- `learn` and `intelligent` modes are not supposed to work for a whole cluster with queries having a dynamically generated structure because these modes store all query class IDs, which are different for all queries in such a workload. Dynamically generated constants are supported, however.

F.2.2. Installation and Setup

The aqo extension is included into Postgres Pro Standard. Once you have Postgres Pro Standard installed, complete the following steps to enable aqo:

1. Add aqo to the [shared_preload_libraries](#) parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'aqo'
```

The aqo library must be preloaded at the server startup, since adaptive query optimization needs to be enabled per cluster.

2. Create the aqo extension using the following query:

```
CREATE EXTENSION aqo;
```

Once the extension is created, you can start optimizing queries.

To disable aqo in the current database, run:

```
DROP EXTENSION aqo;
```

To disable aqo at the cluster level, run:

```
ALTER SYSTEM SET aqo.enable = off;  
SELECT pg_reload_conf();
```

To remove all the aqo data including the collected statistics, call `aqo_reset()`: to remove the data from the current database, run:

```
SELECT aqo_reset();
```

to remove all the data from the aqo storage, run:

```
SELECT aqo_reset(NULL);
```

If you do not want aqo to be loaded at the server restart, remove the line

```
shared_preload_libraries = 'aqo'
```

from the `postgresql.conf` file.

Important

For smooth physical replication transferring aqo data from the primary to a replica, ensure that the same aqo versions are installed on both. You can have different aqo versions installed, but in this case, set `aqo.wal_rw` to `off` on both and anticipate no replication.

F.2.2.1. Configuration

aqo behavior mainly depends on the `aqo.enable`, `aqo.mode` and `aqo.advanced` configuration parameters. Their default values allow you to start learning in the `aqo basic mode` once you just set `aqo.enable` to `on`.

To dynamically change any of these parameters, for example, `mode`, in your current session, run the following command:

```
SET aqo.mode = 'mode';
```

where *mode* is the name of the operation mode to use.

F.2.3. Usage

F.2.3.1. Using aqo in a Basic Mode

By default, `aqo.advanced` is off. This sets a recommended, basic, mode, where statistics is collected for plan nodes (identified by `fss`), and the collected machine learning data is used to correct the cardinality error for all queries whose plan contains a certain plan node. Once you set `aqo.enable` to `on`, aqo starts learning. Execute queries that you need to optimize several times until the plan is good enough and change `aqo.mode` to `frozen`. To apply the machine learning data at the level of the server instance, run the following command:

```
ALTER SYSTEM SET aqo.mode = frozen;  
ALTER SYSTEM SET aqo.enable = on;  
SELECT pg_reload_conf();
```

The machine learning data will be applied not only to the queries on which aqo learned, but to all the queries whose plan contains the nodes for which the statistics was collected. For the machine learning data not affect other queries, set `aqo.advanced` to `on` and collect statistics for individual queries. See [Section F.2.3.2](#) for details.

F.2.3.2. Choosing the Operation Mode for Advanced Query Optimization

If you often run queries of the same class, for example, your application limits the number of possible query classes, you can enable `aqo.advanced` and use the `intelligent` mode to improve planning for these queries. In this mode, aqo analyzes each query execution and stores statistics. Statistics on queries of different classes is stored separately. If performance is not improved after 50 iterations, the aqo extension falls back to the default query planner.

Note

You can view the current query plan using the standard Postgres Pro `EXPLAIN` command with the `ANALYZE` option. For details, see the [Section 14.1](#).

Since the `intelligent` mode tries to learn separately for different query classes, aqo may fail to provide performance improvements if queries in the workload are of multiple different classes or if the classes of the queries in the workload are constantly changing. For such workloads, reset the aqo extension to the `controlled` mode, or try to turn off `aqo.advanced`.

When `aqo.advanced` is on, in the `controlled` mode, aqo does not collect statistics for new query classes, so they will not be optimized, but for known query classes, aqo will continue collecting statistics and using optimized planning algorithms. So use the `controlled` mode only after aqo learned in the `learn` or `intelligent` mode.

After aqo has already learned, `controlled` is the mode recommended for production use. To make aqo run in this mode on your whole production cluster, run

```
ALTER SYSTEM SET aqo.mode = 'controlled';  
SELECT pg_reload_conf();
```

When `aqo.advanced` is on, the `learn` mode collects statistics from all the executed queries and updates the data for query classes. This mode is similar to the `intelligent` mode, except that it does not provide intelligent tuning. This mode is not recommended to be used permanently for a whole cluster because it tries aqo optimizations for every query class, even for those that do not need it, and this may lead to an unnecessary computational overhead and cause performance degradation.

Use the `learn` mode with `aqo.advanced` turned off to handle workloads with dynamically generated query structures. Overall performance improvement is not guaranteed. As this mode lacks intelligent tuning, the performance for some queries may even decrease, but this mode is good for a dynamic workload and consumes less memory than the `intelligent` mode.

When `aqo.advanced` is on, in the `auto` mode, aqo behaves like in the `learn` mode, but the `auto` mode prevents the memory overflow by implementing the least recently used (LRU) cache mechanism. This mechanism ensures that the `aqo.dsm_size_max` and the `aqo.fss_max_items` limits are not exceeded when incoming queries are saved. When the `aqo_query_texts_update` function is called in this mode, aqo does not save query texts and does not free the dynamic shared memory used.

For data that may change significantly between queries, enabling the `aqo.delta_rows` parameter may be useful. With this setting, aqo makes predictions based on the planner's row count estimates. For example, if data is deleted from a table, the planner estimates fewer rows than before. aqo can then use this updated information to predict a lower row count without requiring additional learning steps.

If you want to reduce the impact of aqo on query planning and execution, you can use it in the `frozen` mode. In this mode, aqo only reads the collected statistics, but does not collect any new data.

F.2.3.3. Fine-Tuning aqo

You must have superuser rights to access aqo views and configure advanced query settings.

You can view all the processed query classes and their corresponding hash values in the [aqo_query_texts](#) view:

```
SELECT * FROM aqo_query_texts;
```

To find out the class, that is, hash, of a query and aqo mode, enable [aqo.show_hash](#) (boolean) and [aqo.show_details](#) (boolean) environment variables and execute the query. The output will contain something like this:

```
...
Planning Time: 23.538 ms
...
Execution Time: 249813.875 ms
...
Using aqo: true
AQO mode: LEARN
AQO advanced: OFF
...
Query hash: -2439501042637610315
```

Each query class has its own optimization settings. These settings are shown in the [aqo_queries](#) view:

```
SELECT * FROM aqo_queries;
```

You can manually change these settings to adjust the optimization for a particular query class. For example:

```
-- Add a new query class to the aqo_queries view:

SET aqo.enable='on';
SET aqo.advanced='on';
SET aqo.mode='intelligent';
SELECT * FROM a, b WHERE a.id=b.id;
SET aqo.mode='controlled';

-- Disable auto_tuning, enable both learn_aqo and use_aqo
-- for this query class:

SELECT count(*) FROM aqo_queries,
  LATERAL aqo_queries_update(fs, NULL, true, true, false)
WHERE fs = (SELECT fs FROM aqo_query_texts
WHERE query_text LIKE 'SELECT * FROM a, b WHERE a.id=b.id;');

-- Run EXPLAIN ANALYZE while the plan changes:

EXPLAIN ANALYZE SELECT * FROM a, b WHERE a.id=b.id;
EXPLAIN ANALYZE SELECT * FROM a, b WHERE a.id=b.id;

-- Disable learning to stop statistics collection
-- and use the optimized plan:
```

```
SELECT count(*) FROM aqo_queries,
  LATERAL aqo_queries_update(fs, NULL, false, true, false)
WHERE fs = (SELECT fs FROM aqo_query_texts
WHERE query_text LIKE 'SELECT * FROM a, b WHERE a.id=b.id;');
```

To stop intelligent tuning for a particular query class, disable the `auto_tuning` setting:

```
SELECT count(*) FROM aqo_queries,
  LATERAL aqo_queries_update(fs, NULL, NULL, NULL, false)
```

```
WHERE fs = 'hash';
```

where *hash* is the hash value for this query class. As a result, aqo disables automatic change of the `learn_aqo` and `use_aqo` settings.

To disable further learning for a particular query class, use the following command:

```
SELECT count(*) FROM aqo_queries,  
       LATERAL aqo_queries_update(fs, NULL, false, NULL, false)  
       WHERE fs = 'hash';
```

where *hash* is the hash value for this query class.

To fully disable aqo for all queries and use the default Postgres Pro query planner, run:

```
SELECT count(*) FROM aqo_queries,  
       LATERAL aqo_disable_class(fs, NULL)  
       WHERE fs <> 0;
```

To disable aqo for all queries temporarily in the current session or for the whole cluster, but not remove or change the collected statistics and settings, turn off [aqo.enable](#):

```
SET aqo.enable = 'off';
```

or

```
ALTER SYSTEM SET aqo.enable = 'off'
```

F.2.3.4. Sandbox Mode

You can experiment with aqo without touching its main knowledge base. To do this, execute the command

```
SET aqo.sandbox = ON;
```

This turns on the *sandbox mode*, which means that aqo will work in the isolated environment. However, if you turn on [aqo.sandbox](#) in different SQL sessions, they will use the same data.

Data obtained in the sandbox mode does not get replicated. But the sandbox mode can be used on a standby. Moreover, the only way to train aqo on a standby is turning on the sandbox mode when the replication is turned on, that is, `aqo.wal_rw` is true. Without the sandbox mode, aqo will work on the standby as if `aqo.mode = FROZEN`, that is, it will be able to use the existing knowledge base, but not update or extend it.

F.2.4. Reference

F.2.4.1. Configuration Parameters

`aqo.enable` (boolean)

Defines the state of aqo. If set to `off` aqo does not work except when [aqo.force_collect_stat](#) = `on`.

Default: `off`.

`aqo.mode` (text)

Sets the aqo operation mode. Defines how aqo handles new queries. Possible values:

- `intelligent` — saves new queries with `auto_tuning` enabled. See the description of the [aqo_queries](#) view for more details. May disable aqo for a query in the case of average performance reduction. Only works in this way if [aqo.advanced](#) = `on`, otherwise, this mode works exactly like `learn`.
- `learn` — collects statistics on all the executed queries, learns and makes predictions based on these statistics.
- `controlled` — only learns and makes predictions for known queries.
- `frozen` — makes predictions for known queries, but does not learn from any queries.

- `auto` — behaves like `learn` but prevents memory overflow by implementing the LRU cache mechanism.

Default: `learn`.

`aqo.advanced` (boolean)

Enables the advanced learning routine, which saves separate learning statistics for each query class. Also allows fine-tuning the `use_aqo` and `learn_aqo` settings in the [aqo_queries](#) view. Fine-tuned query settings in the `aqo_query` view continue to work if `aqo.advanced` is disabled.

Default: `off`.

`aqo.force_collect_stat` (boolean)

Collects statistics on query executions in all `aqo` modes and even if `aqo.enable` is `off`.

Default: `off`.

`aqo.show_details` (boolean)

Adds some details to `EXPLAIN` output of a query, such as the prediction or feature-subspace hash, and shows some additional `aqo`-specific on-screen information.

Default: `on`.

`aqo.show_hash` (boolean)

Shows a hash value that uniquely identifies the class of queries or class of plan nodes. `aqo` uses the native query ID to identify a query class for consistency with other extensions, such as [pg_stat_statements](#). So, the query ID can be taken from the `Query hash` field in `EXPLAIN ANALYZE` output of a query.

Default: `on`.

`aqo.join_threshold` (integer)

Ignores queries that contain smaller number of joins, which means that statistics for such queries is not collected.

Default: 0 (no queries are ignored).

`aqo.learn_statement_timeout` (boolean)

Learns on a plan interrupted by the statement timeout.

Default: `off`.

`aqo.statement_timeout` (integer)

Defines the initial value of the *smart statement timeout*, in milliseconds, which is needed to limit the execution time when manually training `aqo` on special queries with a poor cardinality forecast. `aqo` can dynamically change the value of the smart statement timeout during this training. When the cardinality estimation error on nodes exceeds 0.1, the value of `aqo.statement_timeout` is automatically incremented exponentially, but remains not greater than [statement_timeout](#).

Default: 0.

`aqo.wide_search` (boolean)

Enables searching neighbors with the same feature subspace among different query classes. Only has an effect if [aqo.advanced](#) = `on`.

Default: `off`.

`aqo.min_neighbors_for_predicting` (integer)

Defines how many samples collected in previous executions of the query will be used to predict the cardinality next time. If there are fewer of them, aqo will not make any prediction. A too large value may affect performance, but a too small value may reduce the prediction quality.

Default: 3.

`aqo.predict_with_few_neighbors` (boolean)

Enables aqo to make predictions with fewer neighbors than specified by [aqo.min_neighbors_for_predicting](#). When set to `off`, then aqo learns, but does not make predictions until the execution count for the query with different constants reaches 3 (default for `aqo.min_neighbors_for_predicting`).

Default: `on`.

`aqo.fs_max_items` (integer)

Defines the maximum number of feature spaces that aqo can operate with. When this number is exceeded, learning on new query classes will no longer occur, and they will not appear in the views accordingly. This parameter can only be set at server start.

Default: 10000.

`aqo.fss_max_items` (integer)

Defines the maximum number of feature subspaces that aqo can operate with. When this number is exceeded, the selectivity and cardinality for new query plan nodes will no longer be collected, and new feature subspaces will not appear in the [aqo_data](#) view accordingly. This parameter can only be set at server start.

Default: 100000.

`aqo.querytext_max_size` (integer)

Defines the maximum size of the query in the [aqo_query_texts](#) view. This parameter can only be set at server start.

Default: 1000.

`aqo.dsm_size_max` (integer)

Defines the maximum size of dynamic shared memory, in MB, that aqo can allocate to store learning data and query texts. If set to a number that is less than the size of the saved aqo data, the server will not start. This parameter can only be set at server start.

Default: 100.

`aqo.wal_rw` (boolean)

Enables physical replication and allows complete aqo data recovery after failure. When set to `off` on the primary, no data is transferred from it to a replica. When set to `off` on a replica, any data transferred from the primary is ignored. With this value, when the server fails, data can only be restored as of the last checkpoint. This parameter can only be set at server start.

Default: `on`.

`aqo.sandbox` (boolean)

Enables reserving a separate memory area in shared memory to be used by a primary or standby node, which allows collecting and using statistics with the data in this memory area. If enabled on the primary, the extension uses the separate shared memory area that is not replicated to the standby. Changing the value of this parameter resets the aqo cache. Only superusers can change this setting.

Default: `off`.

`aqo.delta_rows` (boolean)

Enables a learning mechanism where `aqo` adjusts the planner's row count estimates with its own predictions. If disabled, `aqo` uses its own predictions.

Default: `off`.

F.2.4.2. Views

F.2.4.2.1. `aqo_query_texts`

The `aqo_query_texts` view classifies all the query classes processed by `aqo`. For each query class, the view shows the text of the first analyzed query of this class.

Table F.1. `aqo_query_texts` View

Column Name	Description
<code>queryid</code>	The unique identifier of the query.
<code>dbid</code>	The identifier of the database.
<code>fs</code>	The identifier of the feature space.
<code>query_text</code>	Text of the first analyzed query of the given class. The query text length is limited by <code>aqo.querytext_max_size</code> .

F.2.4.2.2. `aqo_queries`

The `aqo_queries` view shows optimization settings for different query classes. One query executed in two different databases is stored twice although the `fs` is the same.

Table F.2. `aqo_queries` View

Setting	Description
<code>fs</code>	The identifier of the feature space.
<code>dbid</code>	The identifier of the database in which the query was executed.
<code>learn_aqo</code>	Shows whether statistics collection for this query class is enabled.
<code>use_aqo</code>	Shows whether the <code>aqo</code> cardinality prediction for the next execution of this query class is enabled.
<code>auto_tuning</code>	<p>Shows whether <code>aqo</code> can dynamically change <code>use_aqo</code> and <code>learn_aqo</code> settings for this query class. By default, set to <code>true</code> for new queries if <code>aqo.advanced</code> is on and <code>aqo.mode = intelligent</code>.</p> <p>When <code>auto_tuning</code> is on, if for several successive executions of a query for which <code>use_aqo</code> is off, the cardinality error remains sufficiently small and stable, <code>aqo</code> turns on <code>use_aqo</code>.</p> <p>For queries with <code>learn_aqo = true</code> (it is so for new queries), several first executions are done both using <code>aqo</code> and without it. The faster the query is executed compared to the execution with the standard planner, the more likely <code>aqo</code> will be used for the next query execution. If after a certain number of executions the execution time with</p>

Setting	Description
	aqo appears to be worse than with the standard planner, aqo will never be used for this query class: <code>auto_tuning</code> , <code>use_aqo</code> and <code>learn_aqo</code> are set to <code>off</code> .
<code>smart_timeout</code>	The value of the smart statement timeout for this query class. The initial value of the smart statement timeout for any query is defined by the statement_timeout configuration parameter.
<code>count_increase_timeout</code>	Shows how many times the smart statement timeout increased for this query class.

F.2.4.2.3. aqo_data

The `aqo_data` view shows machine learning data for cardinality estimation refinement. The number of rows is limited by [aqo.fss_max_items](#). To discard all the collected statistics for a particular query class, you can delete all rows from `aqo_data` with the corresponding `fs`.

Table F.3. aqo_data View

Data	Description
<code>fs</code>	The identifier (hash) of the feature space.
<code>fss</code>	The identifier (hash) of the feature subspace.
<code>dbid</code>	The identifier of the database.
<code>delta_rows</code>	If true, aqo makes predictions based on the planner's estimates, otherwise <code>false</code> .
<code>nfeatures</code>	Feature-subspace size for the query plan node.
<code>features</code>	Logarithm of the selectivity which the cardinality prediction is based on.
<code>targets</code>	Cardinality logarithm for the query plan node.
<code>reliability</code>	Confidence level of the learning statistics. Equals: <ul style="list-style-type: none"> • 1 (default) — indicates data obtained after normal execution of a query • 0.1 — indicates data obtained from a partially executed node (not needed as unreliable) • 0.9 — indicates data obtained from a finished node, but from a partially executed statement
<code>oids</code>	List of IDs of tables that were involved in the prediction for this node.
<code>tmpoids</code>	List of IDs of temporary tables that were involved in the prediction for this node.

F.2.4.2.4. aqo_query_stat

The `aqo_query_stat` view shows statistics on query execution, by query class. aqo uses this data when `auto_tuning` is enabled for a particular query class.

Table F.4. aqo_query_stat View

Data	Description
<code>fs</code>	The identifier of the feature space.
<code>dbid</code>	The identifier of the database.

Data	Description
<code>execution_time_with_aqo</code>	Array of execution times for queries run with aqo enabled.
<code>execution_time_without_aqo</code>	Array of execution times for queries run with aqo disabled.
<code>planning_time_with_aqo</code>	Array of planning times for queries run with aqo enabled.
<code>planning_time_without_aqo</code>	Array of planning times for queries run with aqo disabled.
<code>cardinality_error_with_aqo</code>	Array of cardinality estimation errors in the selected query plans with aqo enabled.
<code>cardinality_error_without_aqo</code>	Array of cardinality estimation errors in the selected query plans with aqo disabled.
<code>executions_with_aqo</code>	Number of queries run with aqo enabled.
<code>executions_without_aqo</code>	Number of queries run with aqo disabled.

F.2.4.3. Functions

aqo adds several functions to Postgres Pro catalog.

F.2.4.3.1. Storage Management Functions

Important

Functions `aqo_queries_update`, `aqo_query_texts_update`, `aqo_query_stat_update`, `aqo_data_update` and `aqo_data_delete` modify data files underlying aqo views. Therefore, call these functions only if you understand the logic of adaptive query optimization.

`aqo_cleanup()` → setof integer

Removes data related to query classes that are linked (may be partially) with removed relations. Returns the number of removed feature spaces (classes) and feature subspaces. Insensitive to removing other objects.

`aqo_enable_class(fs bigint, dbid oid)` → void

Sets `learn_aqo`, `use_aqo` and `auto_tuning` (only in the intelligent mode) to true for the query class with the specified `fs` and `dbid`. You can set `dbid` to NULL instead of the ID of the current database.

`aqo_disable_class(fs bigint, dbid oid)` → void

Sets `learn_aqo`, `use_aqo` and `auto_tuning` to false for the query class with the specified `fs` and `dbid`. You can set `dbid` to NULL instead of the ID of the current database.

`aqo_drop_class(fs bigint, dbid oid)` → integer

Removes all data related to the specified query class and database from the aqo storage. You can set `dbid` to NULL instead of the ID of the current database. Returns the number of records removed from the aqo storage.

`aqo_reset(dbid oid)` → bigint

Removes records from the specified database: machine learning data, query texts, statistics and query class preferences. If `dbid` is omitted, removes the data from the current database. If `dbid` is NULL, removes all records from the aqo storage. Returns the number of records removed.

`aqo_queries_update (fs bigint, dbid oid, learn_aqo boolean, use_aqo boolean, auto_tuning boolean) → boolean`

Updates or inserts a record in a data file underlying the [aqo_queries](#) view for the specified *fs* and *dbid*. You can set *dbid* to NULL instead of the ID of the current database. NULL values for parameters being set mean leave them as is. Note that records with a zero value of *fs* or *dbid* cannot be updated. Returns *false* in case of error, *true* otherwise.

`aqo_query_texts_update (fs bigint, dbid oid, query_text text) → boolean`

Updates or inserts a record in a data file underlying the [aqo_query_texts](#) view for the specified *fs* and *dbid*. You can set *dbid* to NULL instead of the ID of the current database. Note that records with a zero value of *fs* or *dbid* cannot be updated. Returns *false* in case of error, *true* otherwise.

`aqo_query_stat_update (fs bigint, dbid oid, execution_time_with_aqo double precision[], execution_time_without_aqo double precision[], planning_time_with_aqo double precision[], planning_time_without_aqo double precision[], cardinality_error_with_aqo double precision[], cardinality_error_without_aqo double precision[], executions_with_aqo bigint[], executions_without_aqo bigint[]) → boolean`

Updates or inserts a record in a data file underlying the [aqo_query_stat](#) view for the specified *fs* and *dbid*. You cannot update a record for a common feature space, i.e., for *fs* or *dbid* equal to zero. You can set *dbid* to NULL instead of the ID of the current database. Returns *false* in case of error, *true* otherwise.

`aqo_data_update (fs bigint, fss integer, dbid oid, delta_rows boolean, nfeatures integer, features double precision[][], targets double precision[], reliability double precision[], oids oid[], tmpoids oid[]) → boolean`

Updates or inserts a record in a data file underlying the [aqo_data](#) view for the specified *fs*, *fss* and *dbid*. You can set *dbid* to NULL instead of the ID of the current database. If you set *delta_rows* to NULL, the value of `aqo.delta_rows` is used. Returns *false* in case of error, *true* otherwise.

`aqo_data_delete (fs bigint, fss integer, dbid oid, delta_rows boolean) → boolean`

Removes a record from a data file underlying the [aqo_data](#) view for the specified *fs*, *fss* and *dbid*. You can set *dbid* to NULL instead of the ID of the current database. If you omit *delta_rows* or set it to NULL, the value of `aqo.delta_rows` is used. Returns *false* in case of error, *true* otherwise.

F.2.4.3.2. Memory Management Functions

`aqo_memory_usage () → setof record`

Shows allocated and used sizes of aqo memory contexts and hash tables. Returns a table:

name

Short description of the memory context or hash table

allocated_size

Total size of the allocated memory

used_size

Size of the currently used memory

F.2.4.3.3. Functions for Analytics

`aqo_cardinality_error (controlled boolean) → setof record`

Shows the cardinality error for the last execution of queries. If *controlled* is true, shows queries executed with aqo enabled. If *controlled* is false, shows queries that were executed with aqo disabled, but that have collected aqo statistics. Returns a table:

num

Sequential number

dbid

The identifier of the database

fs

The identifier of the feature space. Can be zero or the basic hash.

error

aqo error calculated on query plan nodes

nexecs

Number of executions of queries associated with this *fs*

`aqo_execution_time (controlled boolean) → setof record`

Shows the execution time for queries. If *controlled* is true, shows the execution time of the last execution with aqo enabled. If *controlled* is false, returns the average execution time for all logged executions with aqo disabled. Execution time without aqo can be collected when `aqo.mode = intelligent` or `aqo.force_collect_stat = on`. Returns a table:

num

Sequential number

dbid

The identifier of the database

fs

The identifier of the feature space. Can be zero or the basic hash.

exec_time

If *controlled* = true, last query execution time with aqo, otherwise, average execution time for all executions without aqo

nexecs

Number of executions of queries associated with this *fs*

F.2.5. Examples

Example F.1. Learning on a Query (Basic Mode)

Consider optimization of a query using aqo.

When the query is executed for the first time, it is missing in tables underlying aqo views. So there is no data for predicting with aqo for each plan node, and “AQO not used” lines appear in the `EXPLAIN` output:

```
demo=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF)
SELECT bp.*
FROM ticket_flights tf
JOIN flights f ON f.flight_id = tf.flight_id
JOIN boarding_passes bp ON bp.ticket_no = tf.ticket_no AND bp.flight_id = tf.flight_id
WHERE f.scheduled_departure > '2017-08-15 15:00:00+00';
```

QUERY PLAN

```
-----
Hash Join  (cost=63796.33..140286.73 rows=477728 width=25) (actual rows=2215 loops=1)
  AQO not used, fss=8598194613120045129
```

postgrespro-std-18-contrib

Using aqo: true

AQO mode: LEARN

AQO advanced: OFF

Query hash: 402936317627943257

JOINS: 2

(23 rows)

If there is no information on a certain node in the `aqo_data` view, aqo will add the appropriate record there for future learning and predictions except for nodes with `fss=0` in the `EXPLAIN` output. As each of `features` and `targets` in the `aqo_data` view is a logarithm to base e , to get the actual value, raise e to this power. For example: `exp(7.703007682479236)`:

```
demo=# select * from aqo_data;
fs |          fss          | dbid | delta_rows | nfeatures |          features
   |          | targets | reliability |          | oids          | tmpoids
-----+-----+-----+-----+-----+-----+-----
0 | 1362775811343989307 | 16429 | f          |          | 0 |          |
   | {14.454357295615447} | {1}   |          |          | {16452}       |
0 | -6410966714754547713 | 16429 | f          |          | 0 |          |
   | {14.674314116080508} | {1}   |          |          | {16479}       |
0 | -1289471166524579716 | 16429 | f          |          | 1 | {{-1.3775704575284085}} |
   | {9.701371368413994}  | {1}   |          |          | {16458}       |
0 | 8598194613120045129 | 16429 | f          |          | 2 |          |
{{-13.492416828684513,-1.3775704575284085}} | {7.703007682479236} | {1}   |          |
{16479,16458,16452} |
0 | -7651474063207585780 | 16429 | f          |          | 2 |          |
{{-11.092306109090387,-1.3775704575284085}} | {13.056768298305919} | {1}   |          |
{16479,16458} |
(5 rows)
```

When the query is executed for the second time, ago recognizes the query and makes a prediction. Pay attention to the cardinality predicted by ago and the value of ago error ("error=0%").

```
demo=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF)
```

Example F.2. Using the [ajo_query_stat](#) View

The `ajo_query_stats` view shows statistics on the query planning time, query execution time and cardinality error. Based on this data you can make a decision whether to use ajo predictions for different query classes.

Let's query the `ajo_query_stats` view:

```
demo=# SELECT * FROM ajo_query_stat \gx
-[ RECORD 1 ]-----+-----
fs                  | 7809046947949890015
dbid                | 16429
execution_time_with_ajo | {1.039218233,0.925258453,0.831166925,0.779602353}
execution_time_without_ajo | {1.022052611,0.936486619}
planning_time_with_ajo | {0.003305339,0.002129048,0.002538877,0.002142972}
planning_time_without_ajo | {0.000767553,0.000711208}
cardinality_error_with_ajo | 
{0.4854215265638894,0,1.1711726076352047,0.007732205169478082}
cardinality_error_without_ajo | {0.4854215265638894,1.571562511977072}
executions_with_ajo | 4
executions_without_ajo | 2
```

The retrieved data is for the query from [Example F.1](#), which was executed once without ajo for each of the parameters `f.scheduled_departure > '2017-08-10 15:00:00+00'` and `f.scheduled_departure > '2017-08-15 15:00:00+00'` and twice with ajo for each of these parameters. It is clear that with ajo, the cardinality error decreases to 0.0077, while the minimum cardinality error without ajo is 0.4854. Besides, the execution time with ajo is lower than without it. So the conclusion is that ajo learns well on this query, and the prediction can be used for this query class.

Example F.3. Using ajo in the Advanced Mode

The advanced mode allows a more flexible control over ajo. When this mode is activated, that is,

Additional Supplied Modules and Extensions Shipped in postgrespro-std-18-contrib

```
demo=# SET aqo.advanced = on;
```

aqo will collect the machine learning data separately for each query executed. For example:

```
demo=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF)
SELECT bp.*
FROM ticket_flights tf
JOIN flights f ON f.flight_id = tf.flight_id
JOIN boarding_passes bp ON bp.ticket_no = tf.ticket_no AND bp.flight_id = tf.flight_id
WHERE f.scheduled_departure > '2017-08-15 15:00:00+00';
                                QUERY PLAN

{16479,16458} |
(5 rows)

```

We can make a few settings individually for this query. These are values of `learn_aqo`, `use_aqo` and `auto_tuning` in the [aqo_queries](#) view:

```

demo=# SELECT * FROM aqo_queries;
      fs      | dbid | learn_aqo | use_aqo | auto_tuning | smart_timeout |
count_increase_timeout
-----+-----+-----+-----+-----+-----+-----
+-----+
402936317627943257 | 16429 | t          | t          | f          |              | 0 |
0
0 | 0 | f          | f          | f          |              | 0 |
0
(2 rows)

```

Let's set `use_aqo` to false:

```

demo=# SELECT aqo_queries_update(402936317627943257, NULL, NULL, false, NULL);
aqo_queries_update
-----
t
(1 row)

```

Now we change a constant in the query:

```

demo=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF)
SELECT bp.*
FROM ticket_flights tf
JOIN flights f ON f.flight_id = tf.flight_id
JOIN boarding_passes bp ON bp.ticket_no = tf.ticket_no AND bp.flight_id = tf.flight_id
WHERE f.scheduled_departure > '2017-08-10 15:00:00+00';

```

F.2.6. Author

Oleg Ivanov

F.3. auth_delay — pause on authentication failure

`auth_delay` causes the server to pause briefly before reporting authentication failure, to make brute-force attacks on database passwords more difficult. Note that it does nothing to prevent denial-of-service attacks, and may even exacerbate them, since processes that are waiting before reporting authentication failure will still consume connection slots.

In order to function, this module must be loaded via [shared_preload_libraries](#) in `postgresql.conf`.

F.3.1. Configuration Parameters

`auth_delay.milliseconds` (integer)

The number of milliseconds to wait before reporting an authentication failure. The default is 0.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'auth_delay'

auth_delay.milliseconds = '500'
```

F.3.2. Author

KaiGai Kohei <kaigai@ak.jp.nec.com>

F.4. auto_explain — log execution plans of slow queries

The `auto_explain` module provides a means for logging execution plans of slow statements automatically, without having to run `EXPLAIN` by hand. This is especially helpful for tracking down un-optimized queries in large applications.

The module provides no SQL-accessible functions. To use it, simply load it into the server. You can load it into an individual session:

```
LOAD 'auto_explain';
```

(You must be superuser to do that.) More typical usage is to preload it into some or all sessions by including `auto_explain` in [session_preload_libraries](#) or [shared_preload_libraries](#) in `postgresql.conf`. Then you can track unexpectedly slow queries no matter when they happen. Of course there is a price in overhead for that.

F.4.1. Configuration Parameters

There are several configuration parameters that control the behavior of `auto_explain`. Note that the default behavior is to do nothing, so you must set at least `auto_explain.log_min_duration` if you want any results.

`auto_explain.log_min_duration` (integer)

`auto_explain.log_min_duration` is the minimum statement execution time, in milliseconds, that will cause the statement's plan to be logged. Setting this to 0 logs all plans. -1 (the default) disables logging of plans. For example, if you set it to 250ms then all statements that run 250ms or longer will be logged. Only superusers can change this setting.

`auto_explain.log_parameter_max_length` (integer)

`auto_explain.log_parameter_max_length` controls the logging of query parameter values. A value of -1 (the default) logs the parameter values in full. 0 disables logging of parameter values. A value greater than zero truncates each parameter value to that many bytes. Only superusers can change this setting.

`auto_explain.log_analyze` (boolean)

`auto_explain.log_analyze` causes `EXPLAIN ANALYZE` output, rather than just `EXPLAIN` output, to be printed when an execution plan is logged. This parameter is off by default. Only superusers can change this setting.

Note

When this parameter is on, per-plan-node timing occurs for all statements executed, whether or not they run long enough to actually get logged. This can have an extremely negative impact on performance. Turning off `auto_explain.log_timing` ameliorates the performance cost, at the price of obtaining less information.

`auto_explain.log_buffers` (boolean)

`auto_explain.log_buffers` controls whether buffer usage statistics are printed when an execution plan is logged; it's equivalent to the `BUFFERS` option of `EXPLAIN`. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_wal` (boolean)

`auto_explain.log_wal` controls whether WAL usage statistics are printed when an execution plan is logged; it's equivalent to the `WAL` option of `EXPLAIN`. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_timing` (boolean)

`auto_explain.log_timing` controls whether per-node timing information is printed when an execution plan is logged; it's equivalent to the `TIMING` option of `EXPLAIN`. The overhead of repeatedly reading the system clock can slow down queries significantly on some systems, so it may be useful to set this parameter to off when only actual row counts, and not exact times, are needed. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is on by default. Only superusers can change this setting.

`auto_explain.log_triggers` (boolean)

`auto_explain.log_triggers` causes trigger execution statistics to be included when an execution plan is logged. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_verbose` (boolean)

`auto_explain.log_verbose` controls whether verbose details are printed when an execution plan is logged; it's equivalent to the `VERBOSE` option of `EXPLAIN`. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_settings` (boolean)

`auto_explain.log_settings` controls whether information about modified configuration options is printed when an execution plan is logged. Only options affecting query planning with value different from the built-in default value are included in the output. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_format` (enum)

`auto_explain.log_format` selects the `EXPLAIN` output format to be used. The allowed values are `text`, `xml`, `json`, and `yaml`. The default is `text`. Only superusers can change this setting.

`auto_explain.log_level` (enum)

`auto_explain.log_level` selects the log level at which `auto_explain` will log the query plan. Valid values are `DEBUG5`, `DEBUG4`, `DEBUG3`, `DEBUG2`, `DEBUG1`, `INFO`, `NOTICE`, `WARNING`, and `LOG`. The default is `LOG`. Only superusers can change this setting.

`auto_explain.log_nested_statements` (boolean)

`auto_explain.log_nested_statements` causes nested statements (statements executed inside a function) to be considered for logging. When it is off, only top-level query plans are logged. This parameter is off by default. Only superusers can change this setting.

`auto_explain.sample_rate` (real)

`auto_explain.sample_rate` causes `auto_explain` to only explain a fraction of the statements in each session. The default is 1, meaning explain all the queries. In case of nested statements, either all will be explained or none. Only superusers can change this setting.

In ordinary usage, these parameters are set in `postgresql.conf`, although superusers can alter them on-the-fly within their own sessions. Typical usage might be:

```
# postgresql.conf
session_preload_libraries = 'auto_explain'

auto_explain.log_min_duration = '3s'
```

F.4.2. Example

```
postgres=# LOAD 'auto_explain';
postgres=# SET auto_explain.log_min_duration = 0;
```

```
postgres=# SET auto_explain.log_analyze = true;
postgres=# SELECT count(*)
           FROM pg_class, pg_index
           WHERE oid = indrelid AND indisunique;
```

This might produce log output such as:

```
LOG:  duration: 0.196 ms plan:
       Query Text: SELECT count(*)
                   FROM pg_class, pg_index
                   WHERE oid = indrelid AND indisunique;
       Aggregate  (cost=16.79..16.80 rows=1 width=0) (actual time=3.626..3.627 rows=1.00
loops=1)
         -> Hash Join  (cost=4.17..16.55 rows=92 width=0) (actual time=3.349..3.594
rows=92.00 loops=1)
           Hash Cond: (pg_class.oid = pg_index.indrelid)
             -> Seq Scan on pg_class  (cost=0.00..9.55 rows=255 width=4) (actual
time=0.016..0.140 rows=255.00 loops=1)
               -> Hash  (cost=3.02..3.02 rows=92 width=4) (actual time=3.238..3.238
rows=92.00 loops=1)
                 Buckets: 1024  Batches: 1  Memory Usage: 4kB
                 -> Seq Scan on pg_index  (cost=0.00..3.02 rows=92 width=4) (actual
time=0.008..3.187 rows=92.00 loops=1)
                   Filter: indisunique
       Planning Time: 0.548 ms
```

Note that Postgres Pro added a new field to the output to show planning time.

Postgres Professional, Moscow, Russia

F.5. basebackup_to_shell — example "shell" pg_basebackup module

`basebackup_to_shell` adds a custom basebackup target called `shell`. This makes it possible to run `pg_basebackup --target=shell` or, depending on how this module is configured, `pg_basebackup --target=shell:DETAIL_STRING`, and cause a server command chosen by the server administrator to be executed for each tar archive generated by the backup process. The command will receive the contents of the archive via standard input.

This module is primarily intended as an example of how to create a new backup targets via an extension module, but in some scenarios it may be useful for its own sake. In order to function, this module must be loaded via [shared_preload_libraries](#) or [local_preload_libraries](#).

F.5.1. Configuration Parameters

`basebackup_to_shell.command (string)`

The command which the server should execute for each archive generated by the backup process. If `%f` occurs in the command string, it will be replaced by the name of the archive (e.g. `base.tar`). If `%d` occurs in the command string, it will be replaced by the target detail provided by the user. A target detail is required if `%d` is used in the command string, and prohibited otherwise. For security reasons, it may contain only alphanumeric characters. If `%%` occurs in the command string, it will be replaced by a single `%`. If `%` occurs in the command string followed by any other character or at the end of the string, an error occurs.

`basebackup_to_shell.required_role (string)`

The role required in order to make use of the `shell` backup target. If this is not set, any replication user may make use of the `shell` backup target.

F.5.2. Author

Robert Haas <rhaas@postgresql.org>

F.6. basic_archive — an example WAL archive module

`basic_archive` is an example of an archive module. This module copies completed WAL segment files to the specified directory. This may not be especially useful, but it can serve as a starting point for developing your own archive module. For more information about archive modules, see [Chapter 49](#).

In order to function, this module must be loaded via [archive_library](#), and [archive_mode](#) must be enabled.

F.6.1. Configuration Parameters

`basic_archive.archive_directory` (string)

The directory where the server should copy WAL segment files. This directory must already exist. The default is an empty string, which effectively halts WAL archiving, but if [archive_mode](#) is enabled, the server will accumulate WAL segment files in the expectation that a value will soon be provided.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
archive_mode = 'on'
archive_library = 'basic_archive'
basic_archive.archive_directory = '/path/to/archive/directory'
```

F.6.2. Notes

Server crashes may leave temporary files with the prefix `archtemp` in the archive directory. It is recommended to delete such files before restarting the server after a crash. It is safe to remove such files while the server is running as long as they are unrelated to any archiving still in progress, but users should use extra caution when doing so.

Nathan Bossart

F.7. bloom — bloom filter index access method

`bloom` provides an index access method based on *Bloom filters*.

A Bloom filter is a space-efficient data structure that is used to test whether an element is a member of a set. In the case of an index access method, it allows fast exclusion of non-matching tuples via signatures whose size is determined at index creation.

A signature is a lossy representation of the indexed attribute(s), and as such is prone to reporting false positives; that is, it may be reported that an element is in the set, when it is not. So index search results must always be rechecked using the actual attribute values from the heap entry. Larger signatures reduce the odds of a false positive and thus reduce the number of useless heap visits, but of course also make the index larger and hence slower to scan.

This type of index is most useful when a table has many attributes and queries test arbitrary combinations of them. A traditional btree index is faster than a bloom index, but it can require many btree indexes to support all possible queries where one needs only a single bloom index. Note however that bloom indexes only support equality queries, whereas btree indexes can also perform inequality and range searches.

F.7.1. Parameters

A bloom index accepts the following parameters in its `WITH` clause:

`length`

Length of each signature (index entry) in bits. It is rounded up to the nearest multiple of 16. The default is 80 bits and the maximum is 4096.

`col1 – col32`

Number of bits generated for each index column. Each parameter's name refers to the number of the index column that it controls. The default is 2 bits and the maximum is 4095. Parameters for index columns not actually used are ignored.

F.7.2. Examples

This is an example of creating a bloom index:

```
CREATE INDEX bloomidx ON tbloom USING bloom (i1,i2,i3)
WITH (length=80, col1=2, col2=2, col3=4);
```

The index is created with a signature length of 80 bits, with attributes `i1` and `i2` mapped to 2 bits, and attribute `i3` mapped to 4 bits. We could have omitted the `length`, `col1`, and `col2` specifications since those have the default values.

Here is a more complete example of bloom index definition and usage, as well as a comparison with equivalent btree indexes. The bloom index is considerably smaller than the btree index, and can perform better.

```
=# CREATE TABLE tbloom AS
SELECT
    (random() * 1000000)::int as i1,
    (random() * 1000000)::int as i2,
    (random() * 1000000)::int as i3,
    (random() * 1000000)::int as i4,
    (random() * 1000000)::int as i5,
    (random() * 1000000)::int as i6
FROM
    generate_series(1,10000000);
SELECT 10000000
```

A sequential scan over this large table takes a long time:

```
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
                                QUERY PLAN
-----
Seq Scan on tbloom  (cost=0.00..213744.00 rows=250 width=24) (actual
time=357.059..357.059 rows=0.00 loops=1)
  Filter: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Filter: 10000000
  Buffers: shared hit=63744
Planning Time: 0.346 ms
Execution Time: 357.076 ms
(6 rows)
```

Even with the btree index defined the result will still be a sequential scan:

```
=# CREATE INDEX btreeidx ON tbloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('btreeidx'));
pg_size_pretty
-----
386 MB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
                                QUERY PLAN
-----
Seq Scan on tbloom  (cost=0.00..213744.00 rows=2 width=24) (actual
time=351.016..351.017 rows=0.00 loops=1)
  Filter: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Filter: 10000000
  Buffers: shared hit=63744
Planning Time: 0.138 ms
Execution Time: 351.035 ms
(6 rows)
```

Having the bloom index defined on the table is better than btree in handling this type of search:

```
=# CREATE INDEX bloomidx ON tbloom USING bloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('bloomidx'));
pg_size_pretty
-----
153 MB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
                                QUERY PLAN
-----
Bitmap Heap Scan on tbloom  (cost=1792.00..1799.69 rows=2 width=24) (actual
time=22.605..22.606 rows=0.00 loops=1)
  Recheck Cond: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Index Recheck: 2300
  Heap Blocks: exact=2256
  Buffers: shared hit=21864
-> Bitmap Index Scan on bloomidx  (cost=0.00..178436.00 rows=1 width=0) (actual
time=20.005..20.005 rows=2300.00 loops=1)
  Index Cond: ((i2 = 898732) AND (i5 = 123451))
  Index Searches: 1
```

```
Buffers: shared hit=19608
Planning Time: 0.099 ms
Execution Time: 22.632 ms
(11 rows)
```

Now, the main problem with the btree search is that btree is inefficient when the search conditions do not constrain the leading index column(s). A better strategy for btree is to create a separate index on each column. Then the planner will choose something like this:

```
=# CREATE INDEX btreeidx1 ON tbloom (i1);
CREATE INDEX
=# CREATE INDEX btreeidx2 ON tbloom (i2);
CREATE INDEX
=# CREATE INDEX btreeidx3 ON tbloom (i3);
CREATE INDEX
=# CREATE INDEX btreeidx4 ON tbloom (i4);
CREATE INDEX
=# CREATE INDEX btreeidx5 ON tbloom (i5);
CREATE INDEX
=# CREATE INDEX btreeidx6 ON tbloom (i6);
CREATE INDEX
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
                                QUERY PLAN
-----
Bitmap Heap Scan on tbloom  (cost=9.29..13.30 rows=1 width=24) (actual
time=0.032..0.033 rows=0.00 loops=1)
  Recheck Cond: ((i5 = 123451) AND (i2 = 898732))
  Buffers: shared read=6
    -> BitmapAnd  (cost=9.29..9.29 rows=1 width=0) (actual time=0.047..0.047 rows=0.00
loops=1)
      Buffers: shared hit=6
        -> Bitmap Index Scan on btreeidx5  (cost=0.00..4.52 rows=11 width=0) (actual
time=0.026..0.026 rows=7.00 loops=1)
          Index Cond: (i5 = 123451)
          Index Searches: 1
          Buffers: shared hit=3
        -> Bitmap Index Scan on btreeidx2  (cost=0.00..4.52 rows=11 width=0) (actual
time=0.007..0.007 rows=8.00 loops=1)
          Index Cond: (i2 = 898732)
          Index Searches: 1
          Buffers: shared hit=3
Planning Time: 0.264 ms
Execution Time: 0.047 ms
(15 rows)
```

Although this query runs much faster than with either of the single indexes, we pay a penalty in index size. Each of the single-column btree indexes occupies 88.5 MB, so the total space needed is 531 MB, over three times the space used by the bloom index.

F.7.3. Operator Class Interface

An operator class for bloom indexes requires only a hash function for the indexed data type and an equality operator for searching. This example shows the operator class definition for the `text` data type:

```
CREATE OPERATOR CLASS text_ops
DEFAULT FOR TYPE text USING bloom AS
    OPERATOR      1      =(text, text),
    FUNCTION      1      hashtext(text);
```

F.7.4. Limitations

- Only operator classes for `int4` and `text` are included with the module.
- Only the `=` operator is supported for search. But it is possible to add support for arrays with union and intersection operations in the future.
- `bloom` access method doesn't support `UNIQUE` indexes.
- `bloom` access method doesn't support searching for `NULL` values.

F.7.5. Authors

Teodor Sigaev <teodor@postgrespro.ru>, Postgres Professional, Moscow, Russia

Alexander Korotkov <a.korotkov@postgrespro.ru>, Postgres Professional, Moscow, Russia

Oleg Bartunov <obartunov@postgrespro.ru>, Postgres Professional, Moscow, Russia

F.8. btree_gin — GIN operator classes with B-tree behavior

`btree_gin` provides GIN operator classes that implement B-tree equivalent behavior for the data types `int2`, `int4`, `int8`, `float4`, `float8`, `timestamp with time zone`, `timestamp without time zone`, `time with time zone`, `time without time zone`, `date`, `interval`, `oid`, `money`, `"char"`, `varchar`, `text`, `bytea`, `bit`, `varbit`, `macaddr`, `macaddr8`, `inet`, `cidr`, `uuid`, `name`, `bool`, `bpchar`, and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they are useful for GIN testing and as a base for developing other GIN operator classes. Also, for queries that test both a GIN-indexable column and a B-tree-indexable column, it might be more efficient to create a multicolumn GIN index that uses one of these operator classes than to create two separate indexes that would have to be combined via bitmap ANDing.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.8.1. Example Usage

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIN (a);
-- query
SELECT * FROM test WHERE a < 10;
```

F.8.2. Authors

Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megeera/oddmuse/index.cgi/Gin> for additional information.

F.9. btree_gist — GiST operator classes with B-tree behavior

`btree_gist` provides GiST index operator classes that implement B-tree equivalent behavior for the data types `int2`, `int4`, `int8`, `float4`, `float8`, `numeric`, `timestamp with time zone`, `timestamp without time zone`, `time with time zone`, `time without time zone`, `date`, `interval`, `oid`, `money`, `char`, `varchar`, `text`, `bytea`, `bit`, `varbit`, `macaddr`, `macaddr8`, `inet`, `cidr`, `uuid`, `bool` and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they provide some other features that are not available with a B-tree index, as described below. Also, these operator classes are useful when a multicolumn GiST index is needed, wherein some of the columns are of data types that are only indexable with GiST but other columns are just simple data types. Lastly, these operator classes are useful for GiST testing and as a base for developing other GiST operator classes.

In addition to the typical B-tree search operators, `btree_gist` also provides index support for `<>` (“not equals”). This may be useful in combination with an [exclusion constraint](#), as described below.

Also, for data types for which there is a natural distance metric, `btree_gist` defines a distance operator `<->`, and provides GiST index support for nearest-neighbor searches using this operator. Distance operators are provided for `int2`, `int4`, `int8`, `float4`, `float8`, `timestamp with time zone`, `timestamp without time zone`, `time without time zone`, `date`, `interval`, `oid`, and `money`.

By default `btree_gist` builds GiST index with `sortsupport` in *sorted* mode. This usually results in much faster index built speed. It is still possible to revert to buffered built strategy by using the `buffering` parameter when creating the index.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.9.1. Example Usage

Simple example using `btree_gist` instead of `btree`:

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIST (a);
-- query
SELECT * FROM test WHERE a < 10;
-- nearest-neighbor search: find the ten entries closest to "42"
SELECT *, a <-> 42 AS dist FROM test ORDER BY a <-> 42 LIMIT 10;
```

Use an [exclusion constraint](#) to enforce the rule that a cage at a zoo can contain only one kind of animal:

```
=> CREATE TABLE zoo (
    cage    INTEGER,
    animal  TEXT,
    EXCLUDE USING GIST (cage WITH =, animal WITH <>)
);

=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'lion');
ERROR:  conflicting key value violates exclusion constraint "zoo_cage_animal_excl"
DETAIL:  Key (cage, animal)=(123, lion) conflicts with existing key (cage,
        animal)=(123, zebra).
=> INSERT INTO zoo VALUES(124, 'lion');
```

F.9.2. Authors

Teodor Sigaev (<teodor@stack.net>), Oleg Bartunov (<oleg@sai.msu.su>), Janko Richter (<janko-richter@yahoo.de>), and Paul Jungwirth (<pj@illuminatedcomputing.com>). See <http://www.sai.msu.su/~megera/postgres/gist/> for additional information.

F.10. citext — a case-insensitive character string type

The `citext` module provides a case-insensitive character string type, `citext`. Essentially, it internally calls `lower` when comparing values. Otherwise, it behaves almost exactly like `text`.

Tip

Consider using *nondeterministic collations* (see [Section 22.2.2.4](#)) instead of this module. They can be used for case-insensitive comparisons, accent-insensitive comparisons, and other combinations, and they handle more Unicode special cases correctly.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.10.1. Rationale

The standard approach to doing case-insensitive matches in Postgres Pro has been to use the `lower` function when comparing values, for example

```
SELECT * FROM tab WHERE lower(col) = LOWER(?);
```

This works reasonably well, but has a number of drawbacks:

- It makes your SQL statements verbose, and you always have to remember to use `lower` on both the column and the query value.
- It won't use an index, unless you create a functional index using `lower`.
- If you declare a column as `UNIQUE` or `PRIMARY KEY`, the implicitly generated index is case-sensitive. So it's useless for case-insensitive searches, and it won't enforce uniqueness case-insensitively.

The `citext` data type allows you to eliminate calls to `lower` in SQL queries, and allows a primary key to be case-insensitive. `citext` is locale-aware, just like `text`, which means that the matching of upper case and lower case characters is dependent on the rules of the database's `LC_CTYPE` setting. Again, this behavior is identical to the use of `lower` in queries. But because it's done transparently by the data type, you don't have to remember to do anything special in your queries.

F.10.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE users (  
    nick CITEXT PRIMARY KEY,  
    pass TEXT    NOT NULL  
);  
  
INSERT INTO users VALUES ( 'larry',  sha256(random()::text::bytea) );  
INSERT INTO users VALUES ( 'Tom',    sha256(random()::text::bytea) );  
INSERT INTO users VALUES ( 'Damian',  sha256(random()::text::bytea) );  
INSERT INTO users VALUES ( 'NEAL',   sha256(random()::text::bytea) );  
INSERT INTO users VALUES ( 'Bjørn',   sha256(random()::text::bytea) );  
  
SELECT * FROM users WHERE nick = 'Larry';
```

The `SELECT` statement will return one tuple, even though the `nick` column was set to `larry` and the query was for `Larry`.

F.10.3. String Comparison Behavior

`citext` performs comparisons by converting each string to lower case (as though `lower` were called) and then comparing the results normally. Thus, for example, two strings are considered equal if `lower` would produce identical results for them.

In order to emulate a case-insensitive collation as closely as possible, there are `citext`-specific versions of a number of string-processing operators and functions. So, for example, the regular expression operators `~` and `~*` exhibit the same behavior when applied to `citext`: they both match case-insensitively. The same is true for `!~` and `!~*`, as well as for the `LIKE` operators `~~` and `~~*`, and `!~~` and `!~~*`. If you'd like to match case-sensitively, you can cast the operator's arguments to `text`.

Similarly, all of the following functions perform matching case-insensitively if their arguments are `citext`:

- `regexp_match()`
- `regexp_matches()`
- `regexp_replace()`
- `regexp_split_to_array()`
- `regexp_split_to_table()`
- `replace()`
- `split_part()`
- `strpos()`
- `translate()`

For the `regexp` functions, if you want to match case-sensitively, you can specify the “c” flag to force a case-sensitive match. Otherwise, you must cast to `text` before using one of these functions if you want case-sensitive behavior.

F.10.4. Limitations

- `citext`'s case-folding behavior depends on the `LC_CTYPE` setting of your database. How it compares values is therefore determined when the database is created. It is not truly case-insensitive in the terms defined by the Unicode standard. Effectively, what this means is that, as long as you're happy with your collation, you should be happy with `citext`'s comparisons. But if you have data in different languages stored in your database, users of one language may find their query results are not as expected if the collation is for another language.
- As of PostgreSQL 9.1, you can attach a `COLLATE` specification to `citext` columns or data values. Currently, `citext` operators will honor a non-default `COLLATE` specification while comparing case-folded strings, but the initial folding to lower case is always done according to the database's `LC_CTYPE` setting (that is, as though `COLLATE "default"` were given). This may be changed in a future release so that both steps follow the input `COLLATE` specification.
- `citext` is not as efficient as `text` because the operator functions and the B-tree comparison functions must make copies of the data and convert it to lower case for comparisons. Also, only `text` can support B-Tree deduplication. However, `citext` is slightly more efficient than using `lower` to get case-insensitive matching.
- `citext` doesn't help much if you need data to compare case-sensitively in some contexts and case-insensitively in other contexts. The standard answer is to use the `text` type and manually use the `lower` function when you need to compare case-insensitively; this works all right if case-insensitive comparison is needed only infrequently. If you need case-insensitive behavior most of the time and case-sensitive infrequently, consider storing the data as `citext` and explicitly casting the column to `text` when you want case-sensitive comparison. In either situation, you will need two indexes if you want both types of searches to be fast.
- The schema containing the `citext` operators must be in the current `search_path` (typically `public`); if it is not, the normal case-sensitive `text` operators will be invoked instead.
- The approach of lower-casing strings for comparison does not handle some Unicode special cases correctly, for example when one upper-case letter has two lower-case letter equivalents. Unicode

distinguishes between *case mapping* and *case folding* for this reason. Use nondeterministic collations instead of `citext` to handle that correctly.

F.10.5. Author

David E. Wheeler <david@kineticode.com>

Inspired by the original `citext` module by Donald Fraser.

F.11. cube — a multi-dimensional cube data type

This module implements a data type `cube` for representing multidimensional cubes.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.11.1. Syntax

[Table F.5](#) shows the valid external representations for the `cube` type. x , y , etc. denote floating-point numbers.

Table F.5. Cube External Representations

External Syntax	Meaning
x	A one-dimensional point (or, zero-length one-dimensional interval)
(x)	Same as above
$x1, x2, \dots, xn$	A point in n -dimensional space, represented internally as a zero-volume cube
$(x1, x2, \dots, xn)$	Same as above
$(x), (y)$	A one-dimensional interval starting at x and ending at y or vice versa; the order does not matter
$[(x), (y)]$	Same as above
$(x1, \dots, xn), (y1, \dots, yn)$	An n -dimensional cube represented by a pair of its diagonally opposite corners
$[(x1, \dots, xn), (y1, \dots, yn)]$	Same as above

It does not matter which order the opposite corners of a cube are entered in. The `cube` functions automatically swap values if needed to create a uniform “lower left — upper right” internal representation. When the corners coincide, `cube` stores only one corner along with an “is point” flag to avoid wasting space.

White space is ignored on input, so $[(x), (y)]$ is the same as $[(x), (y)]$.

F.11.2. Precision

Values are stored internally as 64-bit floating point numbers. This means that numbers with more than about 16 significant digits will be truncated.

F.11.3. Usage

[Table F.6](#) shows the specialized operators provided for type `cube`.

Table F.6. Cube Operators

Operator	Description
<code>cube && cube</code>	<code>→ boolean</code> Do the cubes overlap?
<code>cube @> cube</code>	<code>→ boolean</code> Does the first cube contain the second?
<code>cube <@ cube</code>	<code>→ boolean</code> Is the first cube contained in the second?
<code>cube -> integer</code>	<code>→ float8</code> Extracts the n -th coordinate of the cube (counting from 1).

Operator	Description
<code>cube ~> integer → float8</code>	Extracts the n -th coordinate of the cube, counting in the following way: $n = 2 * k - 1$ means lower bound of k -th dimension, $n = 2 * k$ means upper bound of k -th dimension. Negative n denotes the inverse value of the corresponding positive coordinate. This operator is designed for KNN-GiST support.
<code>cube <-> cube → float8</code>	Computes the Euclidean distance between the two cubes.
<code>cube <#> cube → float8</code>	Computes the taxicab (L-1 metric) distance between the two cubes.
<code>cube <=> cube → float8</code>	Computes the Chebyshev (L-inf metric) distance between the two cubes.

In addition to the above operators, the usual comparison operators shown in [Table 9.1](#) are available for type `cube`. These operators first compare the first coordinates, and if those are equal, compare the second coordinates, etc. They exist mainly to support the b-tree index operator class for `cube`, which can be useful for example if you would like a UNIQUE constraint on a `cube` column. Otherwise, this ordering is not of much practical use.

The `cube` module also provides a GiST index operator class for `cube` values. A `cube` GiST index can be used to search for values using the `=`, `&&`, `@>`, and `<@` operators in WHERE clauses.

In addition, a `cube` GiST index can be used to find nearest neighbors using the metric operators `<->`, `<#>`, and `<=>` in ORDER BY clauses. For example, the nearest neighbor of the 3-D point (0.5, 0.5, 0.5) could be found efficiently with:

```
SELECT c FROM test ORDER BY c <-> cube(array[0.5,0.5,0.5]) LIMIT 1;
```

The `~>` operator can also be used in this way to efficiently retrieve the first few values sorted by a selected coordinate. For example, to get the first few cubes ordered by the first coordinate (lower left corner) ascending one could use the following query:

```
SELECT c FROM test ORDER BY c ~> 1 LIMIT 5;
```

And to get 2-D cubes ordered by the first coordinate of the upper right corner descending:

```
SELECT c FROM test ORDER BY c ~> 3 DESC LIMIT 5;
```

[Table F.7](#) shows the available functions.

Table F.7. Cube Functions

Function	Description	Example(s)
<code>cube (float8) → cube</code>	Makes a one dimensional cube with both coordinates the same.	<code>cube(1) → (1)</code>
<code>cube (float8, float8) → cube</code>	Makes a one dimensional cube.	<code>cube(1, 2) → (1), (2)</code>
<code>cube (float8[]) → cube</code>	Makes a zero-volume cube using the coordinates defined by the array.	<code>cube(ARRAY[1,2,3]) → (1, 2, 3)</code>
<code>cube (float8[], float8[]) → cube</code>		

Function	Description	Example(s)
	Makes a cube with upper right and lower left coordinates as defined by the two arrays, which must be of the same length.	<code>cube (ARRAY[1,2], ARRAY[3,4])</code> → (1, 2), (3, 4)
<code>cube (cube, float8)</code> → cube	Makes a new cube by adding a dimension on to an existing cube, with the same values for both endpoints of the new coordinate. This is useful for building cubes piece by piece from calculated values.	<code>cube ('(1,2), (3,4) '::cube, 5)</code> → (1, 2, 5), (3, 4, 5)
<code>cube (cube, float8, float8)</code> → cube	Makes a new cube by adding a dimension on to an existing cube. This is useful for building cubes piece by piece from calculated values.	<code>cube ('(1,2), (3,4) '::cube, 5, 6)</code> → (1, 2, 5), (3, 4, 6)
<code>cube_dim (cube)</code> → integer	Returns the number of dimensions of the cube.	<code>cube_dim ('(1,2), (3,4) ')</code> → 2
<code>cube_ll_coord (cube, integer)</code> → float8	Returns the <i>n</i> -th coordinate value for the lower left corner of the cube.	<code>cube_ll_coord ('(1,2), (3,4) ', 2)</code> → 2
<code>cube_ur_coord (cube, integer)</code> → float8	Returns the <i>n</i> -th coordinate value for the upper right corner of the cube.	<code>cube_ur_coord ('(1,2), (3,4) ', 2)</code> → 4
<code>cube_is_point (cube)</code> → boolean	Returns true if the cube is a point, that is, the two defining corners are the same.	<code>cube_is_point (cube(1,1))</code> → t
<code>cube_distance (cube, cube)</code> → float8	Returns the distance between two cubes. If both cubes are points, this is the normal distance function.	<code>cube_distance ('(1,2) ', '(3,4) ')</code> → 2.8284271247461903
<code>cube_subset (cube, integer[])</code> → cube	Makes a new cube from an existing cube, using a list of dimension indexes from an array. Can be used to extract the endpoints of a single dimension, or to drop dimensions, or to reorder them as desired.	<code>cube_subset (cube ('(1,3,5), (6,7,8) '), ARRAY[2])</code> → (3), (7) <code>cube_subset (cube ('(1,3,5), (6,7,8) '), ARRAY[3,2,1,1])</code> → (5, 3, 1, 1), (8, 7, 6, 6)
<code>cube_union (cube, cube)</code> → cube	Produces the union of two cubes.	<code>cube_union ('(1,2) ', '(3,4) ')</code> → (1, 2), (3, 4)
<code>cube_inter (cube, cube)</code> → cube	Produces the intersection of two cubes.	<code>cube_inter ('(1,2) ', '(3,4) ')</code> → (3, 4), (1, 2)
<code>cube_enlarge (c cube, r double, n integer)</code> → cube	Increases the size of the cube by the specified radius <i>r</i> in at least <i>n</i> dimensions. If the radius is negative the cube is shrunk instead. All defined dimensions are changed by the radius <i>r</i> .	

Function	Description	Example(s)
	Lower-left coordinates are decreased by r and upper-right coordinates are increased by r . If a lower-left coordinate is increased to more than the corresponding upper-right coordinate (this can only happen when $r < 0$) then both coordinates are set to their average. If n is greater than the number of defined dimensions and the cube is being enlarged ($r > 0$), then extra dimensions are added to make n altogether; 0 is used as the initial value for the extra coordinates. This function is useful for creating bounding boxes around a point for searching for nearby points.	<code>cube_enlarge(' (1,2), (3,4) ', 0.5, 3)</code> \rightarrow <code>(0.5, 1.5, -0.5), (3.5, 4.5, 0.5)</code>

F.11.4. Defaults

This union:

```
select cube_union(' (0,5,2), (2,3,1) ', '0');
cube_union
-----
(0, 0, 0), (2, 5, 2)
(1 row)
```

does not contradict common sense, neither does the intersection:

```
select cube_inter(' (0,-1), (1,1) ', ' (-2), (2) ');
cube_inter
-----
(0, 0), (1, 0)
(1 row)
```

In all binary operations on differently-dimensioned cubes, the lower-dimensional one is assumed to be a Cartesian projection, i. e., having zeroes in place of coordinates omitted in the string representation. The above examples are equivalent to:

```
cube_union(' (0,5,2), (2,3,1) ', ' (0,0,0), (0,0,0) ');
cube_inter(' (0,-1), (1,1) ', ' (-2,0), (2,0) ');
```

The following containment predicate uses the point syntax, while in fact the second argument is internally represented by a box. This syntax makes it unnecessary to define a separate point type and functions for (box,point) predicates.

```
select cube_contains(' (0,0), (1,1) ', '0.5,0.5');
cube_contains
-----
t
(1 row)
```

F.11.5. Notes

For examples of usage, see the regression test `sql/cube.sql`.

To make it harder for people to break things, there is a limit of 100 on the number of dimensions of cubes. This is set in `cubedata.h` if you need something bigger.

F.11.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

My thanks are primarily to Prof. Joe Hellerstein (<https://dsf.berkeley.edu/jmh/>) for elucidating the gist of the GiST (<http://gist.cs.berkeley.edu/>), and to his former student Andy Dong for his example written for Illustra. I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

Minor updates to this package were made by Bruno Wolff III <bruno@wolff.to> in August/September of 2002. These include changing the precision from single precision to double precision and adding some new functions.

Additional updates were made by Joshua Reich <josh@root.net> in July 2006. These include `cube(float8[], float8[])` and cleaning up the code to use the V1 call protocol instead of the deprecated V0 protocol.

F.12. daterange_inclusive — upper bound-inclusive daterange

`daterange_inclusive` is an extension to the built-in `daterange` range type. By default, `daterange` excludes the upper bound of the range — `[]`, whereas `daterange_inclusive` does not — `[]`. Other than the covered range bound, there are no other differences between `daterange` and `daterange_inclusive`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.12.1. Rationale

At times, it is more convenient to output date ranges with inclusive upper bounds. For example, it may apply to employees' absences. If an employee is absent from January 1, 2025, to January 10, 2025, using the `daterange` range type will prevent the database from outputting this date range in its entirety. In such cases, you would need to manually subtract one day from the output. The `daterange_inclusive` extension addresses this issue.

F.12.2. Usage Example

```
CREATE EXTENSION daterange_inclusive;
SELECT daterange('2024-01-01,2024-06-01');
       daterange
-----
[2024-01-01,2024-06-02)

SELECT daterange_inclusive('2024-01-01,2024-06-01');
       daterange_inclusive
-----
[2024-01-01,2024-06-01]
```

F.13. `dbcopies_decoding` — 1C module for updating database copies

`dbcopies_decoding` is a 1C module for updating database copies. It is implemented as a logical replication plug-in and provided in `postgrespro-std-18-contrib`. For the module to work properly, `wal_level` must be set to `logical`. For more information about this module contact 1C support.

F.14. dblink — connect to other Postgres Pro databases

`dblink` is a module that supports connections to other Postgres Pro databases from within a database session.

`dblink` can report the following wait events under the wait event type `Extension`.

`DblinkConnect`

Waiting to establish a connection to a remote server.

`DblinkGetConnect`

Waiting to establish a connection to a remote server when it could not be found in the list of already-opened connections.

`DblinkGetResult`

Waiting to receive the results of a query from a remote server.

See also [postgres_fdw](#), which provides roughly the same functionality using a more modern and standards-compliant infrastructure.

dblink_connect

`dblink_connect` — opens a persistent connection to a remote database

Synopsis

```
dblink_connect(text connstr) returns text  
dblink_connect(text connname, text connstr) returns text
```

Description

`dblink_connect()` establishes a connection to a remote Postgres Pro database. The server and database to be contacted are identified through a standard libpq connection string. Optionally, a name can be assigned to the connection. Multiple named connections can be open at once, but only one unnamed connection is permitted at a time. The connection will persist until closed or until the database session is ended.

The connection string may also be the name of an existing foreign server. It is recommended to use the foreign-data wrapper `dblink_fdw` when defining the foreign server. See the example below, as well as [CREATE SERVER](#) and [CREATE USER MAPPING](#).

Arguments

connname

The name to use for this connection; if omitted, an unnamed connection is opened, replacing any existing unnamed connection.

connstr

libpq-style connection info string, for example `hostaddr=127.0.0.1 port=5432 dbname=mydb user=postgres password=mypasswd options=-csearch_path=`. For details see [Section 32.1.1](#). Alternatively, the name of a foreign server.

Return Value

Returns status, which is always OK (since any error causes the function to throw an error instead of returning).

Notes

If untrusted users have access to a database that has not adopted a [secure schema usage pattern](#), begin each session by removing publicly-writable schemas from `search_path`. One could, for example, add `options=-csearch_path=` to *connstr*. This consideration is not specific to `dblink`; it applies to every interface for executing arbitrary SQL commands.

The foreign-data wrapper `dblink_fdw` has an additional Boolean option `use_scram_passthrough` that controls whether `dblink` will use the SCRAM pass-through authentication to connect to the remote database. With SCRAM pass-through authentication, `dblink` uses SCRAM-hashed secrets instead of plain-text user passwords to connect to the remote server. This avoids storing plain-text user passwords in PostgreSQL system catalogs. See the documentation of the equivalent [use_scram_passthrough](#) option of `postgres_fdw` for further details and restrictions.

Only superusers may use `dblink_connect` to create connections that use neither password authentication, SCRAM pass-through, nor GSSAPI-authentication. If non-superusers need this capability, use `dblink_connect_u` instead.

It is unwise to choose connection names that contain equal signs, as this opens a risk of confusion with connection info strings in other `dblink` functions.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');  
dblink_connect
```

```

-----
OK
(1 row)

SELECT dblink_connect('myconn', 'dbname=postgres options=-csearch_path=');
dblink_connect
-----
OK
(1 row)

-- FOREIGN DATA WRAPPER functionality
-- Note: local connections that don't use SCRAM pass-through require password
--       authentication for this to work properly. Otherwise, you will receive
--       the following error from dblink_connect():
--       ERROR: password is required
--       DETAIL: Non-superuser cannot connect if the server does not request a
--       password.
--       HINT: Target server's authentication method must be changed.

CREATE SERVER fdtest FOREIGN DATA WRAPPER dblink_fdw OPTIONS (hostaddr '127.0.0.1',
    dbname 'contrib_regression');

```

dblink_connect_u

`dblink_connect_u` — opens a persistent connection to a remote database, insecurely

Synopsis

```
dblink_connect_u(text connstr) returns text  
dblink_connect_u(text connname, text connstr) returns text
```

Description

`dblink_connect_u()` is identical to `dblink_connect()`, except that it will allow non-superusers to connect using any authentication method.

If the remote server selects an authentication method that does not involve a password, then impersonation and subsequent escalation of privileges can occur, because the session will appear to have originated from the user as which the local Postgres Pro server runs. Also, even if the remote server does demand a password, it is possible for the password to be supplied from the server environment, such as a `~/.pgpass` file belonging to the server's user. This opens not only a risk of impersonation, but the possibility of exposing a password to an untrustworthy remote server. Therefore, `dblink_connect_u()` is initially installed with all privileges revoked from `PUBLIC`, making it un-callable except by superusers. In some situations it may be appropriate to grant `EXECUTE` permission for `dblink_connect_u()` to specific users who are considered trustworthy, but this should be done with care. It is also recommended that any `~/.pgpass` file belonging to the server's user *not* contain any records specifying a wildcard host name.

For further details see `dblink_connect()`.

dblink_disconnect

`dblink_disconnect` — closes a persistent connection to a remote database

Synopsis

```
dblink_disconnect() returns text  
dblink_disconnect(text connname) returns text
```

Description

`dblink_disconnect()` closes a connection previously opened by `dblink_connect()`. The form with no arguments closes an unnamed connection.

Arguments

connname

The name of a named connection to be closed.

Return Value

Returns status, which is always `OK` (since any error causes the function to throw an error instead of returning).

Examples

```
SELECT dblink_disconnect();  
dblink_disconnect  
-----  
OK  
(1 row)  
  
SELECT dblink_disconnect('myconn');  
dblink_disconnect  
-----  
OK  
(1 row)
```

dblink

`dblink` — executes a query in a remote database

Synopsis

```
dblink(text connname, text sql [, bool fail_on_error]) returns setof record
dblink(text connstr, text sql [, bool fail_on_error]) returns setof record
dblink(text sql [, bool fail_on_error]) returns setof record
```

Description

`dblink` executes a query (usually a `SELECT`, but it can be any SQL statement that returns rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

connstr

A connection info string, as previously described for `dblink_connect`.

sql

The SQL query that you wish to execute in the remote database, for example `select * from foo`.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a `NOTICE`, and the function returns no rows.

Return Value

The function returns the row(s) produced by the query. Since `dblink` can be used with any query, it is declared to return `record`, rather than specifying any particular set of columns. This means that you must specify the expected set of columns in the calling query — otherwise Postgres Pro would not know what to expect. Here is an example:

```
SELECT *
FROM dblink('dbname=mydb options=-csearch_path=',
            'select pronomame, prosrc from pg_proc')
AS t1(pronomame name, prosrc text)
WHERE pronomame LIKE 'bytea%';
```

The “alias” part of the `FROM` clause must specify the column names and types that the function will return. (Specifying column names in an alias is actually standard SQL syntax, but specifying column types is a Postgres Pro extension.) This allows the system to understand what `*` should expand to, and what `pronomame` in the `WHERE` clause refers to, in advance of trying to execute the function. At run time, an error will be thrown if the actual query result from the remote database does not have the same number of columns shown in the `FROM` clause. The column names need not match, however, and `dblink` does not insist on exact type matches either. It will succeed so long as the returned data strings are valid input for the column type declared in the `FROM` clause.

Notes

A convenient way to use `dblink` with predetermined queries is to create a view. This allows the column type information to be buried in the view, instead of having to spell it out in every query. For example,

```
CREATE VIEW myremote_pg_proc AS
  SELECT *
    FROM dblink('dbname=postgres options=-csearch_path=',
                'select proname, prosrc from pg_proc')
    AS t1(proname name, prosrc text);

SELECT * FROM myremote_pg_proc WHERE proname LIKE 'bytea%';
```

Examples

```
SELECT * FROM dblink('dbname=postgres options=-csearch_path=',
                    'select proname, prosrc from pg_proc')
  AS t1(proname name, prosrc text) WHERE proname LIKE 'bytea%';
 proname | prosrc
```

```

(14 rows)

dblink_exec

`dblink_exec` — executes a command in a remote database

Synopsis

```
dblink_exec(text connname, text sql [, bool fail_on_error]) returns text
dblink_exec(text connstr, text sql [, bool fail_on_error]) returns text
dblink_exec(text sql [, bool fail_on_error]) returns text
```

Description

`dblink_exec` executes a command (that is, any SQL statement that doesn't return rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

connstr

A connection info string, as previously described for `dblink_connect`.

sql

The SQL command that you wish to execute in the remote database, for example `insert into foo values (0, 'a', '{"a0","b0","c0"}')`.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

Return Value

Returns status, either the command's status string or `ERROR`.

Examples

```
SELECT dblink_connect('dbname=dblink_test_standby');
 dblink_connect
-----
 OK
(1 row)

SELECT dblink_exec('insert into foo values(21, ''z'', ''{"a0","b0","c0"}'');');
 dblink_exec
-----
 INSERT 943366 1
(1 row)

SELECT dblink_connect('myconn', 'dbname=regression');
 dblink_connect
```

```
-----
OK
(1 row)

SELECT dblink_exec('myconn', 'insert into foo values(21, ''z'',
''{"a0","b0","c0"}'');');
      dblink_exec
-----

INSERT 6432584 1
(1 row)

SELECT dblink_exec('myconn', 'insert into pg_class values (''foo''),false);
NOTICE:  sql error
DETAIL:  ERROR:  null value in column "relnamespace" violates not-null constraint

      dblink_exec
-----

ERROR
(1 row)
```

dblink_open

`dblink_open` — opens a cursor in a remote database

Synopsis

```
dblink_open(text cursorname, text sql [, bool fail_on_error]) returns text
dblink_open(text connname, text cursorname, text sql [, bool fail_on_error]) returns
text
```

Description

`dblink_open()` opens a cursor in a remote database. The cursor can subsequently be manipulated with `dblink_fetch()` and `dblink_close()`.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

cursorname

The name to assign to this cursor.

sql

The `SELECT` statement that you wish to execute in the remote database, for example `select * from pg_class`.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

Return Value

Returns status, either `OK` or `ERROR`.

Notes

Since a cursor can only persist within a transaction, `dblink_open` starts an explicit transaction block (`BEGIN`) on the remote side, if the remote side was not already within a transaction. This transaction will be closed again when the matching `dblink_close` is executed. Note that if you use `dblink_exec` to change data between `dblink_open` and `dblink_close`, and then an error occurs or you use `dblink_disconnect` before `dblink_close`, your change *will be lost* because the transaction will be aborted.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
-----
OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
dblink_open
-----
OK
(1 row)
```

dblink_fetch

`dblink_fetch` — returns rows from an open cursor in a remote database

Synopsis

```
dblink_fetch(text cursorname, int howmany [, bool fail_on_error]) returns setof record
dblink_fetch(text connname, text cursorname, int howmany [, bool fail_on_error])
returns setof record
```

Description

`dblink_fetch` fetches rows from a cursor previously established by `dblink_open`.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

cursorname

The name of the cursor to fetch from.

howmany

The maximum number of rows to retrieve. The next *howmany* rows are fetched, starting at the current cursor position, moving forward. Once the cursor has reached its end, no more rows are produced.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

Return Value

The function returns the row(s) fetched from the cursor. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

Notes

On a mismatch between the number of return columns specified in the `FROM` clause, and the actual number of columns returned by the remote cursor, an error will be thrown. In this event, the remote cursor is still advanced by as many rows as it would have been if the error had not occurred. The same is true for any other error occurring in the local query after the remote `FETCH` has been done.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
```

```
-----
OK
(1 row)
```

```
SELECT dblink_open('foo', 'select proname, prosrc from pg_proc where proname like
''bytea%'');
dblink_open
```

```
-----
OK
(1 row)
```

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
 funcname | source
-----+-----
 byteacat | byteacat
 byteacmp | byteacmp
 byteaeq  | byteaeq
 byteage  | byteage
 byteagt  | byteagt
(5 rows)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
 funcname | source
-----+-----
 byteain  | byteain
 byteale  | byteale
 bytealike | bytealike
 bytealt  | bytealt
 byteane  | byteane
(5 rows)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
 funcname | source
-----+-----
 byteanlike | byteanlike
 byteaout   | byteaout
(2 rows)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
 funcname | source
-----+-----
(0 rows)
```

dblink_close

`dblink_close` — closes a cursor in a remote database

Synopsis

```
dblink_close(text cursorname [, bool fail_on_error]) returns text
dblink_close(text connname, text cursorname [, bool fail_on_error]) returns text
```

Description

`dblink_close` closes a cursor previously opened with `dblink_open`.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

cursorname

The name of the cursor to close.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

Return Value

Returns status, either `OK` or `ERROR`.

Notes

If `dblink_open` started an explicit transaction block, and this is the last remaining open cursor in this connection, `dblink_close` will issue the matching `COMMIT`.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
 dblink_connect
-----
 OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
 dblink_open
-----
 OK
(1 row)

SELECT dblink_close('foo');
 dblink_close
-----
 OK
(1 row)
```

dblink_get_connections

`dblink_get_connections` — returns the names of all open named dblink connections

Synopsis

```
dblink_get_connections() returns text[]
```

Description

`dblink_get_connections` returns an array of the names of all open named dblink connections.

Return Value

Returns a text array of connection names, or NULL if none.

Examples

```
SELECT dblink_get_connections();
```

dblink_error_message

`dblink_error_message` — gets last error message on the named connection

Synopsis

```
dblink_error_message(text connname) returns text
```

Description

`dblink_error_message` fetches the most recent remote error message for a given connection.

Arguments

connname

Name of the connection to use.

Return Value

Returns last error message, or OK if there has been no error in this connection.

Notes

When asynchronous queries are initiated by `dblink_send_query`, the error message associated with the connection might not get updated until the server's response message is consumed. This typically means that `dblink_is_busy` or `dblink_get_result` should be called prior to `dblink_error_message`, so that any error generated by the asynchronous query will be visible.

Examples

```
SELECT dblink_error_message('dtest1');
```

dblink_send_query

`dblink_send_query` — sends an async query to a remote database

Synopsis

```
dblink_send_query(text connname, text sql) returns int
```

Description

`dblink_send_query` sends a query to be executed asynchronously, that is, without immediately waiting for the result. There must not be an async query already in progress on the connection.

After successfully dispatching an async query, completion status can be checked with `dblink_is_busy`, and the results are ultimately collected with `dblink_get_result`. It is also possible to attempt to cancel an active async query using `dblink_cancel_query`.

Arguments

connname

Name of the connection to use.

sql

The SQL statement that you wish to execute in the remote database, for example `select * from pg_class`.

Return Value

Returns 1 if the query was successfully dispatched, 0 otherwise.

Examples

```
SELECT dblink_send_query('dtest1', 'SELECT * FROM foo WHERE f1 < 3');
```

dblink_is_busy

`dblink_is_busy` — checks if connection is busy with an async query

Synopsis

```
dblink_is_busy(text connname) returns int
```

Description

`dblink_is_busy` tests whether an async query is in progress.

Arguments

connname

Name of the connection to check.

Return Value

Returns 1 if connection is busy, 0 if it is not busy. If this function returns 0, it is guaranteed that `dblink_get_result` will not block.

Examples

```
SELECT dblink_is_busy('dtest1');
```

dblink_get_notify

dblink_get_notify — retrieve async notifications on a connection

Synopsis

```
dblink_get_notify() returns setof (notify_name text, be_pid int, extra text)
dblink_get_notify(text connname) returns setof (notify_name text, be_pid int, extra
text)
```

Description

dblink_get_notify retrieves notifications on either the unnamed connection, or on a named connection if specified. To receive notifications via dblink, LISTEN must first be issued, using dblink_exec. For details see [LISTEN](#) and [NOTIFY](#).

Arguments

connname

The name of a named connection to get notifications on.

Return Value

Returns setof (notify_name text, be_pid int, extra text), or an empty set if none.

Examples

```
SELECT dblink_exec('LISTEN virtual');
 dblink_exec
-----
LISTEN
(1 row)
```

```
SELECT * FROM dblink_get_notify();
 notify_name | be_pid | extra
-----+-----+-----
(0 rows)
```

```
NOTIFY virtual;
NOTIFY
```

```
SELECT * FROM dblink_get_notify();
 notify_name | be_pid | extra
-----+-----+-----
virtual      |    1229 |
(1 row)
```

dblink_get_result

`dblink_get_result` — gets an async query result

Synopsis

`dblink_get_result(text connname [, bool fail_on_error])` returns `setof record`

Description

`dblink_get_result` collects the results of an asynchronous query previously sent with `dblink_send_query`. If the query is not already completed, `dblink_get_result` will wait until it is.

Arguments

connname

Name of the connection to use.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

Return Value

For an async query (that is, an SQL statement returning rows), the function returns the row(s) produced by the query. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

For an async command (that is, an SQL statement not returning rows), the function returns a single row with a single text column containing the command's status string. It is still necessary to specify that the result will have a single text column in the calling `FROM` clause.

Notes

This function *must* be called if `dblink_send_query` returned 1. It must be called once for each query sent, and one additional time to obtain an empty set result, before the connection can be used again.

When using `dblink_send_query` and `dblink_get_result`, `dblink` fetches the entire remote query result before returning any of it to the local query processor. If the query returns a large number of rows, this can result in transient memory bloat in the local session. It may be better to open such a query as a cursor with `dblink_open` and then fetch a manageable number of rows at a time. Alternatively, use plain `dblink()`, which avoids memory bloat by spooling large result sets to disk.

Examples

```
contrib_regression=# SELECT dblink_connect('dtest1', 'dbname=contrib_regression');
dblink_connect
-----
OK
(1 row)

contrib_regression=# SELECT * FROM
contrib_regression-# dblink_send_query('dtest1', 'select * from foo where f1 < 3') AS
t1;
t1
----
1
(1 row)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
```

```
 f1 | f2 |      f3
----+-----+-----
  0 | a  | {a0,b0,c0}
  1 | b  | {a1,b1,c1}
  2 | c  | {a2,b2,c2}
(3 rows)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
```

```
 f1 | f2 | f3
----+-----+----
(0 rows)
```

```
contrib_regression=# SELECT * FROM
contrib_regression=# dblink_send_query('dtest1', 'select * from foo where f1 < 3;
select * from foo where f1 > 6') AS t1;
```

```
 t1
----
  1
(1 row)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
```

```
 f1 | f2 |      f3
----+-----+-----
  0 | a  | {a0,b0,c0}
  1 | b  | {a1,b1,c1}
  2 | c  | {a2,b2,c2}
(3 rows)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
```

```
 f1 | f2 |      f3
----+-----+-----

```

dblink_cancel_query

`dblink_cancel_query` — cancels any active query on the named connection

Synopsis

```
dblink_cancel_query(text connname) returns text
```

Description

`dblink_cancel_query` attempts to cancel any query that is in progress on the named connection. Note that this is not certain to succeed (since, for example, the remote query might already have finished). A cancel request simply improves the odds that the query will fail soon. You must still complete the normal query protocol, for example by calling `dblink_get_result`.

Arguments

connname

Name of the connection to use.

Return Value

Returns `OK` if the cancel request has been sent, or the text of an error message on failure.

Examples

```
SELECT dblink_cancel_query('dtest1');
```

dblink_get_pkey

`dblink_get_pkey` — returns the positions and field names of a relation's primary key fields

Synopsis

`dblink_get_pkey(text relname)` returns `setof dblink_pkey_results`

Description

`dblink_get_pkey` provides information about the primary key of a relation in the local database. This is sometimes useful in generating queries to be sent to remote databases.

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

Return Value

Returns one row for each primary key field, or no rows if the relation has no primary key. The result row type is defined as

```
CREATE TYPE dblink_pkey_results AS (position int, colname text);
```

The `position` column simply runs from 1 to *N*; it is the number of the field within the primary key, not the number within the table's columns.

Examples

```
CREATE TABLE foobar (  
    f1 int,  
    f2 int,  
    f3 int,  
    PRIMARY KEY (f1, f2, f3)  
);  
CREATE TABLE  
  
SELECT * FROM dblink_get_pkey('foobar');  
 position | colname  
-----+-----  
        1 | f1  
        2 | f2  
        3 | f3  
(3 rows)
```

dblink_build_sql_insert

`dblink_build_sql_insert` — builds an `INSERT` statement using a local tuple, replacing the primary key field values with alternative supplied values

Synopsis

```
dblink_build_sql_insert(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] src_pk_att_vals_array,  
                        text[] tgt_pk_att_vals_array) returns text
```

Description

`dblink_build_sql_insert` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds an SQL `INSERT` command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.)

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

primary_key_attnums

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

num_primary_key_atts

The number of primary key fields.

src_pk_att_vals_array

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

tgt_pk_att_vals_array

Values of the primary key fields to be placed in the resulting `INSERT` command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in *primary_key_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_insert('foo', '1 2', 2, '{"1", "a"}', '{"1", "b''a"}');  
       dblink_build_sql_insert
```

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

```
INSERT INTO foo(f1,f2,f3) VALUES('1','b' 'a','1')
(1 row)
```

dblink_build_sql_delete

`dblink_build_sql_delete` — builds a DELETE statement using supplied values for primary key field values

Synopsis

```
dblink_build_sql_delete(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] tgt_pk_att_vals_array) returns text
```

Description

`dblink_build_sql_delete` can be useful in doing selective replication of a local table to a remote database. It builds an SQL DELETE command that will delete the row with the given primary key values.

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

primary_key_attnums

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

num_primary_key_atts

The number of primary key fields.

tgt_pk_att_vals_array

Values of the primary key fields to be used in the resulting DELETE command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in *primary_key_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_delete('MyFoo', '1 2', 2, '{"1", "b"}');  
      dblink_build_sql_delete  
-----  
DELETE FROM "MyFoo" WHERE f1='1' AND f2='b'  
(1 row)
```

dblink_build_sql_update

`dblink_build_sql_update` — builds an UPDATE statement using a local tuple, replacing the primary key field values with alternative supplied values

Synopsis

```
dblink_build_sql_update(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] src_pk_att_vals_array,  
                        text[] tgt_pk_att_vals_array) returns text
```

Description

`dblink_build_sql_update` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds an SQL UPDATE command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.) The UPDATE command always assigns all fields of the row — the main difference between this and `dblink_build_sql_insert` is that it's assumed that the target row already exists in the remote table.

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

primary_key_attnums

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

num_primary_key_atts

The number of primary key fields.

src_pk_att_vals_array

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

tgt_pk_att_vals_array

Values of the primary key fields to be placed in the resulting UPDATE command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in *primary_key_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_update('foo', '1 2', 2, '{"1", "a"}', '{"1", "b"}');
```

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

dblink_build_sql_update

```
UPDATE foo SET f1='1',f2='b',f3='1' WHERE f1='1' AND f2='b'
(1 row)
```

F.15. dict_int — example full-text search dictionary for integers

`dict_int` is an example of an add-on dictionary template for full-text search. The motivation for this example dictionary is to control the indexing of integers (signed and unsigned), allowing such numbers to be indexed while preventing excessive growth in the number of unique words, which greatly affects the performance of searching.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.15.1. Configuration

The dictionary accepts three options:

- The `maxlen` parameter specifies the maximum number of digits allowed in an integer word. The default value is 6.
- The `rejectlong` parameter specifies whether an overlength integer should be truncated or ignored. If `rejectlong` is `false` (the default), the dictionary returns the first `maxlen` digits of the integer. If `rejectlong` is `true`, the dictionary treats an overlength integer as a stop word, so that it will not be indexed. Note that this also means that such an integer cannot be searched for.
- The `absval` parameter specifies whether leading “+” or “-” signs should be removed from integer words. The default is `false`. When `true`, the sign is removed before `maxlen` is applied.

F.15.2. Usage

Installing the `dict_int` extension creates a text search template `intdict_template` and a dictionary `intdict` based on it, with the default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY intdict (MAXLEN = 4, REJECTLONG = true);
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb# select ts_lexize('intdict', '12345678');
ts_lexize
-----
{123456}
```

but real-world usage will involve including it in a text search configuration as described in [Chapter 12](#). That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
ALTER MAPPING FOR int, uint WITH intdict;
```

F.16. dict_xsyn — example synonym full-text search dictionary

`dict_xsyn` (Extended Synonym Dictionary) is an example of an add-on dictionary template for full-text search. This dictionary type replaces words with groups of their synonyms, and so makes it possible to search for a word using any of its synonyms.

F.16.1. Configuration

A `dict_xsyn` dictionary accepts the following options:

- `matchorig` controls whether the original word is accepted by the dictionary. Default is `true`.
- `matchsynonyms` controls whether the synonyms are accepted by the dictionary. Default is `false`.
- `keeporig` controls whether the original word is included in the dictionary's output. Default is `true`.
- `keepsynonyms` controls whether the synonyms are included in the dictionary's output. Default is `true`.
- `rules` is the base name of the file containing the list of synonyms. This file must be stored in `$SHAREDIR/tsearch_data/` (where `$SHAREDIR` means the Postgres Pro installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `rules` parameter).

The rules file has the following format:

- Each line represents a group of synonyms for a single word, which is given first on the line. Synonyms are separated by whitespace, thus:

```
word syn1 syn2 syn3
```
- The sharp (`#`) sign is a comment delimiter. It may appear at any position in a line. The rest of the line will be skipped.

Look at `xsyn_sample.rules`, which is installed in `$SHAREDIR/tsearch_data/`, for an example.

F.16.2. Usage

Installing the `dict_xsyn` extension creates a text search template `xsyn_template` and a dictionary `xsyn` based on it, with default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false);
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb=# SELECT ts_lexize('xsyn', 'word');
       ts_lexize
-----
{syn1,syn2,syn3}
```

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true);
ALTER TEXT SEARCH DICTIONARY
```

```
mydb=# SELECT ts_lexize('xsyn', 'word');
       ts_lexize
-----
{word,syn1,syn2,syn3}
```

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false,
MATCHSYNONYMS=true);
```

```
ALTER TEXT SEARCH DICTIONARY
```

```
mydb=# SELECT ts_lexize('xsyn', 'syn1');
       ts_lexize
```

```
-----
```

```
{syn1,syn2,syn3}
```

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true,
      MATCHORIG=false, KEEPSYNONYMS=false);
```

```
ALTER TEXT SEARCH DICTIONARY
```

```
mydb=# SELECT ts_lexize('xsyn', 'syn1');
       ts_lexize
```

```
-----
```

```
{word}
```

Real-world usage will involve including it in a text search configuration as described in [Chapter 12](#). That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
```

```
    ALTER MAPPING FOR word, asciiword WITH xsyn, english_stem;
```

F.17. dump_stat — functions to backup and recover the pg_statistic table

The `dump_stat` module provides functions that allow you to backup and recover the contents of the `pg_statistic` table. When performing a dump/restore, you can use `dump_stat` to migrate the original statistics to the new server instead of running the `ANALYZE` command for the whole database cluster, which can significantly reduce downtime for large databases. The `dump_statistic` function generates `INSERT` statements which can later be applied to a compatible database. To successfully restore statistical data, you must install the extension on both the original and the recipient servers since these statements rely on the provided `dump_stat` functions.

Note that the definition of the `pg_statistic` table might change occasionally, which means that generated dump might be incompatible with future releases of Postgres Pro.

F.17.1. Installation

The `dump_stat` extension is included into Postgres Pro. Once you have Postgres Pro installed, you must execute the `CREATE EXTENSION` command to enable `dump_stat`, as follows:

```
CREATE EXTENSION dump_stat;
```

F.17.2. Functions

`anyarray_to_text(array anyarray)` returns text

Returns the given array as text.

`dump_statistic()` returns setof text

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic`, excluding the ones that contain statistical data for tables in the `information_schema` and `pg_catalog` schemas.

The `INSERT` statement takes form of

```
WITH upsert as (  
  UPDATE pg_catalog.pg_statistic SET column_name = expression [, ...]  
  WHERE starelid = t_relname::regclass  
    AND to_attnum(t_relname, staattnum) = t_attnum  
    AND to_atttype(t_relname, staattnum) = t_atttype  
    AND stainherit = t_stainherit  
  RETURNING *)
```

```
ins as (  
  SELECT expression [, ...]  
  WHERE NOT EXISTS (SELECT * FROM upsert)  
    AND to_attnum(t_relname, t_attnum) IS NOT NULL  
    AND to_atttype(t_relname, t_attnum) = t_atttype)  
INSERT INTO pg_catalog.pg_statistic SELECT * FROM ins;
```

where *expression* can be one of:

```
array_in(array_text, type_name::regtype::oid, -1)  
value::type_name
```

To save the produced statements, redirect the `psql` output into a file using standard `psql` options. For details on the available `psql` options, see [psql](#). Meta-commands starting with a backslash are not supported.

For example, to save statistics for the `dbname` database into a `dump_stat.sql` file, run:

```
$ psql -XAtq -c "SELECT dump_statistic()" dbname > dump_stat.sql
```

`dump_statistic(schema_name text)` returns setof text

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an INSERT statement per each tuple of the `pg_statistic` that relates to some table in the `schema_name` schema.

`dump_statistic(schema_name text, table_name text)` returns setof text

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an INSERT statement per each tuple of the `pg_statistic` that relates to the specified `schema_name.table_name` table.

`dump_statistic(relation regclass)` returns setof text

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an INSERT statement per each tuple of the `pg_statistic` that contains statistical data for the specified relation.

`to_schema_qualified_operator(opid oid)` returns text

Fetches the schema-qualified operator name by operator id `opid`. For example:

```
test=# SELECT to_schema_qualified_operator('+(int,int)::regoperator);
           to_schema_qualified_operator
-----
pg_catalog.+(pg_catalog.int4, pg_catalog.int4)
(1 row)
```

`to_schema_qualified_type(typid oid)` returns text

Fetches the schema-qualified type name by type id `typid`.

`to_schema_qualified_relation(relid oid)` returns text

Fetches the schema-qualified relation name by relation id `relid`.

`anyarray_elemtype(arr anyarray)` returns oid

Returns the element type of the given array as oid. For example:

```
test=# SELECT anyarray_elemtype(array_in('{1,2,3}', 'int'::regtype, -1));
           anyarray_elemtype
-----
                        23
(1 row)
```

`to_attname(relation regclass, colnum int2)` returns text

Given a relation name `relation` and a column number `colnum`, returns the column name as text.

`to_attnum(relation regclass, col text)` returns int2

Given a relation name `relation` and a column name `col`, returns the column number as int2.

`to_atttype(relation regclass, col text)` returns text

Given a relation name `relation` and a column name `col`, returns the schema-qualified column type as text.

`to_atttype(relation regclass, colnum int2)` returns text

Given a relation name `relation` and a column number `colnum`, returns the schema-qualified column type as text.

`to_namespace(nsp text)` returns oid

`to_namespace` duplicates the behavior of the cast to the `regnamespace` type, which is not present in the PostgreSQL 9.4 release (and prior releases). This function returns the oid of the given schema.

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

`get_namespace(relation oid)` returns oid

`get_namespace` returns the schema of the given relation as oid.

F.18. earthdistance — calculate great-circle distances

The `earthdistance` module provides two different approaches to calculating great circle distances on the surface of the Earth. The one described first depends on the `cube` module. The second one is based on the built-in `point` data type, using longitude and latitude for the coordinates.

In this module, the Earth is assumed to be perfectly spherical. (If that's too inaccurate for you, you might want to look at the [PostGIS](#) project.)

The `cube` module must be installed before `earthdistance` can be installed (although you can use the `CASCADE` option of `CREATE EXTENSION` to install both in one command).

Caution

It is strongly recommended that `earthdistance` and `cube` be installed in the same schema, and that that schema be one for which `CREATE` privilege has not been and will not be granted to any untrusted users. Otherwise there are installation-time security hazards if `earthdistance`'s schema contains objects defined by a hostile user. Furthermore, when using `earthdistance`'s functions after installation, the entire search path should contain only trusted schemas.

F.18.1. Cube-Based Earth Distances

Data is stored in cubes that are points (both corners are the same) using 3 coordinates representing the x, y, and z distance from the center of the Earth. A [domain](#) `earth` over type `cube` is provided, which includes constraint checks that the value meets these restrictions and is reasonably close to the actual surface of the Earth.

The radius of the Earth is obtained from the `earth()` function. It is given in meters. But by changing this one function you can change the module to use some other units, or to use a different value of the radius that you feel is more appropriate.

This package has applications to astronomical databases as well. Astronomers will probably want to change `earth()` to return a radius of `180/pi()` so that distances are in degrees.

Functions are provided to support input in latitude and longitude (in degrees), to support output of latitude and longitude, to calculate the great circle distance between two points and to easily specify a bounding box usable for index searches.

The provided functions are shown in [Table F.8](#).

Table F.8. Cube-Based Earthdistance Functions

Function	Description
<code>earth() → float8</code>	Returns the assumed radius of the Earth.
<code>sec_to_gc (float8) → float8</code>	Converts the normal straight line (secant) distance between two points on the surface of the Earth to the great circle distance between them.
<code>gc_to_sec (float8) → float8</code>	Converts the great circle distance between two points on the surface of the Earth to the normal straight line (secant) distance between them.
<code>ll_to_earth (float8, float8) → earth</code>	Returns the location of a point on the surface of the Earth given its latitude (argument 1) and longitude (argument 2) in degrees.

Function	Description
<code>latitude (earth) → float8</code>	Returns the latitude in degrees of a point on the surface of the Earth.
<code>longitude (earth) → float8</code>	Returns the longitude in degrees of a point on the surface of the Earth.
<code>earth_distance (earth, earth) → float8</code>	Returns the great circle distance between two points on the surface of the Earth.
<code>earth_box (earth, float8) → cube</code>	Returns a box suitable for an indexed search using the <code>cube @></code> operator for points within a given great circle distance of a location. Some points in this box are further than the specified great circle distance from the location, so a second check using <code>earth_distance</code> should be included in the query.

F.18.2. Point-Based Earth Distances

The second part of the module relies on representing Earth locations as values of type `point`, in which the first component is taken to represent longitude in degrees, and the second component is taken to represent latitude in degrees. Points are taken as (longitude, latitude) and not vice versa because longitude is closer to the intuitive idea of x-axis and latitude to y-axis.

A single operator is provided, shown in [Table F.9](#).

Table F.9. Point-Based Earthdistance Operators

Operator	Description
<code>point <@> point → float8</code>	Computes the distance in statute miles between two points on the Earth's surface.

Note that unlike the `cube`-based part of the module, units are hardwired here: changing the `earth()` function will not affect the results of this operator.

One disadvantage of the longitude/latitude representation is that you need to be careful about the edge conditions near the poles and near +/- 180 degrees of longitude. The `cube`-based representation avoids these discontinuities.

F.19. fasttrun — a transaction unsafe function to truncate temporary tables

The `fasttrun` module provides transaction unsafe function to truncate temporary tables without growing `pg_class` size.

This module is required for 1C Enterprise support.

Fast truncate operation is not transactional, so its results cannot be rolled back and become immediately visible in all sessions regardless of isolation level.

F.19.1. Function

There is a function call example:

```
select fasttruncate('TABLE_NAME');
```

F.19.2. Test example

For tests you can use this example:

```
create or replace function f() returns void as $$
begin
  for i in 1..1000
  loop
    PERFORM fasttruncate('tt1');
  end loop;
end;
$$ language plpgsql;
```

F.19.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

F.20. file_fdw — access data files in the server's file system

The `file_fdw` module provides the foreign-data wrapper `file_fdw`, which can be used to access data files in the server's file system, or to execute programs on the server and read their output. The data file or program output must be in a format that can be read by `COPY FROM`; see [COPY](#) for details. Access to data files is currently read-only.

A foreign table created using this wrapper can have the following options:

`filename`

Specifies the file to be read. Relative paths are relative to the data directory. Either `filename` or `program` must be specified, but not both.

`program`

Specifies the command to be executed. The standard output of this command will be read as though `COPY FROM PROGRAM` were used. Either `program` or `filename` must be specified, but not both.

`format`

Specifies the data format, the same as `COPY`'s `FORMAT` option.

`header`

Specifies whether the data has a header line, the same as `COPY`'s `HEADER` option.

`delimiter`

Specifies the data delimiter character, the same as `COPY`'s `DELIMITER` option.

`quote`

Specifies the data quote character, the same as `COPY`'s `QUOTE` option.

`escape`

Specifies the data escape character, the same as `COPY`'s `ESCAPE` option.

`null`

Specifies the data null string, the same as `COPY`'s `NULL` option.

`encoding`

Specifies the data encoding, the same as `COPY`'s `ENCODING` option.

`on_error`

Specifies how to behave when encountering an error converting a column's input value into its data type, the same as `COPY`'s `ON_ERROR` option.

`reject_limit`

Specifies the maximum number of errors tolerated while converting a column's input value to its data type, the same as `COPY`'s `REJECT_LIMIT` option.

`log_verbosity`

Specifies the amount of messages emitted by `file_fdw`, the same as `COPY`'s `LOG_VERBOSITY` option.

Note that while `COPY` allows options such as `HEADER` to be specified without a corresponding value, the foreign table option syntax requires a value to be present in all cases. To activate `COPY` options typically written without a value, you can pass the value `TRUE`, since all such options are Booleans.

A column of a foreign table created using this wrapper can have the following options:

`force_not_null`

This is a Boolean option. If true, it specifies that values of the column should not be matched against the null string (that is, the table-level `null` option). This has the same effect as listing the column in COPY's `FORCE_NOT_NULL` option.

`force_null`

This is a Boolean option. If true, it specifies that values of the column which match the null string are returned as `NULL` even if the value is quoted. Without this option, only unquoted values matching the null string are returned as `NULL`. This has the same effect as listing the column in COPY's `FORCE_NULL` option.

COPY's `FORCE_QUOTE` option is currently not supported by `file_fdw`.

These options can only be specified for a foreign table or its columns, not in the options of the `file_fdw` foreign-data wrapper, nor in the options of a server or user mapping using the wrapper.

Changing table-level options requires being a superuser or having the privileges of the role `pg_read_server_files` (to use a filename) or the role `pg_execute_server_program` (to use a program), for security reasons: only certain users should be able to control which file is read or which program is run. In principle regular users could be allowed to change the other options, but that's not supported at present.

When specifying the `program` option, keep in mind that the option string is executed by the shell. If you need to pass any arguments to the command that come from an untrusted source, you must be careful to strip or escape any characters that might have special meaning to the shell. For security reasons, it is best to use a fixed command string, or at least avoid passing any user input in it.

For a foreign table using `file_fdw`, `EXPLAIN` shows the name of the file to be read or program to be run. For a file, unless `COSTS OFF` is specified, the file size (in bytes) is shown as well.

Example F.5. Create a Foreign Table for Postgres Pro CSV Logs

One of the obvious uses for `file_fdw` is to make the Postgres Pro activity log available as a table for querying. To do this, first you must be [logging to a CSV file](#), which here we will call `pglog.csv`. First, install `file_fdw` as an extension:

```
CREATE EXTENSION file_fdw;
```

Then create a foreign server:

```
CREATE SERVER pglog FOREIGN DATA WRAPPER file_fdw;
```

Now you are ready to create the foreign data table. Using the `CREATE FOREIGN TABLE` command, you will need to define the columns for the table, the CSV file name, and its format:

```
CREATE FOREIGN TABLE pglog (  
    log_time timestamp(3) with time zone,  
    user_name text,  
    database_name text,  
    process_id integer,  
    connection_from text,  
    session_id text,  
    session_line_num bigint,  
    command_tag text,  
    session_start_time timestamp with time zone,  
    virtual_transaction_id text,  
    transaction_id bigint,  
    error_severity text,
```

```
sql_state_code text,  
message text,  
detail text,  
hint text,  
internal_query text,  
internal_query_pos integer,  
context text,  
query text,  
query_pos integer,  
location text,  
application_name text,  
backend_type text,  
leader_pid integer,  
query_id bigint  
) SERVER pglog  
OPTIONS ( filename 'log/pglog.csv', format 'csv' );
```

That's it — now you can query your log directly. In production, of course, you would need to define some way to deal with log rotation.

Example F.6. Create a Foreign Table with an Option on a Column

To set the `force_null` option for a column, use the `OPTIONS` keyword.

```
CREATE FOREIGN TABLE films (  
  code char(5) NOT NULL,  
  title text NOT NULL,  
  rating text OPTIONS (force_null 'true')  
) SERVER film_server  
OPTIONS ( filename 'films/db.csv', format 'csv' );
```

F.21. fulleq — an additional equivalence operator for compatibility with Microsoft SQL Server

The `fulleq` module provides additional equivalence operator for compatibility with Microsoft SQL Server.

This module is required for 1C Enterprise support.

F.21.1. Overview

The Postgres Pro equivalence operator is defined to return NULL when both operands are NULLs. However, the Microsoft SQL Servers family traditionally defines other semantic for equivalence operator, where operator returns TRUE in the case of both nulled operands. This module provides such operator with MS SQL semantic.

F.21.2. Operator `fulleq`

The `==` operator is defined for the following data types:

- `bool`
- `bytea`
- `char`
- `name`
- `int2`
- `int4`
- `int8`
- `int2vector`
- `text`
- `oid`
- `xid`
- `cid`
- `oidvector`
- `float4`
- `float8`
- `abstime`
- `reltime`
- `macaddr`
- `inet`
- `cidr`
- `varchar`
- `date`
- `time`
- `timestamp`
- `timestampz`
- `interval`
- `timetz`

F.21.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

F.22. fuzzystrmatch — determine string similarities and distance

The `fuzzystrmatch` module provides several functions to determine similarities and distance between strings.

Caution

At present, the `soundex`, `metaphone`, `dmetaphone`, and `dmetaphone_alt` functions do not work well with multibyte encodings (such as UTF-8). Use `daitch_mokotoff` or `levenshtein` with such data.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.22.1. Soundex

The Soundex system is a method of matching similar-sounding names by converting them to the same code. It was initially used by the United States Census in 1880, 1900, and 1910. Note that Soundex is not very useful for non-English names.

The `fuzzystrmatch` module provides two functions for working with Soundex codes:

```
soundex(text) returns text  
difference(text, text) returns int
```

The `soundex` function converts a string to its Soundex code. The `difference` function converts two strings to their Soundex codes and then reports the number of matching code positions. Since Soundex codes have four characters, the result ranges from zero to four, with zero being no match and four being an exact match. (Thus, the function is misnamed — `similarity` would have been a better name.)

Here are some usage examples:

```
SELECT soundex('hello world!');  
  
SELECT soundex('Anne'), soundex('Ann'), difference('Anne', 'Ann');  
SELECT soundex('Anne'), soundex('Andrew'), difference('Anne', 'Andrew');  
SELECT soundex('Anne'), soundex('Margaret'), difference('Anne', 'Margaret');  
  
CREATE TABLE s (nm text);  
  
INSERT INTO s VALUES ('john');  
INSERT INTO s VALUES ('joan');  
INSERT INTO s VALUES ('wobbly');  
INSERT INTO s VALUES ('jack');  
  
SELECT * FROM s WHERE soundex(nm) = soundex('john');  
  
SELECT * FROM s WHERE difference(s.nm, 'john') > 2;
```

F.22.2. Daitch-Mokotoff Soundex

Like the original Soundex system, Daitch-Mokotoff Soundex matches similar-sounding names by converting them to the same code. However, Daitch-Mokotoff Soundex is significantly more useful for non-English names than the original system. Major improvements over the original system include:

- The code is based on the first six meaningful letters rather than four.
- A letter or combination of letters maps into ten possible codes rather than seven.
- Where two consecutive letters have a single sound, they are coded as a single number.

- When a letter or combination of letters may have different sounds, multiple codes are emitted to cover all possibilities.

This function generates the Daitch-Mokotoff soundex codes for its input:

`daitch_mokotoff(source text)` returns `text[]`

The result may contain one or more codes depending on how many plausible pronunciations there are, so it is represented as an array.

Since a Daitch-Mokotoff soundex code consists of only 6 digits, *source* should be preferably a single word or name.

Here are some examples:

```
SELECT daitch_mokotoff('George');
       daitch_mokotoff
-----
 {595000}

SELECT daitch_mokotoff('John');
       daitch_mokotoff
-----
 {160000,460000}

SELECT daitch_mokotoff('Bierschbach');
               daitch_mokotoff
-----
 {794575,794574,794750,794740,745750,745740,747500,747400}

SELECT daitch_mokotoff('Schwarzenegger');
       daitch_mokotoff
-----
 {479465}
```

For matching of single names, returned text arrays can be matched directly using the `&&` operator: any overlap can be considered a match. A GIN index may be used for efficiency, see [Section 63.4](#) and this example:

```
CREATE TABLE s (nm text);
CREATE INDEX ix_s_dm ON s USING gin (daitch_mokotoff(nm)) WITH (fastupdate = off);

INSERT INTO s (nm) VALUES
 ('Schwarzenegger'),
 ('John'),
 ('James'),
 ('Steinman'),
 ('Steinmetz');

SELECT * FROM s WHERE daitch_mokotoff(nm) && daitch_mokotoff('Swartzenegger');
SELECT * FROM s WHERE daitch_mokotoff(nm) && daitch_mokotoff('Jane');
SELECT * FROM s WHERE daitch_mokotoff(nm) && daitch_mokotoff('Jens');
```

For indexing and matching of any number of names in any order, Full Text Search features can be used. See [Chapter 12](#) and this example:

```
CREATE FUNCTION soundex_tsvector(v_name text) RETURNS tsvector
BEGIN ATOMIC
    SELECT to_tsvector('simple',
                      string_agg(array_to_string(daitch_mokotoff(n), ' '), ' '))
```

```
FROM regexp_split_to_table(v_name, '\s+') AS n;
END;

CREATE FUNCTION soundex_tsquery(v_name text) RETURNS tsquery
BEGIN ATOMIC
    SELECT string_agg('(' || array_to_string(daitch_mokotoff(n), '|') || ')',
    '&')::tsquery
    FROM regexp_split_to_table(v_name, '\s+') AS n;
END;

CREATE TABLE s (nm text);
CREATE INDEX ix_s_txt ON s USING gin (soundex_tsvector(nm)) WITH (fastupdate = off);

INSERT INTO s (nm) VALUES
    ('John Doe'),
    ('Jane Roe'),
    ('Public John Q.'),
    ('George Best'),
    ('John Yamson');

SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('john');
SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('jane doe');
SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('john public');
SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('besst, giorgio');
SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('Jameson John');
```

If it is desired to avoid recalculation of soundex codes during index rechecks, an index on a separate column can be used instead of an index on an expression. A stored generated column can be used for this; see [Section 5.4](#).

F.22.3. Levenshtein

This function calculates the Levenshtein distance between two strings:

```
levenshtein(source text, target text, ins_cost int, del_cost int, sub_cost int) returns
int
levenshtein(source text, target text) returns int
levenshtein_less_equal(source text, target text, ins_cost int, del_cost int, sub_cost
int, max_d int) returns int
levenshtein_less_equal(source text, target text, max_d int) returns int
```

Both `source` and `target` can be any non-null string, with a maximum of 255 characters. The cost parameters specify how much to charge for a character insertion, deletion, or substitution, respectively. You can omit the cost parameters, as in the second version of the function; in that case they all default to 1.

`levenshtein_less_equal` is an accelerated version of the Levenshtein function for use when only small distances are of interest. If the actual distance is less than or equal to `max_d`, then `levenshtein_less_equal` returns the correct distance; otherwise it returns some value greater than `max_d`. If `max_d` is negative then the behavior is the same as `levenshtein`.

Examples:

```
test=# SELECT levenshtein('GUMBO', 'GAMBOL');
 levenshtein
-----
          2
(1 row)

test=# SELECT levenshtein('GUMBO', 'GAMBOL', 2, 1, 1);
```

```
levenshtein
-----
          3
(1 row)

test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 2);
 levenshtein_less_equal
-----
          3
(1 row)

test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 4);
 levenshtein_less_equal
-----
          4
(1 row)
```

F.22.4. Metaphone

Metaphone, like Soundex, is based on the idea of constructing a representative code for an input string. Two strings are then deemed similar if they have the same codes.

This function calculates the metaphone code of an input string:

`metaphone(source text, max_output_length int)` returns text

`source` has to be a non-null string with a maximum of 255 characters. `max_output_length` sets the maximum length of the output metaphone code; if longer, the output is truncated to this length.

Example:

```
test=# SELECT metaphone('GUMBO', 4);
 metaphone
-----
      KM
(1 row)
```

F.22.5. Double Metaphone

The Double Metaphone system computes two “sounds like” strings for a given input string — a “primary” and an “alternate”. In most cases they are the same, but for non-English names especially they can be a bit different, depending on pronunciation. These functions compute the primary and alternate codes:

`dmetaphone(source text)` returns text
`dmetaphone_alt(source text)` returns text

There is no length limit on the input strings.

Example:

```
test=# SELECT dmetaphone('gumbo');
 dmetaphone
-----
      KMP
(1 row)
```

F.23. hstore — hstore key/value datatype

This module implements the `hstore` data type for storing sets of key/value pairs within a single Postgres Pro value. This can be useful in various scenarios, such as rows with many attributes that are rarely examined, or semi-structured data. Keys and values are simply text strings.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.23.1. hstore External Representation

The text representation of an `hstore`, used for input and output, includes zero or more `key => value` pairs separated by commas. Some examples:

```
k => v
foo => bar, baz => whatever
"1-a" => "anything at all"
```

The order of the pairs is not significant (and may not be reproduced on output). Whitespace between pairs or around the `=>` sign is ignored. Double-quote keys and values that include whitespace, commas, `=`s or `>`s. To include a double quote or a backslash in a key or value, escape it with a backslash.

Each key in an `hstore` is unique. If you declare an `hstore` with duplicate keys, only one will be stored in the `hstore` and there is no guarantee as to which will be kept:

```
SELECT 'a=>1,a=>2'::hstore;
 hstore
-----
"a"=>"1"
```

A value (but not a key) can be an SQL `NULL`. For example:

```
key => NULL
```

The `NULL` keyword is case-insensitive. Double-quote the `NULL` to treat it as the ordinary string “NULL”.

Note

Keep in mind that the `hstore` text format, when used for input, applies *before* any required quoting or escaping. If you are passing an `hstore` literal via a parameter, then no additional processing is needed. But if you're passing it as a quoted literal constant, then any single-quote characters and (depending on the setting of the `standard_conforming_strings` configuration parameter) backslash characters need to be escaped correctly. See [Section 4.1.2.1](#) for more on the handling of string constants.

On output, double quotes always surround keys and values, even when it's not strictly necessary.

F.23.2. hstore Operators and Functions

The operators provided by the `hstore` module are shown in [Table F.10](#), the functions in [Table F.11](#).

Table F.10. hstore Operators

Operator	Description	Example(s)
<code>hstore -> text → text</code>	Returns value associated with given key, or <code>NULL</code> if not present.	<code>'a=>x, b=>y'::hstore -> 'a' → x</code>
<code>hstore -> text [] → text []</code>	Returns values associated with given keys, or <code>NULL</code> if not present.	

Operator	Description	Example(s)
		'a=>x, b=>y, c=>z'::hstore -> ARRAY['c','a'] → {"z","x"}
hstore hstore → hstore	Concatenates two hstores.	'a=>b, c=>d'::hstore 'c=>x, d=>q'::hstore → "a"=>"b", "c"=>"x", "d"=>"q"
hstore ? text → boolean	Does hstore contain key?	'a=>1'::hstore ? 'a' → t
hstore ?& text[] → boolean	Does hstore contain all the specified keys?	'a=>1,b=>2'::hstore ?& ARRAY['a','b'] → t
hstore ? text[] → boolean	Does hstore contain any of the specified keys?	'a=>1,b=>2'::hstore ? ARRAY['b','c'] → t
hstore @> hstore → boolean	Does left operand contain right?	'a=>b, b=>1, c=>NULL'::hstore @> 'b=>1' → t
hstore <@ hstore → boolean	Is left operand contained in right?	'a=>c'::hstore <@ 'a=>b, b=>1, c=>NULL' → f
hstore - text → hstore	Deletes key from left operand.	'a=>1, b=>2, c=>3'::hstore - 'b'::text → "a"=>"1", "c"=>"3"
hstore - text[] → hstore	Deletes keys from left operand.	'a=>1, b=>2, c=>3'::hstore - ARRAY['a','b'] → "c"=>"3"
hstore - hstore → hstore	Deletes pairs from left operand that match pairs in the right operand.	'a=>1, b=>2, c=>3'::hstore - 'a=>4, b=>2'::hstore → "a"=>"1", "c"=>"3"
anyelement #= hstore → anyelement	Replaces fields in the left operand (which must be a composite type) with matching values from hstore.	ROW(1,3) #= 'f1=>11'::hstore → (11,3)
%% hstore → text[]	Converts hstore to an array of alternating keys and values.	%% 'a=>foo, b=>bar'::hstore → {a,foo,b,bar}
%# hstore → text[]	Converts hstore to a two-dimensional key/value array.	%# 'a=>foo, b=>bar'::hstore → {{a,foo},{b,bar}}

Table F.11. hstore Functions

Function	Description	Example(s)
<code>hstore (record) → hstore</code>	Constructs an hstore from a record or row.	<code>hstore(ROW(1,2)) → "f1"=>"1", "f2"=>"2"</code>
<code>hstore (text[]) → hstore</code>	Constructs an hstore from an array, which may be either a key/value array, or a two-dimensional array.	<code>hstore(ARRAY['a','1','b','2']) → "a"=>"1", "b"=>"2"</code> <code>hstore(ARRAY[['c','3'],['d','4']]) → "c"=>"3", "d"=>"4"</code>
<code>hstore (text[], text[]) → hstore</code>	Constructs an hstore from separate key and value arrays.	<code>hstore(ARRAY['a','b'], ARRAY['1','2']) → "a"=>"1", "b"=>"2"</code>
<code>hstore (text, text) → hstore</code>	Makes a single-item hstore.	<code>hstore('a', 'b') → "a"=>"b"</code>
<code>akeys (hstore) → text[]</code>	Extracts an hstore's keys as an array.	<code>akeys('a=>1,b=>2') → {a,b}</code>
<code>skeys (hstore) → setof text</code>	Extracts an hstore's keys as a set.	<code>skeys('a=>1,b=>2') →</code> <code>a</code> <code>b</code>
<code>avals (hstore) → text[]</code>	Extracts an hstore's values as an array.	<code>avals('a=>1,b=>2') → {1,2}</code>
<code>svals (hstore) → setof text</code>	Extracts an hstore's values as a set.	<code>svals('a=>1,b=>2') →</code> <code>1</code> <code>2</code>
<code>hstore_to_array (hstore) → text[]</code>	Extracts an hstore's keys and values as an array of alternating keys and values.	<code>hstore_to_array('a=>1,b=>2') → {a,1,b,2}</code>
<code>hstore_to_matrix (hstore) → text[]</code>	Extracts an hstore's keys and values as a two-dimensional array.	<code>hstore_to_matrix('a=>1,b=>2') → {{a,1},{b,2}}</code>
<code>hstore_to_json (hstore) → json</code>	Converts an hstore to a json value, converting all non-null values to JSON strings. This function is used implicitly when an hstore value is cast to json.	<code>hstore_to_json('"a key"=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4') → {"a key": "1", "b": "t", "c": null, "d": "12345", "e": "012345", "f": "1.234", "g": "2.345e+4"}</code>

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

Function	Description	Example(s)
<code>hstore_to_jsonb (hstore) → jsonb</code>	Converts an <code>hstore</code> to a <code>jsonb</code> value, converting all non-null values to JSON strings. This function is used implicitly when an <code>hstore</code> value is cast to <code>jsonb</code> .	<code>hstore_to_jsonb('"a key"=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4') → {"a key": "1", "b": "t", "c": null, "d": "12345", "e": "012345", "f": "1.234", "g": "2.345e+4"}</code>
<code>hstore_to_json_loose (hstore) → json</code>	Converts an <code>hstore</code> to a <code>json</code> value, but attempts to distinguish numerical and Boolean values so they are unquoted in the JSON.	<code>hstore_to_json_loose('"a key"=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4') → {"a key": 1, "b": true, "c": null, "d": 12345, "e": "012345", "f": 1.234, "g": 2.345e+4}</code>
<code>hstore_to_jsonb_loose (hstore) → jsonb</code>	Converts an <code>hstore</code> to a <code>jsonb</code> value, but attempts to distinguish numerical and Boolean values so they are unquoted in the JSON.	<code>hstore_to_jsonb_loose('"a key"=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4') → {"a key": 1, "b": true, "c": null, "d": 12345, "e": "012345", "f": 1.234, "g": 2.345e+4}</code>
<code>slice (hstore, text[]) → hstore</code>	Extracts a subset of an <code>hstore</code> containing only the specified keys.	<code>slice('a=>1,b=>2,c=>3'::hstore, ARRAY['b','c','x']) → "b"=>"2", "c"=>"3"</code>
<code>each (hstore) → setof record (key text, value text)</code>	Extracts an <code>hstore</code> 's keys and values as a set of records.	<code>select * from each('a=>1,b=>2') →</code> <pre> key value -----+----- a 1 b 2 </pre>
<code>exist (hstore, text) → boolean</code>	Does <code>hstore</code> contain key?	<code>exist('a=>1', 'a') → t</code>
<code>defined (hstore, text) → boolean</code>	Does <code>hstore</code> contain a non-NULL value for key?	<code>defined('a=>NULL', 'a') → f</code>
<code>delete (hstore, text) → hstore</code>	Deletes pair with matching key.	<code>delete('a=>1,b=>2', 'b') → "a"=>"1"</code>
<code>delete (hstore, text[]) → hstore</code>	Deletes pairs with matching keys.	<code>delete('a=>1,b=>2,c=>3', ARRAY['a','b']) → "c"=>"3"</code>
<code>delete (hstore, hstore) → hstore</code>	Deletes pairs matching those in the second argument.	<code>delete('a=>1,b=>2', 'a=>4,b=>2'::hstore) → "a"=>"1"</code>
<code>populate_record (anyelement, hstore) → anyelement</code>		

Function	Description	Example(s)
	Replaces fields in the left operand (which must be a composite type) with matching values from <code>hstore</code> .	
	<code>populate_record(ROW(1,2), 'f1=>42'::hstore)</code>	<code>→ (42,2)</code>

In addition to these operators and functions, values of the `hstore` type can be subscripted, allowing them to act like associative arrays. Only a single subscript of type `text` can be specified; it is interpreted as a key and the corresponding value is fetched or stored. For example,

```
CREATE TABLE mytable (h hstore);
INSERT INTO mytable VALUES ('a=>b, c=>d');
SELECT h['a'] FROM mytable;
h
---
b
(1 row)
```

```
UPDATE mytable SET h['c'] = 'new';
SELECT h FROM mytable;
h
-----
"a"=>"b", "c"=>"new"
(1 row)
```

A subscripted fetch returns `NULL` if the subscript is `NULL` or that key does not exist in the `hstore`. (Thus, a subscripted fetch is not greatly different from the `->` operator.) A subscripted update fails if the subscript is `NULL`; otherwise, it replaces the value for that key, adding an entry to the `hstore` if the key does not already exist.

F.23.3. Indexes

`hstore` has GiST and GIN index support for the `@>`, `?`, `?&` and `?|` operators. For example:

```
CREATE INDEX hidx ON testhstore USING GIST (h);

CREATE INDEX hidx ON testhstore USING GIN (h);
```

`gist_hstore_ops` GiST opclass approximates a set of key/value pairs as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default length is 16 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

```
CREATE INDEX hidx ON testhstore USING GIST (h gist_hstore_ops(siglen=32));
```

`hstore` also supports `btree` or `hash` indexes for the `=` operator. This allows `hstore` columns to be declared `UNIQUE`, or to be used in `GROUP BY`, `ORDER BY` or `DISTINCT` expressions. The sort ordering for `hstore` values is not particularly useful, but these indexes may be useful for equivalence lookups. Create indexes for `=` comparisons as follows:

```
CREATE INDEX hidx ON testhstore USING BTREE (h);

CREATE INDEX hidx ON testhstore USING HASH (h);
```

F.23.4. Examples

Add a key, or update an existing key with a new value:

```
UPDATE tab SET h['c'] = '3';
```

Another way to do the same thing is:

```
UPDATE tab SET h = h || hstore('c', '3');
```

If multiple keys are to be added or changed in one operation, the concatenation approach is more efficient than subscripting:

```
UPDATE tab SET h = h || hstore(array['q', 'w'], array['11', '12']);
```

Delete a key:

```
UPDATE tab SET h = delete(h, 'k1');
```

Convert a record to an `hstore`:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');
```

```
SELECT hstore(t) FROM test AS t;
           hstore
-----
"col1"=>"123", "col2"=>"foo", "col3"=>"bar"
(1 row)
```

Convert an `hstore` to a predefined record type:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);

SELECT * FROM populate_record(null::test,
                              '"col1"=>"456", "col2"=>"zzz"');
 col1 | col2 | col3
-----+-----+-----
  456 | zzz  |
(1 row)
```

Modify an existing record using the values from an `hstore`:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');

SELECT (r).* FROM (SELECT t #= '"col3"=>"baz"' AS r FROM test t) s;
 col1 | col2 | col3
-----+-----+-----
  123 | foo  | baz
(1 row)
```

F.23.5. Statistics

The `hstore` type, because of its intrinsic liberality, could contain a lot of different keys. Checking for valid keys is the task of the application. The following examples demonstrate several techniques for checking keys and obtaining statistics.

Simple example:

```
SELECT * FROM each('aaa=>bq, b=>NULL, ""=>1');
```

Using a table:

```
CREATE TABLE stat AS SELECT (each(h)).key, (each(h)).value FROM testhstore;
```

Online statistics:

```
SELECT key, count(*) FROM
```

```
(SELECT (each(h)).key FROM testhstore) AS stat
GROUP BY key
ORDER BY count DESC, key;
```

key		count
line		883
query		207
pos		203
node		202
space		197
status		195
public		194
title		190
org		189

.....

F.23.6. Compatibility

As of PostgreSQL 9.0, `hstore` uses a different internal representation than previous versions. This presents no obstacle for dump/restore upgrades since the text representation (used in the dump) is unchanged.

In the event of a binary upgrade, upward compatibility is maintained by having the new code recognize old-format data. This will entail a slight performance penalty when processing data that has not yet been modified by the new code. It is possible to force an upgrade of all values in a table column by doing an `UPDATE` statement as follows:

```
UPDATE tablename SET hstorecol = hstorecol || '';
```

Another way to do it is:

```
ALTER TABLE tablename ALTER hstorecol TYPE hstore USING hstorecol || '';
```

The `ALTER TABLE` method requires an `ACCESS EXCLUSIVE` lock on the table, but does not result in bloating the table with old row versions.

F.23.7. Transforms

Additional extensions are available that implement transforms for the `hstore` type for the languages PL/Perl and PL/Python. The extensions for PL/Perl are called `hstore_plperl` and `hstore_plperlu`, for trusted and untrusted PL/Perl. If you install these transforms and specify them when creating a function, `hstore` values are mapped to Perl hashes. The extension for PL/Python is called `hstore_plpython3u`. If you use it, `hstore` values are mapped to Python dictionaries.

F.23.8. Authors

Oleg Bartunov <oleg@sai.msu.su>, Moscow, Moscow University, Russia

Teodor Sigaev <teodor@sigaev.ru>, Moscow, Delta-Soft Ltd., Russia

Additional enhancements by Andrew Gierth <andrew@tao11.riddles.org.uk>, United Kingdom

F.24. Hunspell Dictionaries Modules

These modules provide Hunspell dictionaries for various languages. Upon installation of the module into database using `CREATE EXTENSION` command, text search dictionary and configuration objects in the public schema appear.

Table F.12. Modules

Language	Extension name	Dictionary name	Configuration name
American English	hunspell_en_us	english_hunspell	english_hunspell
Dutch	hunspell_nl_nl	dutch_hunspell	dutch_hunspell
French	hunspell_fr	french_hunspell	french_hunspell
Russian	hunspell_ru_ru	russian_hunspell	russian_hunspell

F.24.1. Examples

Text search objects will be created after installation of a dictionary module. We can test created configuration:

```
SELECT * FROM ts_debug('english_hunspell', 'abilities');
  alias | description | token | dictionaries |
  dictionary | lexemes
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
  asciiword | Word, all ASCII | abilities | {english_hunspell,english_stem} |
  english_hunspell | {ability}
(1 row)
```

Or you can create your own text search configuration. For example, with the created dictionaries and with the `Snowball` dictionary you can create mixed russian-english configuration:

```
CREATE TEXT SEARCH CONFIGURATION russian_en (
  COPY = simple
);

ALTER TEXT SEARCH CONFIGURATION russian_en
  ALTER MAPPING FOR asciiword, asciihword, hword_asciipart
  WITH english_hunspell, english_stem;

ALTER TEXT SEARCH CONFIGURATION russian_en
  ALTER MAPPING FOR word, hword, hword_part
  WITH russian_hunspell, russian_stem;
```

You can create mixed dictionaries only for languages with different alphabets. If languages have similar alphabets then Postgres Pro can not decide which dictionary should be used.

A text search configuration which is created with a dictionary module is ready to use. For example, in this text you can search some words:

```
SELECT to_tsvector('english_hunspell', 'The blue whale is the largest animal');
      to_tsvector
-----
'animal':7 'blue':2 'large':6 'whale':3
(1 row)
```

Search query might looks like this:

```
SELECT to_tsvector('english_hunspell', 'The blue whale is the largest animal')
  @@ to_tsquery('english_hunspell', 'large & whale');
?column?
```

```
-----  
t  
(1 row)
```

With this configurations you can search a text using GIN or GIST indexes. For example, there is a table with GIN index:

```
CREATE TABLE table1 (t varchar);  
INSERT INTO table1 VALUES ('The blue whale is the largest animal');  
CREATE INDEX t_idx ON table1 USING GIN (to_tsvector('english_hunspell', "t"));
```

For this table you can execute the following query:

```
SELECT * FROM table1 where to_tsvector('english_hunspell', t)  
@@ to_tsquery('english_hunspell', 'blue & animal');  
t
```

```
-----  
The blue whale is the largest animal  
(1 row)
```

F.25. hypopg — support for hypothetical indexes

F.25.1. Description

hypopg is a Postgres Pro extension, adding support for *hypothetical indexes*.

A hypothetical, or virtual, index is an index that does not really exist, and therefore does not cost CPU, disk, or any resource to create. They are useful to find out whether specific indexes can increase the performance for problematic queries, since you can discover if Postgres Pro will use these indexes or not without having to spend resources to create them.

F.25.2. Installation

The hypopg extension is provided with Postgres Pro as a separate pre-built package `hypopg-ent-16` (for the detailed installation instructions, see [Chapter 16](#)). Once you have Postgres Pro installed, create the hypopg extension:

```
CREATE EXTENSION hypopg;
```

hypopg is now available. You can check easily if the extension is present using `psql`:

```
\dx
      List of installed extensions
  Name      | Version | Schema      | Description
  -----+-----+-----+-----
  hypopg    | 1.4.1   | public      | Hypothetical indexes for Postgres Pro
  plpgsql   | 1.0     | pg_catalog  | PL/pgSQL procedural language
(2 rows)
```

As you can see, hypopg is installed.

F.25.3. Functions

hypopg is useful if you want to check if some index would help one or multiple queries. Therefore, you should already know what are the queries you need to optimize, and ideas on which indexes you want to try.

Also, the hypothetical indexes that hypopg will create are not stored in any catalog, but in your connection private memory. Therefore, it won't bloat any table and won't impact any concurrent connection.

Moreover, since the hypothetical indexes don't really exist, hypopg makes sure they will only be using a simple `EXPLAIN` statement (without the `ANALYZE` option).

The following access methods are supported:

- `btree`
- `brin`
- `hash`
- `bloom` (requires the [bloom](#) extension to be installed)

Note

Using hypopg requires some knowledge on the [EXPLAIN](#) command.

F.25.3.1. Create a Hypothetical Index

```
hypopg_create_index()
```

For clarity, let's see how it works with a very simple test case:

```
CREATE TABLE hypo (id integer, val text) ;
INSERT INTO hypo SELECT i, 'line ' || i FROM generate_series(1, 100000) i ;
VACUUM ANALYZE hypo ;
```

This table doesn't have any index. Let's assume we want to check if an index would help a simple query. First, let's see how it behaves:

```
EXPLAIN SELECT val FROM hypo WHERE id = 1;
               QUERY PLAN
-----
Seq Scan on hypo  (cost=0.00..1791.00 rows=1 width=14)
  Filter: (id = 1)
(2 rows)
```

A plain sequential scan is used, since no index exists on the table. A simple btree index on the `id` column should help this query. Let's check with `hypopg`. The function `hypopg_create_index()` will accept any standard `CREATE INDEX` statement(s) (any other statement passed to this function will be ignored), and create a hypothetical index for each:

```
SELECT * FROM hypopg_create_index('CREATE INDEX ON hypo (id)') ;
 indexrelid |      indexname
-----+-----
      18284 | <18284>btree_hypo_id
(1 row)
```

The function returns two columns:

- the object identifier of the hypothetical index
- the generated hypothetical index name

We can run the `EXPLAIN` again to see if Postgres Pro would use this index:

```
EXPLAIN SELECT val FROM hypo WHERE id = 1;
               QUERY PLAN
-----
Index Scan using <18284>btree_hypo_id on hypo  (cost=0.04..8.06 rows=1 width=10)
  Index Cond: (id = 1)
(2 rows)
```

Yes, Postgres Pro would use such an index. Just to be sure, let's check that the hypothetical index won't be used to actually run the query:

```
EXPLAIN ANALYZE SELECT val FROM hypo WHERE id = 1;
               QUERY PLAN
-----
Seq Scan on hypo  (cost=0.00..1791.00 rows=1 width=10) (actual time=0.046..46.390
rows=1 loops=1)
  Filter: (id = 1)
  Rows Removed by Filter: 99999
Planning time: 0.160 ms
Execution time: 46.460 ms
(5 rows)
```

That's all you need to create hypothetical indexes and see if Postgres Pro would use such indexes.

F.25.3.2. Manipulate Hypothetical Indexes

The `hypopg_list_indexes` view lists all hypothetical indexes that have been created.

```
SELECT * FROM hypopg_list_indexes ;
 indexrelid |      index_name      | schema_name | table_name | am_name
-----+-----+-----+-----+-----
      18284 | <18284>btree_hypo_id | public      | hypo      | btree
```

(1 row)

hypopg()

hypopg() lists all hypothetical indexes that have been created with the same format as pg_index.

```
SELECT * FROM hypopg() ;
      indexname      | indexrelid | indrelid | innatts | indisunique | indkey |
indcollation | indclass | indoption | indexprs | indpred | amid
-----+-----+-----+-----+-----+-----+-----
<18284>btree_hypo_id |      13543 |      18122 |        1 | f          | 1      | 0
      | 1978      | <NULL>      | <NULL>      | <NULL>      | 403
(1 row)
```

hypopg_get_indexdef(oid)

hypopg_get_indexdef(oid) lists the CREATE INDEX statements that would recreate a stored hypothetical index.

```
SELECT index_name, hypopg_get_indexdef(indexrelid) FROM hypopg_list_indexes ;
      index_name      | hypopg_get_indexdef
-----+-----
<18284>btree_hypo_id | CREATE INDEX ON public.hypo USING btree (id)
(1 row)
```

hypopg_relation_size(oid)

hypopg_relation_size(oid) estimates how big a hypothetical index would be:

```
SELECT index_name, pg_size_pretty(hypopg_relation_size(indexrelid))
FROM hypopg_list_indexes ;
      index_name      | pg_size_pretty
-----+-----
<18284>btree_hypo_id | 2544 kB
(1 row)
```

hypopg_drop_index(oid)

hypopg_drop_index(oid) removes the given hypothetical index.

hypopg_reset()

hypopg_reset() removes all hypothetical indexes.

F.25.3.3. Hypothetically Hide Existing Indexes

hypopg_hide_index(oid)

You can hide both existing and hypothetical indexes hypothetically. If you want to test it as described in the documentation, you should first use hypopg_reset() to clear the effects of any other hypothetical indexes.

As a simple case, let's consider two indexes:

```
SELECT hypopg_reset();
CREATE INDEX ON hypo(id);
CREATE INDEX ON hypo(id, val);
EXPLAIN SELECT * FROM hypo WHERE id = 1;
               QUERY PLAN
-----
Index Only Scan using hypo_id_val_idx on hypo  (cost=0.29..8.30 rows=1 width=13)
Index Cond: (id = 1)
(2 rows)
```

The query plan is using the `hypo_id_val_idx` index now.

`hypopg_hide_index(oid)` allows you to hide an index in the `EXPLAIN` output by using its OID. It returns true if the index was successfully hidden, and false otherwise.

```
SELECT hypopg_hide_index('hypo_id_val_idx'::REGCLASS);
 hypopg_hide_index
```

```
-----
```

```
t
(1 row)
```

```
EXPLAIN SELECT * FROM hypo WHERE id = 1;
               QUERY PLAN
```

```
-----
```

```
Index Scan using hypo_id_idx on hypo  (cost=0.29..8.30 rows=1 width=13)
Index Cond: (id = 1)
(2 rows)
```

As an example, let's assume that the query plan is currently using the `hypo_id_val_idx` index. To continue testing, use the `hypopg_hide_index(oid)` function to hide another index.

```
SELECT hypopg_hide_index('hypo_id_idx'::REGCLASS);
 hypopg_hide_index
```

```
-----
```

```
t
(1 row)
```

```
EXPLAIN SELECT * FROM hypo WHERE id = 1;
               QUERY PLAN
```

```
-----
```

```
Seq Scan on hypo  (cost=0.00..180.00 rows=1 width=13)
Filter: (id = 1)
(2 rows)
```

`hypopg_unhide_index(oid)`

`hypopg_unhide_index(oid)` restores a previously hidden index in the `EXPLAIN` output by using its OID. It returns true if the index was successfully restored, and false otherwise.

```
SELECT hypopg_unhide_index('hypo_id_idx'::regclass);
 hypopg_unhide_index
```

```
-----
```

```
t
(1 row)
```

```
EXPLAIN SELECT * FROM hypo WHERE id = 1;
               QUERY PLAN
```

```
-----
```

```
Index Scan using hypo_id_idx on hypo  (cost=0.29..8.30 rows=1 width=13)
Index Cond: (id = 1)
(2 rows)
```

`hypopg_unhide_all_index(oid)`

`hypopg_unhide_all_index()` restores all hidden indexes and returns void.

`hypopg_hidden_indexes()`

`hypopg_hidden_indexes()` returns a list of OIDs for all hidden indexes.

```
SELECT * FROM hypopg_hidden_indexes();
 indexid
```

```
-----  
526604  
(1 rows)
```

The `hypopg_hidden_indexes` view returns a formatted list of all hidden indexes.

```
SELECT * FROM hypopg_hidden_indexes;  
indexrelid | index_name | schema_name | table_name | am_name | is_hypo  
-----+-----+-----+-----+-----+-----  
526604 | hypo_id_val_idx | public | hypo | btree | f  
(1 rows)
```

Note

Hypothetical indexes can be hidden as well.

```
SELECT hypopg_create_index('CREATE INDEX ON hypo(id)');  
hypopg_create_index  
-----  
(12659,<12659>btree_hypo_id)  
(1 row)
```

```
EXPLAIN SELECT * FROM hypo WHERE id = 1;  
QUERY PLAN  
-----  
Index Scan using "<12659>btree_hypo_id" on hypo (cost=0.04..8.05 rows=1 width=13)  
Index Cond: (id = 1)  
(2 rows)
```

Now that the hypothetical index is being used, we can try hiding it to see the change:

```
SELECT hypopg_hide_index(12659);  
hypopg_hide_index  
-----  
t  
(1 row)
```

```
EXPLAIN SELECT * FROM hypo WHERE id = 1;  
QUERY PLAN  
-----  
Index Scan using hypo_id_idx on hypo (cost=0.29..8.30 rows=1 width=13)  
Index Cond: (id = 1)  
(2 rows)
```

```
SELECT * FROM hypopg_hidden_indexes;  
indexrelid | index_name | schema_name | table_name | am_name | is_hypo  
-----+-----+-----+-----+-----+-----  
12659 | <12659>btree_hypo_id | public | hypo | btree | t  
526604 | hypo_id_val_idx | public | hypo | btree | f  
(2 rows)
```

Note

If a hypothetical index has been hidden, it will be automatically unhidden when it is deleted using `hypopg_drop_index(oid)` or `hypopg_reset()`.

```
SELECT hypopg_drop_index(12659);
```

```
SELECT * FROM hypopg_hidden_indexes;
 indexrelid |      index_name      | schema_name | table_name | am_name | is_hypo
-----+-----+-----+-----+-----+-----
      526604 | hypo_id_val_idx      | public      | hypo       | btree   | f
(2 rows)
```

F.25.4. GUC Parameters

The following configuration parameters (GUCs) are available, and can be changed interactively:

`hypopg.enabled`

Defaults to `on`. Use this parameter to globally enable or disable `hypopg`. When `hypopg` is disabled, no hypothetical index will be used, but the defined hypothetical indexes won't be removed.

`hypopg.use_real_oids`

Defaults to `off`. By default, `hypopg` won't use "real" object identifiers, but instead borrow ones from the `~ 14000 / 16384` (respectively the lowest unused OID less than `FirstNormalObjectId` and `FirstNormalObjectId`) range, which are reserved by Postgres Pro for future usage in future releases. This doesn't cause any problem, as the free range is dynamically computed the first time a connection uses `hypopg`, and has the advantage to work on a standby server. But the drawback is that you can't have more than approximately 2500 hypothetical indexes at the same time, and creating a new hypothetical index will become very slow once more than the maximum number of objects has been created until `hypopg_reset()` is called.

If those drawbacks are problematic, you can enable this parameter. `hypopg` will then ask for a real object identifier, which will need to obtain more locks and won't work on a standby, but will allow using the full range of object identifiers.

Note that switching this parameter doesn't require resetting the entries, both can coexist at the same time.

F.26. intagg — integer aggregator and enumerator

The `intagg` module provides an integer aggregator and an enumerator. `intagg` is now obsolete, because there are built-in functions that provide a superset of its capabilities. However, the module is still provided as a compatibility wrapper around the built-in functions.

F.26.1. Functions

The aggregator is an aggregate function `int_array_aggregate(integer)` that produces an integer array containing exactly the integers it is fed. This is a wrapper around `array_agg`, which does the same thing for any array type.

The enumerator is a function `int_array_enum(integer[])` that returns `setof integer`. It is essentially the reverse operation of the aggregator: given an array of integers, expand it into a set of rows. This is a wrapper around `unnest`, which does the same thing for any array type.

F.26.2. Sample Uses

Many database systems have the notion of a many to many table. Such a table usually sits between two indexed tables, for example:

```
CREATE TABLE left_table (id INT PRIMARY KEY, ...);
CREATE TABLE right_table (id INT PRIMARY KEY, ...);
CREATE TABLE many_to_many (id_left INT REFERENCES left_table,
                             id_right INT REFERENCES right_table);
```

It is typically used like this:

```
SELECT right_table.*
FROM right_table JOIN many_to_many ON (right_table.id = many_to_many.id_right)
WHERE many_to_many.id_left = item;
```

This will return all the items in the right hand table for an entry in the left hand table. This is a very common construct in SQL.

Now, this methodology can be cumbersome with a very large number of entries in the `many_to_many` table. Often, a join like this would result in an index scan and a fetch for each right hand entry in the table for a particular left hand entry. If you have a very dynamic system, there is not much you can do. However, if you have some data which is fairly static, you can create a summary table with the aggregator.

```
CREATE TABLE summary AS
  SELECT id_left, int_array_aggregate(id_right) AS rights
  FROM many_to_many
  GROUP BY id_left;
```

This will create a table with one row per left item, and an array of right items. Now this is pretty useless without some way of using the array; that's why there is an array enumerator. You can do

```
SELECT id_left, int_array_enum(rights) FROM summary WHERE id_left = item;
```

The above query using `int_array_enum` produces the same results as

```
SELECT id_left, id_right FROM many_to_many WHERE id_left = item;
```

The difference is that the query against the summary table has to get only one row from the table, whereas the direct query against `many_to_many` must index scan and fetch a row for each entry.

On one system, an `EXPLAIN` showed a query with a cost of 8488 was reduced to a cost of 329. The original query was a join involving the `many_to_many` table, which was replaced by:

```
SELECT id_right, count(id_right) FROM
  ( SELECT id_left, int_array_enum(rights) AS id_right
    FROM summary
```

**Additional Supplied Modules
and Extensions Shipped in**
postgrespro-std-18-contrib

```
JOIN (SELECT id FROM left_table
      WHERE id = item) AS lefts
ON (summary.id_left = lefts.id)
) AS list
GROUP BY id_right
ORDER BY count DESC;
```

F.27. intarray — manipulate arrays of integers

The `intarray` module provides a number of useful functions and operators for manipulating null-free arrays of integers. There is also support for indexed searches using some of the operators.

All of these operations will throw an error if a supplied array contains any `NULL` elements.

Many of these operations are only sensible for one-dimensional arrays. Although they will accept input arrays of more dimensions, the data is treated as though it were a linear array in storage order.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.27.1. intarray Functions and Operators

The functions provided by the `intarray` module are shown in [Table F.13](#), the operators in [Table F.14](#).

Table F.13. intarray Functions

Function Description Example(s)
<code>icount (integer[]) → integer</code> Returns the number of elements in the array. <code>icount ('{1,2,3}'::integer[]) → 3</code>
<code>sort (integer[], dir text) → integer[]</code> Sorts the array in either ascending or descending order. <i>dir</i> must be <code>asc</code> or <code>desc</code> . <code>sort ('{1,3,2}'::integer[], 'desc') → {3,2,1}</code>
<code>sort (integer[]) → integer[]</code> <code>sort_asc (integer[]) → integer[]</code> Sorts in ascending order. <code>sort(array[11,77,44]) → {11,44,77}</code>
<code>sort_desc (integer[]) → integer[]</code> Sorts in descending order. <code>sort_desc(array[11,77,44]) → {77,44,11}</code>
<code>uniq (integer[]) → integer[]</code> Removes adjacent duplicates. Often used with <code>sort</code> to remove all duplicates. <code>uniq ('{1,2,2,3,1,1}'::integer[]) → {1,2,3,1}</code> <code>uniq(sort ('{1,2,3,2,1}'::integer[])) → {1,2,3}</code>
<code>idx (integer[], item integer) → integer</code> Returns index of the first array element matching <i>item</i> , or 0 if no match. <code>idx(array[11,22,33,22,11], 22) → 2</code>
<code>subarray (integer[], start integer, len integer) → integer[]</code> Extracts the portion of the array starting at position <i>start</i> , with <i>len</i> elements. <code>subarray ('{1,2,3,2,1}'::integer[], 2, 3) → {2,3,2}</code>
<code>subarray (integer[], start integer) → integer[]</code> Extracts the portion of the array starting at position <i>start</i> . <code>subarray ('{1,2,3,2,1}'::integer[], 2) → {2,3,2,1}</code>
<code>intset (integer) → integer[]</code> Makes a single-element array. <code>intset (42) → {42}</code>

Table F.14. intarray Operators

Operator	Description
<code>integer[] && integer[] → boolean</code>	Do arrays overlap (have at least one element in common)?
<code>integer[] @> integer[] → boolean</code>	Does left array contain right array?
<code>integer[] <@ integer[] → boolean</code>	Is left array contained in right array?
<code># integer[] → integer</code>	Returns the number of elements in the array.
<code>integer[] # integer → integer</code>	Returns index of the first array element matching the right argument, or 0 if no match. (Same as <code>idx</code> function.)
<code>integer[] + integer → integer[]</code>	Adds element to end of array.
<code>integer[] + integer[] → integer[]</code>	Concatenates the arrays.
<code>integer[] - integer → integer[]</code>	Removes entries matching the right argument from the array.
<code>integer[] - integer[] → integer[]</code>	Removes elements of the right array from the left array.
<code>integer[] integer → integer[]</code>	Computes the union of the arguments.
<code>integer[] integer[] → integer[]</code>	Computes the union of the arguments.
<code>integer[] & integer[] → integer[]</code>	Computes the intersection of the arguments.
<code>integer[] @@ query_int → boolean</code>	Does array satisfy query? (see below)
<code>query_int ~~ integer[] → boolean</code>	Does array satisfy query? (commutator of @@)

The operators `&&`, `@>` and `<@` are equivalent to Postgres Pro's built-in operators of the same names, except that they work only on integer arrays that do not contain nulls, while the built-in operators work for any array type. This restriction makes them faster than the built-in operators in many cases.

The `@@` and `~~` operators test whether an array satisfies a *query*, which is expressed as a value of a specialized data type `query_int`. A *query* consists of integer values that are checked against the elements of the array, possibly combined using the operators `&` (AND), `|` (OR), and `!` (NOT). Parentheses can be used as needed. For example, the query `1 & (2 | 3)` matches arrays that contain 1 and also contain either 2 or 3.

F.27.2. Index Support

`intarray` provides index support for the `&&`, `@>`, and `@@` operators, as well as regular array equality.

Two parameterized GiST index operator classes are provided: `gist__int_ops` (used by default) is suitable for small- to medium-size data sets, while `gist__intbig_ops` uses a larger signature and is more

suitable for indexing large data sets (i.e., columns containing a large number of distinct array values). The implementation uses an RD-tree data structure with built-in lossy compression.

`gist__int_ops` approximates an integer set as an array of integer ranges. Its optional integer parameter `numranges` determines the maximum number of ranges in one index key. The default value of `numranges` is 100. Valid values are between 1 and 253. Using larger arrays as GiST index keys leads to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

`gist__intbig_ops` approximates an integer set as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 16 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

There is also a non-default GIN operator class `gin__int_ops`, which supports these operators as well as `<@`.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

F.27.3. Example

```
-- a message can be in one or more "sections"
CREATE TABLE message (mid INT PRIMARY KEY, sections INT[], ...);

-- create specialized index with signature length of 32 bytes
CREATE INDEX message_rdtree_idx ON message USING GIST (sections gist__intbig_ops
(siglen = 32));

-- select messages in section 1 OR 2 - OVERLAP operator
SELECT message.mid FROM message WHERE message.sections && '{1,2}';

-- select messages in sections 1 AND 2 - CONTAINS operator
SELECT message.mid FROM message WHERE message.sections @> '{1,2}';

-- the same, using QUERY operator
SELECT message.mid FROM message WHERE message.sections @@ '1&2'::query_int;
```

F.27.4. Authors

All work was done by Teodor Sigaev (<teodor@sigaev.ru>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megera/postgres/gist/> for additional information. Andrey Oktyabrski did a great work on adding new functions and operations.

F.28. isn — data types for international standard numbers (ISBN, EAN, UPC, etc.)

The `isn` module provides data types for the following international product numbering standards: EAN13, UPC, ISBN (books), ISMN (music), and ISSN (serials). Numbers are validated on input according to a hard-coded list of prefixes; this list of prefixes is also used to hyphenate numbers on output. Since new prefixes are assigned from time to time, the list of prefixes may be out of date. It is hoped that a future version of this module will obtain the prefix list from one or more tables that can be easily updated by users as needed; however, at present, the list can only be updated by modifying the source code and recompiling. Alternatively, prefix validation and hyphenation support may be dropped from a future version of this module.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.28.1. Data Types

Table F.15 shows the data types provided by the `isn` module.

Table F.15. isn Data Types

Data Type	Description
EAN13	European Article Numbers, always displayed in the EAN13 display format
ISBN13	International Standard Book Numbers to be displayed in the new EAN13 display format
ISMN13	International Standard Music Numbers to be displayed in the new EAN13 display format
ISSN13	International Standard Serial Numbers to be displayed in the new EAN13 display format
ISBN	International Standard Book Numbers to be displayed in the old short display format
ISMN	International Standard Music Numbers to be displayed in the old short display format
ISSN	International Standard Serial Numbers to be displayed in the old short display format
UPC	Universal Product Codes

Some notes:

1. ISBN13, ISMN13, ISSN13 numbers are all EAN13 numbers.
2. EAN13 numbers aren't always ISBN13, ISMN13 or ISSN13 (some are).
3. Some ISBN13 numbers can be displayed as ISBN.
4. Some ISMN13 numbers can be displayed as ISMN.
5. Some ISSN13 numbers can be displayed as ISSN.
6. UPC numbers are a subset of the EAN13 numbers (they are basically EAN13 without the first 0 digit).
7. All UPC, ISBN, ISMN and ISSN numbers can be represented as EAN13 numbers.

Internally, all these types use the same representation (a 64-bit integer), and all are interchangeable. Multiple types are provided to control display formatting and to permit tighter validity checking of input that is supposed to denote one particular type of number.

The `ISBN`, `ISMN`, and `ISSN` types will display the short version of the number (ISxN 10) whenever it's possible, and will show ISxN 13 format for numbers that do not fit in the short version. The `EAN13`, `ISBN13`, `ISMN13` and `ISSN13` types will always display the long version of the ISxN (EAN13).

F.28.2. Casts

The `isn` module provides the following pairs of type casts:

- `ISBN13 <=> EAN13`
- `ISMN13 <=> EAN13`
- `ISSN13 <=> EAN13`
- `ISBN <=> EAN13`
- `ISMN <=> EAN13`
- `ISSN <=> EAN13`
- `UPC <=> EAN13`
- `ISBN <=> ISBN13`
- `ISMN <=> ISMN13`
- `ISSN <=> ISSN13`

When casting from `EAN13` to another type, there is a run-time check that the value is within the domain of the other type, and an error is thrown if not. The other casts are simply relabelings that will always succeed.

F.28.3. Functions and Operators

The `isn` module provides the standard comparison operators, plus B-tree and hash indexing support for all these data types. In addition, there are several specialized functions, shown in [Table F.16](#). In this table, `isn` means any one of the module's data types.

Table F.16. `isn` Functions

Function	Description
<code>make_valid (isn) → isn</code>	Clears the invalid-check-digit flag of the value.
<code>is_valid (isn) → boolean</code>	Checks for the presence of the invalid-check-digit flag.
<code>isn_weak (boolean) → boolean</code>	Sets the weak input mode, and returns the new setting. This function is retained for backward compatibility. The recommended way to set weak mode is via the <code>isn_weak</code> configuration parameter.
<code>isn_weak () → boolean</code>	Returns the current status of the weak mode. This function is retained for backward compatibility. The recommended way to check weak mode is via the <code>isn_weak</code> configuration parameter.

F.28.4. Configuration Parameters

`isn_weak (boolean)`

`isn_weak` enables the weak input mode, which allows ISBN input values to be accepted even when their check digit is wrong. The default is `false`, which rejects invalid check digits.

Why would you want to use the weak mode? Well, it could be that you have a huge collection of ISBN numbers, and that there are so many of them that for weird reasons some have the wrong check digit (perhaps the numbers were scanned from a printed list and the OCR got the numbers wrong, perhaps the numbers were manually captured... who knows). Anyway, the point is you might want to clean the

mess up, but you still want to be able to have all the numbers in your database and maybe use an external tool to locate the invalid numbers in the database so you can verify the information and validate it more easily; so for example you'd want to select all the invalid numbers in the table.

When you insert invalid numbers in a table using the weak mode, the number will be inserted with the corrected check digit, but it will be displayed with an exclamation mark (!) at the end, for example 0-11-000322-5!. This invalid marker can be checked with the `is_valid` function and cleared with the `make_valid` function.

You can also force the insertion of marked-as-invalid numbers even when not in the weak mode, by appending the `!` character at the end of the number.

Another special feature is that during input, you can write `?` in place of the check digit, and the correct check digit will be inserted automatically.

F.28.5. Examples

```
--Using the types directly:
SELECT isbn('978-0-393-04002-9');
SELECT isbn13('0901690546');
SELECT issn('1436-4522');

--Casting types:
-- note that you can only cast from ean13 to another type when the
-- number would be valid in the realm of the target type;
-- thus, the following will NOT work: select isbn(ean13('0220356483481'));
-- but these will:
SELECT upc(ean13('0220356483481'));
SELECT ean13(upc('220356483481'));

--Create a table with a single column to hold ISBN numbers:
CREATE TABLE test (id isbn);
INSERT INTO test VALUES('9780393040029');

--Automatically calculate check digits (observe the '?'):
INSERT INTO test VALUES('220500896?');
INSERT INTO test VALUES('978055215372?');

SELECT issn('3251231?');
SELECT ismn('979047213542?');

--Using the weak mode:
SET isn.weak TO true;
INSERT INTO test VALUES('978-0-11-000533-4');
INSERT INTO test VALUES('9780141219307');
INSERT INTO test VALUES('2-205-00876-X');
SET isn.weak TO false;

SELECT id FROM test WHERE NOT is_valid(id);
UPDATE test SET id = make_valid(id) WHERE id = '2-205-00876-X!';

SELECT * FROM test;

SELECT isbn13(id) FROM test;
```

F.28.6. Bibliography

The information to implement this module was collected from several sites, including:

- <https://www.isbn-international.org/>

- <https://www.issn.org/>
- <https://www.ismn-international.org/>
- <https://www.wikipedia.org/>

The prefixes used for hyphenation were also compiled from:

- <https://www.gs1.org/standards/id-keys>
- https://en.wikipedia.org/wiki/List_of_ISBN_registration_groups
- <https://www.isbn-international.org/content/isbn-users-manual/29>
- https://en.wikipedia.org/wiki/International_Standard_Music_Number
- <https://www.ismn-international.org/ranges/tools>

Care was taken during the creation of the algorithms and they were meticulously verified against the suggested algorithms in the official ISBN, ISMN, ISSN User Manuals.

F.28.7. Author

Germán Méndez Bravo (Kronuz), 2004–2006

This module was inspired by Garrett A. Wollman's `isbn_issn` code.

F.29. jquery — a language to query jsonb data type

jQuery is a language to query jsonb data type. Its primary goal is to provide an additional functionality for jsonb, such as a simple and effective way for search in nested objects and arrays, as well as additional comparison operators with index support.

jQuery is implemented by means of a jquery data type (similar to tsquery) and the @@ match operator for jsonb.

F.29.1. Installation

Postgres Pro Standard distribution includes jquery as a contrib module. Once you complete Postgres Pro Standard installation, create the jquery extension, as follows:

```
CREATE EXTENSION jquery;
```

F.29.2. JSON query language

jQuery extension contains jquery datatype which represents whole JSON query as a single value (like tsquery does for fulltext search). The query is an expression on JSON-document values.

Simple expression is specified as *path binary_operator value* or *path unary_operator*. See the following examples.

- `x = "abc"` - value of key "x" is equal to "abc";
- `$ @> [4, 5, "zzz"]` - the JSON document is an array containing values 4, 5 and "zzz";
- `"abc xyz" >= 10` - value of key "abc xyz" is greater than or equal to 10;
- `volume IS NUMERIC` - type of key "volume" is numeric.
- `$ = true` - the whole JSON document is just a true.
- `similar_ids.@# > 5` - similar_ids is an array or object of length greater than 5;
- `similar_product_ids.# = "0684824396"` - array similar_product_ids contains string "0684824396".
- `*.color = "red"` - there is object somewhere which key "color" has value "red".
- `foo = *` - key "foo" exists in object.

Path selects set of JSON values to be checked using given operators. In the simplest case, path is just a key name. In general, path is key names and placeholders combined by dot signs. Path can use the following placeholders:

- `#` - any index of array;
- `#N` - Nth index of array;
- `%` - any key of object;
- `*` - any sequence of array indexes and object keys;
- `@#` - length of array or object, could be only used as last component of path;
- `$` - the whole JSON document as single value, could be only the whole path.

Expression is true when operator is true against at least one value selected by path.

Key names could be given either with or without double quotes. Key names without double quotes shouldn't contain spaces, start with number, or concur with jquery keyword.

The supported binary operators are:

- Equality operator: `=`;
- Numeric comparison operators: `>`, `>=`, `<`, `<=`;
- Search in the list of scalar values using `IN` operator;
- Array comparison operators: `&&` (overlap), `@>` (contains), `<@` (contained in).
- Filtering operator: `~~`. Taking jsonb data as the left operand and a jquery expression as the right operand, this operator checks that jsonb data contains any entries that satisfy the condition provided in a jquery expression and returns an array of such entries, if any.

The supported unary operators are:

- Check for existence operator: `= *`;
- Check for type operators: `IS ARRAY`, `IS NUMERIC`, `IS OBJECT`, `IS STRING` and `IS BOOLEAN`.

Expressions could be complex. Complex expression is a set of expressions combined by logical operators (`AND`, `OR`, `NOT`) and grouped using parentheses.

Examples of complex expressions are given below.

- `a = 1 AND (b = 2 OR c = 3) AND NOT d = 1`
- `x.% = true OR x.# = true`

Prefix expressions are expressions given in the form `path (subexpression)`. In this case `path` selects JSON values to be checked using given subexpression. Check results are aggregated in the same way as in simple expressions.

- `#(a = 1 AND b = 2)` - an array contains an element where the `a` key is 2 and the `b` key is 2
- `%($ >= 10 AND $ <= 20)` - an object contains a key with a value between 10 and 20

Path also could contain the following special placeholders with "every" semantics:

- `#:` - every index of array;
- `%:` - every key of object;
- `*` - every sequence of array indexes and object keys.

Consider the following example.

```
%.#:( $ >= 0 AND $ <= 1 )
```

This example could be read as follows: there is at least one key for which the value is an array of numerics between 0 and 1.

We can rewrite this example in the following form with extra parentheses.

```
%(#:( $ >= 0 AND $ <= 1 ) )
```

The first placeholder `%` checks that expression in parentheses is true for at least one value in object. The second placeholder `#:` checks that the value is an array and all its elements satisfy expressions in parentheses.

We can rewrite this example without `#:` placeholder as follows.

```
%(NOT #(NOT ( $ >= 0 AND $ <= 1 ) ) AND $ IS ARRAY)
```

In this example we transform assertion that every element of array satisfies some condition to assertion that there is no one element which doesn't satisfy the same condition.

Some examples of using paths are given below.

- `numbers.#: IS NUMERIC` - every element of "numbers" array is numeric.
- `*:($ IS OBJECT OR $ IS BOOLEAN)` - JSON is a structure of nested objects with booleans as leaf values.
- `#.:%:($ >= 0 AND $ <= 1)` - each element of array is object containing only numeric values between 0 and 1.
- `documents.#:.% = *` - "documents" is an array of objects containing at least one key.
- `%.#:($ IS STRING)` - JSON object contains at least one array of strings.
- `%.% = true` - at least one array element is an object that contains at least one "true" value.

Usage of path operators and parentheses needs some explanation. When same path operators are used multiple times they may refer to different values while you can refer to the same value multiple times by using parentheses and `$` operator. See the following examples.

- `# < 10 AND # > 20` - there is an element less than 10 and another element greater than 20.

- `#($ < 10 AND $ > 20)` - there is an element that is both less than 10 and greater than 20 (impossible).
- `#($ >= 10 AND $ <= 20)` - there is an element between 10 and 20.
- `# >= 10 AND # <= 20` - there is an element greater than or equal to 10 and another element less than or equal to 20. The query can be satisfied by an array with no elements between 10 and 20, for instance `[0,30]`.

Same rules apply when you search inside objects and branchy structures.

Type checking operators and "every" placeholders are useful for document schema validation. JQuery matching operator `@@` is immutable and can be used in CHECK constraint. See the following example.

```
CREATE TABLE js (  
    id serial,  
    data jsonb,  
    CHECK (data @@ '  
        name IS STRING AND  
        similar_ids.#: IS NUMERIC AND  
        points.#:(x IS NUMERIC AND y IS NUMERIC) '::jsquery));
```

In this example check constraint validates that in "data" jsonb column: value of "name" key is string, value of "similar_ids" key is array of numerics, value of "points" key is array of objects which contain numeric values in "x" and "y" keys.

See our [pgconf.eu presentation](https://pgconf.eu/presentation) for more examples.

F.29.3. GIN indexes

JsQuery extension contains two operator classes (opclasses) for GIN which provide different kinds of query optimization.

- `jsonb_path_value_ops`
- `jsonb_value_path_ops`

In each of two GIN opclasses jsonb documents are decomposed into entries. Each entry is associated with a particular value and its path. Difference between opclasses is in the entry representation, comparison, and usage for search optimization.

For example, jsonb document `{"a": [{ "b": "xyz", "c": true }, 10], "d": { "e": [7, false] }}` would be decomposed into the following entries:

- `"a".#."b"."xyz"`
- `"a".#."c".true`
- `"a".#.10`
- `"d"."e".#.7`
- `"d"."e".#.false`

Since JQuery doesn't support search in a particular array index, we consider all array elements to be equivalent. Thus, each array element is marked with the same # sign in the path.

Major problem in the entries representation is its size. In the given example key "a" is presented three times. In the large branchy documents with long keys size of naive entries representation becomes unreasonable. Both opclasses address this issue but in a slightly different way.

F.29.3.1. jsonb_path_value_ops

`jsonb_path_value_ops` represents entry as pair of path hash and value. The following pseudocode illustrates it.

```
(hash(path_item_1.path_item_2. ... .path_item_n); value)
```

In comparison of entries path hash is the higher part of entry and value is its lower part. This determines the features of this opclass. Since path is hashed and it is higher part of entry we need to know the full

path to the value in order to use it for search. However, once path is specified we can use both exact and range searches very efficiently.

F.29.3.2. jsonb_value_path_ops

jsonb_value_path_ops represents entry as pair of value and bloom filter of path.

```
(value; bloom(path_item_1) | bloom(path_item_2) | ... | bloom(path_item_n))
```

In comparison of entries value is the higher part of entry and bloom filter of path is its lower part. This determines the features of this opclass. Since value is the higher part of entry we can perform only exact value search efficiently. Range value search is possible as well but we would have to filter all the different paths where matching values occur. Bloom filter over path items allows index usage for conditions containing % and * in their paths.

F.29.3.3. Query optimization

JsQuery opclasses perform complex query optimization. Thus it's valuable for developer or administrator to see the result of such optimization. Unfortunately, opclasses aren't allowed to do any custom output to the EXPLAIN. That's why JsQuery provides the following functions which allows to see how particular opclass optimizes given query.

- gin_debug_query_path_value(jsquery) - for jsonb_path_value_ops
- gin_debug_query_value_path(jsquery) - for jsonb_value_path_ops

Result of these functions is a textual representation of query tree which leaves are GIN search entries. The following examples show different results of query optimization by different opclasses.

```
# SELECT gin_debug_query_path_value('x = 1 AND (*.y = 1 OR y = 2)');
gin_debug_query_path_value
-----
x = 1 , entry 0           +

# SELECT gin_debug_query_value_path('x = 1 AND (*.y = 1 OR y = 2)');
gin_debug_query_value_path
-----
AND                        +
  x = 1 , entry 0          +
  OR                       +
    *.y = 1 , entry 1      +
    y = 2 , entry 2        +
```

Unfortunately, jsonb has no statistics yet. That's why JsQuery optimizer has to do imperative decision while selecting conditions to be evaluated using index. This decision is made by assumption that some condition types are less selective than others. Optimizer divides conditions into the following selectivity class (listed by descending of selectivity).

1. Equality ($x = c$)
2. Range ($c1 < x < c2$)
3. Inequality ($x > c$)
4. Is (x is type)
5. Any ($x = *$)

Optimizer evades index evaluation of less selective conditions when possible. For example, in the $x = 1$ AND $y > 0$ query $x = 1$ is assumed to be more selective than $y > 0$. That's why index isn't used for evaluation of $y > 0$.

```
# SELECT gin_debug_query_path_value('x = 1 AND y > 0');
gin_debug_query_path_value
-----
x = 1 , entry 0           +
```

With lack of statistics decisions made by optimizer can be inaccurate. That's why JQuery supports hints. Comments `/*-- index */` and `/*-- noindex */` placed in the conditions force optimizer to use and not to use index correspondingly.

```
SELECT gin_debug_query_path_value('x = 1 AND y /*-- index */ > 0');
gin_debug_query_path_value
-----
AND                               +
  x = 1 , entry 0                 +
  y > 0 , entry 1                 +

SELECT gin_debug_query_path_value('x /*-- noindex */ = 1 AND y > 0');
gin_debug_query_path_value
-----
y > 0 , entry 0                 +
```

F.30. lo — manage large objects

The `lo` module provides support for managing Large Objects (also called LOs or BLOBs). This includes a data type `lo` and a trigger `lo_manage`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.30.1. Rationale

One of the problems with the JDBC driver (and this affects the ODBC driver also), is that the specification assumes that references to BLOBs (Binary Large Objects) are stored within a table, and if that entry is changed, the associated BLOB is deleted from the database.

As Postgres Pro stands, this doesn't occur. Large objects are treated as objects in their own right; a table entry can reference a large object by OID, but there can be multiple table entries referencing the same large object OID, so the system doesn't delete the large object just because you change or remove one such entry.

Now this is fine for Postgres Pro-specific applications, but standard code using JDBC or ODBC won't delete the objects, resulting in orphan objects — objects that are not referenced by anything, and simply occupy disk space.

The `lo` module allows fixing this by attaching a trigger to tables that contain LO reference columns. The trigger essentially just does a `lo_unlink` whenever you delete or modify a value referencing a large object. When you use this trigger, you are assuming that there is only one database reference to any large object that is referenced in a trigger-controlled column!

The module also provides a data type `lo`, which is really just a [domain](#) over the `oid` type. This is useful for differentiating database columns that hold large object references from those that are OIDs of other things. You don't have to use the `lo` type to use the trigger, but it may be convenient to use it to keep track of which columns in your database represent large objects that you are managing with the trigger. It is also rumored that the ODBC driver gets confused if you don't use `lo` for BLOB columns.

F.30.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE image (title text, raster lo);

CREATE TRIGGER t_raster BEFORE UPDATE OR DELETE ON image
    FOR EACH ROW EXECUTE FUNCTION lo_manage(raster);
```

For each column that will contain unique references to large objects, create a `BEFORE UPDATE OR DELETE` trigger, and give the column name as the sole trigger argument. You can also restrict the trigger to only execute on updates to the column by using `BEFORE UPDATE OF column_name`. If you need multiple `lo` columns in the same table, create a separate trigger for each one, remembering to give a different name to each trigger on the same table.

F.30.3. Limitations

- Dropping a table will still orphan any objects it contains, as the trigger is not executed. You can avoid this by preceding the `DROP TABLE` with `DELETE FROM table`.

`TRUNCATE` has the same hazard.

If you already have, or suspect you have, orphaned large objects, see the [vacuumlo](#) module to help you clean them up. It's a good idea to run `vacuumlo` occasionally as a back-stop to the `lo_manage` trigger.

- Some frontends may create their own tables, and will not create the associated trigger(s). Also, users may not remember (or know) to create the triggers.

Peter Mount <peter@retep.org.uk>

F.31. ltree — hierarchical tree-like data type

This module implements a data type `ltree` for representing labels of data stored in a hierarchical tree-like structure. Extensive facilities for searching through label trees are provided.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.31.1. Definitions

A *label* is a sequence of alphanumeric characters, underscores, and hyphens. Valid alphanumeric character ranges are dependent on the database locale. For example, in C locale, the characters `A-Za-z0-9_` are allowed. Labels must be no more than 1000 characters long.

Examples: `42`, `Personal_Services`

A *label path* is a sequence of zero or more labels separated by dots, for example `L1.L2.L3`, representing a path from the root of a hierarchical tree to a particular node. The length of a label path cannot exceed 65535 labels.

Example: `Top.Countries.Europe.Russia`

The `ltree` module provides several data types:

- `ltree` stores a label path.
- `lquery` represents a regular-expression-like pattern for matching `ltree` values. A simple word matches that label within a path. A star symbol (`*`) matches zero or more labels. These can be joined with dots to form a pattern that must match the whole label path. For example:

<code>foo</code>	<i>Match the exact label path foo</i>
<code>*.foo.*</code>	<i>Match any label path containing the label foo</i>
<code>*.foo</code>	<i>Match any label path whose last label is foo</i>

Both star symbols and simple words can be quantified to restrict how many labels they can match:

<code>{n}</code>	<i>Match exactly n labels</i>
<code>{n, }</code>	<i>Match at least n labels</i>
<code>{n, m}</code>	<i>Match at least n but not more than m labels</i>
<code>{, m}</code>	<i>Match at most m labels — same as <code>{0, m}</code></i>
<code>foo{n, m}</code>	<i>Match at least n but not more than m occurrences of foo</i>
<code>foo{, }</code>	<i>Match any number of occurrences of foo, including zero</i>

In the absence of any explicit quantifier, the default for a star symbol is to match any number of labels (that is, `{, }`) while the default for a non-star item is to match exactly once (that is, `{1}`).

There are several modifiers that can be put at the end of a non-star `lquery` item to make it match more than just the exact match:

<code>@</code>	<i>Match case-insensitively, for example <code>a@</code> matches <code>A</code></i>
<code>*</code>	<i>Match any label with this prefix, for example <code>foo*</code> matches <code>foobar</code></i>
<code>%</code>	<i>Match initial underscore-separated words</i>

The behavior of `%` is a bit complicated. It tries to match words rather than the entire label. For example `foo_bar%` matches `foo_bar_baz` but not `foo_barbaz`. If combined with `*`, prefix matching applies to each word separately, for example `foo_bar%*` matches `foo1_bar2_baz` but not `foo1_br2_baz`.

Also, you can write several possibly-modified non-star items separated with `|` (OR) to match any of those items, and you can put `!` (NOT) at the start of a non-star group to match any label that doesn't match any of the alternatives. A quantifier, if any, goes at the end of the group; it means some number of matches for the group as a whole (that is, some number of labels matching or not matching any of the alternatives).

Here's an annotated example of `lquery`:

```
Top.*{0,2}.sport*@.!football|tennis{1,}.Russ*|Spain
a.  b.      c.      d.      e.
```

This query will match any label path that:

- a. begins with the label `Top`
 - b. and next has zero to two labels before
 - c. a label beginning with the case-insensitive prefix `sport`
 - d. then has one or more labels, none of which match `football` nor `tennis`
 - e. and then ends with a label beginning with `Russ` or exactly matching `Spain`.
- `ltxquery` represents a full-text-search-like pattern for matching `ltree` values. An `ltxquery` value contains words, possibly with the modifiers `@`, `*`, `%` at the end; the modifiers have the same meanings as in `lquery`. Words can be combined with `&` (AND), `|` (OR), `!` (NOT), and parentheses. The key difference from `lquery` is that `ltxquery` matches words without regard to their position in the label path.

Here's an example `ltxquery`:

```
Europe & Russia*@ & !Transportation
```

This will match paths that contain the label `Europe` and any label beginning with `Russia` (case-insensitive), but not paths containing the label `Transportation`. The location of these words within the path is not important. Also, when `%` is used, the word can be matched to any underscore-separated word within a label, regardless of position.

Note: `ltxquery` allows whitespace between symbols, but `ltree` and `lquery` do not.

F.31.2. Operators and Functions

Type `ltree` has the usual comparison operators `=`, `<>`, `<`, `>`, `<=`, `>=`. Comparison sorts in the order of a tree traversal, with the children of a node sorted by label text. In addition, the specialized operators shown in [Table F.17](#) are available.

Table F.17. `ltree` Operators

Operator	Description
<code>ltree @> ltree → boolean</code> Is left argument an ancestor of right (or equal)?	
<code>ltree <@ ltree → boolean</code> Is left argument a descendant of right (or equal)?	
<code>ltree ~ lquery → boolean</code> <code>lquery ~ ltree → boolean</code> Does <code>ltree</code> match <code>lquery</code> ?	
<code>ltree ? lquery[] → boolean</code> <code>lquery[] ? ltree → boolean</code> Does <code>ltree</code> match any <code>lquery</code> in array?	
<code>ltree @ ltxquery → boolean</code> <code>ltxquery @ ltree → boolean</code> Does <code>ltree</code> match <code>ltxquery</code> ?	
<code>ltree ltree → ltree</code>	

Operator	Description
	Concatenates <code>ltree</code> paths.
<code>ltree text → ltree</code> <code>text ltree → ltree</code>	Converts <code>text</code> to <code>ltree</code> and concatenates.
<code>ltree[] @> ltree → boolean</code> <code>ltree <@ ltree[] → boolean</code>	Does array contain an ancestor of <code>ltree</code> ?
<code>ltree[] <@ ltree → boolean</code> <code>ltree @> ltree[] → boolean</code>	Does array contain a descendant of <code>ltree</code> ?
<code>ltree[] ~ lquery → boolean</code> <code>lquery ~ ltree[] → boolean</code>	Does array contain any path matching <code>lquery</code> ?
<code>ltree[] ? lquery[] → boolean</code> <code>lquery[] ? ltree[] → boolean</code>	Does <code>ltree</code> array contain any path matching any <code>lquery</code> ?
<code>ltree[] @ ltxtquery → boolean</code> <code>ltxtquery @ ltree[] → boolean</code>	Does array contain any path matching <code>ltxtquery</code> ?
<code>ltree[] ?@> ltree → ltree</code>	Returns first array entry that is an ancestor of <code>ltree</code> , or <code>NULL</code> if none.
<code>ltree[] ?<@ ltree → ltree</code>	Returns first array entry that is a descendant of <code>ltree</code> , or <code>NULL</code> if none.
<code>ltree[] ?~ lquery → ltree</code>	Returns first array entry that matches <code>lquery</code> , or <code>NULL</code> if none.
<code>ltree[] ?@ ltxtquery → ltree</code>	Returns first array entry that matches <code>ltxtquery</code> , or <code>NULL</code> if none.

The operators `<@`, `@>`, `@` and `~` have analogues `^<@`, `^@>`, `^@`, `^~`, which are the same except they do not use indexes. These are useful only for testing purposes.

The available functions are shown in [Table F.18](#).

Table F.18. `ltree` Functions

Function	Description	Example(s)
<code>subltree (ltree, start integer, end integer) → ltree</code>	Returns subpath of <code>ltree</code> from position <code>start</code> to position <code>end-1</code> (counting from 0).	<code>subltree('Top.Child1.Child2', 1, 2) → Child1</code>
<code>subpath (ltree, offset integer, len integer) → ltree</code>	Returns subpath of <code>ltree</code> starting at position <code>offset</code> , with length <code>len</code> . If <code>offset</code> is negative, subpath starts that far from the end of the path. If <code>len</code> is negative, leaves that many labels off the end of the path.	<code>subpath('Top.Child1.Child2', 0, 2) → Top.Child1</code>

Function	Description	Example(s)
<code>subpath (ltree, offset integer) → ltree</code>	Returns subpath of <code>ltree</code> starting at position <code>offset</code> , extending to end of path. If <code>offset</code> is negative, subpath starts that far from the end of the path.	<code>subpath('Top.Child1.Child2', 1) → Child1.Child2</code>
<code>nlevel (ltree) → integer</code>	Returns number of labels in path.	<code>nlevel('Top.Child1.Child2') → 3</code>
<code>index (a ltree, b ltree) → integer</code>	Returns position of first occurrence of <code>b</code> in <code>a</code> , or -1 if not found.	<code>index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6') → 6</code>
<code>index (a ltree, b ltree, offset integer) → integer</code>	Returns position of first occurrence of <code>b</code> in <code>a</code> , or -1 if not found. The search starts at position <code>offset</code> ; negative <code>offset</code> means start <code>-offset</code> labels from the end of the path.	<code>index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6', -4) → 9</code>
<code>text2ltree (text) → ltree</code>	Casts <code>text</code> to <code>ltree</code> .	
<code>ltree2text (ltree) → text</code>	Casts <code>ltree</code> to <code>text</code> .	
<code>lca (ltree [, ltree [, ...]]) → ltree</code>	Computes longest common ancestor of paths (up to 8 arguments are supported).	<code>lca('1.2.3', '1.2.3.4.5.6') → 1.2</code>
<code>lca (ltree[]) → ltree</code>	Computes longest common ancestor of paths in array.	<code>lca(array['1.2.3'::ltree, '1.2.3.4']) → 1.2</code>

F.31.3. Indexes

`ltree` supports several types of indexes that can speed up the indicated operators:

- B-tree index over `ltree`: `<`, `<=`, `=`, `>=`, `>`
- Hash index over `ltree`: `=`
- GiST index over `ltree` (`gist_ltree_ops` opclass): `<`, `<=`, `=`, `>=`, `>`, `@>`, `<@`, `@`, `~`, `?`

`gist_ltree_ops` GiST opclass approximates a set of path labels as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 8 bytes. The length must be a positive multiple of `int` alignment (4 bytes on most machines) up to 2024. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with the default signature length of 8 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (path);
```

Example of creating such an index with a signature length of 100 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (path gist_ltree_ops(siglen=100));
```

- GiST index over `ltree[]` (`gist__ltree_ops` opclass): `ltree[] <@ ltree, ltree @> ltree[], @, ~, ?`

`gist__ltree_ops` GiST opclass works similarly to `gist_ltree_ops` and also takes signature length as a parameter. The default value of `siglen` in `gist__ltree_ops` is 28 bytes.

Example of creating such an index with the default signature length of 28 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path);
```

Example of creating such an index with a signature length of 100 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path  
gist__ltree_ops(siglen=100));
```

Note: This index type is lossy.

F.31.4. Example

This example uses the following data (also available in file `contrib/ltree/ltreetest.sql` in the source distribution):

```
CREATE TABLE test (path ltree);  
INSERT INTO test VALUES ('Top');  
INSERT INTO test VALUES ('Top.Science');  
INSERT INTO test VALUES ('Top.Science.Astronomy');  
INSERT INTO test VALUES ('Top.Science.Astronomy.Astrophysics');  
INSERT INTO test VALUES ('Top.Science.Astronomy.Cosmology');  
INSERT INTO test VALUES ('Top.Hobbies');  
INSERT INTO test VALUES ('Top.Hobbies.Amateurs_Astronomy');  
INSERT INTO test VALUES ('Top.Collections');  
INSERT INTO test VALUES ('Top.Collections.Pictures');  
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy');  
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Stars');  
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Galaxies');  
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Astronauts');  
CREATE INDEX path_gist_idx ON test USING GIST (path);  
CREATE INDEX path_idx ON test USING BTREE (path);  
CREATE INDEX path_hash_idx ON test USING HASH (path);
```

Now, we have a table `test` populated with data describing the hierarchy shown below:

```
          Top  
        /  |  \  
    Science Hobbies Collections  
      /      |      \  
Astronomy Amateurs_Astronomy Pictures  
  /  \  
Astrophysics Cosmology  
                                Astronomy  
                              /  |  \  
                          Galaxies Stars Astronauts
```

We can do inheritance:

```
ltreetest=> SELECT path FROM test WHERE path <@ 'Top.Science';  
           path
```

```
-----  
Top.Science  
Top.Science.Astronomy  
Top.Science.Astronomy.Astrophysics  
Top.Science.Astronomy.Cosmology  
(4 rows)
```

Here are some examples of path matching:

**Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib**

```
ltreetest=> SELECT path FROM test WHERE path ~ '*.Astronomy.*';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
Top.Collections.Pictures.Astronomy
Top.Collections.Pictures.Astronomy.Stars
Top.Collections.Pictures.Astronomy.Galaxies
Top.Collections.Pictures.Astronomy.Astronauts
(7 rows)
```

```
ltreetest=> SELECT path FROM test WHERE path ~ '.*!pictures@.Astronomy.*';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(3 rows)
```

Here are some examples of full text search:

```
ltreetest=> SELECT path FROM test WHERE path @ 'Astro*% & !pictures@';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
Top.Hobbies.Amateurs_Astronomy
(4 rows)
```

```
ltreetest=> SELECT path FROM test WHERE path @ 'Astro* & !pictures@';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(3 rows)
```

Path construction using functions:

```
ltreetest=> SELECT subpath(path,0,2) || 'Space' || subpath(path,2) FROM test WHERE path <@
'Top.Science.Astronomy';
           ?column?
```

```
-----
Top.Science.Space.Astronomy
Top.Science.Space.Astronomy.Astrophysics
Top.Science.Space.Astronomy.Cosmology
(3 rows)
```

We could simplify this by creating an SQL function that inserts a label at a specified position in a path:

```
CREATE FUNCTION ins_label(ltree, int, text) RETURNS ltree
AS 'select subpath($1,0,$2) || $3 || subpath($1,$2);'
LANGUAGE SQL IMMUTABLE;
```

```
ltreetest=> SELECT ins_label(path,2,'Space') FROM test WHERE path <@
'Top.Science.Astronomy';
           ins_label
```

```
Top.Science.Space.Astronomy
Top.Science.Space.Astronomy.Astrophysics
Top.Science.Space.Astronomy.Cosmology
(3 rows)
```

F.31.5. Transforms

The `ltree_plpython3u` extension implements transforms for the `ltree` type for PL/Python. If installed and specified when creating a function, `ltree` values are mapped to Python lists. (The reverse is currently not supported, however.)

F.31.6. Authors

All work was done by Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megera/postgres/gist/> for additional information. Authors would like to thank Eugeny Rodichev for helpful discussions. Comments and bug reports are welcome.

F.32. mchar — additional data types for compatibility with Microsoft SQL Server

The `mchar` module provides additional data types for compatibility with Microsoft SQL Server (MS SQL).

F.32.1. Overview

This module has been designed to improve 1C Enterprise support, most popular Russian CRM and ERP system.

It implements types `MCHAR` and `MVARCHAR`, which are bug-to-bug compatible with MS SQL `CHAR` and `VARCHAR` respectively. Additionally, these types use the ICU library for comparison and case conversion, so their behavior is identical across different operating systems.

Postgres Pro also includes `citext` extension which provides types similar to `MCHAR`. But this extension doesn't emulate MS-SQL behavior concerning end-of-value whitespace.

Differences from Postgres Pro standard `CHAR` and `VARCHAR` are:

- Case insensitive comparison
- Handling of the whitespace at the end of string
- These types are always stored as two-byte unicode value regardless of database encoding.

F.32.2. Additional types

- `mchar` — analog of the MS SQL char type
- `mvarchar` — analog of the MS SQL varchar type

F.32.3. MCHAR and MVARCHAR features

- Defines `length(str)` function
- Defines `substr(str, pos[, length])` function
- Defines `||` operator, which would be applied to concatenate any (`mchar` and `mvarchar`) arguments
- Defines set of operators: `<`, `<=`, `=`, `>=`, `>` for case-insensitive comparison (ICU)
- Defines set of operators: `&<`, `&<=`, `&=`, `&>=`, `&>` to case-sensitive comparison (ICU)
- Implicit cast between `mchar` and `mvarchar` types
- B-tree and Hash-index support
- The `LIKE [ESCAPE]` operator support
- The `SIMILAR TO [ESCAPE]` operator support
- The `~` operator (POSIX regexp) support
- Index support for the `LIKE` operator

F.32.4. Authors

Oleg Bartunov <oleg@sai.msu.ru>
Teodor Sigaev <teodor@sigaev.ru>

F.33. `online_analyze` — update statistics after INSERT, UPDATE, DELETE, SELECT INTO, or COPY operations

The `online_analyze` module provides a set of features that immediately update statistics after INSERT, UPDATE, DELETE, SELECT INTO, or COPY operations for the affected tables.

Note

It is not recommended to use this module with modern versions of 1C.

However, you can enable `online_analyze` if background updates do not provide the desired result or if the optimizer frequently fails to estimate the row count.

The instruction below is relevant only if you decide to use the module.

F.33.1. Module Loading

To use `online_analyze` module, load the shared library:

```
LOAD 'online_analyze';
```

F.33.2. Module Configuration

You can configure `online_analyze` using the following custom variables (default values are shown):

- `online_analyze.enable = on`

Enables `online_analyze`.

- `online_analyze.verbose = on`

Executes `ANALYZE VERBOSE`.

Note

Since `verbose` is a reserved SQL key word, this parameter has to be double-quoted when used in SQL queries. For example:

```
ALTER SYSTEM SET "online_analyze.verbose" = 'off';
```

- `online_analyze.scale_factor = 0.1`

Fraction of table size to start online analysis (similar to [autovacuum_analyze_scale_factor](#)).

- `online_analyze.threshold = 50`

Minimum number of row updates before starting online analysis (similar to [autovacuum_analyze_threshold](#)).

- `online_analyze.min_interval = 10000`

Minimum time interval between `ANALYZE` calls per table, in milliseconds.

- `online_analyze.table_type = "all"`

Type(s) of tables for online analysis. Possible values are: `all`, `persistent`, `temporary`, `none`.

- `online_analyze.exclude_tables = ""`

List of tables to exclude from online analysis.

- `online_analyze.include_tables = ''`

List of tables to include in online analysis (`online_analyze.include_tables` **overrides** `online_analyze.exclude_tables`).

- `online_analyze.local_tracking = off`

Enables per-backend tracking for temporary tables by `online_analyze`. When this variable is set to `off`, `online_analyze` uses the default system statistics for temporary tables.

- `online_analyze.lower_limit = 0`

Minimum number of rows in a table required to trigger `online_analyze`.

- `online_analyze.capacity_threshold = 100000`

Maximum number of temporary tables to store in local cache.

F.33.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

F.34. pageinspect — low-level inspection of database pages

The `pageinspect` module provides functions that allow you to inspect the contents of database pages at a low level, which is useful for debugging purposes. All of these functions may be used only by superusers.

F.34.1. General Functions

`get_raw_page(relname text, fork text, blkno bigint)` returns `bytea`

`get_raw_page` reads the specified block of the named relation and returns a copy as a `bytea` value. This allows a single time-consistent copy of the block to be obtained. `fork` should be 'main' for the main data fork, 'fsm' for the [free space map](#), 'vm' for the [visibility map](#), or 'init' for the initialization fork.

`get_raw_page(relname text, blkno bigint)` returns `bytea`

A shorthand version of `get_raw_page`, for reading from the main fork. Equivalent to `get_raw_page(relname, 'main', blkno)`

`page_header(page bytea)` returns `record`

`page_header` shows fields that are common to all Postgres Pro heap and index pages.

A page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM page_header(get_raw_page('pg_class', 0));
   lsn      | checksum | flags  | lower | upper | special | pagesize | version |
   prune_xid
-----+-----+-----+-----+-----+-----+-----+-----+
0/24A1B50 |          0 |      1 |   232 |   368 |        8192 |   8192 |        4 |
0
```

The returned columns correspond to the fields in the `PageHeaderData` struct.

The `checksum` field is the checksum stored in the page, which might be incorrect if the page is somehow corrupted. If data checksums are disabled for this instance, then the value stored is meaningless.

`page_checksum(page bytea, blkno bigint)` returns `smallint`

`page_checksum` computes the checksum for the page, as if it was located at the given block.

A page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT page_checksum(get_raw_page('pg_class', 0), 0);
 page_checksum
-----
        13443
```

Note that the checksum depends on the block number, so matching block numbers should be passed (except when doing esoteric debugging).

The checksum computed with this function can be compared with the `checksum` result field of the function `page_header`. If data checksums are enabled for this instance, then the two values should be equal.

`fsm_page_contents(page bytea)` returns `text`

`fsm_page_contents` shows the internal node structure of an FSM page. For example:

```
test=# SELECT fsm_page_contents(get_raw_page('pg_class', 'fsm', 0));
```

The output is a multiline string, with one line per node in the binary tree within the page. Only those nodes that are not zero are printed. The so-called "next" pointer, which points to the next slot to be returned from the page, is also printed.

F.34.2. Heap Functions

`heap_page_items`(page bytea) returns setof record

`heap_page_items` shows all line pointers on a heap page. For those line pointers that are in use, tuple headers as well as tuple raw data are also shown. All tuples are shown, whether or not the tuples were visible to an MVCC snapshot at the time the raw page was copied.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_items(get_raw_page('pg_class', 0));
```

The `heap_tuple_infomask_flags` function can be used to unpack the flag bits of `t_infomask` and `t_infomask2` for heap tuples.

`tuple_data_split`(rel_oid oid, t_data bytea, t_infomask integer, t_infomask2 integer, t_bits text [, do_detoast bool]) returns bytea[]

`tuple_data_split` splits tuple data into attributes in the same way as backend internals.

```
test=# SELECT tuple_data_split('pg_class'::regclass, t_data, t_infomask,
    t_infomask2, t_bits) FROM heap_page_items(get_raw_page('pg_class', 0));
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

If `do_detoast` is true, attributes will be detoasted as needed. Default value is false.

`heap_page_item_attrs`(page bytea, rel_oid regclass [, do_detoast bool]) returns setof record

`heap_page_item_attrs` is equivalent to `heap_page_items` except that it returns tuple raw data as an array of attributes that can optionally be detoasted by `do_detoast` which is false by default.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_item_attrs(get_raw_page('pg_class', 0),
    'pg_class'::regclass);
```

`heap_tuple_infomask_flags`(t_infomask integer, t_infomask2 integer) returns record

`heap_tuple_infomask_flags` decodes the `t_infomask` and `t_infomask2` returned by `heap_page_items` into a human-readable set of arrays made of flag names, with one column for all the flags and one column for combined flags. For example:

```
test=# SELECT t_ctid, raw_flags, combined_flags
    FROM heap_page_items(get_raw_page('pg_class', 0)),
    LATERAL heap_tuple_infomask_flags(t_infomask, t_infomask2)
    WHERE t_infomask IS NOT NULL OR t_infomask2 IS NOT NULL;
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

Combined flags are displayed for source-level macros that take into account the value of more than one raw bit, such as `HEAP_XMIN_FROZEN`.

F.34.3. B-Tree Functions

`bt_metap`(relname text) returns record

`bt_metap` returns information about a B-tree index's metapage. For example:

```
test=# SELECT * FROM bt_metap('pg_cast_oid_index');
-[ RECORD 1 ]-----+-----
magic                | 340322
version              | 4
root                 | 1
```

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

level	0
fastroot	1
fastlevel	0
last_cleanup_num_delpages	0
last_cleanup_num_tuples	230
allequalimage	f

`bt_page_stats(relname text, blkno bigint)` returns record

`bt_page_stats` returns summary information about a data page of a B-tree index. For example:

```
test=# SELECT * FROM bt_page_stats('pg_cast_oid_index', 1);
-[ RECORD 1 ]-+-----
blkno         | 1
type          | 1
live_items    | 224
dead_items    | 0
avg_item_size | 16
page_size     | 8192
free_size     | 3668
btpo_prev     | 0
btpo_next     | 0
btpo_level    | 0
btpo_flags    | 3
```

`bt_multi_page_stats(relname text, blkno bigint, blk_count bigint)` returns setof record

`bt_multi_page_stats` returns the same information as `bt_page_stats`, but does so for each page of the range of pages beginning at `blkno` and extending for `blk_count` pages. If `blk_count` is negative, all pages from `blkno` to the end of the index are reported on. For example:

```
test=# SELECT * FROM bt_multi_page_stats('pg_proc_oid_index', 5, 2);
-[ RECORD 1 ]-+-----
blkno         | 5
type          | 1
live_items    | 367
dead_items    | 0
avg_item_size | 16
page_size     | 8192
free_size     | 808
btpo_prev     | 4
btpo_next     | 6
btpo_level    | 0
btpo_flags    | 1
-[ RECORD 2 ]-+-----
blkno         | 6
type          | 1
live_items    | 367
dead_items    | 0
avg_item_size | 16
page_size     | 8192
free_size     | 808
btpo_prev     | 5
btpo_next     | 7
btpo_level    | 0
btpo_flags    | 1
```

`bt_page_items(relname text, blkno bigint)` returns setof record

`bt_page_items` returns detailed information about all of the items on a B-tree index page. For example:

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

```
test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data, dead, htid, tids[0:2] AS
some_tids
FROM bt_page_items('tenk2_hundred', 5);

(13 rows)
```

This is a B-tree leaf page. All tuples that point to the table happen to be posting list tuples (all of which store a total of 100 6 byte TIDs). There is also a “high key” tuple at `itemoffset` number 1. `ctid` is used to store encoded information about each tuple in this example, though leaf page tuples often store a heap TID directly in the `ctid` field instead. `tids` is the list of TIDs stored as a posting list.

In an internal page (not shown), the block number part of `ctid` is a “downlink”, which is a block number of another page in the index itself. The offset part (the second number) of `ctid` stores encoded information about the tuple, such as the number of columns present (suffix truncation may have removed unneeded suffix columns). Truncated columns are treated as having the value “minus infinity”.

`htid` shows a heap TID for the tuple, regardless of the underlying tuple representation. This value may match `ctid`, or may be decoded from the alternative representations used by posting list tuples and tuples from internal pages. Tuples in internal pages usually have the implementation level heap TID column truncated away, which is represented as a NULL `htid` value.

Note that the first item on any non-rightmost page (any page with a non-zero value in the `btpo_next` field) is the page’s “high key”, meaning its `data` serves as an upper bound on all items appearing on the page, while its `ctid` field does not point to another block. Also, on internal pages, the first real data item (the first item that is not a high key) reliably has every column truncated away, leaving no actual value in its `data` field. Such an item does have a valid downlink in its `ctid` field, however.

For more details about the structure of B-tree indexes, see [Section 63.1.4.1](#). For more details about deduplication and posting lists, see [Section 63.1.4.3](#).

bt_page_items(page bytea) returns setof record

It is also possible to pass a page to bt_page_items as a bytea value. A page image obtained with get_raw_page should be passed as argument. So the last example could also be rewritten like this:

```
test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data, dead, htid, tids[0:2] AS
some_tids
FROM bt_page_items(get_raw_page('tenk2_hundred', 5));
 itemoffset |      ctid      | itemlen | nulls | vars |          data          | dead | htid |
-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+
          1 | (16,1)         |      16 | f      | f      | 30 00 00 00 00 00 00 00 |      |      |
          2 | (16,8292)      |     616 | f      | f      | 24 00 00 00 00 00 00 00 | f      |      |
(1,6)      | {"(1,6)","(10,22)"} |      3 | f      | f      | 25 00 00 00 00 00 00 00 | f      |      |
          3 | (16,8292)      |     616 | f      | f      | 26 00 00 00 00 00 00 00 | f      |      |

(13 rows)
```

All the other details are the same as explained in the previous item.

F.34.4. BRIN Functions

brin_page_type(page bytea) returns text

brin_page_type returns the page type of the given BRIN index page, or throws an error if the page is not a valid BRIN page. For example:

```
test=# SELECT brin_page_type(get_raw_page('brinidx', 0));
 brin_page_type
-----
 meta
```

brin_metapage_info(page bytea) returns record

brin_metapage_info returns assorted information about a BRIN index metapage. For example:

```
test=# SELECT * FROM brin_metapage_info(get_raw_page('brinidx', 0));
 magic | version | pagesperpage | lastrevmappage
-----+-----+-----+-----+
0xA8109CFA |      1 |          4 |          2
```

`brin_revmap_data(page bytea)` returns setof `tid`

`brin_revmap_data` returns the list of tuple identifiers in a BRIN index range map page. For example:

```
test=# SELECT * FROM brin_revmap_data(get_raw_page('brinidx', 2)) LIMIT 5;
      pages
```

```
-----
(6,137)
(6,138)
(6,139)
(6,140)
(6,141)
```

`brin_page_items(page bytea, index oid)` returns setof `record`

`brin_page_items` returns the data stored in the BRIN data page. For example:

```
test=# SELECT * FROM brin_page_items(get_raw_page('brinidx', 5),
                                     'brinidx')
```

```
      ORDER BY blknum, attnum LIMIT 6;
 itemoffset | blknum | attnum | allnulls | hasnulls | placeholder | empty | value
-----+-----+-----+-----+-----+-----+-----+-----
+-----+
      137 |      0 |      1 | t        | f        | f          | f     |
      137 |      0 |      2 | f        | f        | f          | f     | {1 ..
88}
      138 |      4 |      1 | t        | f        | f          | f     |
      138 |      4 |      2 | f        | f        | f          | f     | {89 ..
176}
      139 |      8 |      1 | t        | f        | f          | f     |
      139 |      8 |      2 | f        | f        | f          | f     | {177 ..
264}
```

The returned columns correspond to the fields in the `BrinMemTuple` and `BrinValues` structs.

F.34.5. GIN Functions

`gin_metapage_info(page bytea)` returns `record`

`gin_metapage_info` returns information about a GIN index metapage. For example:

```
test=# SELECT * FROM gin_metapage_info(get_raw_page('gin_index', 0));
```

```
-[ RECORD 1 ]-----+-----
pending_head      | 4294967295
pending_tail      | 4294967295
tail_free_size    | 0
n_pending_pages   | 0
n_pending_tuples  | 0
n_total_pages     | 7
n_entry_pages     | 6
n_data_pages      | 0
n_entries         | 693
version           | 2
```

`gin_page_opaque_info(page bytea)` returns `record`

`gin_page_opaque_info` returns information about a GIN index opaque area, like the page type. For example:

```
test=# SELECT * FROM gin_page_opaque_info(get_raw_page('gin_index', 2));
```

```
 rightlink | maxoff | flags
-----+-----+-----
          5 |      0 | {data,leaf,compressed}
```

(1 row)

`gin_leafpage_items(page bytea)` returns setof record

`gin_leafpage_items` returns information about the data stored in a compressed GIN leaf page. For example:

```
test=# SELECT first_tid, nbytes, tids[0:5] AS some_tids
        FROM gin_leafpage_items(get_raw_page('gin_test_idx', 2));
 first_tid | nbytes | some_tids
-----+-----+-----
(8,41)    |    244 | {"(8,41)","(8,43)","(8,44)","(8,45)","(8,46)"}
(10,45)   |    248 | {"(10,45)","(10,46)","(10,47)","(10,48)","(10,49)"}
(12,52)   |    248 | {"(12,52)","(12,53)","(12,54)","(12,55)","(12,56)"}
(14,59)   |    320 | {"(14,59)","(14,60)","(14,61)","(14,62)","(14,63)"}
(167,16)  |    376 | {"(167,16)","(167,17)","(167,18)","(167,19)","(167,20)"}
(170,30)  |    376 | {"(170,30)","(170,31)","(170,32)","(170,33)","(170,34)"}
(173,44)  |    197 | {"(173,44)","(173,45)","(173,46)","(173,47)","(173,48)"}
(7 rows)
```

F.34.6. GiST Functions

`gist_page_opaque_info(page bytea)` returns record

`gist_page_opaque_info` returns information from a GiST index page's opaque area, such as the NSN, rightlink and page type. For example:

```
test=# SELECT * FROM gist_page_opaque_info(get_raw_page('test_gist_idx', 2));
 lsn | nsn | rightlink | flags
-----+-----+-----+-----
0/1 | 0/0 |          1 | {leaf}
(1 row)
```

`gist_page_items(page bytea, index_oid regclass)` returns setof record

`gist_page_items` returns information about the data stored in a page of a GiST index. For example:

```
test=# SELECT * FROM gist_page_items(get_raw_page('test_gist_idx', 0),
        'test_gist_idx');
 itemoffset |   ctid   | itemlen | dead | keys
-----+-----+-----+-----+-----
          1 | (1,65535) |      40 | f    | (p)=("(185,185),(1,1)")
          2 | (2,65535) |      40 | f    | (p)=("(370,370),(186,186)")
          3 | (3,65535) |      40 | f    | (p)=("(555,555),(371,371)")
          4 | (4,65535) |      40 | f    | (p)=("(740,740),(556,556)")
          5 | (5,65535) |      40 | f    | (p)=("(870,870),(741,741)")
          6 | (6,65535) |      40 | f    | (p)=("(1000,1000),(871,871)")
(6 rows)
```

`gist_page_items_bytea(page bytea)` returns setof record

Same as `gist_page_items`, but returns the key data as a raw bytea blob. Since it does not attempt to decode the key, it does not need to know which index is involved. For example:

```
test=# SELECT * FROM gist_page_items_bytea(get_raw_page('test_gist_idx', 0));
 itemoffset |   ctid   | itemlen | dead | key_data
-----+-----+-----+-----+-----
          1 | (1,65535) |      40 | f    | \x000000100ffff2800000000000000c064400000000000c064400000000000f03f000000000000f03f
          2 | (2,65535) |      40 | f    | \x000000200ffff2800000000000000c074400000000000c074400000000000e06440000000000e06440
```

F.34.7. Hash Functions

`hash_page_type(page bytea)` returns text

`hash_page_type` returns page type of the given HASH index page. For example:

```
test=# SELECT hash_page_type(get_raw_page('con_hash_index', 0));
 hash_page_type
-----
metapage
```

`hash_page_stats(page bytea)` returns setof record

`hash_page_stats` returns information about a bucket or overflow page of a HASH index. For example:

```
test=# SELECT * FROM hash_page_stats(get_raw_page('con_hash_index', 1));
-[ RECORD 1 ]-----+-----
live_items          | 407
dead_items          | 0
page_size           | 8192
free_size           | 8
hasho_prevblkno     | 4096
hasho_nextblkno     | 8474
hasho_bucket        | 0
hasho_flag          | 66
hasho_page_id       | 65408
```

`hash_page_items(page bytea)` returns setof record

`hash_page_items` returns information about the data stored in a bucket or overflow page of a HASH index page. For example:

```
test=# SELECT * FROM hash_page_items(get_raw_page('con_hash_index', 1)) LIMIT 5;
 itemoffset |      ctid      |      data
-----+-----+-----
1 | (899,77) | 1053474816

`hash_bitmap_info(index oid, blkno bigint)` returns record

`hash_bitmap_info` shows the status of a bit in the bitmap page for a particular overflow page of HASH index. For example:

```
test=# SELECT * FROM hash_bitmap_info('con_hash_index', 2052);
 bitmapblkno | bitmapbit | bitstatus
-----+-----+-----
65 | 3 | t
```

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

hash_metapage_info(page bytea) returns record

hash_metapage_info returns information stored in the meta page of a HASH index. For example:

```
test=# SELECT magic, version, ntuples, ffactor, bsize, bmsize, bmshift,  
test-#         maxbucket, highmask, lowmask, ovflpoint, firstfree, nmaps, procid,  
test-#         regexp_replace(spares::text, '(\,0)*}', '{}') as spares,  
test-#         regexp_replace(mapp::text, '(\,0)*}', '{}') as mapp  
test=# FROM hash_metapage_info(get_raw_page('con_hash_index', 0));  
-[ RECORD 1 ]-----
```

```
-----  
magic      | 105121344  
version    | 4  
ntuples    | 500500  
ffactor    | 40  
bsize      | 8152  
bmsize     | 4096  
bmshift    | 15  
maxbucket  | 12512  
highmask   | 16383  
lowmask    | 8191  
ovflpoint  | 28  
firstfree  | 1204  
nmaps      | 1  
procid     | 450  
spares     | {0,0,0,0,0,0,1,1,1,1,1,1,1,1,3,4,4,4,45,55,58,59,  
508,567,628,704,1193,1202,1204}  
mapp       | {65}
```

F.35. passwordcheck — verify password strength

The `passwordcheck` module checks users' passwords whenever they are set with [CREATE ROLE](#) or [ALTER ROLE](#) (it doesn't work, if a non-default profile is assigned to the user). If a password is considered too weak, it will be rejected and the command will terminate with an error.

To enable this module, add '`$libdir/passwordcheck`' to [shared_preload_libraries](#) in `postgresql.conf`, then restart the server.

Caution

To prevent unencrypted passwords from being sent across the network, written to the server log or otherwise stolen by a database administrator, Postgres Pro allows the user to supply pre-encrypted passwords. Many client programs make use of this functionality and encrypt the password before sending it to the server.

This limits the usefulness of the `passwordcheck` module, because in that case it can only try to guess the password. For this reason, `passwordcheck` is not recommended if your security requirements are high. It is more secure to use an external authentication method such as GSSAPI (see [Chapter 19](#)) than to rely on passwords within the database.

F.35.1. Configuration Parameters

`passwordcheck.min_password_length` (integer)

The minimum acceptable password length in bytes. The default is 8. Only superusers can change this setting.

Note

This parameter has no effect if a user supplies a pre-encrypted password.

In ordinary usage, this parameter is set in `postgresql.conf`, but superusers can alter it on-the-fly within their own sessions. Typical usage might be:

```
# postgresql.conf
passwordcheck.min_password_length = 12
```

F.36. pg_buffercache — inspect Postgres Pro buffer cache state

The `pg_buffercache` module provides a means for examining what's happening in the shared buffer cache in real time. It also offers a low-level way to evict data from it, for testing purposes.

This module provides the `pg_buffercache_pages()` function (wrapped in the `pg_buffercache` view), the `pg_buffercache_numa_pages()` function (wrapped in the `pg_buffercache_numa` view), the `pg_buffercache_summary()` function, the `pg_buffercache_usage_counts()` function, the `pg_buffercache_evict()` function, the `pg_buffercache_evict_relation()` function and the `pg_buffercache_evict_all()` function.

The `pg_buffercache_pages()` function returns a set of records, each row describing the state of one shared buffer entry. The `pg_buffercache` view wraps the function for convenient use.

The `pg_buffercache_numa_pages()` function provides NUMA node mappings for shared buffer entries. This information is not part of `pg_buffercache_pages()` itself, as it is much slower to retrieve. The `pg_buffercache_numa` view wraps the function for convenient use.

The `pg_buffercache_summary()` function returns a single row summarizing the state of the shared buffer cache.

The `pg_buffercache_usage_counts()` function returns a set of records, each row describing the number of buffers with a given usage count.

By default, use of the above functions is restricted to superusers and roles with privileges of the `pg_monitor` role. Access may be granted to others using `GRANT`.

The `pg_buffercache_evict()` function allows a block to be evicted from the buffer pool given a buffer identifier. Use of this function is restricted to superusers only.

The `pg_buffercache_evict_relation()` function allows all unpinned shared buffers in the relation to be evicted from the buffer pool given a relation identifier. Use of this function is restricted to superusers only.

The `pg_buffercache_evict_all()` function allows all unpinned shared buffers to be evicted in the buffer pool. Use of this function is restricted to superusers only.

F.36.1. The pg_buffercache View

The definitions of the columns exposed by the view are shown in [Table F.19](#).

Table F.19. pg_buffercache Columns

Column Type	Description
bufferid integer	ID, in the range 1.. <code>shared_buffers</code>
relfilenode oid (references <code>pg_class</code> .relfilenode)	Filenode number of the relation
reltablespace oid (references <code>pg_tablespace</code> .oid)	Tablespace OID of the relation
reldatabase oid (references <code>pg_database</code> .oid)	Database OID of the relation
relforknumber smallint	

Column Type	Description
	Fork number within the relation
relblocknumber bigint	Page number within the relation
isdirty boolean	Is the page dirty?
usagecount smallint	Clock-sweep access count
pinning_backends integer	Number of backends pinning this buffer

There is one row for each buffer in the shared cache. Unused buffers are shown with all fields null except `bufferid`. Shared system catalogs are shown as belonging to database zero.

Because the cache is shared by all the databases, there will normally be pages from relations not belonging to the current database. This means that there may not be matching join rows in `pg_class` for some rows, or that there could even be incorrect joins. If you are trying to join against `pg_class`, it's a good idea to restrict the join to rows having `reldatabase` equal to the current database's OID or zero.

Since buffer manager locks are not taken to copy the buffer state data that the view will display, accessing `pg_buffercache` view has less impact on normal buffer activity but it doesn't provide a consistent set of results across all buffers. However, we ensure that the information of each buffer is self-consistent.

F.36.2. The `pg_buffercache_numa` View

The definitions of the columns exposed by the view are shown in [Table F.20](#).

Table F.20. `pg_buffercache_numa` Columns

Column Type	Description
bufferid integer	ID, in the range 1.. <code>shared_buffers</code>
os_page_num bigint	number of OS memory page for this buffer
numa_node int	ID of NUMA node

As NUMA node ID inquiry for each page requires memory pages to be paged-in, the first execution of this function can take a noticeable amount of time. In all the cases (first execution or not), retrieving this information is costly and querying the view at a high frequency is not recommended.

Warning

When determining the NUMA node, the view touches all memory pages for the shared memory segment. This will force allocation of the shared memory, if it wasn't allocated already, and the memory may get allocated in a single NUMA node (depending on system configuration).

F.36.3. The `pg_buffercache_summary()` Function

The definitions of the columns exposed by the function are shown in [Table F.21](#).

Table F.21. `pg_buffercache_summary()` Output Columns

Column Type	Description
<code>buffers_used int4</code>	Number of used shared buffers
<code>buffers_unused int4</code>	Number of unused shared buffers
<code>buffers_dirty int4</code>	Number of dirty shared buffers
<code>buffers_pinned int4</code>	Number of pinned shared buffers
<code>usagecount_avg float8</code>	Average usage count of used shared buffers

The `pg_buffercache_summary()` function returns a single row summarizing the state of all shared buffers. Similar and more detailed information is provided by the `pg_buffercache` view, but `pg_buffercache_summary()` is significantly cheaper.

Like the `pg_buffercache` view, `pg_buffercache_summary()` does not acquire buffer manager locks. Therefore concurrent activity can lead to minor inaccuracies in the result.

F.36.4. The `pg_buffercache_usage_counts()` Function

The definitions of the columns exposed by the function are shown in [Table F.22](#).

Table F.22. `pg_buffercache_usage_counts()` Output Columns

Column Type	Description
<code>usage_count int4</code>	A possible buffer usage count
<code>buffers int4</code>	Number of buffers with the usage count
<code>dirty int4</code>	Number of dirty buffers with the usage count
<code>pinned int4</code>	Number of pinned buffers with the usage count

The `pg_buffercache_usage_counts()` function returns a set of rows summarizing the states of all shared buffers, aggregated over the possible usage count values. Similar and more detailed information is provided by the `pg_buffercache` view, but `pg_buffercache_usage_counts()` is significantly cheaper.

Like the `pg_buffercache` view, `pg_buffercache_usage_counts()` does not acquire buffer manager locks. Therefore concurrent activity can lead to minor inaccuracies in the result.

F.36.5. The `pg_buffercache_evict()` Function

The `pg_buffercache_evict()` function takes a buffer identifier, as shown in the `bufferid` column of the `pg_buffercache` view. It returns information about whether the buffer was evicted and flushed. The `buffer_evicted` column is true on success, and false if the buffer wasn't valid, if it couldn't be evicted because it was pinned, or if it became dirty again after an attempt to write it out. The `buffer_flushed` column is true if the buffer was flushed. This does not necessarily mean that buffer was flushed by us, it might be flushed by someone else. The result is immediately out of date upon return, as the buffer might become valid again at any time due to concurrent activity. The function is intended for developer testing only.

F.36.6. The `pg_buffercache_evict_relation()` Function

The `pg_buffercache_evict_relation()` function is very similar to the `pg_buffercache_evict()` function. The difference is that the `pg_buffercache_evict_relation()` takes a relation identifier instead of buffer identifier. It tries to evict all buffers for all forks in that relation. It returns the number of evicted buffers, flushed buffers and the number of buffers that could not be evicted. Flushed buffers haven't necessarily been flushed by us, they might have been flushed by someone else. The result is immediately out of date upon return, as buffers might immediately be read back in due to concurrent activity. The function is intended for developer testing only.

F.36.7. The `pg_buffercache_evict_all()` Function

The `pg_buffercache_evict_all()` function is very similar to the `pg_buffercache_evict()` function. The difference is, the `pg_buffercache_evict_all()` function does not take an argument; instead it tries to evict all buffers in the buffer pool. It returns the number of evicted buffers, flushed buffers and the number of buffers that could not be evicted. Flushed buffers haven't necessarily been flushed by us, they might have been flushed by someone else. The result is immediately out of date upon return, as buffers might immediately be read back in due to concurrent activity. The function is intended for developer testing only.

F.36.8. Sample Output

```
regression=# SELECT n.nspname, c.relname, count(*) AS buffers
              FROM pg_buffercache b JOIN pg_class c
              ON b.relfilenode = pg_relation_filenode(c.oid) AND
                 b.reldatabase IN (0, (SELECT oid FROM pg_database
                                     WHERE datname = current_database()))
              JOIN pg_namespace n ON n.oid = c.relnamespace
              GROUP BY n.nspname, c.relname
              ORDER BY 3 DESC
              LIMIT 10;
```

Mark Kirkwood <markir@paradise.net.nz>

Design suggestions: Neil Conway <neilc@samurai.com>

Debugging advice: Tom Lane <tgl@sss.pgh.pa.us>

F.37. pgcrypto — cryptographic functions

The `pgcrypto` module provides cryptographic functions for Postgres Pro.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

`pgcrypto` requires OpenSSL and won't be installed if OpenSSL support was not selected when Postgres Pro was built.

F.37.1. General Hashing Functions

F.37.1.1. `digest()`

`digest(data text, type text)` returns `bytea`
`digest(data bytea, type text)` returns `bytea`

Computes a binary hash of the given *data*. *type* is the algorithm to use. Standard algorithms are `md5`, `sha1`, `sha224`, `sha256`, `sha384` and `sha512`. Moreover, any digest algorithm OpenSSL supports is automatically picked up.

If you want the digest as a hexadecimal string, use `encode()` on the result. For example:

```
CREATE OR REPLACE FUNCTION sha1(bytea) returns text AS $$  
    SELECT encode(digest($1, 'sha1'), 'hex')  
$$ LANGUAGE SQL STRICT IMMUTABLE;
```

F.37.1.2. `hmac()`

`hmac(data text, key text, type text)` returns `bytea`
`hmac(data bytea, key bytea, type text)` returns `bytea`

Calculates hashed MAC for *data* with key *key*. *type* is the same as in `digest()`.

This is similar to `digest()` but the hash can only be recalculated knowing the key. This prevents the scenario of someone altering data and also changing the hash to match.

If the key is larger than the hash block size it will first be hashed and the result will be used as key.

F.37.2. Password Hashing Functions

The functions `crypt()` and `gen_salt()` are specifically designed for hashing passwords. `crypt()` does the hashing and `gen_salt()` prepares algorithm parameters for it.

The algorithms in `crypt()` differ from the usual MD5 or SHA-1 hashing algorithms in the following respects:

1. They are slow. As the amount of data is so small, this is the only way to make brute-forcing passwords hard.
2. They use a random value, called the *salt*, so that users having the same password will have different encrypted passwords. This is also an additional defense against reversing the algorithm.
3. They include the algorithm type in the result, so passwords hashed with different algorithms can co-exist.
4. Some of them are adaptive — that means when computers get faster, you can tune the algorithm to be slower, without introducing incompatibility with existing passwords.

Table F.23 lists the algorithms supported by the `crypt()` function.

Table F.23. Supported Algorithms for `crypt()`

Algorithm	Max Password Length	Adaptive?	Salt Bits	Output Length	Description
bf	72	yes	128	60	Blowfish-based, variant 2a

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

Algorithm	Max Password Length	Adaptive?	Salt Bits	Output Length	Description
md5	unlimited	no	48	34	MD5-based crypt
xdes	8	yes	24	20	Extended DES
des	8	no	12	13	Original UNIX crypt
sha256crypt	unlimited	yes	up to 32	80	Adapted from publicly available reference implementation Unix crypt using SHA-256 and SHA-512
sha512crypt	unlimited	yes	up to 32	123	Adapted from publicly available reference implementation Unix crypt using SHA-256 and SHA-512

F.37.2.1. crypt ()

`crypt(password text, salt text)` returns text

Calculates a crypt(3)-style hash of *password*. When storing a new password, you need to use `gen_salt()` to generate a new *salt* value. To check a password, pass the stored hash value as *salt*, and test whether the result matches the stored value.

Example of setting a new password:

```
UPDATE ... SET pswhash = crypt('new password', gen_salt('md5'));
```

Example of authentication:

```
SELECT (pswhash = crypt('entered password', pswhash)) AS pswmatch FROM ... ;
```

This returns `true` if the entered password is correct.

F.37.2.2. gen_salt ()

`gen_salt(type text [, iter_count integer])` returns text

Generates a new random salt string for use in `crypt()`. The salt string also tells `crypt()` which algorithm to use.

The *type* parameter specifies the hashing algorithm. The accepted types are: `des`, `xdes`, `md5`, `bf`, `sha256crypt` and `sha512crypt`. The last two, `sha256crypt` and `sha512crypt` are modern SHA-2 based password hashes.

The *iter_count* parameter lets the user specify the iteration count, for algorithms that have one. The higher the count, the more time it takes to hash the password and therefore the more time to break it. Although with too high a count the time to calculate a hash may be several years — which is somewhat impractical. If the *iter_count* parameter is omitted, the default iteration count is used. Allowed values for *iter_count* depend on the algorithm and are shown in [Table F.24](#).

Table F.24. Iteration Counts for crypt ()

Algorithm	Default	Min	Max
xdes	725	1	16777215
bf	6	4	31
sha256crypt, sha512crypt	5000	1000	999999999

For `xdes` there is an additional limitation that the iteration count must be an odd number.

To pick an appropriate iteration count, consider that the original DES crypt was designed to have the speed of 4 hashes per second on the hardware of that time. Slower than 4 hashes per second would probably dampen usability. Faster than 100 hashes per second is probably too fast.

Table F.25 gives an overview of the relative slowness of different hashing algorithms. The table shows how much time it would take to try all combinations of characters in an 8-character password, assuming that the password contains either only lower case letters, or upper- and lower-case letters and numbers. In the `crypt-bf` entries, the number after a slash is the `iter_count` parameter of `gen_salt`.

The default `iter_count` for `sha256crypt` and `sha512crypt` of 5000 is considered too low for modern hardware, but can be adjusted to generate stronger password hashes. Otherwise both hashes, `sha256crypt` and `sha512crypt` are considered safe.

Table F.25. Hash Algorithm Speeds

Algorithm	Hashes/sec	For [a-z]	For [A-Za-z0-9]	Duration relative to md5 hash
crypt-bf/8	1792	4 years	3927 years	100k
crypt-bf/7	3648	2 years	1929 years	50k
crypt-bf/6	7168	1 year	982 years	25k
crypt-bf/5	13504	188 days	521 years	12.5k
crypt-md5	171584	15 days	41 years	1k
crypt-des	23221568	157.5 minutes	108 days	7
sha1	37774272	90 minutes	68 days	4
md5 (hash)	150085504	22.5 minutes	17 days	1

Notes:

- The machine used is an Intel Mobile Core i3.
- `crypt-des` and `crypt-md5` algorithm numbers are taken from John the Ripper v1.6.38 `-test` output.
- `md5 hash` numbers are from `mdcrack` 1.2.
- `sha1` numbers are from `lcrack-20031130-beta`.
- `crypt-bf` numbers are taken using a simple program that loops over 1000 8-character passwords. That way the speed with different numbers of iterations can be shown. For reference: `john -test` shows 13506 loops/sec for `crypt-bf/5`. (The very small difference in results is in accordance with the fact that the `crypt-bf` implementation in `pgcrypto` is the same one used in John the Ripper.)

Note that “try all combinations” is not a realistic exercise. Usually password cracking is done with the help of dictionaries, which contain both regular words and various mutations of them. So, even somewhat word-like passwords could be cracked much faster than the above numbers suggest, while a 6-character non-word-like password may escape cracking. Or not.

F.37.3. PGP Encryption Functions

The functions here implement the encryption part of the OpenPGP ([RFC 4880](#)) standard. Supported are both symmetric-key and public-key encryption.

An encrypted PGP message consists of 2 parts, or *packets*:

- Packet containing a session key — either symmetric-key or public-key encrypted.
- Packet containing data encrypted with the session key.

When encrypting with a symmetric key (i.e., a password):

1. The given password is hashed using a String2Key (S2K) algorithm. This is rather similar to `crypt()` algorithms — purposefully slow and with random salt — but it produces a full-length binary key.
2. If a separate session key is requested, a new random key will be generated. Otherwise the S2K key will be used directly as the session key.
3. If the S2K key is to be used directly, then only S2K settings will be put into the session key packet. Otherwise the session key will be encrypted with the S2K key and put into the session key packet.

When encrypting with a public key:

1. A new random session key is generated.
2. It is encrypted using the public key and put into the session key packet.

In either case the data to be encrypted is processed as follows:

1. Optional data-manipulation: compression, conversion to UTF-8, and/or conversion of line-endings.
2. The data is prefixed with a block of random bytes. This is equivalent to using a random IV.
3. A SHA-1 hash of the random prefix and data is appended.
4. All this is encrypted with the session key and placed in the data packet.

F.37.3.1. `pgp_sym_encrypt()`

`pgp_sym_encrypt(data text, psw text [, options text])` returns `bytea`
`pgp_sym_encrypt_bytea(data bytea, psw text [, options text])` returns `bytea`

Encrypt *data* with a symmetric PGP key *psw*. The *options* parameter can contain option settings, as described below.

F.37.3.2. `pgp_sym_decrypt()`

`pgp_sym_decrypt(msg bytea, psw text [, options text])` returns `text`
`pgp_sym_decrypt_bytea(msg bytea, psw text [, options text])` returns `bytea`

Decrypt a symmetric-key-encrypted PGP message.

Decrypting `bytea` data with `pgp_sym_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_sym_decrypt_bytea` is fine.

The *options* parameter can contain option settings, as described below.

F.37.3.3. `pgp_pub_encrypt()`

`pgp_pub_encrypt(data text, key bytea [, options text])` returns `bytea`
`pgp_pub_encrypt_bytea(data bytea, key bytea [, options text])` returns `bytea`

Encrypt *data* with a public PGP key *key*. Giving this function a secret key will produce an error.

The *options* parameter can contain option settings, as described below.

F.37.3.4. `pgp_pub_decrypt()`

`pgp_pub_decrypt(msg bytea, key bytea [, psw text [, options text]])` returns `text`
`pgp_pub_decrypt_bytea(msg bytea, key bytea [, psw text [, options text]])` returns `bytea`

Decrypt a public-key-encrypted message. *key* must be the secret key corresponding to the public key that was used to encrypt. If the secret key is password-protected, you must give the password in *psw*. If there is no password, but you want to specify options, you need to give an empty password.

Decrypting `bytea` data with `pgp_pub_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_pub_decrypt_bytea` is fine.

The *options* parameter can contain option settings, as described below.

F.37.3.5. `pgp_key_id()`

`pgp_key_id(bytea)` returns text

`pgp_key_id` extracts the key ID of a PGP public or secret key. Or it gives the key ID that was used for encrypting the data, if given an encrypted message.

It can return 2 special key IDs:

- `SYMKEY`

The message is encrypted with a symmetric key.

- `ANYKEY`

The message is public-key encrypted, but the key ID has been removed. That means you will need to try all your secret keys on it to see which one decrypts it. `pgcrypto` itself does not produce such messages.

Note that different keys may have the same ID. This is rare but a normal event. The client application should then try to decrypt with each one, to see which fits — like handling `ANYKEY`.

F.37.3.6. `armor()`, `dearmor()`

`armor(data bytea [, keys text[], values text[]])` returns text

`dearmor(data text)` returns bytea

These functions wrap/unwrap binary data into PGP ASCII-armor format, which is basically Base64 with CRC and additional formatting.

If the *keys* and *values* arrays are specified, an *armor header* is added to the armored format for each key/value pair. Both arrays must be single-dimensional, and they must be of the same length. The keys and values cannot contain any non-ASCII characters.

F.37.3.7. `pgp_armor_headers`

`pgp_armor_headers(data text, key out text, value out text)` returns setof record

`pgp_armor_headers()` extracts the armor headers from *data*. The return value is a set of rows with two columns, key and value. If the keys or values contain any non-ASCII characters, they are treated as UTF-8.

F.37.3.8. Options for PGP Functions

Options are named to be similar to GnuPG. An option's value should be given after an equal sign; separate options from each other with commas. For example:

```
pgp_sym_encrypt(data, psw, 'compress-algo=1, cipher-algo=aes256')
```

All of the options except `convert-crlf` apply only to encrypt functions. Decrypt functions get the parameters from the PGP data.

The most interesting options are probably `compress-algo` and `unicode-mode`. The rest should have reasonable defaults.

F.37.3.8.1. `cipher-algo`

Which cipher algorithm to use.

Values: `bf`, `aes128`, `aes192`, `aes256`, `3des`, `cast5`

Default: `aes128`

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

F.37.3.8.2. compress-algo

Which compression algorithm to use. Only available if Postgres Pro was built with zlib.

Values:

0 - no compression

1 - ZIP compression

2 - ZLIB compression (= ZIP plus meta-data and block CRCs)

Default: 0

Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.37.3.8.3. compress-level

How much to compress. Higher levels compress smaller but are slower. 0 disables compression.

Values: 0, 1-9

Default: 6

Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.37.3.8.4. convert-crlf

Whether to convert `\n` into `\r\n` when encrypting and `\r\n` to `\n` when decrypting. RFC 4880 specifies that text data should be stored using `\r\n` line-feeds. Use this to get fully RFC-compliant behavior.

Values: 0, 1

Default: 0

Applies to: pgp_sym_encrypt, pgp_pub_encrypt, pgp_sym_decrypt, pgp_pub_decrypt

F.37.3.8.5. disable-mdc

Do not protect data with SHA-1. The only good reason to use this option is to achieve compatibility with ancient PGP products, predating the addition of SHA-1 protected packets to RFC 4880. Recent gnupg.org and pgp.com software supports it fine.

Values: 0, 1

Default: 0

Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.37.3.8.6. sess-key

Use separate session key. Public-key encryption always uses a separate session key; this option is for symmetric-key encryption, which by default uses the S2K key directly.

Values: 0, 1

Default: 0

Applies to: pgp_sym_encrypt

F.37.3.8.7. s2k-mode

Which S2K algorithm to use.

Values:

0 - Without salt. Dangerous!

1 - With salt but with fixed iteration count.

3 - Variable iteration count.

Default: 3

Applies to: pgp_sym_encrypt

F.37.3.8.8. s2k-count

The number of iterations of the S2K algorithm to use. It must be a value between 1024 and 65011712, inclusive.

Default: A random value between 65536 and 253952

Applies to: pgp_sym_encrypt, only with s2k-mode=3

F.37.3.8.9. s2k-digest-algo

Which digest algorithm to use in S2K calculation.

Values: md5, sha1

Default: sha1

Applies to: pgp_sym_encrypt

F.37.3.8.10. s2k-cipher-algo

Which cipher to use for encrypting separate session key.

Values: bf, aes, aes128, aes192, aes256

Default: use cipher-algo

Applies to: pgp_sym_encrypt

F.37.3.8.11. unicode-mode

Whether to convert textual data from database internal encoding to UTF-8 and back. If your database already is UTF-8, no conversion will be done, but the message will be tagged as UTF-8. Without this option it will not be.

Values: 0, 1

Default: 0

Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.37.3.9. Generating PGP Keys with GnuPG

To generate a new key:

```
gpg --gen-key
```

The preferred key type is “DSA and Elgamal”.

For RSA encryption you must create either DSA or RSA sign-only key as master and then add an RSA encryption subkey with `gpg --edit-key`.

To list keys:

```
gpg --list-secret-keys
```

To export a public key in ASCII-armor format:

```
gpg -a --export KEYID > public.key
```

To export a secret key in ASCII-armor format:

```
gpg -a --export-secret-keys KEYID > secret.key
```

You need to use `dearmor()` on these keys before giving them to the PGP functions. Or if you can handle binary data, you can drop `-a` from the command.

For more details see `man gpg`, *The GNU Privacy Handbook* and other documentation on <https://www.gnupg.org/>.

F.37.3.10. Limitations of PGP Code

- No support for signing. That also means that it is not checked whether the encryption subkey belongs to the master key.
- No support for encryption key as master key. As such practice is generally discouraged, this should not be a problem.
- No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with `pgcrypto`, but create new ones, as the usage scenario is rather different.

F.37.4. Raw Encryption Functions

These functions only run a cipher over data; they don't have any advanced features of PGP encryption. Therefore they have some major problems:

1. They use user key directly as cipher key.
2. They don't provide any integrity checking, to see if the encrypted data was modified.
3. They expect that users manage all encryption parameters themselves, even IV.
4. They don't handle text.

So, with the introduction of PGP encryption, usage of raw encryption functions is discouraged.

`encrypt(data bytea, key bytea, type text)` returns `bytea`

`decrypt(data bytea, key bytea, type text)` returns `bytea`

`encrypt_iv(data bytea, key bytea, iv bytea, type text)` returns `bytea`

`decrypt_iv(data bytea, key bytea, iv bytea, type text)` returns `bytea`

Encrypt/decrypt data using the cipher method specified by *type*. The syntax of the *type* string is:

`algorithm [- mode] [/pad: padding]`

where *algorithm* is one of:

- `bf` — Blowfish
- `aes` — AES (Rijndael-128, -192 or -256)

and *mode* is one of:

- `cbc` — next block depends on previous (default)
- `cfb` — next block depends on previous encrypted block
- `ecb` — each block is encrypted separately (for testing only)

and *padding* is one of:

- `pkcs` — data may be any length (default)
- `none` — data must be multiple of cipher block size

So, for example, these are equivalent:

`encrypt(data, 'fooz', 'bf')`

`encrypt(data, 'fooz', 'bf-cbc/pad:pkcs')`

In `encrypt_iv` and `decrypt_iv`, the *iv* parameter is the initial value for the CBC and CFB mode; it is ignored for ECB. It is clipped or padded with zeroes if not exactly block size. It defaults to all zeroes in the functions without this parameter.

F.37.5. Random-Data Functions

`gen_random_bytes(count integer)` returns `bytea`

Returns *count* cryptographically strong random bytes. At most 1024 bytes can be extracted at a time. This is to avoid draining the randomness generator pool.

`gen_random_uuid()` returns `uuid`

Returns a version 4 (random) UUID. (Obsolete, this function internally calls the [core function](#) of the same name.)

F.37.6. OpenSSL Support Functions

`fips_mode()` returns boolean

Returns `true` if OpenSSL is running with FIPS mode enabled, otherwise `false`.

F.37.7. Configuration Parameters

There is one configuration parameter that controls the behavior of `pgcrypto`.

`pgcrypto.builtin_crypto_enabled` (enum)

`pgcrypto.builtin_crypto_enabled` determines if the built in crypto functions `gen_salt()`, and `crypt()` are available for use. Setting this to `off` disables these functions. `on` (the default) enables these functions to work normally. `fips` disables these functions if OpenSSL is detected to operate in FIPS mode.

In ordinary usage, this parameter is set in `postgresql.conf`, although superusers can alter it on-the-fly within their own sessions.

F.37.8. Notes

F.37.8.1. Configuration

`pgcrypto` configures itself according to the findings of the main Postgres Pro `configure` script. The options that affect it are `--with-zlib` and `--with-ssl=openssl`.

When compiled with `zlib`, PGP encryption functions are able to compress data before encrypting.

`pgcrypto` requires OpenSSL. Otherwise, it will not be built or installed.

When compiled against OpenSSL 3.0.0 and later versions, the legacy provider must be activated in the `openssl.cnf` configuration file in order to use older ciphers like DES or Blowfish.

F.37.8.2. NULL Handling

As is standard in SQL, all functions return NULL, if any of the arguments are NULL. This may create security risks on careless usage.

F.37.8.3. Security Limitations

All `pgcrypto` functions run inside the database server. That means that all the data and passwords move between `pgcrypto` and client applications in clear text. Thus you must:

1. Connect locally or use SSL connections.
2. Trust both system and database administrator.

If you cannot, then better do crypto inside client application.

The implementation does not resist *side-channel attacks*. For example, the time required for a `pgcrypto` decryption function to complete varies among ciphertexts of a given size.

F.37.9. Author

Marko Kreen <markokr@gmail.com>

`pgcrypto` uses code from the following sources:

Algorithm	Author	Source origin
DES crypt	David Burren and others	FreeBSD libcrypt
MD5 crypt	Poul-Henning Kamp	FreeBSD libcrypt
Blowfish crypt	Solar Designer	www.openwall.com

F.38. pg_freespacemap — examine the free space map

The `pg_freespacemap` module provides a means for examining the [free space map](#) (FSM). It provides a function called `pg_freespace`, or two overloaded functions, to be precise. The functions show the value recorded in the free space map for a given page, or for all pages in the relation.

By default use is restricted to superusers and roles with privileges of the `pg_stat_scan_tables` role. Access may be granted to others using `GRANT`.

F.38.1. Functions

`pg_freespace(rel regclass IN, blkno bigint IN) returns int2`

Returns the amount of free space on the page of the relation, specified by `blkno`, according to the FSM.

`pg_freespace(rel regclass IN, blkno OUT bigint, avail OUT int2)`

Displays the amount of free space on each page of the relation, according to the FSM. A set of (`blkno bigint`, `avail int2`) tuples is returned, one tuple for each page in the relation.

The values stored in the free space map are not exact. They're rounded to precision of 1/256th of `BLCKSZ` (32 bytes with default `BLCKSZ`), and they're not kept fully up-to-date as tuples are inserted and updated.

For indexes, what is tracked is entirely-unused pages, rather than free space within pages. Therefore, the values are not meaningful, just whether a page is in-use or empty.

F.38.2. Sample Output

```
postgres=# SELECT * FROM pg_freespace('foo');
```

blkno	avail
0	0
1	0
2	0
3	32
4	704
5	704
6	704
7	1216
8	704
9	704
10	704
11	704
12	704
13	704
14	704
15	704
16	704
17	704
18	704
19	3648

(20 rows)

```
postgres=# SELECT * FROM pg_freespace('foo', 7);
```

pg_freespace
1216

(1 row)

F.38.3. Author

Original version by Mark Kirkwood <markir@paradise.net.nz>. Rewritten in version 8.4 to suit new FSM implementation by Heikki Linnakangas <heikki@enterprisedb.com>

F.39. pg_proaudit — enables detailed logging of various security events

The `pg_proaudit` extension enables detailed logging of various security events.

`pg_proaudit` works in parallel with the standard PostgreSQL logging solutions (logging collector) and does not depend on them. Security event log of the `pg_proaudit` extension is stored separately from the server log. At the Postgres Pro Standard startup, `pg_proaudit` launches a special background process to log security events.

Logging rules are stored in the `pg_proaudit.conf` configuration file located in the cluster data directory (PGDATA). It is a text file that can be edited directly using operating system facilities. To modify the file using SQL, you can use several `pg_proaudit` functions. The `pg_proaudit_settings` view displays the current `pg_proaudit` rules, even if they have not been saved into the `pg_proaudit.conf` file yet.

All the logged events belong to the following classes:

- DDL commands for creating, changing, and deleting DBMS objects (databases, tablespaces, schemas, tables, views, sequences, languages, functions)
- access control commands for database objects (GRANT, REVOKE)
- DML commands for access to database objects (INSERT, UPDATE, DELETE, SELECT, TRUNCATE for tables and/or views, EXECUTE for functions)
- database authentication/disconnection events
- all commands executed by a particular user

Security events can be logged both in the centralized logging solution of the operating system (syslog) and in the standard file-system files. Event logs can be written both into the syslog and into the files simultaneously. For clear identification, all `pg_proaudit` records in the syslog are marked with `AUDIT`. Event log files are written in the CSV format. Each event is logged on a separate line that contains the following fields:

- date and time of the event
- current user name
- database name
- server process ID (PID)
- severity level: `INFO` or `ERROR`
- serial number of the command in a session
- subcommand number in complex commands (CREATE TABLE ... AS SELECT ...)
- operator name
- object type
- object name
- operator execution results: `SUCCESS` or `FAILURE`
- additional information like error message in case of `FAILURE` or connection parameters and the application name for the `AUTHENTICATE` event; unfinished authentication attempts are marked as [EOF. No credentials provided]
- text of the SQL command
- parameters of the command (for example, for `PREPARE`)
- session user name
- unique ID of the event (in the [UUIDv7](#) format)
- transaction ID (XID)
- virtual transaction ID (VXID)

An event contains the information about both `session_user` and `current_user` of the session. Therefore, it will be possible to identify the user, even if they execute the `SET ROLE` command to change user identifier.

The XID and VXID values can be zero if an event does not relate to a transaction (e. g. the `DISCONNECT` event).

You can define a directory to store security log files and set up log file rotation. `pg_proaudit` can switch to a new log file either after the specified time interval, or when the specified size of the log file is exceeded. This enables you to define a workflow for cleaning up security event logs.

Postgres Pro user with the `SUPERUSER` attribute should grant access to the `pg_proaudit` extension and security event log files only to the user with the information security administrator role.

F.39.1. Installing the `pg_proaudit` Extension

The `pg_proaudit` extension is a built-in extension included into Postgres Pro Standard. To enable `pg_proaudit`, complete the following steps:

1. Add `pg_proaudit` to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'pg_proaudit'
```

2. Restart the database server for the changes to take effect. To verify that the `pg_proaudit` library was installed correctly, you can run the following command:

```
SHOW shared_preload_libraries;
```

3. In each database for which you are going to log security events, create the `pg_proaudit` extension using the following query:

```
CREATE EXTENSION pg_proaudit;
```

The `pg_proaudit` extension adds several functions for managing the `pg_proaudit.conf` file, the `pg_proaudit_settings` view that displays the current `pg_proaudit` rules and event triggers.

F.39.2. Uninstalling the `pg_proaudit` Extension

To properly uninstall `pg_proaudit`, complete the following steps:

1. Delete the `pg_proaudit` extension using the following query:

```
DROP EXTENSION pg_proaudit;
```

2. Remove `pg_proaudit` from the `shared_preload_libraries` variable in the `postgresql.conf` file.

Skip this step if you have several databases in the cluster and you want to remove the extension only for one of them. In this case, it is recommended to remove logging rules related to the corresponding database prior to uninstalling the extension.

F.39.3. Functions to Configure Security Event Logging

To configure security event logging, `pg_proaudit` provides an SQL interface that consists of several functions and the `pg_proaudit_settings` view.

```
pg_proaudit_set_rule(db_name text, event_type text, object_type text, object_name text,  
role_name text, comment text)
```

Creates the logging rule with the specified parameters. When the `pg_proaudit_set_rule()` function completes, security event logging starts immediately, but the `pg_proaudit.conf` file is not updated. To save the changes in the `pg_proaudit.conf` file, call the `pg_proaudit_save()` function.

Arguments:

- *db_name* — name of the database for which the logging rule is established. An empty string or `NULL` specified in this argument means that events are logged for all databases where the `pg_proaudit` extension is created. When set to `current_database()`, events for the current database are logged.
- *event_type* — type of the event that needs to be logged, including SQL operator names, as well as `AUTHENTICATE` and `DISCONNECT` events. When set to `ALL`, as well as when an empty string or

NULL is specified, enables logging for all events available for the specified object type. For example, for the TABLE object type, the ALL keyword enables logging for commands SELECT, INSERT, UPDATE, DELETE, TRUNCATE, COPY, as well as CREATE, ALTER, DROP. You can also set up logging of event classes by specifying the following values: ALL_DDL, ALL_DDL_NONTEMP, ALL_DML, ALL_DML_NONTEMP, ALL_MOD, ALL_PROC, ALL_ROLE, and MISC. For the full list of possible *event_type* values, see [Section F.39.5](#).

- *object_type* — type of the object for which security events need to be logged. When set to ALL, as well as when an empty string or the NULL is specified, enables logging of events for all object types. For example, specify FOREIGN TABLE object type for the SELECT event to log all attempts to access foreign tables. Use NULL if *event_type* is set to AUTHENTICATE, DISCONNECT, SET, or RESET, and the ROLE value for all events that reference user actions, such as CREATE USER or DROP USER. The following object types are supported: COMPOSITE TYPE, DATABASE, EVENT TRIGGER, FUNCTION, INDEX, PREPARED STATEMENT, ROLE, SEQUENCE, SCHEMA, TABLE, FOREIGN TABLE, TOAST TABLE, TABLESPACE, VIEW, MATERIALIZED VIEW, CATALOG RELATION, and CATALOG FUNCTION.

Note

To log security events for system catalog objects, it is required to enable the [pg_proaudit.log_catalog_access](#) configuration parameter. Otherwise, these events will not be logged, even if the CATALOG RELATION, CATALOG FUNCTION, or ALL object type is specified in the rule.

- *object_name* — name of the object for which the logging rule is established. When an empty string or NULL is specified, enables logging of events for all object names.
- *role_name* — name of the role for which the logging rule is established. If specified, allows logging the actions caused by the user who has the privileges of the role. This means that at least one of the user session attributes, *session_user* or *current_user*, should either be equal to the *role_name*, or be directly or indirectly a member of this role. When an empty string or NULL is specified, enables logging of actions caused by any user. When set to [current_role](#), the logging rule is established for the user current role.
- *comment* — comment to describe the created logging rule. This argument does not affect the rule execution and is not reflected in the log.

```
pg_proaudit_remove_rule(db_name text, event_type text, object_type text, object_name
text, role_name text)
```

Removes the specific logging rule with the set parameters. To save the changes in the `pg_proaudit.conf` file, call the `pg_proaudit_save()` function.

Note

If the rule that you want to remove is configured to log the DISCONNECT event type, then disconnect events may still be logged after the rule is removed. For additional information, see [Section F.39.3.1](#).

Arguments:

- *db_name* — name of the database for which the logging rule needs to be removed.
- *event_type* — type of the event for which the logging rule needs to be removed. For the full list of possible *event_type* values, see [Section F.39.5](#).
- *object_type* — type of the object for which the logging rule needs to be removed.
- *object_name* — name of the object for which the logging rule needs to be removed.
- *role_name* — name of the role for which the logging rule needs to be removed.

```
pg_proaudit_show()
```

Returns logged events in a table view. This function is used by the `pg_proaudit_settings` view.

```
pg_proaudit_reload()
```

Reads logging configuration from the `pg_proaudit.conf` file. You must call this function if the `pg_proaudit.conf` file was modified manually using the operating system facilities.

```
pg_proaudit_reset()
```

Removes all logging rules. To save information about the canceled logging in the `pg_proaudit.conf` file, call the `pg_proaudit_save()` function.

```
pg_proaudit_save()
```

Saves logging rules from memory into the `pg_proaudit.conf` file. The `pg_proaudit.conf` file is located in the cluster data directory (PGDATA). You cannot change the `pg_proaudit.conf` file location.

F.39.3.1. Handling Database Disconnection Events

When a logging rule is configured for `DISCONNECT` event type, and a user authenticates in a database, then the `pg_proaudit` extension checks whether the corresponding disconnection event satisfies the rule and must be logged.

If the event must be logged, then the removal of the logging rule has no effect on the event. This event will be logged no matter if the logging rule exists at the moment of disconnect.

Consider the following example:

1. An administrator configures the following logging rule:

```
SELECT pg_proaudit_set_rule ('postgres', 'DISCONNECT', null, null, null, 'Any  
disconnect from the postgres DB');
```

2. A user connects to the `postgres` database and goes through authentication.

For the rule in effect, a corresponding disconnection event will be logged later.

3. The administrator removes the logging rule, while the user is still connected to the database:

```
SELECT pg_proaudit_remove_rule('postgres', 'DISCONNECT', null, null, null);
```

4. The user disconnects from the database.

The corresponding disconnection event is logged despite the removal of the logging rule.

F.39.3.2. Handling Object Names

Comparison of string representations of names for database, user, role and other objects is case-insensitive even if the object name in the database is enclosed in quotes. These string representations are stored as lower-case strings.

Strings representing object names need to be passed to functions `pg_proaudit_set_rule` and `pg_proaudit_remove_rule` as regular strings: a single quote needs repeating, and other characters are passed as is, without escaping or wrapping.

For example, rules for tables `table1` and `"TaBlE1"` will be the same, and their names can be passed in upper-case or lower-case characters. The same holds for roles. As for databases, before creating a rule, `pg_proaudit` checks whether this database actually exists, and this check is case-sensitive.

The following examples illustrate creation of "weird" object names and specifying correct audit rules for them.

```
create table "TaBlE'"123"();  
SELECT pg_proaudit_set_rule(current_database(), null, null, 'public.TabLe'"'"'123',  
    null, 'tst cmnt');  
create table "taBlE""123"();
```

```
SELECT pg_proaudit_set_rule(null, null, null, 'public.tablE"123', null);

create schema "(BIG!) Schema";
create table "(BIG!) Schema"."My Tab.lE"();
SELECT pg_proaudit_set_rule(null, null, null, '(BIG!) Schema.My Tab.lE', null);

create role "Some '@#$$' person" with login;
SELECT pg_proaudit_set_rule(null, 'authenticate', null, null, 'Some ''@#$$'' person');

create role "Some '@#$$' person" with superuser;
\c - "Some '@#$$' person"
SELECT pg_proaudit_set_rule(null, 'disconnect', null, null, current_user);

create database " D B 1";
SELECT pg_proaudit_set_rule(' D B 1', 'authenticate', null, null, null);

create database " D b 2";
\c " D b 2"
create extension pg_proaudit;
SELECT pg_proaudit_set_rule(current_database(), 'disconnect', null, null, null);
```

F.39.4. pg_proaudit_settings View

This view displays the current `pg_proaudit` rules, even if they have not been saved into the `pg_proaudit.conf` file yet. The `pg_proaudit_settings` view consists of the following columns:

- `db_name` (text) — name of the database for which to log security events.
- `event_type` (text) — event type to log.
- `object_type` (text) — type of the object for which security events are to be logged.
- `object_name` (text) — name of the object for which security events are to be logged.
- `role_name` (text) — the role on behalf of which logged actions are performed.
- `comment` (text) — comment to describe the created logging rule.

F.39.5. Security Events

You can configure the `pg_proaudit` extension to log classes of security events and specific events by specifying the respective value in the `event_type` argument of the `pg_proaudit_set_rule()` function.

The following classes of security events are supported:

- `ALL_DDL`: CREATE, ALTER, DROP for any database object except stored procedures and functions.
- `ALL_DDL_NONTEMP`: same as `ALL_DDL` but the scope is limited to the objects that are not contained in `pg_temp_nnn` temporary schemas.
- `ALL_DML`: SELECT, INSERT, UPDATE, DELETE, TRUNCATE for any table type; EXECUTE for functions and stored procedures.
- `ALL_DML_NONTEMP`: same as `ALL_DML` but the scope is limited to the objects that are not contained in `pg_temp_nnn` temporary schemas.
- `ALL_MOD`: INSERT, UPDATE, DELETE, TRUNCATE for any table type.
- `ALL_PROC`: CREATE, ALTER, DROP for any function and stored procedure.
- `ALL_ROLE`: CREATE, ALTER, DROP for USER, ROLE, GROUP, PROFILE, as well as execution of the GRANT command.
- `MISC`: all events not related to any of the other classes mentioned above.

The following specific security events are supported:

- ANALYZE
- AUTHENTICATE
- DISCONNECT
- ALTER AGGREGATE
- ALTER COLLATION
- ALTER CONVERSION
- ALTER DATABASE

- ALTER DEFAULT PRIVILEGES
- ALTER DOMAIN
- ALTER EVENT TRIGGER
- ALTER EXTENSION
- ALTER FOREIGN DATA WRAPPER
- ALTER FOREIGN TABLE
- ALTER FUNCTION
- ALTER INDEX
- ALTER LANGUAGE
- ALTER LARGE OBJECT
- ALTER MATERIALIZED VIEW
- ALTER OPERATOR
- ALTER OPERATOR CLASS
- ALTER OPERATOR FAMILY
- ALTER POLICY
- ALTER PROFILE
- ALTER ROLE, ALTER USER, ALTER GROUP
- ALTER RULE
- ALTER SCHEMA
- ALTER SEQUENCE
- ALTER SERVER
- ALTER SYSTEM
- ALTER TABLE
- ALTER TABLESPACE
- ALTER TEXT SEARCH CONFIGURATION
- ALTER TEXT SEARCH DICTIONARY
- ALTER TEXT SEARCH PARSER
- ALTER TEXT SEARCH TEMPLATE
- ALTER TRIGGER
- ALTER TYPE
- ALTER USER MAPPING
- ALTER VIEW
- CHECKPOINT
- CLUSTER
- COMMENT
- COPY
- CREATE ACCESS METHOD
- CREATE AGGREGATE
- CREATE CAST
- CREATE COLLATION
- CREATE CONVERSION
- CREATE DATABASE
- CREATE DOMAIN
- CREATE EVENT TRIGGER
- CREATE EXTENSION
- CREATE FOREIGN DATA WRAPPER
- CREATE FOREIGN TABLE
- CREATE FUNCTION
- CREATE INDEX
- CREATE LANGUAGE
- CREATE MATERIALIZED VIEW
- CREATE OPERATOR
- CREATE OPERATOR CLASS
- CREATE OPERATOR FAMILY
- CREATE POLICY
- CREATE PROFILE
- CREATE ROLE, CREATE USER, CREATE GROUP
- CREATE RULE

- CREATE SCHEMA
- CREATE SEQUENCE
- CREATE SERVER
- CREATE TABLE, CREATE TABLE AS, SELECT INTO
- CREATE TABLESPACE
- CREATE TEXT SEARCH CONFIGURATION
- CREATE TEXT SEARCH DICTIONARY
- CREATE TEXT SEARCH PARSER
- CREATE TEXT SEARCH TEMPLATE
- CREATE TRANSFORM
- CREATE TRIGGER
- CREATE TYPE
- CREATE USER MAPPING
- CREATE VIEW
- DEALLOCATE
- DELETE
- DISCARD ALL
- DISCARD PLANS
- DISCARD SEQUENCES
- DISCARD TEMP
- DO
- DROP ACCESS METHOD
- DROP AGGREGATE
- DROP CAST
- DROP COLLATION
- DROP CONVERSION
- DROP DATABASE
- DROP DOMAIN
- DROP EVENT TRIGGER
- DROP EXTENSION
- DROP FOREIGN DATA WRAPPER
- DROP FOREIGN TABLE
- DROP FUNCTION
- DROP INDEX
- DROP LANGUAGE
- DROP MATERIALIZED VIEW
- DROP OPERATOR
- DROP OPERATOR CLASS
- DROP OPERATOR FAMILY
- DROP OWNED
- DROP POLICY
- DROP PROFILE

- REASSIGN OWNED
- REFRESH MATERIALIZED VIEW
- REINDEX
- RESET
- REVOKE
- SECURITY LABEL
- SELECT
- SET
- UPDATE
- TRUNCATE TABLE
- VACUUM

F.39.6. Security Event Log Configuration Parameters

The `pg_proaudit` extension provides several configuration parameters for managing security event log files. These parameters can be set in the `postgresql.conf` configuration file, or with the help of the `ALTER SYSTEM` command. For the changes to take effect, call the `pg_reload_conf()` function or restart the database server. For additional configuration, the [syslog_ident](#) and [syslog_facility](#) configuration parameters can be used.

`pg_proaudit.log_destination` (string)

Defines the method for logging security events. Possible values are:

- `csvlog` — log security events in a CSV file.
- `syslog` — log security events in syslog.

You can specify one or more values separated by commas.

Default: `csvlog`

`pg_proaudit.log_catalog_access` (boolean)

Specifies whether to log access to system catalog objects in the `pg_catalog` schema.

When set to `off`, no events will be logged, even if there are rules for the `CATALOG RELATION`, `CATALOG FUNCTION`, or `ALL` object types.

It is not recommended to set the parameter to `on`, if you do not plan to log events for system catalog objects. Doing otherwise may impact Postgres Pro performance, even if there are no rules for the aforementioned object types.

Default: `off`

`pg_proaudit.log_command_text` (boolean)

Specifies whether to log the SQL command text for security events.

Default: `on`

`pg_proaudit.log_directory` (string)

Specifies the path to the directory that stores CSV log files. This can be an absolute path, or a relative path to the cluster data directory (`PGDATA`). This parameter is used if [pg_proaudit.log_destination](#) contains the `csvlog` value.

Default: `pg_proaudit`

`pg_proaudit.log_filename` (string)

Defines the filenames of the created security event log files. The filename template can contain %-escapes, similar to the ones listed in the `strftime` specification of the Open Group (<http://pubs.opengroup.org/onlinepubs/009695399/functions/strftime.html>). This parameter is used if `pg_proaudit.log_destination` contains the `csvlog` value.

Default: `postgresql-%Y-%m-%d_%H%M%S.log`

`pg_proaudit.log_rotation_size` (integer)

Sets the maximum size of the CSV log file, in kilobytes. When this size is achieved, `pg_proaudit` creates a new file for logging security events. This parameter is used if `pg_proaudit.log_destination` contains the `csvlog`. If set to 0, disables size-based creation of new log files.

Default: 10MB

`pg_proaudit.log_rotation_age` (integer)

Sets the maximum lifetime of a log file, in minutes. After this timeframe has elapsed, `pg_proaudit` creates a new file for logging security events. This parameter is used if `pg_proaudit.log_destination` contains the `csvlog` value. If set to 0, disables time-based creation of new log files.

Default: 1 day

`pg_proaudit.log_truncate_on_rotation` (boolean)

Specifies whether to truncate log files when logging is switched to an existing log file. If set to `off`, `pg_proaudit` appends new log entries to the end of the file. This parameter is used if `pg_proaudit.log_destination` contains the `csvlog` value.

Default: `off`

`pg_proaudit.max_rules_count` (integer)

Specifies the maximum number of rules allowed. For the parameter changes to take effect, the database server must be restarted.

Default: 500

F.39.7. Viewing Security Event Log

Security event log files are text files that can be viewed by the operating system facilities. To access log files using SQL, you can use the `file_fdw` extension — a foreign data wrapper for accessing files on the database server. To use this method, complete the following steps:

1. Install the `file_fdw` and create an external server:

```
CREATE EXTENSION file_fdw;  
CREATE SERVER pg_proauditlog FOREIGN DATA WRAPPER file_fdw;
```

2. Create a foreign table, specifying the columns and the absolute path to the log file. The actual log file location is determined by the `pg_proaudit.log_directory` and `pg_proaudit.log_filename` parameters.

```
CREATE FOREIGN TABLE pg_proaudit_log  
    ( log_time timestamp(3) with time zone,  
      current_usr_name text,  
      database_name text,  
      session_pid text,  
      error_severity text,  
      session_line_num bigint,  
      session_line_subcommand_num bigint,
```

```
event_type text,  
object_type text,  
object_name text,  
status text,  
error_message text,  
query_text text,  
query_args text,  
session_usr_name text,  
uuid text,  
xid text,  
vxid text )
```

```
SERVER pg_proauditlog  
OPTIONS (filename 'absolute_file_path_to_log_file.csv', FORMAT 'csv' );
```

Make sure that the `pg_proaudit.log_destination` parameter contains the `csvlog` value, which enables writing security event logs to CSV files.

F.39.8. Examples

As an example, let's set up logging for the following security events:

- authentications/disconnections to the `postgres` database
- all actions of the user if at least one of the user session attributes, `session_user` or `current_user`, is either explicitly set to the `postgres` role, or is directly or indirectly a member of this role
- creating, updating, and deleting any tables
- all operations on the `app_table` table that belongs to the `public` schema

All events must be logged in the CSV format and stored for a week. It is required to set up SQL access to the security event log. To complete the scenario, do the following:

In `psql`, check that the preliminary setup of the `pg_proaudit` extension is complete in the `postgres` database:

```
SHOW shared_preload_libraries;  
shared_preload_libraries  
-----  
pg_proaudit  
  
\dx pg_proaudit  
List of installed extensions  
Name | Version | Schema | Description  
-----+-----+-----+-----  
pg_proaudit | 2.0 | public | provides auditing functionality
```

Add the following lines to the `postgresql.conf` configuration file:

```
pg_proaudit.log_destination = 'csvlog'  
pg_proaudit.log_directory = 'audit'  
pg_proaudit.log_filename = 'audit-%u.csv'  
pg_proaudit.log_rotation_age = 1440  
pg_proaudit.log_rotation_size = 0  
pg_proaudit.log_truncate_on_rotation = on  
pg_proaudit.log_command_text = on
```

For the changes to take effect, run the following query:

```
SELECT pg_reload_conf();
```

Check that the following parameters are set as expected:

```
SHOW pg_proaudit.log_destination;
```

```
SHOW pg_proaudit.log_directory;
SHOW pg_proaudit.log_filename;
SHOW pg_proaudit.log_rotation_age;
SHOW pg_proaudit.log_rotation_size;
SHOW pg_proaudit.log_truncate_on_rotation;
SHOW pg_proaudit.log_command_text;
```

Suppose your PGDATA environment variable points to the cluster data directory. Since the pg_proaudit.log_directory defines a relative path to the log files, they will be located in the \$PGDATA/audit directory. Let's create an empty file for each day of the week and make them available to their owner only:

```
touch $PGDATA/audit/audit-1.csv
touch $PGDATA/audit/audit-2.csv
touch $PGDATA/audit/audit-3.csv
touch $PGDATA/audit/audit-4.csv
touch $PGDATA/audit/audit-5.csv
touch $PGDATA/audit/audit-6.csv
touch $PGDATA/audit/audit-7.csv
chmod 600 $PGDATA/audit/audit-*.csv
```

Create a table for reading log entries:

```
CREATE TABLE pg_proaudit_log (
    log_time timestamp(3) with time zone,
    current_usr_name text,
    database_name text,
    session_pid text,
    error_severity text,
    session_line_num bigint,
    session_line_subcommand_num bigint,
    event_type text,
    object_type text,
    object_name text,
    status text,
    error_message text,
    query_text text,
    query_args text,
    session_usr_name text,
    uuid text,
    xid text,
    vxid text
);
```

Install the file_fdw extension and create an external server:

```
CREATE EXTENSION file_fdw;
CREATE SERVER pg_proauditlog FOREIGN DATA WRAPPER file_fdw;
```

Now let's create seven child foreign tables for the pg_proaudit_log table, for each day of the week:

```
CREATE FOREIGN TABLE pg_proaudit_log_1 () INHERITS (pg_proaudit_log) SERVER
pg_proauditlog
    OPTIONS (filename '/path_to_PGDATA/audit/audit-1.csv', FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_2 () INHERITS (pg_proaudit_log) SERVER
pg_proauditlog
    OPTIONS (filename '/path_to_PGDATA/audit/audit-2.csv', FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_3 () INHERITS (pg_proaudit_log) SERVER
pg_proauditlog
    OPTIONS (filename '/path_to_PGDATA/audit/audit-3.csv', FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_4 () INHERITS (pg_proaudit_log) SERVER
pg_proauditlog
```

**Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib**

```
OPTIONS (filename '/path_to_PGDATA/audit/audit-4.csv', FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_5 () INHERITS (pg_proaudit_log) SERVER
pg_proauditlog
OPTIONS (filename '/path_to_PGDATA/audit/audit-5.csv', FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_6 () INHERITS (pg_proaudit_log) SERVER
pg_proauditlog
OPTIONS (filename '/path_to_PGDATA/audit/audit-6.csv', FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_7 () INHERITS (pg_proaudit_log) SERVER
pg_proauditlog
OPTIONS (filename '/path_to_PGDATA/audit/audit-7.csv', FORMAT 'csv');
```

To set up logging for the required security events, connect to the postgres database and execute the following commands:

```
SELECT pg_proaudit_set_rule (current_database(), 'AUTHENTICATE', null, null, null, 'Any
authentication in the current DB');
SELECT pg_proaudit_set_rule (current_database(), 'DISCONNECT', null, null, null, 'Any
disconnect from the current DB');
SELECT pg_proaudit_set_rule (current_database(), 'ALL', 'TABLE', null, null, 'Any
operations with any table in the current DB');
SELECT pg_proaudit_set_rule (current_database(), 'ALL', null, null, 'postgres', 'Any
operation by "postgres" user in the current DB');
```

Create the app_table table and enable logging for all operations on this table:

```
CREATE TABLE app_table (id int, name text);
SELECT pg_proaudit_set_rule (current_database(), 'ALL', null, 'public.app_table',
null);
```

Check that event logging is configured as expected:

```
SELECT * FROM pg_proaudit_settings;
db_name | event_type | object_type | object_name | role_name |
comment
-----+-----+-----+-----+-----+
postgres | authenticate | ALL | | | Any
authentication in the current DB
postgres | disconnect | ALL | | | Any disconnect
from the current DB
postgres | ALL | table | | | Any operations
with any table in the current DB
postgres | ALL | ALL | | postgres | Any operation
by "postgres" user in the current DB
postgres | ALL | ALL | public.app_table | |
(5 rows)
```

Save these logging rules into the pg_proaudit.conf file, so that they are not lost after the server restart:

```
SELECT pg_proaudit_save();
```

Let's run several queries on the app_table table:

```
INSERT INTO app_table VALUES (1, 'first');
SELECT * FROM app_table;
```

Check the log entries for the app_table table:

```
SELECT to_char(log_time, 'DD.MM.YY HH24:MI:SS') AS when, current_usr_name,
session_pid, event_type, query_text, session_usr_name
FROM pg_proaudit_log
WHERE object_name = 'public.app_table';
```

**Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib**

when query_text	current_usr_name	session_pid	event_type

(3 rows)				

We have set up a weekly rotation of log files, with the log file switched once a day. It means that queries to the `pg_proaudit_log` table will return only those security events that have happened in the latest week. Older events will be automatically removed at log file rotation. To define additional access constraints for specific log entries, you can create separate views based on queries to the `pg_proaudit_log` table and grant read rights to such views using built-in Postgres Pro access control methods.

F.40. pgpro_autopart — dynamic partition creation

The `pgpro_autopart` extension enables dynamic creation of partitions, that is automatic partitioning when data is added or modified in a table. The fastest way to create partitions is to do it manually or on schedule using a scheduler. However, for some tasks the speed of adding data does not matter much. For such tasks, `pgpro_autopart` implements automatic partitioning using triggers on a view of a partitioned table.

F.40.1. Installation

The `pgpro_autopart` extension is included in Postgres Pro. To enable `pgpro_autopart`, create the extension using the following query:

```
CREATE EXTENSION pgpro_autopart;
```

F.40.2. Usage

The `pgpro_autopart` extension uses the `ap_enable_automatic_partition_creation` function for automatic partitioning.

Note

Note that the extension works only with newly created tables. It cannot be used with existing partitioned tables, since it cannot track partitions previously created by users.

First, this function adds the `real_` prefix to the specified table name. Then, it creates a view with the original table name and adds the `INSTEAD OF INSERT/UPDATE` triggers to it.

Note

Note that the database administrator should grant privileges on the view created by the `ap_enable_automatic_partition_creation` function manually. It is expected that these privileges are the same as on the parent table.

These triggers work as follows:

- `INSTEAD OF INSERT`: When an entry is inserted into the view, `pgpro_autopart` searches for a partition for this entry. If the partition is not found, it is created. Then this entry is inserted into the partitioned table.
- `INSTEAD OF UPDATE`: When an entry is updated in the view, `pgpro_autopart` searches for a partition for this entry. If the partition is not found, it is created. Then this entry is updated in the partitioned table.

Note

The `INSERT` or `UPDATE` statement must contain a value for a partitioning key.

When using a sequence as the key value, it is required to explicitly set the value using `nextval()` because it can not be omitted. Otherwise, the `INSERT` or `UPDATE` operation will fail.

Currently, only tables with partitioning by range (`BY RANGE`) are supported, having one column of the `date`, `timestamp`, `timestampz`, `smallint`, `int`, or `bigint` type as a key.

When creating partitions for a partitioning key of `date/timestamp` types, valid values of the interval are `year`, `quarter`, `month`, and `day`. That is, a new partition is created for each new year, quarter, month or day.

Names for new partitions follow a strict format: a partitioned table name is followed by a suffix indicating the interval for which the partition is created. For example, for the following interval types table names will be as follows:

day

`real_t_day_2024_05_13` for the `real_t_day` table

month

`real_t_month_2024_05` for the `real_t_month` table

quarter

`real_t_quarter_2024_2` for the `real_t_quarter` table

year

`real_t_year_2025` for the `real_t_year` table

int

`real_t_int_120_130` for the `real_t_int` table

bigint

`"real_t_bigint_-60_-50"` for the `real_t_bigint` table

The `INSTEAD OF INSERT/UPDATE` triggers check the presence of a partition for *each* inserted or updated entry, and it can slow down the performance.

Since the original partitioned table is renamed, you should use its name with the `real_` prefix to work directly with the table.

Important

Remember that the maximum length for the table name in Postgres Pro is 63 bytes. When `pg_pro_autopart` creates a partition, it automatically adds up to 29 bytes (prefix `real_`, two underscores, symbols of borders) to the table name for the `int` type and up to 51 bytes for the `bigint` type of the partition key. It is the user's responsibility to choose appropriate table names to avoid errors.

F.40.3. `ap_tables_view` View

Tables with enabled automatic partitioning are shown in the `ap_tables_view` view. Here is an example of the data in the view.

```
SELECT * FROM ap_tables_view;
 apt_relname | apt_relschema | apt_mode
-----+-----
+-----+-----+-----
 t_month1    | user_schema   | automatic partition creation with using triggers on VIEW
 (C-implementation)
 t_bigint1   | user_schema   | automatic partition creation with using triggers on VIEW
 (C-implementation)
(2 rows)
```

F.40.4. Functions

`ap_enable_automatic_partition_creation(a_relname text[, a_relschema text], a_interval text)` returns void

This function is used for tables with a partitioning key of the `date`, `timestamp`, or `timestampz` type. It renames the partitioned table `a_relname` (of the `a_relschema` schema) by adding the `real_` prefix.

The function then creates a view with the same name as the original table and adds the `INSTEAD OF INSERT/UPDATE` triggers to it. These triggers create a new partition when needed. The limits of the partition are determined by the defined `a_interval` (year, quarter, month, day).

```
ap_enable_automatic_partition_creation(a_relname text[, a_relschema text], a_interval
smallint, a_firstval smallint) returns void
ap_enable_automatic_partition_creation(a_relname text[, a_relschema text], a_interval
int, a_firstval int) returns void
ap_enable_automatic_partition_creation(a_relname text[, a_relschema text], a_interval
bigint, a_firstval bigint) returns void
```

These functions are used for tables with a partitioning key of the `smallint`, `int`, or `bigint` type. They rename the partitioned table `a_relname` (of the `a_relschema` schema) by adding the `real_` prefix. The function then creates a view with the same name as the original table and the `INSTEAD OF INSERT/UPDATE` triggers for it. These triggers create a new partition when needed. The limits of the partition are determined by the original `a_firstval` value, from which the intervals are counted, and the `a_interval` value defining the interval length.

```
ap_disable_automatic_partition_creation(a_relname text[, a_relschema text]) returns void
```

The function removes the triggers created by the `ap_enable_automatic_partition_creation` function for the view of the defined partitioned table `a_relname` (of the `a_relschema` schema). It also deletes the view and renames the partitioned table, removing the `real_` prefix from its name.

F.40.5. Example

This example illustrates the usage of `pgpro_autopart` with the partitioning key of the `bigint` type.

Create the extension.

```
CREATE EXTENSION pgpro_autopart;
```

Create the table partitioned `BY RANGE` with one-column key of the `bigint` type.

```
CREATE TABLE t_bigint (b bigint, i int) PARTITION BY RANGE (b);
```

Use the extension to rename the `t_bigint` table into `real_t_bigint`, create the `t_bigint` view for this table, and then create the `INSTEAD OF INSERT/UPDATE` triggers. Note that the initial value for creating partitions is 100, and partitions are created at intervals of 10 in both directions.

```
SELECT ap_enable_automatic_partition_creation('t_bigint', 10, 100);
ap_enable_automatic_partition_creation
```

```
-----
(1 row)
```

Insert two entries into the table. The `real_t_bigint_110_120` partition will be created automatically after the first entry.

```
INSERT INTO t_bigint VALUES (111, 1);
NOTICE:  New partition "public"."real_t_bigint_110_120" created
INSERT 0 1
INSERT INTO t_bigint VALUES (114, 2);
INSERT 0 1
```

Change the key field for one of the entries. This will automatically create the `real_t_bigint_-60_-50` partition.

```
UPDATE t_bigint SET b = -55 WHERE b = 114 RETURNING *;
NOTICE:  New partition "public"."real_t_bigint_-60_-50" created
 b | i
----+---
-55 | 2
```

```
(1 row)
UPDATE 1
```

Check partitions of the `real_t_bigint` table. There should be two of them.

```
SELECT
  c.oid::pg_catalog.regclass AS "name",
  pg_catalog.pg_get_expr(c.relpartbound, c.oid) AS "condition"
FROM
  pg_catalog.pg_class c,
  pg_catalog.pg_inherits i
WHERE
  c.oid = i.inhrelid AND i.inhparent = 'real_t_bigint'::regclass;
      name      |
-----+-----
real_t_bigint_110_120 | FOR VALUES FROM ('110') TO ('120')
"real_t_bigint_-60_-50" | FOR VALUES FROM ('-60') TO ('-50')
(2 rows)
```

Check the data in the `real_t_bigint` table and its partitions. The table should contain two entries:

```
SELECT * FROM real_t_bigint;
  b  | i
-----+---
-55 | 2
111 | 1
(2 rows)
```

There should be one entry in the `real_t_bigint_110_120` partition:

```
SELECT * FROM real_t_bigint_110_120;
  b  | i
-----+---
111 | 1
(1 row)
```

And also there should be one entry in the `real_t_bigint_-60_-50` partition.

```
SELECT * FROM "real_t_bigint_-60_-50";
  b  | i
-----+---
-55 | 2
(1 row)
```

Disable triggers, drop the view, and rename the `real_t_bigint` table into `t_bigint`.

```
SELECT ap_disable_automatic_partition_creation('t_bigint');
ap_disable_automatic_partition_creation
-----
(1 row)
```

Drop the table and the extension.

```
DROP TABLE t_bigint;
DROP TABLE
DROP EXTENSION pgpro_autopart;
DROP EXTENSION
```

F.41. pg_logicalinspect — logical decoding components inspection

The `pg_logicalinspect` module provides SQL functions that allow you to inspect the contents of logical decoding components. It allows the inspection of serialized logical snapshots of a running Postgres Pro database cluster, which is useful for debugging or educational purposes.

By default, use of these functions is restricted to superusers and members of the `pg_read_server_files` role. Access may be granted by superusers to others using `GRANT`.

F.41.1. Functions

`pg_get_logical_snapshot_meta(filename text)` returns record

Gets logical snapshot metadata about a snapshot file that is located in the server's `pg_logical/snapshots` directory. The `filename` argument represents the snapshot file name. For example:

```
postgres=# SELECT * FROM pg_ls_logicalsnapdir();
-[ RECORD 1 ]+-----
name          | 0-40796E18.snap
size          | 152
modification  | 2024-08-14 16:36:32+00

postgres=# SELECT * FROM pg_get_logical_snapshot_meta('0-40796E18.snap');
-[ RECORD 1 ]-----
magic         | 1369563137
checksum      | 1028045905
version       | 6

postgres=# SELECT ss.name, meta.* FROM pg_ls_logicalsnapdir() AS ss,
pg_get_logical_snapshot_meta(ss.name) AS meta;
-[ RECORD 1 ]-----
name          | 0-40796E18.snap
magic         | 1369563137
checksum      | 1028045905
version       | 6
```

If `filename` does not match a snapshot file, the function raises an error.

`pg_get_logical_snapshot_info(filename text)` returns record

Gets logical snapshot information about a snapshot file that is located in the server's `pg_logical/snapshots` directory. The `filename` argument represents the snapshot file name. For example:

```
postgres=# SELECT * FROM pg_ls_logicalsnapdir();
-[ RECORD 1 ]+-----
name          | 0-40796E18.snap
size          | 152
modification  | 2024-08-14 16:36:32+00

postgres=# SELECT * FROM pg_get_logical_snapshot_info('0-40796E18.snap');
-[ RECORD 1 ]+-----+-----
state          | consistent
xmin           | 751
xmax           | 751
start_decoding_at | 0/40796AF8
two_phase_at   | 0/40796AF8
initial_xmin_horizon | 0
building_full_snapshot | f
in_slot_creation | f
```

Additional Supplied Modules and Extensions Shipped in postgrespro-std-18-contrib

```

last_serialized_snapshot | 0/0
next_phase_at           | 0
committed_count         | 0
committed_xip           |
catchchange_count       | 2
catchchange_xip         | {751,752}

postgres=# SELECT ss.name, info.* FROM pg_ls_logicalsnapdir() AS ss,
pg_get_logical_snapshot_info(ss.name) AS info;
-[ RECORD 1 ]-----+-----
name                | 0-40796E18.snap
state                | consistent
xmin                 | 751
xmax                 | 751
start_decoding_at   | 0/40796AF8
two_phase_at        | 0/40796AF8
initial_xmin_horizon | 0
building_full_snapshot | f
in_slot_creation     | f
last_serialized_snapshot | 0/0
next_phase_at        | 0
committed_count      | 0
committed_xip        |
catchchange_count    | 2
catchchange_xip      | {751,752}

```

If *filename* does not match a snapshot file, the function raises an error.

F.41.2. Author

Bertrand Drouvot <bertranddrouvot.pg@gmail.com>

F.42. pg_overexplain — allow EXPLAIN to dump even more details

The `pg_overexplain` module extends `EXPLAIN` with new options that provide additional output. It is mostly intended to assist with debugging of and development of the planner, rather than for general use. Since this module displays internal details of planner data structures, it may be necessary to refer to the source code to make sense of the output. Furthermore, the output is likely to change whenever (and as often as) those data structures change.

To use it, simply load it into the server. You can load it into an individual session:

```
LOAD 'pg_overexplain';
```

You can also preload it into some or all sessions by including `pg_overexplain` in [session_preload_libraries](#) or [shared_preload_libraries](#) in `postgresql.conf`.

F.42.1. EXPLAIN (DEBUG)

The `DEBUG` option displays miscellaneous information from the plan tree that is not normally shown because it is not expected to be of general interest. For each individual plan node, it will display the following fields. See `Plan` in `nodes/plannodes.h` for additional documentation of these fields.

- **Disabled Nodes.** Normal `EXPLAIN` determines whether a node is disabled by checking whether the node's count of disabled nodes is larger than the sum of the counts for the underlying nodes. This option shows the raw counter value.
- **Parallel Safe.** Indicates whether it would be safe for a plan tree node to appear beneath a `Gather` or `Gather Merge` node, regardless of whether it is actually below such a node.
- **Plan Node ID.** An internal ID number that should be unique for every node in the plan tree. It is used to coordinate parallel query activity.
- **extParam and allParam.** Information about which numbered parameters affect this plan node or its children. In text mode, these fields are only displayed if they are non-empty sets.

Once per query, the `DEBUG` option will display the following fields. See `PlannedStmt` in `nodes/plannodes.h` for additional detail.

- **Command Type.** For example, `select` or `update`.
- **Flags.** A comma-separated list of Boolean structure member names from the `PlannedStmt` that are set to `true`. It covers the following structure members: `hasReturning`, `hasModifyingCTE`, `canSetTag`, `transientPlan`, `dependsOnRole`, `parallelModeNeeded`.
- **Subplans Needing Rewind.** Integer IDs of subplans that may need to be rewound by the executor.
- **Relation OIDs.** OIDs of relations upon which this plan depends.
- **Executor Parameter Types.** Type OID for each executor parameter (e.g. when a nested loop is chosen and a parameter is used to pass a value down to an inner index scan). Does not include parameters supplied to a prepared statement by the user.
- **Parse Location.** Location within the query string supplied to the planner where this query's text can be found. May be `Unknown` in some contexts. Otherwise, may be `NNN to end` for some integer `NNN` or `NNN for MMM bytes` for some integers `NNN` and `MMM`.

F.42.2. EXPLAIN (RANGE_TABLE)

The `RANGE_TABLE` option displays information from the plan tree specifically concerning the query's range table. Range table entries correspond roughly to items appearing in the query's `FROM` clause, but with numerous exceptions. For example, subqueries that are proved unnecessary may be deleted from the range table entirely, while inheritance expansion adds range table entries for child tables that are not named directly in the query.

Range table entries are generally referenced within the query plan by a range table index, or RTI. Plan nodes that reference one or more RTIs will be labelled accordingly, using one of the following fields: `Scan RTI`, `Nominal RTI`, `Exclude Relation RTI`, `Append RTIs`.

In addition, the query as a whole may maintain lists of range table indexes that are needed for various purposes. These lists will be displayed once per query, labelled as appropriate as `Unprunable RTIs` or `Result RTIs`. In text mode, these fields are only displayed if they are non-empty sets.

Finally, but most importantly, the `RANGE_TABLE` option will display a dump of the query's entire range table. Each range table entry is labelled with the appropriate range table index, the kind of range table entry (e.g. `relation`, `subquery`, or `join`), followed by the contents of various range table entry fields that are not normally part of `EXPLAIN` output. Some of these fields are only displayed for certain kinds of range table entries. For example, `Eref` is displayed for all types of range table entries, but `CTE Name` is displayed only for range table entries of type `cte`.

For more information about range table entries, see the definition of `RangeTblEntry` in `nodes/plannodes.h`.

F.43. pgpro_bindump — a replication protocol module for backup and restore

pgpro_bindump is a module designed to implement additional commands for the Postgres Pro replication protocol, specifically for use with the [pg_probackup3](#) utility. pgpro_bindump offers the following benefits:

- Simplified communication: pgpro_bindump does not require the SSH protocol and associated configurations to connect to a database server.
- Integrated WAL transfer: WAL files are transferred together with data files, reducing the risk of data loss during backups.
- Optimized storage: Files are not copied as they are, but are archived using the pg_probackup3 own format, CBOR (RFC 8949 Concise Binary Object Representation), which enhances the storage efficiency.

F.43.1. Architecture

A dedicated backend process is created to handle connections from external applications. You can use the pg_probackup3 utility or a custom application to send requests to this backend.

Multiple connections can be established for the same application if needed.

Since the pgpro_bindump module has direct access to the database files, it does not require any additional permissions.

pgpro_bindump uses the [libpgprobackup](#), along with its built-in encoder module, to send data to the application.

The walsender_plugin_libraries plugin has been added to simplify the process of adding and utilizing new replication commands, including custom ones.

F.43.2. Limitations and Requirements

pgpro_bindump currently has the following limitations and requirements:

- libpgprobackup.so and libpb3_encoder.so are required for pgpro_bindump operation.

F.43.3. Installation and Setup

The pgpro_bindump module is included in Postgres Pro as part of the postgrespro-std-18-contrib package (for the installation instructions, see [Chapter 16](#)). Once you complete Postgres Pro installation, follow the steps below.

1. Specify the following parameters in the postgresql.conf file:

```
shared_preload_libraries = 'pgpro_bindump'
wal_level = 'replica' # or 'logical'
walsender_plugin_libraries = 'pgpro_bindump'
```

2. Restart the Postgres Pro instance.

F.43.4. Replication Commands

The pgpro_bindump module implements the following replication commands:

- just-noop — a do-nothing command.
- start_backup — starts the backup process.
- copy_files — copies files in the CBOR format.

- `stop_backup` — stops the backup process.

The backup process runs in the PRO mode — an advanced data source mode that incorporates all available optimizations and enhancements, including the proprietary replication protocol and specialized replication commands.

To send commands from a user application to `pgpro_bindump` and to receive the output data from `pgpro_bindump` by the application, use `libpq`.

Note

An established connection to a running Postgres Pro server is required.

F.43.4.1. `start_backup`

```
start_backup LABEL label, INCR_MODE incr_mode, START_LSN start_lsn,  
TRANSFER_MODE transfer_mode,  
[TRANSFER_BUFFER_SIZE buffer_size]
```

Starts the backup process. Sends the following data to the application:

- `start_lsn` — LSN at the start of the backup.
- `start_tli` — the timeline ID at the start of the backup.
- `min_xid` — the minimal transaction ID at the start of the backup.
- `min_multixact` — the minimal multixact ID at the start of the backup.
- `tablespace_list` — a list of tablespaces included in the backup.
- `database_list` — a list of databases included in the backup.

`LABEL label`

The name of the backup.

`INCR_MODE incr_mode`

The type of incremental backup. Possible values: `PTRACK`, `DELTA`.

`START_LSN start_lsn`

An `XLogRecPtr` value representing LSN at the start of the backup.

`TRANSFER_MODE transfer_mode`

The method to be used for sending data from a server to an application. Possible values:

- `raw` — unpacked data is sent in random blocks of arbitrary size.
- `packed` — packed data is sent in blocks of 128 KB with a common header.

`packed` is the default value.

`TRANSFER_BUFFER_SIZE buffer_size`

A numeric value representing the buffer size. The preset (unchanged) value is 131072 (128 KB).

F.43.4.2. `copy_files`

```
copy_files VERIFY_CHECKSUMS [TRUE | FALSE], COMPRESS_ALG compress_alg,  
COMPRESS_LVL compress_lvl, TRANSFER_MODE transfer_mode,  
[INCR_MODE incr_mode], [START_LSN start_lsn], [TRANSFER_BUFFER_SIZE buffer_size],  
[WORKER_INFO number_of_workers:worker_id]
```

Forwards blocks of data files and WAL files packaged in the CBOR format.

VERIFY_CHECKSUMS

A boolean value (`true` or `false`) indicating whether to verify checksums.

COMPRESS_ALG *compress_alg*

The compression algorithm to be used. Possible values: `zlib`, `zstd`, `lz4`, `none`.

COMPRESS_LVL *compress_lvl*

The compression level. Possible values: 1, 2, 3, 4, 5.

TRANSFER_MODE *transfer_mode*

The method to be used for sending data from a server to an application. Possible values:

- `raw` — unpacked data is sent in random blocks of arbitrary size.
- `packed` — packed data is sent in blocks of 128 KB with a common header.

`packed` is the default value.

INCR_MODE *incr_mode*

The type of incremental backup. Possible values: `PTRACK`, `DELTA`.

START_LSN *start_lsn*

An `XLogRecPtr` value representing LSN at the start of the backup.

TRANSFER_BUFFER_SIZE *buffer_size*

A numeric value representing the buffer size. The preset (unchanged) value is 131072 (128 KB).

WORKER_INFO *number_of_workers:worker_id*

The number of workers and the worker ID.

F.43.4.3. stop_backup

```
stop_backup STREAM [TRUE | FALSE], COMPRESS_ALG compress_alg,  
COMPRESS_LVL compress_lvl,  
[EXTERNALS externals] [TRANSFER_BUFFER_SIZE buffer_size], [TRANSFER_MODE transfer_mode]
```

Completes the copy process and closes the existing connection. Sends the following data to the application:

- `stop_lsn` — LSN at the end of the backup.
- `stop_tli` — the timeline ID at the end of the backup.
- The `backup.control` file.
- A set of WAL files (only if WAL streaming is enabled).

STREAM

A boolean value (`true` or `false`) indicating whether WAL streaming is enabled.

COMPRESS_ALG *compress_alg*

The compression algorithm to be used. Possible values: `zlib`, `zstd`, `lz4`, `none`.

COMPRESS_LVL *compress_lvl*

The compression level. Possible values: 1, 2, 3, 4, 5.

EXTERNALS *externals*

A list of external directories.

TRANSFER_BUFFER_SIZE *buffer_size*

A numeric value representing the buffer size. The preset (unchanged) value is 131072 (128 KB).

TRANSFER_MODE *transfer_mode*

The method to be used for sending data from a server to an application. Possible values:

- `raw` — unpacked data is sent in random blocks of arbitrary size.
- `packed` — packed data is sent in blocks of 128 KB with a common header.

`packed` is the default value.

F.43.5. Authors

Postgres Professional, Moscow, Russia.

F.44. pg_prewarm — preload relation data into buffer caches

The `pg_prewarm` module provides a convenient way to load relation data into either the operating system buffer cache or the Postgres Pro buffer cache. Prewarming can be performed manually using the `pg_prewarm` function, or can be performed automatically by including `pg_prewarm` in [shared_preload_libraries](#). In the latter case, the system will run a background worker which periodically records the contents of shared buffers in a file called `autoprewarm.blocks` and will, using 2 background workers, reload those same blocks after a restart.

F.44.1. Functions

```
pg_prewarm(regclass, mode text default 'buffer', fork text default 'main',  
           first_block int8 default null,  
           last_block int8 default null) RETURNS int8
```

The first argument is the relation to be prewarmed. The second argument is the prewarming method to be used, as further discussed below; the third is the relation fork to be prewarmed, usually `main`. The fourth argument is the first block number to prewarm (`NULL` is accepted as a synonym for zero). The fifth argument is the last block number to prewarm (`NULL` means prewarm through the last block in the relation). The return value is the number of blocks prewarmed.

There are three available prewarming methods. `prefetch` issues asynchronous prefetch requests to the operating system, if this is supported, or throws an error otherwise. `read` reads the requested range of blocks; unlike `prefetch`, this is synchronous and supported on all platforms and builds, but may be slower. `buffer` reads the requested range of blocks into the database buffer cache.

Note that with any of these methods, attempting to prewarm more blocks than can be cached — by the OS when using `prefetch` or `read`, or by Postgres Pro when using `buffer` — will likely result in lower-numbered blocks being evicted as higher numbered blocks are read in. Prewarmed data also enjoys no special protection from cache evictions, so it is possible that other system activity may evict the newly prewarmed blocks shortly after they are read; conversely, prewarming may also evict other data from cache. For these reasons, prewarming is typically most useful at startup, when caches are largely empty.

```
autoprewarm_start_worker() RETURNS void
```

Launch the main autoprewarm worker. This will normally happen automatically, but is useful if automatic prewarm was not configured at server startup time and you wish to start up the worker at a later time.

```
autoprewarm_dump_now() RETURNS int8
```

Update `autoprewarm.blocks` immediately. This may be useful if the autoprewarm worker is not running but you anticipate running it after the next restart. The return value is the number of records written to `autoprewarm.blocks`.

F.44.2. Configuration Parameters

```
pg_prewarm.autoprewarm (boolean)
```

Controls whether the server should run the autoprewarm worker. This is on by default. This parameter can only be set at server start.

```
pg_prewarm.autoprewarm_interval (integer)
```

This is the interval between updates to `autoprewarm.blocks`. The default is 300 seconds. If set to 0, the file will not be dumped at regular intervals, but only when the server is shut down.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
```

```
shared_preload_libraries = 'pg_prewarm'
```

```
pg_prewarm.autoprewarm = true  
pg_prewarm.autoprewarm_interval = 300s
```

F.45. pg_query_state — a facility to know the current state of query execution on working backend

The `pg_query_state` module provides facility to know the current state of query execution on working backend.

F.45.1. Overview

Each non-utility query statement (SELECT/INSERT/UPDATE/DELETE) after optimization/planning stage is translated into plan tree, which is kind of imperative representation of declarative SQL query. EXPLAIN ANALYZE request allows to demonstrate execution statistics gathered from each node of plan tree (full time of execution, number of rows emitted to upper nodes, etc). But this statistics is collected after execution of query. This module allows to show actual statistics of query running on external backend. At that, format of resulting output is almost identical to ordinal EXPLAIN ANALYZE. Thus users are able to track of query execution in progress. In fact, this module is able to explore external backend and determine its actual state. Particularly it's helpful when backend executes a heavy query or gets stuck.

F.45.2. Use cases

Using this module there can help in the following things:

- detect a long query (along with other monitoring tools);
- supervise query execution.

F.45.3. Installation

To install `pg_query_state`, complete the following steps:

1. Add the library name to the `shared_preload_libraries` parameter in the `postgresql.conf` file as follows:

```
shared_preload_libraries = 'pg_query_state'
```

2. Reload the database server for the changes to take effect.
3. Create the `pg_query_state` extension using the following query:

```
CREATE EXTENSION pg_query_state;
```

4. If you need to upgrade the `pg_query_state` extension, use `ALTER EXTENSION UPDATE`.

F.45.4. Functions

F.45.4.1. pg_query_state

```
pg_query_state (integer pid,  
                verbose boolean DEFAULT FALSE,  
                costs    boolean DEFAULT FALSE,  
                timing    boolean DEFAULT FALSE,  
                buffers   boolean DEFAULT FALSE,  
                triggers  boolean DEFAULT FALSE,  
                format    text    DEFAULT 'text')  
  
returns TABLE (pid integer,  
                frame_number integer,  
                query_text text,  
                plan text,  
                leader_pid integer)
```

Extract current query state from backend with specified `pid`. Since parallel query can spawn multiple workers and function call causes nested subqueries so that state of execution may be viewed as stack of running queries, return value of `pg_query_state` has type `TABLE (pid integer, frame_number integer, query_text text, plan text, leader_pid integer)`. It represents tree structure consisting of leader

process and its spawned workers identified by `pid`. Each worker refers to leader through `leader_pid` column. For leader process the value of this column is `null`. The state of each process is represented as stack of function calls. Each frame of that stack is specified as correspondence between `frame_number` starting from zero, `query_text` and `plan` with online statistics columns.

Thus, user can see the states of main query and queries generated from function calls for leader process and all workers spawned from it.

In process of execution some nodes of plan tree can take loops of full execution. Therefore statistics for each node consists of two parts: average statistics for previous loops just like in `EXPLAIN ANALYZE` output and statistics for current loop if node have not finished.

Optional arguments:

- `verbose` - use `EXPLAIN VERBOSE` for plan printing;
- `costs` - costs for each node;
- `timing` - print timing data for each node, if collecting of timing statistics is turned off on called side resulting output will contain WARNING message `timing statistics disabled`;
- `buffers` - print buffers usage, if collecting of buffers statistics is turned off on called side resulting output will contain WARNING message `buffers statistics disabled`;
- `triggers` - include triggers statistics in result plan trees;
- `format` - `EXPLAIN` format to be used for plans printing, possible values: `text`, `xml`, `json`, `yaml`.

If callable backend is not executing any query the function prints INFO message about backend's state taken from `pg_stat_activity` view if it exists there.

Calling role have to be superuser or member of the role whose backend is being called. Otherwise function prints ERROR message `permission denied`.

F.45.4.2. `pg_progress_bar`

```
pg_progress_bar (integer pid)
    returns FLOAT
```

Returns the current progress of query execution. This function extracts the state of the current query from the backend process with the specified `pid`. Then, it collects the actual and expected row counts from all plan nodes, and computes the overall progress ratio for the entire execution tree. As a result, the function returns a numeric value from 0 to 1 that means the query execution progress.

This function can be used in the Postgres Pro GUI to display the graphical progress bar indicator.

If there is no information about the current query state or it is impossible to calculate the query execution progress, the corresponding message is displayed.

This function can be called only by members of the role that owns the backend process or superusers.

F.45.4.3. `pg_progress_bar_visual`

```
pg_progress_bar_visual (integer pid,
                        integer delay)
    returns VOID
```

Cyclically calculates the current progress of query execution and prints it in the text form. The function extracts the state of the current query from the backend process with the specified `pid` with the interval defined in the `delay` parameter (in seconds).

This function is a cyclic version of the [pg_progress_bar](#) function but returns `void`. Unlike `pg_progress_bar`, the `pg_progress_bar_visual` function can be used to track the query execution progress without using the GUI.

If there is no information about the current query state or it is impossible to calculate the query execution progress, the corresponding message is displayed.

This function can be called only by members of the role that owns the backend process or superusers.

F.45.5. Configuration settings

There are several user-accessible GUC variables designed to toggle the whole module and the collecting of specific statistic parameters while query is running:

- `pg_query_state.enable` - disable (or enable) `pg_query_state` completely, default value is `true`
- `pg_query_state.enable_timing` - collect timing data for each node, default value is `false`
- `pg_query_state.enable_buffers` - collect buffers usage, default value is `false`

These parameters are set on called side before running any queries whose states are attempted to extract. **WARNING:** if `pg_query_state.enable_timing` is turned off the calling side cannot get time statistics, similarly for `pg_query_state.enable_buffers` parameter.

F.45.6. Usage Examples

Set maximum number of parallel workers on `gather` node equals 2:

```
postgres=# set max_parallel_workers_per_gather = 2;
```

Assume one backend with `pid = 49265` performs a simple query:

```
postgres=# select pg_backend_pid();
pg_backend_pid
-----
    49265
(1 row)
postgres=# select count(*) from foo join bar on foo.c1=bar.c1;
```

Other backend can extract intermediate state of execution that query:

```
postgres=# \x
postgres=# select * from pg_query_state(49265);
-[ RECORD
  1 ]+-----
pid          | 49265
frame_number | 0
query_text   | select count(*) from foo join bar on foo.c1=bar.c1;
plan         | Finalize Aggregate (Current loop: actual rows=0, loop number=1)
              |
              |      -> Gather (Current loop: actual rows=0, loop number=1)
              |
              |      Workers Planned: 2
              |
              |      Workers Launched: 2
              |
              |      -> Partial Aggregate (Current loop: actual rows=0, loop
number=1)
              |
              |      -> Nested Loop (Current loop: actual rows=12, loop
number=1)
              |
              |      Join Filter: (foo.c1 = bar.c1)
              |
              |      Rows Removed by Join Filter: 5673232
              |
              |      -> Parallel Seq Scan on foo (Current loop: actual
rows=12, loop number=1)
              |
              |      -> Seq Scan on bar (actual rows=500000 loops=11)
              |      (Current loop: actual rows=173244, loop number=12)
leader_pid   | (null)
-[ RECORD
  2 ]+-----
```

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

```

pid          | 49324
frame_number | 0
query_text   | <parallel query>
plan         | Partial Aggregate (Current loop: actual rows=0, loop number=1)
              |
              |      -> Nested Loop (Current loop: actual rows=10, loop number=1)
              |      +
              |      |      Join Filter: (foo.c1 = bar.c1)
              |      |      +
              |      |      Rows Removed by Join Filter: 4896779
              |      |      +
              |      |      -> Parallel Seq Scan on foo (Current loop: actual rows=10, loop
number=1)      |      +
              |      |      -> Seq Scan on bar (actual rows=500000 loops=9) (Current loop:
actual rows=396789, loop number=10)
leader_pid   | 49265
-[ RECORD
3 ]+-----
pid          | 49323
frame_number | 0
query_text   | <parallel query>
plan         | Partial Aggregate (Current loop: actual rows=0, loop number=1)
              |
              |      -> Nested Loop (Current loop: actual rows=11, loop number=1)
              |      +
              |      |      Join Filter: (foo.c1 = bar.c1)
              |      |      +
              |      |      Rows Removed by Join Filter: 5268783
              |      |      +
              |      |      -> Parallel Seq Scan on foo (Current loop: actual rows=11, loop
number=1)      |      +
              |      |      -> Seq Scan on bar (actual rows=500000 loops=10) (Current loop:
actual rows=268794, loop number=11)
leader_pid   | 49265

```

In example above working backend spawns two parallel workers with pids 49324 and 49323. Their leader_pid column's values clarify that these workers belong to the main backend. Seq Scan node has statistics on passed loops (average number of rows delivered to Nested Loop and number of passed loops are shown) and statistics on current loop. Other nodes has statistics only for current loop as this loop is first (loop number = 1).

Assume first backend executes some function:

```
postgres=# select n_join_foo_bar();
```

Other backend can get the follow output:

```

postgres=# select * from pg_query_state(49265);
-[ RECORD
1 ]+-----
pid          | 49265
frame_number | 0
query_text   | select n_join_foo_bar();
plan         | Result (Current loop: actual rows=0, loop number=1)
leader_pid   | (null)
-[ RECORD
2 ]+-----
pid          | 49265

```

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

frame_number		1
query_text		SELECT (select count(*) from foo join bar on foo.c1=bar.c1)
plan		Result (Current loop: actual rows=0, loop number=1)
		+
		InitPlan 1 (returns \$0)
		+
		-> Aggregate (Current loop: actual rows=0, loop number=1)
		+
		-> Nested Loop (Current loop: actual rows=51, loop number=1)
		+
		Join Filter: (foo.c1 = bar.c1)
		+
		Rows Removed by Join Filter: 51636304
		+
		-> Seq Scan on bar (Current loop: actual rows=52, loop
number=1)		+
		-> Materialize (actual rows=1000000 loops=51) (Current
loop: actual rows=636355, loop number=52)+		
		-> Seq Scan on foo (Current loop: actual
rows=1000000, loop number=1)		
leader_pid		(null)

First row corresponds to function call, second - to query which is in the body of that function.

We can get result plans in different format (e.g. json):

```
postgres=# select * from pg_query_state(pid := 49265, format := 'json');
-[ RECORD 1 ]+-----
pid          | 49265
frame_number | 0
query_text   | select * from n_join_foo_bar();
plan         | {
              |   "Plan": {
              |     "Node Type": "Function Scan",
              |     "Parallel Aware": false,
              |     "Function Name": "n_join_foo_bar",
              |     "Alias": "n_join_foo_bar",
              |     "Current loop": {
              |       "Actual Loop Number": 1,
              |       "Actual Rows": 0
              |     }
              |   }

F.45.7. Progress Bar Usage Examples

The first backend process executes the following sample query:

```
postgres=# insert into table_name select generate_series(1,10000000);
```

Another backend process can get the execution process of the query above as follows:

```
postgres=# SELECT pid FROM pg_stat_activity where query like 'insert%';
 pid
-----
 23877
(1 row)
```

```
postgres=# SELECT pg_progress_bar(23877);
 pg_progress_bar
-----
          0.6087927
(1 row)
```

To display a visual representation of the query execution progress, run the following query:

```
postgres=# SELECT pg_progress_bar_visual(23877, 1);
Progress = 0.043510
Progress = 0.085242
Progress = 0.124921
Progress = 0.168168
Progress = 0.213803
Progress = 0.250362
Progress = 0.292632
Progress = 0.331454
Progress = 0.367509
Progress = 0.407450
Progress = 0.448646
Progress = 0.488171
Progress = 0.530559
Progress = 0.565558
Progress = 0.608039
Progress = 0.645778
Progress = 0.654842

F.46. pgrowlocks — show a table's row locking information

The `pgrowlocks` module provides a function to show row locking information for a specified table.

By default use is restricted to superusers, roles with privileges of the `pg_stat_scan_tables` role, and users with `SELECT` permissions on the table.

F.46.1. Overview

`pgrowlocks(text)` returns `setof record`

The parameter is the name of a table. The result is a set of records, with one row for each locked row within the table. The output columns are shown in [Table F.26](#).

Table F.26. `pgrowlocks` Output Columns

Name	Type	Description
<code>locked_row</code>	<code>tid</code>	Tuple ID (TID) of locked row
<code>locker</code>	<code>xid</code>	Transaction ID of locker, or multixact ID if multitransaction; see Section 65.1
<code>multi</code>	<code>boolean</code>	True if locker is a multitransaction
<code>xids</code>	<code>xid[]</code>	Transaction IDs of lockers (more than one if multitransaction)
<code>modes</code>	<code>text[]</code>	Lock mode of lockers (more than one if multitransaction), an array of For Key Share, For Share, For No Key Update, No Key Update, For Update, Update.
<code>pids</code>	<code>integer[]</code>	Process IDs of locking backends (more than one if multitransaction)

`pgrowlocks` takes `AccessShareLock` for the target table and reads each row one by one to collect the row locking information. This is not very speedy for a large table. Note that:

1. If an `ACCESS EXCLUSIVE` lock is taken on the table, `pgrowlocks` will be blocked.
2. `pgrowlocks` is not guaranteed to produce a self-consistent snapshot. It is possible that a new row lock is taken, or an old lock is freed, during its execution.

`pgrowlocks` does not show the contents of locked rows. If you want to take a look at the row contents at the same time, you could do something like this:

```
SELECT * FROM accounts AS a, pgrowlocks('accounts') AS p
WHERE p.locked_row = a.ctid;
```

Be aware however that such a query will be very inefficient.

F.46.2. Sample Output

```
=# SELECT * FROM pgrowlocks('t1');
locked_row | locker | multi | xids  |      modes      | pids
-----+-----+-----+-----+-----+-----
(0,1)      |    609 |   f    | {609} | {"For Share"}   | {3161}
(0,2)      |    609 |   f    | {609} | {"For Share"}   | {3161}
(0,3)      |    607 |   f    | {607} | {"For Update"}  | {3107}
```

F.47. pg_stat_statements — track statistics of SQL planning and execution

The `pg_stat_statements` module provides a means for tracking planning and execution statistics of all SQL statements executed by a server.

The module must be loaded by adding `pg_stat_statements` to [shared_preload_libraries](#) in `postgresql.conf`, because it requires additional shared memory. This means that a server restart is needed to add or remove the module. In addition, query identifier calculation must be enabled in order for the module to be active, which is done automatically if [compute_query_id](#) is set to `auto` or `on`, or any third-party module that calculates query identifiers is loaded.

When `pg_stat_statements` is active, it tracks statistics across all databases of the server. To access and manipulate these statistics, the module provides views `pg_stat_statements` and `pg_stat_statements_info`, and the utility functions `pg_stat_statements_reset` and `pg_stat_statements`. These are not available globally but can be enabled for a specific database with `CREATE EXTENSION pg_stat_statements`.

F.47.1. The pg_stat_statements View

The statistics gathered by the module are made available via a view named `pg_stat_statements`. This view contains one row for each distinct combination of database ID, user ID, query ID and whether it's a top-level statement or not (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in [Table F.27](#).

Table F.27. pg_stat_statements Columns

Column Type	Description
<code>userid oid</code> (references <code>pg_authid .oid</code>)	OID of user who executed the statement
<code>dbid oid</code> (references <code>pg_database .oid</code>)	OID of database in which the statement was executed
<code>toplevel bool</code>	True if the query was executed as a top-level statement (always true if <code>pg_stat_statements.track</code> is set to <code>top</code>)
<code>queryid bigint</code>	Hash code to identify identical normalized queries.
<code>query text</code>	Text of a representative statement
<code>plans bigint</code>	Number of times the statement was planned (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>total_plan_time double precision</code>	Total time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>min_plan_time double precision</code>	Minimum time spent planning the statement, in milliseconds. This field will be zero if <code>pg_stat_statements.track_planning</code> is disabled, or if the counter has been reset using the <code>pg_stat_statements_reset</code> function with the <code>minmax_only</code> parameter set to <code>true</code> and never been planned since.
<code>max_plan_time double precision</code>	Maximum time spent planning the statement, in milliseconds. This field will be zero if <code>pg_stat_statements.track_planning</code> is disabled, or if the counter has been reset using the

Column Type	Description
<code>pg_stat_statements_reset</code>	function with the <code>minmax_only</code> parameter set to <code>true</code> and never been planned since.
<code>mean_plan_time</code> double precision	Mean time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>stddev_plan_time</code> double precision	Population standard deviation of time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>calls</code> bigint	Number of times the statement was executed
<code>total_exec_time</code> double precision	Total time spent executing the statement, in milliseconds
<code>min_exec_time</code> double precision	Minimum time spent executing the statement, in milliseconds, this field will be zero until this statement is executed first time after reset performed by the <code>pg_stat_statements_reset</code> function with the <code>minmax_only</code> parameter set to <code>true</code>
<code>max_exec_time</code> double precision	Maximum time spent executing the statement, in milliseconds, this field will be zero until this statement is executed first time after reset performed by the <code>pg_stat_statements_reset</code> function with the <code>minmax_only</code> parameter set to <code>true</code>
<code>mean_exec_time</code> double precision	Mean time spent executing the statement, in milliseconds
<code>stddev_exec_time</code> double precision	Population standard deviation of time spent executing the statement, in milliseconds
<code>rows</code> bigint	Total number of rows retrieved or affected by the statement
<code>shared_blks_hit</code> bigint	Total number of shared block cache hits by the statement
<code>shared_blks_read</code> bigint	Total number of shared blocks read by the statement
<code>shared_blks_dirtied</code> bigint	Total number of shared blocks dirtied by the statement
<code>shared_blks_written</code> bigint	Total number of shared blocks written by the statement
<code>local_blks_hit</code> bigint	Total number of local block cache hits by the statement
<code>local_blks_read</code> bigint	Total number of local blocks read by the statement
<code>local_blks_dirtied</code> bigint	Total number of local blocks dirtied by the statement
<code>local_blks_written</code> bigint	Total number of local blocks written by the statement
<code>temp_blks_read</code> bigint	Total number of temp blocks read by the statement
<code>temp_blks_written</code> bigint	Total number of temp blocks written by the statement
<code>shared_blk_read_time</code> double precision	

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

Column Type	Description
	Total time the statement spent reading shared blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
shared_blk_write_time double precision	Total time the statement spent writing shared blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
local_blk_read_time double precision	Total time the statement spent reading local blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
local_blk_write_time double precision	Total time the statement spent writing local blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
temp_blk_read_time double precision	Total time the statement spent reading temporary file blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
temp_blk_write_time double precision	Total time the statement spent writing temporary file blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
wal_records bigint	Total number of WAL records generated by the statement
wal_fpi bigint	Total number of WAL full page images generated by the statement
wal_bytes numeric	Total amount of WAL generated by the statement in bytes
wal_buffers_full bigint	Number of times the WAL buffers became full
jit_functions bigint	Total number of functions JIT-compiled by the statement
jit_generation_time double precision	Total time spent by the statement on generating JIT code, in milliseconds
jit_inlining_count bigint	Number of times functions have been inlined
jit_inlining_time double precision	Total time spent by the statement on inlining functions, in milliseconds
jit_optimization_count bigint	Number of times the statement has been optimized
jit_optimization_time double precision	Total time spent by the statement on optimizing, in milliseconds
jit_emission_count bigint	Number of times code has been emitted
jit_emission_time double precision	Total time spent by the statement on emitting code, in milliseconds
jit_deform_count bigint	Total number of tuple deform functions JIT-compiled by the statement
jit_deform_time double precision	Total time spent by the statement on JIT-compiling tuple deform functions, in milliseconds
parallel_workers_to_launch bigint	Number of parallel workers planned to be launched

Column Type	Description
parallel_workers_launched bigint	Number of parallel workers actually launched
stats_since timestamp with time zone	Time at which statistics gathering started for this statement
minmax_stats_since timestamp with time zone	Time at which min/max statistics gathering started for this statement (fields min_plan_time , max_plan_time , min_exec_time and max_exec_time)

For security reasons, only superusers and roles with privileges of the `pg_read_all_stats` role are allowed to see the SQL text and `queryid` of queries executed by other users. Other users can see the statistics, however, if the view has been installed in their database.

Plannable queries (that is, `SELECT`, `INSERT`, `UPDATE`, `DELETE`, and `MERGE`) and utility commands are combined into a single `pg_stat_statements` entry whenever they have identical query structures according to an internal hash calculation. Typically, two queries will be considered the same for this purpose if they are semantically equivalent except for the values of literal constants appearing in the query.

Note

The following details about constant replacement and `queryid` only apply when `compute_query_id` is enabled. If you use an external module instead to compute `queryid`, you should refer to its documentation for details.

When a constant's value has been ignored for purposes of matching the query to other queries, the constant is replaced by a parameter symbol, such as `$1`, in the `pg_stat_statements` display. The rest of the query text is that of the first query that had the particular `queryid` hash value associated with the `pg_stat_statements` entry.

Queries on which normalization can be applied may be observed with constant values in `pg_stat_statements`, especially when there is a high rate of entry deallocations. To reduce the likelihood of this happening, consider increasing `pg_stat_statements.max`. The `pg_stat_statements_info` view, discussed below in [Section F.47.2](#), provides statistics about entry deallocations.

In some cases, queries with visibly different texts might get merged into a single `pg_stat_statements` entry; as explained above, this is expected to happen for semantically equivalent queries. In addition, if the only difference between queries is the number of elements in a list of constants, the list will get squashed down to a single element but shown with a commented-out list indicator:

```
=# SELECT pg_stat_statements_reset();
=# SELECT * FROM test WHERE a IN (1, 2, 3, 4, 5, 6, 7);
=# SELECT * FROM test WHERE a IN (1, 2, 3, 4, 5, 6, 7, 8);
=# SELECT query, calls FROM pg_stat_statements
   WHERE query LIKE 'SELECT%';
-[ RECORD 1 ]-----
query | SELECT * FROM test WHERE a IN ($1 /*, ... */)
calls | 2
```

In addition to these cases, there is a small chance of hash collisions causing unrelated queries to be merged into one entry. (This cannot happen for queries belonging to different users or databases, however.)

Since the `queryid` hash value is computed on the post-parse-analysis representation of the queries, the opposite is also possible: queries with identical texts might appear as separate entries, if they have different meanings as a result of factors such as different `search_path` settings.

Consumers of `pg_stat_statements` may wish to use `queryid` (perhaps in combination with `dbid` and `userid`) as a more stable and reliable identifier for each entry than its query text. However, it is important to understand that there are only limited guarantees around the stability of the `queryid` hash value. Since the identifier is derived from the post-parse-analysis tree, its value is a function of, among other things, the internal object identifiers appearing in this representation. This has some counterintuitive implications. For example, `pg_stat_statements` will consider two apparently-identical queries to be distinct, if they reference for example a function that was dropped and recreated between the executions of the two queries. Conversely, if a table is dropped and recreated between the executions of queries, two apparently-identical queries may be considered the same. However, if the alias for a table is different for otherwise-similar queries, these queries will be considered distinct. The hashing process is also sensitive to differences in machine architecture and other facets of the platform. Furthermore, it is not safe to assume that `queryid` will be stable across major versions of Postgres Pro.

Two servers participating in replication based on physical WAL replay can be expected to have identical `queryid` values for the same query. However, logical replication schemes do not promise to keep replicas identical in all relevant details, so `queryid` will not be a useful identifier for accumulating costs across a set of logical replicas. If in doubt, direct testing is recommended.

Generally, it can be assumed that `queryid` values are stable between minor version releases of Postgres Pro, providing that instances are running on the same machine architecture and the catalog metadata details match. Compatibility will only be broken between minor versions as a last resort.

The parameter symbols used to replace constants in representative query texts start from the next number after the highest `$n` parameter in the original query text, or `$1` if there was none. It's worth noting that in some cases there may be hidden parameter symbols that affect this numbering. For example, PL/pgSQL uses hidden parameter symbols to insert values of function local variables into queries, so that a PL/pgSQL statement like `SELECT i + 1 INTO j` would have representative text like `SELECT i + $2`.

The representative query texts are kept in an external disk file, and do not consume shared memory. Therefore, even very lengthy query texts can be stored successfully. However, if many long query texts are accumulated, the external file might grow unmanageably large. As a recovery method if that happens, `pg_stat_statements` may choose to discard the query texts, whereupon all existing entries in the `pg_stat_statements` view will show null `query` fields, though the statistics associated with each `queryid` are preserved. If this happens, consider reducing `pg_stat_statements.max` to prevent recurrences.

`plans` and `calls` aren't always expected to match because planning and execution statistics are updated at their respective end phase, and only for successful operations. For example, if a statement is successfully planned but fails during the execution phase, only its planning statistics will be updated. If planning is skipped because a cached plan is used, only its execution statistics will be updated.

F.47.2. The `pg_stat_statements_info` View

The statistics of the `pg_stat_statements` module itself are tracked and made available via a view named `pg_stat_statements_info`. This view contains only a single row. The columns of the view are shown in [Table F.28](#).

Table F.28. `pg_stat_statements_info` Columns

Column	Type	Description
<code>dealloc bigint</code>		Total number of times <code>pg_stat_statements</code> entries about the least-executed statements were deallocated because more distinct statements than <code>pg_stat_statements.max</code> were observed
<code>stats_reset</code>	timestamp with time zone	Time at which all statistics in the <code>pg_stat_statements</code> view were last reset.

F.47.3. Functions

`pg_stat_statements_reset(userid Oid, dbid Oid, queryid bigint, minmax_only boolean)` returns timestamp with time zone

`pg_stat_statements_reset` discards statistics gathered so far by `pg_stat_statements` corresponding to the specified `userid`, `dbid` and `queryid`. If any of the parameters are not specified, the default value 0 (invalid) is used for each of them and the statistics that match with other parameters will be reset. If no parameter is specified or all the specified parameters are 0 (invalid), it will discard all statistics. If all statistics in the `pg_stat_statements` view are discarded, it will also reset the statistics in the `pg_stat_statements_info` view. When `minmax_only` is true only the values of minimum and maximum planning and execution time will be reset (i.e. `min_plan_time`, `max_plan_time`, `min_exec_time` and `max_exec_time` fields). The default value for `minmax_only` parameter is false. Time of last min/max reset performed is shown in `minmax_stats_since` field of the `pg_stat_statements` view. This function returns the time of a reset. This time is saved to `stats_reset` field of `pg_stat_statements_info` view or to `minmax_stats_since` field of the `pg_stat_statements` view if the corresponding reset was actually performed. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

`pg_stat_statements(showtext boolean)` returns setof record

The `pg_stat_statements` view is defined in terms of a function also named `pg_stat_statements`. It is possible for clients to call the `pg_stat_statements` function directly, and by specifying `showtext := false` have query text be omitted (that is, the `OUT` argument that corresponds to the view's `query` column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all `pg_stat_statements` itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the `pg_stat_statements` data.

F.47.4. Configuration Parameters

`pg_stat_statements.max (integer)`

`pg_stat_statements.max` is the maximum number of statements tracked by the module (i.e., the maximum number of rows in the `pg_stat_statements` view). If more distinct statements than that are observed, information about the least-executed statements is discarded. The number of times such information was discarded can be seen in the `pg_stat_statements_info` view. The default value is 5000. This parameter can only be set at server start.

`pg_stat_statements.track (enum)`

`pg_stat_statements.track` controls which statements are counted by the module. Specify `top` to track top-level statements (those issued directly by clients), `all` to also track nested statements (such as statements invoked within functions), or `none` to disable statement statistics collection. The default value is `top`. Only superusers can change this setting.

`pg_stat_statements.track_utility (boolean)`

`pg_stat_statements.track_utility` controls whether utility commands are tracked by the module. Utility commands are all those other than `SELECT`, `INSERT`, `UPDATE`, `DELETE`, and `MERGE`. The default value is `on`. Only superusers can change this setting.

`pg_stat_statements.track_planning (boolean)`

`pg_stat_statements.track_planning` controls whether planning operations and duration are tracked by the module. Enabling this parameter may incur a noticeable performance penalty, especially when statements with identical query structure are executed by many concurrent connections which compete to update a small number of `pg_stat_statements` entries. The default value is `off`. Only superusers can change this setting.

`pg_stat_statements.save` (boolean)

`pg_stat_statements.save` specifies whether to save statement statistics across server shutdowns. If it is `off` then statistics are not saved at shutdown nor reloaded at server start. The default value is `on`. This parameter can only be set in the `postgresql.conf` file or on the server command line.

The module requires additional shared memory proportional to `pg_stat_statements.max`. Note that this memory is consumed whenever the module is loaded, even if `pg_stat_statements.track` is set to `none`.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'pg_stat_statements'

compute_query_id = on
pg_stat_statements.max = 10000
pg_stat_statements.track = all
```

F.47.5. Sample Output

```
bench=# SELECT pg_stat_statements_reset();

F.47.6. Authors

Takahiro Itagaki <itagaki.takahiro@oss.ntt.co.jp>. Query normalization added by Peter Geoghegan <peter@2ndquadrant.com>.

F.48. pgstattuple — obtain tuple-level statistics

The `pgstattuple` module provides various functions to obtain tuple-level statistics.

Because these functions return detailed page-level information, access is restricted by default. By default, only the role `pg_stat_scan_tables` has `EXECUTE` privilege. Superusers of course bypass this restriction. After the extension has been installed, users may issue `GRANT` commands to change the privileges on the functions to allow others to execute them. However, it might be preferable to add those users to the `pg_stat_scan_tables` role instead.

F.48.1. Functions

`pgstattuple(regclass)` returns record

`pgstattuple` returns a relation's physical length, percentage of “dead” tuples, and other info. This may help users to determine whether vacuum is necessary or not. The argument is the target relation's name (optionally schema-qualified) or OID. For example:

```
test=> SELECT * FROM pgstattuple('pg_catalog.pg_proc');
-[ RECORD 1 ]-----+-----
table_len          | 458752
tuple_count        | 1470
tuple_len          | 438896
tuple_percent      | 95.67
dead_tuple_count   | 11
dead_tuple_len     | 3157
dead_tuple_percent | 0.69
free_space         | 8932
free_percent       | 1.95
```

The output columns are described in [Table F.29](#).

Table F.29. pgstattuple Output Columns

Column	Type	Description
<code>table_len</code>	<code>bigint</code>	Physical relation length in bytes
<code>tuple_count</code>	<code>bigint</code>	Number of live tuples
<code>tuple_len</code>	<code>bigint</code>	Total length of live tuples in bytes
<code>tuple_percent</code>	<code>float8</code>	Percentage of live tuples
<code>dead_tuple_count</code>	<code>bigint</code>	Number of dead tuples
<code>dead_tuple_len</code>	<code>bigint</code>	Total length of dead tuples in bytes
<code>dead_tuple_percent</code>	<code>float8</code>	Percentage of dead tuples
<code>free_space</code>	<code>bigint</code>	Total free space in bytes
<code>free_percent</code>	<code>float8</code>	Percentage of free space

Note

The `table_len` will always be greater than the sum of the `tuple_len`, `dead_tuple_len` and `free_space`. The difference is accounted for by fixed page overhead, the per-page table of pointers to tuples, and padding to ensure that tuples are correctly aligned.

`pgstattuple` acquires only a read lock on the relation. So the results do not reflect an instantaneous snapshot; concurrent updates will affect them.

`pgstattuple` judges a tuple is “dead” if `HeapTupleSatisfiesDirty` returns false.

`pgstattuple(text)` returns record

This is the same as `pgstattuple(regclass)`, except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatindex(regclass)` returns record

`pgstatindex` returns a record showing information about a B-tree index. For example:

```
test=> SELECT * FROM pgstatindex('pg_cast_oid_index');
-[ RECORD 1 ]-----+-----
version           | 2
tree_level        | 0
index_size         | 16384
root_block_no     | 1
internal_pages    | 0
leaf_pages        | 1
empty_pages       | 0
deleted_pages     | 0
avg_leaf_density  | 54.27
leaf_fragmentation | 0
```

The output columns are:

Column	Type	Description
version	integer	B-tree version number
tree_level	integer	Tree level of the root page
index_size	bigint	Total index size in bytes
root_block_no	bigint	Location of root page (zero if none)
internal_pages	bigint	Number of “internal” (upper-level) pages
leaf_pages	bigint	Number of leaf pages
empty_pages	bigint	Number of empty pages
deleted_pages	bigint	Number of deleted pages
avg_leaf_density	float8	Average density of leaf pages
leaf_fragmentation	float8	Leaf page fragmentation

The reported `index_size` will normally correspond to one more page than is accounted for by `internal_pages` + `leaf_pages` + `empty_pages` + `deleted_pages`, because it also includes the index's metapage.

As with `pgstattuple`, the results are accumulated page-by-page, and should not be expected to represent an instantaneous snapshot of the whole index.

`pgstatindex(text)` returns record

This is the same as `pgstatindex(regclass)`, except that the target index is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatginindex(regclass)` returns record

`pgstatginindex` returns a record showing information about a GIN index. For example:

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

```
test=> SELECT * FROM pgstatginindex('test_gin_index');
-[ RECORD 1 ]--+-
version      | 1
pending_pages | 0
pending_tuples | 0
```

The output columns are:

Column	Type	Description
version	integer	GIN version number
pending_pages	integer	Number of pages in the pending list
pending_tuples	bigint	Number of tuples in the pending list

pgstathashindex(regclass) returns record

pgstathashindex returns a record showing information about a HASH index. For example:

```
test=> select * from pgstathashindex('con_hash_index');
-[ RECORD 1 ]--+-
version      | 4
bucket_pages | 33081
overflow_pages | 0
bitmap_pages | 1
unused_pages | 32455
live_items   | 10204006
dead_items   | 0
free_percent | 61.8005949100872
```

The output columns are:

Column	Type	Description
version	integer	HASH version number
bucket_pages	bigint	Number of bucket pages
overflow_pages	bigint	Number of overflow pages
bitmap_pages	bigint	Number of bitmap pages
unused_pages	bigint	Number of unused pages
live_items	bigint	Number of live tuples
dead_tuples	bigint	Number of dead tuples
free_percent	float	Percentage of free space

pg_relpages(regclass) returns bigint

pg_relpages returns the number of pages in the relation.

pg_relpages(text) returns bigint

This is the same as `pg_relpages(regclass)`, except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

pgstattuple_approx(regclass) returns record

pgstattuple_approx is a faster alternative to `pgstattuple` that returns approximate results. The argument is the target relation's name or OID. For example:

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

```
test=> SELECT * FROM pgstattuple_approx('pg_catalog.pg_proc'::regclass);
-[ RECORD 1 ]-----+-----
table_len          | 573440
scanned_percent    | 2
approx_tuple_count | 2740
approx_tuple_len   | 561210
approx_tuple_percent | 97.87
dead_tuple_count   | 0
dead_tuple_len     | 0
dead_tuple_percent | 0
approx_free_space  | 11996
approx_free_percent | 2.09
```

The output columns are described in [Table F.30](#).

Whereas `pgstattuple` always performs a full-table scan and returns an exact count of live and dead tuples (and their sizes) and free space, `pgstattuple_approx` tries to avoid the full-table scan and returns exact dead tuple statistics along with an approximation of the number and size of live tuples and free space.

It does this by skipping pages that have only visible tuples according to the visibility map (if a page has the corresponding VM bit set, then it is assumed to contain no dead tuples). For such pages, it derives the free space value from the free space map, and assumes that the rest of the space on the page is taken up by live tuples.

For pages that cannot be skipped, it scans each tuple, recording its presence and size in the appropriate counters, and adding up the free space on the page. At the end, it estimates the total number of live tuples based on the number of pages and tuples scanned (in the same way that `VACUUM` estimates `pg_class.relpages`).

Table F.30. `pgstattuple_approx` Output Columns

Column	Type	Description
<code>table_len</code>	<code>bigint</code>	Physical relation length in bytes (exact)
<code>scanned_percent</code>	<code>float8</code>	Percentage of table scanned
<code>approx_tuple_count</code>	<code>bigint</code>	Number of live tuples (estimated)
<code>approx_tuple_len</code>	<code>bigint</code>	Total length of live tuples in bytes (estimated)
<code>approx_tuple_percent</code>	<code>float8</code>	Percentage of live tuples
<code>dead_tuple_count</code>	<code>bigint</code>	Number of dead tuples (exact)
<code>dead_tuple_len</code>	<code>bigint</code>	Total length of dead tuples in bytes (exact)
<code>dead_tuple_percent</code>	<code>float8</code>	Percentage of dead tuples
<code>approx_free_space</code>	<code>bigint</code>	Total free space in bytes (estimated)
<code>approx_free_percent</code>	<code>float8</code>	Percentage of free space

In the above output, the free space figures may not match the `pgstattuple` output exactly, because the free space map gives us an exact figure, but is not guaranteed to be accurate to the byte.

F.48.2. Authors

Tatsuo Ishii, Satoshi Nagayasu and Abhijit Menon-Sen

F.49. pg_surgery — perform low-level surgery on relation data

The `pg_surgery` module provides various functions to perform surgery on a damaged relation. These functions are unsafe by design and using them may corrupt (or further corrupt) your database. For example, these functions can easily be used to make a table inconsistent with its own indexes, to cause `UNIQUE` or `FOREIGN KEY` constraint violations, or even to make tuples visible which, when read, will cause a database server crash. They should be used with great caution and only as a last resort.

F.49.1. Functions

`heap_force_kill(regclass, tid[])` returns void

`heap_force_kill` marks “used” line pointers as “dead” without examining the tuples. The intended use of this function is to forcibly remove tuples that are not otherwise accessible. For example:

```
test=> select * from t1 where ctid = '(0, 1)';
ERROR:  could not access status of transaction 4007513275
DETAIL:  Could not open file "pg_xact/0EED": No such file or directory.
```

```
test=# select heap_force_kill('t1'::regclass, ARRAY['(0, 1)']::tid[]);
 heap_force_kill
-----
```

```
(1 row)
```

```
test=# select * from t1 where ctid = '(0, 1)';
(0 rows)
```

`heap_force_freeze(regclass, tid[])` returns void

`heap_force_freeze` marks tuples as frozen without examining the tuple data. The intended use of this function is to make accessible tuples which are inaccessible due to corrupted visibility information, or which prevent the table from being successfully vacuumed due to corrupted visibility information. For example:

```
test=> vacuum t1;
ERROR:  found xmin 507 from before relfrozenxid 515
CONTEXT:  while scanning block 0 of relation "public.t1"
```

```
test=# select ctid from t1 where xmin = 507;
 ctid
-----
```

```
(0,3)
(1 row)
```

```
test=# select heap_force_freeze('t1'::regclass, ARRAY['(0, 3)']::tid[]);
 heap_force_freeze
-----
```

```
(1 row)
```

```
test=# select ctid from t1 where xmin = 2;
 ctid
-----
```

```
(0,3)
(1 row)
```

F.49.2. Authors

F.50. pg_trgm — support for similarity of text using trigram matching

The `pg_trgm` module provides functions and operators for determining the similarity of alphanumeric text based on trigram matching, as well as index operator classes that support fast searching for similar strings.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.50.1. Trigram (or Trigraph) Concepts

A trigram is a group of three consecutive characters taken from a string. We can measure the similarity of two strings by counting the number of trigrams they share. This simple idea turns out to be very effective for measuring the similarity of words in many natural languages.

Note

`pg_trgm` ignores non-word characters (non-alphanumerics) when extracting trigrams from a string. Each word is considered to have two spaces prefixed and one space suffixed when determining the set of trigrams contained in the string. For example, the set of trigrams in the string “cat” is “ c”, “ ca”, “cat”, and “at ”. The set of trigrams in the string “foo|bar” is “ f”, “ fo”, “foo”, “oo ”, “ b”, “ ba”, “bar”, and “ar ”.

F.50.2. Functions and Operators

The functions provided by the `pg_trgm` module are shown in [Table F.31](#), the operators in [Table F.32](#).

Table F.31. pg_trgm Functions

Function	Description
<code>similarity (text, text) → real</code>	Returns a number that indicates how similar the two arguments are. The range of the result is zero (indicating that the two strings are completely dissimilar) to one (indicating that the two strings are identical).
<code>show_trgm (text) → text[]</code>	Returns an array of all the trigrams in the given string. (In practice this is seldom useful except for debugging.)
<code>word_similarity (text, text) → real</code>	Returns a number that indicates the greatest similarity between the set of trigrams in the first string and any continuous extent of an ordered set of trigrams in the second string. For details, see the explanation below.
<code>strict_word_similarity (text, text) → real</code>	Same as <code>word_similarity</code> , but forces extent boundaries to match word boundaries. Since we don't have cross-word trigrams, this function actually returns greatest similarity between first string and any continuous extent of words of the second string.
<code>show_limit () → real</code>	Returns the current similarity threshold used by the <code>%</code> operator. This sets the minimum similarity between two words for them to be considered similar enough to be misspellings of each other, for example. (<i>Deprecated</i> ; instead use <code>SHOW pg_trgm.similarity_threshold</code> .)
<code>set_limit (real) → real</code>	

Function	Description
	Sets the current similarity threshold that is used by the % operator. The threshold must be between 0 and 1 (default is 0.3). Returns the same value passed in. (<i>Deprecated</i> ; instead use <code>SET pg_trgm.similarity_threshold</code> .)

Consider the following example:

```
# SELECT word_similarity('word', 'two words');
word_similarity
-----
0.8
(1 row)
```

In the first string, the set of trigrams is {" w", " wo", "wor", "ord", "rd "}. In the second string, the ordered set of trigrams is {" t", " tw", "two", "wo ", " w", " wo", "wor", "ord", "rds", "ds "}. The most similar extent of an ordered set of trigrams in the second string is {" w", " wo", "wor", "ord"}, and the similarity is 0.8.

This function returns a value that can be approximately understood as the greatest similarity between the first string and any substring of the second string. However, this function does not add padding to the boundaries of the extent. Thus, the number of additional characters present in the second string is not considered, except for the mismatched word boundaries.

At the same time, `strict_word_similarity` selects an extent of words in the second string. In the example above, `strict_word_similarity` would select the extent of a single word 'words', whose set of trigrams is {" w", " wo", "wor", "ord", "rds", "ds "}.

```
# SELECT strict_word_similarity('word', 'two words'), similarity('word', 'words');
strict_word_similarity | similarity
-----+-----
0.571429 | 0.571429
(1 row)
```

Thus, the `strict_word_similarity` function is useful for finding the similarity to whole words, while `word_similarity` is more suitable for finding the similarity for parts of words.

Table F.32. pg_trgm Operators

Operator	Description
<code>text % text → boolean</code>	Returns <code>true</code> if its arguments have a similarity that is greater than the current similarity threshold set by <code>pg_trgm.similarity_threshold</code> .
<code>text <% text → boolean</code>	Returns <code>true</code> if the similarity between the trigram set in the first argument and a continuous extent of an ordered trigram set in the second argument is greater than the current word similarity threshold set by <code>pg_trgm.word_similarity_threshold</code> parameter.
<code>text %> text → boolean</code>	Commutator of the <code><%</code> operator.
<code>text <<% text → boolean</code>	Returns <code>true</code> if its second argument has a continuous extent of an ordered trigram set that matches word boundaries, and its similarity to the trigram set of the first argument is greater than the current strict word similarity threshold set by the <code>pg_trgm.strict_word_similarity_threshold</code> parameter.
<code>text %>> text → boolean</code>	

Operator	Description
	Commutator of the <<% operator.
<code>text <-> text → real</code>	Returns the “distance” between the arguments, that is one minus the <code>similarity()</code> value.
<code>text <<-> text → real</code>	Returns the “distance” between the arguments, that is one minus the <code>word_similarity()</code> value.
<code>text <->> text → real</code>	Commutator of the <<-> operator.
<code>text <<<-> text → real</code>	Returns the “distance” between the arguments, that is one minus the <code>strict_word_similarity()</code> value.
<code>text <->>> text → real</code>	Commutator of the <<<-> operator.

F.50.3. GUC Parameters

`pg_trgm.similarity_threshold (real)`

Sets the current similarity threshold that is used by the % operator. The threshold must be between 0 and 1 (default is 0.3).

`pg_trgm.word_similarity_threshold (real)`

Sets the current word similarity threshold that is used by the <% and %> operators. The threshold must be between 0 and 1 (default is 0.6).

`pg_trgm.strict_word_similarity_threshold (real)`

Sets the current strict word similarity threshold that is used by the <<% and %>> operators. The threshold must be between 0 and 1 (default is 0.5).

F.50.4. Index Support

The `pg_trgm` module provides GiST and GIN index operator classes that allow you to create an index over a text column for the purpose of very fast similarity searches. These index types support the above-described similarity operators, and additionally support trigram-based index searches for `LIKE`, `ILIKE`, `~`, `~*` and `=` queries. The similarity comparisons are case-insensitive in a default build of `pg_trgm`. Inequality operators are not supported. Note that those indexes may not be as efficient as regular B-tree indexes for equality operator.

Example:

```
CREATE TABLE test_trgm (t text);
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops);
```

or

```
CREATE INDEX trgm_idx ON test_trgm USING GIN (t gin_trgm_ops);
```

`gist_trgm_ops` GiST opclass approximates a set of trigrams as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default length is 12 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

```
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops(siglen=32));
```

At this point, you will have an index on the `t` column that you can use for similarity searching. A typical query is

```
SELECT t, similarity(t, 'word') AS sml
FROM test_trgm
WHERE t % 'word'
ORDER BY sml DESC, t;
```

This will return all values in the text column that are sufficiently similar to *word*, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

A variant of the above query is

```
SELECT t, t <-> 'word' AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes. It will usually beat the first formulation when only a small number of the closest matches is wanted.

Also you can use an index on the `t` column for word similarity or strict word similarity. Typical queries are:

```
SELECT t, word_similarity('word', t) AS sml
FROM test_trgm
WHERE 'word' <% t
ORDER BY sml DESC, t;
```

and

```
SELECT t, strict_word_similarity('word', t) AS sml
FROM test_trgm
WHERE 'word' <<% t
ORDER BY sml DESC, t;
```

This will return all values in the text column for which there is a continuous extent in the corresponding ordered trigram set that is sufficiently similar to the trigram set of *word*, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

Possible variants of the above queries are:

```
SELECT t, 'word' <<-> t AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

and

```
SELECT t, 'word' <<<-> t AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes.

Beginning in PostgreSQL 9.1, these index types also support index searches for `LIKE` and `ILIKE`, for example

```
SELECT * FROM test_trgm WHERE t LIKE '%foo%bar';
```

The index search works by extracting trigrams from the search string and then looking these up in the index. The more trigrams in the search string, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

Beginning in PostgreSQL 9.3, these index types also support index searches for regular-expression matches (`~` and `~*` operators), for example

```
SELECT * FROM test_trgm WHERE t ~ '(foo|bar)';
```

The index search works by extracting trigrams from the regular expression and then looking these up in the index. The more trigrams that can be extracted from the regular expression, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

For both `LIKE` and regular-expression searches, keep in mind that a pattern with no extractable trigrams will degenerate to a full-index scan.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

F.50.5. Text Search Integration

Trigram matching is a very useful tool when used in conjunction with a full text index. In particular it can help to recognize misspelled input words that will not be matched directly by the full text search mechanism.

The first step is to generate an auxiliary table containing all the unique words in the documents:

```
CREATE TABLE words AS SELECT word FROM
    ts_stat('SELECT to_tsvector(''simple'', bodytext) FROM documents');
```

where `documents` is a table that has a text field `bodytext` that we wish to search. The reason for using the `simple` configuration with the `to_tsvector` function, instead of using a language-specific configuration, is that we want a list of the original (unstemmed) words.

Next, create a trigram index on the word column:

```
CREATE INDEX words_idx ON words USING GIN (word gin_trgm_ops);
```

Now, a `SELECT` query similar to the previous example can be used to suggest spellings for misspelled words in user search terms. A useful extra test is to require that the selected words are also of similar length to the misspelled word.

Note

Since the `words` table has been generated as a separate, static table, it will need to be periodically regenerated so that it remains reasonably up-to-date with the document collection. Keeping it exactly current is usually unnecessary.

F.51. pg_tsparser — an extension for text search

pg_tsparser is a Postgres Pro extension for text search. This extension modifies the default text parsing strategy for words that include:

- underscores
- numbers and letters separated by the hyphen character

In addition to separate word parts returned by default, pg_tsparser also returns the whole word.

F.51.1. Installation and Setup

pg_tsparser is included into the Postgres Pro distribution. To enable pg_tsparser, once Postgres Pro is installed, create the pg_tsparser extension for each database you are planning to use:

```
CREATE EXTENSION pg_tsparser;
```

Once pg_tsparser is enabled, you can create your own text search configuration. In addition to pg_tsparser, you can use any available dictionary.

For example, you can create english_ts configuration for the English language, as follows:

```
CREATE TEXT SEARCH CONFIGURATION english_ts (  
    PARSER = tsparser  
);
```

```
COMMENT ON TEXT SEARCH CONFIGURATION english_ts IS 'text search configuration for  
english language';
```

```
ALTER TEXT SEARCH CONFIGURATION english_ts  
    ADD MAPPING FOR email, file, float, host, hword_numpart, int,  
    numhword, numword, sfloat, uint, url, url_path, version  
    WITH simple;
```

```
ALTER TEXT SEARCH CONFIGURATION english_ts  
    ADD MAPPING FOR asciiword, asciihword, hword_asciipart,  
    word, hword, hword_part  
    WITH english_stem;
```

F.51.2. Examples

The following examples illustrate the difference in search results returned by pg_tsparser and the default parser:

```
SELECT to_tsvector('english', 'pg_trgm') as def_parser,  
       to_tsvector('english_ts', 'pg_trgm') as new_parser;  
def_parser | new_parser  
-----+-----  
'pg':1 'trgm':2 | 'pg':2 'pg_trgm':1 'trgm':3  
(1 row)
```

```
SELECT to_tsvector('english', '123-abc') as def_parser,  
       to_tsvector('english_ts', '123-abc') as new_parser;  
def_parser | new_parser  
-----+-----  
'123':1 'abc':2 | '123':2 '123-abc':1 'abc':3  
(1 row)
```

```
SELECT to_tsvector('english', 'rel-3.2-A') as def_parser,  
       to_tsvector('english_ts', 'rel-3.2-A') as new_parser;
```

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

def_parser		new_parser
-----+-----		
'-3.2':2 'rel':1		'3.2':3 'rel':2 'rel-3.2-a':1
(1 row)

F.51.3. Authors

Postgres Professional, Moscow, Russia

F.52. pg_variables — functions for working with variables of various types

The `pg_variables` module provides functions for working with variables of various types. The created variables are only available in the current user session.

F.52.1. Installation

The `pg_variables` extension is included into Postgres Pro. Once you have Postgres Pro installed, you must execute the [CREATE EXTENSION](#) command to enable `pg_variables`, as follows:

```
CREATE EXTENSION pg_variables;
```

F.52.2. Usage

The `pg_variables` module provides several functions for creating, reading, and managing variables of scalar, record, and array types. See the following sections for function descriptions and syntax:

- [Section F.52.3.1](#) describes functions for scalar variables.
- [Section F.52.3.2](#) describes functions for collections of record variables.
- [Section F.52.3.3](#) describes functions for array variables.
- [Section F.52.3.4](#) describes functions for general collection variables.
- [Section F.52.3.6](#) lists functions you can use to manage all variables in your current session.

For detailed usage examples, see [Section F.52.5](#).

F.52.2.1. Using Transactional Variables

By default, the created variables are non-transactional. Once successfully set, a variable exists for the whole session, regardless of rollbacks, if any. For example:

```
SELECT pgv_set('vars', 'int1', 101);
BEGIN;
SELECT pgv_set('vars', 'int2', 102);
ROLLBACK;

SELECT * FROM pgv_list() order by package, name;
 package | name | is_transactional
-----+-----+-----
 vars    | int1 | f
 vars    | int2 | f
```

If you would like to use variables that support transactions and savepoints, pass the optional `is_transactional` flag as the last parameter when creating this variable:

```
BEGIN;
SELECT pgv_set('vars', 'trans_int', 101, true);
SAVEPOINT sp1;
SELECT pgv_set('vars', 'trans_int', 102, true);
ROLLBACK TO sp1;
COMMIT;
SELECT pgv_get('vars', 'trans_int', NULL::int);
 pgv_get
-----
      101
```

You must use the `is_transactional` flag every time you change the value of a transactional variable using `pgv_set()` or `pgv_insert()` functions. Otherwise, an error occurs. Other functions do not require this flag.

```
SELECT pgv_insert('pack', 'var_record', row(123::int, 'text'::text), true);
```

```
SELECT pgv_insert('pack', 'var_record', row(456::int, 'another text'::text));
ERROR:  variable "var_record" already created as TRANSACTIONAL

SELECT pgv_delete('pack', 'var_record', 123::int);
```

If the `pgv_free()` or `pgv_remove()` function calls are rolled back, the affected transactional variables will be restored, unlike non-transactional variables, which are removed permanently. For example:

```
SELECT pgv_set('pack', 'var_reg', 123);
SELECT pgv_set('pack', 'var_trans', 456, true);
BEGIN;
SELECT pgv_free();
ROLLBACK;
SELECT * FROM pgv_list();
 package |   name   | is_transactional
-----+-----+-----
 pack    | var_trans | t
```

F.52.3. Functions

F.52.3.1. Scalar Variables

The following functions support scalar variables:

Function	Returns
<code>pgv_set(package text, name text, value anynonarray, is_transactional bool default false)</code>	void
<code>pgv_get(package text, name text, var_type anynonarray, strict bool default true)</code>	anynonarray

To use the `pgv_get()` function, you must first create a package and a variable using the `pgv_set()` function. If the specified package or variable does not exist, an error occurs:

```
SELECT pgv_get('vars', 'int1', NULL::int);
ERROR:  unrecognized package "vars"

SELECT pgv_get('vars', 'int1', NULL::int);
ERROR:  unrecognized variable "int1"
```

`pgv_get()` function checks the variable type. If the specified type does not match the type of the variable, an error is raised:

```
SELECT pgv_get('vars', 'int1', NULL::text);
ERROR:  variable "int1" requires "integer" value
```

F.52.3.2. Collections of Records

The following functions support collections of record variables:

Function	Returns	Description
<code>pgv_insert(package text, name text, r record, is_transactional bool default false)</code>	void	Inserts a record into a collection variable for the specified package. If the package or variable does not exist, it is created automatically. The first column of <code>r</code> is

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

Function	Returns	Description
		the primary key. If a record with the same primary key already exists or this collection variable has a different structure, an error is raised.
<code>pgv_update(package text, name text, r record)</code>	boolean	Updates a record with the corresponding primary key (the first column of <code>r</code> is the primary key). Returns <code>true</code> if the record was found. If this collection variable has a different structure, an error is raised.
<code>pgv_delete(package text, name text, value anynonarray)</code>	boolean	Deletes a record with the corresponding primary key (the first column of <code>r</code> is the primary key). Returns <code>true</code> if the record was found and <code>false</code> otherwise.
<code>pgv_select(package text, name text)</code>	set of records	Returns the collection variable records.
<code>pgv_select(package text, name text, value anynonarray)</code>	record	Returns the record with the corresponding primary key (the first column of <code>r</code> is a primary key).
<code>pgv_select(package text, name text, value anyarray)</code>	set of records	Returns the collection variable records with the corresponding primary keys (the first column of <code>r</code> is a primary key).

To use `pgv_update()`, `pgv_delete()` and `pgv_select()` functions, you must first create a package and a variable using the `pgv_insert()` function. The variable type and the record type must be the same; otherwise, an error occurs.

F.52.3.3. Arrays

The following functions support array variables:

Function	Returns
<code>pgv_set(package text, name text, value anyarray, is_transactional bool default false)</code>	void
<code>pgv_get(package text, name text, var_type anyarray, strict bool default true)</code>	anyarray

Usage instructions for these functions are the same as those provided in [Section F.52.3.1](#) for scalar variables.

F.52.3.4. General Collections

The following functions support general collection variables:

Function	Returns	Description
<code>pgv_set_elem(package text, name text, key int, value anyelement, is_</code>	void	Sets a value for the element with the key <code>key</code> of the collection variable <code>name</code> in the package <code>package</code> . If the package or variable

Function	Returns	Description
<p>transactional bool default false)</p> <p>pgv_set_elem(package text, name text, key text, value anyelement, is_transactional bool default false)</p>		<p>does not exist, it is created automatically. Inside one collection, only keys of the same type are allowed. The <code>key</code> argument can have either <code>int</code> or <code>text</code> type. If an element with the specified key already exists, its value is set to the new one. <code>is_transactional</code> shows whether the new variable is transactional and equals <code>false</code> by default. So if the variable already exists, it must be transactional/non-transactional as indicated by <code>is_transactional</code>, otherwise an error is raised. If the collection already exists and its value type does not match the type of the new value, an error is also raised.</p>
<p>pgv_get_elem(package text, name text, key int, val_type anyelement)</p> <p>pgv_get_elem(package text, name text, key text, val_type anyelement)</p>	anyelement	<p>Returns the value of the element with the key <code>key</code> of the collection variable <code>name</code> in the package <code>package</code>. If there is no element with the specified key in this collection, returns NULL. The <code>key</code> argument can have either <code>int</code> or <code>text</code> type. If the package or variable does not exist, an error is raised. If the specified variable is not a collection, an error is also raised. The <code>val_type</code> argument is required to properly determine the return type.</p>
<p>pgv_remove_elem(package text, name text, key int)</p> <p>pgv_remove_elem(package text, name text, key text)</p>	void	<p>Removes the element with the key <code>key</code> from the collection variable <code>name</code> in the package <code>package</code>. If there is no element with the specified key in this collection, does nothing. The <code>key</code> argument can have either <code>int</code> or <code>text</code> type. If the package or variable does not exist, an error is raised. If the specified variable is not a collection, an error is also raised.</p>

Important

Collections initialized with `pgv_set_elem()` and with `pgv_insert()` are not considered compatible.

F.52.3.5. Iterators

The following functions are provided to use iterators to traverse collection variables. These functions work with collections initialized with both `pgv_set_elem()` and `pgv_insert()`.

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

Function	Returns	Description
<code>pgv_first(package text, name text, key_type anyelement)</code>	<code>anyelement</code>	Returns the first key from the collection variable. Collections are sorted by the key in ascending order. <code>key_type</code> is required to determine the return value. If the <code>name</code> passed is the name of a non-collection variable, an error is raised.
<code>pgv_last(package text, name text, key_type anyelement)</code>	<code>anyelement</code>	Returns the last key from the collection variable. Collections are sorted by the key in ascending order. <code>key_type</code> is required to determine the return value. If the <code>name</code> passed is the name of a non-collection variable, an error is raised.
<code>pgv_next(package text, name text, key anyelement)</code>	<code>anyelement</code>	Returns the next key from the collection variable. The <code>key</code> passed may not exist in the collection. Returns NULL if used for the last key in the collection. Collections are sorted by the key in ascending order. If the <code>name</code> passed is the name of a non-collection variable, an error is raised.
<code>pgv_prior(package text, name text, key anyelement)</code>	<code>anyelement</code>	Returns the previous key from the collection variable. The <code>key</code> passed may not exist in the collection. Returns NULL if used for the first key in the collection. Collections are sorted by the key in ascending order. If the <code>name</code> passed is the name of a non-collection variable, an error is raised.
<code>pgv_count(package text, name text)</code>	<code>integer</code>	Returns the number of elements in the collection. If the <code>name</code> passed is the name of a non-collection variable, an error is raised.

F.52.3.6. Miscellaneous Functions

Function	Returns	Description
<code>pgv_exists(package text, name text)</code>	<code>bool</code>	Returns <code>true</code> if the specified package and variable exist and <code>false</code> otherwise.
<code>pgv_exists(package text)</code>	<code>bool</code>	Returns <code>true</code> if the specified package exists and <code>false</code> otherwise.
<code>pgv_remove(package text, name text)</code>	<code>void</code>	Removes the variable with the specified name. The specified

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

Function	Returns	Description
		package and variable must exist; otherwise, an error is raised.
<code>pgv_remove(package text)</code>	void	Removes the specified package and all the corresponding variables. The specified package must exist; otherwise, an error is raised.
<code>pgv_free()</code>	void	Removes all packages and variables.
<code>pgv_list()</code>	<code>table(package text, name text, is_transactional bool)</code>	Displays all the available variables and the corresponding packages, as well as whether each variable is transactional.
<code>pgv_stats()</code>	<code>table(package text, allocated_memory bigint)</code>	Returns the list of assigned packages and the amount of memory used by variables, in bytes. If you are using transactional variables, this list also includes all deleted packages that still may be restored by a <code>ROLLBACK</code> . This function only supports Postgres Pro 9.6 or higher.

F.52.3.7. Deprecated Functions

F.52.3.7.1. Integer Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_int(package text, name text, value int, is_transactional bool default false)</code>	void
<code>pgv_get_int(package text, name text, strict bool default true)</code>	int

F.52.3.7.2. Text Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_text(package text, name text, value text, is_transactional bool default false)</code>	void
<code>pgv_get_text(package text, name text, strict bool default true)</code>	text

F.52.3.7.3. Numeric Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_numeric(package text, name text, value numeric, is_transactional bool default false)</code>	void

Function	Returns
<code>pgv_get_numeric(package text, name text, strict bool default true)</code>	numeric

F.52.3.7.4. Timestamp Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_timestamp(package text, name text, value timestamp, is_transactional bool default false)</code>	void
<code>pgv_get_timestamp(package text, name text, strict bool default true)</code>	timestamp

F.52.3.7.5. Timestamp with timezone Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_timestamptz(package text, name text, value timestamptz, is_transactional bool default false)</code>	void
<code>pgv_get_timestamptz(package text, name text, strict bool default true)</code>	timestamptz

F.52.3.7.6. Date Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_date(package text, name text, value date, is_transactional bool default false)</code>	void
<code>pgv_get_date(package text, name text, strict bool default true)</code>	date

F.52.3.7.7. Jsonb Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_jsonb(package text, name text, value jsonb, is_transactional bool default false)</code>	void
<code>pgv_get_jsonb(package text, name text, strict bool default true)</code>	jsonb

F.52.4. Important Notes

F.52.4.1. Collations in Collections

Collections are stored in ascending order. In the case of `text` keys, you need a collation to determine the order of elements. If no collation is specified when inserting the first element of a collection, the default collation is used. Otherwise, the specified collation is used.

F.52.4.2. Cursors for Set-Returning Functions

All set-returning functions except `pgv_select(package, variable)` fix their return results at first `FETCH` from the cursor and are not affected by further data manipulation.

The results of `pgv_select(package, variable)` are received dynamically and are affected by transactions/changes in the collection. For `pgv_select()` called for a transactional collection, cursors look at the snapshot of the collection when the first `FETCH` was executed, but consider changes that were made in that transaction and in committed subtransactions.

F.52.5. Examples

Define scalar variables using the `pgv_set()` function, and then return their values using the `pgv_get()` function:

```
SELECT pgv_set('vars', 'int1', 101);
SELECT pgv_set('vars', 'int2', 102);
SELECT pgv_set('vars', 'text1', 'text variable'::text);

SELECT pgv_get('vars', 'int1', NULL::int);
pgv_get
-----
      101

SELECT pgv_get('vars', 'int2', NULL::int);
pgv_get
-----
      102

SELECT pgv_get('vars', 'text1', NULL::text);
pgv_get
-----
text variable
```

Let's assume we have the `tab` table and examine several examples of using record variables:

```
CREATE TABLE tab (id int, t varchar);
INSERT INTO tab VALUES (0, 'str00'), (1, 'str11');
```

You can use the following functions to work with record variables:

```
SELECT pgv_insert('vars', 'r1', tab) FROM tab;

SELECT pgv_select('vars', 'r1');
pgv_select
-----
(1,str11)
(0,str00)

SELECT pgv_select('vars', 'r1', 1);
pgv_select
-----
(1,str11)

SELECT pgv_select('vars', 'r1', 0);
pgv_select
-----
(0,str00)

SELECT pgv_select('vars', 'r1', ARRAY[1, 0]);
```

```
pgv_select
-----
(1, str11)
(0, str00)

SELECT pgv_delete('vars', 'r1', 1);

SELECT pgv_select('vars', 'r1');
pgv_select
-----
(0, str00)
```

Consider the behavior of a transactional variable `var_text` when changed before and after savepoints:

```
SELECT pgv_set('pack', 'var_text', 'before transaction block'::text, true);
BEGIN;
SELECT pgv_set('pack', 'var_text', 'before savepoint'::text, true);
SAVEPOINT sp1;
SELECT pgv_set('pack', 'var_text', 'savepoint sp1'::text, true);
SAVEPOINT sp2;
SELECT pgv_set('pack', 'var_text', 'savepoint sp2'::text, true);
RELEASE sp2;
SELECT pgv_get('pack', 'var_text', NULL::text);
pgv_get
-----
savepoint sp2

ROLLBACK TO sp1;
SELECT pgv_get('pack', 'var_text', NULL::text);
pgv_get
-----
before savepoint

ROLLBACK;
SELECT pgv_get('pack', 'var_text', NULL::text);
pgv_get
-----
before transaction block
```

If you create a variable after `BEGIN` or `SAVEPOINT` statements and then rollback to the previous state, the transactional variable is removed:

```
BEGIN;
SAVEPOINT sp1;
SAVEPOINT sp2;
SELECT pgv_set('pack', 'var_int', 122, true);
RELEASE SAVEPOINT sp2;
SELECT pgv_get('pack', 'var_int', NULL::int);
pgv_get
-----
122

ROLLBACK TO sp1;
SELECT pgv_get('pack', 'var_int', NULL::int);
ERROR: unrecognized variable "var_int"
COMMIT;
```

List the available packages and variables:

```
SELECT * FROM pgv_list() ORDER BY package, name;
```

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

package	name	is_transactional
pack	var_text	t
vars	int1	f
vars	int2	f
vars	r1	f
vars	text1	f

Get the amount of memory used by variables, in bytes:

```
SELECT * FROM pgv_stats() ORDER BY package;
package | allocated_memory
-----+-----
pack    |                16384
vars    |                32768
```

Delete the specified variables or packages:

```
SELECT pgv_remove('vars', 'int1');
SELECT pgv_remove('vars');
```

Delete all packages and variables:

```
SELECT pgv_free();
```

These examples show usage of collection variables and iterator functions:

```
sql
SELECT pgv_set_elem('pack', 'var', 1, 1);
SELECT pgv_set_elem('pack', 'var', 5, 5);
SELECT pgv_set_elem('pack', 'var', 10, 10);

SELECT pgv_first('pack', 'var', NULL::int);
pgv_first
-----
1

SELECT pgv_last('pack', 'var', NULL::int);
pgv_last
-----
10

SELECT pgv_next('pack', 'var', pgv_first('pack', 'var', NULL::int));
pgv_next
-----
5

SELECT pgv_prior('pack', 'var', pgv_last('pack', 'var', NULL::int));
pgv_prior
-----
5

SELECT pgv_prior('pack', 'var', pgv_first('pack', 'var', NULL::int));
pgv_prior
-----

SELECT pgv_next('pack', 'var', pgv_last('pack', 'var', NULL::int));
pgv_prior
-----

SELECT pgv_next('pack', 'var', 3);
```

```
pgv_next
-----
          5

SELECT pgv_prior('pack', 'var', 3);
pgv_prior
-----
          1

SELECT pgv_get_elem('pack', 'var', pgv_last('pack', 'var', NULL::int), NULL::int);
pgv_get_elem
-----
          10

SELECT pgv_remove_elem('pack', 'var', pgv_last('pack', 'var', NULL::int));
pgv_remove_elem
-----

SELECT pgv_get_elem('pack', 'var', pgv_last('pack', 'var', NULL::int), NULL::int);
pgv_get_elem
-----
          5
(1 row)
```

These examples show how the collation affects the order of elements in a collection. They also show how to iterate over a whole collection with PL/pgSQL loops:

```
sql
SELECT pgv_set_elem('pack', 'var1', 'a' COLLATE "ru_RU", 'a'::text);
SELECT pgv_set_elem('pack', 'var1', 'д' COLLATE "ru_RU", 'д'::text);
SELECT pgv_set_elem('pack', 'var1', 'e' COLLATE "ru_RU", 'e'::text);
SELECT pgv_set_elem('pack', 'var1', 'ë' COLLATE "ru_RU", 'ë'::text);
SELECT pgv_set_elem('pack', 'var1', 'ж' COLLATE "ru_RU", 'ж'::text);
SELECT pgv_set_elem('pack', 'var1', 'я' COLLATE "ru_RU", 'я'::text);
DO
$$
DECLARE
    iter text;
BEGIN
    iter := pgv_first('pack', 'var1', NULL::text);
    WHILE iter IS NOT NULL LOOP
        RAISE NOTICE '%', pgv_get_elem('pack', 'var1', iter, NULL::text);
        iter := pgv_next('pack', 'var1', iter);
    END LOOP;
END;
$$;
NOTICE:  а

Postgres Professional, Moscow, Russia

F.53. pg_visibility — visibility map information and utilities

The `pg_visibility` module provides a means for examining the visibility map (VM) and page-level visibility information of a table. It also provides functions to check the integrity of a visibility map and to force it to be rebuilt.

Three different bits are used to store information about page-level visibility. The all-visible bit in the visibility map indicates that every tuple in the corresponding page of the relation is visible to every current and future transaction. The all-frozen bit in the visibility map indicates that every tuple in the page is frozen; that is, no future vacuum will need to modify the page until such time as a tuple is inserted, updated, deleted, or locked on that page. The page header's `PD_ALL_VISIBLE` bit has the same meaning as the all-visible bit in the visibility map, but is stored within the data page itself rather than in a separate data structure. These two bits will normally agree, but the page's all-visible bit can sometimes be set while the visibility map bit is clear after a crash recovery. The reported values can also disagree because of a change that occurs after `pg_visibility` examines the visibility map and before it examines the data page. Any event that causes data corruption can also cause these bits to disagree.

Functions that display information about `PD_ALL_VISIBLE` bits are much more costly than those that only consult the visibility map, because they must read the relation's data blocks rather than only the (much smaller) visibility map. Functions that check the relation's data blocks are similarly expensive.

F.53.1. Functions

`pg_visibility_map(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean)` returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation.

`pg_visibility(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean)` returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation, plus the `PD_ALL_VISIBLE` bit of that block.

`pg_visibility_map(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean)` returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation.

`pg_visibility(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean)` returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation, plus the `PD_ALL_VISIBLE` bit of each block.

`pg_visibility_map_summary(relation regclass, all_visible OUT bigint, all_frozen OUT bigint)` returns record

Returns the number of all-visible pages and the number of all-frozen pages in the relation according to the visibility map.

`pg_check_frozen(relation regclass, t_ctid OUT tid)` returns setof tid

Returns the TIDs of non-frozen tuples stored in pages marked all-frozen in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

`pg_check_visible(relation regclass, t_ctid OUT tid)` returns setof tid

Returns the TIDs of non-all-visible tuples stored in pages marked all-visible in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

`pg_truncate_visibility_map(relation regclass)` returns void

Truncates the visibility map for the given relation. This function is useful if you believe that the visibility map for the relation is corrupt and wish to force rebuilding it. The first `VACUUM` executed on the given relation after this function is executed will scan every page in the relation and rebuild the visibility map. (Until that is done, queries will treat the visibility map as containing all zeroes.)

By default, these functions are executable only by superusers and roles with privileges of the `pg_stat_scan_tables` role, with the exception of `pg_truncate_visibility_map(relation regclass)` which can only be executed by superusers.

F.54. pg_wait_sampling — collecting sampling-based statistics on wait events

`pg_wait_sampling` is a Postgres Pro extension for collecting sampling-based statistics on wait events.

Starting from the 9.6 version, Postgres Pro Standard provides information about the current wait events for particular processes. However, to get descriptive statistics of the server activity, you have to sample wait events multiple times. The `pg_wait_sampling` extension automates wait events sampling by launching a special background worker. With `pg_wait_sampling` enabled, you can get the following sampling-based data:

- *Waits history* — the list of wait events for recent processes, with timestamps.
- *Waits profile* — the number of wait event samples for all processes over time (per wait event type).
- Current wait events for all processes, including background workers.

Using `pg_wait_sampling`, you can troubleshoot dependencies for queries that process longer than expected. You can see what a particular process is waiting for at each moment of time, and analyze wait events statistics. For the list of possible wait events, see [Table 26.4](#).

In combination with `pg_stat_statements`, this extension can also provide per query statistics.

See Also

[Viewing Statistics on Wait Events](#)

[Reference](#)

F.54.1. Installation

The `pg_wait_sampling` extension is included into Postgres Pro Standard and requires no special prerequisites.

To enable `pg_wait_sampling`, do the following:

1. Add `pg_wait_sampling` to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'pg_wait_sampling'
```

Important

When using the `pg_wait_sampling` with the `pg_stat_statements` extension, place `pg_stat_statements` before `pg_wait_sampling` in the `shared_preload_libraries` variable. This ensures that the `pg_stat_statements` extension does not overwrite query IDs that are used by `pg_wait_sampling`.

2. Create the `pg_wait_sampling` extension using the following query:

```
CREATE EXTENSION pg_wait_sampling;
```

3. Restart the server. Since `pg_wait_sampling` requires additional shared memory and launches a background worker, you must restart the server after adding or removing `pg_wait_sampling`.

Once the extension is created, `pg_wait_sampling` starts collecting statistics on wait events for each process. Optionally, you can change the sampling frequency and configure statistics collection modes using [GUC variables](#).

If you want to stop collecting statistics, drop the `pg_wait_sampling` extension, remove the `pg_wait_sampling` from the `shared_preload_libraries` variable, and restart the server again.

F.54.2. Usage

F.54.2.1. Viewing Statistics on Wait Events

When `pg_wait_sampling` is enabled, wait events are sampled each 10ms by default. You can access the collected statistics through a set of functions and views. If some of your queries appear stalled or take longer than expected, you can review all the current wait events in the `pg_wait_sampling_current` view:

```
SELECT * FROM pg_wait_sampling_current;
```

The returned statistics covers all the active processes, including background workers. To filter the view for a single process, run `pg_wait_sampling_get_current()` function specifying the process ID:

```
SELECT * FROM pg_wait_sampling_get_current(pid);
```

To better understand the dynamics of the recent wait events, you can access the `pg_wait_sampling_history` view that provides the wait events history for the latest processes:

```
SELECT * FROM pg_wait_sampling_history;
```

The returned view displays wait samples per process, with event timestamps. Waits history is implemented as an in-memory ring buffer. By default, the history size is limited to 5000 samples. To save history for a longer period of time, you can modify the `pg_wait_sampling.history_size` variable, or connect a client application to periodically read waits history and dump it to a local storage.

To monitor wait events in your database over time, use the `pg_wait_sampling_profile` view:

```
SELECT * FROM pg_wait_sampling_profile;
```

Waits profile is stored as an in-memory hash table that accumulates samples per each process and each wait event. You can reset waits profile by calling the `pg_wait_sampling_reset_profile()` function. If you connect a client to your database that periodically dumps the wait events data and resets the profile, you can save and compare statistics of wait events intensity over time.

Important

Since wait sampling statistics is stored in RAM, make sure to reset the waits profile from time to time to avoid memory overflow.

If you are not interested in the distribution of wait events between processes, you can set the `pg_wait_sampling.profile_pid` variable to `false`. In this case, the `pid` value for each process is set to zero, and wait samples for all the processes are stored together.

F.54.3. Reference

F.54.3.1. GUC Variables

The `pg_wait_sampling` extension is configured with GUC variables. They are stored in the local memory and can be changed in the `postgresql.conf` file or using the `ALTER SYSTEM` command. For the changes to take effect, reload the server configuration. You can do it, for example, by calling the `pg_reload_conf()` function or executing the `pg_ctl reload` command.

`pg_wait_sampling.history_size` (int4)

Size of in-memory ring buffer for history sampling, in the number of samples.

Default: 5000

`pg_wait_sampling.history_period` (int4)

Time interval for history sampling, in milliseconds.

Default: 10

`pg_wait_sampling.profile_period (int4)`

Time interval for waits profile sampling, in milliseconds.

Default: 10

`pg_wait_sampling.profile_pid (bool)`

Sampling mode for waits profile. If set to `true`, waits profile is collected per process. If you set `pg_wait_sampling.profile_pid` to `false`, waits profile is collected for all processes together. In this case, the `pid` value for each process is set to zero, and the corresponding row contains wait samples for all the processes.

Default: `true`

`pg_wait_sampling.profile_queries (enum)`

Sampling mode for the waits profile. If `pg_wait_sampling.profile_queries` is set to `none`, the `queryid` field in views will be zero. If it is set to `top`, query IDs of only the top level statements are recorded. If it is set to `all`, query IDs of nested statements are recorded. To collect the waits profile per query, ensure that the [pg_stat_statements](#) extension is configured and set `pg_wait_sampling.profile_queries` to `top`. For version 14 or higher, you can compute query IDs by configuring the `compute_query_id` parameter and set the `pg_wait_sampling.profile_queries` value to `top` or `all`. For details, see [Section 18.9.2](#).

Default: `top`

`pg_wait_sampling.sample_cpu (bool)`

The sampling mode that determines whether to perform sampling of on-CPU backends. If `pg_wait_sampling.sample_cpu` is set to `true`, then sampling also includes processes that are not waiting for anything. The wait event columns for such processes will have a `NULL` value.

Default: `true`

F.54.3.2. pg_wait_sampling Views

F.54.3.2.1. pg_wait_sampling_current View

The `pg_wait_sampling_current` view provides the information about the current wait events for all processes, including background workers.

Table F.33. pg_wait_sampling_current View

Column Name	Column Type	Description
<code>pid</code>	<code>int4</code>	Process ID
<code>event_type</code>	<code>text</code>	Name of wait event type
<code>event</code>	<code>text</code>	Name of wait event
<code>queryid</code>	<code>int8</code>	Query ID

F.54.3.2.2. pg_wait_sampling_history View

The `pg_wait_sampling_history` view provides the history of wait events. This data is stored as an in-memory ring buffer.

Table F.34. pg_wait_sampling_history View

Column Name	Column Type	Description
<code>pid</code>	<code>int4</code>	Process ID

Column Name	Column Type	Description
ts	timestampz	Sample timestamp
event_type	text	Name of wait event type
event	text	Name of wait event
queryid	int8	Query ID

F.54.3.2.3. `pg_wait_sampling_profile` View

The `pg_wait_sampling_profile` view provides the profile of wait events. This data is stored as an in-memory hash table.

Table F.35. `pg_wait_sampling_profile` View

Column Name	Column Type	Description
pid	int4	Process ID
event_type	text	Name of wait event type
event	text	Name of wait event
queryid	int8	Query ID
count	int8	Number of samples

F.54.3.3. Functions

`pg_wait_sampling_get_current(pid int4)`

Returns the `pg_wait_sampling_current` view with the list of current wait events. If you set the `pid` argument, the view is filtered for the process with this `pid`.

Arguments:

- `pid` — Optional. The process ID for which to display the current wait events.

`pg_wait_sampling_reset_profile()`

Resets the waits profile and clears the memory.

F.55. pg_walinspect — low-level WAL inspection

The `pg_walinspect` module provides SQL functions that allow you to inspect the contents of write-ahead log of a running Postgres Pro database cluster at a low level, which is useful for debugging, analytical, reporting or educational purposes. It is similar to `pg_waldump`, but accessible through SQL rather than a separate utility.

All the functions of this module will provide the WAL information using the server's current timeline ID.

Note

The `pg_walinspect` functions are often called using an LSN argument that specifies the location at which a known WAL record of interest *begins*. However, some functions, such as `pg_logical_emit_message`, return the LSN *after* the record that was just inserted.

Tip

All of the `pg_walinspect` functions that show information about records that fall within a certain LSN range are permissive about accepting `end_lsn` arguments that are after the server's current LSN. Using an `end_lsn` “from the future” will not raise an error.

It may be convenient to provide the value `FFFFFFFF/FFFFFFFF` (the maximum valid `pg_lsn` value) as an `end_lsn` argument. This is equivalent to providing an `end_lsn` argument matching the server's current LSN.

By default, use of these functions is restricted to superusers and members of the `pg_read_server_files` role. Access may be granted by superusers to others using `GRANT`.

F.55.1. General Functions

`pg_get_wal_record_info(in_lsn pg_lsn)` returns record

Gets WAL record information about a record that is located at or after the `in_lsn` argument. For example:

```
postgres=# SELECT * FROM pg_get_wal_record_info('0/E419E28');
-[ RECORD 1 ]-----+-----
start_lsn      | 0/E419E28
end_lsn        | 0/E419E68
prev_lsn       | 0/E419D78
xid            | 0
resource_manager | Heap2
record_type     | VACUUM
record_length   | 58
main_data_length | 2
fpi_length      | 0
description     | nunused: 5, unused: [1, 2, 3, 4, 5]
block_ref       | blkref #0: rel 1663/16385/1249 fork main blk 364
```

If `in_lsn` isn't at the start of a WAL record, information about the next valid WAL record is shown instead. If there is no next valid WAL record, the function raises an error.

`pg_get_wal_records_info(start_lsn pg_lsn, end_lsn pg_lsn)` returns setof record

Gets information of all the valid WAL records between `start_lsn` and `end_lsn`. Returns one row per WAL record. For example:

```
postgres=# SELECT * FROM pg_get_wal_records_info('0/1E913618', '0/1E913740') LIMIT
1;
```

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

```

-[ RECORD 1 ]-----+-----
start_lsn      | 0/1E913618
end_lsn        | 0/1E913650
prev_lsn       | 0/1E9135A0
xid            | 0
resource_manager | Standby
record_type     | RUNNING_XACTS
record_length   | 50
main_data_length | 24
fpi_length      | 0
description     | nextXid 33775 latestCompletedXid 33774 oldestRunningXid 33775
block_ref       |

```

The function raises an error if *start_lsn* is not available.

`pg_get_wal_block_info(start_lsn pg_lsn, end_lsn pg_lsn, show_data boolean DEFAULT true)`
returns setof record

Gets information about each block reference from all the valid WAL records between *start_lsn* and *end_lsn* with one or more block references. Returns one row per block reference per WAL record. For example:

```
postgres=# SELECT * FROM pg_get_wal_block_info('0/1230278', '0/12302B8');
```

```

-[ RECORD 1 ]-----+-----
start_lsn      | 0/1230278
end_lsn        | 0/12302B8
prev_lsn       | 0/122FD40
block_id       | 0
reltablespace  | 1663
reldatabase    | 1
relfilenode    | 2658
relforknumber  | 0
relblocknumber | 11
xid            | 341
resource_manager | Btree
record_type     | INSERT_LEAF
record_length   | 64
main_data_length | 2
block_data_length | 16
block_fpi_length | 0
block_fpi_info  |
description     | off: 46
block_data      | \x00002a00070010402630000070696400
block_fpi_data  |

```

This example involves a WAL record that only contains one block reference, but many WAL records contain several block references. Rows output by `pg_get_wal_block_info` are guaranteed to have a unique combination of *start_lsn* and *block_id* values.

Much of the information shown here matches the output that `pg_get_wal_records_info` would show, given the same arguments. However, `pg_get_wal_block_info` unnests the information from each WAL record into an expanded form by outputting one row per block reference, so certain details are tracked at the block reference level rather than at the whole-record level. This structure is useful with queries that track how individual blocks changed over time. Note that records with no block references (e.g., COMMIT WAL records) will have no rows returned, so `pg_get_wal_block_info` may actually return *fewer* rows than `pg_get_wal_records_info`.

The `reltablespace`, `reldatabase`, and `relfilenode` parameters reference `pg_tablespace.oid`, `pg_database.oid`, and `pg_class.relfilenode` respectively. The `relforknumber` field is the fork number within the relation for the block reference; see `common/relpath.h` for details.

Tip

The `pg_filenode_relation` function (see [Table 9.103](#)) can help you to determine which relation was modified during original execution.

It is possible for clients to avoid the overhead of materializing block data. This may make function execution significantly faster. When `show_data` is set to `false`, `block_data` and `block_fpi_data` values are omitted (that is, the `block_data` and `block_fpi_data` OUT arguments are `NULL` for all rows returned). Obviously, this optimization is only feasible with queries where block data isn't truly required.

The function raises an error if `start_lsn` is not available.

`pg_get_wal_stats(start_lsn pg_lsn, end_lsn pg_lsn, per_record boolean DEFAULT false)`
returns `setof record`

Gets statistics of all the valid WAL records between `start_lsn` and `end_lsn`. By default, it returns one row per `resource_manager` type. When `per_record` is set to `true`, it returns one row per `record_type`. For example:

```
postgres=# SELECT * FROM pg_get_wal_stats('0/1E847D00', '0/1E84F500')
          WHERE count > 0 AND
              "resource_manager/record_type" = 'Transaction'
          LIMIT 1;
```

```
-[ RECORD 1 ]-----+-----
resource_manager/record_type | Transaction
count                        | 2
count_percentage             | 8
record_size                  | 875
record_size_percentage       | 41.23468426013195
fpi_size                     | 0
fpi_size_percentage          | 0
combined_size                | 875
combined_size_percentage     | 2.8634072910530795
```

The function raises an error if `start_lsn` is not available.

Bharath Rupireddy <bharath.rupireddyforpostgres@gmail.com>

F.56. plantuner — hints for the planner to disable or enable indexes for query execution

The `plantuner` module provides hints for the planner that can disable or enable indexes for query execution.

F.56.1. Motivation

In some cases, it may be required to control the planner by providing hints that make the optimizer ignore some parts of its algorithm. There are many situations when a developer may want to temporarily disable specific index(es), without dropping them, or to instruct the planner to use a specific index.

This version of `plantuner` provides a possibility to hide the specified indexes from Postgres Pro planner, so it will not use them. For some workloads, Postgres Pro could be too pessimistic about newly created tables and assume that there are much more rows in a table than it actually has. If the `plantuner.fix_empty_table` GUC variable is set to `true`, `plantuner` sets to zero the number of pages/tuples of the table that has no blocks in a file.

F.56.2. GUC Variables

`plantuner.disable_index` — list of indexes invisible to planner.

`plantuner.enable_index` — list of indexes visible to planner even if they are hidden by `plantuner.disable_index`.

F.56.3. Example

To enable the module, you can either load `plantuner` shared library in a `psql` session or specify `shared_preload_libraries` option in `postgresql.conf`.

```
=# LOAD 'plantuner';
=# create table test(id int);
=# create index id_idx on test(id);
=# create index id_idx2 on test(id);
=# \d test
      Table "public.test"
  Column | Type   | Modifiers
-----+-----+-----
 id      | integer |
Indexes:
    "id_idx" btree (id)
    "id_idx2" btree (id)
=# explain select id from test where id=1;
               QUERY PLAN
-----
Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
    -> Bitmap Index Scan on id_idx2  (cost=0.00..4.34 rows=12 width=0)
        Index Cond: (id = 1)
(4 rows)
=# set enable_seqscan=off;
=# set plantuner.disable_index='id_idx2';
=# explain select id from test where id=1;
               QUERY PLAN
-----
Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
    -> Bitmap Index Scan on id_idx  (cost=0.00..4.34 rows=12 width=0)
        Index Cond: (id = 1)
```

```
(4 rows)
=# set plantuner.disable_index='id_idx2,id_idx';
=# explain select id from test where id=1;
               QUERY PLAN
-----
Seq Scan on test  (cost=10000000000.00..10000000040.00 rows=12 width=4)
  Filter: (id = 1)
(2 rows)
=# set plantuner.enable_index='id_idx';
=# explain select id from test where id=1;
               QUERY PLAN
-----
Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
    -> Bitmap Index Scan on id_idx  (cost=0.00..4.34 rows=12 width=0)
        Index Cond: (id = 1)
(4 rows)
```

The work sponsored by Nomao project (<http://www.nomao.com>).

F.57. `postgres_fdw` — access data stored in external Postgres Pro servers

The `postgres_fdw` module provides the foreign-data wrapper `postgres_fdw`, which can be used to access data stored in external Postgres Pro servers.

The functionality provided by this module overlaps substantially with the functionality of the older [dblink](#) module. But `postgres_fdw` provides more transparent and standards-compliant syntax for accessing remote tables, and can give better performance in many cases.

To prepare for remote access using `postgres_fdw`:

1. Install the `postgres_fdw` extension using [CREATE EXTENSION](#).
2. Create a foreign server object, using [CREATE SERVER](#), to represent each remote database you want to connect to. Specify connection information, except `user` and `password`, as options of the server object.
3. Create a user mapping, using [CREATE USER MAPPING](#), for each database user you want to allow to access each foreign server. Specify the remote user name and password to use as `user` and `password` options of the user mapping.
4. Create a foreign table, using [CREATE FOREIGN TABLE](#) or [IMPORT FOREIGN SCHEMA](#), for each remote table you want to access. The columns of the foreign table must match the referenced remote table. You can, however, use table and/or column names different from the remote table's, if you specify the correct remote names as options of the foreign table object.

Now you need only `SELECT` from a foreign table to access the data stored in its underlying remote table. You can also modify the remote table using `INSERT`, `UPDATE`, `DELETE`, `COPY`, or `TRUNCATE`. (Of course, the remote user you have specified in your user mapping must have privileges to do these things.)

Note that the `ONLY` option specified in `SELECT`, `UPDATE`, `DELETE` or `TRUNCATE` has no effect when accessing or modifying the remote table.

Note that `postgres_fdw` currently lacks support for `INSERT` statements with an `ON CONFLICT DO UPDATE` clause. However, the `ON CONFLICT DO NOTHING` clause is supported, provided a unique index inference specification is omitted. Note also that `postgres_fdw` supports row movement invoked by `UPDATE` statements executed on partitioned tables, but it currently does not handle the case where a remote partition chosen to insert a moved row into is also an `UPDATE` target partition that will be updated elsewhere in the same command.

It is generally recommended that the columns of a foreign table be declared with exactly the same data types, and collations if applicable, as the referenced columns of the remote table. Although `postgres_fdw` is currently rather forgiving about performing data type conversions at need, surprising semantic anomalies may arise when types or collations do not match, due to the remote server interpreting query conditions differently from the local server.

Note that a foreign table can be declared with fewer columns, or with a different column order, than its underlying remote table has. Matching of columns to the remote table is by name, not position.

F.57.1. FDW Options of `postgres_fdw`

F.57.1.1. Connection Options

A foreign server using the `postgres_fdw` foreign data wrapper can have the same options that `libpq` accepts in connection strings, as described in [Section 32.1.2](#), except that these options are not allowed or have special handling:

- `user`, `password` and `sslpassword` (specify these in a user mapping instead, or use a service file)
- `client_encoding` (this is automatically set from the local server encoding)
- `application_name` - this may appear in *either or both* a connection and [postgres_fdw.application_name](#). If both are present, `postgres_fdw.application_name` overrides the connection setting.

Unlike `libpq`, `postgres_fdw` allows `application_name` to include “escape sequences”. See [postgres_fdw.application_name](#) for details.

- `fallback_application_name` (always set to `postgres_fdw`)
- `sslkey` and `sslcert` - these may appear in *either or both* a connection and a user mapping. If both are present, the user mapping setting overrides the connection setting.

Only superusers may create or modify user mappings with the `sslcert` or `sslkey` settings.

Non-superusers may connect to foreign servers using password authentication or with GSSAPI delegated credentials, so specify the `password` option for user mappings belonging to non-superusers where password authentication is required.

A superuser may override this check on a per-user-mapping basis by setting the user mapping option `password_required 'false'`, e.g.,

```
ALTER USER MAPPING FOR some_non_superuser SERVER loopback_nopw
OPTIONS (ADD password_required 'false');
```

To prevent unprivileged users from exploiting the authentication rights of the unix user the postgres server is running as to escalate to superuser rights, only the superuser may set this option on a user mapping.

Care is required to ensure that this does not allow the mapped user the ability to connect as superuser to the mapped database per CVE-2007-3278 and CVE-2007-6601. Don't set `password_required=false` on the `public` role. Keep in mind that the mapped user can potentially use any client certificates, `.pgpass`, `.pg_service.conf` etc. in the unix home directory of the system user the postgres server runs as. (For details on how home directories are found, see [Section 32.16](#).) They can also use any trust relationship granted by authentication modes like `peer` or `ident` authentication.

F.57.1.2. Object Name Options

These options can be used to control the names used in SQL statements sent to the remote Postgres Pro server. These options are needed when a foreign table is created with names different from the underlying remote table's names.

`schema_name` (string)

This option, which can be specified for a foreign table, gives the schema name to use for the foreign table on the remote server. If this option is omitted, the name of the foreign table's schema is used.

`table_name` (string)

This option, which can be specified for a foreign table, gives the table name to use for the foreign table on the remote server. If this option is omitted, the foreign table's name is used.

`column_name` (string)

This option, which can be specified for a column of a foreign table, gives the column name to use for the column on the remote server. If this option is omitted, the column's name is used.

F.57.1.3. Cost Estimation Options

`postgres_fdw` retrieves remote data by executing queries against remote servers, so ideally the estimated cost of scanning a foreign table should be whatever it costs to be done on the remote server, plus some overhead for communication. The most reliable way to get such an estimate is to ask the remote server and then add something for overhead — but for simple queries, it may not be worth the cost of an additional remote query to get a cost estimate. So `postgres_fdw` provides the following options to control how cost estimation is done:

`use_remote_estimate` (boolean)

This option, which can be specified for a foreign table or a foreign server, controls whether `postgres_fdw` issues remote `EXPLAIN` commands to obtain cost estimates. A setting for a foreign table overrides any setting for its server, but only for that table. The default is `false`.

`fdw_startup_cost` (floating point)

This option, which can be specified for a foreign server, is a floating point value that is added to the estimated startup cost of any foreign-table scan on that server. This represents the additional overhead of establishing a connection, parsing and planning the query on the remote side, etc. The default value is 100.

`fdw_tuple_cost` (floating point)

This option, which can be specified for a foreign server, is a floating point value that is used as extra cost per-tuple for foreign-table scans on that server. This represents the additional overhead of data transfer between servers. You might increase or decrease this number to reflect higher or lower network delay to the remote server. The default value is 0.2.

When `use_remote_estimate` is true, `postgres_fdw` obtains row count and cost estimates from the remote server and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. When `use_remote_estimate` is false, `postgres_fdw` performs local row count and cost estimation and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. This local estimation is unlikely to be very accurate unless local copies of the remote table's statistics are available. Running [ANALYZE](#) on the foreign table is the way to update the local statistics; this will perform a scan of the remote table and then calculate and store statistics just as though the table were local. Keeping local statistics can be a useful way to reduce per-query planning overhead for a remote table — but if the remote table is frequently updated, the local statistics will soon be obsolete.

The following option controls how such an `ANALYZE` operation behaves:

`analyze_sampling` (string)

This option, which can be specified for a foreign table or a foreign server, determines if `ANALYZE` on a foreign table samples the data on the remote side, or reads and transfers all data and performs the sampling locally. The supported values are `off`, `random`, `system`, `bernoulli` and `auto`. `off` disables remote sampling, so all data are transferred and sampled locally. `random` performs remote sampling using the `random()` function to choose returned rows, while `system` and `bernoulli` rely on the built-in `TABLESAMPLE` methods of those names. `random` works on all remote server versions, while `TABLESAMPLE` is supported only since 9.5. `auto` (the default) picks the recommended sampling method automatically; currently it means either `bernoulli` or `random` depending on the remote server version.

F.57.1.4. Remote Execution Options

By default, only `WHERE` clauses using built-in operators and functions will be considered for execution on the remote server. Clauses involving non-built-in functions are checked locally after rows are fetched. If such functions are available on the remote server and can be relied on to produce the same results as they do locally, performance can be improved by sending such `WHERE` clauses for remote execution. This behavior can be controlled using the following option:

`extensions` (string)

This option is a comma-separated list of names of Postgres Pro extensions that are installed, in compatible versions, on both the local and remote servers. Functions and operators that are immutable and belong to a listed extension will be considered shippable to the remote server. This option can only be specified for foreign servers, not per-table.

When using the `extensions` option, *it is the user's responsibility* that the listed extensions exist and behave identically on both the local and remote servers. Otherwise, remote queries may fail or behave unexpectedly.

`fetch_size` (integer)

This option specifies the number of rows `postgres_fdw` should get in each fetch operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is 100.

`batch_size` (integer)

This option specifies the number of rows `postgres_fdw` should insert in each insert operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is 1.

Note the actual number of rows `postgres_fdw` inserts at once depends on the number of columns and the provided `batch_size` value. The batch is executed as a single query, and the libpq protocol (which `postgres_fdw` uses to connect to a remote server) limits the number of parameters in a single query to 65535. When the number of columns * `batch_size` exceeds the limit, the `batch_size` will be adjusted to avoid an error.

This option also applies when copying into foreign tables. In that case the actual number of rows `postgres_fdw` copies at once is determined in a similar way to the insert case, but it is limited to at most 1000 due to implementation restrictions of the `COPY` command.

F.57.1.5. Asynchronous Execution Options

`postgres_fdw` supports asynchronous execution, which runs multiple parts of an `Append` node concurrently rather than serially to improve performance. This execution can be controlled using the following option:

`async_capable` (boolean)

This option controls whether `postgres_fdw` allows foreign tables to be scanned concurrently for asynchronous execution. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `false`.

In order to ensure that the data being returned from a foreign server is consistent, `postgres_fdw` will only open one connection for a given foreign server and will run all queries against that server sequentially even if there are multiple foreign tables involved, unless those tables are subject to different user mappings. In such a case, it may be more performant to disable this option to eliminate the overhead associated with running queries asynchronously.

Asynchronous execution is applied even when an `Append` node contains subplan(s) executed synchronously as well as subplan(s) executed asynchronously. In such a case, if the asynchronous subplans are ones processed using `postgres_fdw`, tuples from the asynchronous subplans are not returned until after at least one synchronous subplan returns all tuples, as that subplan is executed while the asynchronous subplans are waiting for the results of asynchronous queries sent to foreign servers. This behavior might change in a future release.

F.57.1.6. Transaction Management Options

As described in the Transaction Management section, in `postgres_fdw` transactions are managed by creating corresponding remote transactions, and subtransactions are managed by creating corresponding remote subtransactions. When multiple remote transactions are involved in the current local transaction, by default `postgres_fdw` commits or aborts those remote transactions serially when the local transaction is committed or aborted. When multiple remote subtransactions are involved in the current local subtransaction, by default `postgres_fdw` commits or aborts those remote subtransactions serially when the local subtransaction is committed or aborted. Performance can be improved with the following options:

`parallel_commit` (boolean)

This option controls whether `postgres_fdw` commits, in parallel, remote transactions opened on a foreign server in a local transaction when the local transaction is committed. This setting also applies to remote and local subtransactions. This option can only be specified for foreign servers, not per-table. The default is `false`.

`parallel_abort` (boolean)

This option controls whether `postgres_fdw` aborts, in parallel, remote transactions opened on a foreign server in a local transaction when the local transaction is aborted. This setting also applies

to remote and local subtransactions. This option can only be specified for foreign servers, not per-table. The default is `false`.

If multiple foreign servers with these options enabled are involved in a local transaction, multiple remote transactions on those foreign servers are committed or aborted in parallel across those foreign servers when the local transaction is committed or aborted.

When these options are enabled, a foreign server with many remote transactions may see a negative performance impact when the local transaction is committed or aborted.

F.57.1.7. Updatability Options

By default all foreign tables using `postgres_fdw` are assumed to be updatable. This may be overridden using the following option:

`updatable (boolean)`

This option controls whether `postgres_fdw` allows foreign tables to be modified using `INSERT`, `UPDATE` and `DELETE` commands. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`.

Of course, if the remote table is not in fact updatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server. Note however that the `information_schema` views will report a `postgres_fdw` foreign table to be updatable (or not) according to the setting of this option, without any check of the remote server.

F.57.1.8. Truncatability Options

By default all foreign tables using `postgres_fdw` are assumed to be truncatable. This may be overridden using the following option:

`truncatable (boolean)`

This option controls whether `postgres_fdw` allows foreign tables to be truncated using the `TRUNCATE` command. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`.

Of course, if the remote table is not in fact truncatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server.

F.57.1.9. Importing Options

`postgres_fdw` is able to import foreign table definitions using [IMPORT FOREIGN SCHEMA](#). This command creates foreign table definitions on the local server that match tables or views present on the remote server. If the remote tables to be imported have columns of user-defined data types, the local server must have compatible types of the same names.

Importing behavior can be customized with the following options (given in the `IMPORT FOREIGN SCHEMA` command):

`import_collate (boolean)`

This option controls whether column `COLLATE` options are included in the definitions of foreign tables imported from a foreign server. The default is `true`. You might need to turn this off if the remote server has a different set of collation names than the local server does, which is likely to be the case if it's running on a different operating system. If you do so, however, there is a very severe risk that the imported table columns' collations will not match the underlying data, resulting in anomalous query behavior.

Even when this parameter is set to `true`, importing columns whose collation is the remote server's default can be risky. They will be imported with `COLLATE "default"`, which will select the local server's default collation, which could be different.

`import_default` (boolean)

This option controls whether column `DEFAULT` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `false`. If you enable this option, be wary of defaults that might get computed differently on the local server than they would be on the remote server; `nextval()` is a common source of problems. The `IMPORT` will fail altogether if an imported default expression uses a function or operator that does not exist locally.

`import_generated` (boolean)

This option controls whether column `GENERATED` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `true`. The `IMPORT` will fail altogether if an imported generated expression uses a function or operator that does not exist locally.

`import_not_null` (boolean)

This option controls whether column `NOT NULL` constraints are included in the definitions of foreign tables imported from a foreign server. The default is `true`.

Note that constraints other than `NOT NULL` will never be imported from the remote tables. Although Postgres Pro does support check constraints on foreign tables, there is no provision for importing them automatically, because of the risk that a constraint expression could evaluate differently on the local and remote servers. Any such inconsistency in the behavior of a check constraint could lead to hard-to-detect errors in query optimization. So if you wish to import check constraints, you must do so manually, and you should verify the semantics of each one carefully. For more detail about the treatment of check constraints on foreign tables, see [CREATE FOREIGN TABLE](#).

Tables or foreign tables which are partitions of some other table are imported only when they are explicitly specified in `LIMIT TO` clause. Otherwise they are automatically excluded from [IMPORT FOREIGN SCHEMA](#). Since all data can be accessed through the partitioned table which is the root of the partitioning hierarchy, importing only partitioned tables should allow access to all the data without creating extra objects.

F.57.1.10. Connection Management Options

By default, all connections that `postgres_fdw` establishes to foreign servers are kept open in the local session for re-use.

`keep_connections` (boolean)

This option controls whether `postgres_fdw` keeps the connections to the foreign server open so that subsequent queries can re-use them. It can only be specified for a foreign server. The default is `on`. If set to `off`, all connections to this foreign server will be discarded at the end of each transaction.

`use_scram_passthrough` (boolean)

This option controls whether `postgres_fdw` will use the SCRAM pass-through authentication to connect to the foreign server. With SCRAM pass-through authentication, `postgres_fdw` uses SCRAM-hashed secrets instead of plain-text user passwords to connect to the remote server. This avoids storing plain-text user passwords in PostgreSQL system catalogs.

To use SCRAM pass-through authentication:

- The remote server must request the `scram-sha-256` authentication method; otherwise, the connection will fail.
- The remote server can be of any PostgreSQL version that supports SCRAM. Support for `use_scram_passthrough` is only required on the client side (FDW side).
- The user mapping password is not used.
- The server running `postgres_fdw` and the remote server must have identical SCRAM secrets (encrypted passwords) for the user being used on `postgres_fdw` to authenticate on the foreign server (same salt and iterations, not merely the same password).

As a corollary, if FDW connections to multiple hosts are to be made, for example for partitioned foreign tables/sharding, then all hosts must have identical SCRAM secrets for the users involved.

- The current session on the PostgreSQL instance that makes the outgoing FDW connections also must also use SCRAM authentication for its incoming client connection. (Hence “pass-through”: SCRAM must be used going in and out.) This is a technical requirement of the SCRAM protocol.

F.57.2. Functions

`postgres_fdw_get_connections(IN check_conn boolean DEFAULT false, OUT server_name text, OUT user_name text, OUT valid boolean, OUT used_in_xact boolean, OUT closed boolean, OUT remote_backend_pid int4)` returns setof record

This function returns information about all open connections `postgres_fdw` has established from the local session to foreign servers. If there are no open connections, no records are returned.

If `check_conn` is set to `true`, the function checks the status of each connection and shows the result in the `closed` column. This feature is currently available only on systems that support the non-standard `POLLRDHUP` extension to the `poll` system call, including Linux. This is useful to check if all connections used within a transaction are still open. If any connections are closed, the transaction cannot be committed successfully, so it is better to roll back as soon as a closed connection is detected, rather than continuing to the end. Users can roll back the transaction immediately if the function reports connections where both `used_in_xact` and `closed` are `true`.

Example usage of the function:

```
postgres=# SELECT * FROM postgres_fdw_get_connections(true);
 server_name | user_name | valid | used_in_xact | closed | remote_backend_pid
-----+-----+-----+-----+-----+-----
 loopback1  | postgres | t     | t             | f      | 1353340
 loopback2  | public   | t     | t             | f      | 1353120
 loopback3  |          | f     | t             | f      | 1353156
```

The output columns are described in [Table F.36](#).

Table F.36. `postgres_fdw_get_connections` Output Columns

Column	Type	Description
<code>server_name</code>	text	The foreign server name of this connection. If the server is dropped but the connection remains open (i.e., marked as invalid), this will be <code>NULL</code> .
<code>user_name</code>	text	Name of the local user mapped to the foreign server of this connection, or <code>public</code> if a public mapping is used. If the user mapping is dropped but the connection remains open (i.e., marked as invalid), this will be <code>NULL</code> .
<code>valid</code>	boolean	False if this connection is invalid, meaning it is used in the current transaction, but its foreign server or user mapping has been changed or dropped. The invalid connection will be closed at the end of the trans-

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

Column	Type	Description
		action. True is returned otherwise.
used_in_xact	boolean	True if this connection is used in the current transaction.
closed	boolean	True if this connection is closed, false otherwise. NULL is returned if <code>check_conn</code> is set to <code>false</code> or if the connection status check is not available on this platform.
remote_backend_pid	int4	Process ID of the remote backend, on the foreign server, handling the connection. If the remote backend is terminated and the connection is closed (with <code>closed</code> set to <code>true</code>), this still shows the process ID of the terminated backend.

`postgres_fdw_disconnect(server_name text)` returns boolean

This function discards the open connections that are established by `postgres_fdw` from the local session to the foreign server with the given name. Note that there can be multiple connections to the given server using different user mappings. If the connections are used in the current local transaction, they are not disconnected and warning messages are reported. This function returns `true` if it disconnects at least one connection, otherwise `false`. If no foreign server with the given name is found, an error is reported. Example usage of the function:

```
postgres=# SELECT postgres_fdw_disconnect('loopback1');
postgres_fdw_disconnect
-----
t
```

`postgres_fdw_disconnect_all()` returns boolean

This function discards all the open connections that are established by `postgres_fdw` from the local session to foreign servers. If the connections are used in the current local transaction, they are not disconnected and warning messages are reported. This function returns `true` if it disconnects at least one connection, otherwise `false`. Example usage of the function:

```
postgres=# SELECT postgres_fdw_disconnect_all();
postgres_fdw_disconnect_all
-----
t
```

F.57.3. Connection Management

`postgres_fdw` establishes a connection to a foreign server during the first query that uses a foreign table associated with the foreign server. By default this connection is kept and re-used for subsequent queries in the same session. This behavior can be controlled using `keep_connections` option for a foreign server. If multiple user identities (user mappings) are used to access the foreign server, a connection is established for each user mapping.

When changing the definition of or removing a foreign server or a user mapping, the associated connections are closed. But note that if any connections are in use in the current local transaction, they are kept until the end of the transaction. Closed connections will be re-established when they are necessary by future queries using a foreign table.

Once a connection to a foreign server has been established, it's by default kept until the local or corresponding remote session exits. To disconnect a connection explicitly, `keep_connections` option for a foreign server may be disabled, or `postgres_fdw_disconnect` and `postgres_fdw_disconnect_all` functions may be used. For example, these are useful to close connections that are no longer necessary, thereby releasing connections on the foreign server.

F.57.4. Transaction Management

During a query that references any remote tables on a foreign server, `postgres_fdw` opens a transaction on the remote server if one is not already open corresponding to the current local transaction. The remote transaction is committed or aborted when the local transaction commits or aborts. Savepoints are similarly managed by creating corresponding remote savepoints.

The remote transaction uses `SERIALIZABLE` isolation level when the local transaction has `SERIALIZABLE` isolation level; otherwise it uses `REPEATABLE READ` isolation level. This choice ensures that if a query performs multiple table scans on the remote server, it will get snapshot-consistent results for all the scans. A consequence is that successive queries within a single transaction will see the same data from the remote server, even if concurrent updates are occurring on the remote server due to other activities. That behavior would be expected anyway if the local transaction uses `SERIALIZABLE` or `REPEATABLE READ` isolation level, but it might be surprising for a `READ COMMITTED` local transaction. A future Postgres Pro release might modify these rules.

Note that it is currently not supported by `postgres_fdw` to prepare the remote transaction for two-phase commit.

F.57.5. Remote Query Optimization

`postgres_fdw` attempts to optimize remote queries to reduce the amount of data transferred from foreign servers. This is done by sending query `WHERE` clauses to the remote server for execution, and by not retrieving table columns that are not needed for the current query. To reduce the risk of misexecution of queries, `WHERE` clauses are not sent to the remote server unless they use only data types, operators, and functions that are built-in or belong to an extension that's listed in the foreign server's `extensions` option. Operators and functions in such clauses must be `IMMUTABLE` as well. For an `UPDATE` or `DELETE` query, `postgres_fdw` attempts to optimize the query execution by sending the whole query to the remote server if there are no query `WHERE` clauses that cannot be sent to the remote server, no local joins for the query, no row-level local `BEFORE` or `AFTER` triggers or stored generated columns on the target table, and no `CHECK OPTION` constraints from parent views. In `UPDATE`, expressions to assign to target columns must use only built-in data types, `IMMUTABLE` operators, or `IMMUTABLE` functions, to reduce the risk of misexecution of the query.

When `postgres_fdw` encounters a join between foreign tables on the same foreign server, it sends the entire join to the foreign server, unless for some reason it believes that it will be more efficient to fetch rows from each table individually, or unless the table references involved are subject to different user mappings. While sending the `JOIN` clauses, it takes the same precautions as mentioned above for the `WHERE` clauses.

The query that is actually sent to the remote server for execution can be examined using `EXPLAIN VERBOSE`.

F.57.6. Remote Query Execution Environment

In the remote sessions opened by `postgres_fdw`, the `search_path` parameter is set to just `pg_catalog`, so that only built-in objects are visible without schema qualification. This is not an issue for queries generated by `postgres_fdw` itself, because it always supplies such qualification. However, this can pose a hazard for functions that are executed on the remote server via triggers or rules on remote tables. For example, if a remote table is actually a view, any functions used in that view will be executed with the restricted search path. It is recommended to schema-qualify all names in such functions, or else attach `SET search_path` options (see [CREATE FUNCTION](#)) to such functions to establish their expected search path environment.

`postgres_fdw` likewise establishes remote session settings for various parameters:

- `TimeZone` is set to `UTC`
- `DateStyle` is set to `ISO`
- `IntervalStyle` is set to `postgres`
- `extra_float_digits` is set to 3 for remote servers 9.0 and newer and is set to 2 for older versions

These are less likely to be problematic than `search_path`, but can be handled with function `SET` options if the need arises.

It is *not* recommended that you override this behavior by changing the session-level settings of these parameters; that is likely to cause `postgres_fdw` to malfunction.

F.57.7. Cross-Version Compatibility

`postgres_fdw` can be used with remote servers dating back to PostgreSQL 8.3. Read-only capability is available back to 8.1.

A limitation however is that `postgres_fdw` generally assumes that immutable built-in functions and operators are safe to send to the remote server for execution, if they appear in a `WHERE` clause for a foreign table. Thus, a built-in function that was added since the remote server's release might be sent to it for execution, resulting in “function does not exist” or a similar error. This type of failure can be worked around by rewriting the query, for example by embedding the foreign table reference in a sub-`SELECT` with `OFFSET 0` as an optimization fence, and placing the problematic function or operator outside the sub-`SELECT`.

Another limitation is that when executing `INSERT` statements with an `ON CONFLICT DO NOTHING` clause on a foreign table, the remote server must be running PostgreSQL 9.5 or later, as earlier versions do not support this feature.

F.57.8. Wait Events

`postgres_fdw` can report the following wait events under the wait event type `Extension`:

`PostgresFdwCleanupResult`

Waiting for transaction abort on remote server.

`PostgresFdwConnect`

Waiting to establish a connection to a remote server.

`PostgresFdwGetResult`

Waiting to receive the results of a query from a remote server.

F.57.9. Configuration Parameters

`postgres_fdw.application_name` (string)

Specifies a value for `application_name` configuration parameter used when `postgres_fdw` establishes a connection to a foreign server. This overrides `application_name` option of the server object. Note that change of this parameter doesn't affect any existing connections until they are re-established.

`postgres_fdw.application_name` can be any string of any length and contain even non-ASCII characters. However when it's passed to and used as `application_name` in a foreign server, note that it will be truncated to less than `NAMEDATALEN` characters. Anything other than printable ASCII characters are replaced with `C-style hexadecimal escapes`. See `application_name` for details.

`%` characters begin “escape sequences” that are replaced with status information as outlined below. Unrecognized escapes are ignored. Other characters are copied straight to the application name. Note that it's not allowed to specify a plus/minus sign or a numeric literal after the `%` and before the option, for alignment and padding.

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

Escape	Effect
%a	Application name on local server
%c	Session ID on local server (see log_line_prefix for details)
%C	Cluster name on local server (see cluster_name for details)
%u	User name on local server
%d	Database name on local server
%p	Process ID of backend on local server
%%	Literal %

For example, suppose user `local_user` establishes a connection from database `local_db` to foreign_db as user `foreign_user`, the setting `'db=%d, user=%u'` is replaced with `'db=local_db, user=local_user'`.

F.57.10. Examples

Here is an example of creating a foreign table with `postgres_fdw`. First install the extension:

```
CREATE EXTENSION postgres_fdw;
```

Then create a foreign server using [CREATE SERVER](#). In this example we wish to connect to a Postgres Pro server on host `192.83.123.89` listening on port `5432`. The database to which the connection is made is named `foreign_db` on the remote server:

```
CREATE SERVER foreign_server
    FOREIGN DATA WRAPPER postgres_fdw
    OPTIONS (host '192.83.123.89', port '5432', dbname 'foreign_db');
```

A user mapping, defined with [CREATE USER MAPPING](#), is needed as well to identify the role that will be used on the remote server:

```
CREATE USER MAPPING FOR local_user
    SERVER foreign_server
    OPTIONS (user 'foreign_user', password 'password');
```

Now it is possible to create a foreign table with [CREATE FOREIGN TABLE](#). In this example we wish to access the table named `some_schema.some_table` on the remote server. The local name for it will be `foreign_table`:

```
CREATE FOREIGN TABLE foreign_table (
    id integer NOT NULL,
    data text
)
    SERVER foreign_server
    OPTIONS (schema_name 'some_schema', table_name 'some_table');
```

It's essential that the data types and other properties of the columns declared in `CREATE FOREIGN TABLE` match the actual remote table. Column names must match as well, unless you attach `column_name` options to the individual columns to show how they are named in the remote table. In many cases, use of [IMPORT FOREIGN SCHEMA](#) is preferable to constructing foreign table definitions manually.

F.57.11. Author

Shigeru Hanada <shigeru.hanada@gmail.com>

F.58. ptrack — a block-level incremental backup engine for Postgres Pro

PTRACK is a block-level incremental backup engine for Postgres Pro. If PTRACK is enabled, backup tools like [pg_probackup](#) can use its API to get information on the changed blocks on the fly when taking incremental backups. Copying only those blocks that have changed since the previous backup can significantly speed up the creation and minimize the size of backups.

PTRACK is designed to allow false positives, but to never allow false negatives: it means that all changes within the data directory except hint bits are guaranteed to be marked in the PTRACK map file, although some unchanged blocks might be included as well.

F.58.1. Setting up PTRACK

Once you complete Postgres Pro Standard installation, do the following:

1. Add `ptrack` to the [shared_preload_libraries](#) parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'ptrack'
```

2. Set [ptrack.map_size](#) parameter to a positive integer.

For optimal performance, it is recommended to set `ptrack.map_size` to $N / 1024$, where N is the size of the Postgres Pro cluster, in MB. If you set this parameter to a lower value, PTRACK is more likely to map several blocks together, which leads to false-positive results when tracking changed blocks and increases the incremental backup size as unchanged blocks can also be copied into the incremental backup.

Setting `ptrack.map_size` to a higher value does not affect PTRACK operation, but keep in mind that you need up to `ptrack.map_size * 3` MB of additional disk space since PTRACK uses two additional temporary files to ensure durability. It is not recommended to set this parameter to a value higher than 1024. Even for Postgres Pro clusters with $N > 1$ TB, it makes sense to use a higher value only if the efficiency and sizes of backups are more critical than the potential overhead of maintaining a large PTRACK map.

3. Check the [wal_level](#) setting. When using PTRACK, it is required to set the [wal_level](#) parameter to `replica` or higher. Otherwise, you can lose some tracked changes if crash-recovery occurs: some commands do not write WAL at all if `wal_level` is `minimal`, and PTRACK map files are flushed to disk only at checkpoint time.
4. Restart the Postgres Pro Standard instance for the changes to take effect, and then create the PTRACK extension:

```
CREATE EXTENSION ptrack;
```

As a result, several PTRACK functions are created, which are required for accessing PTRACK data.

Once this setup is complete, PTRACK starts tracking all the page changes in the Postgres Pro cluster and creates a `ptrack.map` file that stores the latest LSN values for these pages.

Note

The `ptrack.map_size` parameter can only be set at server start. If you change this parameter, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. To avoid losing recent changes, it is recommended to retake a full backup after modifying this setting.

F.58.2. PTRACK Configuration Parameters

`ptrack.map_size (integer)`

Specifies the size of a PTRACK map file and the amount of shared memory allocated for this file, in MB. The PTRACK map file stores the latest LSN values for all pages of the Postgres Pro cluster that have changed since PTRACK was enabled. It is not recommended to set this parameter to a value higher than 1GB. The 0 value disables PTRACK and cleans up all the related service files.

The `ptrack.map_size` parameter can only be set at server start. If you change this parameter, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. To avoid losing recent changes, it is recommended to retake a full backup after modifying this setting.

Default: 0

F.58.3. PTRACK Functions

`ptrack_init_lsn()` returns `pg_lsn`

Returns the LSN of the last PTRACK map initialization.

`ptrack_get_pagemapset (start_lsn pg_lsn)` returns `setof record`

Returns a list of data files changed since the specified `start_lsn` with the number and bitmap of changed pages for each file.

For example:

```
postgres=# SELECT * FROM ptrack_get_pagemapset ('0/185C8C0');
      path      | pagecount |          pagemap
-----+-----+-----
base/16384/1255 |          3 | \x00100000000050000000000000
base/16384/2674 |          3 | \x0000000900010000000000000000
base/16384/2691 |          1 | \x0000400000000000000000000000
base/16384/2608 |          1 | \x0000000000000000400000000000000000
base/16384/2690 |          1 | \x00040000000000000000000000
```

`ptrack_get_change_stat (start_lsn pg_lsn)` returns `record`

Returns the statistics of changes (number of files, number of changed pages and their total size in MB) since the specified `start_lsn`.

For example:

```
postgres=# SELECT * FROM ptrack_get_change_stat ('0/285C8C8');
 files | pages |      size, MB
-----+-----+-----
    20 |    25 | 0.19531250000000000000
```

`ptrack_version()` returns `text`

Returns PTRACK version.

F.59. rum — an access method to work with the RUM indexes

F.59.1. Introduction

The **rum** module provides access method to work with the RUM indexes. It is based on the GIN access method code.

GIN index allows you to perform fast full-text search using `tsvector` and `tsquery` types. However, full-text search with GIN index has some performance issues because positional and other additional information is not stored.

RUM solves these issues by storing additional information in a posting tree. As compared to GIN, RUM index has the following benefits:

- Faster ranking. Ranking requires positional information. And after the index scan we do not need an additional heap scan to retrieve lexeme positions because RUM index stores them.
- Faster phrase search. This improvement is related to the previous one as phrase search also needs positional information.
- Faster ordering by timestamp. RUM index stores additional information together with lexemes, so it is not necessary to perform a heap scan.
- A possibility to perform depth-first search and therefore return first results immediately.

The drawback of RUM is that it has slower build and insert time as compared to GIN because RUM stores additional information together with keys and uses generic WAL records.

F.59.2. Installation

`rum` is a Postgres Pro Standard extension and it has no special prerequisites.

Install extension as follows:

```
$ psql dbname -c "CREATE EXTENSION rum"
```

F.59.3. Common Operators

The operators provided by the `rum` module are shown in [Table F.37](#):

Table F.37. `rum` Operators

Operator	Returns	Description
<code>tsvector <=> tsquery</code>	<code>float4</code>	Returns distance between <code>tsvector</code> and <code>tsquery</code> values.
<code>timestamp <=> timestamp</code>	<code>float8</code>	Returns distance between two <code>timestamp</code> values.
<code>timestamp <= timestamp</code>	<code>float8</code>	Returns distance only for ascending <code>timestamp</code> values.
<code>timestamp => timestamp</code>	<code>float8</code>	Returns distance only for descending <code>timestamp</code> values.

Note

`rum` introduces its own ranking function that is executed inside the `<=>` operator. It calculates the score (inverted distance) using the specified normalization method. This function is a combination of `ts_rank` and `ts_rank_cd` (see [Section 9.13](#) for details). While `ts_rank` does not support logical

operators and `ts_rank_cd` works poorly with OR queries, the `rum`-specific ranking function overcomes these drawbacks.

F.59.4. Operator Classes

The `rum` extension provides the following operator classes:

`rum_tsvector_ops`

Stores `tsvector` lexemes with positional information. Supports ordering by `<=>` operator and prefix search.

`rum_tsvector_hash_ops`

Stores hash of `tsvector` lexemes with positional information. Supports ordering by `<=>` operator, but does not support prefix search.

`rum_tsvector_addon_ops`

Stores `tsvector` lexemes with additional data of any type supported by `RUM`.

Note

To use the `rum_tsvector_addon_ops` operator class, when creating the `RUM` index with `CREATE INDEX`, specify the `attach` and `to` storage parameters in the `WITH` clause.

`rum_tsvector_hash_addon_ops`

Stores `tsvector` lexemes with additional data of any type supported by `RUM`. Does not support prefix search.

`rum_tsquery_ops`

Stores branches of query tree in additional information.

`rum_anyarray_ops`

Stores `anyarray` elements with length of the array. Supports ordering by `<=>` operator.

Indexable operators: `&&` `@>` `<@` `=` `%`

`rum_anyarray_addon_ops`

Stores `anyarray` elements with additional data of any type supported by `RUM`.

`rum_type_ops`

Stores lexemes of the corresponding type with positional information. The `type` placeholder in the class name must be substituted by one of the following type names: `int2`, `int4`, `int8`, `float4`, `float8`, `money`, `oid`, `timestamp`, `timestampz`, `time`, `timetz`, `date`, `interval`, `macaddr`, `inet`, `cidr`, `text`, `varchar`, `char`, `bytea`, `bit`, `varbit`, `numeric`.

`rum_type_ops` supports ordering by `<=>`, `<=|`, and `|=>` operators. This operator class can be used together with `rum_tsvector_addon_ops`, `rum_tsvector_hash_addon_ops`, and `rum_anyarray_addon_ops` operator classes.

Supported indexable operators depend on the data type:

- `<` `<=` `=` `>=` `>` `<=>` `<=|` `|=>` are supported for `int2`, `int4`, `int8`, `float4`, `float8`, `money`, `oid`, `timestamp`, `timestampz`.

- `< <= = >= >` are supported for time, timetz, date, interval, macaddr, inet, cidr, text, varchar, char, bytea, bit, varbit, numeric.

Note

The following operator classes are now deprecated: `rum_tsvector_timestamp_ops`, `rum_tsvector_timestamptz_ops`, `rum_tsvector_hash_timestamp_ops`, `rum_tsvector_hash_timestamptz_ops`.

F.59.5. Examples

F.59.5.1. rum_tsvector_ops Example

Let's assume we have the following table:

```
CREATE TABLE test_rum(t text, a tsvector);

CREATE TRIGGER tsvectorupdate
BEFORE UPDATE OR INSERT ON test_rum
FOR EACH ROW EXECUTE PROCEDURE tsvector_update_trigger('a', 'pg_catalog.english', 't');

INSERT INTO test_rum(t) VALUES ('The situation is most beautiful');
INSERT INTO test_rum(t) VALUES ('It is a beautiful');
INSERT INTO test_rum(t) VALUES ('It looks like a beautiful place');
```

Then we can create a new index:

```
CREATE INDEX rumidx ON test_rum USING rum (a rum_tsvector_ops);
```

And we can execute the following queries:

```
SELECT t, a <=> to_tsquery('english', 'beautiful | place') AS rank
FROM test_rum
WHERE a @@ to_tsquery('english', 'beautiful | place')
ORDER BY a <=> to_tsquery('english', 'beautiful | place');
      t              | rank
-----+-----
The situation is most beautiful | 0.0303964
It is a beautiful              | 0.0303964
It looks like a beautiful place | 0.0607927
(3 rows)
```

```
SELECT t, a <=> to_tsquery('english', 'place | situation') AS rank
FROM test_rum
WHERE a @@ to_tsquery('english', 'place | situation')
ORDER BY a <=> to_tsquery('english', 'place | situation');
      t              | rank
-----+-----
The situation is most beautiful | 0.0303964
It looks like a beautiful place | 0.0303964
(2 rows)
```

F.59.5.2. rum_tsvector_addon_ops Example

Let's assume we have the following table:

```
CREATE TABLE tsts (id int, t tsvector, d timestamp);

\copy tsts from 'rum/data/tsts.data'
```

```
CREATE INDEX tsts_idx ON tsts USING rum (t rum_tsvector_addon_ops, d)
WITH (attach = 'd', to = 't');
```

Now we can execute the following queries:

```
EXPLAIN (costs off)
  SELECT id, d, d <=> '2016-05-16 14:21:25' FROM tsts WHERE t @@ 'wr&qh' ORDER BY d
  <=> '2016-05-16 14:21:25' LIMIT 5;
                                QUERY PLAN
```

```
-----
Limit
->  Index Scan using tsts_idx on tsts
      Index Cond: (t @@ ''wr'' & ''qh''::tsquery)
      Order By: (d <=> 'Mon May 16 14:21:25 2016'::timestamp without time zone)
(4 rows)
```

```
SELECT id, d, d <=> '2016-05-16 14:21:25' FROM tsts WHERE t @@ 'wr&qh' ORDER BY d <=>
'2016-05-16 14:21:25' LIMIT 5;
```

id	d	?column?
355	Mon May 16 14:21:22.326724 2016	2.673276
354	Mon May 16 13:21:22.326724 2016	3602.673276
371	Tue May 17 06:21:22.326724 2016	57597.326724
406	Wed May 18 17:21:22.326724 2016	183597.326724
415	Thu May 19 02:21:22.326724 2016	215997.326724

(5 rows)

F.59.5.3. rum_tsquery_ops Example

Suppose we have the table:

```
CREATE TABLE query (q tsquery, tag text);

INSERT INTO query VALUES ('supernova & star', 'sn'),
  ('black', 'color'),
  ('big & bang & black & hole', 'bang'),
  ('spiral & galaxy', 'shape'),
  ('black & hole', 'color');
```

```
CREATE INDEX query_idx ON query USING rum(q);
```

We can execute the following fast query:

```
SELECT * FROM query
  WHERE to_tsvector('black holes never exists before we think about them') @@ q;
      q      | tag
-----+-----
'black'      | color
'black' & 'hole' | color
(2 rows)
```

F.59.5.4. rum_anyarray_ops Example

Let's assume we have the following table:

```
CREATE TABLE test_array (i int2[]);

INSERT INTO test_array VALUES ('{}'), ('{0}'), ('{1,2,3,4}'), ('{1,2,3}'), ('{1,2}'),
('{1}');

CREATE INDEX idx_array ON test_array USING rum (i rum_anyarray_ops);
```

Now we can execute the following query using index scan:

```
SET enable_seqscan TO off;

EXPLAIN (COSTS OFF) SELECT * FROM test_array WHERE i && '{1}' ORDER BY i <=> '{1}' ASC;
      QUERY PLAN
-----
Index Scan using idx_array on test_array
  Index Cond: (i && '{1}'::smallint[])
  Order By: (i <=> '{1}'::smallint[])
(3 rows)

SELECT * FROM test_array WHERE i && '{1}' ORDER BY i <=> '{1}' ASC;
      i
-----
 {1}
 {1,2}
 {1,2,3}
 {1,2,3,4}
(4 rows)
```

F.60. seg — a datatype for line segments or floating point intervals

This module implements a data type `seg` for representing line segments, or floating point intervals. `seg` can represent uncertainty in the interval endpoints, making it especially useful for representing laboratory measurements.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.60.1. Rationale

The geometry of measurements is usually more complex than that of a point in a numeric continuum. A measurement is usually a segment of that continuum with somewhat fuzzy limits. The measurements come out as intervals because of uncertainty and randomness, as well as because the value being measured may naturally be an interval indicating some condition, such as the temperature range of stability of a protein.

Using just common sense, it appears more convenient to store such data as intervals, rather than pairs of numbers. In practice, it even turns out more efficient in most applications.

Further along the line of common sense, the fuzziness of the limits suggests that the use of traditional numeric data types leads to a certain loss of information. Consider this: your instrument reads 6.50, and you input this reading into the database. What do you get when you fetch it? Watch:

```
test=> select 6.50 :: float8 as "pH";
      pH
-----
6.5
(1 row)
```

In the world of measurements, 6.50 is not the same as 6.5. It may sometimes be critically different. The experimenters usually write down (and publish) the digits they trust. 6.50 is actually a fuzzy interval contained within a bigger and even fuzzier interval, 6.5, with their center points being (probably) the only common feature they share. We definitely do not want such different data items to appear the same.

Conclusion? It is nice to have a special data type that can record the limits of an interval with arbitrarily variable precision. Variable in the sense that each data element records its own precision.

Check this out:

```
test=> select '6.25 .. 6.50'::seg as "pH";
      pH
-----
6.25 .. 6.50
(1 row)
```

F.60.2. Syntax

The external representation of an interval is formed using one or two floating-point numbers joined by the range operator (`..` or `...`). Alternatively, it can be specified as a center point plus or minus a deviation. Optional certainty indicators (`<`, `>` or `~`) can be stored as well. (Certainty indicators are ignored by all the built-in operators, however.) [Table F.38](#) gives an overview of allowed representations; [Table F.39](#) shows some examples.

In [Table F.38](#), *x*, *y*, and *delta* denote floating-point numbers. *x* and *y*, but not *delta*, can be preceded by a certainty indicator.

Table F.38. `seg` External Representations

<i>x</i>	Single value (zero-length interval)
----------	-------------------------------------

$x \dots y$	Interval from x to y
$x \ (+-) \ \textit{delta}$	Interval from $x - \textit{delta}$ to $x + \textit{delta}$
$x \dots$	Open interval with lower bound x
$\dots x$	Open interval with upper bound x

Table F.39. Examples of Valid `seg` Input

5.0	Creates a zero-length segment (a point, if you will)
~5.0	Creates a zero-length segment and records ~ in the data. ~ is ignored by <code>seg</code> operations, but is preserved as a comment.
<5.0	Creates a point at 5.0. < is ignored but is preserved as a comment.
>5.0	Creates a point at 5.0. > is ignored but is preserved as a comment.
5 (+-) 0.3	Creates an interval 4.7 .. 5.3. Note that the (+-) notation isn't preserved.
50 ..	Everything that is greater than or equal to 50
.. 0	Everything that is less than or equal to 0
1.5e-2 .. 2E-2	Creates an interval 0.015 .. 0.02
1 ... 2	The same as 1...2, or 1 .. 2, or 1..2 (spaces around the range operator are ignored)

Because the `...` operator is widely used in data sources, it is allowed as an alternative spelling of the `..` operator. Unfortunately, this creates a parsing ambiguity: it is not clear whether the upper bound in `0...23` is meant to be 23 or 0.23. This is resolved by requiring at least one digit before the decimal point in all numbers in `seg` input.

As a sanity check, `seg` rejects intervals with the lower bound greater than the upper, for example `5 .. 2`.

F.60.3. Precision

`seg` values are stored internally as pairs of 32-bit floating point numbers. This means that numbers with more than 7 significant digits will be truncated.

Numbers with 7 or fewer significant digits retain their original precision. That is, if your query returns 0.00, you will be sure that the trailing zeroes are not the artifacts of formatting: they reflect the precision of the original data. The number of leading zeroes does not affect precision: the value 0.0067 is considered to have just 2 significant digits.

F.60.4. Usage

The `seg` module includes a GiST index operator class for `seg` values. The operators supported by the GiST operator class are shown in [Table F.40](#).

Table F.40. Seg GiST Operators

Operator	Description
<code>seg << seg → boolean</code>	Is the first <code>seg</code> entirely to the left of the second? <code>[a, b] << [c, d]</code> is true if <code>b < c</code> .
<code>seg >> seg → boolean</code>	Is the first <code>seg</code> entirely to the right of the second? <code>[a, b] >> [c, d]</code> is true if <code>a > d</code> .
<code>seg &< seg → boolean</code>	Does the first <code>seg</code> not extend to the right of the second? <code>[a, b] &< [c, d]</code> is true if <code>b <= d</code> .

Operator	Description
<code>seg &> seg → boolean</code>	Does the first <code>seg</code> not extend to the left of the second? <code>[a, b] &> [c, d]</code> is true if <code>a >= c</code> .
<code>seg = seg → boolean</code>	Are the two <code>segs</code> equal?
<code>seg && seg → boolean</code>	Do the two <code>segs</code> overlap?
<code>seg @> seg → boolean</code>	Does the first <code>seg</code> contain the second?
<code>seg <@ seg → boolean</code>	Is the first <code>seg</code> contained in the second?

In addition to the above operators, the usual comparison operators shown in [Table 9.1](#) are available for type `seg`. These operators first compare (a) to (c), and if these are equal, compare (b) to (d). That results in reasonably good sorting in most cases, which is useful if you want to use ORDER BY with this type.

F.60.5. Notes

For examples of usage, see the regression test `sql/seg.sql`.

The mechanism that converts `(+-)` to regular ranges isn't completely accurate in determining the number of significant digits for the boundaries. For example, it adds an extra digit to the lower boundary if the resulting interval includes a power of ten:

```
postgres=> select '10(+-)1'::seg as seg;
      seg
-----
9.0 .. 11          -- should be: 9 .. 11
```

The performance of an R-tree index can largely depend on the initial order of input values. It may be very helpful to sort the input table on the `seg` column; see the script `sort-segments.pl` for an example.

F.60.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (<https://dsf.berkeley.edu/jmh/>) for elucidating the gist of the GiST (<http://gist.cs.berkeley.edu/>). I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

F.61. sepysql – SELinux-, label-based mandatory access control (MAC) security module

`sepysql` is a loadable module that supports label-based mandatory access control (MAC) based on SELinux security policy.

Warning

The current implementation has significant limitations, and does not enforce mandatory access control for all actions. See [Section F.61.7](#).

F.61.1. Overview

This module integrates with SELinux to provide an additional layer of security checking above and beyond what is normally provided by Postgres Pro. From the perspective of SELinux, this module allows Postgres Pro to function as a user-space object manager. Each table or function access initiated by a DML query will be checked against the system security policy. This check is in addition to the usual SQL permissions checking performed by Postgres Pro.

SELinux access control decisions are made using security labels, which are represented by strings such as `system_u:object_r:sepysql_table_t:s0`. Each access control decision involves two labels: the label of the subject attempting to perform the action, and the label of the object on which the operation is to be performed. Since these labels can be applied to any sort of object, access control decisions for objects stored within the database can be (and, with this module, are) subjected to the same general criteria used for objects of any other type, such as files. This design is intended to allow a centralized security policy to protect information assets independent of the particulars of how those assets are stored.

The `SECURITY LABEL` statement allows assignment of a security label to a database object.

F.61.2. Installation

`sepysql` can only be used on Linux 2.6.28 or higher with SELinux enabled. It is not available on any other platform. You will also need `libselinux` 2.1.10 or higher and `selinux-policy` 3.9.13 or higher (although some distributions may backport the necessary rules into older policy versions).

The `sestatus` command allows you to check the status of SELinux. A typical display is:

```
$ sestatus
SELinux status:                enabled
SELinuxfs mount:              /selinux
Current mode:                  enforcing
Mode from config file:         enforcing
Policy version:                24
Policy from config file:       targeted
```

If SELinux is disabled or not installed, you must set that product up first before installing this module.

To build this module, specify `--with-selinux` (when using `make` and `autoconf`) or `-Dselinux` (when using `meson`). Be sure that the `libselinux-devel` RPM is installed at build time.

To use this module, you must include `sepysql` in the `shared_preload_libraries` parameter in `postgres.conf`. The module will not function correctly if loaded in any other manner. Once the module is loaded, you should execute `sepysql.sql` in each database. This will install functions needed for security label management, and assign initial security labels.

Here is an example showing how to initialize a fresh database cluster with `sepysql` functions and security labels installed. Adjust the paths shown as appropriate for your installation:

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-18-contrib

```
$ export PGDATA=/path/to/data/directory
$ initdb
$ vi $PGDATA/postgresql.conf
  change
    #shared_preload_libraries = ''                # (change requires restart)
  to
    shared_preload_libraries = 'sepgsql'          # (change requires restart)
$ for DBNAME in template0 template1 postgres; do
  postgres --single -F -c exit_on_error=true $DBNAME \
    </usr/local/pgsql/share/contrib/sepgsql.sql >/dev/null
done
```

Please note that you may see some or all of the following notifications depending on the particular versions you have of `libselinux` and `selinux-policy`:

```
/etc/selinux/targeted/contexts/sepgsql_contexts: line 33 has invalid object type
db_blobs
/etc/selinux/targeted/contexts/sepgsql_contexts: line 36 has invalid object type
db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 37 has invalid object type
db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 38 has invalid object type
db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 39 has invalid object type
db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 40 has invalid object type
db_language
```

These messages are harmless and should be ignored.

If the installation process completes without error, you can now start the server normally.

F.61.3. Regression Tests

The `sepgsql` test suite is run if `PG_TEST_EXTRA` contains `sepgsql`. This method is suitable during development of PostgreSQL. Alternatively, there is a way to run the tests to check whether a database instance has been set up properly for `sepgsql`.

Due to the nature of SELinux, running the regression tests for `sepgsql` requires several extra configuration steps, some of which must be done as root.

The manual tests must be run in the `contrib/sepgsql` directory of a configured Postgres Pro build tree. Although they require a build tree, the tests are designed to be executed against an installed server, that is they are comparable to `make installcheck` not `make check`.

First, set up `sepgsql` in a working database according to the instructions in [Section F.61.2](#). Note that the current operating system user must be able to connect to the database as superuser without password authentication.

Second, build and install the policy package for the regression test. The `sepgsql-regtest` policy is a special purpose policy package which provides a set of rules to be allowed during the regression tests. It should be built from the policy source file `sepgsql-regtest.te`, which is done using `make` with a Makefile supplied by SELinux. You will need to locate the appropriate Makefile on your system; the path shown below is only an example. (This Makefile is usually supplied by the `selinux-policy-devel` or `selinux-policy` RPM.) Once built, install this policy package using the `semodule` command, which loads supplied policy packages into the kernel. If the package is correctly installed, `semodule -l` should list `sepgsql-regtest` as an available policy package:

```
$ cd ../contrib/sepgsql
$ make -f /usr/share/selinux/devel/Makefile
$ sudo semodule -u sepgsql-regtest.pp
```

```
$ sudo semodule -l | grep sepysql
sepysql-regtest 1.07
```

Third, turn on `sepysql_regression_test_mode`. For security reasons, the rules in `sepysql-regtest` are not enabled by default; the `sepysql_regression_test_mode` parameter enables the rules needed to launch the regression tests. It can be turned on using the `setsebool` command:

```
$ sudo setsebool sepysql_regression_test_mode on
$ getsebool sepysql_regression_test_mode
sepysql_regression_test_mode --> on
```

Fourth, verify your shell is operating in the `unconfined_t` domain:

```
$ id -Z
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023
```

See [Section F.61.8](#) for details on adjusting your working domain, if necessary.

Finally, run the regression test script:

```
$ ./test_sepysql
```

This script will attempt to verify that you have done all the configuration steps correctly, and then it will run the regression tests for the `sepysql` module.

After completing the tests, it's recommended you disable the `sepysql_regression_test_mode` parameter:

```
$ sudo setsebool sepysql_regression_test_mode off
```

You might prefer to remove the `sepysql-regtest` policy entirely:

```
$ sudo semodule -r sepysql-regtest
```

F.61.4. GUC Parameters

`sepysql.permissive` (boolean)

This parameter enables `sepysql` to function in permissive mode, regardless of the system setting. The default is off. This parameter can only be set in the `postgresql.conf` file or on the server command line.

When this parameter is on, `sepysql` functions in permissive mode, even if SELinux in general is working in enforcing mode. This parameter is primarily useful for testing purposes.

`sepysql.debug_audit` (boolean)

This parameter enables the printing of audit messages regardless of the system policy settings. The default is off, which means that messages will be printed according to the system settings.

The security policy of SELinux also has rules to control whether or not particular accesses are logged. By default, access violations are logged, but allowed accesses are not.

This parameter forces all possible logging to be turned on, regardless of the system policy.

F.61.5. Features

F.61.5.1. Controlled Object Classes

The security model of SELinux describes all the access control rules as relationships between a subject entity (typically, a client of the database) and an object entity (such as a database object), each of which is identified by a security label. If access to an unlabeled object is attempted, the object is treated as if it were assigned the label `unlabeled_t`.

Currently, `sepgsql` allows security labels to be assigned to schemas, tables, columns, sequences, views, and functions. When `sepgsql` is in use, security labels are automatically assigned to supported database objects at creation time. This label is called a default security label, and is decided according to the system security policy, which takes as input the creator's label, the label assigned to the new object's parent object and optionally name of the constructed object.

A new database object basically inherits the security label of the parent object, except when the security policy has special rules known as type-transition rules, in which case a different label may be applied. For schemas, the parent object is the current database; for tables, sequences, views, and functions, it is the containing schema; for columns, it is the containing table.

F.61.5.2. DML Permissions

For tables, `db_table:select`, `db_table:insert`, `db_table:update` or `db_table:delete` are checked for all the referenced target tables depending on the kind of statement; in addition, `db_table:select` is also checked for all the tables that contain columns referenced in the `WHERE` or `RETURNING` clause, as a data source for `UPDATE`, and so on.

Column-level permissions will also be checked for each referenced column. `db_column:select` is checked on not only the columns being read using `SELECT`, but those being referenced in other DML statements; `db_column:update` or `db_column:insert` will also be checked for columns being modified by `UPDATE` or `INSERT`.

For example, consider:

```
UPDATE t1 SET x = 2, y = func1(y) WHERE z = 100;
```

Here, `db_column:update` will be checked for `t1.x`, since it is being updated, `db_column:{select update}` will be checked for `t1.y`, since it is both updated and referenced, and `db_column:select` will be checked for `t1.z`, since it is only referenced. `db_table:{select update}` will also be checked at the table level.

For sequences, `db_sequence:get_value` is checked when we reference a sequence object using `SELECT`; however, note that we do not currently check permissions on execution of corresponding functions such as `lastval()`.

For views, `db_view:expand` will be checked, then any other required permissions will be checked on the objects being expanded from the view, individually.

For functions, `db_procedure:{execute}` will be checked when user tries to execute a function as a part of query, or using fast-path invocation. If this function is a trusted procedure, it also checks `db_procedure:{entrypoint}` permission to check whether it can perform as entry point of trusted procedure.

In order to access any schema object, `db_schema:search` permission is required on the containing schema. When an object is referenced without schema qualification, schemas on which this permission is not present will not be searched (just as if the user did not have `USAGE` privilege on the schema). If an explicit schema qualification is present, an error will occur if the user does not have the requisite permission on the named schema.

The client must be allowed to access all referenced tables and columns, even if they originated from views which were then expanded, so that we apply consistent access control rules independent of the manner in which the table contents are referenced.

The default database privilege system allows database superusers to modify system catalogs using DML commands, and reference or modify toast tables. These operations are prohibited when `sepgsql` is enabled.

F.61.5.3. DDL Permissions

SELinux defines several permissions to control common operations for each object type; such as creation, alter, drop and relabel of security label. In addition, several object types have special permissions to

control their characteristic operations; such as addition or deletion of name entries within a particular schema.

Creating a new database object requires `create` permission. SELinux will grant or deny this permission based on the client's security label and the proposed security label for the new object. In some cases, additional privileges are required:

- `CREATE DATABASE` additionally requires `getattr` permission for the source or template database.
- Creating a schema object additionally requires `add_name` permission on the parent schema.
- Creating a table additionally requires permission to create each individual table column, just as if each table column were a separate top-level object.
- Creating a function marked as `LEAKPROOF` additionally requires `install` permission. (This permission is also checked when `LEAKPROOF` is set for an existing function.)

When `DROP` command is executed, `drop` will be checked on the object being removed. Permissions will be also checked for objects dropped indirectly via `CASCADE`. Deletion of objects contained within a particular schema (tables, views, sequences and procedures) additionally requires `remove_name` on the schema.

When `ALTER` command is executed, `setattr` will be checked on the object being modified for each object types, except for subsidiary objects such as the indexes or triggers of a table, where permissions are instead checked on the parent object. In some cases, additional permissions are required:

- Moving an object to a new schema additionally requires `remove_name` permission on the old schema and `add_name` permission on the new one.
- Setting the `LEAKPROOF` attribute on a function requires `install` permission.
- Using `SECURITY LABEL` on an object additionally requires `relabelfrom` permission for the object in conjunction with its old security label and `relabelto` permission for the object in conjunction with its new security label. (In cases where multiple label providers are installed and the user tries to set a security label, but it is not managed by SELinux, only `setattr` should be checked here. This is currently not done due to implementation restrictions.)

F.61.5.4. Trusted Procedures

Trusted procedures are similar to security definer functions or `setuid` commands. SELinux provides a feature to allow trusted code to run using a security label different from that of the client, generally for the purpose of providing highly controlled access to sensitive data (e.g., rows might be omitted, or the precision of stored values might be reduced). Whether or not a function acts as a trusted procedure is controlled by its security label and the operating system security policy. For example:

```
postgres=# CREATE TABLE customer (
            cid      int primary key,
            cname    text,
            credit    text
        );
CREATE TABLE
postgres=# SECURITY LABEL ON COLUMN customer.credit
            IS 'system_u:object_r:sepgsql_secret_table_t:s0';
SECURITY LABEL
postgres=# CREATE FUNCTION show_credit(int) RETURNS text
            AS 'SELECT regexp_replace(credit, '[0-9]+$', '-xxxx', 'g')
            FROM customer WHERE cid = $1'
            LANGUAGE sql;
CREATE FUNCTION
postgres=# SECURITY LABEL ON FUNCTION show_credit(int)
            IS 'system_u:object_r:sepgsql_trusted_proc_exec_t:s0';
SECURITY LABEL
```

The above operations should be performed by an administrative user.

```
postgres=# SELECT * FROM customer;
ERROR:  SELinux: security policy violation
postgres=# SELECT cid, cname, show_credit(cid) FROM customer;
  cid | cname | show_credit
-----+-----+-----
    1 | taro  | 1111-2222-3333-xxxx
    2 | hanako | 5555-6666-7777-xxxx
(2 rows)
```

In this case, a regular user cannot reference `customer.credit` directly, but a trusted procedure `show_credit` allows the user to print the credit card numbers of customers with some of the digits masked out.

F.61.5.5. Dynamic Domain Transitions

It is possible to use SELinux's dynamic domain transition feature to switch the security label of the client process, the client domain, to a new context, if that is allowed by the security policy. The client domain needs the `setcurrent` permission and also `dyntransition` from the old to the new domain.

Dynamic domain transitions should be considered carefully, because they allow users to switch their label, and therefore their privileges, at their option, rather than (as in the case of a trusted procedure) as mandated by the system. Thus, the `dyntransition` permission is only considered safe when used to switch to a domain with a smaller set of privileges than the original one. For example:

```
regression=# select sepysql_getcon();
              sepysql_getcon
-----
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023
(1 row)

regression=# SELECT sepysql_setcon('unconfined_u:unconfined_r:unconfined_t:s0-
s0:c1.c4');
      sepysql_setcon
-----
t
(1 row)

regression=# SELECT sepysql_setcon('unconfined_u:unconfined_r:unconfined_t:s0-
s0:c1.c1023');
ERROR:  SELinux: security policy violation
```

In this example above we were allowed to switch from the larger MCS range `c1.c1023` to the smaller range `c1.c4`, but switching back was denied.

A combination of dynamic domain transition and trusted procedure enables an interesting use case that fits the typical process life-cycle of connection pooling software. Even if your connection pooling software is not allowed to run most of SQL commands, you can allow it to switch the security label of the client using the `sepysql_setcon()` function from within a trusted procedure; that should take some credential to authorize the request to switch the client label. After that, this session will have the privileges of the target user, rather than the connection pooler. The connection pooler can later revert the security label change by again using `sepysql_setcon()` with `NULL` argument, again invoked from within a trusted procedure with appropriate permissions checks. The point here is that only the trusted procedure actually has permission to change the effective security label, and only does so when given proper credentials. Of course, for secure operation, the credential store (table, procedure definition, or whatever) must be protected from unauthorized access.

F.61.5.6. Miscellaneous

We reject the `LOAD` command across the board, because any module loaded could easily circumvent security policy enforcement.

F.61.6. Sepgsql Functions

Table F.41 shows the available functions.

Table F.41. Sepgsql Functions

Function	Description
<code>sepgsql_getcon ()</code> \rightarrow text	Returns the client domain, the current security label of the client.
<code>sepgsql_setcon (text)</code> \rightarrow boolean	Switches the client domain of the current session to the new domain, if allowed by the security policy. It also accepts <code>NULL</code> input as a request to transition to the client's original domain.
<code>sepgsql_mcstrans_in (text)</code> \rightarrow text	Translates the given qualified MLS/MCS range into raw format if the mcstrans daemon is running.
<code>sepgsql_mcstrans_out (text)</code> \rightarrow text	Translates the given raw MLS/MCS range into qualified format if the mcstrans daemon is running.
<code>sepgsql_restorecon (text)</code> \rightarrow boolean	Sets up initial security labels for all objects within the current database. The argument may be <code>NULL</code> , or the name of a specfile to be used as alternative of the system default.

F.61.7. Limitations

Data Definition Language (DDL) Permissions

Due to implementation restrictions, some DDL operations do not check permissions.

Data Control Language (DCL) Permissions

Due to implementation restrictions, DCL operations do not check permissions.

Row-level access control

Postgres Pro supports row-level access, but `sepgsql` does not.

Covert channels

`sepgsql` does not try to hide the existence of a certain object, even if the user is not allowed to reference it. For example, we can infer the existence of an invisible object as a result of primary key conflicts, foreign key violations, and so on, even if we cannot obtain the contents of the object. The existence of a top secret table cannot be hidden; we only hope to conceal its contents.

F.62. shared_ispell — a shared ispell dictionary

The `shared_ispell` module provides a shared ispell dictionary, i.e. a dictionary that's stored in shared segment. The traditional ispell implementation means that each session initializes and stores the dictionary on it's own, which means a lot of CPU/RAM is wasted.

This extension allocates an area in shared segment (you have to choose the size in advance) and then loads the dictionary into it when it's used for the first time.

F.62.1. Functions

The functions provided by the `shared_ispell` module are shown in [Table F.42](#).

Table F.42. `shared_ispell` Functions

Function	Returns	Description
<code>shared_ispell_reset()</code>	void	Resets the dictionaries (e.g. so that you can reload the updated files from disk). The sessions that already use the dictionaries will be forced to reinitialize them.
<code>shared_ispell_mem_used()</code>	int	Returns a value of used memory of the shared segment by loaded shared dictionaries in bytes.
<code>shared_ispell_mem_available()</code>	int	Returns a value of available memory of the shared segment.
<code>shared_ispell_dicts()</code>	setof(dict_name varchar, affix_name varchar, words int, affixes int, bytes int)	Returns a list of dictionaries loaded in the shared segment.
<code>shared_ispell_stoplists()</code>	setof(stop_name varchar, words int, bytes int)	Returns a list of stopwords loaded in the shared segment.

F.62.2. GUC Parameters

`shared_ispell.max_size` (int)

Defines the maximum size of the shared segment. This is a hard limit, the shared segment is not extensible and you need to set it so that all the dictionaries fit into it and not much memory is wasted.

F.62.3. Using the dictionary

The module needs to allocate space in the shared memory segment. So add this to the config file (or update the current values):

```
# libraries to load
shared_preload_libraries = 'shared_ispell'

# config of the shared memory
shared_ispell.max_size = 32MB
```

To find out how much memory you actually need, use a large value (e.g. 200MB) and load all the dictionaries you want to use. Then use the `shared_ispell_mem_used()` function to find out how much memory was actually used (and set the `shared_ispell.max_size` GUC variable accordingly).

Don't set it exactly to that value, leave there some free space, so that you can reload the dictionaries without changing the GUC `max_size` limit (which requires a restart of the DB). Something like 512kB should be just fine.

The extension defines a `shared_ispell` template that you may use to define custom dictionaries. E.g. you may do this:

```
CREATE TEXT SEARCH DICTIONARY english_shared (
    TEMPLATE = shared_ispell,
    DictFile = en_us,
    AffFile = en_us,
    StopWords = english
);

CREATE TEXT SEARCH CONFIGURATION public.english_shared
    ( COPY = pg_catalog.simple );

ALTER TEXT SEARCH CONFIGURATION english_shared
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
        word, hword, hword_part
    WITH english_shared, english_stem;
```

We can test created configuration:

```
SELECT * FROM ts_debug('english_shared', 'abilities');
  alias | description | token | dictionaries | dictionary
-----+-----+-----+-----+-----
  | lexemes
-----+-----+-----+-----+-----
asciiword | Word, all ASCII | abilities | {english_shared,english_stem} |
english_shared | {ability}
(1 row)
```

Or you can update your own text search configuration. For example, you have the `public.english` dictionary. You can update it to use the `shared_ispell` template:

```
ALTER TEXT SEARCH CONFIGURATION public.english
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
        word, hword, hword_part
    WITH english_shared, english_stem;
```

F.63. spi — Server Programming Interface features/examples

The spi module provides several workable examples of using the [Server Programming Interface](#) (SPI) and triggers. While these functions are of some value in their own right, they are even more useful as examples to modify for your own purposes. The functions are general enough to be used with any table, but you have to specify table and field names (as described below) while creating a trigger.

Each of the groups of functions described below is provided as a separately-installable extension.

F.63.1. refint — Functions for Implementing Referential Integrity

`check_primary_key()` and `check_foreign_key()` are used to check foreign key constraints. (This functionality is long since superseded by the built-in foreign key mechanism, of course, but the module is still useful as an example.)

`check_primary_key()` checks the referencing table. To use, create an `AFTER INSERT OR UPDATE` trigger using this function on a table referencing another table. Specify as the trigger arguments: the referencing table's column name(s) which form the foreign key, the referenced table name, and the column names in the referenced table which form the primary/unique key. To handle multiple foreign keys, create a trigger for each reference.

`check_foreign_key()` checks the referenced table. To use, create an `AFTER DELETE OR UPDATE` trigger using this function on a table referenced by other table(s). Specify as the trigger arguments: the number of referencing tables for which the function has to perform checking, the action if a referencing key is found (`cascade` — to delete the referencing row, `restrict` — to abort transaction if referencing keys exist, `setnull` — to set referencing key fields to null), the triggered table's column names which form the primary/unique key, then the referencing table name and column names (repeated for as many referencing tables as were specified by first argument). Note that the primary/unique key columns should be marked `NOT NULL` and should have a unique index.

Note that if these triggers are executed from another `BEFORE` trigger, they can fail unexpectedly. For example, if a user inserts row1 and then the `BEFORE` trigger inserts row2 and calls a trigger with the `check_foreign_key()`, the `check_foreign_key()` function will not see row1 and will fail.

There are examples in `refint.example`.

F.63.2. autoinc — Functions for Autoincrementing Fields

`autoinc()` is a trigger that stores the next value of a sequence into an integer field. This has some overlap with the built-in “serial column” feature, but it is not the same. The trigger will replace the field's value only if that value is initially zero or null (after the action of the SQL statement that inserted or updated the row). Also, if the sequence's next value is zero, `nextval()` will be called a second time in order to obtain a non-zero value.

To use, create a `BEFORE INSERT` (or optionally `BEFORE INSERT OR UPDATE`) trigger using this function. Specify two trigger arguments: the name of the integer column to be modified, and the name of the sequence object that will supply values. (Actually, you can specify any number of pairs of such names, if you'd like to update more than one autoincrementing column.)

There is an example in `autoinc.example`.

F.63.3. insert_username — Functions for Tracking Who Changed a Table

`insert_username()` is a trigger that stores the current user's name into a text field. This can be useful for tracking who last modified a particular row within a table.

To use, create a `BEFORE INSERT` and/or `UPDATE` trigger using this function. Specify a single trigger argument: the name of the text column to be modified.

There is an example in `insert_username.example`.

F.63.4. moddatetime — Functions for Tracking Last Modification Time

`moddatetime()` is a trigger that stores the current time into a `timestamp` field. This can be useful for tracking the last modification time of a particular row within a table.

To use, create a `BEFORE UPDATE` trigger using this function. Specify a single trigger argument: the name of the column to be modified. The column must be of type `timestamp` or `timestamp with time zone`.

There is an example in `moddatetime.example`.

F.64. sslinfo — obtain client SSL information

The `sslinfo` module provides information about the SSL certificate that the current client provided when connecting to Postgres Pro. The module is useless (most functions will return NULL) if the current connection does not use SSL.

Some of the information available through this module can also be obtained using the built-in system view `pg_stat_ssl`.

This extension won't build at all unless the installation was configured with `--with-ssl=openssl`.

F.64.1. Functions Provided

`ssl_is_used()` returns boolean

Returns true if current connection to server uses SSL, and false otherwise.

`ssl_version()` returns text

Returns the name of the protocol used for the SSL connection (e.g., TLSv1.0, TLSv1.1, TLSv1.2 or TLSv1.3).

`ssl_cipher()` returns text

Returns the name of the cipher used for the SSL connection (e.g., DHE-RSA-AES256-SHA).

`ssl_client_cert_present()` returns boolean

Returns true if current client has presented a valid SSL client certificate to the server, and false otherwise. (The server might or might not be configured to require a client certificate.)

`ssl_client_serial()` returns numeric

Returns serial number of current client certificate. The combination of certificate serial number and certificate issuer is guaranteed to uniquely identify a certificate (but not its owner — the owner ought to regularly change their keys, and get new certificates from the issuer).

So, if you run your own CA and allow only certificates from this CA to be accepted by the server, the serial number is the most reliable (albeit not very mnemonic) means to identify a user.

`ssl_client_dn()` returns text

Returns the full subject of the current client certificate, converting character data into the current database encoding. It is assumed that if you use non-ASCII characters in the certificate names, your database is able to represent these characters, too. If your database uses the SQL_ASCII encoding, non-ASCII characters in the name will be represented as UTF-8 sequences.

The result looks like `/CN=Somebody /C=Some country/O=Some organization`.

`ssl_issuer_dn()` returns text

Returns the full issuer name of the current client certificate, converting character data into the current database encoding. Encoding conversions are handled the same as for `ssl_client_dn`.

The combination of the return value of this function with the certificate serial number uniquely identifies the certificate.

This function is really useful only if you have more than one trusted CA certificate in your server's certificate authority file, or if this CA has issued some intermediate certificate authority certificates.

`ssl_client_dn_field(fieldname text)` returns text

This function returns the value of the specified field in the certificate subject, or NULL if the field is not present. Field names are string constants that are converted into ASN1 object identifiers using the OpenSSL object database. The following values are acceptable:

commonName (alias CN)
surname (alias SN)
name
givenName (alias GN)
countryName (alias C)
localityName (alias L)
stateOrProvinceName (alias ST)
organizationName (alias O)
organizationalUnitName (alias OU)
title
description
initials
postalCode
streetAddress
generationQualifier
description
dnQualifier
x500UniqueIdentifier
pseudonym
role
emailAddress

All of these fields are optional, except `commonName`. It depends entirely on your CA's policy which of them would be included and which wouldn't. The meaning of these fields, however, is strictly defined by the X.500 and X.509 standards, so you cannot just assign arbitrary meaning to them.

`ssl_issuer_field(fieldname text)` returns text

Same as `ssl_client_dn_field`, but for the certificate issuer rather than the certificate subject.

`ssl_extension_info()` returns setof record

Provide information about extensions of client certificate: extension name, extension value, and if it is a critical extension.

F.65. tablefunc — functions that return tables (crosstab and others)

The `tablefunc` module includes various functions that return tables (that is, multiple rows). These functions are useful both in their own right and as examples of how to write C functions that return multiple rows.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.65.1. Functions Provided

Table F.43 summarizes the functions provided by the `tablefunc` module.

Table F.43. tablefunc Functions

Function	Description
<code>normal_rand (numvals integer, mean float8, stddev float8) → setof float8</code>	Produces a set of normally distributed random values.
<code>crosstab (sql text) → setof record</code>	Produces a “pivot table” containing row names plus <i>N</i> value columns, where <i>N</i> is determined by the row type specified in the calling query.
<code>crosstabN (sql text) → setof table_crosstab_ N</code>	Produces a “pivot table” containing row names plus <i>N</i> value columns. <code>crosstab2</code> , <code>crosstab3</code> , and <code>crosstab4</code> are predefined, but you can create additional <code>crosstabN</code> functions as described below.
<code>crosstab (source_sql text, category_sql text) → setof record</code>	Produces a “pivot table” with the value columns specified by a second query.
<code>crosstab (sql text, N integer) → setof record</code>	Obsolete version of <code>crosstab(text)</code> . The parameter <i>N</i> is now ignored, since the number of value columns is always determined by the calling query.
<code>connectby (relname text, keyid_fld text, parent_keyid_fld text [, orderby_fld text], start_with text, max_depth integer [, branch_delim text]) → setof record</code>	Produces a representation of a hierarchical tree structure.

F.65.1.1. normal_rand

`normal_rand(int numvals, float8 mean, float8 stddev)` returns `setof float8`

`normal_rand` produces a set of normally distributed random values (Gaussian distribution).

numvals is the number of values to be returned from the function. *mean* is the mean of the normal distribution of values and *stddev* is the standard deviation of the normal distribution of values.

For example, this call requests 1000 values with a mean of 5 and a standard deviation of 3:

```
test=# SELECT * FROM normal_rand(1000, 5, 3);
normal_rand
-----
 1.56556322244898
 9.10040991424657
 5.36957140345079
-0.369151492880995
 0.283600703686639
```

```
.
.
.
4.82992125404908
9.71308014517282
2.49639286969028
(1000 rows)
```

F.65.1.2. crosstab(text)

```
crosstab(text sql)
crosstab(text sql, int N)
```

The `crosstab` function is used to produce “pivot” displays, wherein data is listed across the page rather than down. For example, we might have data like

```
row1    val11
row1    val12
row1    val13
...
row2    val21
row2    val22
row2    val23
...
```

which we wish to display like

```
row1    val11    val12    val13    ...
row2    val21    val22    val23    ...
...
```

The `crosstab` function takes a text parameter that is an SQL query producing raw data formatted in the first way, and produces a table formatted in the second way.

The `sql` parameter is an SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. `N` is an obsolete parameter, ignored if supplied (formerly this had to match the number of output value columns, but now that is determined by the calling query).

For example, the provided query might produce a set something like:

row_name	cat	value
row1	cat1	val1
row1	cat2	val2
row1	cat3	val3
row1	cat4	val4
row2	cat1	val5
row2	cat2	val6
row2	cat3	val7
row2	cat4	val8

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...') AS ct(row_name text, category_1 text, category_2 text);
```

This example produces a set something like:

	<== value columns ==>	
row_name	category_1	category_2
row1	val1	val2

row2 val5 val6

The `FROM` clause must define the output as one `row_name` column (of the same data type as the first result column of the SQL query) followed by `N value` columns (all of the same data type as the third result column of the SQL query). You can set up as many output value columns as you wish. The names of the output columns are up to you.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. It fills the output value columns, left to right, with the value fields from these rows. If there are fewer rows in a group than there are output value columns, the extra output columns are filled with nulls; if there are more rows, the extra input rows are skipped.

In practice the SQL query should always specify `ORDER BY 1, 2` to ensure that the input rows are properly ordered, that is, values with the same `row_name` are brought together and correctly ordered within the row. Notice that `crosstab` itself does not pay any attention to the second column of the query result; it's just there to be ordered by, to control the order in which the third-column values appear across the page.

Here is a complete example:

```
CREATE TABLE ct(id SERIAL, rowid TEXT, attribute TEXT, value TEXT);
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att1','val1');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att2','val2');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att3','val3');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att4','val4');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att1','val5');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att2','val6');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att3','val7');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att4','val8');
```

```
SELECT *
FROM crosstab(
    'select rowid, attribute, value
    from ct
    where attribute = ''att2'' or attribute = ''att3''
    order by 1,2')
AS ct(row_name text, category_1 text, category_2 text, category_3 text);
```

row_name	category_1	category_2	category_3
test1	val2	val3	
test2	val6	val7	

(2 rows)

You can avoid always having to write out a `FROM` clause to define the output columns, by setting up a custom `crosstab` function that has the desired output row type wired into its definition. This is described in the next section. Another possibility is to embed the required `FROM` clause in a view definition.

Note

See also the `\crosstabview` command in `psql`, which provides functionality similar to `crosstab()`.

F.65.1.3. `crosstabN(text)`

```
crosstabN(text sql)
```

The `crosstabN` functions are examples of how to set up custom wrappers for the general `crosstab` function, so that you need not write out column names and types in the calling `SELECT` query. The `tablefunc` module includes `crosstab2`, `crosstab3`, and `crosstab4`, whose output row types are defined as

```
CREATE TYPE tablefunc_crosstab_N AS (  
    row_name TEXT,  
    category_1 TEXT,  
    category_2 TEXT,  
    .  
    .  
    .  
    category_N TEXT  
);
```

Thus, these functions can be used directly when the input query produces `row_name` and `value` columns of type `text`, and you want 2, 3, or 4 output values columns. In all other ways they behave exactly as described above for the general `crosstab` function.

For instance, the example given in the previous section would also work as

```
SELECT *  
FROM crosstab3(  
    'select rowid, attribute, value  
    from ct  
    where attribute = ''att2'' or attribute = ''att3''  
    order by 1,2');
```

These functions are provided mostly for illustration purposes. You can create your own return types and functions based on the underlying `crosstab()` function. There are two ways to do it:

- Create a composite type describing the desired output columns, similar to the examples in `contrib/tablefunc/tablefunc--1.0.sql`. Then define a unique function name accepting one `text` parameter and returning `setof your_type_name`, but linking to the same underlying `crosstab C` function. For example, if your source data produces row names that are `text`, and values that are `float8`, and you want 5 value columns:

```
CREATE TYPE my_crosstab_float8_5_cols AS (  
    my_row_name text,  
    my_category_1 float8,  
    my_category_2 float8,  
    my_category_3 float8,  
    my_category_4 float8,  
    my_category_5 float8  
);  
  
CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(text)  
    RETURNS setof my_crosstab_float8_5_cols  
    AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;
```

- Use `OUT` parameters to define the return type implicitly. The same example could also be done this way:

```
CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(  
    IN text,  
    OUT my_row_name text,  
    OUT my_category_1 float8,  
    OUT my_category_2 float8,  
    OUT my_category_3 float8,  
    OUT my_category_4 float8,  
    OUT my_category_5 float8)  
    RETURNS setof record  
    AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;
```

F.65.1.4. `crosstab(text, text)`

```
crosstab(text source_sql, text category_sql)
```

The main limitation of the single-parameter form of `crosstab` is that it treats all values in a group alike, inserting each value into the first available column. If you want the value columns to correspond to specific categories of data, and some groups might not have data for some of the categories, that doesn't work well. The two-parameter form of `crosstab` handles this case by providing an explicit list of the categories corresponding to the output columns.

`source_sql` is an SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. It may also have one or more “extra” columns. The `row_name` column must be first. The `category` and `value` columns must be the last two columns, in that order. Any columns between `row_name` and `category` are treated as “extra”. The “extra” columns are expected to be the same for all rows with the same `row_name` value.

For example, `source_sql` might produce a set something like:

```
SELECT row_name, extra_col, cat, value FROM foo ORDER BY 1;
```

row_name	extra_col	cat	value
row1	extra1	cat1	val1
row1	extra1	cat2	val2
row1	extra1	cat4	val4
row2	extra2	cat1	val5
row2	extra2	cat2	val6
row2	extra2	cat3	val7
row2	extra2	cat4	val8

`category_sql` is an SQL statement that produces the set of categories. This statement must return only one column. It must produce at least one row, or an error will be generated. Also, it must not produce duplicate values, or an error will be generated. `category_sql` might be something like:

```
SELECT DISTINCT cat FROM foo ORDER BY 1;
cat
-----
cat1
cat2
cat3
cat4
```

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...', '...')
AS ct(row_name text, extra text, cat1 text, cat2 text, cat3 text, cat4 text);
```

This will produce a result something like:

		<== value columns ==>			
row_name	extra	cat1	cat2	cat3	cat4
row1	extra1	val1	val2		val4
row2	extra2	val5	val6	val7	val8

The `FROM` clause must define the proper number of output columns of the proper data types. If there are N columns in the `source_sql` query's result, the first $N-2$ of them must match up with the first $N-2$ output columns. The remaining output columns must have the type of the last column of the `source_sql` query's result, and there must be exactly as many of them as there are rows in the `category_sql` query's result.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. The output `row_name` column, plus any “extra” columns, are copied from the first row of the group. The output `value` columns are filled with the `value` fields from rows having matching

category values. If a row's category does not match any output of the *category_sql* query, its value is ignored. Output columns whose matching category is not present in any input row of the group are filled with nulls.

In practice the *source_sql* query should always specify `ORDER BY 1` to ensure that values with the same *row_name* are brought together. However, ordering of the categories within a group is not important. Also, it is essential to be sure that the order of the *category_sql* query's output matches the specified output column order.

Here are two complete examples:

```
create table sales(year int, month int, qty int);
insert into sales values(2007, 1, 1000);
insert into sales values(2007, 2, 1500);
insert into sales values(2007, 7, 500);
insert into sales values(2007, 11, 1500);
insert into sales values(2007, 12, 2000);
insert into sales values(2008, 1, 1000);
```

```
select * from crosstab(
    'select year, month, qty from sales order by 1',
    'select m from generate_series(1,12) m'
```

```
) as (
```

```
year int,
"Jan" int,
"Feb" int,
"Mar" int,
"Apr" int,
"May" int,
"Jun" int,
"Jul" int,
"Aug" int,
"Sep" int,
"Oct" int,
"Nov" int,
"Dec" int
```

```
);
```

year	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
2007	1000	1500					500				1500	2000
2008	1000											

(2 rows)

```
CREATE TABLE cth(rowid text, rowdt timestamp, attribute text, val text);
INSERT INTO cth VALUES('test1','01 March 2003','temperature','42');
INSERT INTO cth VALUES('test1','01 March 2003','test_result','PASS');
INSERT INTO cth VALUES('test1','01 March 2003','volts','2.6987');
INSERT INTO cth VALUES('test2','02 March 2003','temperature','53');
INSERT INTO cth VALUES('test2','02 March 2003','test_result','FAIL');
INSERT INTO cth VALUES('test2','02 March 2003','test_startdate','01 March 2003');
INSERT INTO cth VALUES('test2','02 March 2003','volts','3.1234');
```

```
SELECT * FROM crosstab
```

```
(
    'SELECT rowid, rowdt, attribute, val FROM cth ORDER BY 1',
    'SELECT DISTINCT attribute FROM cth ORDER BY 1'
```

```
)
```

```
AS
```

```
(
```

```

rowid text,
rowdt timestamp,
temperature int4,
test_result text,
test_startdate timestamp,
volts float8
);
rowid |          rowdt          | temperature | test_result |          test_startdate
| volts
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
test1 | Sat Mar 01 00:00:00 2003 |          42 | PASS      |
| 2.6987
test2 | Sun Mar 02 00:00:00 2003 |          53 | FAIL      | Sat Mar 01 00:00:00
2003 | 3.1234
(2 rows)

```

You can create predefined functions to avoid having to write out the result column names and types in each query. See the examples in the previous section. The underlying C function for this form of `crosstab` is named `crosstab_hash`.

F.65.1.5. `connectby`

```

connectby(text relname, text keyid_fld, text parent_keyid_fld
[, text orderby_fld ], text start_with, int max_depth
[, text branch_delim ])

```

The `connectby` function produces a display of hierarchical data that is stored in a table. The table must have a key field that uniquely identifies rows, and a parent-key field that references the parent (if any) of each row. `connectby` can display the sub-tree descending from any row.

Table F.44 explains the parameters.

Table F.44. `connectby` Parameters

Parameter	Description
<i>relname</i>	Name of the source relation
<i>keyid_fld</i>	Name of the key field
<i>parent_keyid_fld</i>	Name of the parent-key field
<i>orderby_fld</i>	Name of the field to order siblings by (optional)
<i>start_with</i>	Key value of the row to start at
<i>max_depth</i>	Maximum depth to descend to, or zero for unlimited depth
<i>branch_delim</i>	String to separate keys with in branch output (optional)

The key and parent-key fields can be any data type, but they must be the same type. Note that the *start_with* value must be entered as a text string, regardless of the type of the key field.

The `connectby` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```

SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0,
 '~')
AS t(keyid text, parent_keyid text, level int, branch text, pos int);

```

The first two output columns are used for the current row's key and its parent row's key; they must match the type of the table's key field. The third output column is the depth in the tree and must be

of type `integer`. If a `branch_delim` parameter was given, the next output column is the branch display and must be of type `text`. Finally, if an `orderby_fld` parameter was given, the last output column is a serial number, and must be of type `integer`.

The “branch” output column shows the path of keys taken to reach the current row. The keys are separated by the specified `branch_delim` string. If no branch display is wanted, omit both the `branch_delim` parameter and the branch column in the output column list.

If the ordering of siblings of the same parent is important, include the `orderby_fld` parameter to specify which field to order siblings by. This field can be of any sortable data type. The output column list must include a final integer serial-number column, if and only if `orderby_fld` is specified.

The parameters representing table and field names are copied as-is into the SQL queries that `connectby` generates internally. Therefore, include double quotes if the names are mixed-case or contain special characters. You may also need to schema-qualify the table name.

In large tables, performance will be poor unless there is an index on the parent-key field.

It is important that the `branch_delim` string not appear in any key values, else `connectby` may incorrectly report an infinite-recursion error. Note that if `branch_delim` is not provided, a default value of `~` is used for recursion detection purposes.

Here is an example:

```
CREATE TABLE connectby_tree(keyid text, parent_keyid text, pos int);
```

```
INSERT INTO connectby_tree VALUES('row1',NULL, 0);
INSERT INTO connectby_tree VALUES('row2','row1', 0);
INSERT INTO connectby_tree VALUES('row3','row1', 0);
INSERT INTO connectby_tree VALUES('row4','row2', 1);
INSERT INTO connectby_tree VALUES('row5','row2', 0);
INSERT INTO connectby_tree VALUES('row6','row4', 0);
INSERT INTO connectby_tree VALUES('row7','row3', 0);
INSERT INTO connectby_tree VALUES('row8','row6', 0);
INSERT INTO connectby_tree VALUES('row9','row5', 0);
```

```
-- with branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0, '~')
AS t(keyid text, parent_keyid text, level int, branch text);
keyid | parent_keyid | level |      branch
```

keyid	parent_keyid	level	branch
row2		0	row2
row4	row2	1	row2~row4
row6	row4	2	row2~row4~row6
row8	row6	3	row2~row4~row6~row8
row5	row2	1	row2~row5
row9	row5	2	row2~row5~row9

(6 rows)

```
-- without branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0)
AS t(keyid text, parent_keyid text, level int);
keyid | parent_keyid | level
```

keyid	parent_keyid	level
row2		0
row4	row2	1
row6	row4	2
row8	row6	3
row5	row2	1

```
row9 | row5 | 2
(6 rows)
```

```
-- with branch, with orderby_fld (notice that row5 comes before row4)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0,
 '~')
AS t(keyid text, parent_keyid text, level int, branch text, pos int);
keyid | parent_keyid | level |      branch      | pos
-----+-----+-----+-----+-----
row2  |              | 0     | row2              | 1
row5  | row2         | 1     | row2~row5         | 2
row9  | row5         | 2     | row2~row5~row9    | 3
row4  | row2         | 1     | row2~row4         | 4
row6  | row4         | 2     | row2~row4~row6    | 5
row8  | row6         | 3     | row2~row4~row6~row8 | 6
(6 rows)
```

```
-- without branch, with orderby_fld (notice that row5 comes before row4)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0)
AS t(keyid text, parent_keyid text, level int, pos int);
keyid | parent_keyid | level | pos
-----+-----+-----+-----
row2  |              | 0     | 1
row5  | row2         | 1     | 2
row9  | row5         | 2     | 3
row4  | row2         | 1     | 4
row6  | row4         | 2     | 5
row8  | row6         | 3     | 6
(6 rows)
```

F.65.2. Author

Joe Conway

F.66. tcn — a trigger function to notify listeners of changes to table content

The `tcn` module provides a trigger function that notifies listeners of changes to any table on which it is attached. It must be used as an `AFTER trigger FOR EACH ROW`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

Only one parameter may be supplied to the function in a `CREATE TRIGGER` statement, and that is optional. If supplied it will be used for the channel name for the notifications. If omitted `tcn` will be used for the channel name.

The payload of the notifications consists of the table name, a letter to indicate which type of operation was performed, and column name/value pairs for primary key columns. Each part is separated from the next by a comma. For ease of parsing using regular expressions, table and column names are always wrapped in double quotes, and data values are always wrapped in single quotes. Embedded quotes are doubled.

A brief example of using the extension follows.

```
test=# create table tcndata
test=# (
test(#   a int not null,
test(#   b date not null,
test(#   c text,
test(#   primary key (a, b)
test(# );
CREATE TABLE
test=# create trigger tcndata_tcn_trigger
test=# after insert or update or delete on tcndata
test=# for each row execute function triggered_change_notification();
CREATE TRIGGER
test=# listen tcn;
LISTEN
test=# insert into tcndata values (1, date '2012-12-22', 'one'),
test=#                               (1, date '2012-12-23', 'another'),
test=#                               (2, date '2012-12-23', 'two');
INSERT 0 3
Asynchronous notification "tcn" with payload "\"tcndata\",I,\"a\"='1','b\"='2012-12-22'"
received from server process with PID 22770.
Asynchronous notification "tcn" with payload "\"tcndata\",I,\"a\"='1','b\"='2012-12-23'"
received from server process with PID 22770.
Asynchronous notification "tcn" with payload "\"tcndata\",I,\"a\"='2','b\"='2012-12-23'"
received from server process with PID 22770.
test=# update tcndata set c = 'uno' where a = 1;
UPDATE 2
Asynchronous notification "tcn" with payload "\"tcndata\",U,\"a\"='1','b\"='2012-12-22'"
received from server process with PID 22770.
Asynchronous notification "tcn" with payload "\"tcndata\",U,\"a\"='1','b\"='2012-12-23'"
received from server process with PID 22770.
test=# delete from tcndata where a = 1 and b = date '2012-12-22';
DELETE 1
Asynchronous notification "tcn" with payload "\"tcndata\",D,\"a\"='1','b\"='2012-12-22'"
received from server process with PID 22770.
```

F.67. test_decoding — SQL-based test/example module for WAL logical decoding

`test_decoding` is an example of a logical decoding output plugin. It doesn't do anything especially useful, but can serve as a starting point for developing your own output plugin.

`test_decoding` receives WAL through the logical decoding mechanism and decodes it into text representations of the operations performed.

Typical output from this plugin, used over the SQL logical decoding interface, might be:

```
postgres=# SELECT * FROM pg_logical_slot_get_changes('test_slot', NULL, NULL, 'include-
xids', '0');
 lsn      | xid | data
-----+-----+-----
 0/16D30F8 | 691 | BEGIN
 0/16D32A0 | 691 | table public.data: INSERT: id[int4]:2 data[text]:'arg'
 0/16D32A0 | 691 | table public.data: INSERT: id[int4]:3 data[text]:'demo'
 0/16D32A0 | 691 | COMMIT
 0/16D32D8 | 692 | BEGIN
 0/16D3398 | 692 | table public.data: DELETE: id[int4]:2
 0/16D3398 | 692 | table public.data: DELETE: id[int4]:3
 0/16D3398 | 692 | COMMIT
(8 rows)
```

We can also get the changes of the in-progress transaction, and the typical output might be:

```
postgres[33712]=#* SELECT * FROM pg_logical_slot_get_changes('test_slot', NULL, NULL,
'stream-changes', '1');
 lsn      | xid | data
-----+-----+-----
 0/16B21F8 | 503 | opening a streamed block for transaction TXN 503
 0/16B21F8 | 503 | streaming change for TXN 503
 0/16B2300 | 503 | streaming change for TXN 503
 0/16B2408 | 503 | streaming change for TXN 503
 0/16BEBA0 | 503 | closing a streamed block for transaction TXN 503
 0/16B21F8 | 503 | opening a streamed block for transaction TXN 503
 0/16BECA8 | 503 | streaming change for TXN 503
 0/16BEDB0 | 503 | streaming change for TXN 503
 0/16BEEB8 | 503 | streaming change for TXN 503
 0/16BEBA0 | 503 | closing a streamed block for transaction TXN 503
(10 rows)
```

F.68. `tsm_system_rows` — the `SYSTEM_ROWS` sampling method for `TABLESAMPLE`

The `tsm_system_rows` module provides the table sampling method `SYSTEM_ROWS`, which can be used in the `TABLESAMPLE` clause of a `SELECT` command.

This table sampling method accepts a single integer argument that is the maximum number of rows to read. The resulting sample will always contain exactly that many rows, unless the table does not contain enough rows, in which case the whole table is selected.

Like the built-in `SYSTEM` sampling method, `SYSTEM_ROWS` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are requested.

`SYSTEM_ROWS` does not support the `REPEATABLE` clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.68.1. Examples

Here is an example of selecting a sample of a table with `SYSTEM_ROWS`. First install the extension:

```
CREATE EXTENSION tsm_system_rows;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_ROWS(100);
```

This command will return a sample of 100 rows from the table `my_table` (unless the table does not have 100 visible rows, in which case all its rows are returned).

F.69. `tsm_system_time` — the `SYSTEM_TIME` sampling method for `TABLESAMPLE`

The `tsm_system_time` module provides the table sampling method `SYSTEM_TIME`, which can be used in the `TABLESAMPLE` clause of a `SELECT` command.

This table sampling method accepts a single floating-point argument that is the maximum number of milliseconds to spend reading the table. This gives you direct control over how long the query takes, at the price that the size of the sample becomes hard to predict. The resulting sample will contain as many rows as could be read in the specified time, unless the whole table has been read first.

Like the built-in `SYSTEM` sampling method, `SYSTEM_TIME` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are selected.

`SYSTEM_TIME` does not support the `REPEATABLE` clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.69.1. Examples

Here is an example of selecting a sample of a table with `SYSTEM_TIME`. First install the extension:

```
CREATE EXTENSION tsm_system_time;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_TIME(1000);
```

This command will return as large a sample of `my_table` as it can read in 1 second (1000 milliseconds). Of course, if the whole table can be read in under 1 second, all its rows will be returned.

F.70. unaccent — a text search dictionary which removes diacritics

`unaccent` is a text search dictionary that removes accents (diacritic signs) from lexemes. It's a filtering dictionary, which means its output is always passed to the next dictionary (if any), unlike the normal behavior of dictionaries. This allows accent-insensitive processing for full text search.

The current implementation of `unaccent` cannot be used as a normalizing dictionary for the `thesaurus` dictionary.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.70.1. Configuration

An `unaccent` dictionary accepts the following options:

- `RULES` is the base name of the file containing the list of translation rules. This file must be stored in `$SHAREDIR/tsearch_data/` (where `$SHAREDIR` means the Postgres Pro installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `RULES` parameter).

The rules file has the following format:

- Each line represents one translation rule, consisting of a character with accent followed by a character without accent. The first is translated into the second. For example,

À	A
Á	A
Â	A
Ã	A
Ä	A
Å	A
Æ	AE

The two characters must be separated by whitespace, and any leading or trailing whitespace on a line is ignored.

- Alternatively, if only one character is given on a line, instances of that character are deleted; this is useful in languages where accents are represented by separate characters.
- Actually, each “character” can be any string not containing whitespace, so `unaccent` dictionaries could be used for other sorts of substring substitutions besides diacritic removal.
- Some characters, like numeric symbols, may require whitespaces in their translation rule. It is possible to use double quotes around the translated characters in this case. A double quote needs to be escaped with a second double quote when including one in the translated character. For example:

¼	" 1/4 "
½	" 1/2 "
¾	" 3/4 "
"	" " " "
"	" " " "

- As with other Postgres Pro text search configuration files, the rules file must be stored in UTF-8 encoding. The data is automatically translated into the current database's encoding when loaded. Any lines containing untranslatable characters are silently ignored, so that rules files can contain rules that are not applicable in the current encoding.

A more complete example, which is directly useful for most European languages, can be found in `unaccent.rules`, which is installed in `$SHAREDIR/tsearch_data/` when the `unaccent` module is installed. This rules file translates characters with accents to the same characters without accents, and it also expands ligatures into the equivalent series of simple characters (for example, `Æ` to `AE`).

F.70.2. Usage

Installing the `unaccent` extension creates a text search template `unaccent` and a dictionary `unaccent` based on it. The `unaccent` dictionary has the default parameter setting `RULES='unaccent'`, which makes it immediately usable with the standard `unaccent.rules` file. If you wish, you can alter the parameter, for example

```
mydb=# ALTER TEXT SEARCH DICTIONARY unaccent (RULES='my_rules');
```

or create new dictionaries based on the template.

To test the dictionary, you can try:

```
mydb=# select ts_lexize('unaccent','Hôtel');
 ts_lexize
-----
 {Hotel}
(1 row)
```

Here is an example showing how to insert the `unaccent` dictionary into a text search configuration:

```
mydb=# CREATE TEXT SEARCH CONFIGURATION fr ( COPY = french );
mydb=# ALTER TEXT SEARCH CONFIGURATION fr
        ALTER MAPPING FOR hword, hword_part, word
        WITH unaccent, french_stem;
mydb=# select to_tsvector('fr','Hôtels de la Mer');
 to_tsvector
-----
 'hotel':1 'mer':4
(1 row)

mydb=# select to_tsvector('fr','Hôtel de la Mer') @@ to_tsquery('fr','Hotels');
 ?column?
-----
 t
(1 row)

mydb=# select ts_headline('fr','Hôtel de la Mer',to_tsquery('fr','Hotels'));
 ts_headline
-----
 <b>Hôtel</b> de la Mer
(1 row)
```

F.70.3. Functions

The `unaccent()` function removes accents (diacritic signs) from a given string. Basically, it's a wrapper around `unaccent`-type dictionaries, but it can be used outside normal text search contexts.

`unaccent([dictionary regdictionary,] string text)` returns *text*

If the *dictionary* argument is omitted, the text search dictionary named `unaccent` and appearing in the same schema as the `unaccent()` function itself is used.

For example:

```
SELECT unaccent('unaccent', 'Hôtel');
SELECT unaccent('Hôtel');
```

F.71. uuid-ossdp — a UUID generator

The `uuid-ossdp` module provides functions to generate universally unique identifiers (UUIDs) using one of several standard algorithms. There are also functions to produce certain special UUID constants. This module is only necessary for special requirements beyond what is available in core Postgres Pro. See [Section 9.14](#) for built-in ways to generate UUIDs.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.71.1. uuid-ossdp Functions

[Table F.45](#) shows the functions available to generate UUIDs. The relevant standards ITU-T Rec. X.667, ISO/IEC 9834-8:2005, and [RFC 4122](#) specify four algorithms for generating UUIDs, identified by the version numbers 1, 3, 4, and 5. (There is no version 2 algorithm.) Each of these algorithms could be suitable for a different set of applications.

Table F.45. Functions for UUID Generation

Function	Description
<code>uuid_generate_v1 () → uuid</code>	Generates a version 1 UUID. This involves the MAC address of the computer and a time stamp. Note that UUIDs of this kind reveal the identity of the computer that created the identifier and the time at which it did so, which might make it unsuitable for certain security-sensitive applications.
<code>uuid_generate_v1mc () → uuid</code>	Generates a version 1 UUID, but uses a random multicast MAC address instead of the real MAC address of the computer.
<code>uuid_generate_v3 (namespace uuid, name text) → uuid</code>	Generates a version 3 UUID in the given namespace using the specified input name. The namespace should be one of the special constants produced by the <code>uuid_ns_*</code> () functions shown in Table F.46 . (It could be any UUID in theory.) The name is an identifier in the selected namespace. For example: <pre>SELECT uuid_generate_v3(uuid_ns_url(), 'http://www.postgresql.org');</pre> The name parameter will be MD5-hashed, so the cleartext cannot be derived from the generated UUID. The generation of UUIDs by this method has no random or environment-dependent element and is therefore reproducible.
<code>uuid_generate_v4 () → uuid</code>	Generates a version 4 UUID, which is derived entirely from random numbers.
<code>uuid_generate_v5 (namespace uuid, name text) → uuid</code>	Generates a version 5 UUID, which works like a version 3 UUID except that SHA-1 is used as a hashing method. Version 5 should be preferred over version 3 because SHA-1 is thought to be more secure than MD5.

Table F.46. Functions Returning UUID Constants

Function	Description
<code>uuid_nil () → uuid</code>	Returns a “nil” UUID constant, which does not occur as a real UUID.
<code>uuid_ns_dns () → uuid</code>	Returns a constant designating the DNS namespace for UUIDs.

Function	Description
<code>uuid_ns_url</code> <code>() → uuid</code>	Returns a constant designating the URL namespace for UUIDs.
<code>uuid_ns_oid</code> <code>() → uuid</code>	Returns a constant designating the ISO object identifier (OID) namespace for UUIDs. (This pertains to ASN.1 OIDs, which are unrelated to the OIDs used in Postgres Pro.)
<code>uuid_ns_x500</code> <code>() → uuid</code>	Returns a constant designating the X.500 distinguished name (DN) namespace for UUIDs.

F.71.2. Building `uuid-oss`

Historically this module depended on the OSSP UUID library, which accounts for the module's name. While the OSSP UUID library can still be found at <http://www.ossdp.org/pkg/lib/uuid/>, it is not well maintained, and is becoming increasingly difficult to port to newer platforms. `uuid-oss` can now be built without the OSSP library on some platforms. On FreeBSD and some other BSD-derived platforms, suitable UUID creation functions are included in the core `libc` library. On Linux, macOS, and some other platforms, suitable functions are provided in the `libuuid` library, which originally came from the `e2fsprogs` project (though on modern Linux it is considered part of `util-linux-ng`). When invoking `configure`, specify `--with-uuid=bsd` to use the BSD functions, or `--with-uuid=e2fs` to use `e2fsprogs`' `libuuid`, or `--with-uuid=oss` to use the OSSP UUID library. More than one of these libraries might be available on a particular machine, so `configure` does not automatically choose one.

F.71.3. Author

F.72. xml2 — XPath querying and XSLT functionality

The `xml2` module provides XPath querying and XSLT functionality.

F.72.1. Deprecation Notice

From PostgreSQL 8.3 on, there is XML-related functionality based on the SQL/XML standard in the core server. That functionality covers XML syntax checking and XPath queries, which is what this module does, and more, but the API is not at all compatible. It is planned that this module will be removed in a future version of Postgres Pro in favor of the newer standard API, so you are encouraged to try converting your applications. If you find that some of the functionality of this module is not available in an adequate form with the newer API, please explain your issue to pgsql-hackers@lists.postgresql.org so that the deficiency can be addressed.

F.72.2. Description of Functions

[Table F.47](#) shows the functions provided by this module. These functions provide straightforward XML parsing and XPath queries.

Table F.47. `xml2` Functions

Function	Description
<code>xml_valid (document text) → boolean</code>	Parses the given document and returns true if the document is well-formed XML. (Note: this is an alias for the standard Postgres Pro function <code>xml_is_well_formed()</code> . The name <code>xml_valid()</code> is technically incorrect since validity and well-formedness have different meanings in XML.)
<code>xpath_string (document text, query text) → text</code>	Evaluates the XPath query on the supplied document, and casts the result to <code>text</code> .
<code>xpath_number (document text, query text) → real</code>	Evaluates the XPath query on the supplied document, and casts the result to <code>real</code> .
<code>xpath_bool (document text, query text) → boolean</code>	Evaluates the XPath query on the supplied document, and casts the result to <code>boolean</code> .
<code>xpath_nodeset (document text, query text, toptag text, itemtag text) → text</code>	Evaluates the query on the document and wraps the result in XML tags. If the result is multi-valued, the output will look like: <pre><toptag> <itemtag>Value 1 which could be an XML fragment</itemtag> <itemtag>Value 2....</itemtag> </toptag></pre> <p>If either <code>toptag</code> or <code>itemtag</code> is an empty string, the relevant tag is omitted.</p>
<code>xpath_nodeset (document text, query text, itemtag text) → text</code>	Like <code>xpath_nodeset(document, query, toptag, itemtag)</code> but result omits <code>toptag</code> .
<code>xpath_nodeset (document text, query text) → text</code>	Like <code>xpath_nodeset(document, query, toptag, itemtag)</code> but result omits both tags.
<code>xpath_list (document text, query text, separator text) → text</code>	Evaluates the query on the document and returns multiple values separated by the specified separator, for example <code>Value 1,Value 2,Value 3</code> if <code>separator</code> is <code>,</code> .
<code>xpath_list (document text, query text) → text</code>	This is a wrapper for the above function that uses <code>,</code> as the separator.

F.72.3. xpath_table

`xpath_table(text key, text document, text relation, text xpaths, text criteria)` returns `setof record`

`xpath_table` is a table function that evaluates a set of XPath queries on each of a set of documents and returns the results as a table. The primary key field from the original document table is returned as the first column of the result so that the result set can readily be used in joins. The parameters are described in [Table F.48](#).

Table F.48. `xpath_table` Parameters

Parameter	Description
<i>key</i>	the name of the “key” field — this is just a field to be used as the first column of the output table, i.e., it identifies the record from which each output row came (see note below about multiple values)
<i>document</i>	the name of the field containing the XML document
<i>relation</i>	the name of the table or view containing the documents
<i>xpaths</i>	one or more XPath expressions, separated by
<i>criteria</i>	the contents of the WHERE clause. This cannot be omitted, so use <code>true</code> or <code>1=1</code> if you want to process all the rows in the relation

These parameters (except the XPath strings) are just substituted into a plain SQL SELECT statement, so you have some flexibility — the statement is

```
SELECT <key>, <document> FROM <relation> WHERE <criteria>
```

so those parameters can be *anything* valid in those particular locations. The result from this SELECT needs to return exactly two columns (which it will unless you try to list multiple fields for key or document). Beware that this simplistic approach requires that you validate any user-supplied values to avoid SQL injection attacks.

The function has to be used in a FROM expression, with an AS clause to specify the output columns; for example

```
SELECT * FROM
xpath_table('article_id',
            'article_xml',
            'articles',
            '/article/author|/article/pages|/article/title',
            'date_entered > '2003-01-01' ')
AS t(article_id integer, author text, page_count integer, title text);
```

The AS clause defines the names and types of the columns in the output table. The first is the “key” field and the rest correspond to the XPath queries. If there are more XPath queries than result columns, the extra queries will be ignored. If there are more result columns than XPath queries, the extra columns will be NULL.

Notice that this example defines the `page_count` result column as an integer. The function deals internally with string representations, so when you say you want an integer in the output, it will take the string representation of the XPath result and use Postgres Pro input functions to transform it into an integer (or whatever type the AS clause requests). An error will result if it can't do this — for example if the result is empty — so you may wish to just stick to `text` as the column type if you think your data has any problems.

The calling SELECT statement doesn't necessarily have to be just `SELECT *` — it can reference the output columns by name or join them to other tables. The function produces a virtual table with which you can perform any operation you wish (e.g., aggregation, joining, sorting etc.). So we could also have:

```
SELECT t.title, p.fullname, p.email
FROM xpath_table('article_id', 'article_xml', 'articles',
                '/article/title|article/author/@id',
                'xpath_string(article_xml, '/article/@date') > ''2003-03-20'' ')
  AS t(article_id integer, title text, author_id integer),
  tblPeopleInfo AS p
WHERE t.author_id = p.person_id;
```

as a more complicated example. Of course, you could wrap all of this in a view for convenience.

F.72.3.1. Multivalued Results

The `xpath_table` function assumes that the results of each XPath query might be multivalued, so the number of rows returned by the function may not be the same as the number of input documents. The first row returned contains the first result from each query, the second row the second result from each query. If one of the queries has fewer values than the others, null values will be returned instead.

In some cases, a user will know that a given XPath query will return only a single result (perhaps a unique document identifier) — if used alongside an XPath query returning multiple results, the single-valued result will appear only on the first row of the result. The solution to this is to use the key field as part of a join against a simpler XPath query. As an example:

```
CREATE TABLE test (
  id int PRIMARY KEY,
  xml text
);

INSERT INTO test VALUES (1, '<doc num="C1">
<line num="L1"><a>1</a><b>2</b><c>3</c></line>
<line num="L2"><a>11</a><b>22</b><c>33</c></line>
</doc>');

INSERT INTO test VALUES (2, '<doc num="C2">
<line num="L1"><a>111</a><b>222</b><c>333</c></line>
<line num="L2"><a>111</a><b>222</b><c>333</c></line>
</doc>');

SELECT * FROM
  xpath_table('id','xml','test',
              '/doc/@num|/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
              'true')
  AS t(id int, doc_num varchar(10), line_num varchar(10), val1 int, val2 int, val3 int)
WHERE id = 1 ORDER BY doc_num, line_num
```

id	doc_num	line_num	val1	val2	val3
1	C1	L1	1	2	3
1		L2	11	22	33

To get `doc_num` on every line, the solution is to use two invocations of `xpath_table` and join the results:

```
SELECT t.*,i.doc_num FROM
  xpath_table('id', 'xml', 'test',
              '/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
              'true')
  AS t(id int, line_num varchar(10), val1 int, val2 int, val3 int),
  xpath_table('id', 'xml', 'test', '/doc/@num', 'true')
  AS i(id int, doc_num varchar(10))
WHERE i.id=t.id AND i.id=1
ORDER BY doc_num, line_num;
```

```
id | line_num | val1 | val2 | val3 | doc_num
---+-----+-----+-----+-----+-----
 1 | L1       |    1 |    2 |    3 | C1
 1 | L2       |   11 |   22 |   33 | C1
(2 rows)
```

F.72.4. XSLT Functions

The following functions are available if libxslt is installed:

F.72.4.1. `xslt_process`

`xslt_process(text document, text stylesheet, text paramlist)` returns text

This function applies the XSL stylesheet to the document and returns the transformed result. The `paramlist` is a list of parameter assignments to be used in the transformation, specified in the form `a=1,b=2`. Note that the parameter parsing is very simple-minded: parameter values cannot contain commas!

There is also a two-parameter version of `xslt_process` which does not pass any parameters to the transformation.

F.72.5. Author

John Gray <jgray@azuli.co.uk>

Development of this module was sponsored by Torchbox Ltd. (www.torchbox.com). It has the same BSD license as Postgres Pro.

Appendix G. Postgres Pro Modules and Extensions Shipped as Individual Packages

This appendix contains Postgres Pro modules and extensions that are made available in Postgres Pro Standard as individual packages. These packages are listed in [Section 16.1.5.1](#), and the documentation for each module explains which package to choose to install it. [Appendix F](#) covers more modules and extensions included in the Postgres Pro Standard distribution. The `pg_portal_modify` extension is also shipped as an individual package (see [Section 16.1.5.1](#) for details).

G.1. `pgpro_pwr` — workload reports

The `pgpro_pwr` module is designed to discover most resource-intensive activities in your database. (PWR, pronounced like "power", is an abbreviation of Postgres Pro Workload Reporting.) This extension is based on Postgres Pro's [Statistics Collector](#) views and the `pgpro_stats` or `pg_stat_statements` extension.

Note

Although `pgpro_pwr` can work with the `pg_stat_statements` extension, it is recommended that you use the `pgpro_stats` extension since it provides statement plans, wait events sampling and load distribution statistics for databases, roles, client hosts and applications.

Below, use of `pgpro_stats` is assumed unless otherwise noted.

If you cannot use `pgpro_stats` for an observed database, but the `pg_stat_kcache` extension is available, `pgpro_pwr` can process `pg_stat_kcache` data, which also provides information about CPU resource usage of statements and filesystem load (*rusage*).

`pgpro_pwr` can obtain summary wait statistics from the `pg_wait_sampling` extension. When `pg_wait_sampling` is in use, `pgpro_pwr` will reset the wait sampling profile on every sample.

`pgpro_pwr` is based on cumulative statistics sampling. Each sample contains statistic increments for most active objects and queries since the time when the previous sample was taken, or more concisely, *since the previous sample*. This data is later used to generate reports.

`pgpro_pwr` provides functions to collect samples. Regular sampling allows building a report on the database workload in the past.

`pgpro_pwr` allows you to take explicit samples during batch processing, load testing, etc.

Any time a sample is taken, `pgpro_stats_statements_reset()` (see [pgpro_stats](#) for the function description) is called to ensure that statement statistics will not be lost when the statements count exceed `pgpro_stats.max` (see [Section G.2.7.1](#)). The report will also contain a section informing you of whether the count of captured statements in any sample reaches 90% of `pgpro_stats.max`.

`pgpro_pwr` installed on one Postgres Pro server can also collect statistics from other servers. This feature is useful for gathering workload statistics from hot standbys on the primary server. To benefit from it, make sure that all server names and connection strings are specified and that the `pgpro_pwr` server can connect to all databases on all servers.

G.1.1. `pgpro_pwr` Architecture

The extension consists of the following parts:

- *Historical repository* is a storage for sampling data. The repository is a set of extension tables.

Note

Among the rest, `pgpro_pwr` tables store query texts, which can contain sensitive information. So, for security reasons, restrict access to the repository as appropriate.

- *Sample management engine* comprises functions used to [take samples](#) and maintain the repository by removing obsolete sample data.
- *Report engine* comprises functions for [generating reports](#) based on data from the historical repository.
- *Administrative functions* allow you to create and manage [servers](#) and [baselines](#).

G.1.2. Prerequisites

The prerequisites assume that `pgpro_pwr`, which is usually installed in a *target* cluster, i.e., the cluster that you will mainly track the workload for, the extension can also collect performance data from other clusters.

G.1.2.1. For the `pgpro_pwr` Database

The `pgpro_pwr` extension depends on [PL/pgSQL](#) and the [dblink](#) extension.

G.1.2.2. For the Target Server

The target server must allow connections to all databases from the server where `pgpro_pwr` is running. To connect to the target server, provide a connection string where a particular database on this server is specified. This database is of high importance for `pgpro_pwr` since the functionality of the [pgpro_stats](#) or [pg_stat_statements](#) extensions will be provided through this database. Note, however, that `pgpro_pwr` will also connect to all the other databases on this server.

Optionally, for completeness of gathered statistics:

- If statement statistics are needed in reports, [pgpro_stats](#) must be installed and configured in the aforementioned database. The following settings may affect the completeness and accuracy of gathered statistics:

- `pgpro_stats.max`

Low setting of this parameter may cause some statement statistics to be wiped out before the sample is taken. A report will warn you if the value of `pgpro_stats.max` seems undersized.

- `pgpro_stats.track`

Avoid changing the default value of 'top' (note that the value of 'all' will affect the accuracy of %Total fields for statements-related sections of a report).

- Set the parameters of the Postgres Pro's [Statistics Collector](#) as follows:

```
track_activities = on
track_counts = on
track_io_timing = on
track_wal_io_timing = on    # Since PostgreSQL 14
track_functions = all/pl
```

G.1.3. Installation and Setup

`pgpro_pwr` is provided with Postgres Pro Standard as a separate pre-built package `pgpro-pwr-std-18` (for the detailed installation instructions, see [Chapter 16](#)).

Note

pgpro_pwr creates a bunch of database objects, so installation in a dedicated schema is recommended.

Although the use of pgpro_pwr with superuser privileges does not have any issues, superuser privileges are not necessary. So you can choose one of the following setup procedures depending on your configuration and security requirements or customize them to meet your needs:

G.1.3.1. Simple Setup

Use this setup procedure when pgpro_pwr is to be installed on the target cluster to only track its workload as superuser.

Create a schema for the pgpro_pwr installation and create the extension:

```
CREATE SCHEMA profile;
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

G.1.3.2. Complex Setup

Use this setup procedure when you intend to use pgpro_pwr for tracking workload on one or more servers and need to follow the principle of least privilege.

G.1.3.2.1. In the Target Server Database

Create a user for pgpro_pwr on the target server:

```
CREATE USER pwr_collector PASSWORD 'collector_pwd';
```

Make sure this user has permissions to connect to any database in the target cluster (by default, it is true) and that pg_hba.conf permits such a connection from the pgpro_pwr database host. Also, grant pwr_collector with membership in the pg_read_all_stats role and the EXECUTE privilege on the following functions:

```
GRANT pg_read_all_stats TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgpro_stats_statements_reset TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgpro_stats_totals_reset(text,bigint) TO pwr_collector;
```

Also ensure the SELECT privilege on the pgpro_stats_archiver view:

```
GRANT SELECT ON pgpro_stats_archiver TO pwr_collector;
```

G.1.3.2.2. In the pgpro_pwr Database

Create an unprivileged user:

```
CREATE USER pwr_user;
```

This user will be the owner of the extension schema and will collect samples.

Create a schema for the pgpro_pwr installation:

```
CREATE SCHEMA profile AUTHORIZATION pwr_user;
```

Grant the USAGE privilege on the schema where the dblink extension resides:

```
GRANT USAGE ON SCHEMA public TO pwr_user;
```

Create the extension using pwr_user account:

```
\c - pwr_user
```

```
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

Define the connection parameters of the target server for pgpro_pwr. For example:

```
SELECT profile.create_server('target_server_name', 'host=192.168.1.100 dbname=postgres  
port=5432');
```

The connection string provided will be used in the `dblink_connect()` call while executing the `take_sample()` function.

Note

Connection strings are stored in a pgpro_pwr table in clear-text form. Make sure no other database users can access tables of the pgpro_pwr extension.

G.1.3.3. Setting Up pgpro_pwr Roles

Up to three roles can be distinguished when pgpro_pwr is in operation:

- The *pgpro_pwr owner* role is the owner of the pgpro_pwr extension.
- The *collecting role* is used by pgpro_pwr to connect to databases and collect statistics.
- The *reporting role* is used to generate reports.

If all the actions with pgpro_pwr are performed by the superuser role `postgres`, you can skip most of the setup explained below.

G.1.3.3.1. The pgpro_pwr Owner

This role can be used to perform all actions related to pgpro_pwr. This role will have access to server connection strings, which may contain passwords. You should use this role to call the `take_sample()` function. The `dblink` extension is needed for this user.

Consider an example assuming each extension in its own schema:

```
\c postgres postgres
CREATE SCHEMA dblink;
CREATE EXTENSION dblink SCHEMA dblink;
CREATE USER pwr_usr with password 'pwr_pwd';
GRANT USAGE ON SCHEMA dblink TO pwr_usr;
CREATE SCHEMA profile AUTHORIZATION pwr_usr;
\c postgres pwr_usr
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

G.1.3.3.2. The Collecting Role

This role should be used by pgpro_pwr to connect to databases and collect statistics. Unprivileged users cannot open connections using dblink without a password, so you need to provide the password in the connection string for each server. This role should have access to all supported statistics extensions. It should also be able to perform a reset of statistics extensions.

Consider an example. If you use `pgpro_stats` to collect statistics, set up the collecting role as follows:

```
\c postgres postgres
CREATE SCHEMA pgps;
CREATE EXTENSION pgpro_stats SCHEMA pgps;
CREATE USER pwr_collector with password 'collector_pwd';
GRANT pg_read_all_stats TO pwr_collector;
GRANT USAGE ON SCHEMA pgps TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgps.pgpro_stats_statements_reset TO pwr_collector;
```

If you use [pg_stat_statements](#) to collect statistics, set up the collecting role as follows:

```
\c postgres postgres
CREATE SCHEMA pgss;
CREATE SCHEMA pgsk;
CREATE SCHEMA pgws;
CREATE EXTENSION pg_stat_statements SCHEMA pgss;
CREATE EXTENSION pg_stat_kcache SCHEMA pgsk;
CREATE EXTENSION pg_wait_sampling SCHEMA pgws;
CREATE USER pwr_collector with password 'collector_pwd';
GRANT pg_read_all_stats TO pwr_collector;
GRANT USAGE ON SCHEMA pgss TO pwr_collector;
GRANT USAGE ON SCHEMA pgsk TO pwr_collector;
GRANT USAGE ON SCHEMA pgws TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgss.pg_stat_statements_reset TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgsk.pg_stat_kcache_reset TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgws.pg_wait_sampling_reset_profile TO pwr_collector;
```

Now you should set up a connection string pointing to the database with statistics extensions installed:

```
\c postgres pwr_usr
SELECT profile.set_server_connstr('local', 'dbname=postgres port=5432 host=localhost
user=pwr_collector password=collector_pwd');
```

Password authentication must be configured in the `pg_hba.conf` file for the `pwr_collector` user.

Obviously, the collecting role should be properly configured on all servers observed by `pgpro_pwr`.

Now you should be able to call [take_sample\(\)](#) using the `pwr_usr` role:

```
\c postgres pwr_usr
SELECT * FROM take_sample();
```

And now it's time to configure the scheduler (in our example, the `crontab` command of the `postgres` user):

```
*/30 * * * *    psql -U pwr_usr -d postgres -c 'SELECT profile.take_sample()' > /dev/
null 2>&1
```

Note that you can use the Postgres Pro password file to store passwords.

G.1.3.3.3. The Reporting Role

Any user can build a `pgpro_pwr` report. The minimal privileges needed to generate `pgpro_pwr` reports are granted to the `public` role. However a full report, with query texts, is only available to the member of the `pg_read_all_stats` role. Anyway, the reporting role cannot access server connection strings, so it cannot get the passwords of servers.

G.1.3.3.4. Setting Extension Parameters

In `postgresql.conf`, you can define the following `pgpro_pwr` parameters:

`pgpro_pwr.max` (integer)

Number of top objects (statements, relations, etc.) to be reported in each sorted report table. This parameter affects the size of a sample: the more objects you want to appear in your report, the more objects we need to keep in a sample. The maximum value is 100. Any larger value is lowered to 100.

The default value is 20.

`pgpro_pwr.max_sample_age` (integer)

Retention time of the sample, in days. Samples aged `pgpro_pwr.max_sample_age` days and older are automatically deleted on the next [take_sample\(\)](#) call.

The default value is 7 days.

`pgpro_pwr.max_query_length` (integer)

Maximum query length allowed in reports. All queries in a report will be truncated to `pgpro_pwr.max_query_length` characters.

The default value is 20 000 characters.

`pgpro_pwr.track_sample_timings` (boolean)

Enables collecting detailed timing statistics of `pgpro_pwr`'s own sampling procedures. Set this parameter to diagnose why sampling functions run slowly. Collected timing statistics will be available in the `v_sample_timings` view.

The default value is `off`.

`pgpro_pwr.statements_reset` (boolean)

Controls the `pgpro_stats/pg_stat_statements` statistics reset during taking a sample. Allows you not to reset the statistics during taking a sample due to new techniques employed. When disabled, `pgpro_pwr` will track statement evictions using the value of the `calls` field. However this method does not completely prevent statistics loss. `pg_stat_statements` v1.11 and `pgpro_stats` v1.8 contain time tracking abilities that can reduce the possible data loss. When this setting is disabled, you can temporarily enable it in a session if you want to sometimes perform a reset of `pgpro_stats/pg_stat_statements`.

The default value is `on`.

`pgpro_pwr.relsizes_collect_mode` (text)

Defines the mode of collecting relation sizes. Possible values:

- `off` — collection of relation sizes is based on `pg_class`. Although the relation sizes collected this way are rough, their collection consumes almost no resources.
- `on` — accurate relation sizes are collected for each sample using the `pg_relation_size()` function, which requires a lock on the table and is pretty resource intensive.
- `schedule` — accurate relation sizes are collected in the size-collection window, defined for each server.

The default value is `off`.

G.1.4. Managing Servers

Once installed, `pgpro_pwr` creates one enabled `local` server for the current cluster. If a server is *enabled*, `pgpro_pwr` includes it in sampling when no server is explicitly specified (see `take_sample()` for details). A server that is not enabled is referred to as *disabled*.

The default connection string for a local node contains only `dbname` and `port` parameters. The values of these parameters are taken from the connection used to create the extension. You can change the server connection string using the `set_server_connstr()` function when needed.

G.1.4.1. Server Management Functions

Use the following `pgpro_pwr` functions for server management:

```
create_server(server name, connstr text, enabled boolean DEFAULT TRUE, max_sample_age  
integer DEFAULT NULL description text DEFAULT NULL)
```

Creates a server definition.

Arguments:

- *server* — server name. Must be unique.
- *connstr* — connection string. Must contain all the necessary settings to connect from pgpro_pwr server to the target server database.
- *enabled* — set to include the server in sampling by the `take_sample()` function without arguments.
- *max_sample_age* — retention time of the sample. Overrides the global `pgpro_pwr.max_sample_age` setting for this server.
- *description* — server description text, to be included in reports.

Here is an example of how to create a server definition:

```
SELECT profile.create_server('omega','host=192.168.1.100 dbname=postgres
port=5432');
```

`drop_server(server name)`

Drops a server and all its samples.

`set_server_description(server name description text)`

Sets a new server description.

`set_server_subsampling(server name, subsample_enabled boolean, min_query_duration interval, min_xact_duration interval, min_xact_age integer, min_idle_xact_dur interval hour to second)`

Defines subsample settings for a server.

Arguments:

- *server* — server name.
- *subsample_enabled* — defines whether subsampling is enabled for the server, that is, whether `take_subsample()` function should actually take a subsample.
- *min_query_duration* — the query duration threshold.
- *min_xact_duration* — the transaction duration threshold.
- *min_xact_age* — the transaction age threshold.
- *min_idle_xact_dur_age* — the idle transaction threshold.

`enable_server(server name)`

Includes a server in sampling by the `take_sample()` function without arguments.

`disable_server(server name)`

Excludes a server from sampling by the `take_sample()` function without arguments.

`rename_server(server name, new_name name)`

Renames a server.

`set_server_max_sample_age(server name, max_sample_age integer)`

Sets the retention period for a server (in days). To reset the server retention, set the value of *max_sample_age* to NULL.

`set_server_db_exclude(server name, exclude_db name[])`

Excludes a list of databases on a server from sampling. Use when `pgpro_pwr` is unable to connect to some databases in a cluster (for example, in Amazon RDS instances).

```
set_server_connstr(server name, server_connstr text)
```

Sets the connection string for a server.

```
set_server_setting(server name, setting text, value jsonb)
```

Fine-tunes settings of the server statistics collection. `collect*` settings control which statistics should be collected, and `value` for these settings accepts boolean values, with the default equal to `true`. Available settings:

- `collect_pg_stat_statement` — collect statement statistics using [pg_stat_statements](#) and `pg_stat_kcache` extensions.
- `collect_pg_wait_sampling` — collect wait event statistics using the [pg_wait_sampling](#) extension.
- `collect_objects` — collect all the schema object statistics, that is, tables, indexes, and functions, from [pg_stat_*](#) views.
- `collect_relations` — collect statistics on tables and indexes from [pg_stat_*](#) views.
- `collect_functions` — collect statistics on user functions from the [pg_stat_user_functions](#) view.
- `collect_vacuum_stats` — collect the extended vacuum statistics.

```
show_server_settings(server name)
```

Returns the statistics collection settings for the specified server.

```
show_servers()
```

Displays the list of configured servers.

G.1.5. Managing Samples

A *sample* contains the database workload statistics since the previous sample

G.1.5.1. Sampling Functions

The following `pgpro_pwr` functions relate to sampling:

```
take_sample()  
take_sample(server name [, skip_sizes boolean])
```

Takes samples.

If the parameter is omitted, the function takes a sample on each enabled server. Servers are accessed for sampling sequentially, one by one. The function returns a table with the following columns:

- `server` — server name.
- `result` — result of taking the sample. Can be `OK` if the sample was taken successfully or contain the error trace text in case of exception.
- `elapsed` — time elapsed while the sample was taken.

If called with the parameter, the function takes a sample on the specified server even if this server is disabled. Use when you need different sampling frequencies on specific servers. Returns `0` on success.

Arguments:

- `server` — server name.

- *skip_sizes* — if omitted or set to null, the size-collection policy applies; if *false*, relation sizes are collected; if *true*, the collection of relation sizes is skipped.

`take_sample_subset([sets_cnt integer, current_set integer])`

Takes a sample on each server in a subset of servers. Use to take samples on servers in parallel if you have many enabled servers. Although PL/pgSQL does not support parallel execution, you can call this function in parallel sessions. This function returns the same type as `take_sample()`. If both parameters are omitted, the function behaves like the `take_sample()` function, i.e., it takes a sample on all enabled servers one by one.

Arguments:

- *sets_cnt* — number of subsets to divide all enabled servers into.
- *current_set* — number of the subset to collect samples for. Takes values from 0 through *sets_cnt* - 1. For the specified subset, samples are collected as usual, server by server.

If a reset of statistics since the previous sample was detected, `pgpro_pwr` treats corresponding absolute values as differentials; however, the accuracy will be affected anyway.

`show_samples([server name,] [days integer])`

Returns a table with information on server samples (local server is assumed if *server* is omitted) for the last *days* days (all existing samples are assumed if omitted). This table has the following columns:

- *sample* — sample identifier.
- *sample_time* — time when this sample was taken.
- *dbstats_reset* — NULL or the statistics reset timestamp of the `pg_stat_database` view if the statistics were reset since the previous sample.
- *clustats_reset* — NULL or the statistics reset timestamp of the `pg_stat_bgwriter` view if the statistics were reset since the previous sample.
- *archstats_reset* — NULL or the statistics reset timestamp of the `pg_stat_archiver` view if the statistics were reset since the previous sample.

Sampling functions also maintain the server repository by deleting obsolete samples and baselines according to the retention policy.

G.1.5.2. Taking Samples

To take samples for all enabled servers, call the `take_sample()` function. Usually, one or two samples per hour is sufficient. You can use a cron-like tool to schedule sampling. Here is an example for a 30-minute sampling period:

```
*/30 * * * *    psql -c 'SELECT profile.take_sample()' &> /dev/null
```

However, the results of such a call are not checked for errors. In a production environment, function results can be used for monitoring. This function returns OK for all servers with successfully taken samples and shows error text for failed servers:

```
SELECT * FROM take_sample();
  server  |                               result
-----+-----
| elapsed
+-----+-----
ok_node  | OK
| 00:00:00.48
fail_node | could not establish connection
+| 00:00:00
```

```
+| SQL statement "SELECT dblink_connect('server_connection',server_connstr)"
+|
+| PL/pgSQL function take_sample(integer) line 69 at PERFORM
+|
+| PL/pgSQL function take_sample_subset(integer,integer) line 27 at
assignment+|
+| SQL function "take_sample" statement 1
+|
+| FATAL: database "postgresno" does not exist
|
(2 rows)
```

G.1.5.3. Sample Retention Policy

You can define sample retention at the following levels:

1. *Global*

The value of the `pgpro_pwr.max_sample_age` parameter in the `postgresql.conf` file defines a common retention setting, which is effective if none of other related settings are defined.

2. *Server*

Specifying the `max_sample_age` parameter while creating a server or calling the `set_server_max_sample_age(server,max_sample_age)` function for an existing server defines the retention for the server. A server retention setting overrides `pgpro_pwr.max_sample_age` for a specific server.

3. *Baseline*

A [baseline](#) created overrides all the other retention periods for included samples.

G.1.6. Managing the Collection of Relation Sizes

It may take considerable time to collect sizes of all relations in a database by Postgres Pro relation-size functions. Besides, those functions require `AccessExclusiveLock` on a relation. However, it may be sufficient for you to collect relation sizes on a daily basis. `pgpro_pwr` allows you to skip collecting relation sizes by defining the *size-collection policy* for servers. The policy defines:

- A daily window when the collection of relation sizes is permitted.
- A minimum gap between two samples with relation sizes collected.

When the size-collection policy is defined, sampling functions collect relation sizes only when the sample is taken in the defined window and the previous sample with sizes is older than the gap. The following function defines this policy:

```
set_server_size_sampling(server name, window_start time with time zone DEFAULT NULL,
window_duration interval hour to second DEFAULT NULL, sample_interval interval day to
minute DEFAULT NULL, collect_mode text DEFAULT NULL)
```

Defines the size-collection policy for a server.

Arguments:

- `server` — server name.
- `window_start` — start time of the size-collection window.
- `window_duration` — duration of the size-collection window.
- `sample_interval` — minimum time gap between two samples with relation sizes collected.
- `collect_mode` — when set to `off`, which is the default for new installations, relation sizes are collected from [pg_class](#), when set to `on`, relation sizes are collected using the [pg_rela](#)

`tion_size()` function, when set to `schedule`, `pgpro_pwr` collects the relation size in the size-collection window. This parameter overrides the `relsize_collect_mode` extension parameter. Upgrading from a previous version sets the value of this parameter to `on` or `schedule`, so the previous behavior does not change.

Note

When you build a report between samples either of which lacks relation-size data, relation-growth sections will be based on `pg_class.relpages` data. However, you can expand the report interval bounds to the nearest samples with relation sizes collected using the `with_growth` parameter of [report generation functions](#); this makes the growth data more accurate.

Relation sizes are needed to calculate sequentially scanned volume for tables and explicit vacuum load for indexes.

Example:

```
SELECT set_server_size_sampling('local','23:00+03',interval '2 hour',interval '8 hour',
 'schedule');
```

The `show_servers_size_sampling` function shows size collection policies for all servers:

```
postgres=# SELECT * FROM show_servers_size_sampling();
 server_name | window_start | window_end | window_duration | sample_interval |
limited_collection
-----+-----+-----+-----+-----+-----
+-----+
 local      | 23:00:00+03 | 01:00:00+03 | 02:00:00        | 08:00:00        | t
```

G.1.7. Managing Subsamples

Some performance-related data available in Postgres Pro is not cumulative. For example, the most often used data about session states is available through the `pg_stat_activity` view and can only be obtained with frequent samples. However, the `take_sample()` function is heavy and can take considerable amount of time. So it is not suitable for collecting session state data.

The *subsample* feature provides a new fast `take_subsample()` function. It can be used to collect relatively fast changing data. Every subsample is bound to the next regular sample and is deleted by the retention policy together with it.

The subsample feature can be used to capture the most interesting session states:

- Long running queries
- Long transactions
- Aged transactions, that is, those that hold a snapshot behind a lot of other transactions
- Transactions being in an idle state for a long time

G.1.7.1. Subsampling Functions

The following `pgpro_pwr` functions relate to subsampling:

```
take_subsample()
take_subsample(server name)
```

If the parameter is omitted, the function takes a subsample on each *enabled* server with subsampling enabled (see [set_server_subsampling](#) for details). Server subsamples are taken sequentially, one by one. The function returns a table with the following columns:

- `server` — server name.
- `result` — result of taking the subsample. Can be `OK` if the subsample was taken successfully or contain the error text in case of exception.
- `elapsed` — time elapsed while the subsample was taken.

This tabular return format makes it easy to control subsample creation using an SQL query.

If called with the parameter, the function takes a subsample for the specified server. Use when you need different subsampling frequencies on servers or if you want to take an explicit subsample on a specific server.

Arguments:

- `server` — server name.

Note

Trying to take a subsample during taking a sample fails.

```
take_subsample_subset([sets_cnt integer], [current_set integer])
```

Takes subsamples for a subset of enabled servers with subsampling enabled. Although subsamples should be fast enough for serial processing, subsamples can be taken in parallel, like regular samples. This function returns the same type as `take_subsample()`. If both parameters are omitted, the function behaves like the `take_subsample()` function.

Arguments:

- `sets_cnt` — number of server subsets.
- `current_set` — the subset to process. Takes values from 0 through `sets_cnt - 1`. For the specified subset, subsamples are collected as usual, server by server.

G.1.7.2. Configuring the Subsample Feature

The following settings affect the subsample behaviour:

- `pgpro_pwr.subsample_enabled` — defines whether the `take_subsample()` function should actually take a subsample.
- `pgpro_pwr.min_query_duration` — the long running query threshold.
- `pgpro_pwr.min_xact_duration` — the long transaction threshold.
- `pgpro_pwr.min_xact_age` — the transaction age threshold.
- `pgpro_pwr.min_idle_xact_dur_age` — the idle transaction threshold.

The subsample behavior can be defined at the server level using the [set_server_subsampling](#) function.

The last observed session state is saved in the repository when either of the following threshold-related events happens:

- During query execution, the difference between `now()` and the `query_start` exceeds the `pgpro_pwr.min_query_duration` threshold.
- During a transaction, the difference between `now()` and the `xact_start` exceeds the `pgpro_pwr.min_xact_duration` threshold.
- During a transaction, the `age(backend_xmin)` exceeds the `pgpro_pwr.min_xact_age` threshold.

- During a transaction in a state `idle in transaction` or `idle in transaction (aborted)`, the difference between `now()` and the `state_change` exceeds the `pgpro_pwr.min_idle_xact_duration` threshold.

See [Chapter 26](#) for details of the mentioned fields. Every subsample can hold at most `pgpro_pwr.max` entries for every threshold type.

G.1.7.3. Scheduling Subsamples

Subsamples are fast enough to take them quite often. However usually you do not need more than 2-4 subsamples per minute. Obviously the subsample frequency depends on the shortest used duration of a threshold setting.

Cron only allows one call per minute, so some effort is needed to schedule more frequent subsamples. For example, the `\watch psql` command can be used:

```
echo "select take_subsample(); \watch 15" | psql &> /dev/null
```

The `psql` call can be wrapped in the `systemd` service like this:

```
Description=pgpro_pwr subsampling unit
[Unit]
```

```
[Service]
Type=simple
ExecStart=/bin/sh -c 'echo "select take_subsample(); \watch 15" | /path/to/psql -qo /dev/null'
User=postgres
Group=postgres
```

```
[Install]
WantedBy=multi-user.target
```

G.1.8. Managing Baselines

A *baseline* is a named sequence of samples that has its own retention setting. A baseline can be used as a sample interval in report generation functions. An undefined baseline retention means infinite retention. Use baselines to save information about the database workload for a certain time interval.

G.1.8.1. Baseline Management Functions

Use the following `pgpro_pwr` functions for baseline management:

```
create_baseline([server name,] baseline varchar(25), start_id integer, end_id integer [,
days integer])
create_baseline([server name,] baseline varchar(25), time_range tstzrange [, days in-
teger])
```

Creates a baseline.

Arguments:

- `server` — server name. `local` sever is assumed if omitted.
- `baseline` — baseline name. Must be unique for a server.
- `start_id` — identifier of the first sample in the baseline.
- `end_id` — identifier of the last sample in the baseline.
- `time_range` — time interval for the baseline. The baseline will include all samples for the minimal interval that covers `time_range`.
- `days` — baseline retention time, defined in integer days since `now()`. Omit or set to null for infinite retention.

```
drop_baseline([server name,] baseline varchar(25))
```

Drops a baseline. For the meaning and usage details of function arguments, see [create_baseline](#). Dropping a baseline does not mean dropping all its samples immediately. The baseline retention just no longer applies to them.

```
keep_baseline([server name,] baseline varchar(25) [, days integer])
```

Changes the retention of a baseline. For the meaning and usage details of function arguments, see [create_baseline](#). Omit the *baseline* parameter or pass null to it to change the retention of all existing baselines.

```
show_baselines([server name])
```

Displays existing baselines. Call `show_baselines` to get information about the baselines, such as names, sampling intervals and retention periods. `local` sever is assumed if the *server* parameter is omitted.

G.1.9. Data Export and Import

Collected samples can be exported from one instance of the `pgpro_pwr` extension and then loaded into another one. This feature helps you to move server data from one instance to another or to send collected data to your support team.

G.1.9.1. Data Export

The [export_data](#) function exports data to a regular table. You can use any method available to export this table from your database. For example, you can use the `\copy` meta-command of [psql](#) to obtain a single `csv` file:

```
postgres=# \copy (select * from export_data()) to 'export.csv'
```

G.1.9.2. Data Import

Since data can only be imported from a local table, first, load the data you exported. Using the `\copy` meta-command again:

```
postgres=# CREATE TABLE import (section_id bigint, row_data json);
CREATE TABLE
postgres=# \copy import from 'export.csv'
COPY 6437
```

Now you can import the data by providing the `import` table to the [import_data](#) function:

```
postgres=# SELECT * FROM import_data('import');
```

After successful import, you can drop the `import` table.

Note

If server data is imported for the first time, your local `pgpro_pwr` servers with matching names will cause a conflict during import. To avoid this, you can temporarily rename such servers or you can specify the server name prefix for import operations. However, during import of new data for already imported servers, they are matched by system identifiers, so feel free to rename imported servers. Also keep in mind that `pgpro_pwr` sets servers being imported to the *disabled* state for [take_sample\(\)](#) to bypass them.

G.1.9.3. Export and Import Functions

Use these functions to export or import data:

```
export_data([server name, [min_sample_id integer,] [max_sample_id integer,]] [, obfus-  
cate_queries boolean] [, hide_connstr boolean])
```

Exports collected data.

Arguments:

- *server* — server name. All configured servers are assumed if omitted.
- *min_sample_id*, *max_sample_id* — sample identifiers to bound the export (inclusive). If *min_sample_id* is omitted or set to null, all samples until *max_sample_id* sample are exported; if *max_sample_id* is omitted or set to null, all samples since *min_sample_id* sample are exported.
- *obfuscate_queries* — exports query texts as MD5 hash and excludes server connection strings from export. Pass this argument only when you want to hide query texts.
- *hide_connstr* — excludes server connection strings from export.

```
import_data(data regclass [, server_name_prefix text])
```

Imports previously exported data. Returns the number of actually loaded rows in pgpro_pwr tables.

Arguments:

- *data* is the name of the table containing import data.
- *server_name_prefix* specifies the server name prefix for the import operation. It can be used to avoid name conflicts.

G.1.10. Report Generation Functions

pgpro_pwr reports are generated in HTML format by reporting functions. The following types of reports are available:

- *Regular reports* provide statistics on the workload for an interval.
- *Differential reports* provide statistics on the same objects for two intervals. Corresponding values are located next to each other, which makes it easy to compare the workloads.

Reporting functions take sample identifiers, baselines or time ranges to determine the intervals. For time ranges, these are the minimal intervals that cover the ranges.

G.1.10.1. Regular Reports

Use these functions to generate regular reports:

```
get_report([server name,] start_id integer, end_id integer [, description text [,  
with_growth boolean [, db_exclude name[]]])  
get_report([server name,] time_range tstzrange [, description text [, with_growth boolean  
[, db_exclude name[]]])  
get_report([server name,] baseline varchar(25) [, description text [, with_growth boolean  
[, db_exclude name[]]])
```

Generates a regular report defined by the arguments.

Arguments:

- *server* — server name. local sever is assumed if omitted.
- *start_id* — identifier of the interval starting sample.
- *end_id* — identifier of the interval ending sample.
- *baseline* — baseline name.
- *time_range* — time range.

- *description* — short text to be included in the report as its description.
- *with_growth* — flag requesting interval expansion to the nearest bounds with data on relation growth available. The default value is `false`.
- *db_exclude* — the database exclusion list. Lists databases to be excluded from all report tables having the `Database` column. Use to hide some databases in the report.

```
get_report_latest([server name,])  
get_report_latest([server name [, db_exclude name[]]])
```

Generates a regular report for two latest samples.

Arguments:

- *server* — server name. `local` sever is assumed if omitted.
- *db_exclude* — the database exclusion list. Lists databases to be excluded from all report tables having the `Database` column. Use to hide some databases in the report.

G.1.10.2. Differential Reports

Use this function to generate differential reports:

```
get_diffreport([server name,] start1_id integer, end1_id integer, start2_id integer,  
end2_id integer [, description text [, with_growth boolean [, db_exclude name[]]])  
get_diffreport([server name,] time_range1 tstzrange, time_range2 tstzrange [, description  
text [, with_growth boolean [, db_exclude name[]]])  
get_diffreport([server name,] baseline1 varchar(25), baseline2 varchar(25) [, description  
text [, with_growth boolean [, db_exclude name[]]])  
get_diffreport([server name,] baseline1 varchar(25), time_range2 tstzrange [, description  
text [, with_growth boolean[, db_exclude name[]]])  
get_diffreport([server name,] time_range1 tstzrange, baseline2 varchar(25) [, description  
text [, with_growth boolean[, db_exclude name[]]])  
get_diffreport([server name,] start1_id integer, end1_id integer, baseline2 varchar(25)  
[, description text [, with_growth boolean[, db_exclude name[]]])  
get_diffreport([server name,] baseline1 varchar(25), start2_id integer, end2_id integer  
[, description text [, with_growth boolean[, db_exclude name[]]])
```

Generates a differential report for two intervals. The combinations of arguments provide possible ways to specify the two intervals.

Arguments:

- *server* — server name. `local` sever is assumed if omitted.
- *start1_id, end1_id* — identifiers of the starting and ending samples for the first interval.
- *start2_id, end2_id* — identifiers of the starting and ending samples for the second interval.
- *baseline1* — baseline name for the first interval.
- *baseline2* — baseline name for the second interval.
- *time_range1* — time range for the first interval.
- *time_range2* — time range for the second interval.
- *description* — short text to be included in the report as its description.
- *with_growth* — flag requesting interval expansion to the nearest bounds with data on relation growth available. The default value is `false`.
- *db_exclude* — the database exclusion list. Lists databases to be excluded from all report tables having the `Database` column. Use to hide some databases in the report.

G.1.10.3. Report Generation Example

Generate a report for the `local` server and interval defined by samples:

```
psql -Aqtc "SELECT profile.get_report(480,482)" -o report_480_482.html
```

For any other server, provide its name:

```
psql -Aqtc "SELECT profile.get_report('omega',12,14)" -o report_omega_12_14.html
```

Generate a report using time ranges:

```
psql -Aqtc "SELECT profile.get_report(tstzrange('2020-05-13 11:51:35+03','2020-05-13 11:52:18+03'))" -o report_range.html
```

Generate a relative time-range report:

```
psql -Aqtc "SELECT profile.get_report(tstzrange(now() - interval '1 day',now()))" -o report_last_day.html
```

G.1.11. pgpro_pwr Report Sections

Each `pgpro_pwr` report is divided into sections, described below. The number of top objects reported in each sorted report table is specified by the `pgpro_pwr.max` parameter.

Almost every item in the report can be accentuated by a single mouse click. The accentuated item will be instantly highlighted in all report sections, making it easy to find. The attributes identifying the item will appear in the bottom-right corner of the page. For example, if you click on a database name in the “Database statistics” report table, you can notice a small table with the database attributes in the bottom-right corner of the page.

When you scroll down the report, its table of contents will be available on the right side of the page. It can be hidden with a single mouse click on the “content” tag.

A substring-based filter is also available that helps limit the report contents to particular objects based on a substring. Specifically, substring-based filtering is applied to query texts.

G.1.11.1. Server statistics

Tables in this section of a `pgpro_pwr` report are described below.

The report table “Database statistics” provides per-database statistics for the report interval. The statistics are based on the `pg_stat_database` view. [Table G.1](#) lists columns of this report table.

Table G.1. Database statistics

Column	Description	Field/Calculation
Database	Database name	<code>datname</code>
Commits	Number of committed transactions	<code>xact_commit</code>
Rollbacks	Number of rolled back transactions	<code>xact_rollback</code>
Deadlocks	Number of deadlocks detected	<code>deadlocks</code>
Checksum Failures	Number of data page checksum failures detected in this database. This field is only shown if any checksum failures were detected in this database during the report interval.	<code>checksum_failures</code>

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Checksums Last	Time at which the last data page checksum failure was detected in this database. This field is only shown if any checksum failures were detected in this database during the report interval.	checksum_last_failure
Hit%	Buffer cache hit ratio, i.e., percentage of pages fetched from buffers in all pages fetched	
Read	Number of disk blocks read in this database	blks_read
Hit	Number of times disk blocks were found already in the buffer cache	blks_hit
Ret	Number of returned tuples	tup_returned
Fet	Number of fetched tuples	tup_fetched
Ins	Number of inserted tuples	tup_inserted
Upd	Number of updated tuples	tup_updated
Del	Number of deleted tuples	tup_deleted
Planned Parallel workers	Number of parallel workers planned to be launched by queries on this database	
Launched Parallel workers	Number of parallel workers launched by queries on this database	
Temp Size	Total amount of data written to temporary files by queries in this database	temp_bytes
Temp Files	Number of temporary files created by queries in this database	temp_files
Size	Database size at the time of the last sample in the report interval	pg_database_size()
Growth	Database growth during the report interval	pg_database_size() increment between interval bounds

The report table “Cluster I/O statistics” provides I/O statistics by object types, backend types and contexts. This table is based on the `pg_stat_io` view of the [Cumulative Statistics System](#), available since Postgres Pro 16. [Table G.2](#) lists columns of this report table. Times are provided in seconds.

Table G.2. Cluster I/O statistics

Column	Description
Object	Target object of an I/O operation
Backend	Type of the backend that performed an I/O operation
Context	The context of an I/O operation
Reads Count	Number of read operations
Reads Bytes	Amount of data read
Reads Time	Time spent in read operations

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description
Writes Count	Number of write operations
Writes Bytes	Amount of data written
Writes Time	Time spent in write operations
Writebacks Count	Number of blocks which the process requested the kernel write out to permanent storage
Writebacks Bytes	Amount of data requested for write out to permanent storage
Writebacks Time	Time spent in writeback operations, including the time spent queueing write-out requests and, potentially, the time spent to write out the dirty data
Extends Count	Number of relation extend operations
Extends Bytes	Amount of space used by extend operations
Extends Time	Time spent in extend operations
Hits	The number of times a desired block was found in a shared buffer
Evictions	Number of times a block has been written out from a shared or local buffer in order to make it available for another use
Reuses	The number of times an existing buffer in a size-limited ring buffer outside of shared buffers was reused as part of an I/O operation in the bulkread, bulkwrite, or vacuum contexts
Fsyncs Count	Number of fsync calls. These are only tracked in context normal.
Fsyncs Time	Time spent in fsync operations

The report table “Cluster SLRU statistics” provides access statistics on SLRU (simple least-recently-used) caches. This table is based on the `pg_stat_slru` view of the [Cumulative Statistics System](#). [Table G.3](#) lists columns of this report table. Times are provided in seconds.

Table G.3. Cluster SLRU statistics

Column	Description	Field/Calculation
Name	Name of the SLRU	<code>name</code>
Zeroed	Number of blocks zeroed during initializations	<code>blks_zeroed</code>
Hits	Number of times disk blocks were found already in the SLRU, so that a read was not necessary (this only includes hits in the SLRU, not the operating system's file system cache)	<code>blks_hit</code>
Reads	Number of disk blocks read for this SLRU	<code>blks_read</code>
%Hit	Number of disk block hits for this SLRU as the percentage of Reads + Hits	$\text{blks_hit} * 100 / (\text{blks_read} + \text{blks_hit})$
Writes	Number of disk blocks written for this SLRU	<code>blks_written</code>

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Checked	Number of blocks checked for existence for this SLRU	blks_exists
Flushes	Number of flushes of dirty data for this SLRU	flushes
Truncates	Number of truncates for this SLRU	truncates

Table “Session statistics by database” is available in the report for Postgres Pro databases starting with version 14. This table is based on the `pg_stat_database` view of the [Statistics Collector](#). [Table G.4](#) lists columns of this report table. Times are provided in seconds.

Table G.4. Session statistics by database

Column	Description	Field/Calculation
Database	Database name	
Timing Total	Time spent by database sessions in this database during the report interval (note that statistics are only updated when the state of a session changes, so if sessions have been idle for a long time, this idle time won't be included)	session_time
Timing Active	Time spent executing SQL statements in this database during the report interval (this corresponds to the states <code>active</code> and <code>fastpath function call</code> in <code>pg_stat_activity</code>)	active_time
Timing Idle(T)	Time spent idling while in a transaction in this database during the report interval (this corresponds to the states <code>idle in transaction</code> and <code>idle in transaction (aborted)</code> in <code>pg_stat_activity</code>)	idle_in_transaction_time
Sessions Established	Total number of sessions established to this database during the report interval	sessions
Sessions Abandoned	Number of database sessions to this database that were terminated because connection to the client was lost during the report interval	sessions_abandoned
Sessions Fatal	Number of database sessions to this database that were terminated by fatal errors during the report interval	sessions_fatal
Sessions Killed	Number of database sessions to this database that were terminated by operator intervention during the report interval	sessions_killed

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

In Postgres Pro Standard databases of versions that include [pgpro_stats](#) version starting with 1.4, workload statistics of vacuum processes are available. The “Database vacuum statistics” report table provides per-database aggregated total vacuum statistics based on the `pgpro_stats_vacuum_tables` view. [Table G.5](#) lists columns of this report table. Times are provided in seconds.

Table G.5. Database vacuum statistics

Column	Description	Field/Calculation
Database	Database name	
Blocks fetched	Total number of database blocks fetched by vacuum operations	<code>total_blks_read + total_blks_hit</code>
%Total	Total number of database blocks fetched (read+hit) by vacuum operations as the percentage of all blocks fetched in the cluster	<code>Blocks fetched * 100 / Cluster fetched</code>
Blocks read	Total number of database blocks read by vacuum operations	<code>total_blks_read</code>
%Total	Total number of database blocks read by vacuum operations as the percentage of all blocks read in the cluster	<code>Blocks read * 100 / Cluster read</code>
VM Frozen	Total number of blocks marked all-frozen in the visibility map	<code>pages_frozen</code>
VM Visible	Total number of blocks marked all-visible in the visibility map	<code>pages_all_visible</code>
Tuples deleted	Total number of dead tuples vacuum operations deleted from tables of this database	<code>tuples_deleted</code>
Tuples left	Total number of dead tuples vacuum operations left in tables of this database due to their visibility in transactions	<code>dead_tuples</code>
%Eff	Vacuum efficiency in terms of deleted tuples. This is the percentage of tuples deleted from tables of this database in all dead tuples to be deleted from tables of this database.	<code>tuples_deleted * 100 / (tuples_deleted + dead_tuples)</code>
WAL size	Total amount of WAL bytes generated by vacuum operations performed on tables of this database	<code>wal_bytes</code>
Read I/O time	Time spent reading database blocks by vacuum operations performed on tables of this database	<code>blk_read_time</code>
Write I/O time	Time spent writing database blocks by vacuum operations performed on tables of this database	<code>blk_write_time</code>
%Total	Vacuum I/O time spent as the percentage of whole cluster I/O time	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Total vacuum time	Total time of vacuuming tables of this database	total_time
Delay vacuum time	Time spent sleeping in a vacuum delay point by vacuum operations performed on tables of this database	delay_time
User CPU time	User CPU time of vacuuming tables of this database	user_time
System CPU time	System CPU time of vacuuming tables of this database	system_time
Interrupts	Number of times vacuum operations performed on tables of this database were interrupted on any errors	interrupts

If the [pgpro_stats](#) extension supporting invalidation statistics was available during the report interval, the "Invalidation messages by database" report table provides per-database aggregated total invalidation message statistics. [Table G.6](#) lists columns of this report table.

Table G.6. Invalidation messages by database

Column	Description	Field/Calculation
Database	Database name	
Invalidation messages sent	Total number of invalidation messages sent by backends in this database. Statistics are provided for corresponding message types of <code>pgpro_stats_inval_msgs</code>	Fields of <code>pgpro_stats_totals.inval_msgs</code>
Cache resets	Total number of shared cache resets	<code>pgpro_stats_totals.cache_resets</code>

If the [pgpro_stats](#) extension was available during the report interval, the "Statement statistics by database" report table provides per-database aggregated total statistics for the `pgpro_stats_statements` view data. [Table G.7](#) lists columns of this report table. Times are provided in seconds.

Table G.7. Statement statistics by database

Column	Description	Field/Calculation
Database	Database name	
Calls	Number of times all statements in the database were executed	calls
Plan Time	Time spent planning all statements in the database	Sum of <code>total_plan_time</code>
Exec Time	Time spent executing all statements in the database	Sum of <code>total_exec_time</code>
Read Time	Time spent reading blocks by all statements in the database	Sum of <code>blk_read_time</code>
Write Time	Time spent writing blocks by all statements in the database	Sum of <code>blk_write_time</code>
Trg Time	Time spent executing trigger functions by all statements in the database	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Shared Fetched	Total number of shared blocks fetched by all statements in the database	Sum of (shared_blks_read + shared_blks_hit)
Local Fetched	Total number of local blocks fetched by all statements in the database	Sum of (local_blks_read + local_blks_hit)
Shared Dirtied	Total number of shared blocks dirtied by all statements in the database	Sum of shared_blks_dirtied
Local Dirtied	Total number of local blocks dirtied by all statements in the database	Sum of local_blks_dirtied
Read Temp	Total number of temporary blocks read by all statements in the database	Sum of temp_blks_read
Write Temp	Total number of temporary blocks written by all statements in the database	Sum of temp_blks_written
Read Local	Total number of local blocks read by all statements in the database	Sum of local_blks_read
Write Local	Total number of local blocks written by all statements in the database	Sum of local_blks_written
Statements	Total number of captured statements	
WAL Size	Total amount of WAL generated by all statements in the database	Sum of wal_bytes
WAL buffers full	Number of times the WAL buffers became full	

The “Statement average min/max timings” report table contains per-database aggregated min/max timing statistics from the one of [pgpro_stats](#) or [pg_stat_statements](#) extensions that was available during the report interval, with the precedence of [pgpro_stats](#). This report is sensitive to the fastest and slowest planning and execution of every statement in a cluster. That is, you can see execution and planning stability in your database. [Table G.8](#) lists columns of this report table.

Table G.8. Statement average min/max timings

Column	Description
Database	Database name
Min average planning time (ms)	The average value of min_plan_time for all statements and all samples included in the report
Max average planning time (ms)	The average value of max_plan_time for all statements and all samples included in the report
Delta% of average planning times	Difference between the mean max_plan_time and mean min_plan_time as the percentage of the mean min_plan_time . The less this difference, the more stable query planning in your database is.

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description
Min average execution time (ms)	The average value of <code>min_exec_time</code> for all statements and all samples included in the report
Max average execution time (ms)	The average value of <code>max_exec_time</code> for all statements and all samples included in the report
Delta% of average execution times	Difference between the mean <code>max_exec_time</code> and mean <code>min_exec_time</code> as the percentage of the mean <code>min_exec_time</code> . The less this difference, the more stable query execution in your database is.
Statements	Total count of captured statements

If the JIT-related statistics was available in the statement statistics extension during the report interval, the “JIT statistics by database” report table provides per-database aggregated total statistics of JIT executions. [Table G.9](#) lists columns of this report table. Times are provided in seconds.

Table G.9. JIT statistics by database

Column	Description	Field/Calculation
Database	Database name	
Calls	Number of times all statements in the database were executed	<code>calls</code>
Plan Time	Time spent planning all statements in the database	Sum of <code>total_plan_time</code>
Exec Time	Time spent executing all statements in the database	Sum of <code>total_exec_time</code>
Generation count	Total number of functions JIT-compiled by the statements	Sum of <code>jit_functions</code>
Generation time	Total time spent by the statements on generating JIT code	Sum of <code>jit_generation_time</code>
Inlining count	Number of times functions have been inlined	Sum of <code>jit_inlining_count</code>
Inlining time	Total time spent by statements on inlining functions	Sum of <code>jit_inlining_time</code>
Optimization count	Number of times statements have been optimized	Sum of <code>jit_optimization_count</code>
Optimization time	Total time spent by statements on optimizing	Sum of <code>jit_optimization_time</code>
Emission count	Number of times code has been emitted	Sum of <code>jit_emission_count</code>
Emission time	Total time spent by statements on emitting code	Sum of <code>jit_emission_time</code>
Deform count	Number of tuple deform functions JIT-compiled by the statement of the database	
Deform time	Total time spent by the statements of the database on JIT-compiling the tuple deform functions	

The report table “Cluster statistics” provides data from the `pg_stat_bgwriter` and `pg_stat_checkpoint` views. [Table G.10](#) lists rows of this report table. Times are provided in seconds.

Table G.10. Cluster statistics

Row	Description	Field/Calculation
Scheduled checkpoints	Number of scheduled checkpoints that have been performed	checkpoints_timed
Requested checkpoints	Number of requested checkpoints that have been performed	checkpoints_req
Checkpoints done	Number of checkpoints that have been performed	
Scheduled restartpoints	Number of restartpoints scheduled due to timeout or after a failed attempt to perform a restartpoint	restartpoints_timed
Requested restartpoints	Number of requested restartpoints if any	restartpoints_req
Restartpoints done	Number of restartpoints that have been performed if any	restartpoints_done
Checkpoint write time (s)	Total amount of time that has been spent in the portion of checkpoint and restartpoint processing where files are written to disk	checkpoint_write_time
Checkpoint sync time (s)	Total amount of time that has been spent in the portion of checkpoint and restartpoint processing where files are synchronized to disk	checkpoint_sync_time
Checkpoint buffers written	Number of shared buffers written during checkpoints and restartpoints	buffers_checkpoint
SLRU buffers written by checkpoint	Number of SLRU buffers written during checkpoints and restartpoints	
Background buffers written	Number of buffers written by the background writer	buffers_clean
Backend buffers written	Number of buffers written directly by a backend. Will not be shown since Postgres Pro 17.	buffers_backend
Backend fsync count	Number of times a backend had to execute its own fsync call (normally the background writer handles those even when the backend does its own write). Will not be shown since Postgres Pro 17.	buffers_backend_fsync
Bgwriter interrupts (too many buffers)	Number of times the background writer stopped a cleaning scan because it had written too many buffers	maxwritten_clean
Number of buffers allocated	Total number of buffers allocated	buffers_alloc
WAL generated	Total amount of WAL generated	pg_current_wal_lsn() value increment

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Row	Description	Field/Calculation
Start LSN	Log sequence number at the start of a report interval	<code>pg_current_wal_lsn()</code> at the first sample of a report
End LSN	Log sequence number at the end of a report interval	<code>pg_current_wal_lsn()</code> at the last sample of a report
WAL generated by vacuum	Total amount of WAL generated by vacuum	Based on the <code>wal_bytes</code> field of the <code>pgpro_stats_vacuum_databases</code> view.
WAL segments archived	Total number of archived WAL segments	Based on <code>pg_stat_archiver.archived_count</code>
WAL segments archive failed	Total number of WAL segment archiver failures	Based on <code>pg_stat_archiver.failed_count</code> .
Archiver performance	Average archiver process performance per second	Based on the <code>active_time</code> field of the <code>pgpro_stats_archiver</code> view.
Archive command performance	Average <code>archive_command</code> performance per second	Based on the <code>archive_command_time</code> field of the <code>pgpro_stats_archiver</code> view.

Table “WAL statistics” is available in the report for Postgres Pro databases starting with version 14. This table is based on the `pg_stat_wal` view of the [Statistics Collector](#). [Table G.11](#) lists columns of this report table. Times are provided in seconds.

Table G.11. WAL statistics

Row	Description	Field/Calculation
WAL generated	Total amount of WAL generated during the report interval	<code>wal_bytes</code>
WAL per second	Average amount of WAL generated per second during the report interval	<code>wal_bytes / report_duration</code>
WAL records	Total number of WAL records generated during the report interval	<code>wal_records</code>
WAL FPI	Total number of WAL full page images generated during the report interval	<code>wal_fpi</code>
WAL buffers full	Number of times WAL data was written to disk because WAL buffers became full during the report interval	<code>wal_buffers_full</code>
WAL writes	Number of times WAL buffers were written out to disk via <code>XLogWrite</code> request during the report interval	<code>wal_write</code>
WAL writes per second	Average number of times WAL buffers were written out to disk via <code>XLogWrite</code> request per second during the report interval	<code>wal_write / report_duration</code>
WAL sync	Number of times WAL files were synced to disk via <code>issue_xlog_fsync</code> request during	<code>wal_sync</code>

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Row	Description	Field/Calculation
	the report interval (if <code>fsync</code> is on and <code>wal_sync_method</code> is either <code>fdatasync</code> , <code>fsync</code> or <code>fsync_writethrough</code> , otherwise zero). See Section 27.5 for more information about the internal WAL function <code>issue_xlog_fsync</code> .	
WAL syncs per second	Average number of times WAL files were synced to disk via <code>issue_xlog_fsync</code> request per second during the report interval	<code>wal_sync / report_duration</code>
WAL write time	Total amount of time spent writing WAL buffers to disk via XLog-Write request during the report interval (if <code>track_wal_io_timing</code> is enabled, otherwise zero; for more details, see Section 18.9). This includes the sync time when <code>wal_sync_method</code> is either <code>open_datasync</code> or <code>open_sync</code> .	<code>wal_write_time</code>
WAL write duty	WAL write time as the percentage of the report interval duration	<code>wal_write_time * 100 / report_duration</code>
WAL sync time	Total amount of time spent syncing WAL files to disk via <code>issue_xlog_fsync</code> request during the report interval (if <code>track_wal_io_timing</code> is enabled, <code>fsync</code> is on, and <code>wal_sync_method</code> is either <code>fdatasync</code> , <code>fsync</code> or <code>fsync_writethrough</code> , otherwise zero).	<code>wal_sync_time</code>
WAL sync duty	WAL sync time as the percentage of the report interval duration	<code>wal_sync_time * 100 / report_duration</code>

The report table “Tablespace statistics” provides information on the sizes and growth of tablespaces. [Table G.12](#) lists columns of this report table.

Table G.12. Tablespace statistics

Column	Description	Field/Calculation
Tablespace	Tablespace name	<code>pg_tablespace.spcname</code>
Path	Tablespace path	<code>pg_tablespace_location()</code>
Size	Tablespace size at the time of the last sample in the report interval	<code>pg_tablespace_size()</code>
Growth	Tablespace growth during the report interval	<code>pg_tablespace_size()</code> increment between interval bounds

If the [pgpro_stats](#) extension was available during the report interval, the report table “Wait statistics by database” shows the total wait time by wait event type and database. [Table G.13](#) lists columns of this report table.

Table G.13. Wait statistics by database

Column	Description
Database	Database name
Wait event type	Type of event for which the backends were waiting. Asterisk means aggregation of all wait event types in the database.
Waited (s)	Time spent waiting in events of Wait event type, in seconds
%Total	Percentage of wait time spent in the database events of Wait event type in all wait time for the cluster

If the [pgpro_stats](#) extension was available during the report interval, the report table “Top wait events” shows top wait events in the cluster by wait time. [Table G.14](#) lists columns of this report table.

Table G.14. Top wait events

Column	Description
Database	Database name
Wait event type	The type of event for which the backends were waiting
Wait event	Wait event name for which the backends were waiting
Waited	Total wait time spent in Wait event of the database, in seconds
%Total	Percentage of wait time spent in Wait event of the database in all wait time in the cluster

G.1.11.2. Load distribution

This section of a pgpro_pwr report is based on the `pgpro_stats_totals` view of the [pgpro_stats](#) extension if it was available during the report interval. Each table in this section provides data for the report interval on load distribution for a certain kind of objects for which aggregated statistics are collected, such as databases, applications, hosts, or users. Each table contains one row for each resource (for example, total time or shared blocks written), where load distribution is shown in graphics, as a stacked bar chart for top objects by load of this resource. If the bar chart area that corresponds to an object is too narrow to include captions, point that area to get a hint with the caption, value and percentage. The report tables “Load distribution among heavily loaded databases”, “Load distribution among heavily loaded applications”, “Load distribution among heavily loaded hosts” and “Load distribution among heavily loaded users” show load distribution for respective objects. [Table G.15](#) lists rows of these report tables.

Table G.15. Load distribution

Row	Description	Calculation
Total time (sec.)	Total time spent in the planning and execution of statements	<code>total_plan_time</code> + <code>total_exec_time</code>
Executed count	Number of queries executed	<code>queries_executed</code>
I/O time (sec.)	Total time the statements spent reading or writing blocks (if track_io_timing is enabled, otherwise zero)	<code>blk_read_time</code> + <code>blk_write_time</code>

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Row	Description	Calculation
Blocks fetched	Total number of shared block cache hits and shared blocks read by the statements	<code>shared_blks_hit + shared_blks_read</code>
Shared blocks read	Total number of shared blocks read by the statements	<code>shared_blks_read</code>
Shared blocks dirtied	Total number of shared blocks dirtied by the statements	<code>shared_blks_dirtied</code>
Shared blocks written	Total number of shared blocks written by the statements	<code>shared_blks_written</code>
WAL generated	Total amount of WAL generated by the statements	<code>wal_bytes</code>
Temp and Local blocks written	Total number of temporary and local blocks written by the statements	<code>temp_blks_written + local_blks_written</code>
Temp and Local blocks read	Total number of temp and local blocks read by the statements	<code>temp_blks_read + local_blks_read</code>
Invalidation messages sent	Total number of all invalidation messages sent by backends in this database	<code>(pgpro_stats_totals .invalid_msgs).all</code>
Cache resets	Total number of shared cache resets	<code>pgpro_stats_totals .cache_resets</code>

G.1.11.3. Session states observed by subsamples

This section of a `pgpro_pwr` report provides information about session states captured by subsamples during the report interval.

Tables of this report section are described below.

The report subsection “Chart with session state” visualizes session states captured by subsamples. It is the timeline chart showing captured session states in backends and transactions. Every state contains a popup with session state attributes. Click on a state to see this state in the table of session states.

The report table “Session state statistics by database” shows the aggregated data on session states. Only session states captured in subsamples are counted. [Table G.16](#) lists columns of this report table.

Table G.16. Session state statistics by database

Column	Description
Database	Database name
Summary Active	Overall time of active states captured in subsamples
Summary Idle in xact	Overall time of idle in transaction states captured in subsamples
Summary Idle in xact (A)	Overall time of idle in transaction (aborted) states captured in subsamples
Maximal Active	Time of the longest active state captured in subsamples
Maximal Idle in xact	Time of the longest idle in transaction state captured in subsamples
Maximal Idle in xact (A)	Time of the longest idle in transaction (aborted) state captured in subsamples

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description
Maximal xact age	Maximal transaction age detected in subsamples

The report table “Top 'idle in transaction' session states by duration” shows top `pgpro_pwr.max` longest idle in transaction states that were last observed in the [pg_stat_activity](#) view for each session. [Table G.17](#) lists columns of this report table.

Table G.17. Top 'idle in transaction' session states by duration

Column	Description	Field/Calculation
Database	Database name	<code>datname</code>
User	User name	<code>username</code>
App	Application name	<code>application_name</code>
Pid	Process ID	<code>pid</code>
Xact start	Transaction start timestamp	<code>xact_start</code>
State change	State change timestamp	<code>state_change</code>
State duration	State duration	<code>clock_timestamp() - state_change</code>

The report table “Top 'active' session states by duration” shows top `pgpro_pwr.max` longest active states that were last observed in the [pg_stat_activity](#) view for each session. [Table G.18](#) lists columns of this report table.

Table G.18. Top 'active' session states by duration

Column	Description	Field/Calculation
Database	Database name	<code>datname</code>
User	User name	<code>username</code>
App	Application name	<code>application_name</code>
Pid	Process ID	<code>pid</code>
Xact start	Transaction start timestamp	<code>xact_start</code>
State change	State change timestamp	<code>state_change</code>
State duration	State duration	<code>clock_timestamp() - state_change</code>

The report table “Top states by transaction age” shows top session states by transaction age that were last observed in the [pg_stat_activity](#) view for each session. [Table G.19](#) lists columns of this report table.

Table G.19. Top states by transaction age

Column	Description	Field/Calculation
Database	Database name	<code>datname</code>
User	User name	<code>username</code>
App	Application name	<code>application_name</code>
Pid	Process ID	<code>pid</code>
Xact start	Transaction start timestamp	<code>xact_start</code>
Xact duration	Transaction duration	<code>clock_timestamp() - xact_start</code>

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Age	Transaction age	<code>age (backend_xmin)</code>
State	Session state at the maximum age detected	
State change	State change timestamp	<code>state_change</code>
State duration	State duration	<code>clock_timestamp() - state_change</code>

The report table “Top states by transaction duration” shows top longest session states that were last observed in the [pg_stat_activity](#) view for each session. [Table G.20](#) lists columns of this report table.

Table G.20. Top states by transaction duration

Column	Description	Field/Calculation
Database	Database name	<code>datname</code>
User	User name	<code>username</code>
App	Application name	<code>application_name</code>
Pid	Process ID	<code>pid</code>
Xact start	Transaction start timestamp	<code>xact_start</code>
Xact duration	Transaction duration	<code>clock_timestamp() - xact_start</code>
Age	Transaction age	<code>age (backend_xmin)</code>
State	Session state at the maximum age detected	
State change	State change timestamp	<code>state_change</code>
State duration	State duration	<code>clock_timestamp() - state_change</code>

G.1.11.4. SQL query statistics

This section of a `pgpro_pwr` report provides data for the report interval on top statements by several important statistics. The data is mainly captured from views of the one of [pgpro_stats](#) and [pg_stat_statements](#) extensions that was available during the report interval, with the precedence of `pgpro_stats`. Each statement can be highlighted in all SQL-related sections with a single mouse click on it. This click will also show a query text preview just under the query statistics row. The query text preview can be hidden with a second click on a query.

Tables of this report section are described below.

The report table “Top SQL by elapsed time” shows top statements by the sum of `total_plan_time` and `total_exec_time` fields of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table G.21](#) lists columns of this report table. Times are provided in seconds.

Table G.21. Top SQL by elapsed time

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
%Total	Percentage of elapsed time of this statement plan in the total elapsed time of all statements in the cluster	
Elapsed Time (s)	Total time spent in planning and execution of the statement plan	total_plan_time + total_exec_time
Plan Time (s)	Total time spent in planning of the statement	total_plan_time
Exec Time (s)	Total time spent in execution of the statement plan	total_exec_time
JIT Time (s)	Total time spent by JIT executing this statement plan, in seconds	jit_generation_time + jit_inlining_time + jit_optimization_time + jit_emission_time
Read I/O time (s)	Total time the statement spent reading blocks	blk_read_time
Write I/O time (s)	Total time the statement spent writing blocks	blk_write_time
Usr CPU time (s)	Time spent on CPU in the user space, in seconds	rusage.user_time
Sys CPU time (s)	Time spent on CPU in the system space, in seconds	rusage.system_time
Plans	Number of times the statement was planned	plans
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by planning time” shows top statements by the value of the `total_plan_time` field of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table G.22](#) lists columns of this report table.

Table G.22. Top SQL by planning time

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Plan elapsed(s)	Total time spent in planning of the statement, in seconds	total_plan_time
%Elapsed	Percentage of total_plan_time in the sum of total_plan_time and total_exec_time of this statement plan	
Mean plan time	Mean time spent planning the statement, in milliseconds	mean_plan_time
Min plan time	Minimum time spent planning the statement, in milliseconds	min_plan_time
Max plan time	Maximum time spent planning the statement, in milliseconds	max_plan_time
StdErr plan time	Population standard deviation of time spent planning the statement, in milliseconds	stddev_plan_time
Plans	Number of times the statement was planned	plans
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by execution time” shows top statements by the value of the `total_time` field of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table G.23](#) lists columns of this report table.

Table G.23. Top SQL by execution time

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Exec (s)	Total time spent executing the statement plan, in seconds	total_exec_time

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
%Elapsed	Percentage of <code>total_exec_time</code> of this statement plan in this statement elapsed time	
%Total	Percentage of <code>total_exec_time</code> of this statement plan in the total elapsed time of all statements in the cluster	
JIT Time (s)	Total time spent by JIT executing this statement plan, in seconds	<code>jit_generation_time</code> + <code>jit_inlining_time</code> + <code>jit_optimization_time</code> + <code>jit_emission_time</code>
Read I/O time (s)	Total time spent in reading pages while executing the statement plan, in seconds	<code>blk_read_time</code>
Write I/O time (s)	Total time spent in writing pages while executing the statement plan, in seconds	<code>blk_write_time</code>
Usr CPU time (s)	Time spent on CPU in the user space, in seconds	<code>rusage.user_time</code>
Sys CPU time (s)	Time spent on CPU in the system space, in seconds	<code>rusage.system_time</code>
Rows	Number of rows retrieved or affected by execution of the statement plan	<code>rows</code>
Mean execution time	Mean time spent executing the statement plan, in milliseconds	<code>mean_exec_time</code>
Min execution time	Minimum time spent executing the statement plan, in milliseconds	<code>min_exec_time</code>
Max execution time	Maximum time spent executing the statement plan, in milliseconds	<code>max_exec_time</code>
StdErr execution time	Population standard deviation of time spent executing the statement plan, in milliseconds	<code>stddev_exec_time</code>
Executions	Number of executions of this statement plan	<code>calls</code>
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by mean execution time” shows top `pgpro_pwr.max` statements by the value of the `mean_time` or `mean_exec_time` field of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table G.24](#) lists columns of this report table.

Table G.24. Top SQL by mean execution time

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square

Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Blks fetched	Number of blocks retrieved while executing the statement plan	shared_blks_hit + shared_blks_read
%Total	Percentage of blocks fetched while executing the statement plan in all blocks fetched for all statements in the cluster	
Hits (%)	Percentage of blocks got from buffers in all blocks got	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	total_plan_time + total_exec_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by shared blocks read” shows top statements by the number of shared reads, which helps to detect the most read-intensive statements. [Table G.28](#) lists columns of this report table.

Table G.28. Top SQL by shared blocks read

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Reads	Number of shared blocks read while executing this statement plan	shared_blks_read

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
%Total	Percentage of shared reads for this statement plan in all shared reads of all statements in the cluster	
Hits (%)	Percentage of blocks got from buffers in all blocks got while executing this statement plan	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	<code>total_plan_time</code> + <code>total_exec_time</code>
Rows	Number of rows retrieved or affected by execution of the statement plan	<code>rows</code>
Executions	Number of executions of the statement plan	<code>calls</code>
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by shared blocks dirtied” shows top statements by the number of shared dirtied buffers, which helps to detect statements that do most data changes in the cluster. [Table G.29](#) lists columns of this report table.

Table G.29. Top SQL by shared blocks dirtied

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	<code>planid</code>
Database	Database name for the statement	Derived from <code>dbid</code>
User	Name of the user executing the statement	Derived from <code>userid</code>
Dirtied	Number of shared buffers dirtied while executing this statement plan	<code>shared_blks_dirtied</code>
%Total	Percentage of dirtied shared buffers for this statement plan in all dirtied shared buffers of all statements in the cluster	
Hits (%)	Percentage of blocks got from buffers in all blocks got while executing this statement plan	
WAL	Total amount of WAL bytes generated by the statement plan	<code>wal_bytes</code>

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
%Total	Percentage of WAL bytes generated by the statement plan in total WAL generated in the cluster	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	total_plan_time + total_exec_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by shared blocks written” shows top statements by the number of blocks written. [Table G.30](#) lists columns of this report table.

Table G.30. Top SQL by shared blocks written

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Written	Number of blocks written while executing this statement plan	shared_blks_written
%Total	Percentage of blocks written by this statement plan in all written blocks in the cluster	Percentage of shared_blks_written in (pg_stat_bgwriter.buffer_checkpoint + pg_stat_bgwriter.buffer_clean + pg_stat_bgwriter.buffer_backend)
%BackendW	Percentage of blocks written by this statement plan in all blocks in the cluster written by backends	Percentage of shared_blks_written in pg_stat_bgwriter.buffer_backend
Hits(%)	Percentage of blocks got from buffers in all blocks got while executing this statement plan	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	total_plan_time + total_exec_time

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by WAL size” shows top statements by the amount of WAL generated. [Table G.31](#) lists columns of this report table.

Table G.31. Top SQL by WAL size

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from <code>dbid</code>
User	Name of the user executing the statement	Derived from <code>userid</code>
WAL	Total amount of WAL bytes generated by the statement plan	wal_bytes
%Total	Percentage of WAL bytes generated by the statement plan in total WAL generated in the cluster	
WAL buffers full	Number of times the WAL buffers became full	
Dirtied	Number of shared buffers dirtied while executing this statement plan	shared_blks_dirtied
WAL FPI	Total number of WAL full page images generated by the statement plan	wal_fpi
WAL records	Total number of WAL records generated by the statement plan	wal_records
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by temp usage” shows top statements by temporary I/O, which is calculated as the sum of `temp_blks_read`, `temp_blks_written`, `local_blks_read` and `local_blks_written` fields. [Table G.32](#) lists columns of this report table.

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Table G.32. Top SQL by temp usage

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	<code>planid</code>
Database	Database name for the statement	Derived from <code>dbid</code>
User	Name of the user executing the statement	Derived from <code>userid</code>
Local fetched	Number of local blocks retrieved	<code>local_blks_hit</code> + <code>local_blks_read</code>
Hits(%)	Percentage of local blocks got from buffers in all local blocks got	
Write Local (blk)	Number of blocks written by this statement plan that are used in temporary tables	<code>local_blks_written</code>
Write Local %Total	Percentage of <code>local_blks_written</code> of this statement plan in the total of <code>local_blks_written</code> for all statements in the cluster	
Read Local (blk)	Number of blocks read by this statement plan that are used in temporary tables	<code>local_blks_read</code>
Read Local %Total	Percentage of <code>local_blks_read</code> of this statement plan in the total of <code>local_blks_read</code> for all statements in the cluster	
Write Temp (blk)	Number of temporary blocks written by this statement plan	<code>temp_blks_written</code>
Write Temp %Total	Percentage of <code>temp_blks_written</code> of this statement plan in the total of <code>temp_blks_written</code> for all statements in the cluster	
Read Temp (blk)	Number of temporary blocks read by this statement plan	<code>temp_blks_read</code>
Read Temp %Total	Percentage of <code>temp_blks_read</code> of this statement plan in the total of <code>temp_blks_read</code> for all statements in the cluster	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	<code>total_plan_time</code> + <code>total_exec_time</code>

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by invalidation messages sent” shows top statements by the number of invalidation messages sent. [Table G.33](#) lists columns of this report table.

Table G.33. Top SQL by invalidation messages sent

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	<code>queryid</code>
Plan ID	Internal hash code, computed from the tree of the statement plan	<code>planid</code>
Database	Database name for the statement	Derived from <code>dbid</code>
User	Name of the user executing the statement	Derived from <code>userid</code>
Invalidation messages sent	Total number of invalidation messages sent by backends executing this statement. Statistics are provided for corresponding message types of <code>pgpro_stats_inval_msgs</code>	fields of <code>pgpro_stats_statements.inval_msgs</code>

G.1.11.4.1. rusage statistics

This section is included in the report only if the `pgpro_stats` or `pg_stat_kcache` extension was available during the report interval.

The report table “Top SQL by system and user time” shows top statements by the sum of `user_time` and `system_time` fields of `pg_stat_kcache` or of the `pgpro_stats_totals` view. [Table G.34](#) lists columns of this report table.

Table G.34. Top SQL by system and user time

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Plan User (s)	User CPU time elapsed during planning, in seconds	plan_user_time
Exec User (s)	User CPU time elapsed during execution, in seconds	exec_user_time
User %Total	Percentage of <code>plan_user_time</code> + <code>exec_user_time</code> in the total user CPU time for all statements	
Plan System (s)	System CPU time elapsed during planning, in seconds	plan_system_time
Exec System (s)	System CPU time elapsed during execution, in seconds	exec_system_time
System %Total	Percentage of <code>plan_system_time</code> + <code>exec_system_time</code> in the total system CPU time for all statements	

The report table “Top SQL by reads/writes done by filesystem layer” shows top statements by the sum of reads and writes fields of `pg_stat_kcache`. [Table G.35](#) lists columns of this report table.

Table G.35. Top SQL by reads/writes done by filesystem layer

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Plan Read Bytes	Bytes read during planning	plan_reads
Exec Read Bytes	Bytes read during execution	exec_reads
Read Bytes %Total	Percentage of <code>plan_reads</code> + <code>exec_reads</code> in the total number of bytes read by the filesystem layer for all statements	
Plan Writes	Bytes written during planning	plan_writes
Exec Writes	Bytes written during execution	exec_writes

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Write %Total	Percentage of <code>plan_writes</code> + <code>exec_writes</code> in the total number of bytes written by the filesystem layer for all statements	

G.1.11.5. SQL query wait statistics

If the `pgpro_stats` extension was available during the report interval, this section of the report will contain a table that is split into sections, each showing top statements by overall wait time or by wait time for a certain [wait event type](#). Table sections related to specific wait events follow in the descending order of the total wait time in wait events of this type. [Table G.36](#) lists columns of this report table. Times are provided in seconds.

Table G.36. SQL query wait statistics

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Hash of the statement plan	<code>planid</code>
Database	Database name for the statement	Derived from <code>dbid</code>
User	Name of the user executing the statement	Derived from <code>userid</code>
Waited	Total wait time for all wait events of this statement plan	
%Total	Percentage of the total wait time of this statement plan in all the wait time in the cluster	
Details	Waits of this statement plan by wait types	

If the JIT-related statistics was available in the statement statistics extension during the report interval, the report table “Top SQL by JIT elapsed time” shows top statements by the sum of `jit_*_time` fields of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table G.37](#) lists columns of this report table. Times are provided in seconds.

Table G.37. Top SQL by JIT elapsed time

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	<code>planid</code>

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
JIT Time (s)	Total time spent by JIT executing this statement plan	<code>jit_generation_time + jit_inlining_time + jit_optimization_time + jit_emission_time</code>
Generation count	Total number of functions JIT-compiled by this statement	Sum of <code>jit_functions</code>
Generation time	Total time spent by this statement on generating JIT code	Sum of <code>jit_generation_time</code>
Inlining count	Number of times functions have been inlined	Sum of <code>jit_inlining_count</code>
Inlining time	Total time spent by this statement on inlining functions	Sum of <code>jit_inlining_time</code>
Optimization count	Number of times this statement has been optimized	Sum of <code>jit_optimization_count</code>
Optimization time	Total time spent by this statement on optimizing	Sum of <code>jit_optimization_time</code>
Emission count	Number of times code has been emitted	Sum of <code>jit_emission_count</code>
Emission time	Total time spent by this statement on emitting code	Sum of <code>jit_emission_time</code>
Deform count	Number of tuple deform functions JIT-compiled by the statement	
Deform time	Total time spent by the statement on JIT-compiling the tuple deform	
Plan Time (s)	Total time spent in planning of the statement	<code>total_plan_time</code>
Exec Time (s)	Total time spent in execution of the statement plan	<code>total_exec_time</code>
Read I/O time (s)	Total time the statement spent reading blocks	<code>blk_read_time</code>
Write I/O time (s)	Total time the statement spent writing blocks	<code>blk_write_time</code>
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

G.1.11.6. Top SQL by parallel workers usage

The “Top SQL by parallel workers usage” section of the report shows top statements by planned and launched parallel workers, that is, by the sum of `parallel_workers_to_launch` and `parallel_workers_launched` fields of the `pg_stat_statements` view. Some of these statistics are only available starting with Postgres Pro 18. [Table G.38](#) lists columns of this report table. Times are provided in seconds.

Table G.38. Top SQL by parallel workers usage

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Database	Database name for the statement	Derived from <code>dbid</code>
User	Name of the user executing the statement	Derived from <code>userid</code>
Planned Parallel workers	Number of parallel workers planned to be launched	
Launched Parallel workers	Number of parallel workers actually launched	
Exec (s)	System CPU time elapsed during execution	<code>exec_system_time</code> or <code>system_time</code>
Blks fetched	Number of fetched blocks	<code>shared_blks_hit</code> + <code>shared_blks_read</code>
Shr Reads	Total number of shared blocks read by the statement plan	<code>shared_blks_read</code>
Loc Reads	Total number of local blocks read by the statement plan	<code>local_blks_read</code>
Tmp Reads	Total number of temporary blocks read by the statement plan	<code>temp_blks_read</code>
Read I/O time (s)	Time spent reading blocks	<code>blk_read_time</code>
Write I/O time (s)	Time spent writing blocks	<code>blk_write_time</code>

G.1.11.7. Complete list of SQL texts

The “Complete list of SQL texts” section of the report contains a table that provides query and plan texts for all statements mentioned in the report. Use an appropriate `Query ID/Plan ID` link in any statistics table to see the corresponding query/plan text. [Table G.39](#) lists columns of this report table.

Table G.39. Complete list of SQL texts

Column	Description
ID	Hex representation of the query or plan identifier
Query/Plan Text	Text of the query or statement plan

G.1.11.8. Schema object statistics

Tables in this section of the report show top database objects by statistics from the Postgres Pro's [Statistics Collector](#) views. Report tables that contain data for tables and indexes provide a preview of storage parameters. You can click on a row to see storage parameters of the object right under the row.

The report table “Top tables by estimated sequentially scanned volume” shows top tables by estimated volume read by sequential scans. This can help you find database tables that possibly lack some index. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. The data is based on the `pg_stat_all_tables` view. [Table G.40](#) lists columns of this report table.

Table G.40. Top tables by estimated sequentially scanned volume

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
~SeqBytes	Estimated volume read by sequential scans	Sum of (pg_relation_size() * seq_scan)
SeqScan	Number of sequential scans performed on the table	seq_scan
IxScan	Number of index scans initiated on the table	idx_scan
IxFet	Number of live rows fetched by index scans	idx_tup_fetch
Ins	Number of rows inserted	n_tup_ins
Upd	Number of rows updated	n_tup_upd
Del	Number of rows deleted	n_tup_del
Upd (HOT)	Number of rows HOT updated	n_tup_hot_upd

In the report table “Top tables by blocks fetched”, blocks fetched include blocks being processed from disk (read) and from shared buffers (hit). This report table shows top database tables by the sum of blocks fetched for the table's heap, indexes, TOAST table (if any) and TOAST table index (if any). This can help you focus on tables with excessive processing of blocks. The data is based on the [pg_statio_all_tables](#) view. [Table G.41](#) lists columns of this report table.

Table G.41. Top tables by blocks fetched

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Heap Blks	Number of blocks fetched for the table's heap	heap_blks_read + heap_blks_hit
Heap Blks %Total	Percentage of blocks fetched for the table's heap in all blocks fetched in the cluster	
Ix Blks	Number of blocks fetched for table's indexes	idx_blks_read + idx_blks_hit
Ix Blks %Total	Percentage of blocks fetched for table's indexes in all blocks fetched in the cluster	
TOAST Blks	Number of blocks fetched for the table's TOAST table	toast_blks_read + toast_blks_hit
TOAST Blks %Total	Percentage of blocks fetched for the table's TOAST table in all blocks fetched in the cluster	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
TOAST-Ix Blks	Number of blocks fetched for the table's TOAST index	<code>tidx_blks_read + tidx_blks_hit</code>
TOAST-Ix Blks %Total	Percentage of blocks fetched for the table's TOAST index in all blocks fetched in the cluster	

The report table “Top tables by blocks read” shows top database tables by the number of blocks read for the table's heap, indexes, TOAST table (if any) and TOAST table index (if any). This can help you focus on tables with excessive block readings. The data is based on the [pg_statio_all_tables](#) view. [Table G.42](#) lists columns of this report table.

Table G.42. Top tables by blocks read

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Heap Blks	Number of blocks read for the table's heap	<code>heap_blks_read</code>
Heap Blks %Total	Percentage of blocks read from the table's heap in all blocks read in the cluster	
Ix Blks	Number of blocks read from table's indexes	<code>idx_blks_read</code>
Ix Blks %Total	Percentage of blocks read from table's indexes in all blocks read in the cluster	
TOAST Blks	Number of blocks read from the table's TOAST table	<code>toast_blks_read</code>
TOAST Blks %Total	Percentage of blocks read from the table's TOAST table in all blocks read in the cluster	
TOAST-Ix Blks	Number of blocks read from the table's TOAST index	<code>tidx_blks_read</code>
TOAST-Ix Blks %Total	Percentage of blocks read from the table's TOAST index in all blocks read in the cluster	
Hit (%)	Percentage of table, index, TOAST and TOAST index blocks got from buffers for this table in all blocks got for this table from either file system or buffers	

The report table “Top DML tables” shows top tables by the number of DML-affected rows, i.e., by the sum of `n_tup_ins`, `n_tup_upd` and `n_tup_del` (including TOAST tables). The data is based on the [pg_stat_all_tables](#) view. [Table G.43](#) lists columns of this report table.

Table G.43. Top DML tables

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Ins	Number of rows inserted	n_tup_ins
Upd	Number of rows updated, including HOT	n_tup_upd
Del	Number of rows deleted	n_tup_del
Upd (HOT)	Number of rows HOT updated	n_tup_hot_upd
SeqScan	Number of sequential scans performed on the table	seq_scan
SeqFet	Number of live rows fetched by sequential scans	seq_tup_read
IxScan	Number of index scans initiated on this table	idx_scan
IxFet	Number of live rows fetched by index scans	idx_tup_fetch

The report table “Top tables by updated/deleted tuples” shows top tables by tuples modified by UPDATE/DELETE operations, i.e., by the sum of n_tup_upd and n_tup_del (including TOAST tables). The data is based on the [pg_stat_all_tables](#) view. [Table G.44](#) lists columns of this report table.

Table G.44. Top tables by updated/deleted tuples

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Upd	Number of rows updated, including HOT	n_tup_upd
Upd (HOT)	Number of rows HOT updated	n_tup_hot_upd
Del	Number of rows deleted	n_tup_del
Vacuum Vacuum count	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
Autovacuum Vacuum count	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count
Analyze Analyze count	Number of times this table was manually analyzed	analyze_count
AutoAnalyze Analyze count	Number of times this table was analyzed by the autovacuum daemon	autoanalyze_count

The report table “Top tables by removed all-visible marks” shows top tables by the number of times that the all-visible mark was removed from the visibility map by any backend. This report section is only shown when corresponding statistics are available. [Table G.45](#) lists columns of this report table.

Table G.45. Top tables by removed all-visible marks

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
All-Visible marks cleared	Number of times that the all-visible mark was removed from the relation visibility map	rev_all_visible_pages
All-Visible marks set	Number of times that the all-visible mark was set in the relation visibility map	pages_all_visible
All-Visible marks %Set	Percentage of the number of times that the all-visible mark was set in the number of times that it was set or removed	$\text{pages_all_visible} * 100\% / (\text{rev_all_visible_pages} + \text{pages_all_visible})$
Vacuum	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
AutoVacuum	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count

The report table “Top tables by removed all-frozen marks” shows top tables by the number of times that the all-frozen mark was removed from the visibility map by any backend. This report section is only shown when corresponding statistics are available. [Table G.46](#) lists columns of this report table.

Table G.46. Top tables by removed all-frozen marks

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
All-Frozen marks cleared	Number of times that the all-frozen mark was removed from the relation visibility map	rev_all_frozen_pages
All-Frozen marks set	Number of times that the all-frozen mark was set in the relation visibility map	pages_frozen
All-Frozen marks %Set	Percentage of the number of times that the all-frozen mark was set in the number of times that it was set or removed	$\text{pages_frozen} * 100\% / (\text{rev_all_frozen_pages} + \text{pages_frozen})$

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Vacuum	Number of times this table has been manually vacuumed (not counting <code>VACUUM FULL</code>)	<code>vacuum_count</code>
AutoVacuum	Number of times this table has been vacuumed by the autovacuum daemon	<code>autovacuum_count</code>

The report table “Top tables by new-page updated tuples” shows top tables by the number of rows updated where the successor version goes onto a *new* heap page, leaving behind an original version with a `t_ctid` field that points to a different heap page. These are always non-HOT updates. [Table G.47](#) lists columns of this report table.

Table G.47. Top tables by new-page updated tuples

Column	Description
DB	Database name for the table
Tablespace	Name of the tablespace where the table is located
Schema	Schema name for the table
Table	Table name
NP Upd	Number of rows updated to a new heap page
%Upd	Number of new-page updated rows as the percentage of all rows updated
Upd	Number of rows updated, including HOT
Upd (HOT)	Number of rows HOT updated (i.e., with no separate index update required)

The report table “Top growing tables” shows top tables by growth. The data is based on the `pg_stat_all_tables` view. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. [Table G.48](#) lists columns of this report table.

Table G.48. Top growing tables

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Size	Table size at the time of the last sample in the report interval	<code>pg_table_size()</code> - <code>pg_relation_size(toast)</code>
Growth	Table growth	
Ins	Number of rows inserted	<code>n_tup_ins</code>
Upd	Number of rows updated, including HOT	<code>n_tup_upd</code>
Del	Number of rows deleted	<code>n_tup_del</code>
Upd (HOT)	Number of rows HOT updated	<code>n_tup_hot_upd</code>

In the report table “Top indexes by blocks fetched”, blocks fetched include index blocks processed from disk (read) and from shared buffers (hit). The data is based on the `pg_statio_all_indexes` view. [Table G.49](#) lists columns of this report table.

Table G.49. Top indexes by blocks fetched

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	
Scans	Number of index scans initiated on this index	idx_scan
Blks	Number of blocks fetched for this index	idx_blks_read + idx_blks_hit
%Total	Percentage of blocks fetched for this index in all blocks fetched in the cluster	

The report table “Top indexes by blocks read” is also based on the [pg_statio_all_indexes](#) and [pg_stat_all_indexes](#) views. [Table G.50](#) lists columns of this report table.

Table G.50. Top indexes by blocks read

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	
Scans	Number of index scans initiated on this index	idx_scan
Blk Reads	Number of disk blocks read from this index	idx_blks_read
%Total	Percentage of disk blocks read from this index in all disk blocks read in the cluster	
Hits(%)	Percentage of index blocks got from buffers in all index blocks got for this index	

The report table “Top growing indexes” shows top indexes by growth. The table uses data from the [pg_stat_all_tables](#) and [pg_stat_all_indexes](#) views. When there are no relation sizes collected with [pg_relation_size\(\)](#), relation-size estimates are based on the [pg_class.relpages](#) field. Since such values are less accurate, they are shown in square brackets. [Table G.51](#) lists columns of this report table.

Table G.51. Top growing indexes

Column	Description	Field/Calculation
DB	Database name for the index	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	
Index Size	Index size at the time of the last sample in the report interval	pg_relation_size()
Index Growth	Index growth during the report interval	
Table Ins	Number of rows inserted into the underlying table	n_tup_ins
Table Upd	Number of rows updated in the underlying table, without HOT	n_tup_upd - n_tup_hot_upd
Table Del	Number of rows deleted from the underlying table	n_tup_del

The report table “Unused indexes” shows top non-scanned indexes (during the report interval) by DML operations on underlying tables that caused index support. Constraint indexes are not counted. The table uses data from the `pg_stat_all_tables` view. [Table G.52](#) lists columns of this report table.

Table G.52. Unused indexes

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	
Index Size	Index size at the time of the last sample in the report interval	pg_relation_size()
Index Growth	Index growth during the report interval	
Table Ins	Number of rows inserted into the underlying table	n_tup_ins
Table Upd	Number of rows updated in the underlying table, without HOT	n_tup_upd - n_tup_hot_upd
Table Del	Number of rows deleted from the underlying table	n_tup_del

G.1.11.9. User function statistics

Tables in this section of the report show top functions in the cluster by statistics from the `pg_stat_user_functions` view. Times in the tables are provided in seconds.

The report table “Top functions by total time” shows top functions by the total time elapsed. The report table “Top functions by executions” shows top functions by the number of executions. The report table

“Top trigger functions by total time” shows top trigger functions by the total time elapsed. [Table G.53](#) lists columns of these report tables.

Table G.53. User function statistics

Column	Description	Field/Calculation
DB	Database name for the function	
Schema	Schema name for the function	
Function	Function name	
Executions	Number of times this function has been called	calls
Total Time (s)	Total time spent in this function and all other functions called by it	total_time
Self Time (s)	Total time spent in this function itself, not including other functions called by it	self_time
Mean Time (s)	Mean time of a single function execution	total_time /calls
Mean self Time (s)	Mean self time of a single function execution	self_time /calls

G.1.11.10. Vacuum-related statistics

The report table “Top tables by vacuum time spent” is available if [pgpro_stats](#) can provide extended vacuum statistics. This table shows top tables by total time spent vacuuming them. The data is based on the `pgpro_stats_vacuum_tables` view. [Table G.54](#) lists columns of this report table.

Table G.54. Top tables by vacuum time spent

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Total Vacuum time	Total time of vacuuming this table	total_time
Delay Vacuum time	Time spent sleeping in a vacuum delay point by vacuum operations performed on this table	delay_time
Vacuum Vacuum time	Total time this table was manually vacuumed. This includes the time spent sleeping due to cost-based delays.	
Autovacuum Vacuum time	Total time this table was vacuumed by the autovacuum daemon. This includes the time spent sleeping due to cost-based delays.	
Read I/O time	Time spent reading database blocks by vacuum operations performed on this table	blk_read_time

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Write I/O time	Time spent writing database blocks by vacuum operations performed on this table	blk_write_time
User CPU time	User CPU time of vacuuming tables of this database	user_time
System CPU time	System CPU time of vacuuming tables of this database	system_time
Vacuum Vacuum count	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
Autovacuum Vacuum count	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count
Total Fetched	Total number of database blocks fetched by vacuum operations performed on this table	total_blks_read + total_blks_hit
Heap Fetched	Total number of blocks fetched from this table by vacuum operations performed on it	rel_blks_read + rel_blks_hit
Scanned	Number of pages examined by vacuum operations performed on this table	pages_scanned

The report table “Top tables by analyze time spent” shows top tables by the time spent in manual and automatic analyze. [Table G.55](#) lists columns of this report table. Times are provided in seconds.

Table G.55. Top tables by analyze time spent

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Analyze Analyze time	Total time this table was manually analyzed. This includes the time spent sleeping due to cost-based delays.	
AutoAnalyze Analyze time	Total time this table was analyzed by the autovacuum daemon. This includes the time spent sleeping due to cost-based delays.	
Analyze Analyze count	Number of times this table has been manually analyzed	analyze_count
AutoAnalyze Analyze count	Number of times this table has been analyzed by the autovacuum daemon	autoanalyze_count

The report table “Top indexes by vacuum time spent” is available if [pgpro_stats](#) can provide extended vacuum statistics. This table shows top indexes by total time spent vacuuming them. The data is based on the `pgpro_stats_vacuum_indexes` view. [Table G.56](#) lists columns of this report table.

Table G.56. Top indexes by vacuum time spent

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Index	Index name	
Total Vacuum time	Total time of vacuuming this index	total_time
Delay Vacuum time	Time spent sleeping in a vacuum delay point by vacuum operations performed on this index	delay_time
Read I/O time	Time spent reading database blocks by vacuum operations performed on this index	blk_read_time
Write I/O time	Time spent writing database blocks by vacuum operations performed on this index	blk_write_time
User CPU time	User CPU time of vacuuming this index	user_time
System CPU time	System CPU time of vacuuming this index	system_time
Vacuum Vacuum count	Number of times the underlying table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
Autovacuum Vacuum count	Number of times the underlying table has been vacuumed by the autovacuum daemon	autovacuum_count
Total fetched	Total number of database blocks fetched by vacuum operations performed on the underlying table	total_blks_read + total_blks_hit
Index fetched	Total number of blocks fetched from this index by vacuum operations performed on it	rel_blks_read + rel_blks_hit

The report table “Top tables by blocks vacuum fetched” is available if [pgpro_stats](#) can provide extended vacuum statistics. This table shows top tables by blocks fetched vacuuming these tables. The data is based on the `pgpro_stats_vacuum_tables` view. [Table G.57](#) lists columns of this report table.

Table G.57. Top tables by blocks vacuum fetched

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
DB fetched	Total number of database blocks fetched by vacuum operations performed on this table	total_blks_read + total_blks_hit
%Total	Total number of database blocks fetched by vacuum operations performed on this table as the percentage of all blocks fetched in the cluster	
DB read	Total number of database blocks read by vacuum operations performed on this table	total_blks_read
%Total	Total number of database blocks read by vacuum operations performed on this table as the percentage of all blocks read in the cluster	
Heap fetched	Total number of blocks fetched from this table by vacuum operations performed on it	rel_blks_read + rel_blks_hit
%Rel	Total number of table blocks fetched by vacuum operations performed on this table as the percentage of all blocks fetched from this table	
Heap read	Total number of blocks read from this table by vacuum operations performed on it	rel_blks_read
%Rel	Total number of table blocks read by vacuum operations performed on this table as the percentage of all blocks read from this table	
Scanned	Number of pages examined by vacuum operations performed on this table	pages_scanned

The report table “Top indexes by blocks vacuum fetched” is available if [pgpro_stats](#) can provide extended vacuum statistics. This table shows top indexes by blocks fetched vacuuming underlying tables. The data is based on the `pgpro_stats_vacuum_indexes` view. [Table G.58](#) lists columns of this report table.

Table G.58. Top indexes by blocks vacuum fetched

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Index	Index name	
DB fetched	Total number of database blocks fetched by vacuum operations performed on this index	total_blks_read + total_blks_hit

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
%Total	Total number of database blocks fetched by vacuum operations performed on this index as the percentage of all blocks fetched in the cluster	
DB read	Total number of database blocks read by vacuum operations performed on this index	total_blks_read
%Total	Total number of database blocks read by vacuum operations performed on this index as the percentage of all blocks read in the cluster	
Idx fetched	Total number of blocks fetched from this index by vacuum operations on it	rel_blks_read + rel_blks_hit
%Idx	Total number of index blocks fetched by vacuum operations performed on this index as the percentage of all blocks fetched from this index	
Idx read	Total number of blocks read from this index by vacuum operations performed on it	rel_blks_read
%Idx	Total number of index blocks read by vacuum operations performed on this index as the percentage of all blocks read from this index	

The report table “Top tables by blocks vacuum read” is available if [pgpro_stats](#) can provide extended vacuum statistics. This table shows top tables by blocks read vacuuming these tables. The data is based on the `pgpro_stats_vacuum_indexes` view. [Table G.59](#) lists columns of this report table.

Table G.59. Top tables by blocks vacuum read

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
DB read	Total number of database blocks read by vacuum operations performed on this table	total_blks_read
%Total	Total number of database blocks read by vacuum operations performed on this table as the percentage of all blocks read in the cluster	
%Hit	Total number of database blocks found in shared buffers by vac-

%Idx	Total number of index blocks read by vacuum operations performed on this index as the percentage of all blocks read from this index	
%Hit	Total number of index blocks found in shared buffers by vacuum operations performed on this index as the percentage of index blocks fetched by vacuum operations performed on this index	

The report table “Top tables by dead tuples vacuum left” is available if [pgpro_stats](#) can provide extended vacuum statistics. This table shows top tables by the number of dead tuples left by vacuum due to their visibility in transactions. The data is based on the `pgpro_stats_vacuum_tables` view. [Table G.61](#) lists columns of this report table.

Table G.61. Top tables by dead tuples vacuum left

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Dead tuples left	Total number of dead tuples vacuum operations left in this table due to their visibility in transactions	dead_tuples
Dead tuples deleted	Total number of dead tuples vacuum operations deleted from this table	tuples_deleted
%Eff	Vacuum efficiency in terms of deleted tuples. This is the percentage of dead tuples deleted from this table in all dead tuples to be deleted from this table.	$\text{tuples_deleted} * 100 / (\text{tuples_deleted} + \text{dead_tuples})$
Tuples del	Number of rows deleted	<code>pg_stat_all_tables .n_tup_del</code>
Tuples upd	Number of rows updated (includes HOT updated rows)	<code>pg_stat_all_tables .n_tup_upd</code>
Vacuum	Number of times this table has been manually vacuumed (not counting <code>VACUUM FULL</code>)	<code>vacuum_count</code>
Autovacuum	Number of times this table has been vacuumed by the autovacuum daemon	<code>autovacuum_count</code>

The report table “Top tables by WAL size generated by vacuum” is available if [pgpro_stats](#) can provide extended vacuum statistics. This table shows top tables by the amount of WAL generated by vacuum

operations performed on them. The data is based on the `pgpro_stats_vacuum_tables` view. [Table G.62](#) lists columns of this report table.

Table G.62. Top tables by WAL size generated by vacuum

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
WAL size	Total amount of WAL bytes generated by vacuum operations performed on this table	<code>wal_bytes</code>
%Total	Total amount of WAL bytes generated by vacuum operations performed on this table as the percentage of all WAL generated in the cluster	
WAL FPI	Total number of WAL full page images generated by vacuum operations performed on this table	<code>wal_fpi</code>
Scanned blocks	Number of pages examined by vacuum operations performed on this table	<code>pages_scanned</code>
Dirtied blocks	Number of database blocks dirtied by vacuum operations performed on this table	<code>total_blks_dirtied</code>
Removed blocks	Number of pages removed by vacuum operations performed on this table	<code>pages_removed</code>
Vacuum	Number of times this table has been manually vacuumed (not counting <code>VACUUM FULL</code>)	<code>vacuum_count</code>
Autovacuum	Number of times this table has been vacuumed by the autovacuum daemon	<code>autovacuum_count</code>

The report table “Top tables by vacuum operations” shows top tables by the number of vacuum operations performed (`vacuum_count + autovacuum_count`). The data is based on the `pg_stat_all_tables` view. [Table G.63](#) lists columns of this report table. Times are provided in seconds.

Table G.63. Top tables by vacuum operations

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Vacuum Vacuum count	Number of times this table has been manually vacuumed (not counting <code>VACUUM FULL</code>)	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Autovacuum Vacuum count	Number of times this table has been vacuumed by the autovacuum daemon	
Vacuum Vacuum time	Total time this table was manually vacuumed. This includes the time spent sleeping due to cost-based delays.	
Autovacuum Vacuum time	Total time this table was vacuumed by the autovacuum daemon. This includes the time spent sleeping due to cost-based delays.	
Ins	Number of rows inserted	n_tup_ins
Upd	Number of rows updated (includes HOT updated rows)	n_tup_upd
Del	Number of rows deleted	n_tup_del
Upd (HOT)	Number of rows HOT updated	n_tup_hot_upd

The report table “Top tables by analyze operations” shows top tables by the number of analyze operations performed (`analyze_count + autoanalyze_count`). The data is based on the [pg_stat_all_tables](#) view. [Table G.64](#) lists columns of this report table. Times are provided in seconds.

Table G.64. Top tables by analyze operations

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Analyze Analyze count	Number of times this table has been manually analyzed	analyze_count
AutoAnalyze Analyze count	Number of times this table has been analyzed by the autovacuum daemon	autoanalyze_count
Analyze Analyze time	Total time this table was manually analyzed. This includes the time spent sleeping due to cost-based delays.	
AutoAnalyze Analyze time	Total time this table was analyzed by the autovacuum daemon. This includes the time spent sleeping due to cost-based delays.	
Ins	Number of rows inserted	n_tup_ins
Upd	Number of rows updated, including HOT	n_tup_upd
Del	Number of rows deleted	n_tup_del
Upd (HOT)	Number of rows HOT updated	n_tup_hot_upd

The report table “Top indexes by estimated vacuum load” shows top indexes by estimated implicit vacuum load. This load is calculated as the number of vacuum operations performed on the underlying table multiplied by the index size. The data is based on the [pg_stat_all_indexes](#) view. When there are no relation sizes collected with [pg_relation_size\(\)](#), relation-size estimates are based on the [pg_class.relpages](#) field. Since such values are less accurate, they are shown in square brackets. [Table G.65](#) lists columns of this report table.

Table G.65. Top indexes by estimated vacuum load

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	
~Vacuum bytes	Vacuum load estimation	$(\text{vacuum_count} + \text{autovacuum_count}) * \text{index_size}$
Vacuum Vacuum count	Number of times this table has been manually vacuumed (not counting <code>VACUUM FULL</code>)	
Autovacuum Vacuum count	Number of times this table has been vacuumed by the autovacuum daemon	
IX size	Average index size during the report interval	
Relsize	Average relation size during the report interval	

The report table “Top tables by dead tuples ratio” shows top tables larger than 5 MB by the ratio of dead tuples. Statistics are valid for the last sample in the report interval. The data is based on the [pg_stat_all_tables](#) view. When there are no relation sizes collected with [pg_relation_size\(\)](#), relation-size estimates are based on the [pg_class.relpages](#) field. Since such values are less accurate, they are shown in square brackets. [Table G.66](#) lists columns of this report table.

Table G.66. Top tables by dead tuples ratio

Column	Description	Field/Calculation
DB	Database name for the table	
Schema	Schema name for the table	
Table	Table name	
Live	Estimated number of live rows	<code>n_live_tup</code>
Dead	Estimated number of dead rows	<code>n_dead_tup</code>
%Dead	Percentage of dead rows in all table rows	
Last AV	Last time at which this table was vacuumed by the autovacuum daemon	<code>last_autovacuum</code>
Size	Table size	$\text{pg_table_size}() - \text{pg_relation_size}(\text{toast})$

The report table “Top tables by modified tuples ratio” shows top tables larger than 5 MB by the ratio of modified tuples. Statistics are valid for the last sample in the report interval. The data is based on the `pg_stat_all_tables` view. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. Table G.67 lists columns of this report table.

Table G.67. Top tables by modified tuples ratio

Column	Description	Field/Calculation
DB	Database name for the table	
Schema	Schema name for the table	
Table	Table name	
Live	Estimated number of live rows	<code>n_live_tup</code>
Dead	Estimated number of dead rows	<code>n_dead_tup</code>
Mod	Estimated number of rows modified since this table was last analyzed	<code>n_mod_since_analyze</code>
%Mod	Percentage of modified rows in all table rows	
Last AA	Last time at which this table was analyzed by the autovacuum daemon	<code>last_autoanalyze</code>
Size	Table size	<code>pg_table_size()</code> - <code>pg_relation_size(toast)</code>

G.1.11.11. Cluster settings during the report interval

This section of the report contains a table with Postgres Pro GUC parameters, values of functions `version()`, `pg_postmaster_start_time()`, `pg_conf_load_time()` and the `system_identifier` field of the `pg_control_system()` function during the report interval. The data in the table is grouped under Defined settings and Default settings. Table G.68 lists columns of this report table.

Table G.68. Cluster settings during the report interval

Column	Description
Setting	Name of the parameter
reset_val	<code>reset_val</code> field of the <code>pg_settings</code> view. Settings changed during the report interval are shown in bold font.
Unit	Unit of the setting
Source	Configuration file where this setting is defined, semicolon, line number
Notes	Timestamp of the sample where this value was first observed

G.1.11.12. Extension versions during the report interval

This section of the report contains a table that lists installed extension versions found in databases during the report interval. `First seen` and `Last seen` columns are not shown if the extension versions have not changed during the report interval. Table G.69 lists columns of this report table.

Table G.69. Extension versions during the report interval

Column	Description
Name	Extension name

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description
DB	Database name
First seen	Timestamp of the sample where this extension version appeared first
Last seen	Timestamp of the sample where this extension version appeared last
Version	Version name of the extension

G.1.12. pgpro_pwr Diagnostic Tools

pgpro_pwr provides self-diagnostic tools.

G.1.12.1. Collecting Detailed Timing Statistics for Sampling Procedures

pgpro_pwr collects detailed timing statistics of taking samples when the `pgpro_pwr.track_sample_timings` parameter is on. You can get the results from the `v_sample_timings` view. [Table G.70](#) lists columns of this view.

Table G.70. `v_sample_timings` View

Column	Description
server_name	Name of the server
sample_id	Sample identifier
sample_time	Time when the sample was taken
sampling_event	Sampling stage. See Table G.71 for descriptions of sampling stages.
time_spent	Time spent in the event

Table G.71. `sampling_event` Description

Event	Description
total	Taking the sample (all stages)
connect	Making dblink connection to the server
get server environment	Getting server GUC parameters, available extensions, etc.
collect database stats	Querying the <code>pg_stat_database</code> view for statistics on databases
calculate database stats	Calculating differential statistics on databases since the previous sample
collect tablespace stats	Querying the <code>pg_tablespace</code> view for statistics on tablespaces
collect statement stats	Collecting statistics on statements using the <code>pg-pro_stats</code> and <code>pg_stat_kcache</code> extensions
collect wait sampling stats	Collecting statistics on statements using the <code>pg_wait_sampling</code> extension
query pg_stat_bgwriter	Collecting cluster statistics using the <code>pg_stat_bgwriter</code> view
query pg_stat_wal	Collecting cluster WAL statistics using the <code>pg_stat_wal</code> view
query pg_stat_io	Collecting cluster I/O statistics using the <code>pg_stat_io</code> view

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Event	Description
query pg_stat_slru	Collecting cluster SLRU statistics using the pg_stat_slru view
query pg_stat_archiver	Collecting cluster statistics using the pg_stat_archiver view
collect object stats	<p>Collecting statistics on database objects. Includes events from Table G.72. Includes the following events:</p> <ul style="list-style-type: none"> • <code>db:dbname get extensions version</code> — Collecting the list of extension versions for the <i>dbname</i> database • <code>db:dbname collect tables stats</code> — Collecting statistics on tables for the <i>dbname</i> database • <code>db:dbname collect indexes stats</code> — Collecting statistics on indexes for the <i>dbname</i> database • <code>db:dbname collect functions stats</code> — Collecting statistics on functions for the <i>dbname</i> database • <code>analyzing collected data</code> — Analyzing partitions of collected data
processing subsamples	Collecting server process statistics using the pg_stat_activity view
disconnect	Closing dblink connection to the server
maintain repository	Executing support routines
calculate tablespace stats	Calculating differential statistics on tablespaces
calculate object stats	<p>Calculating differential statistics on database objects. Includes events from Table G.73 and more:</p> <ul style="list-style-type: none"> • <code>merge new extensions version</code> — Processing the data on extension versions • <code>merge new relation storage parameters</code> — Processing the data on relation storage parameters
calculate cluster stats	Calculating cluster differential statistics
calculate IO stats	Calculating cluster I/O differential statistics
calculate SLRU stats	Calculating cluster SLRU differential statistics
calculate WAL stats	Calculating cluster WAL differential statistics
calculate archiver stats	Calculating archiver differential statistics
delete obsolete samples	Deleting obsolete baselines and samples

Table G.72. Events of Collecting Statistics on Database Objects

Event	Description
<code>db:dbname collect tables stats</code>	Collecting statistics on tables for the <i>dbname</i> database
<code>db:dbname collect indexes stats</code>	Collecting statistics on indexes for the <i>dbname</i> database

Event	Description
<code>db:dbname collect functions stats</code>	Collecting statistics on functions for the <i>dbname</i> database

Table G.73. Events of Calculating Differences of Statistics on Database Objects

Event	Description
<code>calculate tables stats</code>	Calculating differential statistics on tables of all databases
<code>calculate indexes stats</code>	Calculating differential statistics on indexes of all databases
<code>calculate functions stats</code>	Calculating differential statistics on functions of all databases

G.1.13. Important Notes

When using the `pgpro_pwr` extension, be aware of the following:

- Postgres Pro collects execution statistics *after* the execution is complete. If a single execution of a statement lasts for several samples, it will only affect statistics of the last sample (in which the execution completed). Besides, statistics on statements that are still running are unavailable. Maintenance processes, such as vacuum and checkpoint, will update the statistics only on completion.
- Resetting any Postgres Pro statistics may affect the accuracy of the next sample.
- Exclusive locks on relations conflict with calculation of the relation size. If the `take_sample()` function is unable to acquire a lock for a short period of time (3 seconds), it will fail and no sample will be generated.

G.2. `pgpro_stats` — a means for tracking planning and execution statistics of all SQL statements executed by a server

The `pgpro_stats` extension provides a means for tracking planning and execution statistics of all SQL statements executed by a server. It is based on the `pg_stat_statements` module and provides the following additional functionality:

- Storing query plans in addition to query statements.
- Configuring sample rate for statistics collection to reduce overhead.
- Calculating wait event statistics for executed queries.
- Calculating resource usage statistics of statement planning and execution.
- Calculating cache invalidation statistics.
- Calculating additional archiver statistics.
- Providing an interface to statistics about vacuuming databases, tables, and indexes collected by the core system.
- Tracing of application sessions.
- Creating views that emulate other extensions.

Note

When the server gets shut down, `pgpro_stats` saves the collected statistics to two dump files on disk in the format that depends on the number and order of columns in the `pgpro_stats_statements`

and `pgpro_stats_totals` views. If this format has changed in a new `pgpro_stats` version, during the first server restart after upgrading the extension, the saved statistics will fail to be read with an error reported to the log:

```
LOG:  pgpro_stats: could not load statements data file of obsolete format
      "pg_stat/pgpro_stats.stat"
```

or

```
LOG:  pgpro_stats: could not load statements data file of obsolete format
      "pg_stat/pgpro_stats_totals.stat"
```

The contents of the files will be ignored, and respective statistics will be nullified. To learn whether the format has changed, see the [Release Notes](#) for `pgpro_stats` version being installed. To retain the previously collected statistics, download them as CSV files before upgrading.

The background information, along with views and types, related to calculating cache invalidation statistics is provided in a separate section [Section G.2.9](#).

G.2.1. Limitations

- `pgpro_stats` can sometimes fail to match identical parameters in the query statement and the corresponding query plan.
- Some SPI queries are not included into statistics.
- Texts and plans of some SPI queries are not normalized.
- `pgpro_stats` is incompatible with [pg_stat_statements](#), as well as other extensions that use parser, planner, or executor hooks to modify parse and plan trees and execution of the queries. Moreover, if both `pgpro_stats` and [pg_stat_statements](#) are on the list of `shared_preload_libraries`, the database server will not start. Note also that in order to dump the final versions of the queries and plans, `pgpro_stats` should be the last on the list of `shared_preload_libraries`, but some existing extensions may not work at all unless they are the last on this list.
- `pgpro_stats` may not work correctly with third-party extensions that produce `CustomScan` and `ForeignScan` nodes.

G.2.2. Installation and Setup

`pgpro_stats` is provided with Postgres Pro Standard as a separate pre-built package `pgpro-stats-std-18` (for the detailed installation instructions, see [Chapter 16](#)). Once you have `pgpro_stats` installed, complete the following steps to enable `pgpro_stats`:

1. Add `pgpro_stats` to the [shared_preload_libraries](#) parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'pgpro_stats'
```

2. Restart the Postgres Pro Standard instance for the changes to take effect.

Once the server is reloaded, `pgpro_stats` starts tracking statistics across all databases of the cluster. If required, you can change the scope of statistics collection or disable it altogether using `pgpro_stats` [configuration parameters](#).

3. To access the collected statistics, you have to create `pgpro_stats` extension:

```
CREATE EXTENSION pgpro_stats;
```

In addition, query identifier calculation must be enabled in order for `pgpro_stats` to be active, which is done automatically if [compute_query_id](#) is set to `auto` or `on`, or any third-party module that calculates query identifiers is loaded.

G.2.3. Usage

- [Collecting Statistics on Query Statements and Plans](#)
- [Monitoring Custom Metrics](#)

G.2.3.1. Collecting Statistics on Query Statements and Plans

Once installed, the `pgpro_stats` extension starts collecting statistics on the executed statements. The collected data is similar to the one provided by [pg_stat_statements](#), but also includes information on query plans and wait events for each query type. The statistics is saved into an in-memory ring buffer and is accessible through the [pgpro_stats_statements](#) view.

By default, `pgpro_stats` collects statistics on all the executed statements that satisfy the [pgpro_stats.track](#) and [pgpro_stats.track_utility](#) settings. If performance is a concern, you can set a sample rate for queries using the [pgpro_stats.query_sample_rate](#) parameter, and `pgpro_stats` will randomly select queries for statistics calculation at the specified rate.

To collect statistics on wait events, `pgpro_stats` uses time-based sampling. Wait events are sampled at the time interval specified by the [pgpro_stats.profile_period](#) parameter, which is set to 10ms by default. If the sampling shows that the process is waiting, the [pgpro_stats.profile_period](#) value is added to the wait event duration. Thus, time estimation for each wait event remains valid even if the [pgpro_stats.profile_period](#) parameter value has changed. If you are not interested in wait event statistics, you can disable wait event sampling by setting the [pgpro_stats.enable_profile](#) parameter to `false`.

`pgpro_stats_statements.plans` and `pgpro_stats_statements.calls` aren't always expected to match because planning and execution statistics are updated at their respective end phase, and only for successful operations. For example, if a statement is successfully planned but fails during the execution phase, only its planning statistics will be updated. If planning is skipped because a cached plan is used, only its execution statistics will be updated.

As an example, let's create a table with some random data and build an index on this table:

```
CREATE TABLE test AS (SELECT i, random() x FROM generate_series(1,1000000) i);
CREATE INDEX test_x_idx ON test (x);
```

Now run the following query several times using different values for `:x_min` and `:x_max`:

```
select * from test where x >= :x_min and x <= :x_max;
```

The collected statistics should appear in the `pgpro_stats_statements` view:

```
SELECT queryid, query, planid, plan, wait_stats FROM pgpro_stats_statements WHERE query
LIKE 'select * from test where%';
```

```
-[ RECORD
```

```
1 ]-----
queryid      | 1109491335754870054

wait_stats	NULL

G.2.3.2. Monitoring Custom Metrics

With `pgpro_stats`, you can define custom metrics to be monitored. The collected data will be saved into an in-memory ring buffer and then sent to a monitoring system. Unlike direct polling of a database by a monitoring system that can lose some data if the connection is interrupted, this approach allows to get all the collected data regardless of connection issues, as long as this data is still available in the ring buffer.

To set up a custom metric to collect, do the following:

1. For each metric, define all configuration parameters listed in [Section G.2.7.2](#). You must specify a unique numeric identifier of each metric in the parameter names.

For example, to monitor index bloating each 60 seconds, you can define a new metric by setting metrics-related parameters as follows:

```
pgpro_stats.metric_1_name = index_bloat
pgpro_stats.metric_1_query = 'select iname, ibloat, ipages from bloat'
pgpro_stats.metric_1_db = 'postgres'
pgpro_stats.metric_1_user = postgres
pgpro_stats.metric_1_period = '60s'
```

2. Restart the server.

`pgpro_stats` starts collecting statistics on executed statements and saves it into the ring buffer, and the collected data appears in the `pgpro_stats_metrics` view:

```
SELECT * FROM pgpro_stats_metrics;
```

Once the new metric is added, its parameters can be changed without a server restart by simply reloading the `postgresql.conf` configuration file.

3. If required, set up data export to a monitoring system of your choice.

G.2.4. Views

G.2.4.1. The `pgpro_stats_statements` View

The statistics gathered by the module are made available via a view named `pgpro_stats_statements`. This view contains one row for each distinct database ID, user ID and query ID (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in [Table G.74](#).

Table G.74. `pgpro_stats_statements` Columns

Name	Type	References	Description
<code>userid</code>	<code>oid</code>	<code>pg_authid</code> .oid	OID of user who executed the statement
<code>dbid</code>	<code>oid</code>	<code>pg_database</code> .oid	OID of database in which the statement was executed
<code>toplevel</code>	<code>bool</code>		True if the query was executed as a top-level statement (always true if <code>pgpro_stats.track</code> is set to <code>top</code>)
<code>queryid</code>	<code>bigint</code>		Internal hash code, computed from the statement's parse tree
<code>planid</code>	<code>bigint</code>		Internal hash code, computed from the statement's plan tree
<code>query</code>	<code>text</code>		Text of a representative statement
<code>plan</code>	<code>text</code>		The text of the query plan, in the format defined by the <code>pgpro_stats.plan_format</code> configuration parameter
<code>plans</code>	<code>int8</code>		Number of times the statement was planned (if <code>pgpro_stats.track_planning</code> is enabled, otherwise zero)
<code>total_plan_time</code>	<code>float8</code>		Total time spent planning the statement, in milliseconds (if <code>pgpro_stats.track_planning</code> is enabled, otherwise zero).
<code>min_plan_time</code>	<code>float8</code>		Minimum time spent planning the statement, in milliseconds (if <code>pgpro_stats.track_planning</code> is enabled, otherwise zero)
<code>max_plan_time</code>	<code>float8</code>		Maximum time spent planning the statement, in milliseconds (if <code>pg-</code>

and Extensions Shipped
as Individual Packages

Name	Type	References	Description
			<code>pro_stats.track_planning</code> is enabled, otherwise zero)
<code>mean_plan_time</code>	<code>float8</code>		Mean time spent planning the statement, in milliseconds (if <code>pgpro_stats.track_planning</code> is enabled, otherwise zero)
<code>stddev_plan_time</code>	<code>float8</code>		Population standard deviation of time spent planning the statement, in milliseconds (if <code>pgpro_stats.track_planning</code> is enabled, otherwise zero)
<code>plan_rusage</code>	pgpro_stats_rusage		Resource usage statistics of the statement planning.
<code>calls</code>	<code>int8</code>		Number of times the statement was executed
<code>total_exec_time</code>	<code>float8</code>		Total time spent executing the statement, in milliseconds
<code>min_exec_time</code>	<code>float8</code>		Minimum time spent executing the statement, in milliseconds
<code>max_exec_time</code>	<code>float8</code>		Maximum time spent executing the statement, in milliseconds
<code>mean_exec_time</code>	<code>float8</code>		Mean time spent executing the statement, in milliseconds
<code>stddev_exec_time</code>	<code>float8</code>		Population standard deviation of time spent executing the statement, in milliseconds
<code>exec_rusage</code>	pgpro_stats_rusage		Resource usage statistics of the statement execution.
<code>rows</code>	<code>int8</code>		Total number of rows retrieved or affected by the statement
<code>shared_blks_hit</code>	<code>int8</code>		Total number of shared block cache hits by the statement
<code>shared_blks_read</code>	<code>int8</code>		Total number of shared blocks read by the statement

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Name	Type	References	Description
shared_blks_dirtied	int8		Total number of shared blocks dirtied by the statement
shared_blks_written	int8		Total number of shared blocks written by the statement
local_blks_hit	int8		Total number of local block cache hits by the statement
local_blks_read	int8		Total number of local blocks read by the statement
local_blks_dirtied	int8		Total number of local blocks dirtied by the statement
local_blks_written	int8		Total number of local blocks written by the statement
temp_blks_read	int8		Total number of temp blocks read by the statement
temp_blks_written	int8		Total number of temp blocks written by the statement
shared_blk_read_time	float8		Total time the statement spent reading shared blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
shared_blk_write_time	float8		Total time the statement spent writing shared blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
local_blk_read_time	float8		Total time the statement spent reading local blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 17, contains zero.
local_blk_write_time	float8		Total time the statement spent writing local blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 17, contains zero.
temp_blk_read_time	float8		Total time the statement spent reading temp

Name	Type	References	Description
jit_optimization_time	float8		Total time spent by the statement on optimizing, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_emission_count	int8		Number of times code has been emitted by the statement. In Postgres Pro versions lower than 15, contains zero.
jit_emission_time	float8		Total time spent by the statement on emitting code, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_deform_count	int8		Total number of tuple deform functions JIT-compiled by the statement. In Postgres Pro versions lower than 17, contains zero.
jit_deform_time	float8		Total time spent by the statement on JIT-compiling tuple deform functions, in milliseconds. In Postgres Pro versions lower than 17, contains zero.
wait_stats	jsonb		A <code>jsonb</code> object containing statistics on wait events, for each execution of the query that uses the corresponding plan. Each statistic is provided in milliseconds and is a multiple of the pgpro_stats.profile_period configuration parameter.
inval_msgs	pgpro_stats_inval_msgs		Number of cache invalidation messages by type generated by the statement (if this is supported by the server, otherwise zero).
stats_since	timestamp with time zone		Time at which statistics gathering started for this statement
minmax_stats_since	timestamp with time zone		Time at which min/max statistics gathering started for this statement (fields <code>min_plan_</code>

Name	Type	References	Description
			time ,max_plan_ time ,min_exec_time and max_exec_time)

In some cases, queries with visibly different texts might get merged into a single `pgpro_stats_state-ments` entry; as explained above, this is expected to happen for semantically equivalent queries. In addition, if the only difference between queries is the number of elements in a list of constants, the list will get squashed down to a single element but shown with a commented-out list indicator:

In addition to these cases, there is a small chance of hash collisions causing unrelated queries to be merged into one entry. (This cannot happen for queries belonging to different users or databases, however.)

```
SELECT 1::int, 'abc'::VARCHAR(3), 2::int;
```

[illegible]

Replacement of numbers in plan texts has an exception for version numbers of XML documents. If in the original query such a number is represented with a constant, e.g., '1.0', it is retained as is in the plan

text rather than replaced with `$k`. If the version number of an XML document is represented with an expression, replacement of constants follows usual rules.

G.2.4.2. The `pgpro_stats_totals` View

The aggregate statistics gathered by the module are made available via a view named `pgpro_stats_totals`. This view contains one row for each distinct object (up to the maximum number of distinct objects that the module can track). The columns of the view are shown in [Table G.75](#).

Table G.75. `pgpro_stats_totals` Columns

Name	Type	Description
<code>object_type</code>	text	Type of the object for which aggregated statistics are collected: "cluster", "database", "user", "client_addr", "application", "backend", "session"
<code>object_id</code>	bigint	ID of the object: oid for databases and users, pid for backends, sid for sessions, NULL for others
<code>object_name</code>	text	Textual name of the object or NULL
<code>queries_planned</code>	int8	Number of queries planned
<code>total_plan_time</code>	float8	Total time spent in the planning of statements, in milliseconds
<code>total_plan_rusage</code>	pgpro_stats_rusage	Aggregate resource usage statistics of the statement planning
<code>queries_executed</code>	int8	Number of queries executed
<code>total_exec_time</code>	float8	Total time spent in the execution of statements, in milliseconds
<code>total_exec_rusage</code>	pgpro_stats_rusage	Aggregate resource usage statistics of the statement execution
<code>rows</code>	int8	Total number of rows retrieved or affected by the statements
<code>shared_blks_hit</code>	int8	Total number of shared block cache hits by the statements
<code>shared_blks_read</code>	int8	Total number of shared blocks read by the statements
<code>shared_blks_dirtied</code>	int8	Total number of shared blocks dirtied by the statements
<code>shared_blks_written</code>	int8	Total number of shared blocks written by the statements
<code>local_blks_hit</code>	int8	Total number of local block cache hits by the statements
<code>local_blks_read</code>	int8	Total number of local blocks read by the statements
<code>local_blks_dirtied</code>	int8	Total number of local blocks dirtied by the statements
<code>local_blks_written</code>	int8	Total number of local blocks written by the statements
<code>temp_blks_read</code>	int8	Total number of temp blocks read by the statements

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Name	Type	Description
temp_blks_written	int8	Total number of temp blocks written by the statements
shared_blk_read_time	float8	Total time the statements spent reading shared blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
shared_blk_write_time	float8	Total time the statements spent writing shared blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
local_blk_read_time	float8	Total time the statements spent reading local blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 17, contains zero.
local_blk_write_time	float8	Total time the statements spent writing local blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 17, contains zero.
temp_blk_read_time	float8	Total time the statements spent reading temp blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 15, contains zero.
temp_blk_write_time	float8	Total time the statements spent writing temp blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 15, contains zero.
wal_records	int8	Total number of WAL records generated by the statements
wal_fpi	int8	Total number of WAL full page images generated by the statements
wal_bytes	numeric	Total amount of WAL bytes generated by the statements
jit_functions	int8	Total number of functions JIT-compiled by the statements. In Postgres Pro versions lower than 15, contains zero.
jit_generation_time	float8	Total time spent by the statements on generating JIT code, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_inlining_count	int8	Number of times functions used in the statements have been in-

Name	Type	Description
		lined. In Postgres Pro versions lower than 15, contains zero.
jit_inlining_time	float8	Total time spent by the statements on inlining functions, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_optimization_count	int8	Number of times the statements have been optimized. In Postgres Pro versions lower than 15, contains zero.
jit_optimization_time	float8	Total time spent by the statements on optimizing, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_emission_count	int8	Number of times code has been emitted by the statements. In Postgres Pro versions lower than 15, contains zero.
jit_emission_time	float8	Total time spent by the statements on emitting code, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_deform_count	int8	Total number of tuple deform functions JIT-compiled by the statements. In Postgres Pro versions lower than 17, contains zero.
jit_deform_time	float8	Total time spent by the statements on JIT-compiling tuple deform functions, in milliseconds. In Postgres Pro versions lower than 17, contains zero.
wait_stats	jsonb	A <code>jsonb</code> object containing statistics on wait events for each execution of the queries. Each statistic is provided in milliseconds and is a multiple of the <code>pgpro_stats.profile_period</code> configuration parameter.
inval_msgs	pgpro_stats_inval_msgs	Number of cache invalidation messages by type generated by the statements (if this is supported by the server, otherwise zero).
cache_resets	int4	Number of shared cache resets (only for cluster, databases and backends). Gets incremented for a backend when it receives a full cache reset message.

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Name	Type	Description
stats_since	timestamp with time zone	Time at which statistics gathering started for the statements

G.2.4.3. The pgpro_stats_info View

The statistics of the `pgpro_stats` module itself are tracked and made available via a view named `pgpro_stats_info`. This view contains only a single row. The columns of the view are shown in [Table G.76](#).

Table G.76. pgpro_stats_info Columns

Name	Type	Description
dealloc	bigint	Total number of times <code>pgpro_stats_statements</code> entries about the least-executed statements were deallocated because more distinct statements than <code>pgpro_stats.max</code> were observed
stats_reset	timestamp with time zone	Time at which all statistics in the <code>pgpro_stats_statements</code> view were last reset

G.2.4.4. The pgpro_stats_metrics View

The metrics gathered by `pgpro_stats` are displayed in the `pgpro_stats_metrics` view. The table below describes the columns of the view.

Table G.77. pgpro_stats_metrics Columns

Name	Type	Description
metric_number	int4	A unique ID of the collected metric assigned by user. This ID is included into parameter names that define the metric.
metric_name	text	The name of the metric defined by the <code>pgpro_stats.metric_N_name</code> parameter
db_name	text	The name of the database for which a particular metric was collected
ts	timestampz	The time when the metric value got calculated
value	jsonb	The result of the query used for metric measurement. It is serialized in <code>jsonb</code> as an array of objects received via <code>to_jsonb(resulting_row)</code> . If an error occurs, a single object is returned that contains <code>code</code> , <code>message</code> , <code>detail</code> , and <code>hint</code> fields.

G.2.4.5. The pgpro_stats_archiver View

The `pgpro_stats_archiver` view will contain one row showing data about the archiver process of the cluster.

Table G.78. pgpro_stats_archiver Columns

Column	Type	Description
archived_count	bigint	Number of WAL files that have been successfully archived
last_archived_wal	text	Name of the last WAL file successfully archived
last_archived_time	timestamp with time zone	Time of the last successful archive operation
failed_count	bigint	Number of failed attempts for archiving WAL files
last_failed_wal	text	Name of the WAL file of the last failed archival operation
last_failed_time	timestamp with time zone	Time of the last failed archival operation
active_time	int8	Overall time that the archiver process was active
archive_command_time	int8	Overall execution time of the archive command
stats_reset	timestamp with time zone	Time at which these statistics were last reset

G.2.4.6. The pgpro_stats_vacuum_database View

Important

Starting with Postgres Pro 16, this view contains no data because the statistics to be displayed are available through the catalog view `pg_stats_vacuum_database` (see [System Views](#) for details).

The `pgpro_stats_vacuum_database` view will contain one row for each database in the current cluster, showing statistics about vacuuming that database. These statistics are collected by the core system as explained in [Section 26.2](#). The table below describes the columns of the view.

Table G.79. pgpro_stats_vacuum_database Columns

Column	Type	Description
dbid	oid	OID of a database
total_blks_read	int8	Number of database blocks read by vacuum operations performed on this database
total_blks_hit	int8	Number of times database blocks were found in the buffer cache by vacuum operations performed on this database
total_blks_dirtied	int8	Number of database blocks dirtied by vacuum operations performed on this database
total_blks_written	int8	Number of database blocks written by vacuum operations performed on this database
wal_records	int8	Total number of WAL records generated by vacuum operations performed on this database

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Type	Description
wal_fpi	int8	Total number of WAL full page images generated by vacuum operations performed on this database
wal_bytes	numeric	Total amount of WAL bytes generated by vacuum operations performed on this database
blk_read_time	float8	Time spent reading database blocks by vacuum operations performed on this database, in milliseconds (if track_io_timing is enabled, otherwise zero)
blk_write_time	float8	Time spent writing database blocks by vacuum operations performed on this database, in milliseconds (if track_io_timing is enabled, otherwise zero)
delay_time	float8	Time spent sleeping in a vacuum delay point by vacuum operations performed on this database, in milliseconds (see Section 18.10.2 for details)
system_time	float8	System CPU time of vacuuming this database, in milliseconds
user_time	float8	User CPU time of vacuuming this database, in milliseconds
total_time	float8	Total time of vacuuming this database, in milliseconds
interrupts	int4	Number of times vacuum operations performed on this database were interrupted on any errors

G.2.4.7. The `pgpro_stats_vacuum_tables` View

Important

Starting with Postgres Pro 16, this view contains no data because the statistics to be displayed are available through the catalog view `pg_stats_vacuum_tables` (see [System Views](#) for details).

The `pgpro_stats_vacuum_tables` view will contain one row for each table in the current database (including TOAST tables), showing statistics about vacuuming that specific table. These statistics are collected by the core system as explained in [Section 26.2](#). The table below describes the columns of the view.

Table G.80. `pgpro_stats_vacuum_tables` Columns

Column	Type	Description
relid	oid	OID of a table
schema	name	Name of the schema this table is in
relname	name	Name of this table

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Type	Description
total_blks_read	int8	Number of database blocks read by vacuum operations performed on this table
total_blks_hit	int8	Number of times database blocks were found in the buffer cache by vacuum operations performed on this table
total_blks_dirtied	int8	Number of database blocks dirtied by vacuum operations performed on this table
total_blks_written	int8	Number of database blocks written by vacuum operations performed on this table
rel_blks_read	int8	Number of blocks vacuum operations read from this table
rel_blks_hit	int8	Number of times blocks of this table were already found in the buffer cache by vacuum operations, so that a read was not necessary (this only includes hits in the Postgres Pro buffer cache, not the operating system's file system cache)
pages_scanned	int8	Number of pages examined by vacuum operations performed on this table
pages_removed	int8	Number of pages removed from the physical storage by vacuum operations performed on this table
pages_frozen	int8	Number of times vacuum operations marked pages of this table as all-frozen in the visibility map
pages_all_visible	int8	Number of times vacuum operations marked pages of this table as all-visible in the visibility map
tuples_deleted	int8	Number of dead tuples vacuum operations deleted from this table
tuples_frozen	int8	Number of tuples of this table that vacuum operations marked as frozen
dead_tuples	int8	Number of dead tuples vacuum operations left in this table due to their visibility in transactions
index_vacuum_count	int8	Number of times indexes on this table were vacuumed
rev_all_frozen_pages	int8	Number of times the all-frozen mark in the visibility map was removed for pages of this table

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Type	Description
rev_all_visible_pages	int8	Number of times the all-visible mark in the visibility map was removed for pages of this table
wal_records	int8	Total number of WAL records generated by vacuum operations performed on this table
wal_fpi	int8	Total number of WAL full page images generated by vacuum operations performed on this table
wal_bytes	numeric	Total amount of WAL bytes generated by vacuum operations performed on this table
blk_read_time	float8	Time spent reading database blocks by vacuum operations performed on this table, in milliseconds (if track_io_timing is enabled, otherwise zero)
blk_write_time	float8	Time spent writing database blocks by vacuum operations performed on this table, in milliseconds (if track_io_timing is enabled, otherwise zero)
delay_time	float8	Time spent sleeping in a vacuum delay point by vacuum operations performed on this table, in milliseconds (see Section 18.10.2 for details)
system_time	float8	System CPU time of vacuuming this table, in milliseconds
user_time	float8	User CPU time of vacuuming this table, in milliseconds
total_time	float8	Total time of vacuuming this table, in milliseconds
interrupts	integer	Number of times vacuum operations performed on this table were interrupted on any errors

Columns `total_*`, `wal_*` and `blk_*` include data on vacuuming indexes on this table, while columns `system_time` and `user_time` only include data on vacuuming the heap.

G.2.4.8. The `pgpro_stats_vacuum_indexes` View

Important

Starting with Postgres Pro 16, this view contains no data because the statistics to be displayed are available through the catalog view `pg_stats_vacuum_indexes` (see [System Views](#) for details).

The `pgpro_stats_vacuum_indexes` view will contain one row for each index in the current database (including TOAST table indexes), showing statistics about vacuuming that specific index. These statistics are collected by the core system as explained in [Section 26.2](#). The table below describes the columns of the view.

Table G.81. pgpro_stats_vacuum_indexes Columns

Column	Type	Description
relid	oid	OID of an index
schema	name	Name of the schema this index is in
relname	name	Name of this index
total_blks_read	int8	Number of database blocks read by vacuum operations performed on this index
total_blks_hit	int8	Number of times database blocks were found in the buffer cache by vacuum operations performed on this index
total_blks_dirtied	int8	Number of database blocks dirtied by vacuum operations performed on this index
total_blks_written	int8	Number of database blocks written by vacuum operations performed on this index
rel_blks_read	int8	Number of blocks vacuum operations read from this index
rel_blks_hit	int8	Number of times blocks of this index were already found in the buffer cache by vacuum operations, so that a read was not necessary (this only includes hits in the Postgres Pro buffer cache, not the operating system's file system cache)
pages_deleted	int8	Number of pages deleted by vacuum operations performed on this index
tuples_deleted	int8	Number of dead tuples vacuum operations deleted from this index
wal_records	int8	Total number of WAL records generated by vacuum operations performed on this index
wal_fpi	int8	Total number of WAL full page images generated by vacuum operations performed on this index
wal_bytes	numeric	Total amount of WAL bytes generated by vacuum operations performed on this index
blk_read_time	float8	Time spent reading database blocks by vacuum operations performed on this index, in milliseconds (if track_io_timing is enabled, otherwise zero)
blk_write_time	float8	Time spent writing database blocks by vacuum operations

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Type	Description
		performed on this index, in milliseconds (if track_io_timing is enabled, otherwise zero)
delay_time	float8	Time spent sleeping in a vacuum delay point by vacuum operations performed on this index, in milliseconds (see Section 18.10.2 for details)
system_time	float8	System CPU time of vacuuming this index, in milliseconds
user_time	float8	User CPU time of vacuuming this index, in milliseconds
total_time	float8	Total time of vacuuming this index, in milliseconds
interrupts	integer	Number of times vacuum operations performed on this index were interrupted on any errors

G.2.5. Data Types

G.2.5.1. The pgpro_stats_rusage Type

`pgpro_stats_rusage` is a record type that contains resource usage statistics of statement planning/execution. The fields of this type are shown in [Table G.82](#).

Table G.82. `pgpro_stats_rusage` Fields

Name	Type	Description
reads	bigint	Number of bytes read by the filesystem layer
writes	bigint	Number of bytes written by the filesystem layer
user_time	double precision	User CPU time used
system_time	double precision	System CPU time used
minflts	bigint	Number of page reclaims (soft page faults)
majflts	bigint	Number of page faults (hard page faults)
nswaps	bigint	Number of swaps
msgsnds	bigint	Number of IPC messages sent
msgrcvd	bigint	Number of IPC messages received
nsignals	bigint	Number of signals received
nvcsws	bigint	Number of voluntary context switches
nivcsws	bigint	Number of involuntary context switches

G.2.6. Functions

`pgpro_stats_statements_reset(userid Oid, dbid Oid, queryid bigint, planid bigint, minmax_only boolean)` returns timestamp with time zone

`pgpro_stats_statements_reset` discards statistics gathered so far by `pgpro_stats` corresponding to the specified `userid`, `dbid`, `queryid`, and `planid`. If any of the parameters are not specified, the default value 0(invalid) is used for each of them and the statistics that match with other parameters will be reset. If no parameter is specified or all the specified parameters are 0(invalid), it will discard all statistics. If all statistics in the `pgpro_stats_statements` view are discarded, it will also reset the statistics in the `pgpro_stats_info` view. When `minmax_only` is true only the values of minimum and maximum planning and execution time will be reset (i.e. `min_plan_time`, `max_plan_time`, `min_exec_time` and `max_exec_time` fields). The default value for `minmax_only` parameter is false. Time of last min/max reset performed is shown in `minmax_stats_since` field of the `pgpro_stats_statements` view. This function returns the time of a reset. This time is saved to `stats_reset` field of `pgpro_stats_info` view or to `minmax_stats_since` field of the `pgpro_stats_statements` view if the corresponding reset was actually performed. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

Note

As statistics in the `pgpro_stats_vacuum_database`, `pgpro_stats_vacuum_tables`, and `pgpro_stats_vacuum_indexes` views are collected by the core system, to reset them, call the `pg_stat_reset()` function (see [Section 26.2.26](#) for details).

`pgpro_stats_statements(showtext boolean)` returns setof record

The `pgpro_stats_statements` view is defined in terms of a function also named `pgpro_stats_statements`. Users can also call the `pgpro_stats_statements` function directly, and by specifying `showtext := false` make query text be omitted (that is, the `OUT` argument that corresponds to the view's `query` column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all `pgpro_stats` itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the `pgpro_stats_statements` data.

`pgpro_stats_info()` returns record

`pgpro_stats_info` view is defined in terms of a function also named `pgpro_stats_info`. Users can also call the `pgpro_stats_info` function directly.

`pgpro_stats_totals_reset(type text, id bigint)` returns timestamp with timezone

`pgpro_stats_totals_reset` discards statistics gathered so far by `pgpro_stats` corresponding to the specified object `type` and `id`. If no parameter is specified or the `type` parameter is set to 0, all statistics will be discarded. If `type` is set to a valid object type, then if `id` is specified, then statistics will be discarded only for the specified object, else, statistics will be discarded for all objects of the specified type. Otherwise, no statistics will be discarded. This function returns the time of a reset. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

`pgpro_stats_totals()` returns setof record

The `pgpro_stats_totals` view is defined in terms of a function also named `pgpro_stats_totals`. Users can also call the `pgpro_stats_totals` function directly.

`pgpro_stats_metrics()` returns setof record

Defines the `pgpro_stats_metrics` view, which is described in detail in [Table G.77](#).

`pgpro_stats_get_archiver()` returns setof record

Defines the `pgpro_stats_archiver` view, which is described in detail in [Table G.78](#).

`pgpro_stats_wal_sender_crc_errors()` returns bigint

In Postgres Pro Enterprise, returns the number of errors detected by the WAL sender process when the `wal_sender_check_crc` parameter is on. In Postgres Pro Standard, returns zero. Note that this counter is reset to zero when the cluster restarts.

`pgpro_stats_vacuum_database(dboid oid)` returns setof record

Defines the row of the `pgpro_stats_vacuum_database` view, which is described in detail in [Table G.79](#), for the database specified by `dboid`.

`pgpro_stats_vacuum_tables(dboid oid, relid oid)` returns setof record

Defines the row of the `pgpro_stats_vacuum_tables` view, which is described in detail in [Table G.80](#), for the database specified by `dboid` and table specified by `relid`. If `relid = 0`, the statistics for each table in the specified database are returned.

`pgpro_stats_vacuum_indexes(dboid oid, relid oid)` returns setof record

Defines the row of the `pgpro_stats_vacuum_indexes` view, which is described in detail in [Table G.81](#), for the database specified by `dboid` and index specified by `relid`. If `relid = 0`, the statistics for each index in the specified database are returned.

G.2.6.1. Functions for Creating Views that Emulate Other Extensions

`pgpro_stats` can create views similar to those available in [pg_stat_statements](#) and [pg_stat_kcache](#) extensions. Specifically, [pg_stat_statements](#), `pg_stat_statements_info`, `pg_stat_kcache` and `pg_stat_kcache_detail` views can be created. Each view is only created in a Postgres Pro version if it is available in `pg_stat_statements/pg_stat_kcache` extension for the same version of Postgres Pro/PostgreSQL. For example, the `pg_stat_statements_info` view is only created in Postgres Pro versions starting with 14. The following functions enable creating these views:

`pgpro_stats_create_pg_stat_statements_compatible_views()` returns void

Creates `pg_stat_statements` and `pg_stat_statements_info` views.

`pgpro_stats_create_pg_stat_kcache_compatible_views()` returns void

Creates `pg_stat_kcache` and `pg_stat_kcache_detail` views.

By default, these functions can only be executed by superusers. Access may be granted to others using `GRANT`.

To create `pg_stat_statements*` views, drop the `pg_stat_statements` extension if it was previously installed and call the function:

```
select pgpro_stats_create_pg_stat_statements_compatible_views();
```

To create `pg_stat_kcache*` views, drop the `pg_stat_kcache` extension if it was previously installed and call the function:

```
select pgpro_stats_create_pg_stat_kcache_compatible_views();
```

Once the views are created, you can work with them as if the `pg_stat_statements/pg_stat_kcache` extension is installed.

If you need to remove the views created earlier, do it in a regular way:

```
drop view pg_stat_statements;  
drop view pg_stat_statements_info;  
drop view pg_stat_kcache;  
drop view pg_stat_kcache_detail;
```

G.2.7. Configuration Parameters

G.2.7.1. General Settings

`pgpro_stats.max` (integer)

`pgpro_stats` only collects statistics about most frequent queries. The less frequently a query appears during the server operation, the less probable its inclusion in the statistics. Rare queries are almost immediately evicted from the statistics by more frequent queries. The `pgpro_stats.max` parameter defines the maximum number of unique pairs (normalized query text, normalized plan text) tracked by the module, (i.e., the maximum number of rows in the `pgpro_stats_statements` view). The larger this value, the larger the number of queries for which the information is stored. But this is achieved at the cost of reduced server performance when waiting for locks trying to access the statistics table in the shared memory and when periodically collecting garbage in the file with texts of queries and plans. The default value is 5000. This parameter can only be set at server start.

`pgpro_stats.max_totals` (integer)

`pgpro_stats.max_totals` is the maximum number of objects tracked by the module (i.e., the maximum number of rows in the `pgpro_stats_totals` view). If more distinct objects than that are observed, information about least-used objects is discarded. The default value is 1000. This parameter can only be set at server start.

`pgpro_stats.track` (enum)

`pgpro_stats.track` controls which statements are counted by the module. Specify `top` to track top-level statements (those issued directly by clients), `all` to also track nested statements (such as statements invoked within functions) with nesting level not greater than 100, or `none` to disable statement statistics collection. The default value is `top`. Only superusers can change this setting.

`pgpro_stats.track_utility` (boolean)

`pgpro_stats.track_utility` controls whether utility commands are tracked by the module. Utility commands are all those other than `SELECT`, `INSERT`, `UPDATE` and `DELETE`. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_planning` (boolean)

`pgpro_stats.track_planning` controls whether planning operations and duration are tracked by the module. Enabling this parameter may incur a noticeable performance penalty, especially when statements with identical query structure are executed by many concurrent connections which compete to update a small number of `pgpro_stats_statements` entries. The default value is `off`. Only superusers can change this setting.

`pgpro_stats.track_totals` (boolean)

`pgpro_stats.track_totals` controls whether aggregate statistics for objects (cluster, users, databases etc.) are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_cluster` (boolean)

`pgpro_stats.track_cluster` controls whether aggregate statistics for the cluster are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_databases` (boolean)

`pgpro_stats.track_databases` controls whether aggregate statistics for the databases are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_users` (boolean)

`pgpro_stats.track_users` controls whether aggregate statistics for the users are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_applications` (boolean)

`pgpro_stats.track_applications` controls whether aggregate statistics for the applications (whose names are set by `application_name`) are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_client_addr` (boolean)

`pgpro_stats.track_client_addr` controls whether aggregate statistics for the client IP addresses are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_backends` (boolean)

`pgpro_stats.track_backends` controls whether aggregate statistics for the backends are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.save` (boolean)

`pgpro_stats.save` specifies whether to save statement statistics across server shutdowns. If it is `off` then statistics are neither saved at shutdown nor reloaded at server start. The default value is `on`. This parameter can only be set in the `postgresql.conf` file or on the server command line.

`pgpro_stats.plan_format` (text)

`pgpro_stats.plan_format` selects the `EXPLAIN` format for the query plan. Possible values are `text`, `xml`, `json`, and `yaml`. The default value is `text`. Changing this parameter requires a server restart.

`pgpro_stats.enable_profile` (boolean)

`pgpro_stats.enable_profile` enables sampling of wait events for separate statements. The default value is `true`. Changing this parameter requires a server restart.

`pgpro_stats.query_sample_rate` (float)

As `pgpro_stats` only collects statistics about most frequent queries, and rare queries are not included in the statistics, you can reduce the effect of the statistics collection on the server performance. This is possible because some time later than the statistics collection starts, almost all the statistics collected by the module will contain queries that are not very infrequent, and the set of types of the collected queries will not further change much if the value of `pgpro_stats.max` is sufficient and the average frequency for most of the frequent queries has no significant changes with the periods larger than the observation time. Such a stationary distribution of collected queries can also be achieved by increasing the time of the statistics collection, for example, twice, but only adding each second query to the statistics instead of every query, or considering each query, but adding queries to the statistics randomly, with a given probability. In this example, it equals 0.5. This allows you to considerably reduce the server load at the cost of increasing the time of the statistics collection. `pgpro_stats.query_sample_rate` is the parameter to implement this approach. For example: if `pgpro_stats.query_sample_rate` is set to 0.2 (1/5), in five hours of the server operation under the above conditions, the statistics will be collected that is similar to the statistics collected with `pgpro_stats.query_sample_rate = 1` in an hour.

You can set up `pgpro_stats.query_sample_rate` by experiment. Choose the observation time depending on the environment of the server operation, for example: one hour. Look at the collected statistics an hour after the start and then an hour later without resetting the statistics. If the main difference appears to be in the increased number of collected queries (`calls`) rather than in the type of the queries, you can safely reduce `pgpro_stats.query_sample_rate` twice. In the case of a considerable difference in the types of the collected queries, increase the observation time and/or the `pgpro_stats.max` parameter.

The default value is 1.0. Changing this parameter requires a server restart.

`pgpro_stats.profile_period` (integer)

`pgpro_stats.profile_period` specifies the period, in milliseconds, during which to sample wait events. The default value is 10. Only superusers can change this setting.

`pgpro_stats.metrics_buffer_size` (integer)

`pgpro_stats.metrics_buffer_size` specifies the size of the ring buffer used for collecting statistical metrics. The default value is 16kB. Changing this parameter requires a server restart.

`pgpro_stats.metrics_workers` (integer)

`pgpro_stats.metrics_workers` specifies the number of workers used to collect statistical metrics. If this parameter is set to 2 or higher, one of the workers serves as the primary worker distributing queries to other workers. If only one worker is available, it gets reloaded to connect to different databases. Setting this parameter to 0 disables metrics collection. The default value is 2. Changing this parameter requires a server restart.

`pgpro_stats.stats_temp_directory` (string)

`pgpro_stats.stats_temp_directory` specifies the directory with the external file to store query texts. This can be a path relative to the data directory or an absolute path. Changing this parameter requires a server restart.

G.2.7.2. Metrics Settings

The following parameters can be used to define a custom metric to collect. The *N* placeholder in the parameter name serves as a unique identifier of the metric to which this setting should apply; it must be set to a non-negative integer for each metric.

When you add these parameters for a new metric, you have to restart the server for the changes to take effect. Once the new metric is added, its parameters can be changed without a server restart by simply reloading the `postgresql.conf` configuration file.

`pgpro_stats.metric_N_name` (text)

The name of metric *N*. This name will be displayed in the `metric_name` column of the `pgpro_stats_metrics` view.

`pgpro_stats.metric_N_query` (text)

The query statement that defines the metric to collect.

`pgpro_stats.metric_N_period` (integer)

The time interval at which to collect metric *N*, in milliseconds. Default: 60000 ms

`pgpro_stats.metric_N_db` (text)

The list of databases for which to collect metric *N*. Database names must be separated by commas. You can specify the `*` character to select all databases in the cluster except the template databases. If you need to analyze the template databases as well, you have to specify them explicitly.

`pgpro_stats.metric_N_user` (text)

The name of the user on behalf of which to collect metric *N*. This user must have access to the database for which the metric is collected.

G.2.8. Tracing of Application Sessions

In `pgpro_stats`, tracing of application sessions is implemented. It is based on filters, which trigger logging the execution of queries that match filtering conditions. Queries and their `EXPLAIN` output are logged in so-called *trace files* specified by the user or in the system log file (if the trace file is not specified). Filters are stored in a table located in the shared memory. The rows of this table represent filters, and the columns contain filtering conditions and `EXPLAIN` options to be used (see [EXPLAIN](#) for details). You should fill this table with filters to start tracing of queries.

Once a database administrator adds a filter in any session, all subsequent executions of queries that match the filter conditions will be traced by all sessions of the instance without a need in the server restart. In other words, filters can be added, deleted, or updated “on the fly”, and tracing with these filters immediately starts for existing and future sessions.

Note

Operations of adding, deleting, or updating filters are not transactional. Changes to the table of filters are not rolled back together with the transaction where these changes were made.

Columns of the table that stores filters are also called *filter attributes*. They are described in [Table G.83](#).

Table G.83. Filter Attributes

Name	Type	Description
filter_id	integer	Unique filter ID, which is automatically assigned to a filter when it is created, numbered from 1.
active	boolean	With the value of <code>false</code> , the filter is not active, which means that queries matching this filter are not logged. Default: <code>true</code> .
alias	name	Filter name, which can be specified for convenience. Only shown in the output of the <code>pgpro_stats_trace_show()</code> function. Default: empty string.
tracefile	name	Name of the trace file, where queries matching the filter and their <code>EXPLAIN</code> output are logged. If this filename is not specified, logging is done to the system log with the log level specified by <code>pgpro_stats.trace_log_level</code> . Trace files are created in <code>PGDATA/pg_stat</code> directory and have <code>trace</code> extension.
pid	integer	Process ID of the backend that executes the statement
database_name	name	Name of the database where the statement is executed
client_addr	name	IP address of the client connected to this backend
application_name	name	Name of the application that invoked execution of the statement
username	name	Name of the user who executes the statement
queryid	bigint	Internal hash code, computed from the statement's parse tree
planid	bigint	Internal hash code, computed from the statement's plan tree
duration	float8	Time spent in the planning and execution of the statement, in milliseconds
plan_time	float8	Time spent in the planning of the statement, in milliseconds

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Name	Type	Description
exec_time	float8	Time spent in the execution of the statement, in milliseconds
user_time	float8	User CPU time used in planning and execution of the statement
system_time	float8	System CPU time used in planning and execution of the statement
rows	int8	Total number of rows retrieved or affected by the statement
shared_blks_hit	int8	Total number of shared block cache hits by the statement
shared_blks_read	int8	Total number of shared blocks read by the statement
shared_blks_fetched	int8	Total number of shared blocks fetched from buffers by the statement
shared_blks_dirtied	int8	Total number of shared blocks dirtied by the statement
shared_blks_written	int8	Total number of shared blocks written by the statement
local_blks_hit	int8	Total number of local block cache hits by the statement
local_blks_read	int8	Total number of local blocks read by the statement
local_blks_fetched	int8	Total number of local blocks fetched from buffers by the statement
local_blks_dirtied	int8	Total number of local blocks dirtied by the statement
local_blks_written	int8	Total number of local blocks written by the statement
temp_blks_read	int8	Total number of temp blocks read by the statement
temp_blks_written	int8	Total number of temp blocks written by the statement
wal_bytes	numeric	Total amount of WAL bytes generated by the statement
total_wait_time	float8	Total time execution of this statement spent waiting
total_inval_msgs	bigint	Total number of cache invalidation messages generated by the statement (if this is supported by the server)
explain_analyze	boolean	If true, the <code>EXPLAIN</code> output will be logged with the <code>ANALYZE</code> option. By default, defined by the pgpro_stats.explain_analyze_default configuration parameter.

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Name	Type	Description
explain_verbose	boolean	If true, the <code>EXPLAIN</code> output will be logged with the <code>VERBOSE</code> option. By default, defined by the pgpro_stats.explain_verbose_default configuration parameter.
explain_costs	boolean	If true, the <code>EXPLAIN</code> output will be logged with the <code>COSTS</code> option. By default, defined by the pgpro_stats.explain_costs_default configuration parameter.
explain_settings	boolean	If true, the <code>EXPLAIN</code> output will be logged with the <code>SETTINGS</code> option. By default, defined by the pgpro_stats.explain_settings_default configuration parameter.
explain_buffers	boolean	If true, the <code>EXPLAIN</code> output will be logged with the <code>BUFFERS</code> option. By default, defined by the pgpro_stats.explain_buffers_default configuration parameter.
explain_wal	boolean	If true, the <code>EXPLAIN</code> output will be logged with the <code>WAL</code> option. By default, defined by the pgpro_stats.explain_wal_default configuration parameter.
explain_timing	boolean	If true, the <code>EXPLAIN</code> output will be logged with the <code>TIMING</code> option. By default, defined by the pgpro_stats.explain_timing_default configuration parameter.
explain_format	text	The value of the <code>FORMAT</code> option of <code>EXPLAIN</code> to be logged, which can be <code>TEXT</code> , <code>XML</code> , <code>JSON</code> , or <code>YAML</code> . By default, defined by the pgpro_stats.plan_format configuration parameter.
time_info	boolean	If true, includes additional information in the session-tracing output in the format defined by <code>explain_format : pid, duration</code> in milliseconds, start time — start time of the query execution, and <code>stop time</code> — end time of the query execution. See Example G.2 for details.

Filter attributes can be divided into the following groups:

- Control attributes, from `filter_id` to `tracefile` in [Table G.83](#).
- Identification attributes, from `pid` to `planid` in [Table G.83](#).
- Threshold attributes, from `duration` to `total_inval_msgs` in [Table G.83](#).

- Attributes that only control the output to the trace file or system log file and do not affect filtering. Most of them specify the `EXPLAIN` options. These are the attributes starting with `explain_analyze` up to the end of [Table G.83](#).

Query execution will be traced if both of these conditions are met:

- For all the specified identification attributes of the filter, the values of the respective characteristics of the query are the same as the values of these attributes.
- For all the specified threshold attributes of the filter, the values of the respective characteristics of the query are greater than or equal to the limits specified in these attributes.

It is allowed not to assign values to attributes. For all the attributes except `active`, you can also explicitly assign the value of `NULL`. If the value of a control attribute is undefined or it was explicitly set to `NULL`, this attribute will be assigned the default value shown in [Table G.83](#). For identification and threshold attributes, undefined or `NULL` values mean that queries will not be filtered by the respective characteristic. If no values are defined for all identification and all threshold attributes, all the queries are taken to be matching this filter and will be logged. If the attributes specifying `EXPLAIN` options are undefined, the default values defined by the configuration parameters will be used (see [Section G.2.8.2](#) for details).

Warning

Although when specifying a filter, you can assign values to any combination of filter attributes, bear in mind that a too general filter will lead to an excessive size of the trace file and will affect the performance more than desired as the main performance overhead is associated with writing to the trace file rather than with checking the filter conditions.

G.2.8.1. Session-Tracing Functions

Specialized functions enable creation, update and deletion of query filters:

`pgpro_stats_trace_insert(VARIADIC "any")` returns integer

Adds a filter to the list of session-tracing filters. A filter must be passed as a sequence of alternating key-value pairs, where the key is the name of the filter attribute from [Table G.83](#) except `filter_id`. For example:

```
pgpro_stats_trace_insert('pid', 42, 'database_name', 'main', 'explain_analyze',
true)
```

Key-value pairs are position-independent: they can be provided in any order, independently of the order of attributes in [Table G.83](#). Some of the attributes can be missing from the sequence. Such attributes will be assigned the default values. Returns the unique `filter_id`, which the function assigns to the added filter.

`pgpro_stats_trace_update(filter_id integer, VARIADIC "any")` returns boolean

Updates a session-tracing filter defined by `filter_id`. Filter attributes to update must be passed as a sequence of alternating key-value pairs, where the key is the name of the filter attribute from [Table G.83](#) except `filter_id`. Key-value pairs are position-independent: they can be provided in any order, independently of the order of attributes in [Table G.83](#). Filter attributes whose values are not explicitly specified will not be changed. The value of `NULL` for identification and threshold attributes resets the values of these attributes, which means that a query will match the conditions of the updated filter regardless of the respective characteristics. Returns `true` on success and `false` otherwise.

`pgpro_stats_trace_delete(filter_id integer)` returns boolean

Deletes a session-tracing filter defined by `filter_id`. Returns `true` on success and `false` otherwise.

`pgpro_stats_trace_reset()` returns integer

Removes all session-tracing filters. Returns the number of removed filters. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

`pgpro_stats_trace_show()` returns set of record

Displays the contents of the table of filters, whose columns are shown in [Table G.83](#).

G.2.8.2. Session-Tracing Configuration Parameters

The following parameters can be used to configure session-tracing logging. Note that `pgpro_stats.explain_*_default` settings define the logging behavior when the corresponding `explain_*` filter attributes (from [Table G.83](#)) are not specified or explicitly set to `NULL`.

`pgpro_stats.explain_analyze_default` (boolean)

If `true`, the `EXPLAIN` output will be logged with the `ANALYZE` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_verbose_default` (boolean)

If `true`, the `EXPLAIN` output will be logged with the `VERBOSE` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_costs_default` (boolean)

If `true`, the `EXPLAIN` output will be logged with the `COSTS` option and without it if `false`. The default value is `true`. Only superusers can change this setting.

`pgpro_stats.explain_settings_default` (boolean)

If `true`, the `EXPLAIN` output will be logged with the `SETTINGS` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_buffers_default` (boolean)

If `true`, the `EXPLAIN` output will be logged with the `BUFFERS` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_wal_default` (boolean)

If `true`, the `EXPLAIN` output will be logged with the `WAL` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_timing_default` (boolean)

If `true`, the `EXPLAIN` output will be logged with the `TIMING` option and without it if `false`. The default value is `true`. Only superusers can change this setting.

`pgpro_stats.trace_log_level` (enum)

Defines the log level at which the `EXPLAIN` output will be logged to the system log file (when the trace file is not specified). Valid values are `DEBUG5`, `DEBUG4`, `DEBUG3`, `DEBUG2`, `DEBUG1`, `INFO`, `NOTICE`, `WARNING`, and `LOG`. The default value is `LOG`.

`pgpro_stats.trace_query_text_size` (int)

Defines the maximum size of query texts in the session-tracing output, in kilobytes. If the size of the query text in kilobytes is larger, it is trimmed to the maximum size. If this parameter is not specified, the default value of zero is used, which means that the whole query texts are output.

G.2.8.3. Examples Related to Session Tracing

Example G.1. Usage of Session-Tracing Functions

Let's add the filter first:

Postgres Pro Modules and Extensions Shipped as Individual Packages

```
SELECT pgpro_stats_trace_insert('alias', 'first', 'pid', pg_backend_pid(),
    'explain_analyze', true);
```

Let's add the filter second and specify logging to the trace file second_tf.trace:

```
SELECT pgpro_stats_trace_insert('alias', 'second', 'database_name', current_database(),
    'explain_costs', false, 'tracefile', 'second_tf');
```

You can view the table with filters as follows:

```
\x auto
SELECT * from pgpro_stats_trace_show();
```

```
-[ RECORD 1 ]-----+-----
filter_id      | 1
active         | t
alias          | first
tracefile      |
pid            | 243183
database_name  |
client_addr    |
application_name |
username       |
queryid        |
planid         |
duration       |
plan_time      |
exec_time      |
user_time      |
system_time    |
rows           |
shared_blks_hit |
shared_blks_read |
shared_blks_fetched |
shared_blks_dirtied |
shared_blks_written |
local_blks_hit |
local_blks_read |
local_blks_fetched |
local_blks_dirtied |
local_blks_written |
temp_blks_read |
temp_blks_written |
wal_bytes      |
total_wait_time |
total_inval_msgs |
explain_analyze | t
explain_verbose | f
explain_costs   | t
explain_settings | f
explain_buffers | f
explain_wal     | f
explain_timing  | t
explain_format  | text
time_info       | f
-[ RECORD 2 ]-----+-----
filter_id      | 2
active         | t
alias          | second
tracefile      | second_tf
pid            |
```

Postgres Pro Modules and Extensions Shipped as Individual Packages

database_name	postgres
client_addr	
application_name	
username	
queryid	
planid	
duration	
plan_time	
exec_time	
user_time	
system_time	
rows	
shared_blks_hit	
shared_blks_read	
shared_blks_fetched	
shared_blks_dirtied	
shared_blks_written	
local_blks_hit	
local_blks_read	
local_blks_fetched	
local_blks_dirtied	
local_blks_written	
temp_blks_read	
temp_blks_written	
wal_bytes	
total_wait_time	
total_inval_msgs	
explain_analyze	f
explain_verbose	f
explain_costs	f
explain_settings	f
explain_buffers	f
explain_wal	f
explain_timing	f
explain_format	text
time_info	f

The following query matches the conditions of both filters, so it must be logged in the system log file and in the specified trace file:

```
SELECT 1 as result;
```

The following is the output to the system log file:

```
2023-04-18 04:52:53.242 MSK [63112] LOG:  Filter 1 triggered explain of the plan:
Query Text: SELECT 1 as result;
Result (cost=0.00..0.01 rows=1 width=4) (actual time=0.003..0.003 rows=1 loops=1)
```

And the following is the output to the `second_tf.trace` trace file:

```
Query Text: SELECT 1 as result;
Result
```

Let's delete the first filter:

```
SELECT pgpro_stats_trace_delete(1);
```

Let's also change `pid` to 2 for the second filter

```
SELECT pgpro_stats_trace_update(2, 'pid', 2);
```

When you execute the query

```
SELECT 2 as result;
```

it does not get logged to `second_tf.trace`.

Now let's remove all filters from the table:

```
SELECT pgpro_stats_trace_reset();
```

Example G.2. Session-Tracing Output with `time_info = true`

The following is an example of the session-tracing output in the JSON format when `time_info = true`:

```
{
  "Pid": 123456,
  "Duration ms": 0.094691,
  "Start time": "2025-01-12 15:39:27.580447+03",
  "Stop time": "2025-01-12 15:39:27.587802+03",
  "Query Text": "SELECT 2 AS Result;",
  "Plan": {
    "Node Type": "Result",
    "Parallel Aware": false,
    "Async Capable": false,
    "Startup Cost": 0.00,
    "Total Cost": 0.01,
    "Plan Rows": 1,
    "Plan Width": 4
  }
}
```

G.2.9. Cache Invalidation Metrics

Among the rest, `pgpro_stats` can collect cache invalidation statistics. This section provides some background information needed to better understand related metrics.

Each backend has its local cache, which allows you to minimize accesses for meta information on tables, for example, to the system catalogs. If a backend changes the meta information, this information must be updated in other backends' caches. This is implemented by sending invalidation messages through a queue: the backend that changed the meta information on some object sends an appropriate message to the queue.

All backends get invalidation messages from the queue. Depending on whether the object for which the invalidation message was received is cached, the backend either ignores the message (when the object is not cached) or updates its cache (when the object is cached). In `pgpro_stats`, most invalidation message counters, unless explicitly stated otherwise for certain counters, are incremented when backends just generate messages, which will only be sent to the queue upon commit of the appropriate transaction. Note that the counters will remain incremented if the transaction is rolled back, although the message will not be sent to the queue.

When a backend that is adding messages to the queue figures out that the queue size reached a certain limit, it starts a cleanup by deleting messages already processed by all backends, and if backends are found that heavily fall behind and thus delay the cleanup, they get a reset signal, which forces them to reset all their caches.

G.2.9.1. The `pgpro_stats_inval_status` View

The `pgpro_stats_inval_status` view shows one row with the current status of the cache invalidation global queue. The columns of the view are shown in [Table G.84](#).

Table G.84. `pgpro_stats_inval_status` Columns

Name	Type	Description
<code>num_inval_messages</code>	<code>int8</code>	Current number of invalidation messages in the queue

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Name	Type	Description
num_inval_queue_cleanups	int8	Number of invalidation queue cleanups done to prevent its overflow
num_inval_queue_resets	int4	Number of cache resets for backends that fail to process messages fast enough

In a working system, `num_inval_messages` usually approximately equals 4000, which means that the queue is pretty full. The speed of the `num_inval_queue_cleanups` growth is determined by how fast invalidation messages are generated. Growth of `num_inval_queue_resets` is normally zero, and non-zero growth indicates either too fast generation of messages or delays in processing messages by backends. Monitoring `num_inval_queue_cleanups` and `num_inval_queue_resets` may in some cases allow you to detect problematic backend/backends as described below.

If for a certain time interval, `num_inval_queue_cleanups` considerably increased, while `num_inval_queue_resets` did not, this indicates that invalidation messages are generated faster and/or backends process them more slowly, but backends still manage to process messages before the queue overflows.

If for a time interval, `num_inval_queue_cleanups` did not considerably increase, while `num_inval_queue_resets` did, this definitely indicates a delay in processing messages by backend(s), and the `cache_resets` column of the `pgpro_stats_totals` view allows you to figure out which backend(s) to blame.

If for a time interval, both counters considerably increased, this also indicates that invalidation messages are generated faster and/or backends process them more slowly, but this time backends fail to process messages before the queue overflows. The `cache_resets` column of the `pgpro_stats_totals` view allows you detect which backend(s) delay message processing. In this case, it is not possible to definitely conclude whether too fast generation of messages or a delay in message processing accounts for the growth of `num_inval_queue_resets`. However, the `totals` counter of the `pgpro_stats_inval_msgs` view may help here. If the change of this counter for that interval is pretty the same as for a previous interval of the same length, you can definitely conclude that the growth is caused by backend delays.

The `pgpro_stats_inval_status` view can be defined in terms of a function:

```
pgpro_stats_inval_status() returns record
```

Defines the `pgpro_stats_inval_status` view, which is described in detail in [Table G.84](#).

G.2.9.2. The `pgpro_stats_inval_msgs` Type

The `pgpro_stats_statements` and `pgpro_stats_totals` views for each corresponding object, show a record of the `pgpro_stats_inval_msgs` record type containing counters for cache invalidation messages. The fields of the type are shown in [Table G.85](#).

Table G.85. `pgpro_stats_inval_msgs` Fields

Name	Type	Description
total	bigint	Total number of invalidation messages
catcache	bigint	Number of selective catalog cache invalidation messages
catalog	bigint	Number of whole catalog cache invalidation messages
relcache	bigint	Number of selective relation cache invalidation messages

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Name	Type	Description
relcache_all	bigint	Number of whole relation cache invalidation messages
smgr	bigint	Number of invalidation messages of open relation files. Gets incremented when the messages are sent to the queue.
relmap	bigint	Number of relation map cache invalidation messages. Gets incremented when the messages are sent to the queue.
snapshot	bigint	Number of catalog snapshot invalidation messages

G.2.10. Authors

Postgres Professional, Moscow, Russia

Appendix H. Third-Party Modules and Extensions Shipped as Individual Packages

This appendix contains third-party modules and extensions that are made available in Postgres Pro Standard as individual packages. These packages are listed in [Section 16.1.5.1](#), and the documentation for each module explains which package to choose to install it. [Appendix F](#) and [Appendix G](#) cover more modules and extensions included in the Postgres Pro Standard distribution. Note also the following extensions that are shipped as individual packages: orafce, pgvector, pldebugger, and plv8 (see [Table 16.3](#) for details).

H.1. oracle_fdw — access to Oracle databases

The `oracle_fdw` module is a Postgres Pro extension that provides a Foreign Data Wrapper for easy and efficient access to Oracle databases, including pushdown of `WHERE` conditions and required columns as well as comprehensive `EXPLAIN` support.

H.1.1. Installation

The `oracle_fdw` extension is provided with Postgres Pro Standard as a separate pre-built package `oracle-fdw-std-18` (for the detailed installation instructions, see [Chapter 16](#)). `oracle_fdw` requires Oracle Instant Client version 19.5.

For RPM-based systems (RHEL, SUSE, Red OS, ROSA, ALT Linux), download the `oracle-instantclient` RPM and install it using `rpm`. If you use a Debian-based system (Ubuntu, Astra Linux), you have to either convert the RPM package to a Debian package using `alien`, and then install it using `dpkg`, or download the ZIP archive of the client and extract the contents of the archive into the `/opt/oracle` directory.

Once you have Postgres Pro Standard installed, create the `oracle_fdw` extension:

```
CREATE EXTENSION oracle_fdw;
```

That will define the required functions and create a foreign data wrapper.

Note that the extension version as shown by the `psql \dx` command or the system catalog `pg_available_extensions` is *not* the installed version of `oracle_fdw`. To get the `oracle_fdw` version, use the [oracle_diag](#) function.

H.1.2. Internals

`oracle_fdw` sets the `MODULE` of the Oracle session to `postgres` and the `ACTION` to the backend process number. This can help identifying the Oracle session and allows you to trace it with `DBMS_MONITOR.SERV_MOD_ACT_TRACE_ENABLE`.

`oracle_fdw` uses Oracle array interface to avoid unnecessary client-server round-trips. The batch size can be configured with the [prefetch](#) table option and is set to 50 by default.

Rather than using a `PLAN_TABLE` to explain an Oracle query (which would require such a table to be created in the Oracle database), `oracle_fdw` uses execution plans stored in the library cache. For that, an Oracle query is *explicitly described*, which forces Oracle to parse the query. The hard part is to find the `SQL_ID` and `CHILD_NUMBER` of the statement in `V$SQL` because the `SQL_TEXT` column contains only the first 1000 bytes of the query. Therefore, `oracle_fdw` adds a comment to the query that contains a hash of the query text. This is used to search in `V$SQL`. The actual execution plan or cost information is retrieved from `V$SQL_PLAN`.

`oracle_fdw` uses transaction isolation level `SERIALIZABLE` on the Oracle side, which corresponds to Postgres Pro's `REPEATABLE READ`. This is necessary because a single Postgres Pro statement can lead to multiple Oracle queries (e.g. during a nested loop join) and the results need to be consistent. Unfortunately, the Oracle implementation of `SERIALIZABLE` has certain quirks; see the [Problems](#) section for more.

The Oracle transaction is committed immediately before the local transaction commits, so that a completed Postgres Pro transaction guarantees that the Oracle transaction has completed. However, there is a small chance that the Postgres Pro transaction cannot complete even though the Oracle transaction is committed. This cannot be avoided without using two-phase transactions and a transaction manager, which is beyond what a foreign data wrapper can reasonably provide. Prepared statements involving Oracle are not supported for the same reason.

H.1.3. Short Simple Example

This is an example how to use `oracle_fdw`. More detailed information is provided in the sections [Options](#) and [Usage](#). You should also read the [documentation on foreign data](#) and the commands referenced there.

For the sake of this example, let's assume you can connect to Oracle as the operating system user `postgres` (or whoever starts the Postgres Pro server) with the following command:

```
sqlplus orauser/orapwd@//dbserver.mydomain.com:1521/ORADB
```

That means that the Oracle client and the environment are set up correctly. It is also assumed that `oracle_fdw` has been installed (see the [Installation](#) section).

We want to access a table defined like this:

```
SQL> DESCRIBE oratab
      Name                               Null?    Type
-----
ID                                NOT NULL NUMBER(5)
TEXT                                VARCHA2 (30)
FLOATING                           NOT NULL NUMBER(7,2)
```

Then configure `oracle_fdw` as a Postgres Pro superuser like this:

```
pgdb=# CREATE EXTENSION oracle_fdw;
pgdb=# CREATE SERVER oradb FOREIGN DATA WRAPPER oracle_fdw
      OPTIONS (dbserver '//dbserver.mydomain.com:1521/ORADB');
```

You can use other naming methods or local connections, see the description of [dbserver](#) below.

It is a good idea to use a superuser only where really necessary, so let's allow a normal user to use the foreign server (this is not required for the example to work but recommended):

```
pgdb=# GRANT USAGE ON FOREIGN SERVER oradb TO pguser;
```

Then you can connect to Postgres Pro as `pguser` and define the following:

```
pgdb=> CREATE USER MAPPING FOR pguser SERVER oradb
      OPTIONS (user 'orauser', password 'orapwd');
```

You can use external authentication to avoid storing Oracle passwords.

```
pgdb=> CREATE FOREIGN TABLE oratab (
      id          integer          OPTIONS (key 'true') NOT NULL,
      text        character varying(30),
      floating    double precision NOT NULL
    ) SERVER oradb OPTIONS (schema 'ORAUSER', table 'ORATAB');
```

Remember that the table and schema name (the latter is optional) must normally be in uppercase.

Now you can use the table like a regular Postgres Pro table.

H.1.4. Usage

H.1.4.1. Oracle Permissions

The Oracle user will need the `CREATE SESSION` privilege and the right to select from the table or view in question. Note that `oracle_fdw` accesses the Oracle table at query planning time to get its definition. This happens *before* permissions on the foreign table are checked. Consequently, you may receive an Oracle error if you try to access a foreign table on which you have no permissions in Postgres Pro. This is expected and no security problem.

For `EXPLAIN VERBOSE`, the user will also need `SELECT` privileges on `V$SQL` and `V$SQL_PLAN`.

H.1.4.2. Connections

`oracle_fdw` caches Oracle connections because it is expensive to create an Oracle session for each individual query. All connections are automatically closed when the Postgres Pro session ends.

The `close_connections` function can be used to close all cached Oracle connections. This can be useful for long-running sessions that do not access foreign tables all the time and want to avoid blocking the resources needed by an open Oracle connection. You cannot call this function inside a transaction that modifies Oracle data.

H.1.4.3. Columns

When you define a foreign table, the columns of the Oracle table are mapped to the Postgres Pro columns in the order of their definition.

`oracle_fdw` will only include those columns in the Oracle query that are actually needed by the Postgres Pro query.

The Postgres Pro table can have more or less columns than the Oracle table. If it has more columns, and these columns are used, you will receive a warning and `NULL` values will be returned.

If you want to `UPDATE` or `DELETE`, make sure that the `key` option is set on all columns that belong to the table's primary key. Failure to do so will result in errors.

H.1.4.4. Data Types

You must define the Postgres Pro columns with data types that `oracle_fdw` can translate (see the conversion table below). This restriction is only enforced if the column actually gets used, so you can define “dummy” columns for untranslatable data types as long as you don't access them (this trick only works with `SELECT`, not when modifying foreign data). If an Oracle value exceeds the size of the Postgres Pro column (e.g., the length of a `varchar` column or the maximal `integer` value), you will receive a runtime error.

These conversions are automatically handled by `oracle_fdw`:

Oracle type	Possible PostgreSQL types
CHAR	char, varchar, text
NCHAR	char, varchar, text
VARCHAR	char, varchar, text
VARCHAR2	char, varchar, text, json
NVARCHAR2	char, varchar, text
CLOB	char, varchar, text, json
LONG	char, varchar, text
RAW	uuid, bytea
BLOB	bytea

BFILE	bytea (read-only)
LONG RAW	bytea
NUMBER	numeric, float4, float8, char, varchar, text
NUMBER(n,m) with m<=0	numeric, float4, float8, int2, int4, int8, boolean, char, varchar, text
FLOAT	numeric, float4, float8, char, varchar, text
BINARY_FLOAT	numeric, float4, float8, char, varchar, text
BINARY_DOUBLE	numeric, float4, float8, char, varchar, text
DATE	date, timestamp, timestamptz, char, varchar, text
TIMESTAMP	date, timestamp, timestamptz, char, varchar, text
TIMESTAMP WITH TIME ZONE	date, timestamp, timestamptz, char, varchar, text
TIMESTAMP WITH LOCAL TIME ZONE	date, timestamp, timestamptz, char, varchar, text
INTERVAL YEAR TO MONTH	interval, char, varchar, text
INTERVAL DAY TO SECOND	interval, char, varchar, text
XMLTYPE	xml, char, varchar, text
MDSYS.SDO_GEOMETRY	geometry (see "PostGIS support" below)

If a NUMBER is converted to a boolean, 0 means false, everything else true.

Inserting or updating XMLTYPE only works with values that do not exceed the maximum length of the VARCHAR2 data type (4000 or 32767, depending on the MAX_STRING_SIZE parameter).

NCLOB is currently not supported because Oracle cannot automatically convert it to the client encoding.

If you want to convert TIMESTAMP WITH LOCAL TIME ZONE to timestamp, consider setting the set_time-zone option on the foreign server.

If you need conversions exceeding the above, define an appropriate view in Oracle or Postgres Pro.

H.1.4.5. WHERE Conditions and ORDER BY Clauses

Postgres Pro will use all applicable parts of the WHERE clause as a filter for the scan. The Oracle query that oracle_fdw constructs will contain a WHERE clause corresponding to these filter criteria whenever such a condition can safely be translated to Oracle SQL. This feature, also known as *push-down* of WHERE clauses, can greatly reduce the number of rows retrieved from Oracle and may enable Oracle's optimizer to choose a good plan for accessing the required tables.

Similarly, ORDER BY clauses will be pushed down to Oracle wherever possible. Note that no ORDER BY condition that sorts by a character string will be pushed down as the sort orders in Postgres Pro and Oracle cannot be guaranteed to be the same.

To make use of that, try to use simple conditions for the foreign table. Choose Postgres Pro column data types that correspond to Oracle's types because otherwise conditions cannot be translated.

The expressions now(), transaction_timestamp(), current_timestamp, current_date, and local-timestamp will be translated correctly.

The output of EXPLAIN will show the Oracle query used so you can see which conditions were translated to Oracle and how.

H.1.4.6. Joins Between Foreign Tables

oracle_fdw can push down joins to the Oracle server, that is, a join between two foreign tables will lead to a single Oracle query that performs the join on the Oracle side.

There are some restrictions when this can happen:

- Both tables must be defined on the same foreign server.
- Joins between three or more tables won't be pushed down.

- The join must be in a `SELECT` statement.
- `oracle_fdw` must be able to push down all join conditions and `WHERE` clauses.
- Cross joins without join conditions are not pushed down.
- If a join is pushed down, `ORDER BY` clauses will not be pushed down.

It is important that table statistics for both foreign tables have been collected with `ANALYZE` for Postgres Pro to determine the best join strategy.

H.1.4.7. Modifying Foreign Data

`oracle_fdw` supports `INSERT`, `UPDATE`, and `DELETE` on foreign tables. This is allowed by default (also in databases upgraded from an earlier Postgres Pro release) and can be disabled by setting the `readonly` table option.

For `UPDATE` and `DELETE` to work, the columns corresponding to the primary key columns of the Oracle table must have the `key` column option set. These columns are used to identify a foreign table row, so make sure that the option is set on *all* columns that belong to the primary key.

If you omit a foreign table column during `INSERT`, that column is set to the value defined in the `DEFAULT` clause on the Postgres Pro foreign table (or `NULL` if there is no `DEFAULT` clause). `DEFAULT` clauses on the corresponding Oracle columns are not used. If the Postgres Pro foreign table does not include all columns of the Oracle table, the Oracle `DEFAULT` clauses will be used for the columns not included in the foreign table definition.

The `RETURNING` clause on `INSERT`, `UPDATE` and `DELETE` is supported except for columns with Oracle data types `LONG` and `LONG RAW` (Oracle doesn't support these data types in the `RETURNING` clause).

Triggers on foreign tables are supported. Triggers defined with `AFTER` and `FOR EACH ROW` require that the foreign table has no columns with Oracle data type `LONG` or `LONG RAW`. This is because such triggers make use of the `RETURNING` clause mentioned above.

While modifying foreign data works, the performance is not particularly good, specifically when many rows are affected, because (owing to the way foreign data wrappers work) each row has to be treated individually.

Transactions are forwarded to Oracle so `BEGIN`, `COMMIT`, `ROLLBACK`, and `SAVEPOINT` work as expected. Prepared statements involving Oracle are not supported. See the [Internals](#) section for details.

Since `oracle_fdw` uses serialized transactions by default, it is possible that data modifying statements lead to a serialization failure:

```
ORA-08177: can't serialize access for this transaction
```

This can happen if concurrent transactions modify the table and gets more likely in long running transactions. Such errors can be identified by their `SQLSTATE` (40001). An application using `oracle_fdw` should retry transactions that fail with this error.

It is possible to use a different transaction isolation level, see [Foreign Server Options](#) for a discussion.

H.1.4.8. EXPLAIN

Postgres Pro's `EXPLAIN` will show the query that is actually issued to Oracle. `EXPLAIN VERBOSE` will show Oracle's execution plan (that will not work with Oracle server 9i or older, see [Problems](#)).

H.1.4.9. ANALYZE

You can use `ANALYZE` to gather statistics on a foreign table. This is supported by `oracle_fdw`.

Without statistics, Postgres Pro has no way to estimate the row count for queries on a foreign table, which can cause bad execution plans to be chosen.

Postgres Pro will *not* automatically gather statistics for foreign tables with the autovacuum daemon like it does for normal tables, so it is particularly important to run `ANALYZE` on foreign tables after creation and whenever the remote table has changed significantly.

Keep in mind that analyzing an Oracle foreign table will result in a full sequential table scan. You can use the table option `sample_percent` to speed this up by using only a sample of the Oracle table.

H.1.4.10. PostGIS Support

The data type `geometry` is only available when PostGIS is installed.

The only supported geometry types are `POINT`, `LINE`, `POLYGON`, `MULTIPOINT`, `MULTILINE`, and `MULTIPOLYGON` in two and three dimensions. Empty PostGIS geometries are not supported because they have no equivalent in Oracle Spatial.

NULL values for Oracle `SRID` will be converted to 0 and vice versa. For other conversions between Oracle `SRID` and PostGIS `SRID`, create a file `srid.map` in the Postgres Pro `share` directory. Each line of this file shall contain an Oracle `SRID` and the corresponding PostGIS `SRID`, separated by a whitespace. Keep the file small for good performance.

H.1.4.11. Support for `IMPORT FOREIGN SCHEMA`

`IMPORT FOREIGN SCHEMA` is supported to bulk import table definitions for all tables in an Oracle schema. In addition to the documentation of `IMPORT FOREIGN SCHEMA`, consider the following:

- `IMPORT FOREIGN SCHEMA` will create foreign tables for all objects found in `ALL_TAB_COLUMNS`. That includes tables, views and materialized views, but not synonyms.
- These are the supported options for `IMPORT FOREIGN SCHEMA`:
 - `case` controls case folding for table and column names during import.

The possible values are:

- `keep`: leave the names as they are in Oracle, usually in upper case.
- `lower`: translate all table and column names to lower case.
- `smart`: only translate names that are all upper case in Oracle (this is the default).
- `collation` is the collation used for case folding for the `lower` and `smart` options of `case`.

The default value is `default`, which is the database's default collation. Only collations in the `pg_catalog` schema are supported. See the `collname` values in the `pg_collation` catalog for a list of possible values.

- `dblink` is the Oracle database link through which the schema is accessed.

This name must be written exactly as it occurs in Oracle's system catalog so normally consist of uppercase letters only.

- `readonly` sets the `readonly` option on all imported tables.
- `skip_tables` (default `false`): don't import tables.
- `skip_views` (default `false`): don't import views.
- `skip_matviews` (default `false`): don't import materialized views.
- `max_long` sets the `max_long` option on all imported tables.
- `sample_percent` sets the `sample_percent` option on all imported tables.
- `prefetch` sets the `prefetch` option on all imported tables.
- `lob_prefetch` sets the `lob_prefetch` option on all imported tables.
- `nchar` sets the `nchar` option on all imported tables.

- `set_timezone` sets the [set_timezone](#) option on all imported tables.
- The Oracle schema name must be written exactly as it is in Oracle, so normally in upper case. Since Postgres Pro translates names to lower case before processing, you must protect the schema name with double quotes (for example, "SCOTT").
- Table names in the `LIMIT TO` or `EXCEPT` clause must be written as they will appear in Postgres Pro after the case folding described above.

Note that `IMPORT FOREIGN SCHEMA` does not work with Oracle server 8i; see the [Problems](#) section for details.

H.1.5. Reference

H.1.5.1. Objects Created by the Extension

```
oracle_fdw_handler() RETURNS fdw_handler  
oracle_fdw_validator(text[], oid) RETURNS void
```

These functions are the handler and validator functions necessary to create a foreign data wrapper.

```
FOREIGN DATA WRAPPER oracle_fdw  
  HANDLER oracle_fdw_handler  
  VALIDATOR oracle_fdw_validator
```

The extension automatically creates a foreign data wrapper named `oracle_fdw`. Normally, that's all you need, and you can proceed to define foreign servers. You can create additional Oracle foreign data wrappers, for example, if you need to set the [nls_lang](#) option (you can alter the existing `oracle_fdw` wrapper, but all modifications will be lost after a dump/restore).

```
oracle_close_connections() RETURNS void
```

This function can be used to close all open Oracle connections in this session. See [Usage](#) for further description.

```
oracle_diag(name DEFAULT NULL) RETURNS text
```

This function is useful for diagnostic purposes only. It will return the versions of `oracle_fdw`, Postgres Pro server, and Oracle client. If called with no argument or `NULL`, it will additionally return the values of some environment variables used for establishing Oracle connections. If called with the name of a foreign server, it will additionally return the Oracle server version.

```
oracle_execute(server name, stmt text) RETURNS void
```

This function can be used to execute arbitrary SQL statements on the remote Oracle server. That will only work with statements that do not return results (typically DDL statements).

Be careful when using this function since it might disturb the transaction management of `oracle_fdw`. Remember that running a DDL statement in Oracle will issue an implicit `COMMIT`. You are best advised to use this function outside of multi-statement transactions.

H.1.5.2. Options

H.1.5.2.1. Foreign Data Wrapper Options

Important

If you modify the default foreign data wrapper `oracle_fdw`, any changes will be lost upon dump/restore. Create a new foreign data wrapper if you want the options to be persistent. The SQL script shipped with the software contains a `CREATE FOREIGN DATA WRAPPER` statement you can use.

[nls_lang]

Sets the `NLS_LANG` environment variable for Oracle to this value. `NLS_LANG` is in the form *language_territory.charset* (for example, `AMERICAN_AMERICA.AL32UTF8`). This must match your database encoding. When this value is not set, `oracle_fdw` will automatically do the right thing if it can and issue a warning if it cannot. Set this only if you know what you are doing. See the [Problems](#) section.

H.1.5.2.2. Foreign Server Options

dbserver

The Oracle database connection string for the remote database. This can be in any of the forms that Oracle supports as long as your Oracle client is configured accordingly. Set this to an empty string for local (`BEQUEATH`) connections.

[isolation_level]

The transaction isolation level to use at the Oracle database. The value can be `serializable`, `read_committed`, or `read_only`. The default is `serializable`.

Note that the Oracle table can be queried more than once during a single Postgres Pro statement (for example, during a nested loop join). To make sure that no inconsistencies caused by race conditions with concurrent transactions can occur, the transaction isolation level must guarantee read stability. This is only guaranteed with Oracle's `SERIALIZABLE` or `READ ONLY` isolation levels.

Unfortunately Oracle's implementation of `SERIALIZABLE` is rather bad and causes serialization errors (ORA-08177) in unexpected situations, like inserts into the table. Using `READ COMMITTED` transactions works around this problem, but *there is a risk of inconsistencies*. If you want to use it, check your execution plans if the foreign scan could be executed more than once.

[nchar]

Setting this option to `on` chooses a more expensive character conversion on the Oracle side. This is required if Oracle tables have `NCHAR` or `NVARCHAR2` columns that contain characters that cannot be represented in the Oracle database character set. The default is `off`.

Setting `nchar` to `on` has a noticeable performance impact, and it causes ORA-01461 errors with `UPDATE` statements that set strings over 2000 bytes (or 16383 if you have `MAX_STRING_SIZE = EXTENDED`). This error seems to be an Oracle bug.

[set_timezone]

Setting this option to `on` sets the Oracle session time zone to the current value of the Postgres Pro parameter `timezone` when the connection to Oracle is made. This is only useful if you plan to use Oracle columns of type `TIMESTAMP WITH LOCAL TIME ZONE` and want to translate them to `timestamp without time zone` in Postgres Pro. The default is `off`.

Note that if you change `timezone` after the Oracle connection has been established, `oracle_fdw` will not change the Oracle session time zone. You can call `oracle_close_connections()` `RETURNS void` in that case so that a new connection is opened the next time you access a foreign table.

If Oracle does not recognize the time zone, connections will fail with an error like “ORA-01882: timezone region not found”.

In that case, either use a different `timezone` or leave the option set to `off` and set the environment variable `ORA_SDTZ` to an appropriate value in the environment of the Postgres Pro server.

H.1.5.2.3. User Mapping Options

user

The Oracle user name for the session. Set this to an empty string for *external authentication* if you don't want to store Oracle credentials in the Postgres Pro database (one simple way is to use an *external password store*).

password

The password for the Oracle user.

H.1.5.2.4. Foreign Table Options

table

The Oracle table name. This name must be written exactly as it occurs in Oracle's system catalog so normally consist of uppercase letters only.

To define a foreign table based on an arbitrary Oracle query, set this option to the query enclosed in parentheses:

```
OPTIONS (table '(SELECT col FROM tab WHERE val = ''string''))
```

Do not set the [schema](#) option in this case. INSERT, UPDATE, and DELETE will work on foreign tables defined on simple queries; if you want to avoid that (or confusing Oracle error messages for more complicated queries), use the table option [readonly](#).

dblink

The Oracle database link through which the table is accessed. This name must be written exactly as it occurs in Oracle's system catalog so normally consist of uppercase letters only.

[schema]

The table's schema (or owner). Useful to access tables that do not belong to the connecting Oracle user. This name must be written exactly as it occurs in Oracle's system catalog so normally consist of uppercase letters only.

[max_long]

The maximal length of any LONG, LONG RAW, and XMLTYPE columns in the Oracle table. Possible values are integers between 1 and 1073741823 (the maximal size of a `bytea` in Postgres Pro). This amount of memory will be allocated at least twice so large values will consume a lot of memory. If [max_long](#) is less than the length of the longest value retrieved, you will receive the error message “ORA-01406: fetched column value was truncated”. The default is 32767.

[readonly]

INSERT, UPDATE, and DELETE are only allowed on tables where this option is not set to yes/on/true. The default is false.

[sample_percent]

This option only influences ANALYZE processing and can be useful to ANALYZE very large tables in a reasonable time.

The value must be between 0.000001 and 100 and defines the percentage of Oracle table blocks that will be randomly selected to calculate Postgres Pro table statistics. This is accomplished using the `SAMPLE BLOCK (x)` clause in Oracle. The default is 100.

ANALYZE will fail with ORA-00933 for tables defined with Oracle queries and may fail with ORA-01446 for tables defined with complex Oracle views.

[prefetch]

Sets the number of rows that will be fetched with a single round-trip between Postgres Pro and Oracle during a foreign table scan. The value must be between 1 and 1000, where a value of zero disables prefetching. The default is 50.

Higher values can speed up performance but will use more memory on the Postgres Pro server.

Note that there is no prefetching if the Oracle table contains columns of the type `MDSYS.SDO_GEOMETRY`.

[lob_prefetch]

Sets the number of bytes that are prefetched for `BLOB`, `CLOB`, and `BFILE` values. LOBs that exceed that size will require additional round trips between Postgres Pro and Oracle so setting this value bigger than the size of your typical LOB will be good for performance. Choosing bigger values for this option can allocate more memory on the server side but will boost performance for large LOBs. The default is 1048576.

H.1.5.2.5. Column Options

[key]

If set to `yes/on/true`, the corresponding column on the foreign Oracle table is considered a primary key column. For `UPDATE` and `DELETE` to work, you must set this option on all columns that belong to the table's primary key. The default is `false`.

[strip_zeros]

If set to `yes/on/true`, ASCII 0 characters will be removed from the string during transfer. Such characters are valid in Oracle but not in Postgres Pro so they will cause an error when read by `oracle_fdw`. This option only makes sense for `character`, `character varying`, and `text` columns. The default is `false`.

H.1.6. Problems

H.1.6.1. Encoding

Characters stored in an Oracle database that cannot be converted to the Postgres Pro database encoding will silently be replaced by replacement characters, typically a normal or inverted question mark, by Oracle. You will get no warning or error messages.

If you use a Postgres Pro database encoding that Oracle does not know (currently these are `EUC_CN`, `EUC_KR`, `LATIN10`, `MULE_INTERNAL`, `WIN874`, and `SQL_ASCII`), non-ASCII characters cannot be translated correctly. You will get a warning in this case, and the characters will be replaced by replacement characters as described above.

You can set the `nls_lang` option of the foreign data wrapper to force a certain Oracle encoding, but the resulting characters will most likely be incorrect and lead to Postgres Pro error messages. This is probably only useful for `SQL_ASCII` encoding if you know what you are doing.

H.1.6.2. Limited Functionality in Old Oracle Versions

The definition of the Oracle system catalogs `V$SQL` and `V$SQL_PLAN` has changed with Oracle 10.1. Using `EXPLAIN VERBOSE` with older Oracle server versions will result in errors like:

```
ERROR:  error describing query: OCISmtExecute failed to execute
        remote query for sql_id
DETAIL:  ORA-00904: "LAST_ACTIVE_TIME": invalid identifier
```

There is no plan to fix this, since Oracle 9i has been out of Extended Support since 2010 and the functionality is not essential.

`IMPORT FOREIGN SCHEMA` throws the following error with Oracle server 8i:

```
ERROR:  error importing foreign schema: OCISmtExecute failed to execute
        column query
DETAIL:  ORA-00904: invalid column name
```

This is because the view `ALL_TAB_COLUMNS` lacks the column `CHAR_LENGTH`, which was added in Oracle 9i.

H.1.6.3. LDAP Libraries

The Oracle client shared library comes with its own LDAP client implementation conforming to [RFC 1823](#) so these functions have the same names as OpenLDAP's. This will lead to a name collision when the Postgres Pro server was configured `--with-ldap`.

The name collision will not be detected because `oracle_fdw` is loaded at runtime, but trouble will happen if anybody calls an LDAP function. Typically, OpenLDAP is loaded first so if Oracle calls an LDAP function (for example, if you use *directory naming* name resolution), the backend will crash. This can lead to messages like the following (seen on Linux) in the Postgres Pro server log:

```
../../../../libraries/libldap/getentry.c:29: ldap_first_entry:  
Assertion `( (ld)->ld_options.ldo_valid == 0x2 )' failed.
```

Since Postgres Pro is built `--with-ldap`, it may work as long as you don't use any LDAP client functionality in Oracle. On some platforms, you can force Oracle's client shared library to be loaded before the Postgres Pro server is started (`LD_PRELOAD` on Linux). Then Oracle's LDAP functions should get used. In that case, Oracle may be able to use LDAP functionality, but using LDAP from Postgres Pro will crash the backend.

You cannot use LDAP functionality both in Postgres Pro and in Oracle.

H.1.6.4. Serialization Errors

In Oracle 11.2 or above, inserting the first row into a newly created Oracle table with `oracle_fdw` will lead to a serialization error.

This is because of an Oracle feature called *deferred segment creation*, which defers allocation of storage space for a new table until the first row is inserted. This causes a serialization failure with serializable transactions.

This is no serious problem; you can work around it by either ignoring that first error or creating the table with `SEGMENT CREATION IMMEDIATE`.

A much nastier problem is that concurrent inserts can sometimes cause serialization errors when an index page is split concurrently with a modifying serializable transaction.

Oracle claims that this is not a bug, and the suggested solution is to retry the transaction that got a serialization error.

H.1.6.5. Oracle Bugs

This is the list of Oracle bugs that affect or have affected `oracle_fdw` in the past.

Bug 2728408 can cause “ORA-8177 cannot serialize access for this transaction” even if no modification of remote data is attempted. It can occur with Oracle server 8.1.7.4 (install one-off patch 2728408) or Oracle server 9.2 (install Patch Set 9.2.0.4 or better).

Oracle client 21c is known not to work for `CLOB` columns (they appear empty). There is no ultimate proof that that is an Oracle bug, but other versions are working fine.

H.1.7. Authors

Laurenz Albe, with notable contributions from Vincent Mora of Oslandia and Tatsuro Yamada of the NTT OSS Center.

H.2. `tds_fdw` — connect to databases that use the TDS protocol

The `tds_fdw` module provides the foreign data wrapper `tds_fdw`, which can connect to databases that use the Tabular Data Stream (TDS) protocol, such as [Sybase](#) databases and [Microsoft SQL Server](#).

This foreign data wrapper requires a library that implements the DB-Library interface, such as FreeTDS. This has been tested with FreeTDS, but not the proprietary implementations of DB-Library.

H.2.1. Limitations

- Unlike `WHERE` and column pushdowns, which are supported when `match_column_names` is enabled, `JOIN` pushdown or write operations are not supported.
- DML operations `INSERT`, `UPDATE`, and `DELETE` with foreign tables are not supported.

H.2.2. Installing `tds_fdw`

`tds_fdw` is provided with Postgres Pro Standard as a separate pre-built package `tds-fdw` (for the detailed installation instructions, see [Chapter 16](#)).

Install the `tds_fdw` extension using [CREATE EXTENSION](#).

H.2.3. Configuring `tds_fdw`

H.2.3.1. Managing Character Sets/Encoding

Although many newer versions of the TDS protocol will only use USC-2 to communicate with the server, FreeTDS converts the UCS-2 to the client character set of your choice. To set the client character set, you can set `client charset` in `freetds.conf`. See [The `freetds.conf` File](#) and [Localization and TDS 7.0](#) for details.

You may need more configuring in case you get an error like this with Microsoft SQL Server when working with Unicode data:

```
NOTICE: DB-Library notice: Msg #: 4004, Msg state: 1, Msg: Unicode data in a Unicode-only
collation or ntext data cannot be sent to clients using DB-Library (such as ISQL) or ODBC
version 3.7 or earlier., Server: PILLIUM\SQLEXPRESS, Process: , Line: 1, Level: 16
```

```
ERROR: DB-Library error: DB #: 4004, DB Msg: General SQL Server error: Check messages
from the SQL Server, OS #: -1, OS Msg: (null), Level: 16
```

In this case, you may have to manually set `tds version` in `freetds.conf` to 7.0 or higher. See [The `freetds.conf` File](#) and [Choosing a TDS protocol version](#) for details.

H.2.3.2. Configuring Encrypted Connections to MSSQL

This needs to be configured at the `freetds.conf`. See [The `freetds.conf` File](#) and under `freetds.conf` settings, look for encryption.

H.2.4. Usage

To prepare for database access using `tds_fdw`:

1. Create a foreign server object, using [CREATE SERVER](#), to represent each database you want to connect to.
2. Create a user mapping, using [CREATE USER MAPPING](#), for each database user you want to allow to access each foreign server.
3. Create a foreign table, using [CREATE FOREIGN TABLE](#) or [IMPORT FOREIGN SCHEMA](#), for each table you want to access.

H.2.4.1. Creating a Foreign Server

To create a foreign server, execute the [CREATE SERVER](#) command providing the following options:

`servername`

The `servername`, address or hostname of the foreign server. This can be a DSN, as specified in `freetds.conf`. See [FreeTDS name lookup](#) for details. You can set this option to a comma-separated

list of server names, then each server is tried until the first connection succeeds. This is useful for automatic failover to a secondary server.

Required: Yes

Default: 127.0.0.1

port

The port of the foreign server. Instead of providing a port here, it can be specified in `freetds.conf` (if `servername` is a DSN).

Required: No

database

The database to connect to for this server

Required: No

dbuse

If `dbuse` is 0, `tds_fdw` will connect directly to `database`. If `dbuse` is not 0, `tds_fdw` will connect to the server's default database and then select the database by calling the DB-Library's `dbuse()` function. For Azure, `dbuse` currently needs to be set to 0.

Required: No

Default: 0

language

The language to use for messages and the locale to use for date formats. FreeTDS may default to U.S. English on most systems. You can probably also change this in `freetds.conf`. For information related to this for MS SQL Server, see [SET LANGUAGE in MS SQL Server](#). For information related to Sybase ASE, see [Sybase ASE login options](#) and [SET LANGUAGE in Sybase ASE](#).

Required: No

character_set

The client character set to use for the connection if you need to set this for some reason. For TDS protocol versions 7.0+, the connection always uses UCS-2, so this parameter does nothing in those cases. See [Localization and TDS 7.0](#) for details.

Required: No

tds_version

The version of the TDS protocol to use for this server. See [Choosing a TDS protocol version](#) and [History of TDS Versions](#) for details.

Required: No

msg_handler

The function used for the TDS message handler. Can be one of the following values:

- `notice`: TDS messages are turned into PostgreSQL notices
- `blackhole`: TDS messages are ignored

Required: No

Default: `blackhole`

fdw_startup_cost

A cost that is used in query planning to represent the overhead of using this foreign data wrapper.

Required: No

`fdw_tuple_cost`

A cost that is used in query planning to represent the overhead of fetching rows from this server.

Required: No

`sqlserver_ansi_mode`

A cost that is used to represent the overhead of fetching rows from this server used in query planning.

This option is supported for SQL Server only. Setting this to `true` will enable the following server-side settings after a successful connection to the foreign server:

- `CONCAT_NULLS_YIELDS_NULL` ON
- `ANSI_NULLS` ON
- `ANSI_WARNINGS` ON
- `QUOTED_IDENTIFIER` ON
- `ANSI_PADDING` ON
- `ANSI_NULL_DFLT_ON` ON

Those parameters in summary are comparable to the SQL Server option `ANSI_DEFAULTS`. In contrast, `sqlserver_ansi_mode` currently does not activate the following options:

- `CURSOR_CLOSE_ON_COMMIT`
- `IMPLICIT_TRANSACTIONS`

This follows the behavior of the native ODBC and OLEDB driver for SQL servers, which explicitly turn them off if not configured otherwise.

Required: No

Default: `false`

Some foreign table options can also be set at the server level. Those include:

- `use_remote_estimate`
- `row_estimate_method`

Example H.1. Create a Foreign Server

```
CREATE SERVER mssql_svr
  FOREIGN DATA WRAPPER tds_fdw
  OPTIONS (servername '127.0.0.1', port '1433', database 'tds_fdw_test', tds_version
    '7.1');
```

H.2.4.2. Creating a User Mapping

To create a user mapping, execute the `CREATE USER MAPPING` command providing the following options:

`username`

The username of the account on the foreign server

Important

If you are using Azure SQL, then your username for the foreign server will need to be in the format `username@servername`. If you only use the username, the authentication will fail.

Required: Yes

password

The password of the account on the foreign server

Required: Yes

Example H.2. Create a User Mapping

```
CREATE USER MAPPING FOR postgres
    SERVER mssql_srv
    OPTIONS (username 'sa', password '');
```

H.2.4.3. Creating a Foreign Table

To create a foreign table, execute the [CREATE FOREIGN TABLE](#) command providing the following options:

query

The query string to use to query the foreign table

Required: Yes (mutually exclusive with [table_name](#))

schema_name

The schema that the table is in. The schema name can also be included in [table_name](#).

Required: No

table_name

The table on the foreign server to query

Aliases: *table*

Required: Yes (mutually exclusive with [query](#))

match_column_names

Match local columns with remote columns by comparing their table names instead of using the order in which they appear in the result set. Required for [WHERE](#) and column pushdowns.

Required: No

use_remote_estimate

Estimate the size of the table by performing some operation on the remote server, as defined by [row_estimate_method](#), instead of using the local estimate, as defined by [local_tuple_estimate](#)

Required: No

local_tuple_estimate

A locally set estimate of the number of tuples that is used when [use_remote_estimate](#) is disabled

Required: No

row_estimate_method

Can be one of the following values:

- `execute`: Execute the query on the remote server and get the actual number of rows in the query
- `showplan_all`: Get the estimated number of rows using *MS SQL Server's* [SET SHOWPLAN_ALL](#)

Required: No

Default: `execute`

Example H.3. Create a Foreign Table

Using a `table_name` definition:

```
CREATE FOREIGN TABLE mssql_table (  
    id integer,  
    data varchar)  
SERVER mssql_svr  
OPTIONS (table_name 'dbo.mytable', row_estimate_method 'showplan_all');
```

Using a `schema_name` and `table_name` definition:

```
CREATE FOREIGN TABLE mssql_table (  
    id integer,  
    data varchar)  
SERVER mssql_svr  
OPTIONS (schema_name 'dbo', table_name 'mytable', row_estimate_method  
'showplan_all');
```

Using a query definition:

```
CREATE FOREIGN TABLE mssql_table (  
    id integer,  
    data varchar)  
SERVER mssql_svr  
OPTIONS (query 'SELECT * FROM dbo.mytable', row_estimate_method 'showplan_all');
```

Setting a remote column name:

```
CREATE FOREIGN TABLE mssql_table (  
    id integer,  
    col2 varchar OPTIONS (column_name 'data'))  
SERVER mssql_svr  
OPTIONS (schema_name 'dbo', table_name 'mytable', row_estimate_method  
'showplan_all');
```

H.2.4.4. Importing a Foreign Schema

To import a foreign schema, execute the [IMPORT FOREIGN SCHEMA](#) command providing the following options:

`import_default`

Controls whether column `DEFAULT` expressions are included in the definitions of foreign tables

Required: No

Default: `false`

`import_not_null`

Controls whether column `NOT NULL` constraints are included in the definitions of foreign tables

Required: No

Default: `true`

Example H.4. Import a Foreign Schema

```
IMPORT FOREIGN SCHEMA dbo  
EXCEPT (mssql_table)  
FROM SERVER mssql_svr  
INTO public
```

```
OPTIONS (import_default 'true');
```

H.2.4.5. Setting Variables

To set a variable, execute the [SET](#) command.

The following variables are available:

```
tds_fdw.show_before_row_memory_stats
```

Print memory context stats to the Postgres Pro log before each row is fetched

```
tds_fdw.show_after_row_memory_stats
```

Print memory context stats to the Postgres Pro log after each row is fetched

```
tds_fdw.show_finished_memory_stats
```

Print memory context stats to the Postgres Pro log when a query is finished

Example H.5. Set a Variable

```
postgres=# SET tds_fdw.show_finished_memory_stats=1;  
SET
```

H.2.4.6. Viewing the Query Issued on the Remote System

To view the query issued on the remote system, execute the [EXPLAIN](#) [[VERBOSE](#)] command.

H.2.5. Author

Geoff Montee

H.3. wal2json — convert WAL changes into JSON via logical decoding

The wal2json module is a Postgres Pro extension for logical decoding that converts database changes from the write-ahead log (WAL) into `JSON` format. Postgres Pro has access to tuples generated by [INSERT](#) and [UPDATE](#) operations. Depending on the configured replica identity, it can also access previous row versions of [UPDATE](#) and [DELETE](#). Changes can be consumed either through the streaming protocol (logical replication slots) or through a specialized SQL API.

Format version 1 generates a `JSON` object per transaction. This object contains all new and old tuples, with optional inclusion of properties such as transaction timestamps, schema-qualified names, data types, and transaction identifiers.

Format version 2 generates a `JSON` object per tuple, with optional `JSON` objects marking transaction start and end. Different tuple properties can also be included.

H.3.1. Installation and Setup

The wal2json extension is provided with Postgres Pro Standard as a separate pre-built package `wal2json-std-18` (for the detailed installation instructions, see [Chapter 16](#)). Once you have Postgres Pro Standard installed, complete the following steps to enable wal2json:

1. Enable logical decoding by setting `wal_level` to `logical` in the `postgresql.conf` file.

Optionally, you can also edit values of the `max_replication_slots` and `max_wal_senders` parameters.

2. Restart the database server for the changes to take effect.

H.3.2. Options

The wal2json module provides a variety of options for managing logical decoding:

`include-xids`

Add transaction IDs to each set of changes in the JSON output. The default is `off`.

`include-timestamp`

Add `timestamp` to each set of changes in the JSON output. The default is `off`.

`include-schemas`

Add the schema name to each change record in the JSON output. The default is `on`.

`include-types`

Add `type` to each change record in the JSON output. The default is `on`.

`include-typmod`

Add type modifiers for columns that have them. The default is `on`.

`include-type-oids`

Add type OIDs. The default is `off`.

`include-domain-data-type`

Replace a domain name with the underlying data type. The default is `off`.

`include-column-positions`

Add the column position (`pg_attribute.attnum`). The default is `off`.

`include-origin`

Add the origin of each change. The default is `off`.

`include-not-null`

Add information whether a column is marked as `not null` in the `columnoptionals` field of the JSON output. The default is `off`.

`include-default`

Add default expressions to the JSON output. The default is `off`.

`include-pk`

Add primary key information including column names and data type to the `pk` field of the JSON output. The default is `off`.

`numeric-data-types-as-string`

Convert values of numeric data types to strings in the JSON output. The JSON specification does not support `Infinity` and `NaN` as valid numeric values. There might be *potential interoperability problems* for double precision numbers. The default is `off`.

`pretty-print`

Add spaces and indentation to the JSON output structure. The default is `off`.

`write-in-chunks`

Enable writing the JSON output in smaller chunks instead of writing the entire changeset at once. This option is used only when `format-version` is set to 1. The default is `off`.

`include-lsn`

Add the `nextlsn` field to each changeset. The default is `off`.

`include-transaction`

Add records denoting the start and end of each transaction to the JSON output. The default is `off`.

`filter-origins`

Exclude changes from the specified origins. The default is empty, which means that no origin will be filtered. The value is a comma-separated list.

`filter-tables`

Exclude rows from the specified tables. The default is empty, which means that no table will be filtered. The value is a comma-separated list. The tables should be schema-qualified. `*.foo` means the `foo` table in all schemas, and `bar.*` means all tables in the `bar` schema. Special characters (space, single quote, comma, period, asterisk) must be escaped with backslash. Schema and table names are case-sensitive. For example, table `"public"."Foo bar"` should be specified as `public.Foo\ bar`.

`add-tables`

Include rows only from the specified tables. The default is empty, which means that all tables from all schemas are included. It follows the same rules as `filter-tables`.

`filter-msg-prefixes`

Exclude messages whose prefix is specified in the option value. The default is empty, which means that no messages will be filtered. The value is a comma-separated list.

`add-msg-prefixes`

Include only messages whose prefix is specified in the option value. The default is all prefixes. The value is a comma-separated list. `wal2json` applies `filter-msg-prefixes` before this option.

`format-version`

Define which output format to use. The default is 1.

`actions`

Define which operations will be included in the JSON output. The default is all actions (`INSERT`, `UPDATE`, `DELETE`, and `TRUNCATE`). However, if you are using `format-version = 1`, `TRUNCATE` is not enabled (for backward compatibility).

H.3.3. Examples

There are two ways to obtain the changes (JSON objects) from `wal2json`: [calling functions via SQL](#) or [pg_recvlogical](#).

H.3.3.1. `pg_recvlogical`

This is an example how to obtain JSON objects from `wal2json` using `pg_recvlogical`. Besides the configuration mentioned above, it is necessary to configure a replication connection to use `pg_recvlogical`. Since Postgres Pro version 10, logical replication matches a normal entry with a database name or keywords such as `all`.

To configure a replication connection and database parameters:

1. Add a replication connection rule to `pg_hba.conf`:

```
local    mydatabase    myuser                                trust
```

2. Optionally, set `max_wal_senders` in `postgresql.conf`:

```
max_wal_senders = 1
```

3. Restart the database server if you changed `max_wal_senders`.

To obtain JSON objects from `wal2json`:

1. Open a terminal and connect to the database:

```
$ pg_recvlogical -d postgres --slot test_slot --create-slot -P wal2json
$ pg_recvlogical -d postgres --slot test_slot --start -o pretty-print=1 -o
add-msg-prefixes=wal2json -f -
```

2. In another terminal:

```
$ cat /tmp/example1.sql
CREATE TABLE table1_with_pk (a SERIAL, b VARCHAR(30), c TIMESTAMP NOT NULL,
PRIMARY KEY(a, c));
CREATE TABLE table1_without_pk (a SERIAL, b NUMERIC(5,2), c TEXT);

BEGIN;
INSERT INTO table1_with_pk (b, c) VALUES('Backup and Restore', now());
INSERT INTO table1_with_pk (b, c) VALUES('Tuning', now());
INSERT INTO table1_with_pk (b, c) VALUES('Replication', now());
SELECT pg_logical_emit_message(true, 'wal2json', 'this message will be
delivered');
SELECT pg_logical_emit_message(true, 'pgoutput', 'this message will be
filtered');
DELETE FROM table1_with_pk WHERE a < 3;
SELECT pg_logical_emit_message(false, 'wal2json', 'this non-transactional
message will be delivered even if you rollback the transaction');

INSERT INTO table1_without_pk (b, c) VALUES(2.34, 'Tapir');
-- it is not added to stream because there isn't a pk or a replica identity
UPDATE table1_without_pk SET c = 'Anta' WHERE c = 'Tapir';
COMMIT;

DROP TABLE table1_with_pk;
DROP TABLE table1_without_pk;

$ psql -At -f /tmp/example1.sql postgres
CREATE TABLE
CREATE TABLE
BEGIN
INSERT 0 1
INSERT 0 1
INSERT 0 1
3/78BFC828
3/78BFC880
DELETE 2
3/78BFC990
INSERT 0 1
UPDATE 1
COMMIT
DROP TABLE
DROP TABLE
```

3. The output in the first terminal might look like this:

```
$ psql -At -f /tmp/example2.sql postgres
CREATE TABLE
CREATE TABLE
```

```
init
BEGIN
INSERT 0 1
INSERT 0 1
INSERT 0 1
3/78C2CA50
3/78C2CAA8
DELETE 2
3/78C2CBD8
INSERT 0 1
UPDATE 1
COMMIT

    }
}
}, {
    "kind": "delete",
    "schema": "public",
    "table": "table2_with_pk",
    "oldkeys": {
        "keynames": ["a", "c"],
        "keytypes": ["integer", "timestamp without time zone"],
        "keyvalues": [2, "2018-03-27 12:05:29.914496"]
    }
}
}, {
    "kind": "insert",
    "schema": "public",
    "table": "table2_without_pk",
    "columnnames": ["a", "b", "c"],
    "columntypes": ["integer", "numeric(5,2)", "text"],
    "columnvalues": [1, 2.34, "Tapir"]
}
]
}
stop
DROP TABLE
DROP TABLE
```

4. To drop the slot in the first terminal:

```
Ctrl+C
$ pg_recvlogical -d postgres --slot test_slot --drop-slot
```

H.3.3.2. Calling SQL Functions

These are examples how to obtain changes from wal2json via SQL.

If `format-version` is set to 1, the script might look like this:

```
$ cat /tmp/example2.sql
CREATE TABLE table2_with_pk (a SERIAL, b VARCHAR(30), c TIMESTAMP NOT NULL,
PRIMARY KEY(a, c));
CREATE TABLE table2_without_pk (a SERIAL, b NUMERIC(5,2), c TEXT);

SELECT 'init' FROM pg_create_logical_replication_slot('test_slot', 'wal2json');

BEGIN;
INSERT INTO table2_with_pk (b, c) VALUES('Backup and Restore', now());
INSERT INTO table2_with_pk (b, c) VALUES('Tuning', now());
```

```
INSERT INTO table2_with_pk (b, c) VALUES('Replication', now());
SELECT pg_logical_emit_message(true, 'wal2json', 'this message will be
delivered');
SELECT pg_logical_emit_message(true, 'pgoutput', 'this message will be
filtered');
DELETE FROM table2_with_pk WHERE a < 3;
SELECT pg_logical_emit_message(false, 'wal2json', 'this non-transactional
message will be delivered even if you rollback the transaction');

INSERT INTO table2_without_pk (b, c) VALUES(2.34, 'Tapir');
-- it is not added to stream because there isn't a pk or a replica identity
UPDATE table2_without_pk SET c = 'Anta' WHERE c = 'Tapir';
COMMIT;

SELECT data FROM pg_logical_slot_get_changes('test_slot', NULL, NULL, 'pretty-
print', '1', 'add-msg-prefixes', 'wal2json');
SELECT 'stop' FROM pg_drop_replication_slot('test_slot');

DROP TABLE table2_with_pk;
DROP TABLE table2_without_pk;
```

The expected output might look like this:

```
$ psql -At -f /tmp/example2.sql postgres
CREATE TABLE
CREATE TABLE
init
BEGIN
INSERT 0 1
INSERT 0 1
INSERT 0 1
3/78C2CA50
3/78C2CAA8
DELETE 2
3/78C2CBD8
INSERT 0 1
UPDATE 1
COMMIT
{
  "change": [
    {
      "kind": "message",
      "transactional": false,
      "prefix": "wal2json",
      "content": "this non-transactional message will be delivered even
if you rollback the transaction"
    }
  ]
}
psql:/tmp/example2.sql:17: WARNING:  table "table2_without_pk" without primary
key or replica identity is nothing
{
  "change": [
    {
      "kind": "insert",
      "schema": "public",
      "table": "table2_with_pk",
```

```

        "columnnames": ["a", "b", "c"],
        "columntypes": ["integer", "character varying(30)", "timestamp without
time zone"],
        "columnvalues": [1, "Backup and Restore", "2018-03-27 12:05:29.914496"]
    },
    {
        "kind": "insert",
        "schema": "public",
        "table": "table2_with_pk",
        "columnnames": ["a", "b", "c"],
        "columntypes": ["integer", "character varying(30)", "timestamp without
time zone"],
        "columnvalues": [2, "Tuning", "2018-03-27 12:05:29.914496"]
    },
    {
        "kind": "insert",
        "schema": "public",
        "table": "table2_with_pk",
        "columnnames": ["a", "b", "c"],
        "columntypes": ["integer", "character varying(30)", "timestamp without
time zone"],
        "columnvalues": [3, "Replication", "2018-03-27 12:05:29.914496"]
    },
    {
        "kind": "message",
        "transactional": true,
        "prefix": "wal2json",
        "content": "this message will be delivered"
    },
    {
        "kind": "delete",
        "schema": "public",
        "table": "table2_with_pk",
        "oldkeys": {
            "keynames": ["a", "c"],
            "keytypes": ["integer", "timestamp without time zone"],
            "keyvalues": [1, "2018-03-27 12:05:29.914496"]
        }
    },
    {
        "kind": "delete",
        "schema": "public",
        "table": "table2_with_pk",
        "oldkeys": {
            "keynames": ["a", "c"],
            "keytypes": ["integer", "timestamp without time zone"],
            "keyvalues": [2, "2018-03-27 12:05:29.914496"]
        }
    },
    {
        "kind": "insert",
        "schema": "public",
        "table": "table2_without_pk",
        "columnnames": ["a", "b", "c"],
        "columntypes": ["integer", "numeric(5,2)", "text"],
        "columnvalues": [1, 2.34, "Tapir"]
    }
]

```

```
}  
stop  
DROP TABLE  
DROP TABLE
```

If `format-version` is set to 2, the script might look like this:

```
$ cat /tmp/example3.sql  
CREATE TABLE table3_with_pk (a SERIAL, b VARCHAR(30), c TIMESTAMP NOT NULL,  
PRIMARY KEY(a, c));  
CREATE TABLE table3_without_pk (a SERIAL, b NUMERIC(5,2), c TEXT);  
  
SELECT 'init' FROM pg_create_logical_replication_slot('test_slot', 'wal2json');  
  
BEGIN;  
INSERT INTO table3_with_pk (b, c) VALUES('Backup and Restore', now());  
INSERT INTO table3_with_pk (b, c) VALUES('Tuning', now());  
INSERT INTO table3_with_pk (b, c) VALUES('Replication', now());  
SELECT pg_logical_emit_message(true, 'wal2json', 'this message will be  
delivered');  
SELECT pg_logical_emit_message(true, 'pgoutput', 'this message will be  
filtered');  
DELETE FROM table3_with_pk WHERE a < 3;  
SELECT pg_logical_emit_message(false, 'wal2json', 'this non-transactional  
message will be delivered even if you rollback the transaction');  
  
INSERT INTO table3_without_pk (b, c) VALUES(2.34, 'Tapir');  
-- it is not added to stream because there isn't a pk or a replica identity  
UPDATE table3_without_pk SET c = 'Anta' WHERE c = 'Tapir';  
COMMIT;  
  
SELECT data FROM pg_logical_slot_get_changes('test_slot', NULL, NULL, 'format-  
version', '2', 'add-msg-prefixes', 'wal2json');  
SELECT 'stop' FROM pg_drop_replication_slot('test_slot');  
  
DROP TABLE table3_with_pk;  
DROP TABLE table3_without_pk;
```

The expected output might look like this:

```
$ psql -At -f /tmp/example3.sql postgres  
CREATE TABLE  
CREATE TABLE  
init  
BEGIN  
INSERT 0 1  
INSERT 0 1  
INSERT 0 1  
3/78CB8F30  
3/78CB8F88  
DELETE 2  
3/78CB90B8  
INSERT 0 1  
UPDATE 1  
COMMIT  
psql:/tmp/example3.sql:20: WARNING: no tuple identifier for UPDATE in table  
"public"."table3_without_pk"
```

Appendix I. Additional Supplied Programs

This appendix, [Appendix F](#), and [Appendix G](#) contain information regarding additional modules available in the Postgres Pro Standard distribution. See [Appendix F](#) and [Appendix G](#) for more information about the server extensions and plug-ins.

This appendix covers the utility programs. Once installed, they are found in the `bin` directory of the Postgres Pro Standard installation and can be used like any other program.

I.1. Additional PostgreSQL/Postgres Pro Client Applications

This section covers PostgreSQL/Postgres Pro additional client applications included in the Postgres Pro Standard distribution. They can be run from anywhere, independent of where the database server resides. See also [Postgres Pro Client Applications](#) for information about client applications that are part of the core Postgres Pro Standard distribution.

oid2name

oid2name — resolve OIDs and file nodes in a Postgres Pro data directory

Synopsis

```
oid2name [option...]
```

Description

oid2name is a utility program that helps administrators to examine the file structure used by Postgres Pro. To make use of it, you need to be familiar with the database file structure, which is described in [Chapter 64](#).

Note

The name “oid2name” is historical, and is actually rather misleading, since most of the time when you use it, you will really be concerned with tables' filenode numbers (which are the file names visible in the database directories). Be sure you understand the difference between table OIDs and table filenodes!

oid2name connects to a target database and extracts OID, filenode, and/or table name information. You can also have it show database OIDs or tablespace OIDs.

Options

oid2name accepts the following command-line arguments:

```
-f filenode
```

```
--filenode=filenode
```

show info for table with filenode *filenode*.

```
-i
```

```
--indexes
```

include indexes and sequences in the listing.

```
-o oid
```

```
--oid=oid
```

show info for table with OID *oid*.

```
-q
```

```
--quiet
```

omit headers (useful for scripting).

```
-s
```

```
--tablespaces
```

show tablespace OIDs.

```
-S
```

```
--system-objects
```

include system objects (those in `information_schema`, `pg_toast` and `pg_catalog` schemas).

```
-t tablename_pattern
```

```
--table=tablename_pattern
```

show info for table(s) matching *tablename_pattern*.

`-V`
`--version`
Print the oid2name version and exit.

`-x`
`--extended`
display more information about each object shown: tablespace name, schema name, and OID.

`-?`
`--help`
Show help about oid2name command line arguments, and exit.

oid2name also accepts the following command-line arguments for connection parameters:

`-d database`
`--dbname=database`
database to connect to.

`-h host`
`--host=host`
database server's host.

`-H host`
database server's host. Use of this parameter is *deprecated* as of Postgres Pro 12.

`-p port`
`--port=port`
database server's port.

`-U username`
`--username=username`
user name to connect as.

To display specific tables, select which tables to show by using `-o`, `-f` and/or `-t`. `-o` takes an OID, `-f` takes a filenode, and `-t` takes a table name (actually, it's a `LIKE` pattern, so you can use things like `foo%`). You can use as many of these options as you like, and the listing will include all objects matched by any of the options. But note that these options can only show objects in the database given by `-d`.

If you don't give any of `-o`, `-f` or `-t`, but do give `-d`, it will list all tables in the database named by `-d`. In this mode, the `-s` and `-i` options control what gets listed.

If you don't give `-d` either, it will show a listing of database OIDs. Alternatively you can give `-s` to get a tablespace listing.

Environment

`PGHOST`
`PGPORT`
`PGUSER`

Default connection parameters.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 32.15](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

Notes

oid2name requires a running database server with non-corrupt system catalogs. It is therefore of only limited use for recovering from catastrophic database corruption situations.

Examples

```
$ # what's in this database server, anyway?
$ oid2name
All databases:
  Oid   Database Name   Tablespace
-----
 17228      alvherre   pg_default
 17255      regression pg_default
 17227      template0  pg_default
    1      template1  pg_default

$ oid2name -s
All tablespaces:
  Oid   Tablespace Name
-----
  1663      pg_default
  1664      pg_global
155151      fastdisk
155152      bigdisk

$ # OK, let's look into database alvherre
$ cd $PGDATA/base/17228

$ # get top 10 db objects in the default tablespace, ordered by size
$ ls -lS * | head -10
-rw----- 1 alvherre alvherre 136536064 sep 14 09:51 155173
-rw----- 1 alvherre alvherre 17965056 sep 14 09:51 1155291
-rw----- 1 alvherre alvherre 1204224 sep 14 09:51 16717
-rw----- 1 alvherre alvherre 581632 sep 6 17:51 1255
-rw----- 1 alvherre alvherre 237568 sep 14 09:50 16674

```

Description

pg_probackup is a utility to manage backup and recovery of Postgres Pro database clusters. It is designed to perform periodic backups of the Postgres Pro instance that enable you to restore the server in case of a failure. pg_probackup supports PostgreSQL 11 or higher.

- [Overview](#)
- [Quick Start](#)
- [Installation and Setup](#)
- [Command-Line Reference](#)
- [Usage](#)

Overview

As compared to other backup solutions, `pg_probackup` offers the following benefits that can help you implement different backup strategies and deal with large amounts of data:

- **Incremental backup:** with three different incremental modes, you can plan the backup strategy in accordance with your data flow. Incremental backups allow you to save disk space and speed up backup as compared to taking full backups. It is also faster to restore the cluster by applying incremental backups than by replaying WAL files.
- **Incremental restore:** speed up restore from backup by reusing valid unchanged pages available in PGDATA.
- **Validation:** automatic data consistency checks and on-demand backup validation without actual data recovery.
- **Verification:** on-demand verification of Postgres Pro instance with the `checkdb` command.
- **Retention:** managing WAL archive and backups in accordance with retention policy. You can configure retention policy based on recovery time or the number of backups to keep, as well as specify time to live (TTL) for a particular backup. Expired backups can be merged or deleted.
- **Parallelization:** running `backup`, `restore`, `merge`, `delete`, `validate`, and `checkdb` processes on multiple parallel threads.
- **Compression:** storing backup data in a compressed state to save disk space.
- **Deduplication:** saving disk space by excluding non-data files (such as `_vm` or `_fsm`) from incremental backups if these files have not changed since they were copied into one of the previous backups in this incremental chain.
- **Remote operations:** backing up Postgres Pro instance located on a remote system or restoring a backup remotely.
- **Backup from standby:** avoiding extra load on master by taking backups from a standby server.
- **External directories:** backing up files and directories located outside of the Postgres Pro data directory (PGDATA), such as scripts, configuration files, logs, or SQL dump files.
- **Backup catalog:** getting the list of backups and the corresponding meta information in plain text or JSON formats.
- **Archive catalog:** getting the list of all WAL timelines and the corresponding meta information in plain text or JSON formats.
- **Partial restore:** restoring only the specified databases.
- **Catchup:** cloning a Postgres Pro instance for a fallen-behind standby server to “catch up” with master.

To manage backup data, `pg_probackup` creates a *backup catalog*. This is a directory that stores all backup files with additional meta information, as well as WAL archives required for point-in-time recovery. You can store backups for different instances in separate subdirectories of a single backup catalog.

Using `pg_probackup`, you can take full or incremental [backups](#):

- **FULL backups** contain all the data files required to restore the database cluster.
- **Incremental backups** operate at the page level, only storing the data that has changed since the previous backup. It allows you to save disk space and speed up the backup process as compared to taking full backups. It is also faster to restore the cluster by applying incremental backups than by replaying WAL files. `pg_probackup` supports the following modes of incremental backups:
 - **DELTA backup.** In this mode, `pg_probackup` reads all data files in the data directory and copies only those pages that have changed since the previous backup. This mode can impose read-only I/O pressure equal to a full backup.
 - **PAGE backup.** In this mode, `pg_probackup` scans all WAL files in the archive from the moment the previous full or incremental backup was taken. Newly created backups contain only the pages that were mentioned in WAL records. This requires all the WAL files since the previous backup to be present in the WAL archive. If the size of these files is comparable to the total size of the database cluster files, speedup is smaller, but the backup still takes less space. You have to configure WAL archiving as explained in [Setting up continuous WAL archiving](#) to make PAGE backups.
 - **PTRACK backup.** In this mode, Postgres Pro tracks page changes on the fly. Continuous archiving is not necessary for it to operate. Each time a relation page is updated, this page is marked

in a special PTRACK bitmap. Tracking implies some minor overhead on the database server operation, but speeds up incremental backups significantly.

`pg_probackup` can take only physical online backups, and online backups require WAL for consistent recovery. So regardless of the chosen backup mode (FULL, PAGE or DELTA), any backup taken with `pg_probackup` must use one of the following *WAL delivery modes*:

- **ARCHIVE**. Such backups rely on [continuous archiving](#) to ensure consistent recovery. This is the default WAL delivery mode.
- **STREAM**. Such backups include all the files required to restore the cluster to a consistent state at the time the backup was taken. Regardless of [continuous archiving](#) having been set up or not, the WAL segments required for consistent recovery are streamed via replication protocol during backup and included into the backup files. That's why such backups are called *autonomous*, or *stand-alone*.

Limitations

`pg_probackup` currently has the following limitations:

- The remote mode is not supported on Windows systems.
- On Unix systems, for Postgres Pro 11, a backup can be made only by the same OS user that has started the Postgres Pro server. For example, if Postgres Pro server is started by user `postgres`, the backup command must also be run by user `postgres`. To satisfy this requirement when taking backups in the [remote mode](#) using SSH, you must set `--remote-user` option to `postgres`.
- The Postgres Pro server from which the backup was taken and the restored server must be compatible by the [block_size](#) and [wal_block_size](#) parameters and have the same major release number. Depending on cluster configuration, Postgres Pro itself may apply additional restrictions, such as CPU architecture or libc/icu versions.

Quick Start

To quickly get started with `pg_probackup`, complete the steps below. This will set up FULL and DELTA backups in the remote mode and demonstrate some basic `pg_probackup` operations. In the following, these terms are used:

- `backup` — Postgres Pro role used to connect to the Postgres Pro cluster.
- `backupdb` — database used to connect to the Postgres Pro cluster.
- `backup_host` — host with the backup catalog.
- `backup_user` — user on `backup_host` running all `pg_probackup` operations.
- `/mnt/backups` — directory on `backup_host` where the backup catalog is stored.
- `postgres_host` — host with the Postgres Pro cluster.
- `postgres` — user on `postgres_host` under which Postgres Pro cluster processes are running.
- `/var/lib/pgpro/std-16/data` — Postgres Pro data directory on `postgres_host`.

Steps to perform:

1. Install `pg_probackup` on both `backup_host` and `postgres_host`.
2. [Set up an SSH connection](#) from `backup_host` to `postgres_host`.
3. [Configure](#) your database cluster for [STREAM backups](#).
4. Initialize the backup catalog:

```
[backup_user@backup_host]$ pg_probackup init -B /mnt/backups
INFO: Backup catalog '/mnt/backups' successfully initialized
```

5. Add a backup instance called `mydb` to the backup catalog:

```
[backup_user@backup_host]$ pg_probackup add-instance \
-B /mnt/backups \
-D /var/lib/pgpro/std-16/data \
--instance=mydb \
--remote-host=postgres_host \
--remote-user=postgres
```

INFO: Instance 'mydb' successfully initialized

6. Make a FULL backup:

```
[backup_user@backup_host] pg_probackup backup \  
-B /mnt/backups \  
-b FULL \  
--instance=mydb \  
--stream \  
--remote-host=postgres_host \  
--remote-user=postgres \  
-U backup \  
-d backupdb
```

INFO: Backup start, pg_probackup version: 2.7.0, instance: mydb, backup ID: S5BX8H, backup mode: FULL, wal mode: STREAM, remote: true, compress-algorithm: none, compress-level: 1

INFO: This PostgreSQL instance was initialized with data block checksums. Data block corruption will be detected

INFO: Database backup start

INFO: wait for pg_backup_start()

INFO: PGDATA size: 30MB

INFO: Current Start LSN: 0/2000028, TLI: 1

INFO: Start transferring data files

INFO: Data files are transferred, time elapsed: 1s

INFO: wait for pg_stop_backup()

INFO: pg_stop_backup() successfully executed

INFO: stop_stream_lsn 0/3000000 currentpos 0/3000000

INFO: backup->stop_lsn 0/20106A8

INFO: Getting the Recovery Time from WAL

INFO: Syncing backup files to disk

INFO: Backup files are synced, time elapsed: 1s

INFO: Validating backup S5BX8H

INFO: Backup S5BX8H data files are valid

INFO: Backup S5BX8H resident size: 46MB

INFO: Backup S5BX8H completed

7. List the backups of the instance:

```
[backup_user@backup_host] pg_probackup show -B /mnt/backups --instance=mydb
```

```
=====
```

Instance	Version	ID	Recovery Time	Mode	WAL Mode	TLI
Time Data	WAL	Zalg	Zratio	Start LSN	Stop LSN	Status
mydb	16	S5BX8H	2023-12-08 03:48:18.500789+00	FULL	STREAM	1/0
2s 30MB 16MB	none	1.00	0/2000028	0/20106A8	OK	

```
=====
```

8. Make an incremental backup in the DELTA mode:

```
[backup_user@backup_host] pg_probackup backup \  
-B /mnt/backups \  
-b delta \  
--instance=mydb \  
--stream \  
--remote-host=postgres_host \  
--remote-user=postgres \  
-U backup \  
-d backupdb
```

INFO: Backup start, pg_probackup version: 2.7.0, instance: mydb, backup ID: S5BXF6, backup mode: DELTA, wal mode: STREAM, remote: true, compress-algorithm: none, compress-level: 1

```
INFO: This PostgreSQL instance was initialized with data block checksums. Data
      block corruption will be detected
INFO: Database backup start
INFO: wait for pg_backup_start()
INFO: Parent backup: S5BX8H
INFO: PGDATA size: 30MB
INFO: Current Start LSN: 0/4000028, TLI: 1
INFO: Parent Start LSN: 0/2000028, TLI: 1
INFO: Start transferring data files
INFO: Data files are transferred, time elapsed: 0
INFO: wait for pg_stop_backup()
INFO: pg_stop_backup() successfully executed
INFO: stop_stream_lsn 0/5000000 currentpos 0/5000000
INFO: backup->stop_lsn 0/4000170
INFO: Getting the Recovery Time from WAL
INFO: Syncing backup files to disk
INFO: Backup files are synced, time elapsed: 0
INFO: Validating backup S5BXF6
INFO: Backup S5BXF6 data files are valid
INFO: Backup S5BXF6 resident size: 16MB
INFO: Backup S5BXF6 completed
```

9. Add or modify some parameters in the `pg_probackup` configuration file, so that you do not have to specify them each time on the command line:

```
[backup_user@backup_host] pg_probackup set-config \
  -B /mnt/backups \
  --instance=mydb \
  --remote-host=postgres_host \
  --remote-user=postgres \
  -U backup \
  -d backupdb
```

10. Check the configuration of the instance:

```
[backup_user@backup_host] pg_probackup show-config -B /mnt/backups --instance=mydb
# Backup instance information
pgdata = /var/lib/pgpro/std-16/data
system-identifier = 7308343830997275541
xlog-seg-size = 16777216
# Connection parameters
pgdatabase = backupdb
pghost = postgres_host
pguser = backup
# Archive parameters
archive-timeout = 5min
# Logging parameters
log-level-console = INFO
log-level-file = OFF
log-format-console = PLAIN
log-format-file = PLAIN
log-filename = pg_probackup.log
log-rotation-size = 0TB
log-rotation-age = 0d
# Retention parameters
retention-redundancy = 0
retention-window = 0
wal-depth = 0
# Compression parameters
```

```
compress-algorithm = none
compress-level = 1
# Remote access parameters
remote-proto = ssh
remote-host = postgres_host
remote-user = postgres
```

Note that the parameters not modified via `set-config` retain their default values.

11. Make another incremental backup in the DELTA mode, omitting the parameters stored in the configuration file earlier:

```
[backup_user@backup_host] pg_probackup backup -B /mnt/backups --instance=mydb -b
delta --stream
INFO: Backup start, pg_probackup version: 2.7.0, instance: mydb, backup ID: S5BXJ1,
      backup mode: DELTA, wal mode: STREAM, remote: true, compress-algorithm: none,
      compress-level: 1
INFO: This PostgreSQL instance was initialized with data block checksums. Data
      block corruption will be detected
INFO: Database backup start
INFO: wait for pg_backup_start()
INFO: Parent backup: S5BXF6
INFO: PGDATA size: 30MB
INFO: Current Start LSN: 0/6000028, TLI: 1
INFO: Parent Start LSN: 0/4000028, TLI: 1
INFO: Start transferring data files
INFO: Data files are transferred, time elapsed: 1s
INFO: wait for pg_stop_backup()
INFO: pg_stop_backup() successfully executed
INFO: stop_stream_lsn 0/7000000 currentpos 0/7000000
INFO: backup->stop_lsn 0/6000170
INFO: Getting the Recovery Time from WAL
INFO: Syncing backup files to disk
INFO: Backup files are synced, time elapsed: 0
INFO: Validating backup S5BXJ1
INFO: Backup S5BXJ1 data files are valid
INFO: Backup S5BXJ1 resident size: 16MB
INFO: Backup S5BXJ1 completed
```

12. List the backups of the instance again:

```
[backup_user@backup_host] pg_probackup show -B /mnt/backups --instance=mydb
=====
Instance  Version  ID      Recovery Time      Mode  WAL Mode  TLI
Time  Data  WAL  Zalg  Zratio  Start LSN  Stop LSN  Status
=====
mydb      16      S5BXJ1  2023-12-08 03:54:38.204761+00  DELTA  STREAM    1/1
1s  119kB  16MB  none   1.00  0/6000028  0/6000170  OK
mydb      16      S5BXF6  2023-12-08 03:52:19.515031+00  DELTA  STREAM    1/1
1s  191kB  16MB  none   1.00  0/4000028  0/4000170  OK
mydb      16      S5BX8H  2023-12-08 03:48:18.500789+00  FULL   STREAM    1/0
2s   30MB  16MB  none   1.00  0/2000028  0/20106A8  OK
```

Installation and Setup

Once you have `pg_probackup` installed, complete the following setup:

- Initialize the backup catalog.
- Add a new backup instance to the backup catalog.
- Configure the database cluster to enable `pg_probackup` backups.

- Optionally, configure SSH for running `pg_probackup` operations in the remote mode.

Initializing the Backup Catalog

`pg_probackup` stores all WAL and backup files in the corresponding subdirectories of the backup catalog.

To initialize the backup catalog, run the following command:

```
pg_probackup init -B backup_dir
```

where `backup_dir` is the path to the backup catalog. If the `backup_dir` already exists, it must be empty. Otherwise, `pg_probackup` returns an error.

The user launching `pg_probackup` must have full access to the `backup_dir` directory.

`pg_probackup` creates the `backup_dir` backup catalog, with the following subdirectories:

- `wal/` — directory for WAL files.
- `backups/` — directory for backup files.

Once the backup catalog is initialized, you can add a new backup instance.

Adding a New Backup Instance

`pg_probackup` can store backups for multiple database clusters in a single backup catalog. To set up the required subdirectories, you must add a backup instance to the backup catalog for each database cluster you are going to back up.

To add a new backup instance, run the following command:

```
pg_probackup add-instance -B backup_dir -D data_dir --instance instance_name  
[remote_options]
```

Where:

- `data_dir` is the data directory of the cluster you are going to back up. To set up and use `pg_probackup`, write access to this directory is required.
- `instance_name` is the name of the subdirectories that will store WAL and backup files for this cluster.
- [remote_options](#) are optional parameters that need to be specified only if `data_dir` is located on a remote system.

`pg_probackup` creates the `instance_name` subdirectories under the `backups/` and `wal/` directories of the backup catalog. The `backups/instance_name` directory contains the `pg_probackup.conf` configuration file that controls `pg_probackup` settings for this backup instance. If you run this command with the [remote_options](#), the specified parameters will be added to `pg_probackup.conf`.

For details on how to fine-tune `pg_probackup` configuration, see [the section called “Configuring pg_probackup”](#).

The user launching `pg_probackup` must have full access to `backup_dir` directory and at least read-only access to `data_dir` directory. If you specify the path to the backup catalog in the `BACKUP_PATH` environment variable, you can omit the corresponding option when running `pg_probackup` commands.

Note

For Postgres Pro 11 or higher, it is recommended to use the `-g` feature, so that backup can be done by any OS user in the same group as the cluster owner. In this case, the user should have read permissions for the cluster directory.

Configuring the Database Cluster

Although `pg_probackup` can be used by a superuser, it is recommended to create a separate role with the minimum permissions required for the chosen backup strategy. In these configuration instructions, the `backup` role is used as an example.

For security reasons, it is recommended to run the configuration SQL queries below in a separate database.

```
postgres=# CREATE DATABASE backupdb;
postgres=# \c backupdb
```

To perform a [backup](#), the following permissions for role `backup` are required only in the database **used for connection** to the Postgres Pro server.

For Postgres Pro versions 11 — 14:

```
BEGIN;
CREATE ROLE backup WITH LOGIN;
GRANT USAGE ON SCHEMA pg_catalog TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_start_backup(text, boolean, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_stop_backup(boolean, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_wal() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_last_wal_replay_lsn() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_control_checkpoint() TO backup;
COMMIT;
```

For Postgres Pro 15 or higher:

```
BEGIN;
CREATE ROLE backup WITH LOGIN;
GRANT USAGE ON SCHEMA pg_catalog TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_backup_start(text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_backup_stop(boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_wal() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_last_wal_replay_lsn() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_control_checkpoint() TO backup;
COMMIT;
```

In the `pg_hba.conf` file, allow connection to the database cluster on behalf of the `backup` role.

Since `pg_probackup` needs to read cluster files directly, `pg_probackup` must be started by (or connected to, if used in the remote mode) the OS user that has read access to all files and directories inside the data directory (`PGDATA`) you are going to back up.

Depending on whether you plan to take [standalone](#) or [archive](#) backups, Postgres Pro cluster configuration will differ, as specified in the sections below. To back up the database cluster from a standby server, run `pg_probackup` in the remote mode, or create PTRACK backups, additional setup is required.

For details, see the sections [Setting up STREAM Backups](#), [Setting up continuous WAL archiving](#), [Setting up Backup from Standby](#), [Configuring the Remote Mode](#), [Setting up Partial Restore](#), and [Setting up PTRACK Backups](#).

Setting up STREAM Backups

To set up the cluster for [STREAM](#) backups, complete the following steps:

- If the `backup` role does not exist, create it with the `REPLICATION` privilege when [Configuring the Database Cluster](#):

```
CREATE ROLE backup WITH LOGIN REPLICATION;
```

- If the `backup` role already exists, grant it with the `REPLICATION` privilege:

```
ALTER ROLE backup WITH REPLICATION;
```

- In the `pg_hba.conf` file, allow replication on behalf of the `backup` role.
- Make sure the parameter `max_wal_senders` is set high enough to leave at least one session available for the backup process.
- Set the parameter `wal_level` to be higher than `minimal`.

If you are planning to take PAGE backups in the STREAM mode or perform PITR with STREAM backups, you still have to configure WAL archiving, as explained in the section [Setting up continuous WAL archiving](#).

Once these steps are complete, you can start taking FULL, PAGE, DELTA, and PTRACK backups in the [STREAM](#) WAL mode.

Note

If you are planning to rely on `.pgpass` for authentication when running backup in STREAM mode, then `.pgpass` must contain credentials for `replication` database, used to establish connection via replication protocol. Example: `pghost:5432:replication:backup_user:my_strong_password`

Setting up Continuous WAL Archiving

Making backups in PAGE backup mode, performing [PITR](#) and making backups with [ARCHIVE](#) WAL delivery mode require [continuous WAL archiving](#) to be enabled. To set up continuous archiving in the cluster, complete the following steps:

- Make sure the `wal_level` parameter is higher than `minimal`.
- If you are configuring archiving on master, `archive_mode` must be set to `on` or `always`. To perform archiving on standby, set this parameter to `always`.
- Set the `archive_command` parameter, as follows:

```
archive_command = '"install_dir/pg_probackup" archive-push -B "backup_dir" --  
instance instance_name --wal-file-name=%f [remote_options]'
```

where `install_dir` is the installation directory of the `pg_probackup` version you are going to use, `backup_dir` and `instance_name` refer to the already initialized backup catalog instance for this database cluster, and `remote_options` only need to be specified to archive WAL on a remote host. For details about all possible `archive-push` parameters, see the section [archive-push](#).

Once these steps are complete, you can start making backups in the [ARCHIVE](#) WAL mode, backups in the PAGE backup mode, as well as perform [PITR](#).

You can view the current state of the WAL archive using the `show` command. For details, see [the section called "Viewing WAL Archive Information"](#).

If you are planning to make PAGE backups and/or backups with [ARCHIVE](#) WAL mode from a standby server that generates a small amount of WAL traffic, without long waiting for WAL segment to fill up, consider setting the [archive_timeout](#) Postgres Pro parameter **on master**. The value of this parameter should be slightly lower than the `--archive-timeout` setting (5 minutes by default), so that there is enough time for the rotated segment to be streamed to standby and sent to WAL archive before the backup is aborted because of `--archive-timeout`.

Note

Instead of using the [archive-push](#) command provided by `pg_probackup`, you can use any other tool to set up continuous archiving as long as it delivers WAL segments into `backup_dir/wal/instance_name` directory. If compression is used, it should be `gzip`, and `.gz` suffix in filename is mandatory.

Note

Instead of configuring continuous archiving by setting the `archive_mode` and `archive_command` parameters, you can opt for using the [pg_receivewal](#) utility. In this case, `pg_receivewal -D directory` option should point to `backup_dir/wal/instance_name` directory. `pg_probackup` supports WAL compression that can be done by `pg_receivewal`. “Zero Data Loss” archive strategy can be achieved only by using `pg_receivewal`.

Setting up Backup from Standby

`pg_probackup` can take backups from a standby server. This requires the following additional setup:

- On the standby server, set the [hot_standby](#) parameter to `on`.
- On the master server, set the [full_page_writes](#) parameter to `on`.
- To perform standalone backups on standby, complete all steps in section [Setting up STREAM Backups](#).
- To perform archive backups on standby, complete all steps in section [Setting up continuous WAL archiving](#).

Once these steps are complete, you can start taking FULL, PAGE, DELTA, or PTRACK backups with appropriate WAL delivery mode: ARCHIVE or STREAM, from the standby server.

Backup from the standby server has the following limitations:

- If the standby is promoted to the master during backup, the backup fails.
- All WAL records required for the backup must contain sufficient full-page writes. This requires you to enable `full_page_writes` on the master, and not to use tools like `pg_compresslog` as [archive_command](#) to remove full-page writes from WAL files.

Setting up Cluster Verification

Logical verification of a database cluster requires the following additional setup. Role `backup` is used as an example:

- Install the [amcheck](#) or [amcheck_next](#) extension **in every database** of the cluster:

```
CREATE EXTENSION amcheck;
```

- Grant the following permissions to the `backup` role **in every database** of the cluster:

```
GRANT SELECT ON TABLE pg_catalog.pg_am TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_class TO backup;
```

```
GRANT SELECT ON TABLE pg_catalog.pg_database TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_namespace TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_extension TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass) TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass, bool) TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass, bool, bool) TO backup;
```

Setting up Partial Restore

If you are planning to use partial restore, complete the following additional step:

- Grant the read-only access to `pg_catalog.pg_database` to the `backup` role only in the database **used for connection** to Postgres Pro server:

```
GRANT SELECT ON TABLE pg_catalog.pg_database TO backup;
```

Configuring the Remote Mode

`pg_probackup` supports the remote mode that allows to perform backup, restore and WAL archiving operations remotely. In this mode, the backup catalog is stored on a local system, while Postgres Pro instance to backup and/or to restore is located on a remote system. Currently the only supported remote protocol is SSH.

Set up SSH

If you are going to use `pg_probackup` in remote mode via SSH, complete the following steps:

1. Install `pg_probackup` on both systems: `backup_host` and `postgres_host`.
2. For communication between the hosts set up a passwordless SSH connection between the `backup_user` user on `backup_host` and the `postgres` user on `postgres_host`:

```
[backup_user@backup_host] ssh-copy-id postgres@postgres_host
```

Where:

- `backup_host` is the system with *backup catalog*.
 - `postgres_host` is the system with the Postgres Pro cluster.
 - `backup_user` is the OS user on `backup_host` used to run `pg_probackup`.
 - `postgres` is the user on `postgres_host` under which Postgres Pro cluster processes are running. For Postgres Pro 11 or higher a more secure approach can be used thanks to `-g` feature.
3. If you are going to rely on [continuous WAL archiving](#), set up a passwordless SSH connection between the `postgres` user on `postgres_host` and the `backup` user on `backup_host`:

```
[postgres@postgres_host] ssh-copy-id backup_user@backup_host
```

4. Make sure `pg_probackup` on `postgres_host` can be located when a connection via SSH is made. For example, for Bash, you can modify `PATH` in `~/.bashrc` of the `postgres` user (above the line in `bashrc` which exits the script for non-interactive shells). Alternatively, for `pg_probackup` commands, specify the path to the directory containing the `pg_probackup` binary on `postgres_host` via the `--remote-path` option.

`pg_probackup` in the remote mode via SSH works as follows:

- Only the following commands can be launched in the remote mode: [add-instance](#), [backup](#), [restore](#), [catchup](#), [archive-push](#), and [archive-get](#).
- Operating in remote mode requires `pg_probackup` binary to be installed on both local and remote systems. The versions of local and remote binary must be the same.
- When started in the remote mode, the main `pg_probackup` process on the local system connects to the remote system via SSH and launches one or more agent processes on the remote system, which are called *remote agents*. The number of remote agents is equal to the `-j/--threads` setting.

- The main `pg_probackup` process uses remote agents to access remote files and transfer data between local and remote systems.
- Remote agents try to minimize the network traffic and the number of round-trips between hosts.
- The main process is usually started on `backup_host` and connects to `postgres_host`, but in case of `archive-push` and `archive-get` commands the main process is started on `postgres_host` and connects to `backup_host`.
- Once data transfer is complete, remote agents are terminated and SSH connections are closed.
- If an error condition is encountered by a remote agent, then all agents are terminated and error details are reported by the main `pg_probackup` process, which exits with an error.
- Compression is always done on `postgres_host`, while decompression is always done on `backup_host`.

Note

You can impose [additional restrictions](#) on SSH settings to protect the system in the event of account compromise.

Note

Setting the number of threads (`-j/--threads` option) to a value greater than 10 for `pg_probackup` working in the remote mode via SSH may result in the actual number of SSH connections exceeding the maximum allowed number of simultaneous SSH connections on the remote server and consequently lead to an “ERROR: Agent error: kex_exchange_identification: Connection closed by remote host” error. To correct the error, either reduce the number of `pg_probackup` threads or adjust the value of `MaxStartups` configuration parameter of the remote SSH server. If SSH is set up as a `xinetd` service on the remote server, adjust the value of the `xinetd` `per_source` configuration parameter rather than `MaxStartups`.

Setting up PTRACK Backups

Note

PTRACK versions lower than 2.0 are deprecated and not supported. Postgres Pro Standard and Postgres Pro Enterprise versions starting with 11.9.1 contain PTRACK 2.0. Upgrade your server to avoid issues in backups that you will take in future and be sure to take fresh backups of your clusters with the upgraded PTRACK since the backups taken with PTRACK 1.x might be corrupt.

If you are going to use PTRACK backups, complete the following additional steps. The role that will perform PTRACK backups (the `backup` role in the examples below) must have access to all the databases of the cluster.

For Postgres Pro 11 or higher:

1. Create PTRACK extension in the database *used for connection* to the Postgres Pro server:

```
CREATE EXTENSION ptrack;
```

2. To enable tracking page updates, set `ptrack.map_size` parameter to a positive integer and restart the server.

For optimal performance, it is recommended to set `ptrack.map_size` to $N / 1024$, where N is the size of the Postgres Pro cluster, in MB. If you set this parameter to a lower value, PTRACK is more likely to map several blocks together, which leads to false-positive results when tracking changed blocks and increases the incremental backup size as unchanged blocks can also be copied into the

incremental backup. Setting `ptrack.map_size` to a higher value does not affect PTRACK operation, but it is not recommended to set this parameter to a value higher than 1024.

Note

If you change the `ptrack.map_size` parameter value, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. Thus, you have to retake a full backup before taking incremental PTRACK backups after changing `ptrack.map_size`.

Usage

Creating a Backup

To create a backup, run the following command:

```
pg_probackup backup -B backup_dir --instance instance_name -b backup_mode
```

Where `backup_mode` can take one of the following values: `FULL`, `DELTA`, `PAGE`, and `PTRACK`.

When restoring a cluster from an incremental backup, `pg_probackup` relies on the parent full backup and all the incremental backups between them, which is called “the backup chain”. Thus, to perform incremental backups, it is necessary to have the last parent full backup with the status `OK` or `DONE` in the directory. If the parent full backup has the `MERGING` or `MERGED` status, an incremental backup cannot be performed.

For example, if merge has already been launched with a single full backup, an attempt to perform an incremental backup will end with the following messages:

```
WARNING: Valid full backup on current timeline 1 is not found, trying to look up on
previous timelines
WARNING: Cannot find valid backup on previous timelines
ERROR: Create new full backup before an incremental one
```

ARCHIVE Mode

ARCHIVE is the default WAL delivery mode.

For example, to make a FULL backup in ARCHIVE mode, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL
```

ARCHIVE backups rely on [continuous archiving](#) to get WAL segments required to restore the cluster to a consistent state at the time the backup was taken.

When a backup is taken, `pg_probackup` ensures that WAL files containing WAL records between `Start LSN` and `Stop LSN` actually exist in `backup_dir/wal/instance_name` directory. `pg_probackup` also ensures that WAL records between `Start LSN` and `Stop LSN` can be parsed. This precaution eliminates the risk of silent WAL corruption.

STREAM Mode

STREAM is the optional WAL delivery mode.

For example, to make a FULL backup in the STREAM mode, add the `--stream` flag to the command from the previous example:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --stream --temp-slot
```

The optional `--temp-slot` flag ensures that the required segments remain available if the WAL is rotated before the backup is complete.

Unlike backups in ARCHIVE mode, STREAM backups include all the WAL segments required to restore the cluster to a consistent state at the time the backup was taken.

During [backup](#) `pg_probackup` streams WAL files containing WAL records between `Start LSN` and `Stop LSN` to `backup_dir/backups/instance_name/backup_id/database/pg_wal` directory. To eliminate the risk of silent WAL corruption, `pg_probackup` also checks that WAL records between `Start LSN` and `Stop LSN` can be parsed.

Even if you are using [continuous archiving](#), STREAM backups can still be useful in the following cases:

- STREAM backups can be restored on the server that has no file access to WAL archive.
- STREAM backups enable you to restore the cluster state at the point in time for which WAL files in archive are no longer available.
- Backup in STREAM mode can be taken from a standby of a server that generates small amount of WAL traffic, without long waiting for WAL segment to fill up.

Page Validation

If [data checksums](#) are enabled in the database cluster, `pg_probackup` uses this information to check correctness of data files during backup. While reading each page, `pg_probackup` checks whether the calculated checksum coincides with the checksum stored in the page header. This guarantees that the Postgres Pro instance and the backup itself have no corrupt pages. Note that `pg_probackup` reads database files directly from the filesystem, so under heavy write load during backup it can show false-positive checksum mismatches because of partial writes. If a page checksum mismatch occurs, the page is re-read and checksum comparison is repeated.

A page is considered corrupt if checksum comparison has failed more than 300 times. In this case, the backup is aborted.

Even if data checksums are not enabled, `pg_probackup` always performs sanity checks for page headers.

External Directories

To back up a directory located outside of the data directory, use the optional `--external-dirs` parameter that specifies the path to this directory. If you would like to add more than one external directory, you can provide several paths separated by colons on Linux systems or semicolons on Windows systems.

For example, to include `/etc/dir1` and `/etc/dir2` directories into the full backup of your `instance_name` instance that will be stored under the `backup_dir` directory on Linux, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --external-dirs=/etc/dir1:/etc/dir2
```

Similarly, to include `C:\dir1` and `C:\dir2` directories into the full backup on Windows, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --external-dirs=C:\dir1;C:\dir2
```

`pg_probackup` recursively copies the contents of each external directory into a separate subdirectory in the backup catalog. Since external directories included into different backups do not have to be the same, when you are restoring the cluster from an incremental backup, only those directories that belong to this particular backup will be restored. Any external directories stored in the previous backups will be ignored.

To include the same directories into each backup of your instance, you can specify them in the `pg_probackup.conf` configuration file using the [set-config](#) command with the `--external-dirs` option.

Performing Cluster Verification

To verify that Postgres Pro database cluster is not corrupt, run the following command:

```
pg_probackup checkdb [-B backup_dir [--instance instance_name]] [-D data_dir] [connection_options]
```

This command performs physical verification of all data files located in the specified data directory by running page header sanity checks, as well as block-level checksum verification if checksums are enabled. If a corrupt page is detected, `checkdb` continues cluster verification until all pages in the cluster are validated.

By default, similar [page validation](#) is performed automatically while a backup is taken by `pg_probackup`. The `checkdb` command enables you to perform such page validation on demand, without taking any backup copies, even if the cluster is not backed up using `pg_probackup` at all.

To perform cluster verification, `pg_probackup` needs to connect to the cluster to be verified. In general, it is enough to specify the backup instance of this cluster for `pg_probackup` to determine the required connection options. However, if `-B` and `--instance` options are omitted, you have to provide [connection options](#) and `data_dir` via environment variables or command-line options.

Physical verification cannot detect logical inconsistencies, missing or nullified blocks and entire files, or similar anomalies. Extensions [amcheck](#) and [amcheck_next](#) provide a partial solution to these problems.

If you would like, in addition to physical verification, to verify all indexes in all databases using these extensions, you can specify the `--amcheck` flag when running the `checkdb` command:

```
pg_probackup checkdb -D data_dir --amcheck [connection_options]
```

You can skip physical verification by specifying the `--skip-block-validation` flag. In this case, you can omit `backup_dir` and `data_dir` options, only [connection options](#) are mandatory:

```
pg_probackup checkdb --amcheck --skip-block-validation [connection_options]
```

Logical verification can be done more thoroughly with the `--heapallindexed` flag by checking that all heap tuples that should be indexed are actually indexed, but at the higher cost of CPU, memory, and I/O consumption.

Validating a Backup

`pg_probackup` calculates checksums for each file in a backup during the backup process. The process of checking checksums of backup data files is called *the backup validation*. By default, validation is run immediately after the backup is taken and right before the restore, to detect possible backup corruption.

If you would like to skip backup validation, you can specify the `--no-validate` flag when running [backup](#) and [restore](#) commands.

To ensure that all the required backup files are present and can be used to restore the database cluster, you can run the [validate](#) command with the exact [recovery target options](#) you are going to use for recovery.

For example, to check that you can restore the database cluster from a backup copy up to transaction ID 4242, run this command:

```
pg_probackup validate -B backup_dir --instance instance_name --recovery-target-xid=4242
```

If validation completes successfully, `pg_probackup` displays the corresponding message. If validation fails, you will receive an error message with the exact time, transaction ID, and LSN up to which the recovery is possible.

If you specify `backup_id` via `-i/--backup-id` option, then only the backup copy with specified backup ID will be validated. If `backup_id` is specified with [recovery target options](#), the `validate` command will check whether it is possible to restore the specified backup to the specified recovery target.

For example, to check that you can restore the database cluster from a backup copy with the `PT8XFX` backup ID up to the specified timestamp, run this command:

```
pg_probackup validate -B backup_dir --instance instance_name -i PT8XFX --recovery-target-time="2017-05-18 14:18:11+03"
```

If you specify the `backup_id` of an incremental backup, all its parents starting from FULL backup will be validated.

If you omit all the parameters, all backups are validated.

Restoring a Cluster

To restore the database cluster from a backup, run the `restore` command with at least the following options:

```
pg_probackup restore -B backup_dir --instance instance_name -i backup_id
```

Where:

- `backup_dir` is the backup catalog that stores all backup files and meta information.
- `instance_name` is the backup instance for the cluster to be restored.
- `backup_id` specifies the backup to restore the cluster from. If you omit this option, `pg_probackup` uses the latest valid backup available for the specified instance. If you specify an incremental backup to restore, `pg_probackup` automatically restores the underlying full backup and then sequentially applies all the necessary increments.

Once the `restore` command is complete, start the database service.

If you restore [ARCHIVE](#) backups, perform [PITR](#), or specify the `--restore-as-replica` flag with the `restore` command to set up a standby server, `pg_probackup` creates a recovery configuration file once all data files are copied into the target directory. This file includes the minimal settings required for recovery, except for the password in the `primary_conninfo` parameter; you have to add the password manually or use the `--primary-conninfo` option, if required. For Postgres Pro 11, recovery settings are written into the `recovery.conf` file. Starting from Postgres Pro 12, `pg_probackup` writes these settings into the `probackup_recovery.conf` file and then includes it into `postgresql.auto.conf`.

If you are restoring a STREAM backup, the restore is complete at once, with the cluster returned to a self-consistent state at the point when the backup was taken. For ARCHIVE backups, Postgres Pro replays all available archived WAL segments, so the cluster is restored to the latest state possible within the current timeline. You can change this behavior by using the [recovery target options](#) with the `restore` command, as explained in [the section called “Performing Point-in-Time \(PITR\) Recovery”](#).

If the cluster to restore contains tablespaces, `pg_probackup` restores them to their original location by default. To restore tablespaces to a different location, use the `--tablespace-mapping/-T` option. Otherwise, restoring the cluster on the same host will fail if tablespaces are in use, because the backup would have to be written to the same directories.

When using the `--tablespace-mapping/-T` option, you must provide absolute paths to the old and new tablespace directories. If a path happens to contain an equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces. For example:

```
pg_probackup restore -B backup_dir --instance instance_name -D data_dir -j 4 -  
i backup_id -T tablespace1_dir=tablespace1_newdir -T tablespace2_dir=tablespace2_newdir
```

To restore the cluster on a remote host, follow the instructions in [the section called “Using pg_probackup in the Remote Mode”](#).

Note

By default, the `restore` command validates the specified backup before restoring the cluster. If you run regular backup validations and would like to save time when restoring the cluster, you can specify the `--no-validate` flag to skip validation and speed up the recovery.

Incremental Restore

The speed of restore from backup can be significantly improved by replacing only invalid and changed pages in already existing Postgres Pro data directory using [incremental restore options](#) with the [restore](#) command.

To restore the database cluster from a backup in incremental mode, run the [restore](#) command with the following options:

```
pg_probackup restore -B backup_dir --instance instance_name -D data_dir -
I incremental_mode
```

Where *incremental_mode* can take one of the following values:

- **CHECKSUM** — read all data files in the data directory, validate header and checksum in every page and replace only invalid pages and those with checksum and LSN not matching with corresponding page in backup. This is the simplest, the most fool-proof incremental mode. Recommended to use by default.
- **LSN** — read the *pg_control* in the data directory to obtain redo LSN and redo TLI, which allows to determine a point in history(shiftpoint), where data directory state shifted from target backup chain history. If shiftpoint is not within reach of backup chain history, then restore is aborted. If shiftpoint is within reach of backup chain history, then read all data files in the data directory, validate header and checksum in every page and replace only invalid pages and those with LSN greater than shiftpoint. This mode offers a greater speed up compared to CHECKSUM, but rely on two conditions to be met. First, [data checksums](#) parameter must be enabled in data directory (to avoid corruption due to hint bits). This condition will be checked at the start of incremental restore and the operation will be aborted if checksums are disabled. Second, the *pg_control* file must be synched with state of data directory. This condition cannot be checked at the start of restore, so it is a user responsibility to ensure that *pg_control* contain valid information. Therefore it is not recommended to use LSN mode in any situation, where *pg_control* cannot be trusted or has been tampered with: after *pg_resetxlog* execution, after restore from backup without recovery been run, etc.
- **NONE** — regular restore without any incremental optimizations.

Regardless of chosen incremental mode, *pg_probackup* will check, that postmaster in given destination directory is not running and *system-identifier* is the same as in the backup.

Suppose you want to return an old master as replica after switchover using incremental restore in LSN mode:

Instance	Version	ID	Recovery Time	Mode	WAL Mode	TLI	Time
Data	WAL	Zalg	Zratio	Start LSN	Stop LSN	Status	
node	12		QBRNBP	2020-06-11 17:40:58+03	DELTA	ARCHIVE	16/15

```

Note

Incremental restore is possible only for backups with `program_version` equal or greater than 2.4.0.

Partial Restore

If you have enabled [partial restore](#) before taking backups, you can restore only some of the databases using [partial restore options](#) with the [restore](#) commands.

To restore the specified databases only, run the [restore](#) command with the following options:

```
pg_probackup restore -B backup_dir --instance instance_name --db-include=database_name
```

The `--db-include` option can be specified multiple times. For example, to restore only databases `db1` and `db2`, run the following command:

```
pg_probackup restore -B backup_dir --instance instance_name --db-include=db1 --db-include=db2
```

To exclude one or more databases from restore, use the `--db-exclude` option:

```
pg_probackup restore -B backup_dir --instance instance_name --db-exclude=database_name
```

The `--db-exclude` option can be specified multiple times. For example, to exclude the databases `db1` and `db2` from restore, run the following command:

```
pg_probackup restore -B backup_dir --instance instance_name --db-exclude=db1 --db-exclude=db2
```

Partial restore relies on lax behavior of Postgres Pro recovery process toward truncated files. For recovery to work properly, files of excluded databases are restored as files of zero size. After the Postgres Pro cluster is successfully started, you must drop the excluded databases using `DROP DATABASE` command.

To decouple a single cluster containing multiple databases into separate clusters with minimal downtime, you can do partial restore of the cluster as a standby using the `--restore-as-replica` option for specific databases.

Note

The `template0` and `template1` databases are always restored.

Note

Due to recovery specifics of Postgres Pro versions earlier than 12, it is advisable that you set the [hot standby](#) parameter to `off` when running partial restore of a Postgres Pro cluster of version earlier than 12. Otherwise the recovery may fail.

Performing Point-in-Time (PITR) Recovery

If you have enabled [continuous WAL archiving](#) before taking backups, you can restore the cluster to its state at an arbitrary point in time (recovery target) using [recovery target options](#) with the [restore](#) command.

You can use both STREAM and ARCHIVE backups for point in time recovery as long as the WAL archive is available at least starting from the time the backup was taken. If `-i/--backup-id` option is omitted, `pg_probackup` automatically chooses the backup that is the closest to the specified recovery target and starts the restore process, otherwise `pg_probackup` will try to restore the specified backup to the specified recovery target.

- To restore the cluster state at the exact time, specify the `--recovery-target-time` option, in the timestamp format. For example:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target-time="2017-05-18 14:18:11+03"
```

- To restore the cluster state up to a specific transaction ID, use the `--recovery-target-xid` option:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target-xid=687
```

- To restore the cluster state up to the specific LSN, use `--recovery-target-lsn` option:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target-lsn=16/B374D848
```

- To restore the cluster state up to the specific named restore point, use `--recovery-target-name` option:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target-name="before_app_upgrade"
```

- To restore the backup to the latest state available in the WAL archive, use `--recovery-target` option with `latest` value:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target="latest"
```

- To restore the cluster to the earliest point of consistency, use `--recovery-target` option with the `immediate` value:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target='immediate'
```

Using pg_probackup in the Remote Mode

`pg_probackup` supports the remote mode that allows to perform backup and restore operations remotely via SSH. In this mode, the backup catalog is stored on a local system, while Postgres Pro instance to be backed up is located on a remote system. You must have `pg_probackup` installed on both systems.

Note

`pg_probackup` relies on passwordless SSH connection for communication between the hosts.

Note

In addition to SSH connection, `pg_probackup` uses a regular connection to the database to manage the remote operation. See the section [Configuring the Database Cluster](#) for details of how to set up a database connection.

The typical workflow is as follows:

- On your backup host, configure `pg_probackup` as explained in the section [Installation and Setup](#). For the `add-instance` and `set-config` commands, make sure to specify [remote options](#) that point to the database host with the Postgres Pro instance.
- If you would like to take remote backups in [PAGE](#) mode, or rely on [ARCHIVE](#) WAL delivery mode, or use [PITR](#), configure continuous WAL archiving from the database host to the backup host as explained in the section [Setting up continuous WAL archiving](#). For the `archive-push` and `archive-get` commands, you must specify the [remote options](#) that point to the backup host with the backup catalog.
- Run `backup` or `restore` commands with [remote options on the backup host](#). `pg_probackup` connects to the remote system via SSH and creates a backup locally or restores the previously taken backup on the remote system, respectively.

For example, to create an archive full backup of a Postgres Pro cluster located on a remote system with host address `192.168.0.2` on behalf of the `postgres` user via SSH connection through port `2302`, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --remote-user=postgres --remote-host=192.168.0.2 --remote-port=2302
```

To restore the latest available backup on a remote system with host address `192.168.0.2` on behalf of the `postgres` user via SSH connection through port `2302`, run:

```
pg_probackup restore -B backup_dir --instance instance_name --remote-user=postgres --remote-host=192.168.0.2 --remote-port=2302
```

Restoring an [ARCHIVE](#) backup or performing [PITR](#) in the remote mode require additional information: destination address, port and username for establishing an SSH connection **from** the host with database **to** the host with the backup catalog. This information will be used by the `restore_command` to copy WAL segments from the archive to the Postgres Pro `pg_wal` directory.

To solve this problem, you can use [Remote WAL Archive Options](#).

For example, to restore latest backup on remote system using remote mode through SSH connection to user `postgres` on host with address `192.168.0.2` via port `2302` and user `backup` on backup catalog host with address `192.168.0.3` via port `2303`, run:

```
pg_probackup restore -B backup_dir --instance instance_name --remote-user=postgres --remote-host=192.168.0.2 --remote-port=2302 --archive-host=192.168.0.3 --archive-port=2303 --archive-user=backup
```

Provided arguments will be used to construct the `restore_command`:

```
restore_command = '"install_dir/pg_probackup" archive-get -B "backup_dir" --instance instance_name --wal-file-path=%p --wal-file-name=%f --remote-host=192.168.0.3 --remote-port=2303 --remote-user=backup'
```

Alternatively, you can use the `--restore-command` option to provide the entire `restore_command`:

```
pg_probackup restore -B backup_dir --instance instance_name --remote-user=postgres --remote-host=192.168.0.2 --remote-port=2302 --restore-command='"install_dir/pg_probackup" archive-get -B "backup_dir" --instance instance_name --wal-file-path=%p --wal-file-name=%f --remote-host=192.168.0.3 --remote-port=2303 --remote-user=backup'
```

Note

The remote mode is currently unavailable for Windows systems.

Running pg_probackup on Parallel Threads

[backup](#), [restore](#), [merge](#), [delete](#), [catchup](#), [checkdb](#), and [validate](#) processes can be executed on several parallel threads. This can significantly speed up pg_probackup operation given enough resources (CPU cores, disk, and network bandwidth).

Parallel execution is controlled by the `-j/--threads` command-line option. For example, to create a backup using four parallel threads, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL -j 4
```

Note

Parallel restore applies only to copying data from the backup catalog to the data directory of the cluster. When Postgres Pro server is started, WAL records need to be replayed, and this cannot be done in parallel.

Configuring pg_probackup

Once the backup catalog is initialized and a new backup instance is added, you can use the `pg_probackup-up.conf` configuration file located in the `backup_dir/backups/instance_name` directory to fine-tune pg_probackup configuration.

For example, [backup](#) and [checkdb](#) commands use a regular Postgres Pro connection. To avoid specifying [connection options](#) each time on the command line, you can set them in the `pg_probackup.conf` configuration file using the [set-config](#) command.

Note

It is **not recommended** to edit `pg_probackup.conf` manually.

Initially, `pg_probackup.conf` contains the following settings:

- `PGDATA` — the path to the data directory of the cluster to back up.
- `system-identifier` — the unique identifier of the Postgres Pro instance.

Additionally, you can define [remote](#), [retention](#), [logging](#), and [compression](#) settings using the `set-config` command:

```
pg_probackup set-config -B backup_dir --instance instance_name
[--external-dirs=external_directory_path] [remote_options] [connection_options]
[retention_options] [logging_options]
```

To view the current settings, run the following command:

```
pg_probackup show-config -B backup_dir --instance instance_name
```

You can override the settings defined in `pg_probackup.conf` when running pg_probackup [commands](#) via the corresponding environment variables and/or command line options.

Specifying Connection Settings

If you define connection settings in the `pg_probackup.conf` configuration file, you can omit connection options in all the subsequent pg_probackup commands. However, if the corresponding environment variables are set, they get higher priority. The options provided on the command line overwrite both environment variables and configuration file settings.

If nothing is given, the default values are taken. By default pg_probackup tries to use local connection via Unix domain socket (`localhost` on Windows) and tries to get the database name and the user name from the `PGUSER` environment variable or the current OS user name.

Managing the Backup Catalog

With `pg_probackup`, you can manage backups from the command line:

- [View backup information](#)
- [View WAL Archive Information](#)
- [Validate backups](#)
- [Merge backups](#)
- [Delete backups](#)

Viewing Backup Information

To view the list of existing backups for every instance, run the command:

```
pg_probackup show -B backup_dir
```

`pg_probackup` displays the list of all the available backups. For example:

```
BACKUP INSTANCE 'node'
```

=====										
Instance	Version	ID	Recovery time		Mode	WAL Mode	TLI	Time	Data	
WAL	Zalg	Zratio	Start LSN	Stop LSN	Status					
=====										
node	10	PYSUE8	2019-10-03 15:51:48+03		FULL	ARCHIVE	1/0	16s	9047kB

node	10	P7XDHB	2018-04-29 05:27:15+03		FULL	STREAM	1/0	11s	39MB	
16MB	none	1.00	0/F000028	0/F000198	OK					

For each backup, the following information is provided:

- **Instance** — the instance name.
- **Version** — Postgres Pro major version.
- **ID** — the backup identifier.
- **Recovery time** — the earliest moment for which you can restore the state of the database cluster.
- **Mode** — the method used to take this backup. Possible values: `FULL`, `PAGE`, `DELTA`, `PTRACK`.
- **WAL Mode** — WAL delivery mode. Possible values: `STREAM` and `ARCHIVE`.
- **TLI** — timeline identifiers of the current backup and its parent.
- **Time** — the time it took to perform the backup.
- **Data** — the size of the data files in this backup. This value does not include the size of WAL files. For `STREAM` backups, the total size of the backup can be calculated as `Data + WAL`.
- **WAL** — the uncompressed size of WAL files that need to be applied during recovery for the backup to reach a consistent state.
- **compress-alg** — compression algorithm used during backup. Possible values: `zlib`, `pglz`, `lz4`, `zstd`, `none`.
- **Zratio** — compression ratio calculated as “uncompressed-bytes” / “data-bytes”.
- **Start LSN** — WAL log sequence number corresponding to the start of the backup process. REDO point for Postgres Pro recovery process to start from.

- **Stop LSN** — WAL log sequence number corresponding to the end of the backup process. Consistency point for Postgres Pro recovery process.
- **Status** — backup status. Possible values:
 - **OK** — the backup is complete and valid.
 - **DONE** — the backup is complete, but was not validated.
 - **RUNNING** — the backup is in progress.
 - **MERGING** — the backup is being merged.
 - **MERGED** — the backup data files were successfully merged, but its metadata is in the process of being updated. Only full backups can have this status.
 - **DELETING** — the backup files are being deleted.
 - **CORRUPT** — some of the backup files are corrupt.
 - **ERROR** — the backup was aborted because of an unexpected error.
 - **ORPHAN** — the backup is invalid because one of its parent backups is corrupt or missing.
 - **HIDDEN_FOR_TEST** — a test script marked the backup as nonexistent. (pg_probackup never sets this status by itself.)

You can restore the cluster from the backup only if the backup status is **OK** or **DONE**.

To get more detailed information about the backup, run the `show` command with the backup ID:

```
pg_probackup show -B backup_dir --instance instance_name -i backup_id
```

The sample output is as follows:

```
#Configuration
backup-mode = FULL
stream = false
compress-alg = zlib
compress-level = 1
from-replica = false

#Compatibility
block-size = 8192
wal-block-size = 8192
checksum-version = 1
program-version = 2.1.3
server-version = 10

#Result backup info
timelineid = 1
start-lsn = 0/04000028
stop-lsn = 0/040000f8
start-time = '2017-05-16 12:57:29'
end-time = '2017-05-16 12:57:31'
end-validation-time = '2017-05-16 12:58:10'
recovery-xid = 597
recovery-time = '2017-05-16 12:57:31'
expire-time = '2020-05-16 12:57:31'
data-bytes = 22288792
wal-bytes = 16777216
uncompressed-bytes = 39961833
pgdata-bytes = 39859393
status = OK
parent-backup-id = 'PT8XFX'
primary_conninfo = 'user=backup passfile=/var/lib/pgsql/.pgpass port=5432
sslmode=disable sslcompression=1 target_session_attrs=any'
```

Detailed output has additional attributes:

- `compress-alg` — compression algorithm used during backup. Possible values: `zlib`, `pglz`, `lz4`, `zstd`, `none`.
- `compress-level` — compression level used during backup.
- `from-replica` — was this backup taken on standby? Possible values: 1, 0.
- `block-size` — the [block_size](#) setting of Postgres Pro cluster at the backup start.
- `checksum-version` — are [data_checksums](#) enabled in the backed up Postgres Pro cluster? Possible values: 1, 0.
- `program-version` — full version of `pg_probackup` binary used to create the backup.
- `start-time` — the backup start time.
- `end-time` — the backup end time.
- `end-validation-time` — the backup validation end time.
- `expire-time` — the point in time when a pinned backup can be removed in accordance with retention policy. This attribute is only available for pinned backups.
- `uncompressed-bytes` — the size of data files before adding page headers and applying compression. You can evaluate the effectiveness of compression by comparing `uncompressed-bytes` to `data-bytes` if compression is used.
- `pgdata-bytes` — the size of Postgres Pro cluster data files at the time of backup. You can evaluate the effectiveness of an incremental backup by comparing `pgdata-bytes` to `uncompressed-bytes`.
- `recovery-xid` — transaction ID at the backup end time.
- `parent-backup-id` — ID of the parent backup. Available only for incremental backups.
- `primary_conninfo` — libpq connection parameters used to connect to the Postgres Pro cluster to take this backup. The password is not included.
- `note` — text note attached to backup.
- `content-crc` — CRC32 checksum of `backup_content.control` file. It is used to detect corruption of backup meta-information.

You can also get the detailed information about the backup in the JSON format:

```
pg_probackup show -B backup_dir --instance instance_name --format=json -i backup_id
```

The sample output is as follows:

```
[
  {
    "instance": "node",
    "backups": [
      {
        "id": "PT91HZ",
        "parent-backup-id": "PT8XFX",

}
]
}
]

```

Viewing WAL Archive Information

To view the information about WAL archive for every instance, run the command:

```
pg_probackup show -B backup_dir [--instance instance_name] --archive
```

pg_probackup displays the list of all the available WAL files grouped by timelines. For example:

```
ARCHIVE INSTANCE 'node'
```

TLI	Parent TLI	Switchpoint	Min Segno	Max Segno	N
segments	Size	Zalg Zratio	N backups	Status	
5	1	0/B000000	000000050000000000000000B	000000050000000000000000C	2
	685kB	lz4 48.00	0	OK	
4	3	0/18000000	00000004000000000000000018	0000000400000000000000001A	3
	648kB	zstd 77.00	0	OK	
3	2	0/15000000	00000003000000000000000015	00000003000000000000000017	3
	648kB	zstd 77.00	0	OK	
2	1	0/B000108	000000020000000000000000B	00000002000000000000000015	5
	892kB	zstd 94.00	1	DEGRADED	
1	0	0/0	00000001000000000000000001	000000010000000000000000A	10
	8774kB	zstd 19.00	1	OK	

For each timeline, the following information is provided:

- **TLI** — timeline identifier.
- **Parent TLI** — identifier of the timeline from which this timeline branched off.
- **Switchpoint** — LSN of the moment when the timeline branched off from its parent timeline.
- **Min Segno** — the first WAL segment belonging to the timeline.
- **Max Segno** — the last WAL segment belonging to the timeline.
- **N segments** — number of WAL segments belonging to the timeline.
- **Size** — the size that files take on disk.
- **Zalg** — compression algorithm used during backup. Possible values: `zlib`, `pglz`, `lz4`, `zstd`, `none`.
- **Zratio** — compression ratio calculated as $N \text{ segments} * wal_segment_size * wal_block_size / \text{Size}$.
- **N backups** — number of backups belonging to the timeline. To get the details about backups, use the JSON format.
- **Status** — status of the WAL archive for this timeline. Possible values:
 - **OK** — all WAL segments between **Min Segno** and **Max Segno** are present.
 - **DEGRADED** — some WAL segments between **Min Segno** and **Max Segno** are missing. To find out which files are lost, view this report in the JSON format.

To get more detailed information about the WAL archive in the JSON format, run the command:

```
pg_probackup show -B backup_dir [--instance instance_name] --archive --format=json
```

The sample output is as follows:

```
[
  {
    "instance": "replica",

```

Most fields are consistent with the plain format, with some exceptions:

- The size is in bytes.
- The `closest-backup-id` attribute contains the ID of the most recent valid backup that belongs to one of the previous timelines. You can use this backup to perform point-in-time recovery to this timeline. If such a backup does not exist, this string is empty.
- The `lost-segments` array provides with information about intervals of missing segments in `DEGRADED` timelines. In `OK` timelines, the `lost-segments` array is empty.
- The `backups` array lists all backups belonging to the timeline. If the timeline has no backups, this array is empty.

Configuring Retention Policy

With `pg_probackup`, you can configure retention policy to remove redundant backups, clean up unneeded WAL files, as well as pin specific backups to ensure they are kept for the specified time, as explained in the sections below. All these actions can be combined together in any way.

Removing Redundant Backups

By default, all backup copies created with `pg_probackup` are stored in the specified backup catalog. To save disk space, you can configure retention policy to remove redundant backup copies.

To configure retention policy, set one or more of the following variables in the `pg_probackup.conf` file via [set-config](#):

```
--retention-redundancy=redundancy
```

Specifies **the number of full backup copies** to keep in the backup catalog.

```
--retention-window=window
```

Defines the earliest point in time for which `pg_probackup` can complete the recovery. This option is set in **the number of days** from the current moment. For example, if `retention-window=7`, `pg_probackup` must keep at least one backup copy that is older than seven days, with all the corresponding WAL files, and all the backups that follow.

If both `--retention-redundancy` and `--retention-window` options are set, both these conditions have to be taken into account when purging the backup catalog. For example, if you set `--retention-redundancy=2` and `--retention-window=7`, `pg_probackup` has to keep two full backup copies, as well as all the backups required to ensure recoverability for the last seven days:

```
pg_probackup set-config -B backup_dir --instance instance_name --retention-redundancy=2
--retention-window=7
```

It is recommended to always keep at least two last parent full backups to avoid errors when creating incremental backups.

To clean up the backup catalog in accordance with retention policy, you have to run the [delete](#) command with [retention flags](#), as shown below, or use the [backup](#) command with these flags to process the outdated backup copies right when the new backup is created.

For example, to remove all backup copies that no longer satisfy the defined retention policy, run the following command with the `--delete-expired` flag:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired
```

If you would like to also remove the WAL files that are no longer required for any of the backups, you should also specify the `--delete-wal` flag:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired --delete-
wal
```

You can also set or override the current retention policy by specifying `--retention-redundancy` and `--retention-window` options directly when running `delete` or `backup` commands:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired --
retention-window=7 --retention-redundancy=2
```

Since incremental backups require that their parent full backup and all the preceding incremental backups are available, if any of such backups expire, they still cannot be removed while at least one incremental backup in this chain satisfies the retention policy. To avoid keeping expired backups that are still required to restore an active incremental one, you can merge them with this backup using the `--merge-expired` flag when running [backup](#) or [delete](#) commands.

Suppose you have backed up the `node` instance in the `backup_dir` directory, with the `--retention-window` option set to 7, and you have the following backups available on April 10, 2019:

```
BACKUP INSTANCE 'node'
```

Instance	Version	ID	Recovery time			Mode	WAL	TLI	Time	Data
WAL	Zalg	Zratio	Start	LSN	Stop LSN	Status				
node	10		P7XDHR	2019-04-10	05:27:15+03	FULL	STREAM	1/0	11s	200MB
16MB	none	1.0	0/18000059	0/18000197	OK					
node	10		P7XDQV	2019-04-08	05:32:59+03	PAGE	STREAM	1/0	11s	19MB
16MB	none	1.0	0/15000060	0/15000198	OK					
node	10		P7XDJA	2019-04-03	05:28:36+03	DELTA	STREAM	1/0	21s	32MB
16MB	none	1.0	0/13000028	0/13000198	OK					
-----retention window-----										
node	10		P7XDHU	2019-04-02	05:27:59+03	PAGE	STREAM	1/0	31s	33MB
16MB	none	1.0	0/11000028	0/110001D0	OK					
node	10		P7XDHB	2019-04-01	05:27:15+03	FULL	STREAM	1/0	11s	200MB
16MB	none	1.0	0/F000028	0/F000198	OK					
node	10		P7XDFT	2019-03-29	05:26:25+03	FULL	STREAM	1/0	11s	200MB
16MB	none	1.0	0/D000028	0/D000198	OK					

Even though P7XDBH and P7XDHU backups are outside the retention window, they cannot be removed as it invalidates the succeeding incremental backups P7XDJA and P7XDQV that are still required, so, if you run the [delete](#) command with the `--delete-expired` flag, only the P7XDFT full backup will be removed.

With the `--merge-expired` option, the P7XDJA backup is merged with the underlying P7XDHU and P7XDBH backups and becomes a full one, so there is no need to keep these expired backups anymore:

```
pg_probackup delete -B backup_dir --instance node --delete-expired --merge-expired
pg_probackup show -B backup_dir
```

```
BACKUP INSTANCE 'node'
```

Instance	Version	ID	Recovery time			Mode	WAL	TLI	Time	Data
WAL	Zalg	Zratio	Start	LSN	Stop LSN	Status				
node	10		P7XDHR	2019-04-10	05:27:15+03	FULL	STREAM	1/0	11s	200MB
16MB	none	1.0	0/18000059	0/18000197	OK					
node	10		P7XDQV	2019-04-08	05:32:59+03	PAGE	STREAM	1/0	11s	19MB
16MB	none	1.0	0/15000060	0/15000198	OK					
node	10		P7XDJA	2019-04-03	05:28:36+03	FULL	STREAM	1/0	21s	32MB
16MB	none	1.0	0/13000028	0/13000198	OK					

The Time field for the merged backup displays the time required for the merge.

Pinning Backups

If you need to keep certain backups longer than the established retention policy allows, you can pin them for arbitrary time. For example:

```
pg_probackup set-backup -B backup_dir --instance instance_name -i backup_id --ttl=30d
```

This command sets the expiration time of the specified backup to 30 days starting from the time indicated in its `recovery-time` attribute.

You can also explicitly set the expiration time for a backup using the `--expire-time` option. For example:

```
pg_probackup set-backup -B backup_dir --instance instance_name -i backup_id --expire-time="2020-01-01 00:00:00+03"
```

Alternatively, you can use the `--ttl` and `--expire-time` options with the [backup](#) command to pin the newly created backup:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --ttl=30d
pg_probackup backup -B backup_dir --instance instance_name -b FULL --expire-
time="2020-01-01 00:00:00+03"
```

To check if the backup is pinned, run the [show](#) command:

```
pg_probackup show -B backup_dir --instance instance_name -i backup_id
```

If the backup is pinned, it has the `expire-time` attribute that displays its expiration time:

```
...
recovery-time = '2017-05-16 12:57:31'
expire-time = '2020-01-01 00:00:00+03'
data-bytes = 22288792
...
```

You can unpin the backup by setting the `--ttl` option to zero:

```
pg_probackup set-backup -B backup_dir --instance instance_name -i backup_id --ttl=0
```

Note

A pinned incremental backup implicitly pins all its parent backups. If you unpin such a backup later, its implicitly pinned parents will also be automatically unpinned.

Configuring WAL Archive Retention Policy

When [continuous WAL archiving](#) is enabled, archived WAL segments can take a lot of disk space. Even if you delete old backup copies from time to time, the `--delete-wal` flag can purge only those WAL segments that do not apply to any of the remaining backups in the backup catalog. However, if point-in-time recovery is critical only for the most recent backups, you can configure WAL archive retention policy to keep WAL archive of limited depth and win back some more disk space.

To configure WAL archive retention policy, you have to run the [set-config](#) command with the `--wal-depth` option that specifies the number of backups that can be used for PITR. This setting applies to all the timelines, so you should be able to perform PITR for the same number of backups on each timeline, if available. [Pinned backups](#) are not included into this count: if one of the latest backups is pinned, `pg_probackup` ensures that PITR is possible for one extra backup.

To remove WAL segments that do not satisfy the defined WAL archive retention policy, you simply have to run the [delete](#) or [backup](#) command with the `--delete-wal` flag. For archive backups, WAL segments between `Start LSN` and `Stop LSN` are always kept intact, so such backups remain valid regardless of the `--wal-depth` setting and can still be restored, if required.

You can also use the `--wal-depth` option with the [delete](#) and [backup](#) commands to override the previously defined WAL archive retention policy and purge old WAL segments on the fly.

Suppose you have backed up the `node` instance in the `backup_dir` directory and configured [continuous WAL archiving](#):

```
pg_probackup show -B backup_dir --instance node
```

```
BACKUP INSTANCE 'node'
```

```
=====
Instance  Version  ID      Recovery Time      Mode  WAL Mode  TLI  Time  Data

16MB none  1.00  0/2000028   0/200ADD8   OK
```

You can check the state of the WAL archive by running the [show](#) command with the `--archive` flag:

```
pg_probackup show -B backup_dir --instance node --archive
```

```
ARCHIVE INSTANCE 'node'
```

```
=====
TLI  Parent TLI  Switchpoint  Min Segno  Max Segno  N
segments Size  Zalg  Zratio  N backups  Status
=====
1    0          0/0          00000001000000000000000001  00000001000000000000000047  71
      36MB  zstd  31.00  6          OK
```

WAL purge without `--wal-depth` cannot achieve much, only one segment is removed:

```
pg_probackup delete -B backup_dir --instance node --delete-wal
```

```
ARCHIVE INSTANCE 'node'
```

```

      34MB  zstd  32.00  6          OK
```

If you would like, for example, to keep only those WAL segments that can be applied to the latest valid backup, set the `--wal-depth` option to 1:

```
pg_probackup delete -B backup_dir --instance node --delete-wal --wal-depth=1
```

```
ARCHIVE INSTANCE 'node'
```

```
=====
TLI  Parent TLI  Switchpoint  Min Segno  Max Segno  N
segments Size  Zalg  Zratio  N backups  Status
=====
1    0          0/0          00000001000000000000000046  00000001000000000000000047  2
      143kB  zstd  228.00  6          OK
```

Alternatively, you can use the `--wal-depth` option with the [backup](#) command:

```
pg_probackup backup -B backup_dir --instance node -b DELTA --wal-depth=1 --delete-wal
```

```
ARCHIVE INSTANCE 'node'
```

```
=====
TLI  Parent TLI  Switchpoint  Min Segno  Max Segno  N
segments Size  Zalg  Zratio  N backups  Status
=====
1    0          0/0          00000001000000000000000048  00000001000000000000000049  1
      72kB  zstd  228.00  7          OK
```

Merging Backups

As you take more and more incremental backups, the total size of the backup catalog can substantially grow. To save disk space, you can merge incremental backups to their parent full backup by running

the `merge` command, specifying the backup ID of the most recent incremental backup you would like to merge:

```
pg_probackup merge -B backup_dir --instance instance_name -i backup_id
```

This command merges backups that belong to a common incremental backup chain. If you specify a full backup, it will be merged with its first incremental backup. If you specify an incremental backup, it will be merged to its parent full backup, together with all incremental backups between them. Once the merge is complete, the full backup takes in all the merged data, and the incremental backups are removed as redundant. Thus, the merge operation is virtually equivalent to retaking a full backup and removing all the outdated backups, but it allows to save much time, especially for large data volumes, as well as I/O and network traffic if you are using `pg_probackup` in the [remote](#) mode.

Before the merge, `pg_probackup` validates all the affected backups to ensure that they are valid. You can check the current backup status by running the [show](#) command with the backup ID:

```
pg_probackup show -B backup_dir --instance instance_name -i backup_id
```

If the merge is still in progress, the backup status is displayed as `MERGING`. For full backups, it can also be shown as `MERGED` while the metadata is being updated at the final stage of the merge. The merge is idempotent, so you can restart the merge if it was interrupted.

Deleting Backups

To delete a backup that is no longer required, run the following command:

```
pg_probackup delete -B backup_dir --instance instance_name -i backup_id
```

This command will delete the backup with the specified `backup_id`, together with all the incremental backups that descend from `backup_id`, if any. This way you can delete some recent incremental backups, retaining the underlying full backup and some of the incremental backups that follow it.

To delete obsolete WAL files that are not necessary to restore any of the remaining backups, use the `--delete-wal` flag:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-wal
```

To delete backups that are expired according to the current retention policy, use the `--delete-expired` flag:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired
```

Expired backups cannot be removed while at least one incremental backup that satisfies the retention policy is based on them. If you would like to minimize the number of backups still required to keep incremental backups valid, specify the `--merge-expired` flag when running this command:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired --merge-expired
```

In this case, `pg_probackup` searches for the oldest incremental backup that satisfies the retention policy and merges this backup with the underlying full and incremental backups that have already expired, thus making it a full backup. Once the merge is complete, the remaining expired backups are deleted.

Before merging or deleting backups, you can run the `delete` command with the `--dry-run` flag, which displays the status of all the available backups according to the current retention policy, without performing any irreversible actions.

To delete all backups with specific status, use the `--status`:

```
pg_probackup delete -B backup_dir --instance instance_name --status=ERROR
```

Deleting backups by status ignores established retention policies.

Cloning and Synchronizing Postgres Pro Instance

`pg_probackup` can create a copy of a Postgres Pro instance directly, without using the backup catalog. To do this, you can run the `catchup` command. It can be useful in the following cases:

- To add a new standby server.

Usually, `pg_basebackup` is used to create a copy of a Postgres Pro instance. If the data directory of the destination instance is empty, the `catchup` command works similarly, but it can be faster if run in parallel mode.

- To have a fallen-behind standby server “catch up” with master.

Under write-intensive load, replicas may fail to replay WAL fast enough to keep up with master and hence may lag behind. A usual solution to create a new replica and switch to it requires a lot of extra space and data transfer. The `catchup` command allows you to update an existing replica much faster by bringing differences from master.

`catchup` is different from other `pg_probackup` operations:

- The backup catalog is not required.
- STREAM WAL delivery mode is only supported.
- Copying external directories is not supported.
- DDL commands `CREATE TABLESPACE/DROP TABLESPACE` cannot be run simultaneously with `catchup`.
- `catchup` takes configuration files, such as `postgresql.conf`, `postgresql.auto.conf`, or `pg_hba.conf`, from the source server and overwrites them on the target server. The `--exclude-path` option allows you to keep the configuration files intact.

To prepare for cloning/synchronizing a Postgres Pro instance, set up the source server as follows:

- [Configure the database cluster](#) for the instance to copy.
- To copy from a remote server, [configure the remote mode](#).
- To use the PTRACK `catchup` mode, [set up PTRACK backups](#).

Before cloning/synchronizing a Postgres Pro instance, ensure that the source server is running and accepting connections. To clone/sync a Postgres Pro instance, on the server with the destination instance, you can run the `catchup` command as follows:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --  
destination-pgdata=path_to_local_dir --stream [connection_options] [remote_options]
```

Where `catchup_mode` can take one of the following values:

- `FULL` — creates a full copy of the Postgres Pro instance. The data directory of the destination instance must be empty for this mode.
- `DELTA` — reads all data files in the data directory and creates an incremental copy for pages that have changed since the destination instance was shut down.
- `PTRACK` — tracking page changes on the fly, only reads and copies pages that have changed since the point of divergence of the source and destination instances.

Warning

PTRACK `catchup` mode requires PTRACK not earlier than 2.0 and hence, Postgres Pro not earlier than 11.

By specifying the `--stream` option, you can set `STREAM` WAL delivery mode of copying, which will include all the necessary WAL files by streaming them from the server via replication protocol.

You can use [connection_options](#) to specify the connection to the source database cluster. If it is located on a different server, also specify [remote_options](#).

If the source database cluster contains tablespaces that must be located in a different directory, additionally specify the `--tablespace-mapping` option:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --
destination-pgdata=path_to_local_dir --stream --tablespace-mapping=OLDDIR=NEWDIR
```

To run the `catchup` command on parallel threads, specify the number of threads with the `--threads` option:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --
destination-pgdata=path_to_local_dir --stream --threads=num_threads
```

Before cloning/synchronising a Postgres Pro instance, you can run the `catchup` command with the `--dry-run` flag to estimate the size of data files to be transferred, but make no changes on disk:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --
destination-pgdata=path_to_local_dir --stream --dry-run
```

For example, assume that a remote standby server with the Postgres Pro instance having `/replica-pgdata` data directory has fallen behind. To sync this instance with the one in `/master-pgdata` data directory, you can run the `catchup` command in the `PTRACK` mode on four parallel threads as follows:

```
pg_probackup catchup --source-pgdata=/master-pgdata --destination-pgdata=/replica-
pgdata -p 5432 -d postgres -U remote-postgres-user --stream --backup-mode=PTRACK
--remote-host=remote-hostname --remote-user=remote-unix-username -j 4 --exclude-
path=postgresql.conf --exclude-path=postgresql.auto.conf --exclude-path=pg_hba.conf --
exclude-path=pg_ident.conf
```

Note that in this example, the configuration files will not be overwritten during synchronization.

Another example shows how you can add a new remote standby server with the Postgres Pro data directory `/replica-pgdata` by running the `catchup` command in the `FULL` mode on four parallel threads:

```
pg_probackup catchup --source-pgdata=/master-pgdata --destination-pgdata=/replica-
pgdata -p 5432 -d postgres -U remote-postgres-user --stream --backup-mode=FULL --
remote-host=remote-hostname --remote-user=remote-unix-username -j 4
```

Command-Line Reference

Commands

This section describes `pg_probackup` commands. Optional parameters are enclosed in square brackets. For detailed parameter descriptions, see the section [Options](#).

version

```
pg_probackup version
```

Prints `pg_probackup` version and edition, as well as Postgres Pro version and edition.

help

```
pg_probackup help [command]
```

Displays the synopsis of `pg_probackup` commands. If one of the `pg_probackup` commands is specified, shows detailed information about the options that can be used with this command.

init

```
pg_probackup init -B backup_dir [--skip-if-exists] [--help]
```

Initializes the backup catalog in `backup_dir` that will store backup copies, WAL archive, and meta information for the backed up database clusters. If the specified `backup_dir` already exists, it must be empty. Otherwise, `pg_probackup` displays a corresponding error message. You can ignore this error by

specifying the `--skip-if-exists` option. Although the backup will not be initialized, the application will return 0 code.

For details, see the section [Initializing the Backup Catalog](#).

add-instance

```
pg_probackup add-instance -B backup_dir -D data_dir --instance instance_name [--skip-if-exists] [--help]
```

Initializes a new backup instance inside the backup catalog *backup_dir* and generates the `pg_probackup.conf` configuration file that controls `pg_probackup` settings for the cluster with the specified *data_dir* data directory. If the catalog was already initialized, you can ignore the error by specifying `--skip-if-exists`.

For details, see the section [Adding a New Backup Instance](#).

del-instance

```
pg_probackup del-instance -B backup_dir --instance instance_name [--help]
```

Deletes all backups and WAL files associated with the specified instance.

set-config

```
pg_probackup set-config -B backup_dir --instance instance_name
[--help] [--pgdata=pgdata-path]
[--retention-redundancy=redundancy] [--retention-window=window] [--wal-depth=wal_depth]
[--compress-algorithm=compression_algorithm] [--compress-level=compression_level]
[-d dbname] [-h host] [-p port] [-U username]
[--archive-timeout=timeout] [--external-dirs=external_directory_path]
[--restore-command=cmdline]
[remote_options] [remote_wal_archive_options] [logging_options]
```

Adds the specified connection, compression, retention, logging, and external directory settings into the `pg_probackup.conf` configuration file, or modifies the previously defined values.

For all available settings, see the [Options](#) section.

It is **not recommended** to edit `pg_probackup.conf` manually.

set-backup

```
pg_probackup set-backup -B backup_dir --instance instance_name -i backup_id
{--ttl=ttl | --expire-time=time}
[--note=backup_note] [--help]
```

Sets the provided backup-specific settings into the `backup.control` configuration file, or modifies the previously defined values.

```
--note=backup_note
```

Sets the text note for backup copy. If *backup_note* contain newline characters, then only substring before first newline character will be saved. Max size of text note is 1 KB. The `'none'` value removes current note.

For all available pinning settings, see the section [Pinning Options](#).

show-config

```
pg_probackup show-config -B backup_dir --instance instance_name [--format=plain|json]
```

Displays all the current `pg_probackup` configuration settings, including those that are specified in the `pg_probackup.conf` configuration file located in the *backup_dir/backups/instance_name* directory and those that were provided on a command line. You can specify the `--format=json` option to get the result in the JSON format. By default, configuration settings are shown as plain text.

To edit `pg_probackup.conf`, use the [set-config](#) command.

show

```
pg_probackup show -B backup_dir
[--help] [--instance instance_name [-i backup_id | --archive]] [--format=plain|json]
[--no-color] [--show-symlinks]
```

Shows the contents of the backup catalog. If *instance_name* and *backup_id* are specified, shows detailed information about this backup. If the `--archive` option is specified, shows the contents of WAL archive of the backup catalog.

By default, the contents of the backup catalog is shown as plain text. You can specify the `--format=json` option to get the result in the JSON format. If `--no-color` flag is used, then the output is not colored.

If the `--show-symlinks` option is specified, the command also shows the links between [merged](#) backups and the original full backups that incremental backups were merged to.

For details on usage, see the sections [Managing the Backup Catalog](#) and [Viewing WAL Archive Information](#).

backup

```
pg_probackup backup -B backup_dir -b backup_mode --instance instance_name
[--help] [-j num_threads] [--progress]
[-C] [--stream [-S slot_name] [--temp-slot]] [--backup-pg-log]
[--no-validate] [--skip-block-validation]
[-w --no-password] [-W --password]
[--archive-timeout=timeout] [--external-dirs=external_directory_path]
[--no-sync] [--note=backup_note]
[connection_options] [compression_options] [remote_options]
[retention_options] [pinning_options] [logging_options]
```

Creates a backup copy of the Postgres Pro instance.

```
-b mode
--backup-mode=mode
```

Specifies the backup mode to use. Possible values are: [FULL](#), [DELTA](#), [PAGE](#), and [PTRACK](#).

```
-C
--smooth-checkpoint
```

Spreads out the checkpoint over a period of time. By default, `pg_probackup` tries to complete the checkpoint as soon as possible.

```
--stream
```

Makes a [STREAM](#) backup, which includes all the necessary WAL files by streaming them from the database server via replication protocol.

```
--temp-slot
```

Creates a temporary physical replication slot for streaming WAL from the backed up Postgres Pro instance. It ensures that all the required WAL segments remain available if WAL is rotated while the backup is in progress. This flag can only be used together with the `--stream` flag. The default slot name is `pg_probackup_slot`, which can be changed using the `--slot/-S` option.

```
-S slot_name
--slot=slot_name
```

Specifies the replication slot for WAL streaming. This option can only be used together with the `--stream` flag.

`--backup-pg-log`

Includes the log directory into the backup. This directory usually contains log messages. By default, log directory is excluded.

`-E external_directory_path`

`--external-dirs=external_directory_path`

Includes the specified directory into the backup by recursively copying its contents into a separate subdirectory in the backup catalog. This option is useful to back up scripts, SQL dump files, and configuration files located outside of the data directory. If you would like to back up several external directories, separate their paths by a colon on Unix and a semicolon on Windows.

`--archive-timeout=wait_time`

Sets the timeout for WAL segment archiving and streaming, in seconds. By default, `pg_probackup` waits 300 seconds.

`--skip-block-validation`

Disables block-level checksum verification to speed up the backup process.

`--no-validate`

Skips automatic validation after the backup is taken. You can use this flag if you validate backups regularly and would like to save time when running backup operations.

`--no-sync`

Do not sync backed up files to disk. You can use this flag to speed up the backup process. Using this flag can result in data corruption in case of operating system or hardware crash. If you use this option, it is recommended to run the [validate](#) command once the backup is complete to detect possible issues.

`--note=backup_note`

Sets the text note for backup copy. If `backup_note` contain newline characters, then only substring before first newline character will be saved. Max size of text note is 1 KB. The `'none'` value removes current note.

Additionally, [connection options](#), [retention options](#), [pinning options](#), [remote mode options](#), [compression options](#), [logging options](#), and [common options](#) can be used.

For details on usage, see the section [Creating a Backup](#).

restore

```
pg_probackup restore -B backup_dir --instance instance_name
[--help] [-D data_dir] [-i backup_id]
[-j num_threads] [--progress]
[-T OLDDIR=NEWDIR] [--external-mapping=OLDDIR=NEWDIR] [--skip-external-dirs]
[-R | --restore-as-replica] [--no-validate] [--skip-block-validation]
[--force] [--no-sync]
[--restore-command=cmdline]
[--primary-conninfo=primary_conninfo]
[-S | --primary-slot-name=slot_name]
[-X wal_dir | --waldir=wal_dir]
[recovery_target_options] [logging_options] [remote_options]
[partial_restore_options] [remote_wal_archive_options]
```

Restores the Postgres Pro instance from a backup copy located in the `backup_dir` backup catalog. If you specify a [recovery target option](#), `pg_probackup` finds the closest backup and restores it to the specified recovery target. If neither the backup ID nor recovery target options are provided, `pg_probackup` uses the most recent backup to perform the recovery.

`-R`
`--restore-as-replica`

Creates a minimal recovery configuration file to facilitate setting up a standby server. If the replication connection requires a password, you must specify the password manually in the [primary_conninfo](#) parameter as it is not included. For Postgres Pro 11 or lower, recovery settings are written into the `recovery.conf` file. Starting from Postgres Pro 12, `pg_probackup` writes these settings into the `probackup_recovery.conf` file in the data directory, and then includes them into the `postgresql.auto.conf` when the cluster is started.

`--primary-conninfo=primary_conninfo`

Sets the [primary_conninfo](#) parameter to the specified value. This option will be ignored unless the `-R` flag is specified.

Example: `--primary-conninfo="host=192.168.1.50 port=5432 user=foo password=foopass"`

`-S`
`--primary-slot-name=slot_name`

Sets the [primary_slot_name](#) parameter to the specified value. This option will be ignored unless the `-R` flag is specified.

`-T OLDDIR=NEWDIR`
`--tablespace-mapping=OLDDIR=NEWDIR`

Relocates the tablespace from the `OLDDIR` to the `NEWDIR` directory at the time of recovery. Both `OLDDIR` and `NEWDIR` must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces.

`--external-mapping=OLDDIR=NEWDIR`

Relocates an external directory included into the backup from the `OLDDIR` to the `NEWDIR` directory at the time of recovery. Both `OLDDIR` and `NEWDIR` must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple directories.

`--skip-external-dirs`

Skip external directories included into the backup with the `--external-dirs` option. The contents of these directories will not be restored.

`--skip-block-validation`

Disables block-level checksum verification to speed up validation. During automatic validation before the restore only file-level checksums will be verified.

`--no-validate`

Skips backup validation. You can use this flag if you validate backups regularly and would like to save time when running restore operations.

`--restore-command=cmdline`

Sets the [restore_command](#) parameter to the specified command. For example: `--restore-command='cp /mnt/server/archivedir/%f "%p"'`

`--force`

Allows to ignore an invalid status of the backup. You can use this flag if you need to restore the Postgres Pro cluster from a corrupt or an invalid backup. Use with caution. If `PGDATA` contains a non-empty directory with system ID different from that of the backup being restored, [incremental restore](#) with this flag overwrites the directory contents (while an error occurs without the flag). If

tablespaces are remapped through the `--tablespace-mapping` option into non-empty directories, the contents of such directories will be deleted.

`--no-sync`

Do not sync restored files to disk. You can use this flag to speed up restore process. Using this flag can result in data corruption in case of operating system or hardware crash. If it happens, you have to run the [restore](#) command again.

`-X wal_dir`

`--waldir=wal_dir`

Specifies the directory where WAL should be stored.

Additionally, [recovery target options](#), [remote mode options](#), [remote WAL archive options](#), [logging options](#), [partial restore options](#), and [common options](#) can be used.

For details on usage, see the section [Restoring a Cluster](#).

checkdb

```
pg_probackup checkdb
[-B backup_dir] [--instance instance_name] [-D data_dir]
[--help] [-j num_threads] [--progress]
[--amcheck [--skip-block-validation] [--checkunique] [--heapallindexed]]
[connection_options] [logging_options]
```

Verifies the Postgres Pro database cluster correctness by detecting physical and logical corruption.

`--amcheck`

Performs logical verification of indexes for the specified Postgres Pro instance if no corruption was found while checking data files. You must have the [amcheck](#) extension or the `amcheck_next` extension installed in the database to check its indexes. For databases without `amcheck`, index verification will be skipped. Additional options `--checkunique` and `--heapallindexed` are effective depending on the version of `amcheck` installed.

`--checkunique`

Verifies unique constraints during logical verification of indexes. You can use this flag only together with the `--amcheck` flag when the `amcheck` extension is installed in the database.

The verification of unique constraints is only possible if in the version of the `amcheck` extension you are using, the `bt_index_check` function takes the `checkunique` parameter.

`--heapallindexed`

Checks that all heap tuples that should be indexed are actually indexed. You can use this flag only together with the `--amcheck` flag.

This check is only possible if in the version of the `amcheck/amcheck_next` extension you are using, the `bt_index_check` function takes the `heapallindexed` parameter.

`--skip-block-validation`

Skip validation of data files. You can use this flag only together with the `--amcheck` flag, so that only logical verification of indexes is performed.

Additionally, [connection options](#) and [logging options](#) can be used.

For details on usage, see the section [Verifying a Cluster](#).

validate

```
pg_probackup validate -B backup_dir
```

```
[--help] [--instance instance_name] [-i backup_id]  
[-j num_threads] [--progress]  
[--skip-block-validation]  
[recovery_target_options] [logging_options]
```

Verifies that all the files required to restore the cluster are present and are not corrupt. If *instance_name* is not specified, `pg_probackup` validates all backups available in the backup catalog. If you specify the *instance_name* without any additional options, `pg_probackup` validates all the backups available for this backup instance. If you specify the *instance_name* with a [recovery target option](#) and/or a *backup_id*, `pg_probackup` checks whether it is possible to restore the cluster using these options.

For details, see the section [Validating a Backup](#).

merge

```
pg_probackup merge -B backup_dir --instance instance_name -i backup_id  
[--help] [-j num_threads] [--progress] [--no-validate] [--no-sync]  
[logging_options]
```

Merges backups that belong to a common incremental backup chain. If you specify a full backup, it will be merged with its first incremental backup. If you specify an incremental backup, it will be merged to its parent full backup, together with all incremental backups between them. Once the merge is complete, the full backup takes in all the merged data, and the incremental backups are removed as redundant.

`--no-validate`

Skips automatic validation before and after merge.

`--no-sync`

Do not sync merged files to disk. You can use this flag to speed up the merge process. Using this flag can result in data corruption in case of operating system or hardware crash.

For details, see the section [Merging Backups](#).

delete

```
pg_probackup delete -B backup_dir --instance instance_name  
[--help] [-j num_threads] [--progress]  
[--retention-redundancy=redundancy] [--retention-window=window] [--wal-depth=wal_depth]  
[--delete-wal]  
{-i backup_id | --delete-expired [--merge-expired] | --merge-expired | --  
status=backup_status}  
[--dry-run] [--no-validate] [--no-sync] [logging_options]
```

Deletes backup with specified *backup_id* or launches the retention purge of backups and archived WAL that do not satisfy the current retention policies.

`--no-validate`

Skips automatic validation before and after retention merge.

`--no-sync`

Do not sync merged files to disk. You can use this flag to speed up the retention merge process. Using this flag can result in data corruption in case of operating system or hardware crash.

For details, see the sections [Deleting Backups](#), [Retention Options](#), and [Configuring Retention Policy](#).

archive-push

```
pg_probackup archive-push -B backup_dir --instance instance_name  
--wal-file-name=wal_file_name [--wal-file-path=wal_file_path]  
[--help] [--no-sync] [--compress] [--no-ready-rename] [--overwrite]  
[-j num_threads] [--batch-size=batch_size]
```

```
[--archive-timeout=timeout]  
[--compress-algorithm=compression_algorithm]  
[--compress-level=compression_level]  
[remote_options] [logging_options]
```

Copies WAL files into the corresponding subdirectory of the backup catalog and validates the backup instance by *instance_name* and system-identifier. If parameters of the backup instance and the cluster do not match, this command fails with the following error message: Refuse to push WAL segment *segment_name* into archive. Instance parameters mismatch.

If the files to be copied already exists in the backup catalog, `pg_probackup` computes and compares their checksums. If the checksums match, `archive-push` skips the corresponding file and returns a successful execution code. Otherwise, `archive-push` fails with an error. If you would like to replace WAL files in the case of checksum mismatch, run the `archive-push` command with the `--overwrite` flag.

Each file is copied to a temporary file with the `.part` suffix. If the temporary file already exists, `pg_probackup` will wait `archive_timeout` seconds before discarding it. After the copy is done, atomic rename is performed. This algorithm ensures that a failed `archive-push` will not stall continuous archiving and that concurrent archiving from multiple sources into a single WAL archive has no risk of archive corruption.

The postgres server requests WAL segments one at a time. To speed up archiving, you can specify the `--batch-size` option to copy WAL segments in batches of the specified size. If `--batch-size` option is used, then you can also specify the `-j` option to copy the batch of WAL segments on multiple threads.

WAL segments copied to the archive are synced to disk unless the `--no-sync` flag is used.

You can use `archive-push` in the [archive_command](#) Postgres Pro parameter to set up [continuous WAL archiving](#).

For details, see sections [Archiving Options](#) and [Compression Options](#).

archive-get

```
pg_probackup archive-get -B backup_dir --instance instance_name --wal-file-  
path=wal_file_path --wal-file-name=wal_file_name  
[-j num_threads] [--batch-size=batch_size]  
[--prefetch-dir=prefetch_dir_path] [--no-validate-wal]  
[--help] [remote_options] [logging_options]
```

Copies WAL files from the corresponding subdirectory of the backup catalog to the cluster's write-ahead log location. This command is automatically set by `pg_probackup` as part of the `restore_command` when restoring backups using a WAL archive. You do not need to set it manually.

The postgres server requests WAL segments one at a time. To speed up recovery, you can specify the `--batch-size` option to copy WAL segments in batches of the specified size. If `--batch-size` option is used, then you can also specify the `-j` option to copy the batch of WAL segments on multiple threads.

For details, see section [Archiving Options](#).

catchup

```
pg_probackup catchup -b catchup_mode  
--source-pgdata=path_to_pgdata_on_remote_server  
--destination-pgdata=path_to_local_dir  
[--help] [-j | --threads=num_threads] [--stream] [--dry-run]  
[--temp-slot] [-P | --perm-slot] [-S | --slot=slot_name]  
[--exclude-path=PATHNAME]  
[-T OLDDIR=NEWDIR]  
[connection_options] [remote_options]
```

Creates a copy of a Postgres Pro instance without using the backup catalog.

`-b catchup_mode`

`--backup-mode=catchup_mode`

Specifies the catchup mode to use. Possible values are: [FULL](#), [DELTA](#), and [PTRACK](#).

`--source-pgdata=path_to_pgdata_on_remote_server`

Specifies the path to the data directory of the instance to be copied. The path can be local or remote.

`--destination-pgdata=path_to_local_dir`

Specifies the path to the local data directory to copy to.

`-j num_threads`

`--threads=num_threads`

Sets the number of parallel threads for `catchup` process.

`--stream`

Copies the instance in [STREAM](#) WAL delivery mode, including all the necessary WAL files by streaming them from the server via replication protocol.

`--dry-run`

Displays the total size of the files to be transferred by `catchup`. This flag initiates a trial run of `catchup`, which does not actually create, delete or move files on disk. WAL streaming is skipped with `--dry-run`. This flag also allows you to check that all the options are correct and cloning/synchronising is ready to run.

`-x=path_prefix`

`--exclude-path=path_prefix`

Specifies a prefix for files to exclude from the synchronization of Postgres Pro instances during copying. The prefix must contain a path relative to the data directory of an instance. If the prefix specifies a directory, all files in this directory will not be synchronized.

Warning

This option is dangerous since excluding files from synchronization can result in incomplete synchronization; use with care.

`--temp-slot`

Creates a *temporary* physical replication slot for streaming WAL from the Postgres Pro instance being copied. It ensures that all the required WAL segments remain available if WAL is rotated while the backup is in progress. This flag can only be used together with the `--stream` flag and cannot be used together with the `--perm-slot` flag. The default slot name is `pg_probackup_slot`, which can be changed using the `--slot/-S` option.

`-P`

`--perm-slot`

Creates a *permanent* physical replication slot for streaming WAL from the Postgres Pro instance being copied. This flag can only be used together with the `--stream` flag and cannot be used together with the `--temp-slot` flag. The default slot name is `pg_probackup_perm_slot`, which can be changed using the `--slot/-S` option.

`-S slot_name`

`--slot=slot_name`

Specifies the replication slot for WAL streaming. This option can only be used together with the `--stream` flag.

```
-T OLDDIR=NEWDIR
--tablespace-mapping=OLDDIR=NEWDIR
```

Relocates the tablespace from the *OLDDIR* to the *NEWDIR* directory at the time of recovery. Both *OLDDIR* and *NEWDIR* must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces.

Additionally, [connection options](#), [remote mode options](#) can be used.

For details on usage, see the section [Cloning and Synchronizing Postgres Pro Instance](#).

Options

This section describes command-line options for `pg_probackup` commands. If the option value can be derived from an environment variable, this variable is specified below the command-line option, in the uppercase. Some values can be taken from the `pg_probackup.conf` configuration file located in the backup catalog.

For details, see [the section called “Configuring pg_probackup”](#).

If an option is specified using more than one method, command-line input has the highest priority, while the `pg_probackup.conf` settings have the lowest priority.

Common Options

The list of general options.

```
-B directory
--backup-path=directory
BACKUP_PATH
```

Specifies the absolute path to the backup catalog. Backup catalog is a directory where all backup files and meta information are stored. Since this option is required for most of the `pg_probackup` commands, you are recommended to specify it once in the `BACKUP_PATH` environment variable. In this case, you do not need to use this option each time on the command line.

```
-D directory
--pgdata=directory
PGDATA
```

Specifies the absolute path to the data directory of the database cluster. This option is mandatory only for the [add-instance](#) command. Other commands can take its value from the `PGDATA` environment variable, or from the `pg_probackup.conf` configuration file.

```
-i backup_id
--backup-id=backup_id
```

Specifies the unique identifier of the backup.

```
-j num_threads
--threads=num_threads
```

Sets the number of parallel threads for backup, restore, merge, validate, checkdb, and archive-push processes.

```
--progress
```

Shows the progress of operations.

```
--help
```

Shows detailed information about the options that can be used with this command.

Recovery Target Options

If [continuous WAL archiving](#) is configured, you can use one of these options together with [restore](#) or [validate](#) commands to specify the moment up to which the database cluster must be restored or validated.

`--recovery-target=immediate|latest`

Defines when to stop the recovery:

- The `immediate` value stops the recovery after reaching the consistent state of the specified backup, or the latest available backup if the `-i/--backup-id` option is omitted. This is the default behavior for STREAM backups.
- The `latest` value continues the recovery until all WAL segments available in the archive are applied. Setting this value of `--recovery-target` also sets `--recovery-target-timeline` to `latest`.

`--recovery-target-timeline=timeline`

Specifies a particular timeline to be used for recovery:

- `current` — the timeline of the specified backup, default.
- `latest` — the timeline of the latest available backup.
- A numeric value.

`--recovery-target-lsn=lsn`

Specifies the LSN of the write-ahead log location up to which recovery will proceed.

`--recovery-target-name=recovery_target_name`

Specifies a named savepoint up to which to restore the cluster.

`--recovery-target-time=time`

Specifies the timestamp up to which recovery will proceed. If the time zone offset is not specified, the local time zone is used.

Example: `--recovery-target-time="2020-01-01 00:00:00+03"`

`--recovery-target-xid=xid`

Specifies the transaction ID up to which recovery will proceed.

`--recovery-target-inclusive=boolean`

Specifies whether to stop just after the specified recovery target (`true`), or just before the recovery target (`false`). This option can only be used together with `--recovery-target-name`, `--recovery-target-time`, `--recovery-target-lsn` or `--recovery-target-xid` options. The default depends on the [recovery_target_inclusive](#) parameter.

`--recovery-target-action=pause|promote|shutdown`

Specifies [recovery_target_action](#) the server should take when the recovery target is reached.

Default: `pause`

Retention Options

You can use these options together with [backup](#) and [delete](#) commands.

For details on configuring retention policy, see the section [Configuring Retention Policy](#).

`--retention-redundancy=redundancy`

Specifies the number of full backup copies to keep in the data directory. Must be a non-negative integer. The zero value disables this setting.

Default: 0

`--retention-window=window`

Number of days of recoverability. Must be a non-negative integer. The zero value disables this setting.

Default: 0

`--wal-depth=wal_depth`

Number of latest valid backups on every timeline that must retain the ability to perform PITR. Must be a non-negative integer. The zero value disables this setting.

Default: 0

`--delete-wal`

Deletes WAL files that are no longer required to restore the cluster from any of the existing backups.

`--delete-expired`

Deletes backups that do not conform to the retention policy defined in the `pg_probackup.conf` configuration file.

`--merge-expired`

Merges the oldest incremental backup that satisfies the requirements of retention policy with its parent backups that have already expired.

`--dry-run`

Displays the current status of all the available backups, without deleting or merging expired backups, if any.

Pinning Options

You can use these options together with [backup](#) and [set-backup](#) commands.

For details on backup pinning, see the section [Backup Pinning](#).

`--ttl=ttl`

Specifies the amount of time the backup should be pinned. Must be a non-negative integer. The zero value unpins the already pinned backup. Supported units: ms, s, min, h, d (s by default).

Example: `--ttl=30d`

`--expire-time=time`

Specifies the timestamp up to which the backup will stay pinned. Must be an ISO-8601 complaint timestamp. If the time zone offset is not specified, the local time zone is used.

Example: `--expire-time="2020-01-01 00:00:00+03"`

Logging Options

You can use these options with any command.

`--no-color`

Disable coloring for console log messages of `warning` and `error` levels.

`--log-level-console=log_level`

Controls which message levels are sent to the console log. Valid values are `verbose`, `log`, `info`, `warning`, `error` and `off`. Each level includes all the levels that follow it. The later the level, the fewer messages are sent. The `off` level disables console logging.

Default: `info`

Note

All console log messages are going to stderr, so the output of [show](#) and [show-config](#) commands does not mingle with log messages.

`--log-level-file=log_level`

Controls which message levels are sent to a log file. Valid values are `verbose`, `log`, `info`, `warning`, `error`, and `off`. Each level includes all the levels that follow it. The later the level, the fewer messages are sent. The `off` level disables file logging.

Default: `off`

`--log-filename=log_filename`

Defines the filenames of the created log files. The filenames are treated as a `strftime` pattern, so you can use %-escapes to specify time-varying filenames.

Default: `pg_probackup.log`

For example, if you specify the `pg_probackup-%u.log` pattern, `pg_probackup` generates a separate log file for each day of the week, with `%u` replaced by the corresponding decimal number: `pg_probackup-1.log` for Monday, `pg_probackup-2.log` for Tuesday, and so on.

This option takes effect if file logging is enabled by the `--log-level-file` option.

`--error-log-filename=error_log_filename`

Defines the filenames of log files for error messages only. The filenames are treated as a `strftime` pattern, so you can use %-escapes to specify time-varying filenames.

Default: `none`

For example, if you specify the `error-pg_probackup-%u.log` pattern, `pg_probackup` generates a separate log file for each day of the week, with `%u` replaced by the corresponding decimal number: `error-pg_probackup-1.log` for Monday, `error-pg_probackup-2.log` for Tuesday, and so on.

This option is useful for troubleshooting and monitoring.

`--log-directory=log_directory`

Defines the directory in which log files will be created. You must specify the absolute path. This directory is created lazily, when the first log message is written.

Default: `$BACKUP_PATH/log/`

`--log-format-console=log_format`

Defines the format of the console log. Only set from the command line. Note that you cannot specify this option in the `pg_probackup.conf` configuration file through the [set-config](#) command and that the [backup](#) command also treats this option specified in the configuration file as an error. Possible values are:

- `plain` — sets the plain-text format of the console log.
- `json` — sets the JSON format of the console log.

Default: `plain`

`--log-format-file=log_format`

Defines the format of log files used. Possible values are:

- `plain` — sets the plain-text format of log files.
- `json` — sets the JSON format of log files.

Default: plain

`--log-rotation-size=log_rotation_size`

Maximum size of an individual log file. If this value is reached, the log file is rotated once a `pg_probackup` command is launched, except `help` and `version` commands. The zero value disables size-based rotation. Supported units: kB, MB, GB, TB (kB by default).

Default: 0

`--log-rotation-age=log_rotation_age`

Maximum lifetime of an individual log file. If this value is reached, the log file is rotated once a `pg_probackup` command is launched, except `help` and `version` commands. The time of the last log file creation is stored in `$BACKUP_PATH/log/log_rotation`. The zero value disables time-based rotation. Supported units: ms, s, min, h, d (min by default).

Default: 0

Connection Options

You can use these options together with `backup`, `catchup`, and `checkdb` commands.

All `libpq` environment variables are supported.

`-d dbname`

`--pgdatabase=dbname`

`PGDATABASE`

Specifies the name of the database to connect to. The connection is used only for managing backup process, so you can connect to any existing database. If this option is not provided on the command line, `PGDATABASE` environment variable, or the `pg_probackup.conf` configuration file, `pg_probackup` tries to take this value from the `PGUSER` environment variable, or from the current user name if `PGUSER` variable is not set.

`-h host`

`--pghost=host`

`PGHOST`

Specifies the host name of the system on which the server is running. If the value begins with a slash, it is used as a directory for the Unix domain socket.

Default: localhost

`-p port`

`--pgport=port`

`PGPORT`

Specifies the TCP port or the local Unix domain socket file extension on which the server is listening for connections.

Default: 5432

`-U username`

`--pguser=username`

`PGUSER`

User name to connect as.

`-w`

`--no-password`

Disables a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file or `PGPASSWORD` environment variable, the connection

attempt will fail. This flag can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`

`--password`

Forces a password prompt. (Deprecated)

Compression Options

You can use these options together with [backup](#) and [archive-push](#) commands.

`--compress-algorithm=compression_algorithm`

Defines the algorithm to use for compressing data files. Possible values are `zlib`, `lz4`, `zstd`, `pglz`, and `none`. If set to any value, but `none`, this option enables compression that uses the corresponding algorithm. Both data files and WAL files are compressed. By default, compression is disabled. For the [archive-push](#) command, the `pglz` compression algorithm is not supported.

Note

`pg_probackup` supports compression algorithms included in the Postgres Pro version. In particular:

- `lz4` is supported for Postgres Pro 14 and higher.
- `zstd` is supported for Postgres Pro 15 and higher.

Default: `none`

`--compress-level=compression_level`

Defines compression level (0 through 9, 0 being no compression and 9 being best compression). This option can be used together with the `--compress-algorithm` option.

Default: `1`

`--compress`

Alias for `--compress-algorithm=zlib` and `--compress-level=1`.

Archiving Options

These options can be used with the [archive-push](#) command in the [archive_command](#) setting and the [archive-get](#) command in the [restore_command](#) setting.

Additionally, [remote mode options](#) and [logging options](#) can be used.

`--wal-file-path=wal_file_path`

Provides the path to the WAL file in `archive_command` and `restore_command`. Use the `%p` variable as the value for this option or explicitly specify the path to a file outside of the data directory. If you skip this option, the path specified in `pg_probackup.conf` will be used.

`--wal-file-name=wal_file_name`

Provides the name of the WAL file in `archive_command` and `restore_command`. Use the `%f` variable as the value for this option for correct processing. If the value of `--wal-file-path` is a path outside of the data directory, explicitly specify the filename.

`--overwrite`

Overwrites archived WAL file. Use this flag together with the [archive-push](#) command if the specified subdirectory of the backup catalog already contains this WAL file and it needs to be replaced with its newer copy. Otherwise, `archive-push` reports that a WAL segment already exists, and aborts the

operation. If the file to replace has not changed, `archive-push` skips this file regardless of the `--overwrite` flag.

`--batch-size=batch_size`

Used to speed up archiving in case of `archive-push` or to speed up recovery in case of `archive-get`. Sets the maximum number of WAL files that can be copied into the archive by a single `archive-push` process, or from the archive by a single `archive-get` process.

`--archive-timeout=wait_time`

Sets the timeout for considering existing `.part` files to be stale. By default, `pg_probackup` waits 300 seconds. This option can be used only with [archive-push](#) command.

`--no-ready-rename`

Do not rename status files in the `archive_status` directory. This option should be used only if `archive_command` contains multiple commands. This option can be used only with [archive-push](#) command.

`--no-sync`

Do not sync copied WAL files to disk. You can use this flag to speed up archiving process. Using this flag can result in WAL archive corruption in case of operating system or hardware crash. This option can be used only with [archive-push](#) command.

`--prefetch-dir=path`

Directory used to store prefetched WAL segments if `--batch-size` option is used. Directory must be located on the same filesystem and on the same mountpoint the `PGDATA/pg_wal` is located. By default files are stored in `PGDATA/pg_wal/pbk_prefetch` directory. This option can be used only with [archive-get](#) command.

`--no-validate-wal`

Do not validate prefetched WAL file before using it. Use this option if you want to increase the speed of recovery. This option can be used only with [archive-get](#) command.

Remote Mode Options

This section describes the options related to running `pg_probackup` operations remotely via SSH. These options can be used with [add-instance](#), [set-config](#), [backup](#), [catchup](#), [restore](#), [archive-push](#), and [archive-get](#) commands.

For details on configuring and using the remote mode, see [the section called “Configuring the Remote Mode”](#) and [the section called “Using pg_probackup in the Remote Mode”](#).

`--remote-proto=proto`

Specifies the protocol to use for remote operations. Currently only the SSH protocol is supported. Possible values are:

- `ssh` enables the remote mode via SSH. This is the default value.
- `none` explicitly disables the remote mode.

You can omit this option if the `--remote-host` option is specified.

`--remote-host=destination`

Specifies the remote host IP address or hostname to connect to.

`--remote-port=port`

Specifies the remote host port to connect to.

Default: 22

`--remote-user=username`

Specifies remote host user for SSH connection. If you omit this option, the current user initiating the SSH connection is used.

`--remote-path=path`

Specifies `pg_probackup` installation directory on the remote system.

`--ssh-options=ssh_options`

Provides a string of SSH command-line options. For example, the following options can be used to set `keep-alive` for SSH connections opened by `pg_probackup`: `--ssh-options="-o ServerAliveCountMax=5 -o ServerAliveInterval=60"`. For the full list of possible options, see [ssh_config manual page](#).

Remote WAL Archive Options

This section describes the options used to provide the arguments for [remote mode options](#) in `archive-get` used in the [restore_command](#) command when restoring ARCHIVE backups or performing PITR.

`--archive-host=destination`

Provides the argument for the `--remote-host` option in the `archive-get` command.

`--archive-port=port`

Provides the argument for the `--remote-port` option in the `archive-get` command.

Default: 22

`--archive-user=username`

Provides the argument for the `--remote-user` option in the `archive-get` command. If you omit this option, the user that has started the Postgres Pro cluster is used.

Default: Postgres Pro user

Incremental Restore Options

This section describes the options for incremental cluster restore. These options can be used with the [restore](#) command.

`-I incremental_mode`

`--incremental-mode=incremental_mode`

Specifies the incremental mode to be used. Possible values are:

- `CHECKSUM` — replace only pages with mismatched checksum and LSN.
- `LSN` — replace only pages with LSN greater than point of divergence.
- `NONE` — regular restore.

Partial Restore Options

This section describes the options for partial cluster restore. These options can be used with the [restore](#) command.

`--db-exclude=dbname`

Specifies the name of the database to exclude from restore. All other databases in the cluster will be restored as usual, including `template0` and `template1`. This option can be specified multiple times for multiple databases.

`--db-include=dbname`

Specifies the name of the database to restore from a backup. All other databases in the cluster will not be restored, with the exception of `template0` and `template1`. This option can be specified multiple times for multiple databases.

Testing and Debugging Options

This section describes options useful only in a test or development environment.

`PGPROBACKUP_TESTS_SKIP_HIDDEN`

Instructs `pg_probackup` to ignore backups marked as hidden. Note that `pg_probackup` can never mark a backup as hidden. It can only be done by directly editing the `backup.control` file. This option can only be set with environment variables.

`--destroy-all-other-dbs`

By default, `pg_probackup` exits with an error if an attempt is made to perform a partial incremental restore since this destroys databases not included in the restore set. This flag allows you to suppress the error and proceed with the partial incremental restore (e.g., to keep a development database snapshot up-to-date with a production one). This option can be used with the [restore](#) command.

Important

Never use this flag in a production cluster.

`PGPROBACKUP_TESTS_SKIP_EMPTY_COMMIT`

Instructs `pg_probackup` to skip empty commits after `pg_backup_stop`.

Versioning

`pg_probackup` follows [semantic](#) versioning.

Authors

Postgres Professional, Moscow, Russia.

Credits

`pg_probackup` utility is based on `pg_arman`, which was originally written by NTT and then developed and maintained by Michael Paquier.

vacuumlo

vacuumlo — remove orphaned large objects from a Postgres Pro database

Synopsis

```
vacuumlo [option...] dbname...
```

Description

vacuumlo is a simple utility program that will remove any “orphaned” large objects from a Postgres Pro database. An orphaned large object (LO) is considered to be any LO whose OID does not appear in any `oid` or `lo` data column of the database.

If you use this, you may also be interested in the `lo_manage` trigger in the [lo](#) module. `lo_manage` is useful to try to avoid creating orphaned LOs in the first place.

All databases named on the command line are processed.

Options

vacuumlo accepts the following command-line arguments:

```
-l limit  
--limit=limit
```

Remove no more than *limit* large objects per transaction (default 1000). Since the server acquires a lock per LO removed, removing too many LOs in one transaction risks exceeding [max_locks_per_transaction](#). Set the limit to zero if you want all removals done in a single transaction.

```
-n  
--dry-run
```

Don't remove anything, just show what would be done.

```
-v  
--verbose
```

Write a lot of progress messages.

```
-V  
--version
```

Print the vacuumlo version and exit.

```
-?  
--help
```

Show help about vacuumlo command line arguments, and exit.

vacuumlo also accepts the following command-line arguments for connection parameters:

```
-h host  
--host=host
```

Database server's host.

```
-p port  
--port=port
```

Database server's port.

```
-U username  
--username=username
```

User name to connect as.

```
-w  
--no-password
```

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

```
-W  
--password
```

Force vacuumlo to prompt for a password before connecting to a database.

This option is never essential, since vacuumlo will automatically prompt for a password if the server demands password authentication. However, vacuumlo will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

Environment

```
PGHOST  
PGPORT  
PGUSER
```

Default connection parameters.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 32.15](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

Notes

vacuumlo works by the following method: First, vacuumlo builds a temporary table which contains all of the OIDs of the large objects in the selected database. It then scans through all columns in the database that are of type `oid` or `lo`, and removes matching entries from the temporary table. (Note: Only types with these names are considered; in particular, domains over them are not considered.) The remaining entries in the temporary table identify orphaned LOs. These are removed.

Author

Peter Mount <peter@retep.org.uk>

I.2. Third-Party Client Applications

This section covers third-party client applications included in the Postgres Pro Standard distribution. They can be run from anywhere, independent of where the database server resides. Note also that the `odbc` driver is available (see [Table 16.3](#) for details).

ldap2pg

ldap2pg — automate the creation, update, and removal of Postgres Pro roles and users from an enterprise directory

Synopsis

```
ldap2pg [option...] [dbname]
```

Description

Out of the box, Postgres Pro is able to check password of an existing role using the LDAP protocol. ldap2pg automates the creation, update and removal of Postgres Pro roles, and users from an enterprise directory.

Managing roles is close to managing privileges as you expect roles to have proper default privileges. Postgres Pro can grant and revoke privileges too.

ldap2pg is provided with Postgres Pro Standard as a separate pre-built package `ldap2pg` (for the detailed installation instructions, see [Chapter 16](#)).

ldap2pg is reported to work with [Samba DC](#), [OpenLDAP](#), [FreeIPA](#), Oracle Internet Directory and Microsoft Active Directory.

ldap2pg **requires** a configuration file called `ldap2pg.yaml`.

Features

- Reads settings from an expressive YAML config file.
- Creates, alters and drops Postgres Pro roles from LDAP searches.
- Creates static roles from YAML to complete LDAP entries.
- Manages role parents (alias *groups*).
- Grants or revokes privileges statically or from LDAP entries.
- Dry run, check mode.
- Logs LDAP searches as `ldapsearch(1)` commands.
- Logs **every** SQL statements.

Requirements

ldap2pg is released as a single binary with no dependencies.

At run time, ldap2pg requires an unprivileged role with `CREATEDB` and `CREATEROLE` options or a superuser access.

ldap2pg does not require to run on the same host as the synchronized Postgres Pro Standard cluster.

With 2MiB of RAM and one vCPU, ldap2pg can synchronize several thousands of roles in seconds, depending on Postgres Pro Standard instance and LDAP directory response time.

Command-Line Reference

ldap2pg tries to be friendly regarding configuration and consistent with `psql`, `OpenLDAP utils` and [The Twelve-Factor App](#). ldap2pg reads its configuration from several sources, in the following order, first prevail:

1. Command-line arguments.
2. Environment variables.
3. Configuration file.
4. `ldaprc`, `ldap.conf`, etc.

The command-line usage is as follows:

```
ldap2pg [OPTIONS] [dbname]
```

Where options are as follows:

`--check`
Check mode: exits with 1 if Postgres Pro instance is unsynchronized.

`--color`
Force color output.

`-c string`
`--config string`
Path to YAML configuration file. Use - for stdin.

`--directory string`
Path to directory containing configuration files.

`--help`
Show help message and exit (default true).

`--ldappassword-file string`
Path to LDAP password file.

`--quiet count`
Decrease log verbosity.

`--real`
Real mode. Apply changes to Postgres Pro instance.

`-skip-privileges`
Turn off privilege synchronization.

`--verbose count`
Increase log verbosity.

`--version`
Show version and exit (default true).

Optional argument `dbname` is alternatively the database name or a `conninfo` string or a URI. See `psql(1)` man page for more information.

By default, `ldap2pg` runs in dry mode. `ldap2pg` requires a configuration file to describe LDAP searches and mappings.

Arguments can be defined multiple times. On conflict, the last argument is used.

Environment Variables

`ldap2pg` has no command-line interface switch to configure Postgres Pro connection. However, `ldap2pg` supports [libpq PG* environment variables](#).

See [psql\(1\)](#) for details on `libpq` environment variables.

The same goes for LDAP, `ldap2pg` supports standard `LDAP*` environment variables and `.ldaprc` files. See `ldap.conf(5)` man page for further details on how to configure. `ldap2pg` accepts two extra variables: `LDAPPASSWORD` and `LDAPPASSWORD_FILE`.

`ldap2pg` loads `.env` file in the `lda2pg.yml`'s parent directory if exists.

Use `true` or `false` for boolean values in environment, e.g. `LDAP2PG_SKIPPRIVILEGES=true`.

Tip

Test Postgres Pro connection using `psql(1)` and LDAP using `ldapwhoami(1)` man pages, `ldap2pg` will be okay and it will be easier to debug the setup and the configuration later.

Logging Setup

`ldap2pg` has several levels of logging:

- **ERROR:** error details. When this happens, `ldap2pg` will crash.
- **WARNING:** `ldap2pg` warns about choices you should be aware of.
- **CHANGE:** only changes applied to Postgres Pro> cluster.
- **INFO (default):** tells what `ldap2pg` is doing, especially before long task.
- **DEBUG:** everything, including raw SQL queries and LDAP searches and introspection details.

The `--quiet` and `--verbose` command-line switches respectively decrease and increase verbosity.

You can select the highest level of verbosity with `LDAP2PG_VERBOSITY` environment variable. For example:

```
$ LDAP2PG_VERBOSITY=DEBUG ldap2pg
12:23:45 INFO    Starting ldap2pg                                version=v6.0-alpha5
runtime=go1.21.0 commit=<none>
12:23:45 WARN    Running a prerelease! Use at your own risks!
12:23:45 DEBUG   Searching configuration file in standard locations.
12:23:45 DEBUG   Found configuration file.                        path=./ldap2pg.yml
$
```

`ldap2pg` output varies whether it is running with a TTY or not. If standard error is a TTY, logging is colored and tweaked for human reading. Otherwise, logging format is pure logfmt, for machine processing. You can force human-readable output by using `--color` command-line interface switch.

ldap2pg.yml File Reference

`ldap2pg` requires a YAML configuration file usually named `ldap2pg.yml` and put in working directory. Everything can be configured from the YAML file: Postgres Pro inspect queries, LDAP searches, privileges and synchronization map.

Warning

`ldap2pg` *requires* a configuration file where the synchronization map is described.

Here are the contents of a tested `ldap2pg.yml`, which can be used as a starting point:

```
#
#
#      L D A P 2 P G      S A M P L E      C O N F I G U R A T I O N
#
# This is a starting point configuration file for ldap2pg.yml. Including static
# roles, groups, privilege and LDAP search.
#
# This configuration assumes the following principles:
#
# - All LDAP users are grouped in `ldap_roles` group.
# - Read privileges are granted to `readers` group.
# - Write privileges are granted to `writers` group.
# - DDL privileges are granted to `owners` group.
# - We have one or more databases with public and maybe a schema.
# - Grants are not specific to a schema. Once you're writer in a database, you
#   are writer to all schemas in it.
```

```
#
# The LDAP directory content is described in test/fixtures/openldap-data.ldif
#
# Adapt to your needs!
#
#
# File format version. Allows ldap2pg to check whether the file is supported.

      (cn=writers)
    )
    "
  role:
    name: '{member.cn}'
    options: LOGIN
    parent: "{cn}"
```

File Location

ldap2pg searches for configuration file in the following order:

1. ldap2pg.yml in current working directory.
2. ~/.config/ldap2pg.yml.
3. /etc/ldap2pg.yml.
4. /etc/ldap2pg/ldap2pg.yml.

If LDAP2PG_CONFIG or --config is set, ldap2pg skips searching the standard file locations. You can specify - to read configuration from standard input. This is helpful to feed ldap2pg with dynamic configuration.

File Structure

ldap2pg.yml is split in several sections:

- postgres: setup Postgres Pro> connection and inspection queries.
- ldap: configuration for LDAP client.
- privileges: the definition of privilege profiles.

- `rules`: the list of LDAP searches and associated mapping to roles and grants.

If you don't know how to begin, a simple tested and well commented [ldap2pg.yml](#) is a good starting point.

About YAML

YAML is a super-set of JSON. A JSON document is a valid YAML document. YAML is a very permissive format where indentation is meaningful. See [this YAML cheatsheet](#) for some example.

In `ldap2pg.yml` file, you will likely use wildcard for global pattern and curly brace for LDAP attribute injection. Take care of protecting these characters with quotes.

```
rules:
  - role: {cn} # It's an invalid YAML dict.
  - role: "{cn}" # It's a string with LDAP attribute injection
```

postgres Section

The `postgres` section defines custom SQL queries for Postgres Pro inspection.

The `postgres` section contains several `*_query` parameters. These parameters can be either a string containing an SQL query or a YAML list to return a static list of values, skipping execution of a query on Postgres Pro cluster.

`databases_query`

The SQL query to list databases names in the cluster. By default, `ldap2pg` searches databases it can connect to and it can reassign objects to its owner. `ldap2pg` loops databases to reassign objects before dropping a role. `ldap2pg` manages privilege on each database.

```
postgres:
  databases_query: "SELECT datname FROM pg_catalog.pg_databases;"
  # OR
  databases_query: [mydb]
```

Note

Configuring a `_query` parameter with a YAML list skips querying the cluster for inspection and forces `ldap2pg` to use a static value.

`fallback_owner`

Name of the role accepting ownership of database of dropped role.

Before dropping a role, `ldap2pg` reassigns objects and purges the access control list (ACL). `ldap2pg` starts by reassigning database owner by the targetted user. The new owner of the database is the *fallback owner*. Other objects are reassigned to each database owner.

`managed_roles_query`

The SQL query to list the name of managed roles.

`ldap2pg` restricts role deletion and privilege edition to managed roles. Usually, this query returns children of a dedicated group like `ldap_roles`. By default, `ldap2pg` manages all roles it has access to.

`public` is a special built-in role in Postgres Pro. If `managed_roles_query` returns `public` role in the list, `ldap2pg` will manage privileges on `public`. By default, `ldap2pg` manages `public` privileges.

The following example tells `ldap2pg` to manage `public` role, `ldap_roles` and any members of `ldap_roles`:

```
postgres:
  managed_roles_query: |
```

```
VALUES
  ('public'),
  ('ldap_roles')
UNION
SELECT DISTINCT role.rolname
FROM pg_roles AS role
JOIN pg_auth_members AS ms ON ms.member = role.oid
JOIN pg_roles AS parent
  ON parent.rolname = 'ldap_roles' AND parent.oid = ms.roleid
ORDER BY 1;
```

roles_blacklist_query

The SQL query returning name and global pattern to blacklist role from management. ldap2pg won't touch anything on these roles. Default value is [postgres, pg_*]. ldap2pg blacklists self user.

```
postgres:
  roles_blacklist_query:
  - postgres
  - "pg_*"
  - "rds_*
```

Warning

Beware that 'foo' is a YAML reference. You must quote pattern *beginning* with '*'.

schemas_query

The SQL query returning the name of managed schemas in a database. ldap2pg executes this query on each databases returned by `databases_query` only if ldap2pg manages privileges. ldap2pg loops on objects in theses schemas when inspecting GRANTS in the cluster.

```
postgres:
  schemas_query: |
    SELECT nspname FROM pg_catalog.pg_namespace
```

ldap Section

The `ldap` section customizes LDAP client behaviour. Configure connection using `ldap.conf` and `LDAP*` environment variables.

known_rdns

List of attributes known to be part of the distinguished name (DN).

ldap2pg skips sub-search for attributes in this list. e.g., {member.cn} won't trigger a sub-search on all members if `cn` is in `known_rdns`. Default value is [n, l, st, o, ou, c, street, dc, uid]. Add a value to fasten synchronization. Remove a value if an attribute is not part of the DN.

```
ldap:
  known_rdns: [cn, uid]
```

privileges Section

The `privileges` top-level section defines Postgres Pro privileges. It is a mapping defining privilege profiles, referenced later in synchronisation map's [grant rule](#). A privilege profile is a list of either references to a privilege type in a Postgres Pro ACL or other profiles. A privilege profile may include another profile, recursively. See [Managing Privileges](#) for details.

```
privileges:
  reading:
```

```
- on: GLOBAL DEFAULT
  type: SELECT
  object: TABLES
writing:
- reading
- on: GLOBAL
  type: SELECT
  object: TABLES
```

A privilege profile whose name starts with `_` is inactive unless included in an active profile.

object

Defines the target object for object-grained ACL.

Actually useful only for `GLOBAL DEFAULT` and `SCHEMA DEFAULT` ACL where the object is the target object class like `TABLES`, `SEQUENCES`, etc. [grant rule](#) defines target schema for `SCHEMA DEFAULT`.

```
privileges:
  reading:
  - type: SELECT
    on: GLOBAL DEFAULT
    object: TABLES
```

type

Type of privilege as described in [Section 5.8](#), e.g., `SELECT`, `REFERENCES`, `USAGE`, etc.

The value can be either a single string or a list of strings. Plural form `types` is valid. When multiple types are defined, a new privilege is defined for each type, each with the same attributes such as `on`.

```
privileges:
  reading:
  - type: USAGE
    on: SCHEMAS
```

on

Target ACL of privilege type. e.g., `TABLES`, `SEQUENCES`, `SCHEMAS`, etc. Note the special cases `ALL TABLES`, `ALL SEQUENCES`, etc. See [Managing Privileges](#) documentation for details.

```
privileges:
  reading:
  - type: SELECT
    on: ALL TABLES
```

rules **Section**

The top-level `rules` section defines synchronisation rules. The section contains is a YAML list. This is the only mandatory parameter in `ldap2pg.yaml`. Each item of `rules` is called a *mapping*. A mapping is a YAML dictionary with any of `role` or `grant` subsection. A mapping can optionnaly have a `description` field and a `ldapsearch` section.

```
rules:
- description: "Define DBA roles"
  ldapsearch:
    base: ...
  roles:
  - name: "{cn}"
    options: LOGIN SUPERUSER
```

The `ldapsearch` subsection is optional. You can define roles and grants without querying a directory.

description

A free string used for logging. This parameter does not accept mustache parameter injection.

ldapsearch

This directive defines LDAP search parameters. It is named after the `ldapsearch` command-line interface utility shipped by OpenLDAP project. Its behaviour should be mostly the same.

Note

This documentation refers to LDAP query as `search` while the word `query` is reserved for SQL query.

`ldapsearch` directives allow and require LDAP attributes injection in `role` and `grant` rules using curly braces. See [Querying Directory with LDAP](#) for details.

base, scope and filter

These parameters have the same meaning, definition and default as `base`, `scope` and `filter` arguments of `ldapsearch` command-line interface utility.

```
rules:
- ldapsearch:
  base: ou=people,dc=acme,dc=tld
  scope: sub
  filter: >
    (&f
      (member=*)
      (cn=group_*)
    )
```

joins

Customizes LDAP sub-search. The `joins` section is a dictionary with attribute name as key and LDAP search parameters as value. LDAP search parameters are the same as for top LDAP search. Actually, a single sub-search is supported.

```
rules:
- ldapsearch:
  joins:
    member:
      filter: ...
      scope: ...
  role:
  - name: "{member.sAMAccountName}"
```

The search base of sub-search is the value of the referencing attribute, e.g., each value of `member`. You can't customize the `base` attribute of sub-search. Likewise, `ldap2pg` infers attributes of sub-searches from `role` and `grant` rules. You can have only a single sub-search per top-level search. You can't do second-level sub-search.

See [Querying Directory with LDAP](#) for details.

Note

Executing a sub-search for each entry of a result set can be very heavy. You may optimize the query by using special LDAP search filter like `memberOf`. Refer to your LDAP directory administrator and documentation for details.

role

Defines a rule to describe one or more roles wanted in the target Postgres Pro cluster. This includes name, options, config, comment and membership. Plural form `roles` is valid. The value can be either a single role rule or a list of role rules.

```
rules:
- role:
  name: dba
  options: SUPERUSER LOGIN
- roles:
  - name: group0
    options: NOLOGIN
  - name: group1
    options: NOLOGIN
```

comment

Defines the SQL comment of a role. Default value is `Managed by ldap2pg`. Accepts LDAP attribute injection.

In case of LDAP attributes injection, you must take care of how many combinations will be generated. If the template generates a single comment, `ldap2pg` will copy the comment for each role generated by the [role rule](#). If the template generates multiple comments, `ldap2pg` associates name and comment. If there is more or less comments generated than name generated, `ldap2pg` fails.

The following example defines a static comment shared by all generated roles:

```
rules:
- roles:
  names:
  - alice
  - bob
  comment: "Static roles from YAML."
```

The following example generates a single comment from LDAP entry distinguished name, copied for all generated roles:

```
rules:
- ldapsearch:
  ...
  role:
    name: "{cn}"
    comment: "Generated from LDAP entry {dn}."
```

The following example generate a unique comment for each roles generated:

```
rules:
- ldapsearch:
  ...
  role:
    name: "{member.cn}"
    comment: "Generated from LDAP entry {member}."
```

Tip

If a role is defined multiple times, parents are merged. Other fields are kept as declared by the first definition of the role.

name

Name of the role wanted in the cluster. The value can be either a single string or a list of strings. Plural form `names` is valid. You can inject LDAP attributes in name using curly braces. When multiple names are defined, a new role is defined for each name, each with the same attributes such as `options` and `parents`. `comment` parameter has a special handling, see [comment](#).

```
rules:
- roles:
  name: "my-role-name"
```

When injecting LDAP attribute in name, each value of the LDAP attribute of each LDAP entry will define a new role. When multiple LDAP attributes are defined in the format, all combination of attributes are generated.

`ldap2pg` protects role name with double quotes in the target Postgres Pro cluster. Capitalization is preserved, spaces are allowed (even if it's a really bad idea).

`ldap2pg` applies [roles_blacklist_query](#) on this parameter.

options

Defines Postgres Pro role options. Can be an SQL-like string or a YAML dictionary. Valid options are `BYPASSRLS`, `CONNECTION LIMIT`, `LOGIN`, `CREATEDB`, `CREATEROLE`, `INHERIT`, `REPLICATION` and `SUPERUSER`. Available options vary following the version of the target Postgres Pro cluster and the privilege of `ldap2pg` user.

```
- roles:
- name: my-dba
  options: LOGIN SUPERUSER
- name: my-group
  options:
    LOGIN: no
    INHERIT: yes
```

config

Defines Postgres Pro configuration parameters that will be set for the role. Must be a YAML dictionary. Available configuration parameters vary following the version of the target Postgres Pro cluster. Some parameters require superuser privileges to be set. `ldap2pg` will fail if it does not have privilege to set a config parameter.

```
- roles:
- name: my-db-writer
  config:
    log_statement: mod
    log_min_duration_sample: 100
```

Setting `config` to `null` (the default) will disable the feature for the role. If `config` is a dict, `ldap2pg` will drop parameter set in cluster but not defined in `ldap2pg` YAML. To reset all parameters, set `config` to an empty dict like below.

```
- roles:
- name: reset-my-configuration
  config: {}
```

Note that LDAP attributes are not expanded in config values.

parent

Name of a parent role. A list of names is accepted. The plural form `parents` is valid too. Parent role is granted with `GRANT ROLE parent TO role;`. `parent` parameter accepts LDAP attributes

injection using curly braces. ldap2pg applies [roles_blacklist_query](#) on this parameter. Parent reference can be local roles not managed by ldap2pg.

```
rules:
- role:
    name: myrole
    parent: myparent
```

before_create

SQL snippet to execute before role creation. `before_create` accepts LDAP attributes injection using curly braces. You are responsible for escaping attribute with either `.identifier()` or `.string()`.

```
rules:
- ldapsearch: ...
  role:
    name: "{cn}"
    before_create: "INSERT INTO log VALUES ({cn.string()})"
```

after_create

SQL snippet to execute after role creation. `after_create` accepts LDAP attributes injection using curly braces. You are responsible for escaping attribute with either `.identifier()` or `.string()`.

```
rules:
- ldapsearch: ...
  role:
    name: "{sAMAccountName}"
    after_create: "CREATE SCHEMA {sAMAccountName.identifier()} AUTHORIZATION
{sAMAccountName.identifier()}"
```

grant

Defines a grant of a privilege to a role with corresponding parameters. Can be a mapping or a list of mapping. Plural form `grants` is valid too.

```
rules:
- grant:
    privilege: reader
    databases: __all__
    schema: public
    role: myrole
```

database

Scope the grant to one or more databases. May be a list of names. Plural form `databases` is valid. Special value `__all__` expands to all managed databases as returned by [databases_query](#). Defaults to `__all__`. Grants found in other databases will be revoked. Accepts LDAP attributes injection using curly braces.

This parameter is ignored for instance-wide privileges (e.g., on `LANGUAGE`).

privilege

Name of a privilege, within the privileges defined in [privileges](#) YAML section. May be a list of names. Plural form `privileges` is valid. Required, there is not default value. Accepts LDAP attribute injection using curly braces.

role

Name of the target role of the grant (*granted role* or *grantee*). Must be listed by [managed_roles_query](#). May be a list of names. Plural form `roles` is valid. Accepts LDAP attribute injection using curly braces. ldap2pg applies [roles_blacklist_query](#) on this parameter.

schema

Name of a schema within the schemas returned by `schemas_query`. Special value `__all__` means *all managed schemas in the databases*. May be a list of names. Plural form `schemas` is valid. Accepts LDAP attribute injection using curly braces.

This parameter is ignored for privileges on `DATABASE` and other instance-wide or database-wide privileges.

owner

Name of role to configure default privileges for. Special value `__auto__` fallbacks to managed roles having `CREATE` privilege on the target schema. May be a list of names. Plural form `owners` is valid. Accepts LDAP attribute injection using curly braces.

acls **Section**

Defines Postgres Pro ACLs. An ACL is set of queries to list GRANTS in the cluster and to manage them by granting or revoking item in the list. ACL is scoped to instance or database. References ACL in privileges profiles. Writing [a custom ACL](#) is tricky, ensure you understand both PostgreSQL and ldap2pg before.

acls

The `acls` top level section is a mapping defining ACLs. All fields are mandatory.

acls:

```
PROCEDURE:
  scope: database
  inspect: |
    WITH ...
  grant: GRANT ...
  revoke: REVOKE ...
```

scope

Scope of the ACL. Can be `instance` or `database`.

inspect

SQL query to list GRANTS in the cluster. The signature of the query depends on the scope. See [custom ACLs](#) for details.

grant

SQL query to grant a privilege. The query accepts templating using angle brackets. Some parameters are injected as keyword, i.e., as raw SQL. Other parameters are quoted as identifiers.

Available parameters:

- `<acl>` name of the ACL. Raw SQL.
- `<database>` name of database to grant on. Quoted identifier.
- `<grantee>` name of role to grant on. Quoted identifier.
- `<object>` name of object to grant on. Quoted identifier.
- `<owner>` name of role to grant to. Quoted identifier.
- `<privilege>` type of privilege. Raw SQL.
- `<schema>` name of schema to grant on. Quoted identifier.

revoke

SQL query to revoke a privilege. Like `grant`, the query accepts templating using angle brackets. Accepts same parameters as `grant`. Having different parameter between `GRANT` and `REVOKE` leads to unexpected behaviour.

Inspecting Postgres Pro Cluster

ldap2pg follows the explicit create/implicit drop and explicit grant/implicit revoke pattern. Thus properly inspecting cluster for what you want to drop/revoke is very crucial to succeed in synchronization.

ldap2pg inspects databases, schemas, roles, owners and grants with SQL queries. You can customize all these queries in the `postgres` YAML section with parameters ending with `_query`. See [the section called “postgres Section”](#) for details.

What Databases to Synchronize?

`databases_query` returns the flat list of databases to manage. The `databases_query` must return the default database as defined in `PGDATABASE`. When dropping roles, ldap2pg loops the databases list to reassign objects and clean GRANTS of the role to be dropped. This databases list also narrows the scope of GRANTS inspection. ldap2pg will revoke GRANTS only on these databases. See [the section called “postgres Section”](#) for details.

```
postgres:
  databases_query: |
    SELECT datname
    FROM pg_catalog.pg_database
    WHERE datallowconn IS TRUE;
```

Synchronize a Subset of Roles

By default, ldap2pg manages all roles from Postgres Pro, it has powers on, minus the default blacklist. If you want ldap2pg to synchronize only a subset of roles, you need to customize inspection query in [postgres:managed_roles_query](#). The following query excludes superusers from synchronization.

```
postgres:
  managed_roles_query: |
    SELECT 'public'
    UNION
    SELECT rolname
    FROM pg_catalog.pg_roles
    WHERE rolsuper IS FALSE
    ORDER BY 1;
```

ldap2pg will only drop, revoke, grant on roles returned by this query.

A common case for this query is to return only members of a group like `ldap_roles`. This way, ldap2pg is scoped to a subset of roles in the cluster.

The `public` role does not exist in the system catalog. Thus if you want ldap2pg to manage `public` privileges, you must include explicitly `public` in the set of managed roles. This is the default. Of course, even if `public` is managed, ldap2pg won't drop or alter it if it's not in the directory.

A safety net to completely ignore some roles is [roles_blacklist_query](#).

```
postgres:
  roles_blacklist_query: [postgres, pg_*] # This is the default.
```

Note

A pattern starting with a `'*'` *must* be quoted. Else you'll end up with a YAML error like “found undefined alias”.

Inspecting Schemas

For schema-wide privileges, ldap2pg needs to know managed schemas for each database. This is the purpose of `schemas_query`.

Configuring Owners Default Privileges

To configure default privileges, use the `default` keyword when referencing a privilege:

```
privileges:
  reading:
    - default: global
      type: SELECT
      on: TABLES
```

Then grant it using `grant` rule:

```
rules:
- grant:
  - privilege: reading
    role: readers
    schema: public
    owner: ownerrole
```

You can use `__auto__` as owner. For each schema, `ldap2pg` will configure every managed role having `CREATE` privilege on schema.

```
rules:
- grant:
  - privilege: reading
    role: readers
    schema: public
    owner __auto__
```

`ldap2pg` configures default privileges last, after all effective privileges. Thus `CREATE` on schema is granted before `ldap2pg` inspects creators on schemas.

Static Queries

You can replace all queries with a **static list** in YAML. This list will be used as if returned by Postgres Pro. That's very handy to freeze a value like databases or schemas.

```
postgres:
  databases_query: [postgres]
  schemas_query: [public]
```

Managing Roles

`ldap2pg` synchronizes Postgres Pro roles in three steps:

1. Loop `rules` and generate wanted roles list from `role` rules.
2. Inspect Postgres Pro for existing roles, their options and their membership.
3. Compare the two roles sets and apply to the Postgres Pro cluster using `CREATE`, `DROP` and `ALTER`.

Each `role` entry in `rules` is a rule to generate zero or more roles with the corresponding parameters. A `role` rule is like a template. `role` rules allow you to deduplicate membership and options by setting a list of names.

You can mix static rules and dynamic rules in the same file.

Running Unprivileged

`ldap2pg` is designed to run unprivileged. Synchronization user needs `CREATEROLE` option to manage other unprivileged roles. `CREATEDB` options allow synchronization user to manage database owners.

`ldap2pg` user must have `createrole_self_grant` set to `inherit`, set to properly handle groups.

```
CREATE ROLE ldap2pg LOGIN CREATEDB CREATEROLE;
ALTER ROLE ldap2pg SET createrole_self_grant TO 'inherit,set';
```

Running unprivileged before PostgreSQL 16 is actually flawed. You'd better just run `ldap2pg` with superuser privileges, you won't feel falsely secured.

Ignoring Roles

`ldap2pg` totally ignores roles matching one of the global pattern defined in `roles_blacklist_query`:

```
postgres:
  # This is the default value.
  roles_blacklist_query: [postgres, pg_*]
```

The role blacklist is also applied to grants. `ldap2pg` will never apply `grant` or `revoke` on a role matching one of the blacklist patterns.

`ldap2pg` blacklists its running user.

Membership

`ldap2pg` manages parents of roles. `ldap2pg` applies `roles_blacklist_query` to parents. However, `ldap2pg` grants unmanaged parents. This way, you can create a group manually and manage its members using `ldap2pg`.

Querying Directory with LDAP

`ldap2pg` reads LDAP searches in `rules` steps in the `ldapssearch` entry.

A LDAP search is **not** mandatory. `ldap2pg` can create roles defined statically from YAML. Each LDAP search is executed once and only once. There is neither loop nor deduplication of LDAP searches.

Tip

`ldap2pg` logs LDAP searches as `ldapssearch` commands. Enable verbose messages to see them.

You can debug a failing search by copy-pasting the command in your shell and update parameters. Once you are okay, translate back the right parameters in the YAML.

Configuring Directory Access

`ldap2pg` reads directory configuration from `ldaprc` file and `LDAP*` environment variables. Known LDAP options are:

- BASE
- BINDDN
- PASSWORD
- REFERRALS
- SASL_AUTHCID
- SASL_AUTHZID
- SASL_MECH
- TIMEOUT
- TLS_REQCERT
- NETWORK_TIMEOUT
- URI

See `ldap.conf(5)` man page for the meaning and format of each options.

Injecting LDAP Attributes

Several parameters accept LDAP attribute injection using curly braces. To do this, wrap attribute name with curly braces like `{cn}` or `{sAMAccountName}`. `ldap2pg` expands to each value of the attribute for each entries of the search.

If the parameter has multiple LDAP attributes, `ldap2pg` expands to all combinations of attributes for each entries.

Given the following LDAP entries:

```
dn: uid=dimitri,cn=Users,dc=bridoulou,dc=fr
objectClass: inetOrgPerson
uid: dimitri
sn: Dimitri
cn: dimitri
mail: dimitri@bridoulou.fr
company: external
dn: cn=domitille,cn=Users,dc=bridoulou,dc=fr
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: person
objectClass: top
cn: domitille
sn: Domitille
company: acme
company: external
```

The format `{company}_{cn}` with the above LDAP entries generates the following strings:

- `acme_domitille`
- `external_domitille`
- `external_dimitri`

The pseudo attribute `dn` is always available and references the distinguished name (DN) of the original LDAP entry.

Accessing RDN and Sub-Search

If an attribute type is DN, you can refer to a relative distinguished name (RDN) with a dot, like this: `<attribute>.<rdn>`. If an RDN has multiple values, only the first value is returned. There is no way to access other values.

For example, if a LDAP entry has `member` attribute with value `cn=toto,cn=Users,dc=bridoulou,dc=fr`, the `{member.cn}` format will generate `toto`. The `{member.dc}` format will generate `ldap`. There is no way to access `acme` and `fr`.

Known RDN are `cn`, `l`, `st`, `o`, `ou`, `c`, `street`, `dc`, and `uid`. Other attributes trigger a sub-search. The format `{member.sAMAccountName}` will issue a sub-search for all `member` value as LDAP search base narrowed to `sAMAccountName` attribute.

LDAP Attribute Case

When injecting a LDAP attribute with curly braces, you can control the case of the value using `.lower()` or `.upper()` methods.

```
- ldapsearch: ...
  role: "{cn.lower()}"
```

Managing Privileges

Managing privileges is tricky. `ldap2pg` tries to make this simpler and safer.

Basics

The base design of `ldap2pg` is as follows. Instead of revoke-everything-regrant design, `ldap2pg` uses inspect-modify design. The process is the same as for roles synchronization, including the three following steps:

1. Loop `rules` and generate wanted grants set.

2. Inspect Postgres Pro cluster for granted privileges.
3. Compare the two sets of grants and update the Postgres Pro cluster using `grant`, `revoke`.

ldap2pg represents privileges with these core objects:

- `Privilege`: An action on an object. e.g., `CONNECT ON DATABASE`.
- `grant`: a privilege granted to a role on an object.
- `ACL`: a list of grants.
- `profile`: a list of privileges.
- `rule`: a template to generate wanted grants.

`ldap2pg.yml` holds profiles and grant rule. `ldap2pg` synchronizes ACL one at a time, database by database. `ldap2pg` synchronizes default privileges last.

By default, `ldap2pg` does not manage any privileges. To enable privilege management, you must define at least one active profile in `privileges` section. The simplest way is to reuse [built-in privilege profiles](#) shipped with `ldap2pg` in an active custom profile.

Defining a Privilege Profile

A privilege profile is a list of references to either a privilege type on an ACL or another profile. `ldap2pg` ships several predefined ACL like `DATABASE`, `LANGUAGE`, etc. A privilege type is `USAGE`, `CONNECT` and so on, as described in [Section 5.8](#). See `privileges` YAML section documentation for details on privilege profile format.

`ldap2pg` loads referenced ACL by inspecting Postgres Pro cluster with carefully crafted queries. `ldap2pg` inspects only ACL referenced in at least one profile. Inspected grants are supposed to revocation unless explicitly wanted by a `grant` rule.

Warning

If it's not granted, revoke it!

Once an ACL is inspected, `ldap2pg` *revokes* all grants found in Postgres Pro instance and not required by a `grant` rule in `rules`.

Extended Intance Inspection

When managing privileges, `ldap2pg` has deeper inspection of Postgres Pro instance. `ldap2pg` inspects schemas after roles synchronization and before synchronizing privileges. `ldap2pg` inspects objects owner after privileges synchronization and before synchronizing default privileges. An object owner is a role having `CREATE` privilege on the schema.

Granting Privilege Profile

Inspecting millions of privileges may consume a lot of resources on Postgres Pro instance. Revoking privileges is known to be slow in Postgres Pro. The best practice is to grant privileges to a group role and let user inherit privileges. With `ldap2pg`, you can define static groups in YAML and inherit them when creating roles from directory.

Use `grant rule` to grant a privilege profile to one or more roles. When granting privileges, you must define the grantee. You may scope the grant to one or more databases, one or more schemas. If the privilege profile includes default privileges, you may define the owners on which to configure default privileges.

By default, a grant applies to all managed databases as returned by `databases_query`, to all schemas of each database as returned by `schemas_query`.

Example

The following example defines three privileges profile. The `rules` defines three groups and grant the corresponding privilege profile:

```
privileges:
  reading:
    - __connect__
    - __usage_on_schemas__
    - __select_on_tables__
  writing:
    - reading # include reading privileges
    - __insert_on_tables__
    - __update_on_tables__
  owning:
    - writing
    - __create_on_schemas__
    - __truncate_on_tables__
rules:
- role:
  - names:
    - readers
    - writers
    - owners
    options: NOLOGIN
- grant:
  - privilege: reading
    role: readers
  - privilege: writing
    role: writers
  - privilege: owning
    role: owners
```

Another way of including reading profile in writing is to writers group to inherit readers group.

Managing Public Privileges

Postgres Pro has a pseudo-role called `public`. It's a wildcard role meaning *every users*. All roles in Postgres Pro implicitly inherits from this `public` role. Granting a privilege to `public` role grants to every roles now and in the future.

Postgres Pro also has the `public` schema. The `public` schema is a real schema available in all databases.

Postgres Pro has some built-in privileges for `public` role. Especially for the `public` schema. For example, `public` has `CONNECT` on all databases by default. This means that you only rely on `pg_hba.conf` to configure access to databases, which requires administrative access to the cluster and a `pg_reload_conf()` call.

By default, `ldap2pg` includes `public` role in managed roles. Predefined ACL knows how to inspect built-in privileges granted to `public`. If you want to preserve `public` role, rewrite `managed_roles_query` to not include `public`.

Managing Default Privileges

If you grant `SELECT` privileges on all tables in a schema to a role, this won't apply to new tables created afterward. Instead of reexecuting `ldap2pg` after the creation of every objects, Postgres Pro provides a way to define default privileges for future objects.

Postgres Pro attaches default privileges to the creator role. When the role creates an object, Postgres Pro applies the corresponding default privileges to the new object. e.g., `ALTER DEFAULT PRIVILEGES FOR ROLE bob GRANT SELECT ON TABLES TO alice;` ensures every new table bob creates will be selectable by alice:

If `ldap2pg` creates and drops creator roles, you want `ldap2pg` to properly configure default privileges on these roles. If you wonder whether to manage privileges with `ldap2pg`, you should at least manage default privileges along creator.

ldap2pg inspects the creators from Postgres Pro, per schemas, not LDAP directory. A creator is a role with `LOGIN` option and `CREATE` privilege on a schema. You can manually set the target owner of a grant to any managed roles.

ldap2pg does not configure privileges on `__all__` schemas. You are supposed to use `GLOBAL DEFAULT ACL` instead. If you want to grant/revoke default privilege per schema, you must reference `SCHEMA DEFAULT ACL`.

The following example configures default privileges for alice to allow bob to `SELECT` on future tables created by alice.

```
privileges:
  reading:
    - type: SELECT
      on: SCHEMA DEFAULT
      object: TABLES
  owning:
    - type: CREATE
      on: SCHEMAS

rules:
- roles:
    names:
      - alice
      - bob
    options: LOGIN
- grant:
    privilege: owning
    role: alice
- grant:
    privilege: reading
    role: bob
```

Postgres Pro has hard-wired global default privileges. If a role does not have global default privileges configured, Postgres Pro assumes some defaults. By default, Postgres Pro just grants privileges on owner. You can see them once you modify the default privileges. Postgres Pro will copy the hard-wired values along with your granted privileges.

If you don't explicitly re-grant these privileges in `ldap2pg.yml`, ldap2pg will revoke these hard-wired privileges. Actually, an owner of table don't need to be granted `SELECT` on its own tables. Thus, the hard-wired defaults are useless. You can let ldap2pg purge these useless defaults.

Built-in Privileges

ldap2pg provides some built-in ACLs and predefined privilege profiles for recurrent usage. There is **no warranty** on these privileges. You have to check privileges configuration on your databases just like you should do with your own code.

Using Predefined Privilege Profiles

A privilege profile is a list of references to a privilege type in an ACL. In ldap2pg, an ACL is a set of queries to inspect, grant revoke privilege on a class of objects. The inspect query expands `aclitem` Postgres Pro type to list all grants from system catalog. Privilege profile can include another profile.

Built-in privilege profile starts and ends with `__`. ldap2pg [disables privilege profile](#) starting with `_`. Thus you have to include built-in privileges profile in another profile to enable them. If two profiles reference the same privilege, ldap2pg will inspect it once.

```
privileges:
  ro:
    - __connect__
```

```
- __usage_on_schemas__
- __select_on_tables__

rw:
- ro
- __insert__

ddl:
- rw
- __all_on_schemas__

rules:
- grant:
    privilege: ddl
    database: mydb
    role: admins
```

Built-in profile's name follows the loose convention below:

- `..._on_all_tables__` references `ALL TABLES IN SCHEMA ACL`. Likewise for sequences and functions.
- `__default_...__` references both global and schema-wide default privileges.
- `..._on_tables__` groups `..._on_all_tables__` and `__default_..._on_tables__`.
- Group starting with `__all_on_...__` is *equivalent* to `ALL PRIVILEGES` in SQL. However, each privilege will be granted individually.
- A privilege specific to one object type does not have `_on_<type>` suffix. E.g., `__delete_on_tables__` is an alias of `__delete__`.

This page does not document the SQL standard and the meaning of each SQL privileges. You will find information on SQL privileges in [GRANT documentation](#) and [ALTER DEFAULT PRIVILEGES documentation](#).

ACL Reference

Here is the list of built-in ACLs.

For effective privileges:

DATABASE

Privilege on database like `CONNECT`, `CREATE`, etc.

SCHEMA

Manage `USAGE` and `CREATE` on schema.

LANGUAGE

Manage `USAGE` on procedural languages.

ALL FUNCTIONS IN SCHEMA

Manage `EXECUTE` on all functions per schema.

ALL SEQUENCES IN SCHEMA

Like above but for sequences.

ALL TABLES IN SCHEMA

Like above but for tables and views.

GLOBAL DEFAULT

Manage default privileges on database.

SCHEMA DEFAULT

Manage default privileges per schema.

ALL ... IN SCHEMA ACL inspects whether a privilege is granted to only a subset of objects. This is a *partial* grant. A partial grant is either revoked if unwanted or re-granted if expected.

You can reference these ACLs using [privileges: on](#) parameter in YAML. Like this:

```
privileges:
  myprofile:
    - type: SELECT
      on: ALL TABLES IN SCHEMA
```

Default privileges reference a privilege type and a class of objects. ldap2pg inspects default privileges for the following object classes:

- SEQUENCES
- FUNCTIONS
- TABLES

You must reference object class in privilege profile using [object](#) parameter in YAML.

You cannot configure custom ACL (yet).

Profiles Reference

Profile `__all_on_functions__`
`__execute_on_functions__`

Profile `__all_on_schemas__`

- `__create_on_schemas__`
- `__usage_on_schemas__`

Profile `__all_on_sequences__`

- `__select_on_sequences__`
- `__update_on_sequences__`
- `__usage_on_sequences__`

Profile `__all_on_tables__`

- `__delete_on_tables__`
- `__insert_on_tables__`
- `__select_on_tables__`
- `__truncate_on_tables__`
- `__update_on_tables__`
- `__references_on_tables__`
- `__trigger_on_tables__`

Profile `__delete_on_tables__`

- `__default_delete_on_tables__`
- `__delete_on_all_tables__`

Profile `__execute_on_functions__`

- `__default_execute_on_functions__`
- `__execute_on_all_functions__`

Profile `__insert_on_tables__`

- `__default_insert_on_tables__`
- `__insert_on_all_tables__`

Profile `__references_on_tables__`

- `__default_references_on_tables__`
- `__references_on_all_tables__`

Profile `__select_on_sequences__`

- `__default_select_on_sequences__`
- `__select_on_all_sequences__`

Profile `__select_on_tables__`

- `__default_select_on_tables__`
- `__select_on_all_tables__`

Profile `__trigger_on_tables__`

- `__default_trigger_on_tables__`
- `__trigger_on_all_tables__`

Profile `__truncate_on_tables__`

- `__default_truncate_on_tables__`
- `__truncate_on_all_tables__`

Profile `__update_on_sequences__`

- `__default_update_on_sequences__`
- `__update_on_all_sequences__`

Profile `__update_on_tables__`

- `__default_update_on_tables__`
- `__update_on_all_tables__`

Profile `__usage_on_sequences__`

- `__default_usage_on_sequences__`
- `__usage_on_all_sequences__`

Privileges Reference

Here is the list of predefined privileges:

Name	Manages
<code>__connect__</code>	CONNECT ON DATABASE
<code>__create_on_schemas__</code>	CREATE ON SCHEMA
<code>__delete_on_all_tables__</code>	DELETE ON ALL TABLES IN SCHEMA
<code>__execute_on_all_functions__</code>	EXECUTE ON ALL FUNCTIONS IN SCHEMA
<code>—</code>	
<code>__insert_on_all_tables__</code>	INSERT ON ALL TABLES IN SCHEMA
<code>__references_on_all_tables__</code>	REFERENCES ON ALL TABLES IN SCHEMA
<code>—</code>	
<code>__select_on_all_sequences__</code>	SELECT ON ALL SEQUENCES IN SCHEMA
<code>__select_on_all_tables__</code>	SELECT ON ALL TABLES IN SCHEMA
	TEMPORARY ON DATABASE
<code>__trigger_on_all_tables__</code>	TRIGGER ON ALL TABLES IN SCHEMA
<code>__truncate_on_all_tables__</code>	TRUNCATE ON ALL TABLES IN SCHEMA
<code>__update_on_all_sequences__</code>	UPDATE ON ALL SEQUENCES IN SCHEMA
<code>__update_on_all_tables__</code>	UPDATE ON ALL TABLES IN SCHEMA

Name	Manages
__usage_on_all_sequences__	USAGE ON ALL SEQUENCES IN SCHEMA
__usage_on_schemas__	USAGE ON SCHEMA

Default Privileges Reference

Here is the list of predefined default privileges. Default privilege profile references both global and schema defaults.

Name	Manages
__default_delete_on_tables__	DELETE ON TABLES
__default_execute_on_functions__	EXECUTE ON FUNCTIONS
__default_insert_on_tables__	INSERT ON TABLES
__default_references_on_tables__	REFERENCES ON TABLES
__default_select_on_sequences__	SELECT ON SEQUENCES
__default_select_on_tables__	SELECT ON TABLES
__default_trigger_on_tables__	TRIGGER ON TABLES
__default_truncate_on_tables__	TRUNCATE ON TABLES
__default_update_on_sequences__	UPDATE ON SEQUENCES
__default_update_on_tables__	UPDATE ON TABLES
__default_usage_on_sequences__	USAGE ON SEQUENCES

Usage Recipes

In this section, you'll find some recipes for various use cases of `ldap2pg`.

Configure `pg_hba.conf` with LDAP

`ldap2pg` does **NOT** configure Postgres Pro for you. You should carefully read [Section 19.10](#) for this point. Having Postgres Pro properly configured **before** writing `ldap2pg.yaml` is a good start. Here is the steps to setup Postgres Pro with LDAP in the best order:

1. Write the LDAP search and test it with `ldapsearch(1)`. This way, you can also check how you connect to your LDAP directory.
2. In Postgres Pro cluster, **manually** create a single role having its password in LDAP directory.
3. Edit `pg_hba.conf` following [Section 19.10](#) until you can effectively login with the single role and the password from LDAP.

Once you have LDAP authentication configured in Postgres Pro cluster, you can move to automate role creation from the LDAP directory using `ldap2pg`:

1. Write a simple `ldap2pg.yaml` with only one LDAP search just to setup `ldap2pg` connection parameters for Postgres Pro and LDAP connection. `ldap2pg` always runs in dry mode by default, so you can safely loop `ldap2pg` execution until you get it right.

2. Then, complete `ldap2pg.yaml` to fit your needs following [the section called “Command-Line Reference”](#). Run `ldap2pg` for real and check that `ldap2pg` maintain your single test role, and that you can still connect to the cluster with it.
3. Finally, you must decide when and how you want to trigger synchronization: a regular cron tab/an Ansible task/manually/ other. Ensure `ldap2pg` execution is frequent, on purpose and notified.

Search LDAP Directory

The first step is to search your LDAP server with `ldapsearch(1)`, the command-line interface tool from OpenLDAP. Like this:

```
$ ldapsearch -H ldaps://ldap.ldap2pg.docker -U testsasl -W
Enter LDAP Password:
SASL/DIGEST-MD5 authentication started
SASL username: testsasl
SASL SSF: 128
SASL data security layer installed.
# extended LDIF
#
# LDAPv3
...
# search result
search: 4
result: 0 Success

# numResponses: 16
# numEntries: 15
$
```

Now save the settings in `ldaprc`:

```
LDAPURI ldaps://ldap.ldap2pg.docker
LDAPSASL_AUTHCID testsasl
```

And in environment: `LDAPPASSWORD=secret`

Next, update your `ldapsearch` to properly match role entries in LDAP server:

```
$ ldapsearch -H ldaps://ldap.ldap2pg.docker -U testsasl -W -b
cn=dba,ou=groups,dc=ldap,dc=ldap2pg,dc=docker ' ' member
...
# dba, groups, ldap.ldap2pg.docker
dn: cn=dba,ou=groups,dc=ldap,dc=ldap2pg,dc=docker
member: cn=Alan,ou=people,dc=ldap,dc=ldap2pg,dc=docker
member: cn=albert,ou=people,dc=ldap,dc=ldap2pg,dc=docker
member: cn=ALICE,ou=people,dc=ldap,dc=ldap2pg,dc=docker

# search result
search: 4
result: 0 Success

...
$
```

Now translate the query in `ldap2pg.yaml` and associate a role mapping to produce roles from each values of each entries returned by the LDAP search:

```
- ldapsearch:
  base: cn=dba,ou=groups,dc=ldap,dc=ldap2pg,dc=docker
  role:
    name: '{member.cn}'
```

```
options: LOGIN SUPERUSER
```

Test it:

```
$ ldap2pg
...
Querying LDAP cn=dba,ou=groups,dc=ldap,dc=ldap2pg,dc=docker...
Would create alan.
Would create albert.
Would update options of alice.
...
Comparison complete.
$
```

Read further on how to control role creation from LDAP entry in [Configuration](#). Once you're satisfied with the comparison output, go real with `--real`.

Using LDAP High-Availability

ldap2pg supports LDAP high availability out of the box just like any OpenLDAP client. Use a space-separated list of URIs to tell all servers.

```
$ LDAPURI="ldaps://ldap1 ldaps://ldap2" ldap2pg
```

See `ldap.conf(5)` for further details.

Running as Non-Superuser

Since Postgres Pro> provides a `CREATEROLE` role option, you can manage roles without superuser privileges. Security-wise, it's a good idea to manage roles without superuser privileges.

Warning

Up to Postgres Pro 15, having `CREATEROLE` is roughly equivalent to being superuser. This because `CREATEROLE` user can grant themselves almost every privileges. Thus ldap2pg supports running unprivileged against Postgres Pro 16 and later only.

ldap2pg supports this case. However, you must be careful about the limitations. Let's call the non-superuser role creating other roles `creator`.

- You can't manage some roles options like `SUPERUSER`, `BYPASSRLS` and `REPLICATION`. Thus you won't be able to detect spurious superusers.
- Ensure `creator` can revoke all grants of managed users.

Removing All Roles

If ever you want to clean all roles in a Postgres Pro cluster, ldap2pg could be helpful. You must explicitly define empty rules.

```
$ echo '{version: 6, rules: []}' | ldap2pg --config -
...
Empty synchronization map. All roles will be dropped!
...
```

In this example, default blacklist applies. ldap2pg never drops its connection role.

ldap2pg as Docker Container

We assume that you are already familiar with Docker and willing to save the setup time.

To run the container simply use the command:

```
$ docker run --rm dalibo/ldap2pg --help
```

The Docker image of `ldap2pg` uses the same configuration options as explained in the [Command-Line Interface](#) and [ldap2pg.yml](#) sections. You can mount the `ldap2pg.yml` configuration file.

```
$ docker run --rm -v ${PWD}/ldap2pg.yml:/workspace/ldap2pg.yml dalibo/ldap2pg
```

You can also export some environment variables with the `-e` option:

```
$ docker run --rm -v ${PWD}/ldap2pg.yml:/workspace/ldap2pg.yml -e
PGDSN=postgres://postgres@localhost:5432/ -e LDAPURI=ldaps://localhost -e
LDAPBINDDN=cn=you,dc=entreprise,dc=fr -e LDAPPASSWORD=pasglop dalibo/ldap2pg
```

Make sure your container can resolve the hostname you are pointing to. If you use some internal name resolution, be sure to add the `-dns=` option to your command pointing to your internal DNS server. You can also find more information [here](#).

Custom ACL

`ldap2pg` comes with built-in ACLs for common objects like `DATABASE`, `SCHEMA`, `TABLE`, `FUNCTION`, etc. Postgres Pro has a lot of other objects like `FOREIGN DATA WRAPPER`, `FOREIGN SERVER`, `FOREIGN TABLE`, `TYPE`, etc. You may also want to manage custom ACL or something else. Writing a custom ACL should help you get the job done.

Note

Writing a custom ACL is quite advanced. You should be familiar with Postgres Pro ACLs and `ldap2pg` configuration. Ensure you have read [Managing Privileges](#) and [ldap2pg.yml File Reference](#) sections, have a good understanding of [Postgres Pro ACL documentation](#) and have successfully synchronized privileges with `ldap2pg`.

Define custom ACL in YAML configuration file.

Use Case

Say you have a custom `enum` type `myenum` in your database.

```
CREATE TYPE public.myenum AS ENUM ('toto', 'titi', 'tata');
```

We want to manage privileges on this object, eventually other types, with a custom ACL.

Naming

Name your ACL after the keyword in `GRANT` or `REVOKE` statement. From `GRANT USAGE ON TYPE mytype TO myrole`, name your ACL `TYPE`.

```
acls:
  TYPE:
    ...
```

Scope

Postgres Pro defines user types per schema. Since we'll hardcode the schema, we will scope our ACL to database.

```
acls:
  TYPE:
    scope: database
```

Grant and Revoke

Writing `GRANT` and `REVOKE` statements is the easiest part. See [grant](#) for details on query format. We'll use the `object` field of `grant` to store the name of the type. Public schema is hardcoded, as explained above.

```
acls:
  TYPE:
```

```
scope: database
grant: GRANT <privilege> ON TYPE public.<object> TO <grantee>;
revoke: REVOKE <privilege> ON TYPE public.<object> FROM <grantee>;
```

Inspect

The inspect query is the most difficult part. You need to master `aclitem`, `aclexplode` and `acldefault` Postgres Pro system built-ins. The signature of the inspect query depends on the scope of the ACL.

For instance scope:

- `type`: a string describing privilege type as SQL keyword.
- `object`: a string describing object name as SQL identifier.
- `grantee`: a string describing role name as SQL identifier.

For database scope:

- `type`: a string describing privilege type as SQL keyword.
- `object`: a string describing object name as SQL identifier.
- `grantee`: a string describing role name as SQL identifier.
- `partial`: a boolean indicating if the grant is partial.

`partial` tells `ldap2pg` to re-grant ALL ... IN SCHEMA privileges. Since our ACL is handling one object at a time, `partial` will always be `false`.

`ldap2pg` sends a single parameter to inspect query: the effective list of privilege types managed by the configuration. This list is an array of text. `ldap2pg` expects query to filter other privileges out of the list.

For TYPE ACL, we will inspect privileges on `pg_type` system catalog.

```
acls:
  TYPE:
    scope: database
    grant: GRANT <privilege> ON <acl> public.<object> TO <grantee>;
    revoke: REVOKE <privilege> ON <acl> public.<object> FROM <grantee>;
    inspect: |
      WITH grants AS (
        SELECT typename,
               (aclexplode(COALESCE(typacl, acldefault('T', typowner)))).privilege_type
      AS priv,
               (aclexplode(COALESCE(typacl, acldefault('T',
typowner)))).grantee::regrole::text AS grantee
        FROM pg_catalog.pg_type
        WHERE typnamespace::regnamespace = 'public'::regnamespace
        AND typtype <> 'b' -- exclude base type.
      )
      SELECT grants.priv AS "privilege",
             grants.typname AS "object",
             CASE grants.grantee WHEN '-' THEN 'public' ELSE grants.grantee END AS
grantee,
             FALSE AS partial
      FROM grants
      WHERE "priv" = ANY ($1)
      ORDER BY 2, 3, 1
    ;
```

As you see, it's not an easy query. This query works on Postgres Pro 17.

Usage

You can now use your custom ACL in a profile. Reference object in profile, not in grant rule.

```
privileges:
```

```

custom:
- type: USAGE
  on: TYPE
  object: myenum

rules:
- roles:
    names:
    - alice
  grant:
    privilege: custom
    role: alice

```

You must reference all types manually in the profile. Executing `ldap2pg` should produce changes in your database:

```

$ ldap2pg
...
16:52:02 CHANGE Would Revoke privileges.           grant="USAGE ON TYPE
myenum TO public" database=db0
16:52:02 CHANGE Would Grant privileges.           grant="USAGE ON TYPE
myenum TO alice" database=db0
16:52:02 INFO    Comparison complete.             searches=0 roles=1
queries=5 grants=1
16:52:02 INFO    Use --real option to apply changes.
16:52:02 INFO    Done.                           elapsed=44.345229ms
mempeak=1.6MiB ldap=0s inspect=28.992071ms sync=0s

```

That's it.

Debugging

If you encounter problem, isolate the issue. Reduce the configuration to your custom ACL. Synchronize a single role, grant to it. Avoid LDAP searches, use only static rules. Synchronize a single database. Enable debug messages with `--verbose` option.

`ldap2pg` works database per database then ACL per ACL. The messages for each ACL are as follow:

First line about your ACL has `acl=TYPE` record attribute.

```

17:13:35 DEBUG   Inspecting grants.                acl=TYPE
scope=database database=db0

```

Then you have messages for inspection: query and arguments. For each grant returned, a `Found grant.` message appears.

```

17:13:35 DEBUG   Executing SQL query:
WITH grants AS (
...
WHERE "priv" = ANY ($1)
ORDER BY 2, 3, 1
;
  arg=[USAGE]
17:13:35 DEBUG   Found grant in Postgres instance.   grant="USAGE ON TYPE
myenum TO public" database=db0

```

Then, `ldap2pg` expands grants generated by rule. For each grant generated, a `Wants grant.` message is printed.

```

17:13:35 DEBUG   Wants grant.                       grant="USAGE ON TYPE
myenum TO alice" database=db0

```

Finally, ldap2pg prints changes it would apply.

```
17:13:35 CHANGE Would Revoke privileges. grant="USAGE ON TYPE
myenum TO public" database=db0
17:13:35 DEBUG Would Execute SQL query:
REVOKE USAGE ON TYPE public."myenum" FROM "public";
17:13:35 CHANGE Would Grant privileges. grant="USAGE ON TYPE
myenum TO alice" database=db0
17:13:35 DEBUG Would Execute SQL query:
GRANT USAGE ON TYPE public."myenum" TO "alice";
```

At the end, ldap2pg prints a conclusion message, even if no changes are required.

```
17:13:35 DEBUG Privileges synchronized. acl=TYPE database=db0
```

pgbadger

pgbadger — rapidly analyze Postgres Pro logs, producing detailed reports and graphs

Synopsis

```
pgbadger [connection-option...] [option...] [logfile...]
```

Description

pgbadger is a Postgres Pro/PostgreSQL log analyzer, which rapidly provides detailed reports based on your log files. pgbadger is provided with Postgres Pro as a standalone Perl script.

logfile can be a single log file, a list of files or a shell command that returns a list of files. To get log content from the standard input, pass “-” as *logfile*.

pgbadger can parse huge log files and compressed files. It can autodetect your log file format (syslog, stderr, csvlog or jsonlog) if the file is long enough. Supported compressed formats are gzip, bzip2, lz4, xz, zip and zstd. For the xz format, you must have an xz version higher than 5.05, which supports the `--robot` option. For pgbadger to determine the uncompressed file size for the lz4 format, the file must be compressed with the `--content-size` option.

pgbadger supports any format of log-line prefixes that can be specified through the [log_line_prefix](#) configuration setting of your `postgresql.conf` configuration file, provided that at least `%t` and `%p` are specified.

[pgbouncer](#) log files can also be parsed.

To speed up log parsing, you can use any of these multiprocessing modes: one core per log file and multiple cores per file. These modes can be combined.

pgbadger can also parse remote log files fetched using a passwordless SSH connection. This mode can be used with compressed files and even supports multiprocessing with multiple cores per file.

Examples of reports can be found at <https://pgbadger.darold.net/#reports>.

Limitations

pgbadger currently has the following limitations:

- Multiprocessing is not supported for compressed log files and CSV files, as well as on Windows.
- CSV format of log files cannot be parsed remotely.
- csvlog logs cannot be passed from the standard input.

Setup and Configuring

pgbadger is provided with Postgres Pro Standard as a separate pre-built package `pgbadger` (for the detailed installation instructions, see [Chapter 16](#)). Once you have pgbadger installed, complete the setup described in sections below.

[Optional] Set up Parsing Specific Log Formats

If you plan to parse CSV log files, install `Text::CSV_XS` Perl module.

[Optional] Set up Export of Statistics

If you want to export statistics as a JSON file, install `JSON::XS` Perl module:

To install this optional module:

- On a Debian-based system, run:

```
sudo apt-get install libjson-xs-perl
```

- On an RPM system, run:

```
sudo yum install perl-JSON-XS
```

[Optional] Set up Parsing Compressed Log Files

By default, pgbadger autodetects the compressed log file format from the file extension and uses decompression utilities accordingly:

- `zcat` for `gz`
- `bzcat` for `bz2`
- `lz4cat` for `lz4`
- `zstdcat` for `zst`
- `unzip` or `xz` for `zip` or `xz`

If the needed utility is outside of your `PATH` directories, use the `--zcat` command-line option to specify the path to the decompression utility. For example:

```
--zcat="/usr/local/bin/gunzip -c" or --zcat="/usr/local/bin/bzip2 -dc"  
--zcat="C:\tools\unzip -p"
```

Note

With the default autodetection of the compressed file format, you can mix `gz`, `bz2`, `lz4`, `xz`, `zip` and `zstd` log files. Once you specified a custom value of `--zcat`, mixing compressed files of different formats is longer possible.

Configure Your Postgres Pro Server

Set the values of certain configuration parameters in your `postgresql.conf`:

- Set up logging SQL queries.

To enable SQL query logging and have the query statistics include actual query strings, set

```
log_min_duration_statement = 0
```

On a busy server you may want to increase this value to only log queries with a longer duration.

If you just want to report the duration and number of queries and do not want details of queries, set `log_min_duration_statement` to `-1`, which disables logging statement durations, and enable `log_duration`.

Enabling `log_min_duration_statement` will add reports about slowest queries and queries that took the most time. Note that if you set `log_statement` to `all`, the setting of `log_min_duration_statement` will have no effect.

Warning

Avoid setting `log_min_duration_statement` to a non-positive value together with enabling `log_duration` and `log_statement` as this will result in wrong counter values and drastically increase the size of your log. Always prefer setting `log_min_duration_statement`.

- Set the log line prefix string in `log_line_prefix`.

It must at least include a time escape sequence (`%t`, `%m` or `%n`) and the process-related escape sequence (`%p` or `%c`). For example, for `stderr` logs, the setting must be at least

```
log_line_prefix = '%t [%p]: '
```

The log line prefix could also specify the user, database name, application name and client IP address. For example,

for stderr logs:

```
log_line_prefix = '%t [%p]: user=%u,db=%d,app=%a,client=%h '
```

or

```
log_line_prefix = '%t [%p]: db=%d,user=%u,app=%a,client=%h '
```

and for syslog logs:

```
log_line_prefix = 'user=%u,db=%d,app=%a,client=%h '
```

or

```
log_line_prefix = 'db=%d,user=%u,app=%a,client=%h '
```

- To get more information from your log files, set certain configuration parameters as follows:

```
log_checkpoints = on
log_connections = on
log_disconnections = on
log_lock_waits = on
log_temp_files = 0
log_autovacuum_min_duration = 0
log_error_verbosity = default
```

To benefit from these settings, do not enable [log_statement](#) as pgbadger does not parse the corresponding log format.

- Set the language in which messages are displayed; messages must be in English with or without locale support:

```
lc_messages='C'
```

or

```
lc_messages='en_US.UTF-8'
```

Locales for other languages, such as `ru_RU.utf8`, are not supported.

Usage

The following are simple examples to illustrate miscellaneous pgbadger usage details.

```
pgbadger /var/lib/pgpro/std-18/data/log/postgresql-2022-01-14_000000.log
pgbadger /var/lib/pgpro/std-18/data/log/postgres.log.2.gz /var/lib/pgpro/std-18/data/
log/postgres.log.1.gz /var/lib/pgpro/std-18/data/log/postgresql-2022-01-14_000000.log
pgbadger /var/lib/pgpro/std-18/data/log/postgresql/postgresql-2022-01-*
pgbadger --exclude-query="^(COPY|COMMIT)" /var/lib/pgpro/std-18/data/log/
postgresql-2022-01-14_000000.log
pgbadger -b "2022-01-25 10:56:11" -e "2022-01-25 10:59:11" /var/lib/pgpro/std-18/data/
log/postgresql-2022-01-25-0000.log
cat /var/lib/pgpro/std-18/data/log/postgresql-2022-01-14_000000.log | pgbadger -
# Log line prefix with stderr log output
pgbadger --prefix '%t [%p]: user=%u,db=%d,client=%h' /var/lib/pgpro/std-18/data/log/
postgresql-2022-08-21*
pgbadger --prefix '%m %u@d %p %r %a : ' /var/lib/pgpro/std-18/data/log/
postgresql-2022-08-21-0000.log
# Log line prefix with syslog log output
pgbadger --prefix 'user=%u,db=%d,client=%h,appname=%a' /var/lib/pgpro/std-18/data/log/
postgresql-2022-08-21*
# Use 8 CPUs to parse 10GB file faster
```

```
pgbadger -j 8 /var/lib/pgpro/std-18/data/log/postgresql-2022-08-21-0000.log
# Use a cron job to report errors weekly
30 23 * * 1 /usr/bin/pgbadger -q -w /var/lib/pgpro/std-18/data/log/
postgresql-2022-01*.log -o /var/www/pg_reports/pg_errors.html
```

Specifying Remote Log Files

Specify remote log files to parse using a URI. Supported protocols are HTTP[S] and [S]FTP. The `curl` command will be used to download the file, and the file will be parsed during download. The SSH protocol is also supported and will use the `ssh` command to get log files, as when the `--remote-host` option is used.

Use these URI notations for the remote log file:

```
pgbadger http://172.12.110.1//var/lib/pgpro/std-18/data/log/
postgresql-2022-01-14_000000.log
pgbadger ftp://username@172.12.110.14/postgresql-2022-01-14_000000.log
pgbadger ssh://username@172.12.110.14:2222//var/lib/pgpro/std-18/data/log/
postgresql-2022-01-14_000000.log*
```

You can parse a local Postgres Pro log and a remote [pgbouncer](#) log file together:

```
pgbadger /var/lib/pgpro/std-18/data/log/postgresql-2022-01-14_000000.log ssh://
username@172.12.110.14/pgbouncer.log
```

Parallel Processing

To enable parallel processing, specify the `-j N` option, where *N* is the number of cores to use.

Parallel processing in pgbadger follows the algorithm below:

```
For each log file
  chunk size = int(file size / N)
  look at start/end offsets of these chunks
  fork N processes and seek to the start offset of each chunk
    each process will terminate when the parser reaches the end offset of its chunk
    each process writes stats into a binary temporary file
  wait for all child processes to terminate
All binary temporary files generated will then be read and loaded into
memory to build the html output.
```

With this method, at start/end of chunks pgbadger may truncate or omit a maximum of *N* queries per log file, which is an insignificant gap if you have millions of queries in your log file. The chance that the query that you were looking for is lost is near zero, so this gap can be considered suitable. Most of the time the query is counted twice, but truncated.

When you have many small log files and many CPUs, it is faster to dedicate one core to one log file at a time. To enable this behavior, specify the `-J N` option instead. Using this method, you can be sure not to lose any queries in the reports. With 200 log files of 10 MB each, the `-J` option starts being really efficient with 8 cores.

Here is a benchmark done on a server with 8 CPUs and a single file of 9.5 GB.

Option	1 CPU	2 CPU	4 CPU	8 CPU
-j	1h41m18	50m25	25m39	15m58
-J	1h41m18	54m28	41m16	34m45

With 200 log files of 10 MB each, which is 2 GB in total, the results are slightly different:

Option	1 CPU	2 CPU	4 CPU	8 CPU
-j	1h41m18	50m25	25m39	15m58
-J	1h41m18	54m28	41m16	34m45

```
-j      | 20m15 | 9m56 | 5m20 | 4m20  
-J      | 20m15 | 9m49 | 5m00 | 2m40
```

So it is recommended to use the `-j` option unless you have hundreds of small log files and can use at least 8 CPUs.

Important

During parallel parsing, `pgbadger` generates a lot of temporary files named `tmp_pgbadgerXXXX.bin` in the `/tmp` directory and removes them at the end.

Building Incremental Reports

The following sample cron job builds a report every week with the incremental behavior assuming that your log file and HTML report are also rotated every week:

```
0 4 * * 1 /usr/bin/pgbadger -q `find /var/lib/pgpro/std-18/data/log/ -mtime -7 -name  
"postgresql.log*"` -o /var/www/pg_reports/pg_errors-`date +%F`.html -l /var/reports/  
pgbadger_incremental_file.dat
```

But better turn on `pgbadger`'s automatic building incremental reports by specifying the `-I/--incremental` option. In this mode, `pgbadger` builds one report per day and a cumulative report per week. The output is first built in the binary format and saved to the output directory, specified by the `-O/--outdir` option, and then daily and weekly reports are built in the HTML format with the main index file. The main index file shows a dropdown menu per week with a link to the week's report and links to daily reports for that week. For example, run `pgbadger` as follows with the file rotated daily:

```
0 4 * * * /usr/bin/pgbadger -I -q /var/lib/pgpro/std-18/data/log/postgresql/  
postgresql.log.1 -O /var/www/pg_reports/
```

You will have all daily and weekly reports. In this mode `pgbadger` will automatically create an incremental file in the output directory, so you do not have to use the `-l` option unless you want to change the path of that file. This means that you can run `pgbadger` in this mode every day on a log file rotated every week and it will not count the log entries twice. To save disk space, you may want to use the `-x/--extra-files` command-line option to force `pgbadger` to write CSS and JavaScript files to the output directory as separate files. The resources will then be loaded using script and link tags.

In the incremental mode, you can also specify the number of weeks to keep in the report by using the `-O/--retention` option:

```
/usr/bin/pgbadger --retention 2 -I -q /var/lib/pgpro/std-18/data/log/postgresql/  
postgresql.log.1 -O /var/www/pg_reports/
```

If `pg_dump` is scheduled to run at 23:00 and 13:00 every day, you can exclude these periods from the report as follows:

```
pgbadger --exclude-time "2013-09-.* (23|13):.*" postgresql.log
```

This will help avoid having `COPY` statements generated by `pg_dump` on top of the list of slowest queries. Alternatively, you can use `--exclude-appname "pg_dump"` to solve this problem in a simpler way.

Rebuilding Reports

To update all HTML reports after fixing a `pgbadger` report or adding a new feature to it, you can rebuild incremental reports. To rebuild all reports in the case a binary file is still available, run:

```
rm /path/to/reports/*.js  
rm /path/to/reports/*.css  
pgbadger -X -I -O /var/www/pg_reports/ --rebuild
```

This will also update all the resource files (JavaScript and CSS). Use the `-E/--explode` option if the reports were built with this option.

Building Monthly Reports

By default, in the incremental mode `pgbadger` only computes daily and weekly reports. To have monthly cumulative reports, you will need to use a separate command to specify the report to build. For example, to build a report for August 2021, run:

```
pgbadger -X --month-report 2021-08 /var/www/pg_reports/
```

This will add a link to the month name to the calendar view of incremental reports to look at the monthly report. The report for a current month can be run every day, and it is entirely rebuilt each time. The monthly report is not built by default because it could take too long. Like when rebuilding reports, if reports were built with the per-database option (`-E/--explode`), it must be used to build the monthly report:

```
pgbadger -E -X --month-report 2021-08 /var/www/pg_reports/
```

Choosing the Report File Format

The `pgbadger` report file format is determined by the extension of the file passed to the `-o/--outfile` option.

Use the binary format (`-o *.bin`) to create custom incremental and cumulative reports.

For example, to refresh a `pgbadger` report every hour from a daily log file, you can run the following commands every hour:

```
# Generate incremental data files in the binary format
pgbadger --last-parsed .pgbadger_last_state_file -o sunday/hourX.bin /var/lib/pgpro/
std-18/data/log/postgresql-Sun.log
# Build a fresh HTML report from the generated binary file
pgbadger sunday/*.bin
```

For another example, assume that you generate one log file per hour. To have reports rebuilt each time the log file is rotated, run:

```
pgbadger -o day1/hour01.bin /var/lib/pgpro/std-18/data/log/postgresql-2022-01-23_10.log
pgbadger -o day1/hour02.bin /var/lib/pgpro/std-18/data/log/postgresql-2022-01-23_11.log
pgbadger -o day1/hour03.bin /var/lib/pgpro/std-18/data/log/postgresql-2022-01-23_12.log
...
```

And to refresh the HTML report, for example, each time after a new binary file is generated, just run:

```
pgbadger -o day1_report.html day1/*.bin
```

Adjust the commands to your particular needs.

Use the JSON format (`-o *.json`) to share data with other languages and to facilitate integration of `pgbadger` output with other monitoring tools, such as Cacti or Graphite.

Select other output formats to meet your particular needs. For example, this command will generate *Tsung* sessions XML file for `SELECT` queries only:

```
pgbadger -S -o sessions.tsung --prefix '%t [%p]: user=%u,db=%d ' /var/lib/pgpro/
std-18/data/log/postgresql-2022-01-14_000000.log
```

Return Codes

`pgbadger` return codes depend on how it terminated as follows:

- 0: was a success
- 1: died on error
- 2: has been interrupted using `Ctrl+C`, for example
- 3: the PID file already exists or cannot be created

- 4: no log file was specified on the command line

Options

This section describes pgbadger command-line options.

`-a minutes`

`--average minutes`

Specifies the number of minutes for which to build average graphs of queries and connections.

Default: 5.

`-A minutes`

`--histo-average minutes`

Specifies the number of minutes for which to build histogram graphs of queries.

Default: 60.

`-b datetime`

`--begin datetime`

Timestamp or time that specifies the start date/time for the data to be parsed in logs.

`-c host`

`--dbclient host`

Only report on log entries for the specified client host.

`-C`

`--nocomment`

Remove `/* ... */` comments from queries.

`-d name`

`--dbname name`

Only report on log entries for the specified database.

`-D`

`--dns-resolv`

Replace client IP addresses with their DNS names.

Warning

This can considerably slow down pgbadger.

`-e datetime`

`--end datetime`

Timestamp or time that specifies the end date/time for the data to be parsed in logs.

`-E`

`--explode`

Build one report per each database. Global information not related to any database gets added to the postgres database report.

`-f logtype`

`--format logtype`

Specifies the log type.

Possible values: syslog, syslog2, stderr, jsonlog, csv, pgbouncer, logplex, rds and redshift. Use when pgbadger cannot detect the log format.

- G
--nograph
Disables graphs in HTML output.
- h
--help
Show detailed information about pbadger options and exit.
- H *path*
--html-outdir *path*
Specifies the path to the directory where the HTML report must be written in the incremental mode. Note that binary files remain in the directory specified by -O/--outdir.
- i *name*
--ident *name*
Specifies the program name used to identify Postgres Pro messages in syslog logs.
Default: postgres.
- I
--incremental
Use the incremental mode, where reports will be generated by days in a separate directory specified by the -O/--outdir option.
- j *number*
--jobs *number*
Specifies the number of jobs to run at the same time. When working with csvlog logs, pgbadger always runs as single job.
Default: 1.
- J *number*
--Jobs *number*
Specifies the number of log files to parse in parallel.
Default: 1.
- l *filename*
--last-parsed *filename*
Specifies the file where the last datetime and line parsed are registered to allow incremental log parsing. Useful to watch errors since the last run or to get one report per day with the log rotated weekly.
- L *filename*
--logfile-list *filename*
Specifies the file containing the list of log files to parse.
- m *size*
--maxlength *size*
Specifies the maximum length of a query in reports. Longer queries will be truncated.

Default: 100000.

-M
--no-multiline

Turns off collecting multiline statements to avoid reporting excessive information, especially on errors that generate a huge report.

-N *name*
--appname *name*

Only report on log entries for the specified application.

-o *filename*
--outfile *filename*

Specifies the filename for the output and determines the report file format: `out.html`, `out.txt`, `out.bin` or `out.json`. Can be used multiple times to output several formats. For the `json` output, ensure that the Perl module `JSON::XS` is installed. To dump the output to stdout, use the value of `-` as filename.

Default: `out.html`, `out.txt`, `out.bin`, `out.json` or `out.tsung`,
for the respective output format.

-O *path*
--outdir *path*

Specifies the directory where out files must be saved.

-p *string*
--prefix *string*

Specifies the value of your custom `log_line_prefix` string, as defined in your `postgresql.conf`. Only use if your log line prefix is different from the standard `log_line_prefix` strings, for example, if your prefix includes additional variables, such as client IP or application name. The string must contain escape sequences for time (`%t`, `%m` or `%n`) and processes (`%p` or `%c`).

-P
--no-prettify

Disables SQL query code prettifier.

-q
--quiet

Disables printing anything to stdout, even the progress bar.

-Q
--query-numbering

Add numbering of queries to the output when used together with `--dump-all-queries` or `--normalized-only`.

-r *address*
--remote-host *address*

Specifies the host to execute the `cat` command on a remote log file to parse the file locally.

-R *number*
--retention *number*

Specifies the number of weeks for which to keep reports in the output directory in the incremental mode. The directories for older weeks and days are automatically removed.

Default: 0 (no reports are removed).

`-s number`
`--sample number`

Specifies the number of query samples to store.

Default: 3.

`-S`
`--select-only`

Only report on SELECT queries.

`-t number`
`--top number`

Specifies the number of queries to store/display.

Default: 20.

`-T string`
`--title string`

Specifies the title of the HTML report page.

`-u username`
`--dbuser username`

Only report on log entries for the specified username.

`-U username`
`--exclude-user username`

Specifies the username to exclude log entries for from the report. Can be used multiple times.

`-v`
`--verbose`

Enables the verbose or debug mode.

Default: off.

`-V`
`--version`

Show pgbadger version and exit.

`-w`
`--watch-mode`

Only report errors, just like [Logwatch](#) can do.

`-W`
`--wide-char`

Encode HTML output of queries in UTF8 to avoid Perl messages “Wide character in print”.

`-x format`
`--extension format`

Specifies the output format. Possible values: text, html, bin or json.

Default: html.

-X
--extra-files
In the incremental mode, write CSS and JavaScript resources to the output directory as separate files.

-z *command*
--zcat *command*
Specifies the full command to run the zcat program. Use if zcat, bzip or unzip is outside of your PATH directories.

-Z +/-XX
--timezone +/-XX
Specifies the number of hours from GMT for the timezone. Use to adjust date/time in JavaScript graphs. The value can be an integer (e.g., 2), or a float, (e.g., 2.5).

--pie-limit *number*
Specifies the number such that instead of lower pie data the sum will be shown.

--exclude-query *regexp*
Specifies the regular expression such that matching queries will be excluded from the report. For example: “^(VACUUM|COMMIT)”. Can be used multiple times.

--exclude-file *filename*
Specifies the path to the file that contains each regular expression to use to exclude matching queries from the report, one expression per line.

--include-query *regexp*
Specifies the regular expression such that only matching queries will be included in the report. Can be used multiple times. For example: “(tbl1|tbl2)”.

--include-file *filename*
Specifies the path to the file that contains each regular expression to use to include matching queries in the report, one expression per line.

--disable-error
Turns off generation of an error report.

--disable-hourly
Turns off generation of an hourly report.

--disable-type
Turns off generation of a report on queries by type, database and user.

--disable-query
Turns off generation of query reports, such as slowest or most frequent queries, queries by users, by database and so on.

--disable-session
Turns off generation of a session report.

--disable-connection
Turns off generation of a connection report.

--disable-lock
Turns off generation of a lock report.

`--disable-temporary`

Turns off generation of a report on temporary files.

`--disable-checkpoint`

Turns off generation of checkpoint/restartpoint reports.

`--disable-autovacuum`

Turns off generation of an autovacuum report.

`--charset name`

Specifies the HTML charset to be used.

Default: utf-8.

`--csv-separator char`

Specifies the CSV field separator.

Default: “,”.

`--exclude-time regexp`

Specifies the regular expression such that log entries for any matching timestamp will be excluded from the report. For example: “2013-04-12 .*”. Can be used multiple times.

`--include-time regexp`

Specifies the regular expression such that log entries for any matching timestamp will be included in the report. For example: “2013-04-12 .*”. Can be used multiple times.

`--exclude-db name`

Specifies the name of the database to exclude related log entries from the report. For example: “outdated_db”. Can be used multiple times.

`--exclude-appname name`

Specifies the name of the application to exclude related log entries from the report. For example: “pg_dump”. Can be used multiple time.

`--exclude-line regexp`

Specifies the regular expression such that any matching log entry will be excluded from the report. Can be used multiple times.

`--exclude-client name`

Specifies the client IP/name to exclude related log entries from the report. Can be used multiple times.

`--anonymize`

Obscure all literals in queries. Useful to hide confidential data.

`--noreport`

Prevents generation of reports in the incremental mode.

`--log-duration`

Associate log entries generated by `log_duration = on` and `log_statement = all`.

`--enable-checksum`

Add the MD5 sum under each query report.

`--journalctl command`

Specifies the command to produce the information similar to what the Postgres Pro log file contains. Usually, like this: `journalctl -u postgrespro-std-18`.

`--pid-dir path`

Specifies the path to store the PID file.

Default: `/tmp`.

`--pid-file filename`

Specifies the name of the PID file to manage concurrent execution of `pgbadger`.

Default: `pgbadger.pid`.

`--rebuild`

Rebuild all HTML reports in incremental output directories that contain binary data files.

`--pgbouncer-only`

Only show [pgbouncer](#)-related menus in the header.

`--start-monday`

In the incremental mode, start calendar weeks on Monday. By default, they start on Sunday.

`--iso-week-number`

In the incremental mode, start calendar weeks on Monday (by default, they start on Sunday) with ISO 8601 week numbering: 01 to 53, where week 1 is the first week of a year that has at least 4 days.

`--normalized-only`

Only dump all normalized queries to `out.txt`.

`--log-timezone +/-XX`

Specifies the number of hours from GMT for the timezone to adjust date/time read from the log file before parsing. The use of this option makes log search with date/time more complicated. The value can be an integer (e.g., 2), or a float, (e.g., 2.5).

`--prettify-json`

Prettify JSON output.

`--month-report YYYY-MM`

Specifies the month (YYYY-MM) to create a cumulative HTML report for. Requires incremental output directories to be set and all the necessary binary data files available.

`--day-report YYYY-MM-DD`

Specifies the day (YYYY-MM-DD) to create an HTML report for. Requires incremental output directories to be set and all the necessary binary data files available.

`--noexplain`

Avoid processing log lines generated by [auto_explain](#).

`--command cmd`

Specifies the command to run to retrieve log entries on stdin. `pgbadger` will open a pipe to this command and parse log entries that it generates.

`--no-week`

Avoid building weekly reports in the incremental mode. Use if building weekly reports takes too long.

`--explain-url URL`

Specifies the URL to override the URL of the graphical explain tool.

Default: <http://explain.depesz.com/>

`--tmpdir path`

Specifies the directory for temporary files.

Default: `File::Spec->tmpdir() || '/tmp'`.

`--no-process-info`

Disables changing the pgbadger process title to help identify this process. Useful for systems where changing process titles is not supported.

`--dump-all-queries`

Dump all queries found in the log file to a text file, replacing bind parameters in the queries at their respective placeholder positions.

`--keep-comments`

Retains comments in normalized queries. Useful to distinguish between same normalized queries.

`--no-progressbar`

Disables displaying the progress bar.

`--dump-raw-csv`

Parse the log and dump the information into CSV format. No further processing is done, no report.

`--include-pid PID`

Only report events related to the session PID (%p). Can be used multiple times.

`--include-session ID`

Only report events related to the session ID (%c). Can be used multiple times.

`--histogram-query VAL`

Use custom inbound for query time histogram. Default inbound in milliseconds: 0,1,5,10,25,50,100,500,1000,10000.

`--histogram-session VAL`

Use custom inbound for session time histogram. Default inbound in milliseconds: 0,500,1000,30000,60000,600000,1800000,3600000,28800000.

Remote Log Connection Options

pgbadger can parse a remote log file fetched using passwordless SSH connection. Use the `-r/--remote-host` option to set the IP address or name of the target host. More options to define SSH connection parameters are as follows:

`--ssh-program ssh`

Specifies the path to the SSH program to use.

Default: `ssh`.

`--ssh-port port`

Specifies the SSH port for the connection.

Default: 22.

`--ssh-user username`

Specifies the username for the connection.

Default: user running pgbadger.

`--ssh-identity filename`

Specifies the path to the identity file.

`--ssh-timeout seconds`

Specifies the timeout in seconds in case of the SSH connection failure.

Default: 10.

`--ssh-option options`

Specifies the list of options to define SSH connection parameters. The following options are always used:

`-o ConnectTimeout=$ssh_timeout -o PreferredAuthentications=hostbased,publickey`

`-o PreferredAuthentications=hostbased,publickey`

pg_repack

pg_repack — utility and Postgres Pro Standard extension to reorganize tables

Synopsis

```
pg_repack [option...] [dbname]
```

Description

pg_repack is a Postgres Pro Standard extension which lets you remove bloat from tables and indexes, and optionally restore the physical order of clustered indexes. Unlike `CLUSTER` and `VACUUM FULL` it works online, without holding an exclusive lock on the processed tables during processing. *pg_repack* is efficient to boot, with performance comparable to using `CLUSTER` directly.

pg_repack is a fork of the previous https://github.com/reorg/pg_reorg project.

You can choose one of the following methods to reorganize data:

- Online `CLUSTER` (ordered by cluster index)
- Ordering by specified columns
- Online `VACUUM FULL` (packing rows only)
- Rebuild or relocate only the indexes of a table

Note

Only superusers can use the utility.

Note

Target table must have a PRIMARY KEY, or at least a UNIQUE total index on a NOT NULL column.

Installation

On Linux systems, *pg_repack* is provided together with Postgres Pro Standard as a separate pre-built package `pg-repack-std-18` and requires the `postgrespro-std-18-server` package to be installed with all the dependencies. For the list of available packages and detailed installation instructions, see [Chapter 16](#). On Windows systems, *pg_repack* is automatically installed as part of Postgres Pro.

Once you have *pg_repack* installed, load the *pg_repack* extension in the database you want to process, as follows:

```
$ psql -c "CREATE EXTENSION pg_repack" -d your_database
```

You can later remove *pg_repack* from a Postgres Pro installation using `DROP EXTENSION pg_repack`.

If you are upgrading from a previous version of *pg_repack*, just drop the old version from the database as explained above and install the new version.

Options

Reorganization Options

```
-a  
--all
```

Attempt to repack all the databases of the cluster. Databases where the *pg_repack* extension is not installed will be skipped.

`-t table`
`--table=table`

Reorganize the specified table(s) only. Multiple tables may be reorganized by writing multiple `-t` switches. By default, all eligible tables in the target databases are reorganized.

`-I table`
`--parent-table=table`

Reorganize both the specified table(s) and its inheritors. Multiple table hierarchies may be reorganized by writing multiple `-I` switches.

`-c schema`
`--schema=schema`

Repack the tables in the specified schema(s) only. Multiple schemas may be repacked by writing multiple `-c` switches. Can be used in conjunction with `--tablespace` to move tables to a different tablespace.

`-o column[, ...]`
`--order-by=column[, ...]`

Perform an online `CLUSTER` ordered by the specified columns.

`-n`
`--no-order`

Perform an online `VACUUM FULL`. Since version 1.2 this is the default for non-clustered tables.

`-N`
`--dry-run`

Show what would be repacked and exit.

`-j num_jobs`
`--jobs=num_jobs`

Create the specified number of extra connections to Postgres Pro, and use these extra connections to parallelize the rebuild of indexes on each table. Parallel index builds are only supported for full-table repacks, not with `--index` or `--only-indexes` options. If your server has extra cores and disk I/O available, this can be a useful way to speed up `pg_repack`.

`-s tablespace`
`--tablespace=tablespace`

Move the repacked tables to the specified tablespace: essentially an online version of `ALTER TABLE ... SET TABLESPACE`. The tables' indexes are left in the original tablespace unless `--moveidx` is specified too.

`-S`
`--moveidx`

Also move the indexes of the repacked tables to the tablespace specified by the `--tablespace` option.

`-i index`
`--index=index`

Repack the specified index(es) only. Multiple indexes may be repacked by writing multiple `-i` switches. May be used in conjunction with `--tablespace` to move the index(es) to a different tablespace.

`-x`
`--only-indexes`

Repack only the indexes of the specified table(s), which must be specified with the `--table` option.

`-T secs`

`--wait-timeout=secs`

`pg_repack` needs to take an exclusive lock at the end of the reorganization. This setting controls how many seconds `pg_repack` will wait to acquire this lock. If the lock cannot be taken after this duration and `--no-kill-backend` option is not specified, `pg_repack` will forcibly cancel the conflicting queries. If you are using Postgres Pro or PostgreSQL version 8.4 or newer, `pg_repack` will fall back to using `pg_terminate_backend()` to disconnect any remaining backends after this timeout has passed twice. The default is 60 seconds.

`-D`

`--no-kill-backend`

Skip repacking a table if the lock cannot be taken for duration specified in `--wait-timeout`, instead of cancelling conflicting queries. The default is `false`.

`-Z`

`--no-analyze`

Disable `ANALYZE` after a full-table reorganization. If not specified, `ANALYZE` is executed after the reorganization.

`-k`

`--no-superuser-check`

Skip the superuser checks in the client. This setting is useful for using `pg_repack` on platforms that support running it as non-superusers.

`-C`

`--exclude-extension`

Skip tables that belong to the specified extension(s). Some extensions may heavily depend on such tables at planning time etc.

`--switch-threshold`

Switch tables when that many tuples are left in the log table. This setting can be used to avoid the inability to catch up with write-heavy tables.

Connection Options

Options to connect to servers. You cannot use `--all` and `--dbname` or `--table` or `--parent-table` together.

`-a`

`--all`

Reorganize all databases.

`[-d] dbname`

`[--dbname=] dbname`

Specifies the name of the database to be reorganized. If this is not specified and `-a` (or `--all`) is not used, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used.

`-h host`

`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`

`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

```
-U username
--username=username
```

User name to connect as.

```
-w
--no-password
```

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

```
-W
--password
```

Force `pg_repack` to prompt for a password before connecting to a database.

This option is never essential, since `pg_repack` will automatically prompt for a password if the server demands password authentication. However, `pg_repack` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

Generic Options

```
-e
--echo
```

Echo the commands that `pg_repack` generates and sends to the server.

```
-E level
--elevel=level
```

Choose the output message level from `DEBUG`, `INFO`, `NOTICE`, `WARNING`, `ERROR`, `LOG`, `FATAL`, and `PANIC`. The default is `INFO`.

```
--help
```

Show help about `pg_repack` command line arguments, and exit.

```
-V
--version
```

Print the `pg_repack` version and exit.

Environment

```
PGDATABASE
PGHOST
PGPORT
PGUSER
```

Default connection parameters

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by `libpq` (see [Section 32.15](#)).

Examples

Perform an online `CLUSTER` of all the clustered tables in the database `test`, and perform an online `VACUUM FULL` of all the non-clustered tables:

```
$ pg_repack test
```

Perform an online `VACUUM FULL` on the tables `foo` and `bar` in the database `test` (an eventual cluster index is ignored):

```
$ pg_repack --no-order --table foo --table bar test
```

Move all indexes of table `foo` to tablespace `tbs`:

```
$ pg_repack -d test --table foo --only-indexes --tablespace tbs
```

Move the specified index to tablespace `tbs`:

```
$ pg_repack -d test --index idx --tablespace tbs
```

Diagnostics

Error messages are reported when `pg_repack` fails. The following list shows the cause of errors.

You need to cleanup by hand after fatal errors. To cleanup, just remove `pg_repack` from the database and install it again.

For Postgres Pro or PostgreSQL 9.1 and newer execute:

```
DROP EXTENSION pg_repack CASCADE
```

in the database where the error occurred, followed by

```
CREATE EXTENSION pg_repack
```

For previous versions load the script `$SHAREDIR/contrib/uninstall_pg_repack.sql` into the database where the error occurred and then load `$SHAREDIR/contrib/pg_repack.sql` again.

```
INFO: database "db" skipped:
```

```
pg_repack VER is not installed in the database:
```

```
pg_repack is not installed in the database when the --all option is specified.
```

Create the `pg_repack` extension in the database.

```
ERROR: pg_repack VER is not installed in the database:
```

```
pg_repack is not installed in the database specified by --dbname
```

Create the `pg_repack` extension in the database.

```
ERROR: program 'pg_repack V1' does not match database library 'pg_repack V2':
```

```
There is a mismatch between the pg_repack binary and the database library  
(.so or .dll).
```

The mismatch could be due to the wrong binary in the `PATH` or the wrong database being addressed. Check the program directory and the database; if they are what expected you may need to repeat `pg_repack` installation.

```
ERROR: extension 'pg_repack V1' required, found 'pg_repack V2':
```

```
The SQL extension found in the database does not match the version required by the  
pg_repack program.
```

You should drop the extension from the database and reload it as described in [the section called “Installation”](#).

```
ERROR: relation "table" must have a primary key or not-null unique keys:
```

The target table doesn't have a PRIMARY KEY or any UNIQUE constraints defined.

Define a PRIMARY KEY or a UNIQUE constraint on the table.

```
ERROR: query failed: ERROR: column "col" does not exist:
The target table doesn't have columns specified by --order-by option.
```

Specify existing columns.

```
WARNING: the table "tbl" already has a trigger called z_repack_trigger:
The trigger was probably installed during a previous attempt
to run pg_repack on the table which was interrupted
and for some reason failed to clean up the temporary objects.
```

You can remove all the temporary objects by dropping and re-creating the extension: see [the section called “Installation”](#) for the details.

```
WARNING: trigger "trg" conflicting on table "tbl":
The target table has a trigger whose name follows z_repack_trigger
in alphabetical order.
```

The `z_repack_trigger` should be the last BEFORE trigger to fire. Please rename your trigger so that it sorts alphabetically before `pg_repack` one; you can use:

```
ALTER TRIGGER zzz_my_trigger
ON sometable RENAME TO yyy_my_trigger;
```

```
ERROR: Another pg_repack command may be running on the table. Please try again later.
```

There is a chance of deadlock when two concurrent `pg_repack` commands are run on the same table. So, try to run the command after some time.

```
WARNING: Cannot create index "schema"."index_xxxxx", already exists
DETAIL: An invalid index may have been left behind by a previous
pg_repack on the table which was interrupted. Please use DROP INDEX
"schema"."index_xxxxx" to remove this index and try again.
```

A temporary index apparently created by `pg_repack` has been left behind, and we do not want to risk dropping this index ourselves. If the index was in fact created by an old `pg_repack` job which didn't get cleaned up, you should just use `DROP INDEX` and try the `repack` command again.

Restrictions

`pg_repack` comes with the following restrictions.

Temporary tables

`pg_repack` cannot reorganize temporary tables.

GiST indexes

`pg_repack` cannot cluster tables by GiST indexes.

DDL commands

You will not be able to perform DDL commands of the target table(s) *except* `VACUUM` or `ANALYZE` while `pg_repack` is working. `pg_repack` will hold an `ACCESS SHARE` lock on the target table during a full-table repack, to enforce this restriction.

If you are using version 1.1.8 or earlier, you must not attempt to perform any DDL commands on the target table(s) while `pg_repack` is running. In many cases `pg_repack` would fail and rollback correctly, but there were some cases in these earlier versions which could result in data corruption.

See also

[clusterdb](#), [vacuumdb](#)

I.3. Additional Postgres Pro Server Applications

This section covers additional Postgres Pro Standard server-related applications. They are typically run on the host where the database server resides. See also [Postgres Pro Server Applications](#) for information about server applications that are part of the core Postgres Pro Standard distribution.

mamonsu

mamonsu — a monitoring agent for collecting Postgres Pro and system metrics

Synopsis

```
mamonsu agent [agent_action]  
  
mamonsu bootstrap -M mamonsu_user [-c | --config] [-x | --create-extensions] [connection_options]  
  
mamonsu export {template | config} filename [export_options]  
  
mamonsu report [report_options] [connection_options]  
  
mamonsu tune [tuning_options] [connection_options]  
  
mamonsu upload [upload_options]  
  
mamonsu zabbix dashboard upload template_name  
  
mamonsu zabbix {template | host | hostgroup} server_action  
  
mamonsu zabbix item {error | lastvalue | lastclock} host_id  
  
mamonsu zabbix version  
  
mamonsu [-c | --config] [-d | --daemonize]  
  
mamonsu --version  
  
mamonsu --help
```

Description

mamonsu is a monitoring agent for collecting Postgres Pro and system metrics that can be visualized on the Zabbix server. Unlike the native Zabbix Agent configured to collect Postgres Pro metrics, mamonsu uses a single database connection, which allows to minimize performance impact on the monitored system.

The mamonsu agent includes the following components:

- A supervisor process that monitors database and system activity.
- Plugins that specify which Postgres Pro and system metrics to collect.
- Customizable configuration and template files that define which plugins to use and how to visualize the collected data.

mamonsu is an active agent, which means that it sends the data to the Zabbix server once it is collected. Pre-configured to monitor multiple Postgres Pro and system metrics out of the box, mamonsu can be extended with your own custom plugins to track other metrics critical for your system.

mamonsu also provides the command-line interface for updating some Zabbix server settings, as well as getting an overview of the monitored system configuration and tuning Postgres Pro and system settings on the fly. You can find the list of all mamonsu commands in [the section called “Command-Line Reference”](#).

Installation and Setup

Important

Before you start installation, attentively read [Compatibility Considerations](#).

To use `mamonsu`, you must create a Zabbix account and set up a Zabbix server as explained in [Zabbix documentation](#). Naturally, you must also have a Postgres Pro instance up and running if you are going to monitor Postgres Pro metrics. If you are configuring your Postgres Pro cluster from scratch, see [Chapter 16](#) and [Section 17.2](#) for Postgres Pro installation and setup instructions, respectively.

Note

While `mamonsu` can collect Postgres Pro metrics from a remote cluster, system metrics are only collected locally. If you choose to collect Postgres Pro metrics remotely, make sure to disable collection of system metrics to avoid confusion, as they will be displayed under the same host in Zabbix.

`mamonsu` is provided with Postgres Pro Standard as a separate pre-built package `mamonsu` (for the detailed installation instructions, see [Chapter 16](#)). Once you have installed `mamonsu`, complete the following steps to set up metrics collection:

1. Optionally, bootstrap `mamonsu`

If you omit this step, metrics can only be collected on behalf of a superuser, which is not recommended.

In this step, the `bootstrap` command sets the `mamonsu` user, creates `mamonsu` schema in the specified or implied database, as well as extensions and objects needed for monitoring.

`bootstrap` has no mandatory options. When run without options, it takes the values needed from the configuration file (`/etc/mamonsu/agent.conf` by default). Below is a simple example of `bootstrap`:

1. In the `[postgres]` section of `agent.conf`, specify connection parameters for the Postgres Pro cluster you are going to monitor. For more details, see [Connection Parameters](#).
2. Run the following command to bootstrap `mamonsu`:

```
mamonsu bootstrap
```

This command will create the user `mamonsu` with the password `mamonsu`, create monitoring functions in the database specified in `agent.conf` and grant the right to execute them to the `mamonsu` user.

In the following example, `bootstrap` options are passed explicitly.

1. Create a non-privileged database user for `mamonsu`. For example:

```
CREATE USER mamonsu_user WITH PASSWORD 'mamonsu_password';
GRANT pg_monitor TO mamonsu_user;
```

2. Create a database that will be used for connection to Postgres Pro. For example:

```
CREATE DATABASE mamonsu_database OWNER mamonsu_user;
```

3. Run the following command to bootstrap `mamonsu`:

```
mamonsu bootstrap -M mamonsu_user -x -c /etc/mamonsu/agent.conf -d
mamonsu_database -U postgres --host myhost --port 5432
```

For details of the options `-M`, `-x` and `-c`, see [bootstrap](#). For details of other options, see [Connection Options](#). This command will create monitoring functions in the `mamonsu_database` and grant the right to execute them to `mamonsu_user`. The `pg_buffercache` extension will also be created to ensure collection of metrics on the shared buffer cache, and the path to the configuration file will be changed.

As a result, a superuser connection is no longer required. Note that `mamonsu` also creates several tables in the `mamonsu` schema in the specified database. Do not delete these tables as they are required for `mamonsu` to work.

2. Configure mamonsu

Edit the `agent.conf` configuration file, which is located in the `/etc/mamonsu/` directory by default.

- Configure Zabbix-related settings. The `address` field must point to the running Zabbix server, while the `client` field must provide the name of the Zabbix host. You can find the list of hosts available for your account in the Zabbix web interface under **Configuration > Hosts**.

```
[zabbix]
; enabled by default
enabled = True
client = zabbix_host_name
address = zabbix_server
```

- By default, mamonsu will collect both Postgres Pro and system metrics. If required, you can disable metrics collection of either type by setting the `enabled` parameter to `False` in the `[postgres]` or `[system]` section of the `agent.conf` file, respectively.

```
[system]
; enabled by default
enabled = True
```

Note

While mamonsu can collect Postgres Pro metrics from a remote cluster, system metrics are only collected locally. If you choose to collect Postgres Pro metrics remotely, make sure to disable collection of system metrics to avoid confusion, as they will be displayed under the same host in Zabbix.

- If you are going to collect Postgres Pro metrics, specify connection parameters for the Postgres Pro cluster you are going to monitor. In the `user`, `password`, and `database` fields, you must specify the `mamonsu_user`, `mamonsu_password`, and the `mamonsu_database` used for bootstrap, respectively. If you skipped the bootstrap, specify superuser credentials and the database to connect to.

```
[postgres]
; enabled by default
enabled = True
user = mamonsu_user
database = mamonsu_database
password = mamonsu_password
port = 5432
```

These are the main mamonsu settings to get started. You can also fine-tune other mamonsu settings as explained in [the section called “Configuration Parameters”](#).

3. Configure how to display metrics on the Zabbix server

1. Generate a template that defines how to visualize the collected metrics on the Zabbix server:

```
mamonsu export template template.xml
```

mamonsu generates the `template.xml` file in your current directory. By default, the name of the template that will be displayed in the Zabbix account is `PostgresPro-OS`, where `OS` is the name of your operating system. To get a template with a different display name, you can run the above command with the `--template-name` option.

2. Optionally, specify your Zabbix account settings in the following environment variables on your monitoring system:

- Set the `ZABBIX_USER` and `ZABBIX_PASSWD` variables to the login and password of your Zabbix account, respectively.
- Set the `ZABBIX_URL` to `http://zabbix/`

If you skip this step, you will have to add the following options to all `mamonsu zabbix` commands that you run:

```
--url=http://zabbix/ --user=zabbix_login --password=zabbix_password
```

3. Upload `template.xml` to the Zabbix server.

```
mamonsu zabbix template export template.xml
```

Alternatively, you can upload the template through the Zabbix web interface: log in to your Zabbix account and select **Templates > Import**.

4. Link the generated template to the host to be monitored.

In the Zabbix web interface, select your host, go to **Templates > Add**, select your template, and click **Update**.

Tip

If you would like to link a template with a new Zabbix host, you can do it from the command line using `mamonsu zabbix` commands. See [the section called “Managing Zabbix Server Settings from the Command Line”](#) for details.

When the setup is complete, start `mamonsu`. For example, on Linux systems, you can start `mamonsu` as a service with the following command:

```
service mamonsu start
```

`mamonsu` picks up all the parameters from the `mamonsu` configuration file and starts monitoring your system.

Command-Line Reference

agent

Syntax:

```
mamonsu agent { metric-list | metric-get metric_name | version }
```

Provide information on the collected metrics from the command line. You can specify one of the following parameters:

`metric-list`

Show the list of metrics that `mamonsu` is collecting. The output of this command provides the item key of each metric, its latest value, and the time when this value was received.

`metric-get metric_name`

Check the latest value for the specified metric. You can get the list of available metrics using the `metric-list` option.

`version`

Display `mamonsu` version.

bootstrap

Syntax:

```
mamonsu bootstrap -M mamonsu_user
                [-c[ config_file] | --config[=config_file]]
                [-x | --create-extensions] [connection_options]
```

Bootstrap mamonsu. This command can take the following options:

-M
Specify a non-privileged user that will own all mamonsu processes.

-c *config_file*
--config=*config_file*
Specify the `agent.conf` file where the `[postgres]` section contains the database name to be used if `--dbname` is not specified through *connection_options*.

Default: `/etc/mamonsu/agent.conf`

-x
--create-extensions
Create auxiliary extensions. The `pg_buffercache` extension will be created, which is no longer created by default. For Postgres Pro 12 or higher, the `bootstrap -x` command will also create functions to work with the `pgpro_stats` extension and grant the right to execute them to the `mamonsu` user.

connection_options
Provide optional *command-line connection parameters*.

export

Syntax:

```
mamonsu export config filename.conf [--add-plugins=plugin_directory]
mamonsu export template filename.xml [--add-plugins=plugin_directory]
                                     [--template-name=template_name]
                                     [--application=application_name]
                                     [--old-zabbix]
```

Generate a template or configuration file for metrics collection. The optional parameters to customize metrics collection are as follows:

--add-plugins=*plugin_directory*
Collect metrics that are defined in custom plugins located in the specified *plugin_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

--template-name=*template_name*
Specify the name of the template that will be displayed on the Zabbix server.

Default: `PostgresPro-OS`, where *OS* is the name of your operating system

--application=*application_name*
Specify an identifier under which the collected metrics will be displayed on the Zabbix server.

Default: `App-PostgresPro-OS`, where *OS* is the name of your operating system

--old-zabbix
Export a template for Zabbix server version 4.2 or lower. By default, the template is generated in a format compatible with Zabbix 4.4 or higher.

export zabbix-parameters

Syntax:

```
mamonsu export zabbix-parameters filename.conf [--add-plugins=plugin_directory]
                                           [--plugin-type={pg | sys | all}]
                                           [--pg-version=version]
                                           [--config=config_file]
```

Export metrics configuration for use with the native [Zabbix agent](#). The optional parameters to customize metrics collection are as follows:

`--add-plugins=plugin_directory`

Collect metrics that are defined in custom plugins located in the specified *plugin_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

`--plugin-type={pg | sys | all}`

Specify the type of metrics to collect:

- `pg` for Postgres Pro metrics.
- `sys` for system metrics.
- `all` for both Postgres Pro and system metrics.

Default: `all`

`--pg-version=version`

Specify the major version of the server for which to configure metrics collection. `mamonsu` can collect metrics for all supported Postgres Pro versions, as well as PostgreSQL versions starting from 9.5.

Default: `10`

`--config=config_file`

Specify the `agent.conf` file to be used as the source for metrics definitions.

Default: `/etc/mamonsu/agent.conf`

export zabbix-template

Syntax:

```
mamonsu export zabbix-template filename.conf [--add-plugins=plugin_directory]
                                           [--plugin-type={pg | sys | all}]
                                           [--template-name=template_name]
                                           [--application=application_name]
                                           [--config=config_file]
                                           [--old-zabbix]
```

Export a template for use with the native Zabbix agent. The optional parameters to customize metrics collection are as follows:

`--add-plugins=plugin_directory`

Collect metrics that are defined in custom plugins located in the specified *plugin_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

`--plugin-type={pg | sys | all}`

Specify the type of metrics to collect:

- `pg` configures Postgres Pro metrics.
- `sys` configures system metrics.
- `all` configures both Postgres Pro and system metrics.

Default: `all`

`--template-name=template_name`

Specify the name of the template that will be displayed on the Zabbix server.

Default: `PostgresPro-OS`, where *OS* is the name of your operating system

`--application=application_name`

Specify an identifier under which the collected metrics will be displayed on the Zabbix server.

Default: `App-PostgresPro-OS`, where *OS* is the name of your operating system

`--config=config_file`

Specify the `agent.conf` file to be used as the source for metrics definitions.

Default: `/etc/mamonsu/agent.conf`

`--old-zabbix`

Export a template for Zabbix server version 4.2 or lower. By default, the template is generated in a format compatible with Zabbix 4.4 or higher.

report

Syntax:

```
mamonsu report [--run-system=Boolean] [--run-postgres=Boolean]
               [--print-report=Boolean] [--report-path=report_file]
               [--disable-sudo] [connection_options]
```

Generate a detailed report on the hardware, operating system, memory usage and other parameters of the monitored system, as well as Postgres Pro configuration.

The following optional parameters customize the report:

`--run-system=Boolean`

Include system information into the generated report.

Default: `True`

`--run-postgres=Boolean`

Include information on Postgres Pro into the generated report.

Default: `True`

`--print-report=Boolean`

Print the report to stdout.

Default: `True`

`--report-path=report_file`

Save the report into the specified file.

Default: `/tmp/report.txt`

`--disable-sudo`

Do not report data that can only be received with superuser rights. This option is only available for Linux systems.

connection_options

Provide optional *command-line connection parameters*.

tune

Syntax:

```
mamonsu tune [--dry-run] [--disable-sudo] [--log-level {INFO|DEBUG|WARN}]
              [--dont-tune-pgbadger] [--dont-reload-postgresql]
              [connection_options]
```

Optimize Postgres Pro and system configuration based on the collected statistics. You can use the following options:

`--dry-run`

Display the settings to be tuned without changing the actual system and Postgres Pro configuration.

`--disable-sudo`

Do not tune the settings that can only be changed by a superuser. This option is only available for Linux systems.

`--dont-tune-pgbadger`

Do not tune *pgbadger* parameters.

`--log-level { INFO | DEBUG | WARN }`

Change the logging level.

Default: INFO

`--dont-reload-postgresql`

Forbid mamonsu to run the `pg_reload_conf()` function. If you specify this option, the modified settings that require reloading Postgres Pro configuration do not take effect immediately.

connection_options

Provide optional *command-line connection parameters*.

upload

Syntax:

```
mamonsu upload [--zabbix-file=metrics_file]
               [--zabbix-address=zabbix_address] [--zabbix-port=port_number]
               [--zabbix-client=zabbix_host_name] [--zabbix-log-level={INFO|DEBUG|
WARN}]
```

Upload metrics data previously saved into a file onto a Zabbix server for visualization. For details on how to save metrics into a file, see [the section called “Logging Parameters”](#).

This command can take the following options:

`--zabbix-address=zabbix_address`

The address of the Zabbix server.

Default: localhost

`--zabbix-port=port_number`

The port of the Zabbix server.

Default: 10051

`--zabbix-file=metrics_file`

A text file that stores the collected metrics data to be visualized, such as `localhost.log`.

`--zabbix-client=zabbix_host_name`

The name of the Zabbix host.

Default: `localhost`

`--zabbix-log-level={INFO|DEBUG|WARN}`

Change the logging level.

Default: `INFO`

zabbix dashboard upload

Syntax:

`mamonsu dashboard upload template_name`

Upload a Zabbix dashboard with the mamonsu metrics to a template on the Zabbix server version 6.0 or higher.

zabbix item

Syntax:

`mamonsu zabbix item {error | lastvalue | lastclock } host_name`

View the specified property of the latest metrics data received by Zabbix for the specified host.

zabbix version

Syntax:

`mamonsu zabbix version`

Get the version of the Zabbix server that mamonsu is connected to.

zabbix host

Syntax:

`mamonsu zabbix host list`

`mamonsu zabbix host show host_name`

`mamonsu zabbix host id host_name`

`mamonsu zabbix host delete host_id`

`mamonsu zabbix host create host_name hostgroup_id template_id mamonsu_address`

`mamonsu zabbix host info {templates | hostgroups | graphs | items} host_id`

Manage Zabbix hosts using one of the actions described in [the section called “Zabbix Server Actions”](#).

zabbix hostgroup

Syntax:

`mamonsu zabbix hostgroup list`

`mamonsu zabbix hostgroup show hostgroup_name`

`mamonsu zabbix hostgroup id hostgroup_name`

```
mamonsu zabbix hostgroup delete hostgroup_id
mamonsu zabbix hostgroup create hostgroup_name
```

Manage Zabbix host groups using one of the actions described in [the section called “Zabbix Server Actions”](#).

zabbix template

Syntax:

```
mamonsu zabbix template list
mamonsu zabbix template show template_name
mamonsu zabbix template id template_name
mamonsu zabbix template delete template_id
mamonsu zabbix template export file
```

Manage Zabbix templates using one of the actions described in [the section called “Zabbix Server Actions”](#).

[--config] [--daemonize]

Syntax:

```
mamonsu [-c config_file | --config=config_file]
        [-d | --daemonize]
```

Start working as a monitoring agent in the foreground or in the background using configuration parameters loaded from the configuration file. If the specified or default configuration file does not exist, exit with an error. Useful for debugging. You can specify the following options:

```
-c config_file
--config=config_file
```

Specify the `agent.conf` file where to load the configuration parameters from.

Default: `/etc/mamonsu/agent.conf`

```
-d
--daemonize
```

Run in the background. Without it, mamonsu will run in the foreground.

--version

Syntax:

```
mamonsu --version
```

Display mamonsu version.

--help

Syntax:

```
mamonsu --help
```

Display mamonsu command-line help.

Connection Options

connection_options provide command-line connection parameters for the target Postgres Pro cluster. *connection_options* can be `--host`, `--port`, `--dbname (-d)`, `--username (-U)`, and `--password (-W)`. The `--dbname` option should specify the *mamonsu_database* created for monitoring purposes. Note that the `--username (-U)` option must specify a superuser that can access the cluster.

If you omit *connection_options*, mamonsu checks the configuration file for the needed settings.

Zabbix Server Actions

Using `mamonsu`, you can control some of the Zabbix server functionality from the command line. Specifically, you can create or delete Zabbix hosts and host groups, as well as generate, import, and delete Zabbix templates using one of the following commands. The *object_name* to use must correspond to the type of the Zabbix object specified in the command: `template`, `host`, or `hostgroup`.

`list`

Display the list of available templates, hosts, or host groups.

`show object_name`

Display the details about the specified template, host, or host group.

`id object_name`

Show the ID of the specified object, which is assigned automatically by the Zabbix server.

`delete object_id`

Delete the object with the specified ID.

`create hostgroup_name`

`create host_name hostgroup_id template_id mamonsu_address`

Create a new host or a host group.

`export template_name`

Generate a Zabbix template.

`info {templates | hostgroups | graphs | items} host_id`

Display detailed information about the templates, host groups, graphs, and metrics available on the host with the specified ID.

Configuration Parameters

The `agent.conf` configuration file is located in the `/etc/mamonsu` directory by default. It provides several groups of parameters that control which metrics to collect and how to log the collected data:

- [connection parameters](#)
- [logging parameters](#)
- [plugin parameters](#)

All parameters must be specified in the `parameter = value` format.

Connection Parameters

[postgres]

The `[postgres]` section controls Postgres Pro metrics collection and can contain the following parameters:

`enabled`

Enables/disables Postgres Pro metrics collection if set to `True` or `False`, respectively.

Default: `True`

`user`

The user on behalf of which the cluster will be monitored. It must be the `mamonsu` user set in `bootstrap`, or a superuser if `bootstrap` was not run.

Default: postgres

password

The password for the specified user.

database

The database to connect to for metrics collection.

Default: postgres

host

The server address to connect to.

Default: localhost

port

The port to connect to.

Default: 5432

application_name

Application name that identifies mamonsu connected to the Postgres Pro cluster.

Default: mamonsu

query_timeout

[statement_timeout](#) for the mamonsu session, in seconds. If a Postgres Pro metric query does not complete within this time interval, it gets terminated.

Default: 10

Alternatively you can specify environment variables rather than the configuration parameters. The following environment variables can be used: PGUSER, PGPASSWORD, PGHOST, PGDATABASE, PGPORT, and PGAPPNAME. See [Section 32.15](#) for their meaning.

[system]

The [system] section controls system metrics collection and can contain the following parameters:

enabled

Enables/disables system metrics collection if set to True or False, respectively.

Default: True

[zabbix]

The [zabbix] section provides connection settings for the Zabbix server and can contain the following parameters:

enabled

Enables/disables sending the collected metrics data to the Zabbix server if set to True or False, respectively.

Default: True

client

The name of the Zabbix host.

address

The address of the Zabbix server.

Default: 127.0.0.1

port

The port of the Zabbix server.

Default: 10051

timeout

Maximum time to wait while connecting to the Zabbix server, in seconds.

Default: 15

[agent]

The [agent] section specifies the location of mamonsu and whether it is allowed to access metrics from the command line:

enabled

Enables/disables metrics collection from the command line using the agent command.

Default: True

host

The address of the system on which mamonsu is running.

Default: 127.0.0.1

port

The port on which mamonsu is running.

Default: 10052

[sender]

The [sender] section controls the queue size of the data to be sent to the Zabbix server:

queue

The maximum number of collected metric values that can be accumulated locally before mamonsu sends them to the Zabbix server. Once the accumulated data is sent, the queue is cleared.

Default: 2048

Logging Parameters

[metric_log]

The [metric_log] section enables storing the collected metrics data in text files locally. This section can contain the following parameters:

enabled

Enables/disables storing the collected metrics data in a text file. If this option is set to True, mamonsu creates the localhost.log file for storing metric values.

Default: False

directory

Specifies the directory where log files with metrics data will be stored.

Default: `/var/log/mamonsu`

`max_size_mb`

The maximum size of a log file, in MB. When the specified size is reached, it is renamed to `localhost.log.archive`, and an empty `localhost.log` file is created.

Default: 1024

[log]

The `[log]` section specifies logging settings for mamonsu and can contain the following parameters:

`file`

Specifies the log filename, which can be preceded by the full path.

`level`

Specifies the debug level. This option can take `DEBUG`, `ERROR`, or `INFO` values.

Default: `INFO`

`format`

The format of the logged data.

Default: `[% (levelname)s] %(asctime)s - %(name)s - %(message)s`

where `levelname` is the debug level, `asctime` returns the current time, `name` specifies the plugin that emitted this log entry or `root` otherwise, and `message` provides the actual log message.

Plugin Parameters

[plugins]

The `[plugins]` section specifies custom plugins to be added for metrics collection and can contain the following parameters:

`enabled`

Enables/disables using custom plugins for metrics collection if set to `True` or `False`, respectively.

Default: `False`

`directory`

Specifies the directory that contains custom plugins for metrics collection. Setting this parameter to `None` forbids using custom plugins.

Default: `/etc/mamonsu/plugins`

If you need to configure any of the plugins you add to mamonsu after installation, you have to add this plugin section to the `agent.conf` file.

The syntax of this section should follow the syntax used with the examples shown below in [the section called “Individual Plugin Sections”](#).

Individual Plugin Sections

All built-in plugins are installed along with mamonsu. To configure a built-in plugin you should find a corresponding section below the Individual Plugin Sections heading and edit its parameter values:

`enabled`

Enables/disables using built-in plugins if set to `True` or `False`, respectively. These values are case-sensitive.

Default: False

interval

Specifies the plugin operation interval, in seconds. The parameter is set with an integer specifying the plugin operation interval in seconds. You can set different intervals for different plugins. For plugins that collect PostgreSQL/ Postgres Pro metrics, for example, autovacuum, checkpoint, etc., this is the interval within which mamonsu accesses the Postgres Pro instance for metrics collection. For system plugins, for example, diskstats, memory, etc., this is the interval within which the operating system is accessed. For service plugins, for example, agentapi, logsender, zbxsender, this is the interval within which their functions are called. Note that the `interval` parameter of the `zbxsender` plugin is associated with the `timeout` parameter of the `[zabbix]` section. The maximum Zabbix server response timeout greater than the plugin operation interval may cause misbehavior of the `zbxsender` plugin: the plugin restarts with an error message if the connection or data transfer require longer time than the value specified in the `interval` parameter.

Default: 60

The example below shows individual plugin sections corresponding to the `preparedtransaction` and the `pgprobackup` built-in plugins:

```
[preparedtransaction]
max_prepared_transaction_time = 60
interval = 60

[pgprobackup]
enabled = false
interval = 300
backup_dirs = /backup_dir1,/backup_dir2
pg_probackup_path = /usr/bin/pg_probackup-11
```

[preparedtransaction]

This plugin gets age in seconds of the oldest prepared transaction and number of all transactions prepared for a two-phase commit. For additional information refer to [PREPARE TRANSACTION](#) and [Section 53.17](#).

The `max_prepared_transaction_time` parameter specifies the threshold in seconds for the age of the prepared transaction.

The plugin collects two metrics: `pgsql.prepared.count` (number of prepared transactions) and `pgsql.prepared.oldest` (oldest prepared transaction age in seconds).

If `pgsql.prepared.oldest` value exceeds the threshold specified by the `max_prepared_transaction_time` parameter, a trigger with the following message is fired: "PostgreSQL prepared transaction is too old on {host}".

[pgprobackup]

This plugin uses [pg_probackup](#) to track its backups' state and gets size of backup directories which store all backup files.

Please note that this plugin counts the total size of all files in the target directory. Make sure that extraneous files are not stored in this directory.

The `backup_dirs` parameter specifies a comma-separated list of paths to directories for which metrics should be collected.

The `pg_probackup_path` parameter specifies the path to `pg_probackup`.

By default this plugin is disabled. To enable it set the `enabled` parameter to `True`.

This plugin collects two metrics: `pg_probackup.dir.size[#backup_directory]` (the size of the target directory) and `pg_probackup.dir.error[#backup_directory]` (backup errors) for each specified `back-up_directory`.

If any generated backup has bad status, like `ERROR`, `CORRUPT`, `ORPHAN`, a trigger is fired.

Usage

Collecting and Viewing Metrics Data

Once started, `mamonsu` begins collecting system and Postgres Pro metrics. The `agent` command enables you to get an overview of the collected metrics from the command line in real time.

To view the list of available metrics, use the `agent metric-list` command:

```
mamonsu agent metric-list
```

The output of this command provides the item key of each metric, its latest value, and the time when this value was received. For example:

```
system.memory[active]          7921004544      1564570818
system.memory[swap_cache]      868352      1564570818
pgsql.connections[idle]        6.0        1564570818
pgsql.archive_command[failed_trying_to_archive] 0      1564570818
```

To view the current value for a specific metric, you can use the `agent metric-get` command:

```
mamonsu agent metric-get metric_name
```

where `metric_name` is the item key of the metric to monitor, as returned by the `metric-list` command. For example, `pgsql.connections[idle]`.

You can view graphs for the collected metrics in the Zabbix web interface under the **Graphs** menu. For details on working with Zabbix, see its official documentation at <https://www.zabbix.com/documentation/current/manual>.

If you have chosen to save all the collected metrics data into a file, as explained in [the section called “Logging Parameters”](#), you can later upload these metrics onto a Zabbix server for visualization using the `upload` command.

Adding Custom Plugins

You can extend `mamonsu` with your own custom plugins, as follows:

1. Save all custom plugins in a single directory, such as `/etc/mamonsu/plugins`.
2. Make sure this directory is specified in your configuration file under the `[plugins]` section:

```
[plugins]
directory = /etc/mamonsu/plugins
```

3. Generate a new Zabbix template to include custom plugins:

```
mamonsu export template template.xml --add-plugins=/etc/mamonsu/plugins
```

4. Upload the generated `template.xml` to the Zabbix server as explained in [the section called “Installation and Setup”](#).

Tuning Postgres Pro and System Configuration

Based on the collected metrics data, `mamonsu` can tune your Postgres Pro and system configuration for optimal performance.

You can get detailed information about the hardware, operating system, memory usage and other parameters of the monitored system, as well as Postgres Pro configuration, as follows:

```
mamonsu report
```

To view the suggested optimizations without applying them, run the `tune` command with the `--dry-run` option:

```
mamonsu tune --dry-run
```

To apply all the suggested changes, run the `tune` command without any parameters:

```
mamonsu tune
```

You can exclude some settings from the report or disable some of the optimizations by passing optional parameters. See [the section called “Command-Line Reference”](#) for the full list of parameters available for `report` and `tune` commands.

Managing Zabbix Server Settings from the Command Line

`mamonsu` enables you to work with the Zabbix server from the command line. You can upload template files to Zabbix, create and delete Zabbix hosts and host groups, link templates with hosts and check the latest metric values.

To set up your Zabbix host from scratch, you can follow these steps:

1. Optionally, specify your Zabbix account settings in the following environment variables on your monitoring system:
 - Set the `ZABBIX_USER` and `ZABBIX_PASSWD` variables to the login and password of your Zabbix account, respectively.
 - Set the `ZABBIX_URL` to `http://zabbix/`

If you skip this step, you will have to add the following options to all `mamonsu zabbix` commands that you run:

```
--url=http://zabbix/ --user=zabbix_login --password=zabbix_password
```

2. Generate a new template file and upload it to the Zabbix server:

```
mamonsu export template template.xml
mamonsu zabbix template export template.xml
```

3. Create a new host group:

```
mamonsu zabbix hostgroup create hostgroup_name
```

4. Check the IDs for this host group and the uploaded template, which are assigned automatically by the Zabbix server:

```
mamonsu zabbix hostgroup id hostgroup_name
mamonsu zabbix template id template_name
```

5. Create a host associated with this group and link it with the uploaded template using a single command:

```
mamonsu zabbix host create host_name hostgroup_id template_id mamonsu_address
```

where *host_name* is the name of the host, *hostgroup_id* and *template_id* are the unique IDs returned in the previous step, and *mamonsu_address* is the IP address of the system on which `mamonsu` runs.

Once your Zabbix host is configured, complete the setup of your monitoring system as explained in [the section called “Installation and Setup”](#).

Exporting Metrics for Native Zabbix Agent

Using `mamonsu`, you can convert system and Postgres Pro metrics definitions to the format supported by the native [Zabbix agent](#).

This feature currently has the following limitations:

- You cannot export metrics if you run `mamonsu` on Windows systems.
- Metrics definitions for `pg_wait_sampling` and CFS features available in Postgres Pro Enterprise are not converted.

Important

To work with Zabbix proxy, you must export settings to the format supported by the native Zabbix agent.

To collect metrics provided by `mamonsu` using the native Zabbix agent, do the following:

1. Generate a configuration file that is compatible with the native Zabbix agent and place it under `/etc/zabbix/zabbix_agent.d/`. You can prepend the filename with the required path:

```
mamonsu export zabbix-parameters /etc/zabbix/zabbix_agent.d/zabbix_agent.conf
```

For all possible options of the `export zabbix-parameters` command, see [the section called “Command-Line Reference”](#).

2. Generate a template for the native Zabbix agent:

```
mamonsu export zabbix-template template.xml
```

For all possible options of the `export zabbix-template` command, see [the section called “Command-Line Reference”](#).

3. Upload the generated template to the Zabbix server, as explained in [the section called “Installation and Setup”](#).
4. If you are going to collect Postgres Pro metrics, change the following macros in the template after the upload:
 - For `{$PG_CONNINFO}`, provide connection parameters for the Postgres Pro server to be monitored.
 - For `{$PG_PATH}`, specify `psql` installation directory.

Compatibility Considerations

If you want to upgrade `mamonsu` to a version that is not compatible with the previous one, what you must do to continue using the application depends on whether you need to retain the metrics data collected.

- If you need to retain the collected data, do the following:
 1. Install the new version of `mamonsu`.
 2. Generate a new template for the Zabbix server.
 3. If you performed a bootstrap using the previous version of `mamonsu`, run the `bootstrap` command again.
 4. Upload the new template to the Zabbix server.
 5. Rename the host for which you want to retain the collected data and leave the old template linked to that host.
 6. Create a new host for the same system and link the new template to it.
 7. Restart `mamonsu`. It will collect data for the new host. The old host will no longer be used, but the data collected will be available.
- If you do not need to retain the collected data, do the following:
 1. Install the new version of `mamonsu`.
 2. Generate a new template for the Zabbix server.

3. If you performed a bootstrap using the previous version of mamonsu, run the `bootstrap` command again.
4. Upload the new template to the Zabbix server.
5. In the settings of the Zabbix host, link the new template to the host instead of the old one.
6. Restart mamonsu. It will start collecting data. All the data collected earlier will be lost.

pgpro_controldata

`pgpro_controldata` — display control information of a PostgreSQL/Postgres Pro database cluster and compatibility information for a cluster and/or server

Synopsis

```
pgpro_controldata [option...]
```

Description

`pgpro_controldata` prints control information, such as the catalog version, initialized by `initdb` command of any PostgreSQL/Postgres Pro server. It also shows information about write-ahead logging and checkpoint processing. This information is cluster-wide and not specific to any database.

`pgpro_controldata` also helps to check compatibility between PostgreSQL/Postgres Pro database servers and clusters. It can print server or cluster parameters that can affect the compatibility and check whether a cluster and server are compatible by comparing those parameters.

`pgpro_controldata` is provided with Postgres Pro Standard as a separate pre-built package `pgpro-controldata` (for the detailed installation instructions, see [Chapter 16](#)).

Options

`pgpro_controldata` accepts the following command-line arguments. If no arguments are specified, `pgpro_controldata` just prints the control information like [pg_controldata](#) does. Note that compatibility-related command-line arguments `-P` and `-S` specified together work the same way as `-C`.

General-Purpose

`-B`
`--bindir`
Specifies the PostgreSQL/Postgres Pro executable directory, needed to get server compatibility parameters.

`-D datadir`
`--pgdata=datadir`
Specifies the file system location of the database configuration files. If this option is omitted, the environment variable `PGDATA` is used.

`-V`
`--version`
Print the `pgpro_controldata` version, then exit.

`-?`
`--help`
Show help about `pgpro_controldata` command-line arguments, then exit.

Compatibility-Related

`-C`
`--compatibility-check`
Display all parameters that can affect compatibility between the specified server and cluster and check whether they are compatible.

Use the `-D` option or the environment variable `PGDATA` to provide the path to the data directory, where read access is required.

If the `-B` option is omitted, the current server is assumed.

The cluster data and the server must have the same byte order and architecture type for this option to work correctly.

`-P`

`--cluster-compatibility-params`

Display all parameters of the specified cluster that can affect the compatibility.

Use the `-D` option or the environment variable `PGDATA` to provide the path to the data directory, where read access is required.

The cluster data and the server must have the same byte order and architecture type for this option to work correctly.

`-S`

`--server-compatibility-params`

Display all parameters of the specified or current server that can affect the compatibility.

If the `-B` option is omitted, the current server is assumed.

Environment

`PGDATA`

Default data directory location

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

pg_integrity_check

`pg_integrity_check` — calculate and validate checksums for controlled files (certified edition only)

Synopsis

```
pg_integrity_check [connection-option...] [-s | --system] [-u | --user] [-c | --catalog] [-o | --output]
[-l filename | --log=filename] [--syslog] [-D datadir] [-C filename] [-v | --verbose] [-? | --help]
```

Description

`pg_integrity_check` is a utility provided with Postgres Pro Standard that can calculate and validate checksums for the objects you would like to control. When running `pg_integrity_check`, you must specify at least one of the options that define the type of the controlled objects: `-s`, `-u`, or `-c` for read-only files, additional files, or system catalog tables, respectively.

If you use the `-o` option, `pg_integrity_check` calculates checksums and writes them into configuration files under the `share/security/` directory. You must have write access to the corresponding files to perform this command. You cannot use the `-o` option together with the `-s` option, since a checksum for read-only files cannot be overwritten.

If you omit the `-o` option, `pg_integrity_check` compares the calculated checksums with the corresponding checksums in the configuration files. If the checksums differ for any of the controlled objects, `pg_integrity_check` displays a message indicating the difference.

For details on using `pg_integrity_check`, see [Section 30.2](#).

Options

connection-options

Standard options for connecting to a database: `-d`, `-h`, `-p`, `-U`. You must specify `-d` and `-U` options when validating checksums for catalog tables with the `-c` option. For detailed description of connection options, see [psql](#).

`-s`
`--system`

Validate checksums for read-only files. Checksums for read-only files control both file contents and file attributes.

`-u`
`--user`

Validate checksums for additional files. Checksums for additional files control both file contents and file attributes.

`-c`
`--catalog`

Validate checksums for system catalog tables. For the `-c` option to work correctly, you must also specify connection parameters for the database. The database server must be started and accept connections.

`-o`
`--output`

Recalculate checksums and write it into a file.

`-l filename`
`--log=filename`

Write checksum validation results into a log file.

`--syslog`

Write checksum validation results into the syslog.

`-D datadir`

Data directory of the database cluster. This option is required to define the filenames for the generated configuration files when using `-u` option.

`-C filename`

The absolute path to the configuration file used for integrity checks of system catalog tables of the selected database. If used with the `-o` option, `pg_integrity_check` writes into the specified file. If no other option is used, `pg_integrity_check` checks data against the specified file.

`-v`

`--verbose`

Print debugging information, including checksum values.

`-?`

`--help`

Print command-line help.

Return Values

0 — checksums are calculated or validated successfully.

1 — an error occurred during the initial checksum calculation for read-only files.

2 — checksum validation revealed changes in one or more of the controlled objects.

3 — an unexpected error occurred during checksum validation.

Examples

Compute checksums for additional files and write them into the `share/security/_var_lib_pgpro_std-18_data.user.conf` configuration file:

```
pg_integrity_check -u -o -D /var/lib/pgpro/std-18/data
```

Check integrity of all controlled objects in the `postgres` database on behalf of the `postgres` user:

```
pg_integrity_check -s -u -c -D /var/lib/pgpro/std-18/data -d postgres -h localhost -p 5432 -U postgres
```

I.4. Third-Party Server Applications

This section covers third-party server-related applications. They are typically run on the host where the database server resides.

pgbouncer

pgbouncer — a connection pooler for Postgres Pro

Synopsis

On Linux systems:

```
pgbouncer [ -d ] [ -R ] [ -v ] [ -u user ] pgbouncer.ini
```

```
pgbouncer -V | -h
```

On Windows:

```
pgbouncer [ -v ] [ -u user ] pgbouncer.ini
```

```
pgbouncer -V | -h
```

To use pgbouncer as a Windows service:

```
pgbouncer.exe --regservice pgbouncer.ini
```

```
pgbouncer.exe --unregservice pgbouncer.ini
```

Description

pgbouncer is a connection pooler for Postgres Pro. Any target application can be connected to pgbouncer as if it were a Postgres Pro server, and pgbouncer will create a connection to the actual server, or it will reuse one of its existing connections.

The aim of pgbouncer is to lower the performance impact of opening new connections to Postgres Pro.

In order not to compromise transaction semantics for connection pooling, pgbouncer supports several types of pooling when rotating connections:

Session pooling

Most polite method. When a client connects, a server connection will be assigned to it for the whole duration the client stays connected. When the client disconnects, the server connection will be put back into the pool. This is the default method.

Transaction pooling

A server connection is assigned to a client only during a transaction. When pgbouncer notices that transaction is over, the server connection will be put back into the pool.

Statement pooling

Most aggressive method. The server connection will be put back into the pool immediately after a query completes. Multi-statement transactions are disallowed in this mode as they would break.

The administration interface of pgbouncer consists of some new `SHOW` commands available when connected to a special “virtual” database `pgbouncer`.

Quick Start

pgbouncer is provided with Postgres Pro Standard as a separate pre-built package `pgbouncer` (for the detailed installation instructions, see [Chapter 16](#)). Basic setup and usage is as follows.

1. Create a `pgbouncer.ini` file. Details in the `pgbouncer(5)` man page. Simple example:

```
[databases]
template1 = host=localhost dbname=template1 auth_user=someuser
```

```
[pgbouncer]
listen_port = 6432
listen_addr = localhost
auth_type = md5
auth_file = userlist.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
```

2. Create a `userlist.txt` file that contains the users allowed in:

```
"someuser" "same_password_as_in_server"
```

3. Launch pgbouncer:

```
$ pgbouncer -d pgbouncer.ini
```

Note

The above command does not work on Windows systems. Instead, pgbouncer must be launched as a service that first needs to be registered, as follows:

```
pgbouncer --regservice
```

4. Have your application (or the `psql` client) connect to pgbouncer instead of directly to the PostgreSQL server:

```
$ psql -p 6432 -U someuser template1
```

5. Manage pgbouncer by connecting to the special administration database pgbouncer and issuing `SHOW HELP`; to begin:

```
$ psql -p 6432 -U someuser pgbouncer
pgbouncer=# SHOW HELP;
NOTICE:  Console usage
DETAIL:
SHOW [HELP|CONFIG|DATABASES|FDS|POOLS|CLIENTS|SERVERS|SOCKETS|LISTS|VERSION|...]
SET key = arg
RELOAD
PAUSE
SUSPEND
RESUME
SHUTDOWN
[...]
```

6. If you made changes to the `pgbouncer.ini` file, you can reload it with:

```
pgbouncer=# RELOAD;
```

LDAP Authentication Configuration

pgbouncer supports LDAP authentication for DBMS users. You can configure LDAP authentication by means of [PAM \(Pluggable Authentication Modules\)](#).

This section contains an example of LDAP authentication configuration.

To enable LDAP authentication via pgbouncer, perform the following steps:

- Ensure you fulfill all the required [prerequisites](#).
- [Configure Postgres Pro](#).
[Configure pgbouncer](#).
- [Configure PAM](#).
- [Test LDAP authentication](#).

Prerequisites

Before you start LDAP configuration, ensure that you have all required packages installed. If required, install any missing packages.

1. To ensure that your pgbouncer installation includes the PAM library (libpam), use the ldd utility:

```
$ ldd /usr/sbin/pgbouncer | grep pam
libpam.so.0 => /lib64/libpam.so.0 (0x00007fb5d6dd7000)
```

2. Ensure that your system includes the pam_ldap module:

```
$ find / -type f -name pam_ldap.so 2>/dev/null
/usr/lib64/security/pam_ldap.so
```

3. (Optional) If necessary, install pam_ldap:

```
apt-get install pam_ldap
```

Configuring Postgres Pro

1. In your Postgres Pro Standard instance, create a test user for LDAP authentication:

```
CREATE USER testuser WITH PASSWORD 'testuser_password';
```

2. In the pg_hba.conf file, specify the connection string for testuser. For example:

```
host      all      testuser      0.0.0.0/0      ldap
ldapurl=ldap_server_uri
ldapbasedn="CN=testuser,CN=Users,DC=postgrespro,DC=ru"
ldapbinddn="CN=service_user,CN=Users,DC=postgrespro,DC=ru"
ldapbindpasswd="service_user_password"
ldapsearchattribute=CN
```

For more information about LDAP authentication configuration options, see [Section 19.10](#).

As a result, the authentication operates as follows:

1. A user connects to Postgres Pro as testuser.
2. Postgres Pro connects to the LDAP server at ldapurl using ldapbinddn and ldapbindpasswd.
3. In ldapbasedn, Postgres Pro searches for an object where ldapsearchattribute is testuser.
4. Postgres Pro verifies the testuser password via LDAP.

Note

In a production environment, it is recommended to specify a container or an OU (OrganizationUnitName) as the ldapbasedn value (for example, CN=Users,DC=postgrespro,DC=ru), so that the user name is not hardcoded, but searched via ldapsearchattribute.

Configuring pgbouncer

1. In the [pgbouncer.ini](#) configuration file, specify the auth_type = pam authentication method.

The example of pgbouncer configuration looks as follows:

```
[pgbouncer]
listen_addr = *
listen_port = 6500
unix_socket_dir = /tmp/
pool_mode = session
max_client_conn = 15000
default_pool_size = 5
peer_id = 1
so_reuseport = 1
auth_type = pam
admin_users=pgbouncer,testuser
stats_users=pgbouncer,testuser

[databases]
* = host=localhost port=5432
```

2. Enable and activate pgbouncer:

```
systemctl enable --now pgbouncer
```

Configuring PAM

1. In the `/etc/pam.d/` directory, create a separate `pgbouncer` configuration with the following content:

```
##PAM-1.0
auth required pam_ldap.so
account required pam_ldap.so
```

Parameter descriptions:

- in the `auth required pam_ldap.so` entry:
 - `auth` is the authentication phase where the user password is verified.
 - `required` is a control flag. It means that if the module returns an error, the authentication fails. However, if successful, execution of other lines continues (i.e., early exit is not allowed).
 - `pam_ldap.so` is the module that communicates with LDAP and validates the specified username and password.
- in the `account required pam_ldap.so` entry:
 - `account` is the authorization or account phase where the system checks whether the user is permitted to log in. The account must be in the correct OU, must not be expired or locked.
 - `required` is a control flag. It means that if LDAP returns the “account invalid” error, the authentication fails.
 - `pam_ldap.so` is the same LDAP module. However, here it is used for password verification rather than for account state check.

2. Configure the module configuration file located at `/etc/pam_ldap.conf`. The configuration example looks as follows:

```
host ldap_server
base CN=Users,DC=postgrespro,DC=ru
binddn CN=service_user,CN=Users,DC=postgrespro,DC=ru
bindpw service_user_password
timelimit 5
bind_timelimit 5
```

pam_login_attribute CN

Parameter descriptions:

- `host` is the LDAP server(s) the client connects to.
- `base` is the base DN (distinguished name) where all search queries in the directory begin.
- `binddn` is the DN of the service account used by PAM to connect to LDAP for user searches.
- `bindpw` is the password for the `binddn` account.
- `timelimit` is the time limit (in seconds) for executing LDAP queries.
- `bind_timelimit` is the timeout (in seconds) for binding with the LDAP server.
- `pam_login_attribute` is the attribute of the LDAP user entry that will be compared to the specified username.

Testing Connection

1. Connect to your DBMS instance via LDAP:

```
psql -h 127.0.0.1 -U testuser -d postgres
```

2. Connect to your DBMS instance via pgbouncer:

```
psql -h 127.0.0.1 -U testuser -d postgres -p 6500
```

In both cases, the server log must display that LDAP is used as an authentication method.

Options

`-d, --daemon`

Run in the background. Without it, the process will run in the foreground. In daemon mode, setting `pidfile` as well as `logfile` or `syslog` is required. No log messages will be written to `stderr` after going into the background.

Note

Does not work on Windows, pgbouncer needs to run as service there.

`-R, --reboot`

Note

This option is deprecated. Instead of this option use a rolling restart with multiple pgbouncer processes listening on the same port using `so_reuseport` instead.

Do an online restart. That means connecting to the running process, loading the open sockets from it, and then using them. If there is no active process, boot normally.

Note

Works only if OS supports Unix sockets and the `unix_socket_dir` is not disabled in configuration. Does not work on Windows. Does not work with TLS connections, they are dropped.

`-u user, --user user`

Switch to the given user on startup.

`-v, --verbose`

Increase verbosity. Can be used multiple times.

`-q, --quiet`

Be quiet: do not log to stderr. This does not affect logging verbosity, only that stderr is not to be used. For use in `init.d` scripts.

`-V, --version`

Show version.

`-h, --help`

Show short help.

`--regservice`

Win32: Register to run as Windows service. The `service_name` configuration parameter value is used as the name to register under.

`--unregservice`

Win32: Unregister Windows service.

Admin Console

The console is available by connecting as normal to the database pgbouncer:

```
$ psql -p 6432 pgbouncer
```

Only users listed in the configuration parameters `admin_users` or `stats_users` are allowed to log in to the console. (Except when `auth_mode=any`, then any user is allowed in as a `stats_user`.)

Additionally, the user name `pgbouncer` is allowed to log in without password, if the login comes via the Unix socket and the client has same Unix user uid as the running process.

The admin console currently only supports the simple query protocol. Some drivers use the extended query protocol for all commands; these drivers will not work for this.

Show Commands

The `SHOW` commands output information. Each command is described below.

SHOW STATS

Shows statistics. In this and related commands, the total figures are since process start, the averages are updated every `stats_period`.

database

Statistics are presented per database.

total_xact_count

Total number of SQL transactions pooled by pgbouncer.

total_query_count

Total number of SQL queries pooled by pgbouncer.

total_received

Total volume in bytes of network traffic received by pgbouncer.

total_sent

Total volume in bytes of network traffic sent by pgbouncer.

`total_xact_time`

Total number of microseconds spent by pgbouncer when connected to Postgres Pro in a transaction, either idle in transaction or executing queries.

`total_query_time`

Total number of microseconds spent by pgbouncer when actively connected to Postgres Pro, executing queries.

`total_wait_time`

Time spent by clients waiting for a server, in microseconds. Updated when a client connection is assigned a backend connection.

`avg_xact_count`

Average transactions per second in last stat period.

`avg_query_count`

Average queries per second in last stat period.

`avg_recv`

Average received (from clients) bytes per second.

`avg_sent`

Average sent (to clients) bytes per second.

`avg_xact_time`

Average transaction duration, in microseconds.

`avg_query_time`

Average query duration, in microseconds.

`avg_wait_time`

Average time spent by clients waiting for a server that were assigned a backend connection within the current `stats_period`, in microseconds (average per second within that period).

SHOW STATS_TOTALS

Subset of `SHOW STATS` showing the total values (`total_`).

SHOW STATS_AVERAGES

Subset of `SHOW STATS` showing the average values (`avg_`).

SHOW TOTALS

Like `SHOW STATS` but aggregated across all databases.

SHOW SERVERS

`type`

S, for server.

`user`

User name pgbouncer uses to connect to server.

`database`

Database name.

state

State of the pgbouncer server connection, one of `active`, `idle`, `used`, `tested`, `new`, `active_cancel`, or `being_canceled`.

addr

IP address of Postgres Pro server.

port

Port of Postgres Pro server.

local_addr

Connection start address on local machine.

local_port

Connection start port on local machine.

connect_time

When the connection was made.

request_time

When last request was issued.

wait

Not used for server connections.

wait_us

Not used for server connections.

close_needed

1 if the connection will be closed as soon as possible, because a configuration file reload or DNS update changed the connection information or `RECONNECT` was issued.

ptr

Address of internal object for this connection. Used as unique ID.

link

Address of client connection the server is paired with.

remote_pid

PID of backend server process. In case connection is made over Unix socket and OS supports getting process ID info, its OS PID. Otherwise it's extracted from cancel packet the server sent, which should be the PID in case the server is Postgres Pro, but it's a random number in case the server is another pgbouncer.

tls

A string with TLS connection information, or empty if not using TLS.

application_name

A string containing the `application_name` set on the linked client connection, or empty if this is not set, or if there is no linked connection.

SHOW CLIENTS

type

C, for client.

`user`

Client connected user.

`database`

Database name.

`state`

State of the client connection, one of `active`, `waiting`, `active_cancel_req`, or `waiting_cancel_req`.

`addr`

IP address of the client.

`port`

Source port of the client.

`local_addr`

Connection end address on local machine.

`local_port`

Connection end port on local machine.

`connect_time`

Timestamp of connect time.

`request_time`

Timestamp of latest client request.

`wait`

Current waiting time in seconds.

`wait_us`

Microsecond part of the current waiting time.

`close_needed`

Not used for clients.

`ptr`

Address of internal object for this connection. Used as unique ID.

`link`

Address of server connection the client is paired with.

`remote_pid`

Process ID, in case client connects over Unix socket and OS supports getting it.

`tls`

A string with TLS connection information, or empty if not using TLS.

`application_name`

A string containing the `application_name` set by the client for this connection, or empty if this is not set.

SHOW POOLS

A new pool entry is made for each couple of (database, user).

database

Database name.

user

User name.

cl_active

Client connections that are either linked to server connections or are idle with no queries waiting to be processed.

cl_waiting

Client connections that have sent queries but have not yet got a server connection.

cl_active_cancel_req

Client connections that have forwarded query cancellations to the server and are waiting for the server response.

cl_waiting_cancel_req

Client connections that have not forwarded query cancellations to the server yet.

sv_active

Server connections that are linked to a client.

sv_active_cancel

Server connections that are currently forwarding a cancel request.

sv_being_canceled

Servers that normally could become idle but are waiting to do so until all in-flight cancel requests have completed that were sent to cancel a query on this server.

sv_idle

Server connections that are unused and immediately usable for client queries.

sv_used

Server connections that have been idle for more than `server_check_delay`, so they need `server_check_query` to run on them before they can be used again.

sv_tested

Server connections that are currently running either `server_reset_query` or `server_check_query`.

sv_login

Server connections currently in the process of logging in.

maxwait

How long the first (oldest) client in the queue has waited, in seconds. If this starts increasing, then the current pool of servers does not handle requests quickly enough. The reason may be either an overloaded server or just too small of a `pool_size` setting.

maxwait_us

Microsecond part of the maximum waiting time.

pool_mode

The pooling mode in use.

SHOW PEER_POOLS

A new `peer_pool` entry is made for each configured peer.

database

ID of the configured peer entry.

cl_active_cancel_req

Client connections that have forwarded query cancellations to the server and are waiting for the server response.

cl_waiting_cancel_req

Client connections that have not forwarded query cancellations to the server yet.

sv_active_cancel

Server connections that are currently forwarding a cancel request.

sv_login

Server connections currently in the process of logging in.

SHOW LISTS

Show following internal information, in columns (not rows):

databases

Count of databases.

users

Count of users.

pools

Count of pools.

free_clients

Count of free clients.

used_clients

Count of used clients.

login_clients

Count of clients in `login` state.

free_servers

Count of free servers.

used_servers

Count of used servers.

dns_names

Count of DNS names in the cache.

`dns_zones`

Count of DNS zones in the cache.

`dns_queries`

Count of in-flight DNS queries.

`dns_pending`

Not used.

SHOW USERS

`name`

The user name.

`pool_mode`

The user's override `pool_mode`, or `NULL` if the default will be used instead.

SHOW DATABASES

`name`

Name of configured database entry.

`host`

Host pgbouncer connects to.

`port`

Port pgbouncer connects to.

`database`

Actual database name pgbouncer connects to.

`force_user`

When the user is part of the connection string, the connection between pgbouncer and Postgres Pro is forced to the given user, whatever the client user.

`pool_size`

Maximum number of server connections.

`min_pool_size`

Minimum number of server connections.

`reserve_pool`

Maximum number of additional connections for this database.

`pool_mode`

The database's override `pool_mode`, or `NULL` if the default will be used instead.

`max_connections`

Maximum number of allowed connections for this database, as set by `max_db_connections`, either globally or per database.

`current_connections`

Current number of connections for this database.

paused

1 if this database is currently paused, else 0.

disabled

1 if this database is currently disabled, else 0.

SHOW PEERS

peer_id

ID of the configured peer entry.

host

Host pgbouncer connects to.

port

Port pgbouncer connects to.

pool_size

Maximum number of server connections that can be made to this peer.

SHOW FDS

Internal command — shows list of file descriptors (FDs) in use with internal state attached to them.

When the connected user has the user name `pgbouncer`, connects through the Unix socket and has the same UID as the running process, the actual FDs are passed over the connection. This mechanism is used to do an online restart.

Note

This does not work on Windows.

This command also blocks the internal event loop, so it should not be used while pgbouncer is in use.

fd

File descriptor numeric value.

task

One of `pooler`, `client` or `server`.

user

User of the connection using the FD.

database

Database of the connection using the FD.

addr

IP address of the connection using the FD, `unix` if a Unix socket is used.

port

Port used by the connection using the FD.

cancel

Cancel key for this connection.

link

File descriptor for corresponding server/client. NULL if idle.

SHOW SOCKETS, SHOW ACTIVE_SOCKETS

Shows low-level information about sockets or only active sockets. This includes the information shown under `SHOW CLIENTS` and `SHOW SERVERS` as well as other more low-level information.

SHOW CONFIG

Show the current configuration settings, one per row, with the following columns:

key

Configuration variable name.

value

Configuration value.

default

Configuration default value.

changeable

Either `yes` or `no`, shows if the variable can be changed while running. If `no`, the variable can be changed only at boot-time. Use `SET` to change a variable at run time.

SHOW MEM

Shows low-level information about the current sizes of various internal memory allocations. The information presented is subject to change.

SHOW DNS_HOSTS

Show host names in DNS cache.

hostname

Host name.

ttd

How many seconds until next lookup.

addrs

Comma separated list of addresses.

SHOW DNS_ZONES

Show DNS zones in cache.

zonename

Zone name.

serial

Current serial.

count

Host names belonging to this zone.

SHOW VERSION

Show the pgbouncer version string.

SHOW STATE

Show the pgbouncer state settings. Current states are active, paused and suspended.

Process Controlling Commands**PAUSE [db]**

pgbouncer tries to disconnect from all servers. Disconnecting each server connection waits for that server connection to be released according to the server pool's pooling mode (in transaction pooling mode, the transaction must complete, in statement mode, the statement must complete, and in session pooling mode the client must disconnect). The command will not return before all server connections have been disconnected. To be used at the time of database restart.

If database name is given, only that database will be paused.

New client connections to a paused database will wait until `RESUME` is called.

DISABLE db

Reject all new client connections on the given database.

ENABLE db

Allow new client connections after a previous `DISABLE` command.

RECONNECT db

Close each open server connection for the given database, or all databases, after it is released (according to the pooling mode), even if its lifetime is not up yet. New server connections can be made immediately and will connect as necessary according to the pool size settings.

This command is useful when the server connection setup has changed, for example to perform a gradual switchover to a new server. It is not necessary to run this command when the connection string in `pgbouncer.ini` has been changed and reloaded (see `RELOAD`) or when DNS resolution has changed, because then the equivalent of this command will be run automatically. This command is only necessary if something downstream of pgbouncer routes the connections.

After this command is run, there could be an extended period where some server connections go to an old destination and some server connections go to a new destination. This is likely only sensible when switching read-only traffic between read-only replicas, or when switching between nodes of a multimaster replication setup. If all connections need to be switched at the same time, `PAUSE` is recommended instead. To close server connections without waiting (for example, in emergency failover rather than gradual switchover scenarios), also consider `KILL`.

KILL db

Immediately drop all client and server connections on given database.

New client connections to a killed database will wait until `RESUME` is called.

SUSPEND

All socket buffers are flushed and pgbouncer stops listening for data on them. The command will not return before all buffers are empty. To be used at the time of pgbouncer online reboot.

New client connections to a suspended database will wait until `RESUME` is called.

RESUME [db]

Resume work from previous `KILL`, `PAUSE`, or `SUSPEND` command.

SHUTDOWN

The pgbouncer process will exit.

RELOAD

The pgbouncer process will reload its configuration files and update changeable settings. This includes the main configuration file as well as the files specified by the settings `auth_file` and `auth_hba_file`.

pgbouncer notices when a configuration file reload changes the connection parameters of a database definition. An existing server connection to the old destination will be closed when the server connection is next released (according to the pooling mode), and new server connections will immediately use the updated connection parameters.

WAIT_CLOSE [*db*]

Wait until all server connections, either of the specified database or of all databases, have cleared the `close_needed` state (see [the section called “SHOW SERVERS”](#)). This can be called after a `RECONNECT` or `RELOAD` to wait until the respective configuration change has been fully activated, for example in switchover scripts.

Other Commands

SET *key* = *arg*

Changes a configuration setting (see also [the section called “SHOW CONFIG”](#)). For example:

```
SET log_connections = 1;
SET server_check_query = 'select 2';
```

(Note that this command is run on the pgbouncer admin console and sets pgbouncer settings. A `SET` command run on another database will be passed to the Postgres Pro backend like any other SQL command.)

Signals

SIGHUP

Reload config. Same as issuing the command `RELOAD` on the console.

SIGINT

Safe shutdown. Same as issuing `PAUSE` and `SHUTDOWN` on the console.

SIGTERM

Immediate shutdown. Same as issuing `SHUTDOWN` on the console.

SIGUSR1

Same as issuing `PAUSE` on the console.

SIGUSR2

Same as issuing `RESUME` on the console.

Libevent Settings

From the libevent documentation:

It is possible to disable support for `epoll`, `kqueue`, `devpoll`, `poll`, or `select` by setting the environment variable `EVENT_NOEPOLL`, `EVENT_NOKQUEUE`, `EVENT_NODEVPOLL`, `EVENT_NOPOLL` or `EVENT_NOSELECT`, respectively.

By setting the environment variable `EVENT_SHOW_METHOD`, libevent displays the kernel notification method that it uses.

pgbouncer.ini Configuration File

The configuration file is in the `.ini` format. Section names are between `[` and `]`. Lines starting with `;` or `#` are taken as comments and ignored. The characters `;` and `#` are not recognized as special when they appear later in the line.

Generic Settings

logfile

Specifies the log file. For daemonization (`-d`), either this or `syslog` has to be set. The log file is kept open, so after rotation, `kill -HUP` or on console `RELOAD`; should be done. On Windows, the service must be stopped and started.

Note that setting `logfile` does not by itself turn off logging to `stderr`. Use the command-line option `-q` or `-d` for that.

Default: not set

pidfile

Specifies the PID file. Without `pidfile` set, daemonization (`-d`) is not allowed.

Default: not set

listen_addr

Specifies a list (comma-separated) of addresses where to listen for TCP connections. You may also use `*` meaning "listen on all addresses". When not set, only Unix socket connections are accepted.

Addresses can be specified numerically (IPv4/IPv6) or by name.

Default: not set

listen_port

Which port to listen on. Applies to both TCP and Unix sockets.

Default: 6432

unix_socket_dir

Specifies the location for Unix sockets. Applies to both the listening socket and server connections. If set to an empty string, Unix sockets are disabled. A value that starts with `@` specifies that a Unix socket in the abstract namespace should be created (currently supported on Linux and Windows).

For online reboot (`-R`) to work, a Unix socket needs to be configured, and it needs to be in the file-system namespace.

Default: `/tmp` (empty on Windows)

unix_socket_mode

File system mode for Unix socket. Ignored for sockets in the abstract namespace. Not supported on Windows.

Default: 0777

unix_socket_group

Group name to use for Unix socket. Ignored for sockets in the abstract namespace. Not supported on Windows.

Default: not set

user

If set, specifies the Unix user to change to after startup. Works only if `pgbouncer` is started as root or if it's already running as the given user.

Not supported on Windows.

Default: not set

`pool_mode`

Specifies when a server connection can be reused by other clients.

`session`

Server is released back to pool after client disconnects. Default.

`transaction`

Server is released back to pool after transaction finishes.

`statement`

Server is released back to pool after query finishes. Transactions spanning multiple statements are disallowed in this mode.

`max_client_conn`

Maximum number of client connections allowed.

When this setting is increased, then the file descriptor limits in the operating system might also have to be increased. Note that the number of file descriptors potentially used is more than `max_client_conn`. If each user connects under its own username to the server, the theoretical maximum used is:

`max_client_conn + (max pool_size * total databases * total users)`

If a database user is specified in the connection string (all users connect under the same user name), the theoretical maximum is:

`max_client_conn + (max pool_size * total databases)`

The theoretical maximum should never be reached, unless somebody deliberately crafts a special load for it. Still, it means you should set the number of file descriptors to a safely high number.

Search for `ulimit` in your favorite shell man page. Note: `ulimit` does not apply in a Windows environment.

Default: 100

`default_pool_size`

How many server connections to allow per user/database pair. Can be overridden in the per-database configuration.

Default: 20

`min_pool_size`

Add more server connections to pool if below this number. Improves the behavior when the normal load suddenly comes back after a period of total inactivity. The value is effectively capped at the pool size.

Default: 0 (disabled)

`reserve_pool_size`

How many additional connections to allow to a pool (see [reserve_pool_timeout](#)). The 0 value disables this parameter.

Default: 0 (disabled)

`reserve_pool_timeout`

If a client has not been serviced in this time, `pgbouncer` enables use of additional connections from the reserve pool. The 0 value disables this parameter. [seconds]

Default: 5.0

`max_db_connections`

Do not allow more than this many server connections per database (regardless of user). This considers the pgbouncer database that the client has connected to, not the Postgres Pro database of the outgoing connection. This can also be set per database in the `[databases]` section.

Note that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: 0 (unlimited)

`max_user_connections`

Do not allow more than this many server connections per user (regardless of database). This considers the pgbouncer user that is associated with a pool, which is either the user specified for the server connection or in absence of that the user the client has connected as. This can also be set per user in the `[users]` section.

Note that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: 0 (unlimited)

`server_round_robin`

By default, pgbouncer reuses server connections in LIFO (last-in, first-out) manner, so that few connections get the most load. This gives best performance if you have a single server serving a database. But if there is a round-robin system behind a database address (TCP, DNS, or host list), then it is better if pgbouncer also uses connections in that manner, thus achieving uniform load.

Default: 0

`track_extra_parameters`

By default, pgbouncer tracks `client_encoding`, `datestyle`, `timezone`, `standard_conforming_strings` and `application_name` parameters per client. To allow other parameters to be tracked, they can be specified here, so that pgbouncer knows that they should be maintained in the client variable cache and restored in the server whenever the client becomes active.

If you need to specify multiple values, use a comma-separated list (e.g. `default_transaction_read-only, IntervalStyle`)

Note

Most parameters cannot be tracked this way. The only parameters that can be tracked are ones that Postgres Pro reports to the client. Postgres Pro has [an official list of parameters that it reports to the client](#). Postgres Pro extensions can change this list though, they can add parameters themselves that they also report, and they can start reporting already existing parameters that Postgres Pro does not report. Notably Citus 12.0+ causes PostgreSQL to also report `search_path`.

The `postgres` protocol allows specifying parameter settings, both directly as a parameter in the startup packet, or inside the `options startup packet`. Parameters specified using both of these methods are supported by `track_extra_parameters`. However, it's not possible to include `options` itself in `track_extra_parameters`, only the parameters contained in `options`.

Default: `IntervalStyle`

`ignore_startup_parameters`

By default, `pgbouncer` allows only parameters it can keep track of in startup packets: `client_encoding`, `datestyle`, `timezone` and `standard_conforming_strings`.

All other parameters will raise an error. To allow other parameters, they can be specified here, so that `pgbouncer` knows that they are handled by the admin and it can ignore them.

If you need to specify multiple values, use a comma-separated list (e.g. `options,extra_float_digits`).

The `postgres` protocol allows specifying parameter settings, both directly as a parameter in the startup packet, or inside the [options startup packet](#). Parameters specified using both of these methods are supported by `ignore_startup_parameters`. It's even possible to include `options` itself in `ignore_startup_parameters`, which results in any unknown parameters contained inside `options` to be ignored.

Default: empty

`peer_id`

The peer ID used to identify this `pgbouncer` process in a group of `pgbouncer` processes that are peered together. The `peer_id` value should be unique within a group of peered `pgbouncer` processes. When set to 0, `pgbouncer` peering is disabled. See also [\[peers\] Section](#) for more information. The maximum value that can be used for the `peer_id` is 16383.

Default: 0

`disable_pqexec`

Disable the Simple Query protocol (PQexec). Unlike the Extended Query protocol, Simple Query allows multiple queries in one packet, which allows some classes of SQL-injection attacks. Disabling it can improve security. Obviously, this means only clients that exclusively use the Extended Query protocol will stay working.

Default: 0

`application_name_add_host`

Add the client host address and port to the application name setting set on connection start. This helps in identifying the source of bad queries, etc. This logic applies only at the start of a connection. If `application_name` is later changed with `SET`, `pgbouncer` does not change it again.

Default: 0

`conffile`

Show location of current configuration file. Changing it will make `pgbouncer` use another configuration file for next `RELOAD` / `SIGHUP`.

Default: file from command line

`service_name`

Used on win32 service registration.

Default: `pgbouncer`

`job_name`

Alias for [service_name](#).

stats_period

Sets how often the averages shown in various `SHOW` commands are updated and how often aggregated statistics are written to the log (but see [log_stats](#)). [seconds]

Default: 60

Authentication Settings

pgbouncer handles its own client authentication and has its own database of users. These settings control this.

auth_type

How to authenticate users.

cert

The client must connect over TLS connection with a valid client certificate. The user name is then taken from the `CommonName` field from the certificate.

md5

Use MD5-based password check. This is the default authentication method. [auth_file](#) may contain both MD5-encrypted and plain-text passwords. If `md5` is configured and a user has a SCRAM secret, then SCRAM authentication is used automatically instead.

scram-sha-256

Use password check with SCRAM-SHA-256. [auth_file](#) has to contain SCRAM secrets or plain-text passwords. Note that SCRAM secrets can only be used for verifying the password of a client but not for logging into a server. To be able to use SCRAM on server connections, use plain-text passwords.

plain

The clear-text password is sent over the wire. Deprecated.

trust

No authentication is done. The user name must still exist in [auth_file](#).

any

Like the `trust` method, but the user name given is ignored. Requires that all databases are configured to log in as a specific user. Additionally, the console database allows any user to log in as admin.

hba

The actual authentication type is loaded from [auth_hba_file](#). This allows different authentication methods for different access paths, for example: connections over Unix socket use `peer` authentication method, connections over TCP must use TLS.

pam

Pluggable Authentication Modules (PAM) method is used to authenticate users, [auth_file](#) is ignored. This method is not compatible with databases using the [auth_user](#) option. The service name reported to PAM is `pgbouncer`. `pam` is not supported in the HBA configuration file.

auth_hba_file

HBA configuration file to use when [auth_type](#) is `hba`.

Default: not set

auth_file

The name of the file to load user names and passwords from. See [the section called “Authentication File Format”](#) for details.

Most authentication types (see [auth_type](#)) require that either [auth_file](#) or [auth_user](#) be set; otherwise there would be no users defined.

Default: not set

auth_user

If [auth_user](#) is set, then any user not specified in [auth_file](#) will be queried through the [auth_query](#) query from `pg_shadow` in the database, using [auth_user](#). The password of [auth_user](#) will be taken from [auth_file](#). (If [auth_user](#) does not require a password, then it does not need to be defined in [auth_file](#).)

Direct access to `pg_shadow` requires admin rights. It's preferable to use a non-superuser that calls a `SECURITY DEFINER` function instead.

Default: not set

auth_query

Query to load user's password from database.

Direct access to `pg_shadow` requires admin rights. It's preferable to use a non-superuser that calls a `SECURITY DEFINER` function instead.

Note that the query is run inside the target database. So if a function is used, it needs to be installed into each database.

Default: `SELECT username, passwd FROM pg_shadow WHERE username=$1`

auth_dbname

Database name in the [\[databases\]](#) section to be used for authentication purposes. This option can be either global or overridden in the connection string if this parameter is specified.

Log Settings

syslog

Toggles syslog on/off. On Windows, the event log is used instead.

Default: 0

syslog_ident

Under what name to send logs to syslog.

Default: `pgbouncer` (program name)

syslog_facility

Under what facility to send logs to syslog. Possibilities: `auth`, `authpriv`, `daemon`, `user`, `local0-7`.

Default: `daemon`

log_connections

Log successful logins.

Default: 1

`log_disconnections`

Log disconnections with reasons.

Default: 1

`log_pooler_errors`

Log error messages the pooler sends to clients.

Default: 1

`log_stats`

Write aggregated statistics into the log, every `stats_period`. This can be disabled if external monitoring tools are used to grab the same data from `SHOW` commands.

Default: 1

`verbose`

Increase verbosity. Mirrors the `-v` switch on the command line. For example, using `-v -v` on the command line is the same as `verbose=2`.

Default: 0

Console Access Control`admin_users`

Comma-separated list of database users that are allowed to connect and run all commands on the console. Ignored when `auth_type` is `any`, in which case any user name is allowed in as admin.

Default: empty

`stats_users`

Comma-separated list of database users that are allowed to connect and run read-only queries on the console. That means all `SHOW` commands except `SHOW FDS`.

Default: empty

Connection Sanity Checks, Timeouts`server_reset_query`

Query sent to server on connection release, before making it available to other clients. At that moment no transaction is in progress, so the value should not include `ABORT` or `ROLLBACK`.

The query is supposed to clean any changes made to the database session so that the next client gets the connection in a well-defined state. The default is `DISCARD ALL`, which cleans everything, but that leaves the next client no pre-cached state. It can be made lighter, e.g. `DEALLOCATE ALL` to just drop prepared statements, if the application does not break when some state is kept around.

When transaction pooling is used, the `server_reset_query` is not used, because in that mode, clients must not use any session-based features, since each transaction ends up in a different connection and thus gets a different session state.

Default: `DISCARD ALL`

`server_reset_query_always`

Whether `server_reset_query` should be run in all pooling modes. When this setting is off (default), the `server_reset_query` will be run only in pools that are in sessions-pooling mode. Connections in transaction-pooling mode should not have any need for a reset query.

This setting is for working around broken setups that run applications that use session features over a transaction-pooled pgbouncer. It changes non-deterministic breakage to deterministic breakage: clients always lose their state after each transaction.

Default: 0

`server_check_delay`

How long to keep released connections available for immediate re-use, without running `server_check_query` on it. If 0 then the query is always run.

Default: 30.0

`server_check_query`

Simple do-nothing query to check if the server connection is alive.

If an empty string, then sanity checking is disabled.

Default: `select 1`

`server_fast_close`

Disconnect a server in session pooling mode immediately or after the end of the current transaction if it is in `close_needed` mode (set by `RECONNECT`, `RELOAD` that changes connection settings, or DNS change), rather than waiting for the session end. In statement or transaction pooling mode, this has no effect since that is the default behavior there.

If because of this setting a server connection is closed before the end of the client session, the client connection is also closed. This ensures that the client notices that the session has been interrupted.

This setting makes connection configuration changes take effect sooner if session pooling and long-running sessions are used. The downside is that client sessions are liable to be interrupted by a configuration change, so client applications will need logic to reconnect and reestablish session state. But note that no transactions will be lost, because running transactions are not interrupted, only idle sessions.

Default: 0

`server_lifetime`

The pooler will close an unused (not currently linked to any client connection) server connection that has been connected longer than this. Setting it to 0 means the connection is to be used only once, then closed. [seconds]

Default: 3600.0

`server_idle_timeout`

If a server connection has been idle more than this many seconds it will be closed. If 0 then timeout is disabled. [seconds]

Default: 600.0

`server_connect_timeout`

If connection and login don't finish in this amount of time, the connection will be closed. [seconds]

Default: 15.0

`server_login_retry`

If login to the server failed, because of failure to connect or from authentication, the pooler waits this much before retrying to connect. During the waiting interval, new clients trying to connect to the failing server will get an error immediately without another connection attempt. [seconds]

The purpose of this behavior is that clients don't unnecessarily queue up waiting for a server connection to become available if the server is not working. However, it also means that if a server is momentarily failing, for example during a restart or if the configuration was erroneous, then it will take at least this long until the pooler will consider connecting to it again. Planned events such as restarts should normally be managed using the `PAUSE` command to avoid this.

Default: 15.0

`client_login_timeout`

If a client connects but does not manage to log in in this amount of time, it will be disconnected. Mainly needed to avoid dead connections stalling `SUSPEND` and thus online restart. [seconds]

Default: 60.0

`autodb_idle_timeout`

If the automatically created (via `"*`") database pools have been unused this many seconds, they are freed. The negative aspect of that is that their statistics are also forgotten. [seconds]

Default: 3600.0

`dns_max_ttl`

How long DNS lookups can be cached. The actual DNS TTL is ignored. [seconds]

Default: 15.0

`dns_nxdomain_ttl`

How long DNS errors and `NXDOMAIN` DNS lookups can be cached. [seconds]

Default: 15.0

`dns_zone_check_period`

Period to check if a zone serial has changed.

`pgbouncer` can collect DNS zones from host names (everything after first dot) and then periodically check if the zone serial changes. If it notices changes, all host names under that zone are looked up again. If any host IP changes, its connections are invalidated.

Default: 0.0 (disabled)

`resolv_conf`

The location of a custom `resolv.conf` file. This is to allow specifying custom DNS servers and perhaps other name resolution options, independent of the global operating system configuration.

The parsing of the file is done by the DNS backend library, not `pgbouncer`, so see the library's documentation for details on allowed syntax and directives.

Default: empty (use operating system defaults)

TLS Settings

`client_tls_sslmode`

TLS mode to use for connections from clients. TLS connections are disabled by default. When enabled, `client_tls_key_file` and `client_tls_cert_file` must be also configured to set up the key and certificate `pgbouncer` uses to accept client connections.

`disable`

Plain TCP. If client requests TLS, it's ignored. Default.

`allow`

If client requests TLS, it is used. If not, plain TCP is used. If the client presents a client certificate, it is not validated.

`prefer`

Same as `allow`.

`require`

The client must use TLS. If not, the client connection is rejected. If the client presents a client certificate, it is not validated.

`verify-ca`

Client must use TLS with valid client certificate.

`verify-full`

Same as `verify-ca`.

`client_tls_key_file`

Private key for pgbouncer to accept client connections.

Default: not set

`client_tls_cert_file`

Certificate for private key. Clients can validate it.

Default: not set

`client_tls_ca_file`

Root certificate file to validate client certificates.

Default: not set

`client_tls_protocols`

Which TLS protocol versions are allowed. Allowed values: `tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`. Shortcuts: `all` (`tlsv1.0,tlsv1.1,tlsv1.2,tlsv1.3`), `secure` (`tlsv1.2,tlsv1.3`), `legacy` (`all`).

Default: `secure`

`client_tls_ciphers`

Allowed TLS ciphers, in OpenSSL syntax. Shortcuts: `default/secure`, `compat/legacy`, `insecure/all`, `normal`, `fast`.

Only connections using TLS version 1.2 and lower are affected. There is currently no setting that controls the cipher choices used by TLS version 1.3 connections.

Default: `fast`

`client_tls_ecdhcurve`

Elliptic Curve name to use for ECDH key exchanges.

Allowed values: `none` (DH is disabled), `auto` (256-bit ECDH), curve name.

Default: `auto`

`client_tls_dheparams`

DHE key exchange type.

Allowed values: `none` (DH is disabled), `auto` (2048-bit DH), `legacy` (1024-bit DH).

Default: `auto`

`server_tls_sslmode`

TLS mode to use for connections to Postgres Pro servers. The default mode is `prefer`.

`disable`

Plain TCP. TLS is not even requested from the server.

`prefer`

TLS connection is always requested first from Postgres Pro. If refused, the connection will be established over plain TCP. Server certificate is not validated. Default.

`require`

Connection must go over TLS. If server rejects it, plain TCP is not attempted. Server certificate is not validated.

`verify-ca`

Connection must go over TLS and server certificate must be valid according to `server_tls_ca_file`. Server host name is not checked against certificate.

`verify-full`

Connection must go over TLS and server certificate must be valid according to `server_tls_ca_file`. Server host name must match certificate information.

`server_tls_ca_file`

Root certificate file to validate Postgres Pro server certificates.

Default: not set

`server_tls_key_file`

Private key for pgbouncer to authenticate against Postgres Pro server.

Default: not set

`server_tls_cert_file`

Certificate for private key. Postgres Pro server can validate it.

Default: not set

`server_tls_protocols`

Which TLS protocol versions are allowed. Allowed values: `tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`. Shortcuts: `all` (`tlsv1.0,tlsv1.1,tlsv1.2,tlsv1.3`), `secure` (`tlsv1.2,tlsv1.3`), `legacy` (`all`).

Default: `secure`

`server_tls_ciphers`

Allowed TLS ciphers, in OpenSSL syntax. Shortcuts: `default/secure`, `compat/legacy`, `insecure/all`, `normal`, `fast`.

Only connections using TLS version 1.2 and lower are affected. There is currently no setting that controls the cipher choices used by TLS version 1.3 connections.

Default: `fast`

Dangerous Timeouts

Setting the following timeouts can cause unexpected errors.

`query_timeout`

Queries running longer than that are canceled. This should be used only with a slightly smaller server-side `statement_timeout`, to apply only for network problems. [seconds]

Default: 0.0 (disabled)

`query_wait_timeout`

Maximum time queries are allowed to spend waiting for execution. If the query is not assigned to a server during that time, the client is disconnected. The 0 value disables this parameter. If this is disabled, clients will be queued indefinitely. [seconds]

This setting is used to prevent unresponsive servers from grabbing up connections. It also helps when the server is down or rejects connections for any reason.

Default: 120.0

`cancel_wait_timeout`

Maximum time cancellation requests are allowed to spend waiting for execution. If the cancel request is not assigned to a server during that time, the client is disconnected. 0 disables. If this is disabled, cancel requests will be queued indefinitely. [seconds]

This setting is used to prevent a client locking up when a cancel cannot be forwarded due to the server being down.

Default: 10.0

`client_idle_timeout`

Client connections idling longer than this many seconds are closed. This should be larger than the client-side connection lifetime settings, and only used for network problems. [seconds]

Default: 0.0 (disabled)

`idle_transaction_timeout`

If a client has been in the “idle in transaction” state longer, it will be disconnected. [seconds]

Default: 0.0 (disabled)

`suspend_timeout`

How long to wait for buffer flush during `SUSPEND` or reboot (`-R`). A connection is dropped if the flush does not succeed. [seconds]

Default: 10

Low-Level Network Settings

`pkt_buf`

Internal buffer size for packets. Affects size of TCP packets sent and general memory usage. Actual libpq packets can be larger than this, so no need to set it large.

Default: 4096

`max_packet_size`

Maximum size for Postgres Pro packets that pgbouncer allows through. One packet is either one query or one result set row. The full result set can be larger.

Default: 2147483647

`listen_backlog`

The value of the `backlog` argument for `listen()`. Determines how many new unanswered connection attempts are kept in the queue. When the queue is full, further new connections are dropped.

Default: 128

`sbuf_loopcnt`

How many times to process data on one connection, before proceeding. Without this limit, one connection with a big result set can stall pgbouncer for a long time. One loop processes one `pkt_buf` amount of data. 0 means no limit.

Default: 5

`so_reuseport`

Specifies whether to set the socket option `SO_REUSEPORT` on TCP listening sockets. On some operating systems, this allows running multiple pgbouncer instances on the same host listening on the same port and having the kernel distribute the connections automatically. This option is a way to get pgbouncer to use more CPU cores. (pgbouncer is single-threaded and uses one CPU core per instance.)

This setting has the desired effect on Linux. On systems that don't support the socket option at all, turning this setting on will result in an error.

Each pgbouncer instance on the same host needs different settings for at least `unix_socket_dir` and `pidfile`, as well as `logfile` if that is used. Also note that if you make use of this option, you can no longer connect to a specific pgbouncer instance via TCP/IP, which might have implications for monitoring and metrics collection.

To make sure query cancellations keep working, you should set up pgbouncer peering between the different pgbouncer processes. For details see the [peer_id configuration option](#) and the [\[peers\] configuration section](#). There's also an example that uses peering and `so_reuseport` in the [Examples section](#).

Default: 0

`tcp_defer_accept`

Sets the `TCP_DEFER_ACCEPT` socket option; see `man 7 tcp` for details. (This is a Boolean option: 1 means enabled. The actual value set if enabled is currently hardcoded to 45 seconds.)

This is currently only supported on Linux.

Default: 1 on Linux, otherwise 0

`tcp_socket_buffer`

Default: not set

`tcp_keepalive`

Turns on basic keepalive with OS defaults.

On Linux, the system defaults are `tcp_keepidle=7200`, `tcp_keepintvl=75`, `tcp_keepcnt=9`. They are probably similar on other operating systems.

Default: 1

`tcp_keepcnt`

Default: not set

`tcp_keepidle`

Default: not set

`tcp_keepintvl`

Default: not set

`tcp_user_timeout`

Sets the `TCP_USER_TIMEOUT` socket option. This specifies the maximum amount of time in milliseconds that transmitted data may remain unacknowledged before the TCP connection is forcibly closed. If set to 0, then operating system's default is used.

This is currently only supported on Linux.

Default: 0

Section [databases]

The section [databases] defines the names of the databases that clients of pgbouncer can connect to and specifies where those connections will be routed. The section contains `key=value` lines like

```
dbname = connection string
```

where the key will be taken as a database name and the value as a connection string, consisting of `key=value` pairs of connection parameters, described below (similar to libpq, but the actual libpq is not used and the set of available features is different).

Example:

```
foodb = host=host1.example.com port=5432
bardb = host=localhost dbname=bazdb
```

The database name can contain characters `_0-9A-Za-z` without quoting. Names that contain other chars need to be quoted with standard SQL ident quoting: double quotes where `"` is taken as single quote.

The database name `pgbouncer` is reserved for the admin console and cannot be used as a key here.

* acts as fallback database: if the exact name does not exist, its value is taken as connection string for the requested database. For example, if there is the following entry (and no other overriding entries):

```
* = host=foo
```

In this case, a connection to pgbouncer specifying a database `bar` will effectively behave as if the following entry exists (taking advantage of the default for `dbname` being the client-side database name):

```
bar = host=foo dbname=bar
```

Such automatically created database entries are cleaned up if they stay idle longer than the time specified by the `autodb_idle_timeout` parameter.

`dbname`

Destination database name.

Default: same as client-side database name

`host`

Host name or IP address to connect to. Host names are resolved at connection time, the result is cached per `dns_max_ttl` parameter. When a host name's resolution changes, existing server connections are automatically closed when they are released (according to the pooling mode), and new server connections immediately use the new resolution. If DNS returns several results, they are used in a round-robin manner.

If the value begins with `/`, then a Unix socket in the file-system namespace is used. If the value begins with `@`, then a Unix socket in the abstract namespace is used.

A comma-separated list of host names or addresses can be specified. In that case, connections are made in a round-robin manner. (If a host list contains host names that in turn resolve via DNS to multiple addresses, the round-robin systems operate independently. This is an implementation dependency that is subject to change.) Note that in a list, all hosts must be available at all times: there are no mechanisms to skip unreachable hosts or to select only available hosts from a list or similar. (This is different from what a host list in `libpq` means.) Also note that this only affects how the destinations of new connections are chosen. See also the setting `server_round_robin` for how clients are assigned to already established server connections.

Examples:

```
host=localhost
host=127.0.0.1
host=2001:0db8:85a3:0000:0000:8a2e:0370:7334
host=/var/run/postgresql
host=192.168.0.1,192.168.0.2,192.168.0.3
```

Default: not set, meaning to use a Unix socket

`port`

Default: 5432

`user`

If `user=` is set, all connections to the destination database will be done with the specified user, meaning that there will be only one pool for this database.

Otherwise `pgbouncer` logs into the destination database with the client user name, meaning that there will be one pool per user.

`password`

If no password is specified here, the password from the `auth_file` or `auth_query` will be used.

`auth_user`

Override of the global `auth_user` setting, if specified.

`pool_size`

Set the maximum size of pools for this database. If not set, the `default_pool_size` is used.

`min_pool_size`

Set the minimum pool size for this database. If not set, the global `min_pool_size` is used.

`reserve_pool`

Set additional connections for this database. If not set, `reserve_pool_size` is used.

`connect_query`

Query to be executed after a connection is established, but before allowing the connection to be used by any clients. If the query raises errors, they are logged but ignored otherwise.

`pool_mode`

Set the pool mode specific to this database. If not set, the default `pool_mode` is used.

`max_db_connections`

Configure a database-wide maximum (i.e. all pools within the database will not have more than this many server connections).

`client_encoding`

Ask specific `client_encoding` from server.

`datestyle`

Ask specific `datestyle` from server.

`timezone`

Ask specific `timezone` from server.

Section [users]

This section contains `key=value` lines like

```
user1 = settings
```

where the key will be taken as a user name and the value as a list of configuration settings specific for this user.

Example:

```
user1 = pool_mode=session
```

Only a few settings are available here.

`pool_mode`

Set the pool mode to be used for all connections from this user. If not set, the database or default `pool_mode` is used.

`max_user_connections`

Configure a maximum for the user (i.e. all pools with the user will not have more than this many server connections).

Section [peers]

This section defines the peers that `pgbouncer` can forward cancellation requests to and where those cancellation requests will be routed.

`pgbouncer` processes can be peered together in a group by defining a `peer_id` value and a `[peers]` section in the configs of all the `pgbouncer` processes. These `pgbouncer` processes can then forward cancellation requests to the process that it originated from. This is needed to make cancellations work when multiple `pgbouncer` processes (possibly on different servers) are behind the same TCP load balancer. Cancellation requests are sent over different TCP connections than the query they are cancelling, so a TCP load balancer might send the cancellation request connection to a different process than the one that it was meant for. By peering them these cancellation requests eventually end up at the right process.

The section contains `key=value` lines like

```
peer_id = connection string
```

where the key will be taken as a `peer_id` and the value as a connection string, consisting of `key=value` pairs of connection parameters, described below (similar to `libpq`, but the actual `libpq` is not used and the set of available features is different).

Example:

```
1 = host=host1.example.com
```

```
2 = host=/tmp/pgbouncer-2 port=5555
```

Note

For peering to work, the `peer_id` of each `pgbouncer` process in the group must be unique within the peered group. And the `[peers]` section should contain entries for each of those peer IDs. An

example can be found in the [Examples](#) section. It is allowed, but not necessary, for the `[peers]` section to contain the `peer_id` of the `pgbouncer` that the config is for. Such an entry will be ignored, but it is allowed to make config management easier. Because it allows using the exact same `[peers]` section for multiple configs.

host

Host name or IP address to connect to. Host names are resolved at connection time, the result is cached per `dns_max_ttl` parameter. If DNS returns several results, they are used in a round-robin manner. But in general it's not recommended to use a hostname that resolves to multiple IPs, because then the cancel request might still be forwarded to the wrong node and it would need to be forwarded again (which is only allowed up to three times).

If the value begins with `/`, then a Unix socket in the file-system namespace is used. If the value begins with `@`, then a Unix socket in the abstract namespace is used.

Examples:

```
host=localhost
host=127.0.0.1
host=2001:0db8:85a3:0000:0000:8a2e:0370:7334
host=/var/run/pgbouncer-1
```

port

Default: 6432

pool_size

If not set, the `default_pool_size` is used.

Include Directive

The `pgbouncer` configuration file can contain include directives, which specify another configuration file to read and process. This allows splitting the configuration file into physically separate parts. The include directives look like this:

```
%include filename
```

If the filename is not an absolute path, it is taken as relative to the current working directory.

Authentication File Format

This section describes the format of the file specified by the `auth_file` setting. It is a text file in the following format:

```
"username1" "password" ...
"username2" "md5abcdef012342345" ...
"username2" "SCRAM-SHA-256$iterations:salt$storedkey:serverkey"
```

There should be at least two fields, surrounded by double quotes. The first field is the user name and the second is either a plain-text, a MD5-hashed password, or a SCRAM secret. `pgbouncer` ignores the rest of the line. Double quotes in a field value can be escaped by writing two double quotes.

Postgres Pro MD5-hashed password format:

```
"md5" + md5(password + username)
```

So user admin with password 1234 will have MD5-hashed password
md545f2603610af569b6155c45067268c6b.

Postgres Pro SCRAM secret format:

```
SCRAM-SHA-256$iterations:salt$storedkey:serverkey
```

The passwords or secrets stored in the authentication file serve two purposes. First, they are used to verify the passwords of incoming client connections, if a password-based authentication method is configured. Second, they are used as the passwords for outgoing connections to the backend server, if the backend server requires password-based authentication (unless the password is specified directly in the database's connection string). The latter works if the password is stored in plain text or MD5-hashed. SCRAM secrets can only be used for logging into a server if the client authentication also uses SCRAM, the pgbouncer database definition does not specify a user name, and the SCRAM secrets are identical in pgbouncer and the Postgres Pro server (same salt and iterations, not merely the same password). This is due to an inherent security property of SCRAM: the stored SCRAM secret cannot by itself be used for deriving login credentials.

The authentication file can be written by hand, but it's also useful to generate it from some other list of users and passwords. See `./etc/mkauth.py` for a sample script to generate the authentication file from the `pg_shadow` system table.

Alternatively, use `auth_query` instead of `auth_file` to avoid having to maintain a separate authentication file.

HBA File Format

The location of the HBA file is specified by the setting `auth_hba_file`. It is only used if `auth_type` is set to `hba`.

The file follows the format of the Postgres Pro `pg_hba.conf` file described in [Section 19.1](#).

- Supported record types: `local`, `host`, `hostssl`, `hostnossl`.
- Database field: Supports `all`, `sameuser`, `@file`, multiple names. Not supported: `replication`, `samerole`, `samegroup`.
- User name field: Supports `all`, `@file`, multiple names. Not supported: `+groupname`.
- Address field: Supports `IPv4`, `IPv6`. Not supported: DNS names, domain prefixes.
- Auth-method field: Only methods supported by pgbouncer's `auth_type` are supported, plus `peer` and `reject`, but except `any` and `pam`, which only work globally. User name map (`map=`) parameter is not supported.

Examples

Small example configuration:

```
[databases]
template1 = host=localhost dbname=template1 auth_user=someuser

[pgbouncer]
pool_mode = session
listen_port = 6432
listen_addr = localhost
auth_type = md5
auth_file = users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
stats_users = stat_collector
```

Database examples:

```
[databases]

; foodb over Unix socket
foodb =

; redirect bardb to bazdb on localhost
bardb = host=localhost dbname=bazdb
```

```
; access to destination database will go with single user
forcedb = host=localhost port=300 user=baz password=foo client_encoding=UNICODE
datestyle=ISO
```

Example of a secure function for auth_query:

```
CREATE OR REPLACE FUNCTION pgbouncer.user_lookup(in i_username text, out uname text,
    out phash text)
RETURNS record AS $$
BEGIN
    SELECT username, passwd FROM pg_catalog.pg_shadow
    WHERE username = i_username INTO uname, phash;
    RETURN;
END; $$ LANGUAGE plpgsql SECURITY DEFINER;
REVOKE ALL ON FUNCTION pgbouncer.user_lookup(text) FROM public, pgbouncer;
GRANT EXECUTE ON FUNCTION pgbouncer.user_lookup(text) TO pgbouncer;
```

Example configs for 2 peered pgbouncer processes to create a multi-core pgbouncer setup using [so_reuseport](#).

The config for the first process:

```
[databases]
postgres = host=localhost dbname=postgres

[peers]
1 = host=/tmp/pgbouncer1
2 = host=/tmp/pgbouncer2

[pgbouncer]
listen_addr=127.0.0.1
auth_file=auth_file.conf
so_reuseport=1
unix_socket_dir=/tmp/pgbouncer1
peer_id=1
```

The config for the second process:

```
[databases]
postgres = host=localhost dbname=postgres

[peers]
1 = host=/tmp/pgbouncer1
2 = host=/tmp/pgbouncer2

[pgbouncer]
listen_addr=127.0.0.1
auth_file=auth_file.conf
so_reuseport=1
; only unix_socket_dir and peer_id are different
unix_socket_dir=/tmp/pgbouncer2
peer_id=2
```

pg_filedump

`pg_filedump` — display formatted contents of a Postgres Pro heap, index, or control file

Synopsis

```
pg_filedump [option...] [file]
```

Description

`pg_filedump` is a utility to format Postgres Pro heap/index/control files into a human-readable form. You can format/dump the files several ways, as listed in the [Options](#) section, as well as dump a straight binary. The type of file (heap/index) can usually be determined automatically by the content of the blocks within the file. However, to format a `pg_control` file you must use the `-c` option. The default is to format the entire file using the block size listed in block 0 and display block relative addresses. These defaults can be modified using run-time options. Some options may seem strange but they are there for a reason. For example, block size. It is there because if the header of block 0 is corrupt, you need a method of forcing a block size.

Installation

`pg_filedump` is provided with Postgres Pro Standard as a separate pre-built package `pg-file-dump-std-18` (for the detailed installation instructions, see [Chapter 16](#)).

Options

Defaults are: relative addressing, range of the entire file, block size as listed on block 0 in the file.

The following options are valid for heap and index files:

`-a`

Display absolute addresses when formatting. Block header information is always block-relative.

`-b`

Display binary block images within a range. The option will turn off all formatting options.

`-d`

Display formatted block content dump. The option will turn off all other formatting options.

`-D attrlist`

Decode tuples using given comma-separated list of types. The list of supported types:

```
bigint
bigserial
bool
char
charN — char(n)
date
float
float4
float8
int
json
macaddr
name
numeric
oid
real
```

```

serial
smallint
smallserial
text
time
timestamp
timetz
uuid
varchar
varcharN — varchar(n)
xid
xml
~ — ignore all attributes left in a tuple

```

- f
Display formatted block content dump along with interpretation.
- h
Display help.
- i
Display interpreted item details.
- k
Verify block checksums.
- o
Do not dump old values.
- R *startblock* [*endblock*]
Display specific block ranges within the file. Blocks are indexed from 0. *startblock*: block to start at. *endblock*: block to end at. A *startblock* without an *endblock* will format a single block.
- s *segsize*
Force segment size to *segsize*.
- t
Dump TOAST files.
- v
Output additional information about TOAST relations.
- n *segnumber*
Force segment number to *segnumber*.
- S *blocksize*
Force block size to *blocksize*.
- x
Force interpreted formatting of block items as index items.
- y
Force interpreted formatting of block items as heap items.

The following options are valid for control files:

`-c`

Interpret the file listed as a control file.

`-f`

Display formatted content dump along with interpretation.

`-S blocksize`

Force block size to *blocksize*.

Additional parameters:

`-m`

Interpret file as `pg_filenode.map` file and print contents. All other options will be ignored.

In most cases, it is recommended to use the `-i` and `-f` options to get the most useful dump output.

Appendix J. External Projects

Postgres Pro is a complex software project, and managing the project is difficult. We have found that many enhancements to Postgres Pro can be more efficiently developed separately from the core project.

J.1. Client Interfaces

There are only two client interfaces included in the base Postgres Pro Standard distribution:

- [libpq](#) is included because it is the primary C language interface, and because many other client interfaces are built on top of it.
- [ECPG](#) is included because it depends on the server-side SQL grammar, and is therefore sensitive to changes in Postgres Pro itself.

All other language interfaces are external projects and are distributed separately. A [list of language interfaces](#) is maintained on the PostgreSQL wiki. Note that some of these packages are not released under the same license as Postgres Pro. For more information on each language interface, including licensing terms, refer to its website and documentation.

https://wiki.postgresql.org/wiki/List_of_drivers

J.2. Administration Tools

There are several administration tools available for Postgres Pro. One of them is [Postgres Pro Enterprise Manager](#), an integrated administration panel for Postgres Pro management. It provides centralized privilege-based access to a unified management and monitoring interface with embedded command line. There are other solutions, e.g. an open-source platform [pgAdmin](#).

J.3. Procedural Languages

Postgres Pro includes several procedural languages with the base distribution: [PL/pgSQL](#), [PL/Tcl](#), [PL/Perl](#), and [PL/Python](#).

In addition, there are a number of procedural languages that are developed and maintained outside the core Postgres Pro distribution. A list of [procedural languages](#) is maintained on the PostgreSQL wiki. Note that some of these projects are not released under the same license as Postgres Pro. For more information on each procedural language, including licensing information, refer to its website and documentation.

https://wiki.postgresql.org/wiki/PL_Matrix

J.4. Extensions

Postgres Pro is designed to be easily extensible. For this reason, extensions loaded into the database can function just like features that are built in. The extensions shipped with Postgres Pro are described in [Appendix F](#). Other extensions are developed independently, like [PostGIS](#). Even Postgres Pro replication solutions can be developed externally. For example, [Slony-I](#) is a popular primary/standby replication solution that is developed independently from the core project.

Appendix K. Configuring Postgres Pro for 1C Solutions

This section describes how to configure Postgres Pro for work with 1C solutions to get the maximum performance and stability.

K.1. Configuring the Locale

Before configuring Postgres Pro for 1C solutions, make sure that the Russian locale is installed on the system and that it is the active locale of the user who creates the database cluster. The following example shows how to set up the `ru_RU.UTF-8` locale for Debian systems:

```
sudo dpkg-reconfigure locales
export LANG="ru_RU.UTF-8"
/opt/pgpro/std-18/bin/pg-setup initdb
```

For more details, see related documentation sections for your operating system and for 1C.

K.2. Basic Server Requirements and Configuration

To provide high performance for 1C solutions, the Postgres Pro server must have at least the following hardware characteristics:

- 8 - 512 GB of RAM
- 4 - 256 CPU cores
- RAID 0-1 or SSD

The exact recommended characteristics depend on your system's specifics and the load on it.

It is recommended to configure the Postgres Pro server as follows:

- Disable the hyper-threading technology.
- Disable energy saving. Otherwise, delays of database responses may increase unpredictably.
- Disable swapping for POSIX/System V shared memory.

K.3. Configuring Server Parameters

This document describes how to specify configuration parameters of the Postgres Pro server for the maximum performance and stability when working with 1C solutions. Edit these parameters in the `postgresql.conf` configuration file. Note that all given parameter values are approximate. They can be considered as a starting point for further fine-tuning.

For fast automatic tuning of Postgres Pro, you can also use the [pgpro_tune](#) utility. It provides the `1c.tune` preset that specifies optimal values for 1C-specific configuration parameters. For detailed information about the usage of this utility, see [its documentation](#).

K.3.1. Connection Parameters

Increase the maximum number of allowed concurrent connections to the database server using the [max_connections](#) configuration parameter. 1C solutions can open a large number of connections even if not all of them are used. Therefore, it is recommended to allow not less than 500 connections. The higher the number of client sessions, the higher the parameter value should be.

```
-- max_connections = 500..10000
```

K.3.2. Memory Consumption Parameters

1. Increase the amount of memory allocated by the database for data caching. To do this, use the [shared_buffers](#) configuration parameter. For good performance, it is recommended to set this parameter to at least 25% of the available system RAM.

```
-- shared_buffers = RAM/4
```

2. Increase the maximum amount of memory used for temporary buffers within each database session to ensure that all temporary tables are handled correctly. To do this, use the [temp_buffers](#) configuration parameter.

The recommended value should be between 32MB and 256MB. The exact value depends on the amount of memory on the server and the number of concurrent connections. The more connections and the smaller the amount of memory, the smaller the parameter value should be.

```
-- temp_buffers = 32..256MB
```

3. Increase the maximum amount of memory to be used by a single query operation before writing to temporary disk files. To do this, use the [work_mem](#) configuration parameter.

When choosing the parameter value, note that a complex query might perform several sort and hash operations at the same time, and each of them can use the specified amount of memory. Also, several running sessions can perform such operations concurrently. Therefore, the total used memory can be many times greater than the specified value. You can fine-tune the parameter value by monitoring the number of temporary files created in the system.

```
-- work_mem = RAM/32..64 or 32MB..256MB
```

4. Increase the maximum amount of memory to be used by maintenance database operations, such as `VACUUM` or `CREATE INDEX`. To do this, use the [maintenance_work_mem](#) configuration parameter.

Note that only one of these operations can be executed at a time by a database session. Therefore, you can set this value significantly larger than `work_mem`. Larger values can improve performance for vacuuming and restoring database dumps.

```
-- maintenance_work_mem = RAM/16..32 or work_mem * 4 or 256MB..4GB
```

5. In the case of significant memory fragmentation, specify the following environment variable in the `/etc/systemd/system/postgresql.service` file:

```
-- Environment = MALLOC_MMAP_THRESHOLD_= 8192
```

K.3.3. Kernel Resource Usage Parameters

Increase the maximum number of simultaneously open files allowed to each server subprocess. To do this, use the [max_files_per_process](#) configuration parameter.

The recommended value is 10000 but it can be increased depending on the load. The maximum allowed value depends on the operating system. If the server reaches the specified limit, it starts to open and close files, which affects the performance. You can monitor open files using the `lsof` command.

```
-- max_files_per_process = 10000
```

K.3.4. Background Writer Parameters

1. Decrease the delay between activity rounds for the background writer using the [bgwriter_delay](#) configuration parameter. Note that a too high parameter value will increase the load on the checkpoint process and the backend processes, while a too low value will result in the full load of one of the cores.

```
-- bgwriter_delay = 20ms
```

2. Increase values for the [bgwriter_lru_multiplier](#) and [bgwriter_lru_maxpages](#) configuration parameters that control the number of dirty buffers written by the background writer in each round.

```
-- bgwriter_lru_multiplier = 4.0
-- bgwriter_lru_maxpages = 400
```

K.3.5. Asynchronous Behavior Parameters

1. Specify the number of concurrent disk I/O operations that any individual Postgres Pro session attempts to initiate in parallel. To do this, use the [effective_io_concurrency](#) configuration parameter. Currently, this parameter affects bitmap heap scans only.

For magnetic drives, a good starting point for this parameter is the number of separate drives comprising a RAID 0 stripe or RAID 1 mirror used for the database. However, too high parameter values will keep the disk array busy, which results in extra CPU overhead.

SSD disks can often process many concurrent requests, so the best value might be in the hundreds.

```
-- effective_io_concurrency = 2
```

2. Set the [max_parallel_workers_per_gather](#) configuration parameter to 0. This disables parallel queries that can be started by `Gather` and `Gather Merge` nodes. Parallel queries may consume very significantly more resources than non-parallel queries.

```
-- max_parallel_workers_per_gather = 0
```

K.3.6. WAL Parameters

1. Leave the [fsync](#) configuration parameter set to `on` (default). In this case, the Postgres Pro server tries to make sure that updates are physically written to disk by issuing the `fsync()` system calls. This ensures that the database cluster can recover to a consistent state after an operating system or hardware crash.

Although disabling the `fsync` parameter often leads to a performance benefit, this can result in unrecoverable data corruption in case of a power failure or system crash.

```
-- fsync = on
```

Important note: if your RAID has a cache and works in the write-back mode, make sure that the disk controller cache has a valid battery. Otherwise, data written to the cache will be lost in the case of a power failure, and the Postgres Pro server will be unable to recover the data.

2. Set the [synchronous_commit](#) configuration parameter to `off`. This means that the Postgres Pro server does not wait for writing WAL records to disk but returns a success indication to the client.

Unlike [fsync](#), setting this parameter to `off` does not create any risk of database inconsistency. An operating system or database crash might only result in some recent transactions being lost. Thus, disabling the `synchronous_commit` parameter is useful when high performance is very important.

```
-- synchronous_commit = off
```

3. Increase values for the [checkpoint_timeout](#), [min_wal_size](#), and [max_wal_size](#) configuration parameters to reduce the frequency of checkpoints. Too frequent checkpoints lead to the significant load on the disk system.

```
-- checkpoint_timeout = 15min
-- min_wal_size = 512MB..4G
-- max_wal_size = 2 * min_wal_size
```

4. Specify the [commit_delay](#) configuration parameter if the average number of transactions per second (TPS) exceeds 1000. This parameter adds a time delay before a WAL flush is initiated and can improve the group commit throughput.

```
-- commit_delay = 1000
```

K.3.7. Query Planning Parameters

1. Specify the [effective_cache_size](#) configuration parameter to define the planner's assumption about the effective size of the disk cache that is available to a single query.

The query optimizer's performance depends on the amount of allocated RAM. A higher value makes it more likely index scans will be used, while a lower value results in using sequential scans.

```
-- effective_cache_size = RAM - shared_buffers
```

2. Specify the [random_page_cost](#) configuration parameter to define the planner's estimate of the cost of a non-sequentially-fetched disk page.

The parameter value is specified relative to the [seq_page_cost](#) parameter, which is set to 1.0 by default. Reducing the [random_page_cost](#) value will cause the system to prefer index scans to sequential scans. The recommended value depends on the seek time of the disk system. The smaller the seek time, the smaller the parameter value should be (but not less than 1.0).

```
-- random_page_cost = 1.5-2.0 (for RAID) or 1.1-1.3 (for SSD)
```

3. Increase the value for the [from_collapse_limit](#) configuration parameter. The planner will merge sub-queries into upper queries if the resulting FROM list would have no more than this many items. Note that smaller parameter values reduce planning time but can lead to less efficient query plans.

```
-- from_collapse_limit = 20
```

4. Increase the value of the [join_collapse_limit](#) configuration parameter. The planner will rewrite explicit JOIN constructs (except FULL JOINS) into lists of FROM items whenever a list contains no more than this many items. Note that smaller parameter values reduce planning time but can lead to less efficient query plans.

```
-- join_collapse_limit = 20
```

5. Leave the [geqo](#) configuration parameter set to on (default). This enables the genetic query optimizer (GEQO) that does query planning using the heuristic search. GEQO reduces planning time for complex queries joining many relations but sometimes may produce plans that are less efficient than plans chosen by the regular exhaustive-search algorithm.

To manage the use of GEQO, specify the [geqo_threshold](#) configuration parameter. GEQO will be used to plan queries that involve at least the specified number of FROM items.

```
-- geqo = on  
-- geqo_threshold = 12
```

6. Set the [jit](#) configuration parameter to off to disable Just-in-Time (JIT) compilation. This compilation is beneficial primarily for long-running CPU-bound queries, such as analytical queries. For short queries, the added overhead will be higher than the time that JIT compilation can save.

```
-- jit = off
```

K.3.8. Automatic Vacuuming Parameters

1. Leave the [autovacuum](#) configuration parameter set to on (default) to run the autovacuum launcher daemon. Note that disabling the autovacuum launcher daemon will lead to increasing the database size and significant performance degradation.

```
-- autovacuum = on
```

2. Increase the maximum number of autovacuum processes that may be running at the same time using the [autovacuum_max_workers](#) configuration parameter. The more write requests are executed in the system, the more autovacuum processes are required.

```
-- autovacuum_max_workers = CPU cores/4..2 (but no less than 4)
```

3. Decrease the minimum delay between autovacuum rounds using the `autovacuum_naptime` configuration parameter. If a parameter value is too high, there can be not enough time to clean the required tables. This will lead to increasing the database size and significant performance degradation. However, a too low parameter value leads to the useless load.

```
-- autovacuum_naptime = 20s
```

K.3.9. Client Connection Parameters

1. Specify the directory in which to create temporary tables and indexes on temporary tables using the `temp_tablespaces` configuration parameter. Typically, 1C solutions use a lot of temporary tables. To increase the performance when working with these tables, locate this directory on separate fast disks.

Before this, you should first create the tablespace using the `CREATE TABLESPACE` command. If characteristics of the target disks differ from the main disks, specify the corresponding value for the `random_page_cost` parameter in this command.

```
-- temp_tablespaces = 'tablespace_name'
```

2. Set the `row_security` configuration parameter to `off` to raise an error if a query's results are filtered by a `row-level security` policy.

```
-- row_security = off
```

K.3.10. Lock Management Parameters

Increase the value for the `max_locks_per_transaction` configuration parameter up to 256. It specifies how many objects per server process or prepared transaction can be locked at the same time.

Typically, 1C solutions use a lot of temporary tables. Every backend process usually contains multiple temporary tables. When closing a connection, Postgres Pro tries to drop all temporary tables in a single transaction, so this transaction may use a lot of locks. If the number of locks exceeds the `max_locks_per_transaction` value, the transaction will fail leaving multiple orphaned temporary tables.

```
-- max_locks_per_transaction = 256
```

K.3.11. Parameters for 1C Compatibility

1. Set the `standard_conforming_strings` configuration parameter to `off` to enable backslash escapes (`\`) in all strings.

```
-- standard_conforming_strings = off
```

2. Set the `escape_string_warning` configuration parameter to `off` to switch off the warning about using the backslash escape symbol.

```
-- escape_string_warning = off
```

K.3.12. Path to `pg_stat_tmp` Subdirectory

Change the default path to the `PGDATA/pg_stat_tmp` subdirectory to locate it separately from the cluster directory. This subdirectory contains temporary files for the statistics subsystem. These files are changed intensively, which creates the significant load on the disk system. It is recommended to locate this subdirectory in `tmpfs` (temporary file storage).

K.4. Additional Modules

K.4.1. Built-In Default Modules

To provide support for 1C solutions, the Postgres Pro distribution includes the following built-in modules that are enabled by default and do not require additional configuration:

- [fasttrun](#) — provides a transaction-unsafe function to truncate temporary tables without growing the size of `pg_class`.
- [fulleq](#) — provides an additional equivalence operator for compatibility with Microsoft SQL Server.
- [mchar](#) — provides additional `MCHAR` and `MVARCHAR` data types for compatibility with Microsoft SQL Server.

K.4.2. dbcopies_decoding

[dbcopies_decoding](#) is a 1C module for updating database copies, which is enabled by default. To use the logical replication mechanism of this module, set the `wal_level` parameter to `logical`.

For more information about this module, contact 1C support.

K.4.3. plantuner

The [plantuner](#) module allows optimizing query execution plans. To configure it for 1C solutions, do the following:

1. Add the library name to the `shared_preload_libraries` variable in the `postgresql.conf` file.
- ```
shared_preload_libraries = 'plantuner'
```
2. Set the `plantuner.fix_empty_table` parameter to `on` to improve planning for recently created empty tables.

```
plantuner.fix_empty_table = on
```

### K.4.4. online\_analyze

The [online\\_analyze](#) module provides a set of features that immediately update statistics after `INSERT`, `UPDATE`, `DELETE`, `SELECT INTO`, or `COPY` operations for the affected tables.

#### Note

It is not recommended to use this module with modern versions of 1C.

However, you can enable `online_analyze` if background updates do not provide the desired result or if the optimizer frequently fails to estimate the row count.

The instruction below is relevant only if you decide to use the module.

To configure this module, follow the steps below.

1. Add the library name to the `shared_preload_libraries` variable in the `postgresql.conf` file.

```
shared_preload_libraries = 'online_analyze'
```

2. Enable this module.

```
online_analyze.enable = on
```

3. Specify the minimum number of row updates before starting online analysis.

```
online_analyze.threshold = 50
```

4. Specify the fraction of the table size to start online analysis.

```
online_analyze.scale_factor = 0.1
```

5. Execute the `ANALYZE` command without `VERBOSE`.

```
online_analyze.verbose = off
```

6. Enable online analysis for temporary tables.

```
online_analyze.table_type = 'temporary'
```

7. Specify the minimum time interval between `ANALYZE` calls per table, in milliseconds.

```
online_analyze.min_interval = 10000
```

---

# Appendix L. Postgres Pro Limits

[Table L.1](#) describes various hard limits of Postgres Pro. However, practical limits, such as performance limitations or available disk space may apply before absolute hard limits are reached.

**Table L.1. Postgres Pro Limitations**

| Item                    | Upper Limit                                                           | Comment                                                                |
|-------------------------|-----------------------------------------------------------------------|------------------------------------------------------------------------|
| database size           | unlimited                                                             |                                                                        |
| number of databases     | 4,294,950,911                                                         |                                                                        |
| relations per database  | 1,431,650,303                                                         |                                                                        |
| relation size           | 32 TB                                                                 | with the default <code>BLCKSZ</code> of 8192 bytes                     |
| rows per table          | limited by the number of tuples that can fit onto 4,294,967,295 pages |                                                                        |
| columns per table       | 1,600                                                                 | further limited by tuple size fitting on a single page; see note below |
| columns in a result set | 1,664                                                                 |                                                                        |
| field size              | 1 GB                                                                  |                                                                        |
| indexes per table       | unlimited                                                             | constrained by maximum relations per database                          |
| columns per index       | 32                                                                    | can be increased by recompiling Postgres Pro                           |
| partition keys          | 32                                                                    | can be increased by recompiling Postgres Pro                           |
| identifier length       | 63 bytes                                                              | can be increased by recompiling Postgres Pro                           |
| function arguments      | 100                                                                   | can be increased by recompiling Postgres Pro                           |
| query parameters        | 65,535                                                                |                                                                        |

The maximum number of columns for a table is further reduced as the tuple being stored must fit in a single 8192-byte heap page. For example, excluding the tuple header, a tuple made up of 1,600 `int` columns would consume 6400 bytes and could be stored in a heap page, but a tuple of 1,600 `bigint` columns would consume 12800 bytes and would therefore not fit inside a heap page. Variable-length fields of types such as `text`, `varchar`, and `char` can have their values stored out of line in the table's TOAST table when the values are large enough to require it. Only an 18-byte pointer must remain inside the tuple in the table's heap. For shorter length variable-length fields, either a 4-byte or 1-byte field header is used and the value is stored inside the heap tuple.

Columns that have been dropped from the table also contribute to the maximum column limit. Moreover, although the dropped column values for newly created tuples are internally marked as null in the tuple's null bitmap, the null bitmap also occupies space.

Each table can store a theoretical maximum of  $2^{32}$  out-of-line values; see [Section 64.2](#) for a detailed discussion of out-of-line storage. This limit arises from the use of a 32-bit OID to identify each such value. The practical limit is significantly less than the theoretical limit, because as the OID space fills up, finding an OID that is still free can become expensive, in turn slowing down INSERT/UPDATE statements. Typically, this is only an issue for tables containing many terabytes of data; partitioning is a possible workaround.

---

# Appendix M. Demo Database

## “Airlines”

This is an overview of a demo database for Postgres Pro. This appendix describes the database schema, which consists of eight tables and several views. The subject field of this database is airline flights in Russia. You can download the database from [our website](#). See [Section M.1](#) for details.

**Figure M.1. Airlines in Russia**

You can use this database for various purposes, such as:

- learning SQL language on your own
- preparing books, manuals, and courses on SQL
- showing Postgres Pro features in stories and articles

When developing this demo database, we pursued several goals:

- Database schema must be simple enough to be understood without extra explanations.
- At the same time, database schema must be complex enough to allow writing meaningful queries.
- The database must contain true-to-life data that will be interesting to work with.

This demo database is distributed under the [PostgreSQL license](#).

You can send us your feedback to [edu@postgrespro.ru](mailto:edu@postgrespro.ru).

## M.1. Installation

The demo database is available at [edu.postgrespro.com](http://edu.postgrespro.com) in three flavors, which differ only in the data size:

- [demo-small-en.zip](#) (21 MB) — flight data for one month (DB size is about 300 MB)

- [demo-medium-en.zip](#) (62 MB) — flight data for three months (DB size is about 700 MB)
- [demo-big-en.zip](#) (232 MB) — flight data for one year (DB size is about 2.5 GB)

The small database is good for writing queries, and it will not take up much disk space. The large database can help you understand the query behavior on large data volumes and consider query optimization.

The files include an SQL script that creates the `demo` database and fills it with data (virtually, it is a backup copy created with the `pg_dump` utility). The owner of the `demo` database will be the DBMS user who runs the script. For example, to create the small database, run the script as the user `postgres` by means of `psql`:

```
psql -f demo_small_YYYYMMDD.sql -U postgres
```

Note that if the `demo` database already exists, it will be deleted and recreated!

## M.2. Schema Diagram

Figure M.2. Bookings Schema Diagram

## M.3. Schema Description

The main entity is a booking (`bookings`).

One booking can include several passengers, with a separate ticket (`tickets`) issued to each passenger. A ticket has a unique number and includes information about the passenger. As such, the passenger is not a separate entity. Both the passenger's name and identity document number can change over time, so it is impossible to uniquely identify all the tickets of a particular person; for simplicity, we can assume that all passengers are unique.

The ticket includes one or more flight segments (`ticket_flights`). Several flight segments can be included into a single ticket if there are no non-stop flights between the points of departure and destination (connecting flights), or if it is a round-trip ticket. Although there is no constraint in the schema, it is assumed that all tickets in the booking have the same flight segments.

Each flight (`flights`) goes from one airport (`airports`) to another. Flights with the same flight number have the same points of departure and destination, but differ in departure date.

At flight check-in, the passenger is issued a boarding pass (`boarding_passes`), where the seat number is specified. The passenger can check in for the flight only if this flight is included into the ticket. The flight-seat combination must be unique to avoid issuing two boarding passes for the same seat.

The number of seats (`seats`) in the aircraft and their distribution between different travel classes depends on the model of the aircraft (`aircrafts`) performing the flight. It is assumed that every aircraft model has only one cabin configuration. Database schema does not check that seat numbers in boarding passes have the corresponding seats in the aircraft (such verification can be done using table triggers, or at the application level).

## M.4. Schema Objects

### M.4.1. List of Relations

| Name                         | Type  | Small | Medium | Big    | Description             |
|------------------------------|-------|-------|--------|--------|-------------------------|
| <code>aircrafts</code>       | view  |       |        |        | Aircraft                |
| <code>aircrafts_data</code>  | table | 16 kB | 16 kB  | 16 kB  | Aircraft (translations) |
| <code>airports</code>        | view  |       |        |        | Airports                |
| <code>airports_data</code>   | table | 56 kB | 56 kB  | 56 kB  | Airports (translations) |
| <code>boarding_passes</code> | table | 31 MB | 102 MB | 427 MB | Boarding passes         |
| <code>bookings</code>        | table | 13 MB | 30 MB  | 105 MB | Bookings                |
| <code>flights</code>         | table | 3 MB  | 6 MB   | 19 MB  | Flights                 |
| <code>flights_v</code>       | view  |       |        |        | Flights                 |
| <code>routes</code>          | view  |       |        |        | Routes                  |
| <code>seats</code>           | table | 88 kB | 88 kB  | 88 kB  | Seats                   |
| <code>ticket_flights</code>  | table | 64 MB | 145 MB | 516 MB | Flight segments         |
| <code>tickets</code>         | table | 47 MB | 107 MB | 381 MB | Tickets                 |

### M.4.2. View `bookings.aircrafts`

Each aircraft model is identified by its three-digit code (`aircraft_code`). The view also includes the name of the aircraft model (`model`) and the maximal flying distance, in kilometers (`range`).

The value of the `model` field is selected according to the chosen language. See [Section M.4.15](#) for details.

| Column                     | Type                 | Modifiers             | Description                 |
|----------------------------|----------------------|-----------------------|-----------------------------|
| <code>aircraft_code</code> | <code>char(3)</code> | <code>not null</code> | Aircraft code, IATA         |
| <code>model</code>         | <code>text</code>    | <code>not null</code> | Aircraft model              |
| <code>range</code>         | <code>integer</code> | <code>not null</code> | Maximal flying distance, km |

View definition:

```
SELECT ml.aircraft_code,
 ml.model ->> lang() AS model,
 ml.range
FROM aircrafts_data ml;
```

### M.4.3. Table `bookings.aircrafts_data`

This is the base table for the `aircrafts` view. The `model` field of this table contains translations of aircraft models to different languages, in the JSONB format. In most cases, this table is not supposed to be used directly.

| Column | Type | Modifiers | Description |
|--------|------|-----------|-------------|
|--------|------|-----------|-------------|

```

-----+-----+-----+-----
aircraft_code | char(3) | not null | Aircraft code, IATA
model | jsonb | not null | Aircraft model
range | integer | not null | Maximal flying distance, km
Indexes:
 PRIMARY KEY, btree (aircraft_code)
Check constraints:
 CHECK (range > 0)
Referenced by:
 TABLE "flights" FOREIGN KEY (aircraft_code)
 REFERENCES aircrafts_data(aircraft_code)
 TABLE "seats" FOREIGN KEY (aircraft_code)
 REFERENCES aircrafts_data(aircraft_code) ON DELETE CASCADE

```

#### M.4.4. View bookings.airports

An airport is identified by a three-letter code (`airport_code`) and has a name (`airport_name`).

There is no separate entity for the city, but there is a city name (`city`) to identify the airports of the same city. The view also includes coordinates (`coordinates`) and the time zone (`timezone`).

The values of the `airport_name` and `city` fields are selected according to the chosen language. See [Section M.4.15](#) for details.

| Column                    | Type                 | Modifiers             | Description                                  |
|---------------------------|----------------------|-----------------------|----------------------------------------------|
| <code>airport_code</code> | <code>char(3)</code> | <code>not null</code> | Airport code                                 |
| <code>airport_name</code> | <code>text</code>    | <code>not null</code> | Airport name                                 |
| <code>city</code>         | <code>text</code>    | <code>not null</code> | City                                         |
| <code>coordinates</code>  | <code>point</code>   | <code>not null</code> | Airport coordinates (longitude and latitude) |
| <code>timezone</code>     | <code>text</code>    | <code>not null</code> | Airport time zone                            |

```

View definition:
SELECT ml.airport_code,
 ml.airport_name ->> lang() AS airport_name,
 ml.city ->> lang() AS city,
 ml.coordinates,
 ml.timezone
FROM airports_data ml;

```

#### M.4.5. Table bookings.airports\_data

This is the base table for the `airports` view. This table contains translations of `airport_name` and `city` values to different languages, in the JSONB format. In most cases, this table is not supposed to be used directly.

| Column                    | Type                 | Modifiers             | Description                                  |
|---------------------------|----------------------|-----------------------|----------------------------------------------|
| <code>airport_code</code> | <code>char(3)</code> | <code>not null</code> | Airport code                                 |
| <code>airport_name</code> | <code>jsonb</code>   | <code>not null</code> | Airport name                                 |
| <code>city</code>         | <code>jsonb</code>   | <code>not null</code> | City                                         |
| <code>coordinates</code>  | <code>point</code>   | <code>not null</code> | Airport coordinates (longitude and latitude) |
| <code>timezone</code>     | <code>text</code>    | <code>not null</code> | Airport time zone                            |

```

Indexes:
 PRIMARY KEY, btree (airport_code)
Referenced by:
 TABLE "flights" FOREIGN KEY (arrival_airport)
 REFERENCES airports_data(airport_code)

```

```
TABLE "flights" FOREIGN KEY (departure_airport)
REFERENCES airports_data(airport_code)
```

### M.4.6. Table bookings.boarding\_passes

At the time of check-in, which opens twenty-four hours before the scheduled departure, the passenger is issued a boarding pass. Like the flight segment, the boarding pass is identified by the ticket number and the flight number.

Boarding passes are assigned sequential numbers (`boarding_no`), in the order of check-ins for the flight (this number is unique only within the context of a particular flight). The boarding pass specifies the seat number (`seat_no`).

| Column                   | Type                    | Modifiers             | Description          |
|--------------------------|-------------------------|-----------------------|----------------------|
| <code>ticket_no</code>   | <code>char(13)</code>   | <code>not null</code> | Ticket number        |
| <code>flight_id</code>   | <code>integer</code>    | <code>not null</code> | Flight ID            |
| <code>boarding_no</code> | <code>integer</code>    | <code>not null</code> | Boarding pass number |
| <code>seat_no</code>     | <code>varchar(4)</code> | <code>not null</code> | Seat number          |

Indexes:

```
PRIMARY KEY, btree (ticket_no, flight_id)
UNIQUE CONSTRAINT, btree (flight_id, boarding_no)
UNIQUE CONSTRAINT, btree (flight_id, seat_no)
```

Foreign-key constraints:

```
FOREIGN KEY (ticket_no, flight_id)
REFERENCES ticket_flights(ticket_no, flight_id)
```

### M.4.7. Table bookings.bookings

Passengers book tickets for themselves, and, possibly, for several other passengers, in advance (`book_date`, not earlier than one month before the flight). The booking is identified by its number (`book_ref`, a six-position combination of letters and digits).

The `total_amount` field stores the total cost of all tickets included into the booking, for all passengers.

| Column                    | Type                       | Modifiers             | Description        |
|---------------------------|----------------------------|-----------------------|--------------------|
| <code>book_ref</code>     | <code>char(6)</code>       | <code>not null</code> | Booking number     |
| <code>book_date</code>    | <code>timestampz</code>    | <code>not null</code> | Booking date       |
| <code>total_amount</code> | <code>numeric(10,2)</code> | <code>not null</code> | Total booking cost |

Indexes:

```
PRIMARY KEY, btree (book_ref)
```

Referenced by:

```
TABLE "tickets" FOREIGN KEY (book_ref) REFERENCES bookings(book_ref)
```

### M.4.8. Table bookings.flights

The natural key of the `bookings.flights` table consists of two fields — `flight_no` and `scheduled_departure`. To make foreign keys for this table more compact, a surrogate key is used as the primary key (`flight_id`).

A flight always connects two points — the airport of departure (`departure_airport`) and arrival (`arrival_airport`). There is no such entity as a “connecting flight”: if there are no non-stop flights from one airport to another, the ticket simply includes several required flight segments.

Each flight has a scheduled date and time of departure (`scheduled_departure`) and arrival (`scheduled_arrival`). The actual departure time (`actual_departure`) and arrival time (`actual_arrival`) can

differ: the difference is usually not very big, but sometimes can be up to several hours if the flight is delayed.

**Flight status** (*status*) can take one of the following values:

Scheduled

The flight is available for booking. It happens one month before the planned departure date; before that time, there is no entry for this flight in the database.

On Time

The flight is open for check-in (in twenty-four hours before the scheduled departure) and is not delayed.

Delayed

The flight is open for check-in (in twenty-four hours before the scheduled departure) but is delayed.

Departed

The aircraft has already departed and is airborne.

Arrived

The aircraft has reached the point of destination.

Cancelled

The flight is canceled.

| Column              | Type        | Modifiers | Description              |
|---------------------|-------------|-----------|--------------------------|
| flight_id           | serial      | not null  | Flight ID                |
| flight_no           | char(6)     | not null  | Flight number            |
| scheduled_departure | timestampz  | not null  | Scheduled departure time |
| scheduled_arrival   | timestampz  | not null  | Scheduled arrival time   |

### M.4.9. Table bookings.seats

Seats define the cabin configuration of each aircraft model. Each seat is defined by its number (`seat_no`) and has an assigned travel class (`fare_conditions`): Economy, Comfort or Business.

| Column          | Type        | Modifiers | Description         |
|-----------------|-------------|-----------|---------------------|
| aircraft_code   | char(3)     | not null  | Aircraft code, IATA |
| seat_no         | varchar(4)  | not null  | Seat number         |
| fare_conditions | varchar(10) | not null  | Travel class        |

```

### M.4.10. Table bookings.ticket\_flights

A flight segment connects a ticket with a flight and is identified by their numbers.

Each flight has its cost (`amount`) and travel class (`fare_conditions`).

| Column          | Type          | Modifiers | Description   |
|-----------------|---------------|-----------|---------------|
| ticket_no       | char(13)      | not null  | Ticket number |
| flight_id       | integer       | not null  | Flight ID     |
| fare_conditions | varchar(10)   | not null  | Travel class  |
| amount          | numeric(10,2) | not null  | Travel cost   |

Indexes:

```
PRIMARY KEY, btree (ticket_no, flight_id)
```

Check constraints:

```
CHECK (amount >= 0)
```

```
CHECK (fare_conditions IN ('Economy', 'Comfort', 'Business'))
```

Foreign-key constraints:

```

```

Referenced by:

```
TABLE "boarding_passes" FOREIGN KEY (ticket_no, flight_id)
```

```
REFERENCES ticket_flights(ticket_no, flight_id)
```

### M.4.11. Table bookings.tickets

A ticket has a unique number (`ticket_no`) that consists of 13 digits.

The ticket includes a passenger ID (`passenger_id`) — the identity document number, — their first and last names (`passenger_name`), and contact information (`contact_data`).

Neither the passenger ID, nor the name is permanent (for example, one can change the last name or passport), so it is impossible to uniquely identify all tickets of a particular passenger.

| Column    | Type     | Modifiers | Description   |
|-----------|----------|-----------|---------------|
| ticket_no | char(13) | not null  | Ticket number |

|                |             |          |                               |
|----------------|-------------|----------|-------------------------------|
| book_ref       | char(6)     | not null | Booking number                |
| passenger_id   | varchar(20) | not null | Passenger ID                  |
| passenger_name | text        | not null | Passenger name                |
| contact_data   | jsonb       |          | Passenger contact information |

Indexes:

PRIMARY KEY, btree (ticket\_no)

Foreign-key constraints:

FOREIGN KEY (book\_ref) REFERENCES bookings(book\_ref)

Referenced by:

TABLE "ticket\_flights" FOREIGN KEY (ticket\_no) REFERENCES tickets(ticket\_no)

## M.4.12. View bookings.flights\_v

There is a `flights_v` view over the `flights` table that provides additional information:

- Details about the airport of departure — `departure_airport`, `departure_airport_name`, `departure_city`
- Details about the airport of arrival — `arrival_airport`, `arrival_airport_name`, `arrival_city`
- Local departure time — `scheduled_departure_local`, `actual_departure_local`
- Local arrival time — `scheduled_arrival_local`, `actual_arrival_local`
- Flight duration — `scheduled_duration`, `actual_duration`.

| Column                    | Type        | Description                                                       |
|---------------------------|-------------|-------------------------------------------------------------------|
| flight_id                 | integer     | Flight ID                                                         |
| flight_no                 | char(6)     | Flight number                                                     |
| scheduled_departure       | timestamp   | Scheduled departure time                                          |
| scheduled_departure_local | timestamp   | Scheduled departure time,<br>local time at the point of departure |
| scheduled_arrival         | timestamp   | Scheduled arrival time                                            |

| scheduled_duration        | interval    | Scheduled flight duration                                         |
| departure_airport         | char(3)     | Departure airport code                                            |
| departure_airport_name    | text        | Departure airport name                                            |
| departure_city            | text        | City of departure                                                 |
| arrival_airport           | char(3)     | Arrival airport code                                              |
| arrival_airport_name      | text        | Arrival airport name                                              |
| arrival_city              | text        | City of arrival                                                   |
| status                    | varchar(20) | Flight status                                                     |
| aircraft_code             | char(3)     | Aircraft code, IATA                                               |
| actual_departure          | timestamp   | Actual departure time                                             |
| actual_departure_local    | timestamp   | Actual departure time,<br>local time at the point of departure    |
| actual_arrival            | timestamp   | Actual arrival time                                               |
| actual_arrival_local      | timestamp   | Actual arrival time,<br>local time at the point of destination    |
| actual_duration           | interval    | Actual flight duration                                            |

## M.4.13. View bookings.routes

The `bookings.flights` table contains some redundancies, which you can use to single out route information (flight number, airports of departure and destination) that does not depend on the exact flight dates.

Such information is shown in the `routes` view.

| Column                              | Type                   | Description                                     |
|-------------------------------------|------------------------|-------------------------------------------------|
| <code>flight_no</code>              | <code>char(6)</code>   | Flight number                                   |
| <code>departure_airport</code>      | <code>char(3)</code>   | Departure airport code                          |
| <code>departure_airport_name</code> | <code>text</code>      | Departure airport name                          |
| <code>departure_city</code>         | <code>text</code>      | City of departure                               |
| <code>arrival_airport</code>        | <code>char(3)</code>   | Arrival airport code                            |
| <code>arrival_airport_name</code>   | <code>text</code>      | Arrival airport name                            |
| <code>arrival_city</code>           | <code>text</code>      | City of arrival                                 |
| <code>aircraft_code</code>          | <code>char(3)</code>   | Aircraft code, IATA                             |
| <code>duration</code>               | <code>interval</code>  | Flight duration                                 |
| <code>days_of_week</code>           | <code>integer[]</code> | Days of the week on which flights are performed |

#### M.4.14. Function `bookings.now`

The demo database contains “snapshots” of data — similar to a backup copy of a real system captured at some point in time. For example, if a flight has the `Departed` status, it means that the aircraft had already departed and was airborne at the time of the backup copy.

The “snapshot” time is saved in the `bookings.now()` function. You can use this function in demo queries for cases where you would use the `now()` function in a real database.

In addition, the return value of this function determines the version of the demo database. The latest version available is of August 15, 2017.

#### M.4.15. Function `bookings.lang`

Some fields in the demo database are available in English and Russian. Translations to other languages are not provided, but are easy to add. The `bookings.lang` returns the value of the `bookings.lang` parameter, that is, the language in which these fields will be displayed.

This function is used in the `aircrafts` and `airports` views and is not intended to be used directly in queries.

### M.5. Usage

#### M.5.1. Schema `bookings`

The `bookings` schema contains all objects of the demo database. When you connect to the database, `search_path` configuration parameter is automatically set to `bookings, public`, so you do not need to specify the schema name explicitly.

However, for the `bookings.now` function, you always have to specify the schema to distinguish this function from the standard `now` function.

#### M.5.2. Translations

By default, values of several translatable fields are shown in Russian. These are `airport_name` and `city` of the `airports` view, as well as `model` of the `aircrafts` view.

You can choose to display these fields in another language (although only the English translation is provided in the demo database). To switch to English, set the `bookings.lang` parameter to `en`. It may be convenient to choose the language at the database level:

```
ALTER DATABASE demo SET bookings.lang = en;
```

You have to reconnect to the database for this command to take effect. For other methods of settings configuration parameters, see [Section 18.1](#).

In the examples below, the English language is selected for translatable fields.

### M.5.3. Sample Queries

To better understand the contents of the demo database, let's take a look at the results of several simple queries.

The results displayed below were received on a small database version (demo-small) of August 15, 2017. If the same queries return different data on your system, check your demo database version (using the `bookings.now` function). Some minor deviations may be caused by the difference between your local time and Moscow time, or your locale settings.

All flights are operated by several types of aircraft:

```
SELECT * FROM aircrafts;
```

| aircraft_code | model               | range |
|---------------|---------------------|-------|
| 773           | Boeing 777-300      | 11100 |
| 763           | Boeing 767-300      | 7900  |
| SU9           | Sukhoi SuperJet-100 | 3000  |
| 320           | Airbus A320-200     | 5700  |
| 321           | Airbus A321-200     | 5600  |
| 319           | Airbus A319-100     | 6700  |
| 733           | Boeing 737-300      | 4200  |
| CN1           | Cessna 208 Caravan  | 1200  |
| CR2           | Bombardier CRJ-200  | 2700  |

(9 rows)

For each aircraft type, a separate list of seats is supported. For example, in a small Cessna 208 Caravan, one can select the following seats:

```
SELECT a.aircraft_code,
 a.model,
 s.seat_no,
 s.fare_conditions
FROM aircrafts a
 JOIN seats s ON a.aircraft_code = s.aircraft_code
WHERE a.model = 'Cessna 208 Caravan'
ORDER BY s.seat_no;
```

| aircraft_code | model              | seat_no | fare_conditions |
|---------------|--------------------|---------|-----------------|
| CN1           | Cessna 208 Caravan | 1A      | Economy         |
| CN1           | Cessna 208 Caravan | 1B      | Economy         |
| CN1           | Cessna 208 Caravan | 2A      | Economy         |
| CN1           | Cessna 208 Caravan | 2B      | Economy         |
| CN1           | Cessna 208 Caravan | 3A      | Economy         |
| CN1           | Cessna 208 Caravan | 3B      | Economy         |
| CN1           | Cessna 208 Caravan | 4A      | Economy         |
| CN1           | Cessna 208 Caravan | 4B      | Economy         |
| CN1           | Cessna 208 Caravan | 5A      | Economy         |
| CN1           | Cessna 208 Caravan | 5B      | Economy         |
| CN1           | Cessna 208 Caravan | 6A      | Economy         |
| CN1           | Cessna 208 Caravan | 6B      | Economy         |

(12 rows)

**Bigger aircraft have more seats of various travel classes:**

```
SELECT s2.aircraft_code,
 string_agg (s2.fare_conditions || '(' || s2.num::text || ')',
 ', ') as fare_conditions
FROM (
 SELECT s.aircraft_code, s.fare_conditions, count(*) as num
 FROM seats s
 GROUP BY s.aircraft_code, s.fare_conditions
 ORDER BY s.aircraft_code, s.fare_conditions
) s2
GROUP BY s2.aircraft_code
ORDER BY s2.aircraft_code;
```

| aircraft_code | fare_conditions                         |
|---------------|-----------------------------------------|
| 319           | Business(20), Economy(96)               |
| 320           | Business(20), Economy(120)              |
| 321           | Business(28), Economy(142)              |
| 733           | Business(12), Economy(118)              |
| 763           | Business(30), Economy(192)              |
| 773           | Business(30), Comfort(48), Economy(324) |
| CN1           | Economy(12)                             |
| CR2           | Economy(50)                             |
| SU9           | Business(12), Economy(85)               |

(9 rows)

**The demo database contains the list of airports of almost all major Russian cities. Most cities have only one airport. The exceptions are:**

```
SELECT a.airport_code as code,
 a.airport_name,
 a.city,
 a.coordinates
FROM airports a
WHERE a.city IN (
 SELECT aa.city
 FROM airports aa
 GROUP BY aa.city
 HAVING COUNT(*) > 1
)
ORDER BY a.city, a.airport_code;
```

| code | airport_name           | city      | coordinates                          |
|------|------------------------|-----------|--------------------------------------|
| DME  | Domodedovo             | Moscow    | (37.9062995910645, 55.4087982177734) |
|      | International Airport  |           |                                      |
| SVO  | Sheremetyevo           | Moscow    | (37.4146, 55.972599)                 |
|      | International Airport  |           |                                      |
| VKO  | Vnukovo                | Moscow    | (37.2615013123, 55.5914993286)       |
|      | International Airport  |           |                                      |
| ULV  | Ulyanovsk              | Ulyanovsk | (48.2266998291, 54.2682991028)       |
|      | Baratayevka Airport    |           |                                      |
| ULY  | Ulyanovsk East Airport | Ulyanovsk | (48.8027000427246, 54.4010009765625) |

(5 rows)

To learn about your flying options from one point to another, it is convenient to use the `routes` materialized view that aggregates information on all flights. For example, here are the destinations where you can get from Volgograd on specific days of the week, with flight duration:

```
SELECT r.arrival_city as city,
 r.arrival_airport as code,
 r.arrival_airport_name as airport_name,
 r.days_of_week,
 r.duration
FROM routes r
WHERE r.departure_city = 'Volgograd';
```

| city        | code | airport_name                       | days_of_week    | duration |
|-------------|------|------------------------------------|-----------------|----------|
| Moscow      | SVO  | Sheremetyevo International Airport | {1,2,3,4,5,6,7} | 01:15:00 |
| Chelyabinsk | CEK  | Chelyabinsk Balandino Airport      | {1,2,3,4,5,6,7} | 01:50:00 |
| Rostov      | ROV  | Rostov-on-Don Airport              | {1,2,3,4,5,6,7} | 00:30:00 |
| Moscow      | VKO  | Vnukovo International Airport      | {1,2,3,4,5,6,7} | 01:10:00 |
| Cheboksary  | CSY  | Cheboksary Airport                 | {1,2,3,4,5,6,7} | 02:45:00 |
| Tomsk       | TOF  | Bogashevo Airport                  | {1}             | 03:50:00 |

(6 rows)

The database was formed at the moment returned by the `bookings.now()` function:

```
SELECT bookings.now() as now;
```

| now                    |
|------------------------|
| 2017-08-15 18:00:00+03 |

In relation to this moment, all flights are classified as past and future flights:

```
SELECT status,
 count(*) as count,
 min(scheduled_departure) as min_scheduled_departure,
 max(scheduled_departure) as max_scheduled_departure
FROM flights
GROUP BY status
ORDER BY min_scheduled_departure;
```

| status    | count | min_scheduled_departure | max_scheduled_departure |
|-----------|-------|-------------------------|-------------------------|
| Arrived   | 16707 | 2017-07-16 01:50:00+03  | 2017-08-15 17:25:00+03  |
| Cancelled | 414   | 2017-07-19 11:35:00+03  | 2017-09-14 20:55:00+03  |

| Delayed   | 41    | 2017-08-15 15:15:00+03  | 2017-08-16 17:25:00+03  |
| On Time   | 518   | 2017-08-15 17:55:00+03  | 2017-08-16 18:00:00+03  |
| Scheduled | 15383 | 2017-08-16 18:05:00+03  | 2017-09-14 20:40:00+03  |

(6 rows)

Let's find the next flight from Yekaterinburg to Moscow. The `flight` table is not very convenient for such queries, as it does not include information on the cities of departure and arrival. That is why we will use the `flights_v` view:

```
\x
SELECT f.*
FROM flights_v f
WHERE f.departure_city = 'Yekaterinburg'
AND f.arrival_city = 'Moscow'
AND f.scheduled_departure > bookings.now()
ORDER BY f.scheduled_departure
LIMIT 1;
```

```
-[RECORD 1]-----+-----
flight_id | 10927
flight_no | PG0226
scheduled_departure | 2017-08-16 08:10:00+03
scheduled_departure_local | 2017-08-16 10:10:00
scheduled_arrival | 2017-08-16 09:55:00+03
scheduled_arrival_local | 2017-08-16 09:55:00
scheduled_duration | 01:45:00
departure_airport | SVX
departure_airport_name | Koltsovo Airport
departure_city | Yekaterinburg
arrival_airport | SVO
arrival_airport_name | Sheremetyevo International Airport
arrival_city | Moscow
status | On Time
aircraft_code | 773
actual_departure |
actual_departure_local |
actual_arrival |
actual_arrival_local |
actual_duration |
```

Note that the `flights_v` view shows both Moscow time and local time at the airports of departure and arrival.

## M.5.4. Bookings

Each booking can include several tickets, one for each passenger. The ticket, in its turn, can include several flight segments. The complete information about the booking is stored in three tables: `bookings`, `tickets`, and `ticket_flights`.

Let's find several most expensive bookings:

```
SELECT *
FROM bookings
ORDER BY total_amount desc
LIMIT 10;
```

| book_ref | book_date              | total_amount |
|----------|------------------------|--------------|
| 3B54BB   | 2017-07-05 17:08:00+03 | 1204500.00   |
| 3AC131   | 2017-07-31 01:06:00+03 | 1087100.00   |
| 65A6EA   | 2017-07-03 06:28:00+03 | 1065600.00   |
| D7E9AA   | 2017-08-08 05:29:00+03 | 1062800.00   |
| EF479E   | 2017-08-02 15:58:00+03 | 1035100.00   |
| 521C53   | 2017-07-08 09:25:00+03 | 985500.00    |
| 514CA6   | 2017-07-27 05:07:00+03 | 955000.00    |
| D70BD9   | 2017-07-05 12:47:00+03 | 947500.00    |
| EC7EDA   | 2017-07-02 16:13:00+03 | 946800.00    |

```
8E4370 | 2017-07-28 02:04:00+03 | 945700.00
(10 rows)
```

Let's take a look at the tickets included into the booking with code 521C53:

```
SELECT ticket_no,
 passenger_id,
 passenger_name
FROM tickets
WHERE book_ref = '521C53';
```

| ticket_no     | passenger_id | passenger_name     |
|---------------|--------------|--------------------|
| 0005432661914 | 8234 547529  | IVAN IVANOV        |
| 0005432661915 | 2034 201228  | ANTONINA KUZNECOVA |

(2 rows)

If we would like to know, which flight segments are included into Antonina Kuznecova's ticket, we can use the following query:

```
SELECT to_char(f.scheduled_departure, 'DD.MM.YYYY') AS when,
 f.departure_city || ' (' || f.departure_airport || ')' AS departure,
 f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
 tf.fare_conditions AS class,
 tf.amount
FROM ticket_flights tf
 JOIN flights_v f ON tf.flight_id = f.flight_id
WHERE tf.ticket_no = '0005432661915'
ORDER BY f.scheduled_departure;
```

| when       | departure             | arrival               | class    | amount    |
|------------|-----------------------|-----------------------|----------|-----------|
| 29.07.2017 | Moscow (SVO)          | Anadyr (DYR)          | Business | 185300.00 |
| 02.08.2017 | Anadyr (DYR)          | Khabarovsk (KHV)      | Business | 92200.00  |
| 03.08.2017 | Khabarovsk (KHV)      | Blagoveshchensk (BQS) | Business | 18000.00  |
| 08.08.2017 | Blagoveshchensk (BQS) | Khabarovsk (KHV)      | Business | 18000.00  |
| 12.08.2017 | Khabarovsk (KHV)      | Anadyr (DYR)          | Economy  | 30700.00  |
| 17.08.2017 | Anadyr (DYR)          | Moscow (SVO)          | Business | 185300.00 |

(6 rows)

As we can see, high booking cost is explained by multiple long-haul flights in business class.

Some of the flight segments in this ticket have earlier dates than the `bookings.now()` return value: it means that these flights had already happened. The last flight had not happened yet at the time of the database creation. After the check-in, a boarding pass with the allocated seat number is issued. We can check the exact seats occupied by Antonina (note the outer left join with table `boarding_passes`):

```
SELECT to_char(f.scheduled_departure, 'DD.MM.YYYY') AS when,
 f.departure_city || ' (' || f.departure_airport || ')' AS departure,
 f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
 f.status,
 bp.seat_no
FROM ticket_flights tf
 JOIN flights_v f ON tf.flight_id = f.flight_id
 LEFT JOIN boarding_passes bp ON tf.flight_id = bp.flight_id
 AND tf.ticket_no = bp.ticket_no
WHERE tf.ticket_no = '0005432661915'
```

```
ORDER BY f.scheduled_departure;
```

| when       | departure             | arrival               | status    | seat_no |
|------------|-----------------------|-----------------------|-----------|---------|
| 29.07.2017 | Moscow (SVO)          | Anadyr (DYR)          | Arrived   | 5C      |
| 02.08.2017 | Anadyr (DYR)          | Khabarovsk (KHV)      | Arrived   | 1D      |
| 03.08.2017 | Khabarovsk (KHV)      | Blagoveshchensk (BQS) | Arrived   | 2C      |
| 08.08.2017 | Blagoveshchensk (BQS) | Khabarovsk (KHV)      | Arrived   | 2D      |
| 12.08.2017 | Khabarovsk (KHV)      | Anadyr (DYR)          | Arrived   | 20B     |
| 17.08.2017 | Anadyr (DYR)          | Moscow (SVO)          | Scheduled |         |

(6 rows)

## M.5.5. New Booking

Let's try to send Aleksandr Radishchev from Saint Petersburg to Moscow — the route that made him famous. Naturally, he will travel for free and in business class. We have already found a flight for tomorrow, and a return flight a week later.

```
BEGIN;
```

```
INSERT INTO bookings (book_ref, book_date, total_amount)
VALUES ('_QWE12', bookings.now(), 0);
```

```
INSERT INTO tickets (ticket_no, book_ref, passenger_id, passenger_name)
VALUES ('_0000000000001', '_QWE12', '1749 051790', 'ALEKSANDR RADISHCHEV');
```

```
INSERT INTO ticket_flights (ticket_no, flight_id, fare_conditions, amount)
VALUES ('_0000000000001', 8525, 'Business', 0),
 ('_0000000000001', 4967, 'Business', 0);
```

```
COMMIT;
```

To avoid conflicts with the range of values present in the database, identifiers are started with an underscore.

We will check in Aleksandr for tomorrow's flight right away:

```
INSERT INTO boarding_passes (ticket_no, flight_id, boarding_no, seat_no)
VALUES ('_0000000000001', 8525, 1, '1A');
```

Now let's check the booking information:

```
SELECT b.book_ref,
 t.ticket_no,
 t.passenger_id,
 t.passenger_name,
 tf.fare_conditions,
 tf.amount,
 f.scheduled_departure_local,
 f.scheduled_arrival_local,
 f.departure_city || ' (' || f.departure_airport || ')' AS departure,
 f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
 f.status,
 bp.seat_no
FROM bookings b
 JOIN tickets t ON b.book_ref = t.book_ref
 JOIN ticket_flights tf ON tf.ticket_no = t.ticket_no
```

```

 JOIN flights_v f ON tf.flight_id = f.flight_id
 LEFT JOIN boarding_passes bp ON tf.flight_id = bp.flight_id
 AND tf.ticket_no = bp.ticket_no
WHERE b.book_ref = '_QWE12'
ORDER BY t.ticket_no, f.scheduled_departure;

```

```

-[RECORD 1]-----+-----
book_ref | _QWE12
ticket_no | _0000000000001
passenger_id | 1749 051790
passenger_name | ALEKSANDR RADISHCHEV
fare_conditions | Business
amount | 0.00
scheduled_departure_local | 2017-08-16 09:45:00
scheduled_arrival_local | 2017-08-16 10:35:00
departure | St. Petersburg (LED)
arrival | Moscow (SVO)
status | On Time
seat_no | 1A
-[RECORD 2]-----+-----
book_ref | _QWE12
ticket_no | _0000000000001
passenger_id | 1749 051790
passenger_name | ALEKSANDR RADISHCHEV

# Appendix O. Glossary

This is a list of terms and their meaning in the context of PostgreSQL and relational database systems in general.

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACID                         | <i>Atomicity</i> , <i>Consistency</i> , <i>Isolation</i> , and <i>Durability</i> . This set of properties of database transactions is intended to guarantee validity in concurrent operation and even in event of errors, power failures, etc.                                                                                                                                                                                                                                                                                   |
| Aggregate function (routine) | A <i>function</i> that combines ( <i>aggregates</i> ) multiple input values, for example by counting, averaging or adding, yielding a single output value.<br><br>For more information, see <a href="#">Section 9.21</a> .<br><br>See Also <a href="#">Window function (routine)</a> .                                                                                                                                                                                                                                           |
| Access Method                | Interfaces which Postgres Pro use in order to access data in tables and indexes. This abstraction allows for adding support for new types of data storage.<br><br>For more information, see <a href="#">Chapter 60</a> and <a href="#">Chapter 61</a> .                                                                                                                                                                                                                                                                          |
| Analytic function            | See <a href="#">Window function (routine)</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Analyze (operation)          | The act of collecting statistics from data in <i>tables</i> and other <i>relations</i> to help the <i>query planner</i> to make decisions about how to execute <i>queries</i> .<br><br>(Don't confuse this term with the <code>ANALYZE</code> option to the <code>EXPLAIN</code> command.)<br><br>For more information, see <a href="#">ANALYZE</a> .                                                                                                                                                                            |
| Asynchronous I/O (AIO)       | Asynchronous I/O (AIO) describes performing I/O in a non-blocking way (asynchronously), in contrast to synchronous I/O, which blocks for the entire duration of the I/O.<br><br>With AIO, starting an I/O operation is separated from waiting for the result of the operation, allowing multiple I/O operations to be initiated concurrently, as well as performing CPU heavy operations concurrently with I/O. The price for that increased concurrency is increased complexity.<br><br>See Also <a href="#">Input/Output</a> . |
| Atomic                       | In reference to a <i>datum</i> : the fact that its value cannot be broken down into smaller components.<br><br>In reference to a <i>database transaction</i> : see <i>atomicity</i> .                                                                                                                                                                                                                                                                                                                                            |
| Atomicity                    | The property of a <i>transaction</i> that either all its operations complete as a single unit or none do. In addition, if a system failure occurs during the execution of a transaction, no partial results are visible after recovery. This is one of the ACID properties.                                                                                                                                                                                                                                                      |
| Attribute                    | An element with a certain name and data type found within a <i>tuple</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Autovacuum (process)         | A set of background processes that routinely perform <i>vacuum</i> and <i>analyze</i> operations. The <i>auxiliary process</i> that coordinates the work and is always present (unless autovacuum is disabled) is known as the <i>autovacuum launcher</i> , and the processes that carry out the tasks are known as the <i>autovacuum workers</i> .<br><br>For more information, see <a href="#">Section 23.1.6</a> .                                                                                                            |

|                        |        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Auxiliary process      |        | A process within an <i>instance</i> that is in charge of some specific background task for the instance. The auxiliary processes consist of the <i>autovacuum launcher</i> (but not the autovacuum workers), the <i>background writer</i> , the <i>checkpointer</i> , the <i>logger</i> , the <i>startup process</i> , the <i>WAL archiver</i> , the <i>WAL receiver</i> (but not the <i>WAL senders</i> ), the <i>WAL summarizer</i> , and the <i>WAL writer</i> .                                                                                                                                                                                                                                                                                       |
| Backend (process)      |        | <p>Process of an <i>instance</i> which acts on behalf of a <i>client session</i> and handles its requests.</p> <p>(Don't confuse this term with the similar terms <i>Background Worker</i> or <i>Background Writer</i>).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Background (process)   | worker | <p>Process within an <i>instance</i>, which runs system- or user-supplied code. Serves as infrastructure for several features in PostgreSQL, such as <i>logical replication</i> and <i>parallel queries</i>. In addition, <i>Extensions</i> can add custom background worker processes.</p> <p>For more information, see <a href="#">Chapter 46</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                  |
| Background (process)   | writer | <p>An <i>auxiliary process</i> that writes dirty <i>data pages</i> from <i>shared memory</i> to the file system. It wakes up periodically, but works only for a short period in order to distribute its expensive I/O activity over time to avoid generating larger I/O peaks which could block other processes.</p> <p>For more information, see <a href="#">Section 18.4.4</a>.</p>                                                                                                                                                                                                                                                                                                                                                                     |
| Base Backup            |        | A binary copy of all <i>database cluster</i> files. It is generated by the tool <i>pg_basebackup</i> . In combination with WAL files it can be used as the starting point for recovery, log shipping, or streaming replication.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Bloat                  |        | Space in data pages which does not contain current row versions, such as unused (free) space or outdated row versions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Bootstrap superuser    |        | <p>The first <i>user</i> initialized in a <i>database cluster</i>.</p> <p>This user owns all system catalog tables in each database. It is also the role from which all granted permissions originate. Because of these things, this role may not be dropped.</p> <p>This role also behaves as a normal <i>database superuser</i>, and its superuser status cannot be removed.</p>                                                                                                                                                                                                                                                                                                                                                                        |
| Buffer Access Strategy |        | <p>Some operations will access a large number of <i>pages</i>. A <i>Buffer Access Strategy</i> helps to prevent these operations from evicting too many pages from <i>shared buffers</i>.</p> <p>A Buffer Access Strategy sets up references to a limited number of <i>shared buffers</i> and reuses them circularly. When the operation requires a new page, a victim buffer is chosen from the buffers in the strategy ring, which may require flushing the page's dirty data and possibly also unflushed <i>WAL</i> to permanent storage.</p> <p>Buffer Access Strategies are used for various operations such as sequential scans of large tables, VACUUM, COPY, CREATE TABLE AS SELECT, ALTER TABLE, CREATE DATABASE, CREATE INDEX, and CLUSTER.</p> |
| Cast                   |        | <p>A conversion of a <i>datum</i> from its current data type to another data type.</p> <p>For more information, see <a href="#">CREATE CAST</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Catalog                | <p>The SQL standard uses this term to indicate what is called a <i>database</i> in PostgreSQL's terminology.</p> <p>(Don't confuse this term with <i>system catalog</i>).</p> <p>For more information, see <a href="#">Section 21.1</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Check constraint       | <p>A type of <i>constraint</i> defined on a <i>relation</i> which restricts the values allowed in one or more <i>attributes</i>. The check constraint can make reference to any attribute of the same row in the relation, but cannot reference other rows of the same relation or other relations.</p> <p>For more information, see <a href="#">Section 5.5</a>.</p>                                                                                                                                                                                                                                                                                                                                                         |
| Checkpoint             | <p>A point in the <i>WAL</i> sequence at which it is guaranteed that the heap and index data files have been updated with all information from <i>shared memory</i> modified before that checkpoint; a <i>checkpoint record</i> is written and flushed to WAL to mark that point.</p> <p>A checkpoint is also the act of carrying out all the actions that are necessary to reach a checkpoint as defined above. This process is initiated when pre-defined conditions are met, such as a specified amount of time has passed, or a certain volume of records has been written; or it can be invoked by the user with the command <code>CHECKPOINT</code>.</p> <p>For more information, see <a href="#">Section 27.5</a>.</p> |
| Checkpointer (process) | An <i>auxiliary process</i> that is responsible for executing <i>checkpoints</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Class (archaic)        | See <a href="#">Relation</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Client (process)       | Any process, possibly remote, that establishes a <i>session</i> by <i>connecting</i> to an <i>instance</i> to interact with a <i>database</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Cluster owner          | <p>The operating system user that owns the <i>data directory</i> and under which the <code>postgres</code> process is run. It is required that this user exist prior to creating a new <i>database cluster</i>.</p> <p>On operating systems with a <code>root</code> user, said user is not allowed to be the cluster owner.</p>                                                                                                                                                                                                                                                                                                                                                                                              |
| Column                 | An <i>attribute</i> found in a <i>table</i> or <i>view</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Commit                 | <p>The act of finalizing a <i>transaction</i> within the <i>database</i>, which makes it visible to other transactions and assures its <i>durability</i>.</p> <p>For more information, see <a href="#">COMMIT</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Concurrency            | The concept that multiple independent operations happen within the <i>database</i> at the same time. In PostgreSQL, concurrency is controlled by the <i>multiversion concurrency control</i> mechanism.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Connection             | <p>An established line of communication between a client process and a <i>back-end</i> process, usually over a network, supporting a <i>session</i>. This term is sometimes used as a synonym for session.</p> <p>For more information, see <a href="#">Section 18.3</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Consistency            | The property that the data in the <i>database</i> is always in compliance with <i>integrity constraints</i> . Transactions may be allowed to violate some of the constraints transiently before it commits, but if such violations are not resolved                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|                    |            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|                    |            | by the time it commits, such a transaction is automatically <i>rolled back</i> . This is one of the ACID properties.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Constraint         |            | <p>A restriction on the values of data allowed within a <i>table</i>, or in attributes of a <i>domain</i>.</p> <p>For more information, see <a href="#">Section 5.5</a>.</p>                                                                                                                                                                                                                                                                                                                                                          |
| Cumulative System  | Statistics | <p>A system which, if enabled, accumulates statistical information about the <i>instance</i>'s activities.</p> <p>For more information, see <a href="#">Section 26.2</a>.</p>                                                                                                                                                                                                                                                                                                                                                         |
| Data area          |            | See <a href="#">Data directory</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Database           |            | <p>A named collection of <i>local SQL objects</i>.</p> <p>For more information, see <a href="#">Section 21.1</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Database cluster   |            | <p>A collection of databases and global SQL objects, and their common static and dynamic metadata. Sometimes referred to as a <i>cluster</i>. A database cluster is created using the <i>initdb</i> program.</p> <p>In PostgreSQL, the term <i>cluster</i> is also sometimes used to refer to an instance. (Don't confuse this term with the SQL command <code>CLUSTER</code>.)</p> <p>See also <i>cluster owner</i>, the operating-system owner of a cluster, and <i>bootstrap superuser</i>, the PostgreSQL owner of a cluster.</p> |
| Database server    |            | See <a href="#">Instance</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Database superuser |            | <p>A role having <i>superuser status</i> (see <a href="#">Section 20.2</a>).</p> <p>Frequently referred to as <i>superuser</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                   |
| Data directory     |            | <p>The base directory on the file system of a <i>server</i> that contains all data files and subdirectories associated with a <i>database cluster</i> (with the exception of <i>tablespaces</i>, and optionally <i>WAL</i>). The environment variable <code>PGDATA</code> is commonly used to refer to the data directory.</p> <p>A <i>cluster</i>'s storage space comprises the data directory plus any additional tablespaces.</p> <p>For more information, see <a href="#">Section 64.1</a>.</p>                                   |
| Data page          |            | <p>The basic structure used to store relation data. All pages are of the same size. Data pages are typically stored on disk, each in a specific file, and can be read to <i>shared buffers</i> where they can be modified, becoming <i>dirty</i>. They become clean when written to disk. New pages, which initially exist in memory only, are also dirty until written.</p>                                                                                                                                                          |
| Datum              |            | The internal representation of one value of an SQL data type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Delete             |            | <p>An SQL command which removes <i>rows</i> from a given <i>table</i> or <i>relation</i>.</p> <p>For more information, see <a href="#">DELETE</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                |
| Domain             |            | <p>A user-defined data type that is based on another underlying data type. It acts the same as the underlying type except for possibly restricting the set of allowed values.</p> <p>For more information, see <a href="#">Section 8.18</a>.</p>                                                                                                                                                                                                                                                                                      |

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Durability               | The assurance that once a <i>transaction</i> has been <i>committed</i> , the changes remain even after a system failure or crash. This is one of the ACID properties.                                                                                                                                                                                                                                                                                             |
| Epoch                    | See <a href="#">Transaction ID</a> .                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Extension                | <p>A software add-on package that can be installed on an <i>instance</i> to get extra features.</p> <p>For more information, see <a href="#">Section 36.17</a>.</p>                                                                                                                                                                                                                                                                                               |
| File segment             | <p>A physical file which stores data for a given <i>relation</i>. File segments are limited in size by a configuration value (typically 1 gigabyte), so if a relation exceeds that size, it is split into multiple segments.</p> <p>For more information, see <a href="#">Section 64.1</a>.</p> <p>(Don't confuse this term with the similar term <i>WAL segment</i>).</p>                                                                                        |
| Foreign data wrapper     | <p>A means of representing data that is not contained in the local <i>database</i> so that it appears as if were in local <i>table(s)</i>. With a foreign data wrapper it is possible to define a <i>foreign server</i> and <i>foreign tables</i>.</p> <p>For more information, see <a href="#">CREATE FOREIGN DATA WRAPPER</a>.</p>                                                                                                                              |
| Foreign key              | A type of <i>constraint</i> defined on one or more <i>columns</i> in a <i>table</i> which requires the value(s) in those <i>columns</i> to identify zero or one <i>row</i> in another (or, infrequently, the same) <i>table</i> .                                                                                                                                                                                                                                 |
| Foreign server           | <p>A named collection of <i>foreign tables</i> which all use the same <i>foreign data wrapper</i> and have other configuration values in common.</p> <p>For more information, see <a href="#">CREATE SERVER</a>.</p>                                                                                                                                                                                                                                              |
| Foreign table (relation) | <p>A <i>relation</i> which appears to have <i>rows</i> and <i>columns</i> similar to a regular <i>table</i>, but will forward requests for data through its <i>foreign data wrapper</i>, which will return <i>result sets</i> structured according to the definition of the <i>foreign table</i>.</p> <p>For more information, see <a href="#">CREATE FOREIGN TABLE</a>.</p>                                                                                      |
| Fork                     | Each of the separate segmented file sets in which a relation is stored. The <i>main fork</i> is where the actual data resides. There also exist two secondary forks for metadata: the <i>free space map</i> and the <i>visibility map</i> . <i>Unlogged relations</i> also have an <i>init fork</i> .                                                                                                                                                             |
| Free space map (fork)    | <p>A storage structure that keeps metadata about each data page of a table's main fork. The free space map entry for each page stores the amount of free space that's available for future tuples, and is structured to be efficiently searched for available space for a new tuple of a given size.</p> <p>For more information, see <a href="#">Section 64.3</a>.</p>                                                                                           |
| Function (routine)       | <p>A type of routine that receives zero or more arguments, returns zero or more output values, and is constrained to run within one transaction. Functions are invoked as part of a query, for example via <code>SELECT</code>. Certain functions can return <i>sets</i>; those are called <i>set-returning functions</i>.</p> <p>Functions can also be used for <i>triggers</i> to invoke.</p> <p>For more information, see <a href="#">CREATE FUNCTION</a>.</p> |
| GMT                      | See <a href="#">UTC</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Grant              | <p>An SQL command that is used to allow a <a href="#">user</a> or <a href="#">role</a> to access specific objects within the <a href="#">database</a>.</p> <p>For more information, see <a href="#">GRANT</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Heap               | <p>Contains the values of <a href="#">row</a> attributes (i.e., the data) for a <a href="#">relation</a>. The heap is realized within one or more <a href="#">file segments</a> in the relation's <a href="#">main fork</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Host               | <p>A computer that communicates with other computers over a network. This is sometimes used as a synonym for <a href="#">server</a>. It is also used to refer to a computer where <a href="#">client processes</a> run.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Index (relation)   | <p>A <a href="#">relation</a> that contains data derived from a <a href="#">table</a> or <a href="#">materialized view</a>. Its internal structure supports fast retrieval of and access to the original data.</p> <p>For more information, see <a href="#">CREATE INDEX</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                         |
| Incremental backup | <p>A special <a href="#">base backup</a> that for some files may contain only those pages that were modified since a previous backup, as opposed to the full contents of every file. Like base backups, it is generated by the tool <a href="#">pg_basebackup</a>.</p> <p>To restore incremental backups the tool <a href="#">pg_combinebackup</a> is used, which combines incremental backups with a base backup. Afterwards, recovery can use <a href="#">WAL</a> to bring the <a href="#">database cluster</a> to a consistent state.</p> <p>For more information, see <a href="#">Section 24.3.3</a>.</p>                                                             |
| Input/Output (I/O) | <p>Input/Output (I/O) describes the communication between a program and peripheral devices. In the context of database systems, I/O commonly, but not exclusively, refers to interaction with storage devices or the network.</p> <p>See Also <a href="#">Asynchronous I/O</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                       |
| Insert             | <p>An SQL command used to add new data into a <a href="#">table</a>.</p> <p>For more information, see <a href="#">INSERT</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Instance           | <p>A group of <a href="#">backend</a> and <a href="#">auxiliary processes</a> that communicate using a common shared memory area. One <a href="#">postmaster process</a> manages the instance; one instance manages exactly one <a href="#">database cluster</a> with all its databases. Many instances can run on the same <a href="#">server</a> as long as their TCP ports do not conflict.</p> <p>The instance handles all key features of a DBMS: read and write access to files and shared memory, assurance of the ACID properties, <a href="#">connections</a> to <a href="#">client processes</a>, privilege verification, crash recovery, replication, etc.</p> |
| Isolation          | <p>The property that the effects of a transaction are not visible to <a href="#">concurrent transactions</a> before it commits. This is one of the ACID properties.</p> <p>For more information, see <a href="#">Section 13.2</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Join               | <p>An operation and SQL keyword used in <a href="#">queries</a> for combining data from multiple <a href="#">relations</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Key                | <p>A means of identifying a <a href="#">row</a> within a <a href="#">table</a> or other <a href="#">relation</a> by values contained within one or more <a href="#">attributes</a> in that relation.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Lock               | <p>A mechanism that allows a process to limit or prevent simultaneous access to a resource.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Log file                                 | <p>Log files contain human-readable text lines about events. Examples include login failures, long-running queries, etc.</p> <p>For more information, see <a href="#">Section 23.3</a>.</p>                                                                                                                                                                                                                                                                                                                                                                        |
| Logged                                   | <p>A <a href="#">table</a> is considered <i>logged</i> if changes to it are sent to the <a href="#">WAL</a>. By default, all regular tables are logged. A table can be specified as <i>unlogged</i> either at creation time or via the <code>ALTER TABLE</code> command.</p>                                                                                                                                                                                                                                                                                       |
| Logger (process)                         | <p>An <i>auxiliary process</i> which, if enabled, writes information about database events into the current <i>log file</i>. When reaching certain time- or volume-dependent criteria, a new log file is created. Also called <i>syslogger</i>.</p> <p>For more information, see <a href="#">Section 18.8</a>.</p>                                                                                                                                                                                                                                                 |
| Logical replication cluster              | <p>A set of publisher and subscriber instances with the publisher instance replicating changes to the subscriber instance.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Log record                               | <p>Archaic term for a <a href="#">WAL record</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Log sequence number (LSN)                | <p>Byte offset into the <a href="#">WAL</a>, increasing monotonically with each new <a href="#">WAL record</a>.</p> <p>For more information, see <code>pg_lsn</code> and <a href="#">Section 27.6</a>.</p>                                                                                                                                                                                                                                                                                                                                                         |
| LSN                                      | <p>See <a href="#">Log sequence number</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Master (server)                          | <p>See <a href="#">Primary (server)</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Materialized                             | <p>The property that some information has been pre-computed and stored for later use, rather than computing it on-the-fly.</p> <p>This term is used in <a href="#">materialized view</a>, to mean that the data derived from the view's query is stored on disk separately from the sources of that data.</p> <p>This term is also used to refer to some multi-step queries to mean that the data resulting from executing a given step is stored in memory (with the possibility of spilling to disk), so that it can be read multiple times by another step.</p> |
| Materialized view (relation)             | <p>A <a href="#">relation</a> that is defined by a <code>SELECT</code> statement (just like a <a href="#">view</a>), but stores data in the same way that a <a href="#">table</a> does. It cannot be modified via <code>INSERT</code>, <code>UPDATE</code>, <code>DELETE</code>, or <code>MERGE</code> operations.</p> <p>For more information, see <a href="#">CREATE MATERIALIZED VIEW</a>.</p>                                                                                                                                                                  |
| Merge                                    | <p>An SQL command used to conditionally add, modify, or remove <a href="#">rows</a> in a given <a href="#">table</a>, using data from a source <a href="#">relation</a>.</p> <p>For more information, see <a href="#">MERGE</a>.</p>                                                                                                                                                                                                                                                                                                                               |
| Multi-version concurrency control (MVCC) | <p>A mechanism designed to allow several <a href="#">transactions</a> to be reading and writing the same rows without one process causing other processes to stall. In PostgreSQL, MVCC is implemented by creating copies (<i>versions</i>) of <a href="#">tuples</a> as they are modified; after transactions that can see the old versions terminate, those old versions need to be removed.</p>                                                                                                                                                                 |
| Null                                     | <p>A concept of non-existence that is a central tenet of relational database theory. It represents the absence of a definite value.</p>                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Optimizer                                | <p>See <a href="#">Query planner</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parallel query               | The ability to handle parts of executing a <a href="#">query</a> to take advantage of parallel processes on servers with multiple CPUs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Partition                    | <p>One of several disjoint (not overlapping) subsets of a larger set.</p> <p>In reference to a <a href="#">partitioned table</a>: One of the tables that each contain part of the data of the partitioned table, which is said to be the <i>parent</i>. The partition is itself a table, so it can also be queried directly; at the same time, a partition can sometimes be a partitioned table, allowing hierarchies to be created.</p> <p>In reference to a <a href="#">window function</a> in a <a href="#">query</a>, a partition is a user-defined criterion that identifies which neighboring <a href="#">rows</a> of the <a href="#">query's result set</a> can be considered by the function.</p> |
| Partitioned table (relation) | A <a href="#">relation</a> that is in semantic terms the same as a <a href="#">table</a> , but whose storage is distributed across several <a href="#">partitions</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Postmaster (process)         | <p>The very first process of an <a href="#">instance</a>. It starts and manages the <a href="#">auxiliary processes</a> and creates <a href="#">backend processes</a> on demand.</p> <p>For more information, see <a href="#">Section 17.3</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Primary key                  | A special case of a <a href="#">unique constraint</a> defined on a <a href="#">table</a> or other <a href="#">relation</a> that also guarantees that all of the <a href="#">attributes</a> within the <a href="#">primary key</a> do not have <a href="#">null</a> values. As the name implies, there can be only one primary key per table, though it is possible to have multiple unique constraints that also have no null-capable attributes.                                                                                                                                                                                                                                                         |
| Primary (server)             | When two or more <a href="#">databases</a> are linked via <a href="#">replication</a> , the <a href="#">server</a> that is considered the authoritative source of information is called the <i>primary</i> , also known as a <i>master</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Procedure (routine)          | <p>A type of routine. Their distinctive qualities are that they do not return values, and that they are allowed to make transactional statements such as COMMIT and ROLLBACK. They are invoked via the CALL command.</p> <p>For more information, see <a href="#">CREATE PROCEDURE</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                               |
| Query                        | A request sent by a client to a <a href="#">backend</a> , usually to return results or to modify data on the database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Query planner                | The part of PostgreSQL that is devoted to determining ( <i>planning</i> ) the most efficient way to execute <a href="#">queries</a> . Also known as <i>query optimizer</i> , <i>optimizer</i> , or simply <i>planner</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Record                       | See <a href="#">Tuple</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Recycling                    | See <a href="#">WAL file</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Referential integrity        | A means of restricting data in one <a href="#">relation</a> by a <a href="#">foreign key</a> so that it must have matching data in another <a href="#">relation</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Relation                     | <p>The generic term for all objects in a <a href="#">database</a> that have a name and a list of <a href="#">attributes</a> defined in a specific order. <a href="#">Tables</a>, <a href="#">sequences</a>, <a href="#">views</a>, <a href="#">foreign tables</a>, <a href="#">materialized views</a>, composite types, and <a href="#">indexes</a> are all relations.</p> <p>More generically, a relation is a set of tuples; for example, the result of a query is also a relation.</p> <p>In PostgreSQL, <i>Class</i> is an archaic synonym for <i>relation</i>.</p>                                                                                                                                   |

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Replica (server) | <p>A <a href="#">database</a> that is paired with a <a href="#">primary</a> database and is maintaining a copy of some or all of the primary database's data. The foremost reasons for doing this are to allow for greater access to that data, and to maintain availability of the data in the event that the <a href="#">primary</a> becomes unavailable.</p>                                                                                                                                       |
| Replication      | <p>The act of reproducing data on one <a href="#">server</a> onto another server called a <a href="#">replica</a>. This can take the form of <i>physical replication</i>, where all file changes from one server are copied verbatim, or <i>logical replication</i> where a defined subset of data changes are conveyed using a higher-level representation.</p>                                                                                                                                      |
| Restartpoint     | <p>A variant of a <a href="#">checkpoint</a> performed on a <a href="#">replica</a>.</p> <p>For more information, see <a href="#">Section 27.5</a>.</p>                                                                                                                                                                                                                                                                                                                                               |
| Result set       | <p>A <a href="#">relation</a> transmitted from a <a href="#">backend process</a> to a <a href="#">client</a> upon the completion of an SQL command, usually a <code>SELECT</code> but it can be an <code>INSERT</code>, <code>UPDATE</code>, <code>DELETE</code>, or <code>MERGE</code> command if the <code>RETURNING</code> clause is specified.</p> <p>The fact that a result set is a relation means that a query can be used in the definition of another query, becoming a <i>subquery</i>.</p> |
| Revoke           | <p>A command to prevent access to a named set of <a href="#">database</a> objects for a named list of <a href="#">roles</a>.</p> <p>For more information, see <a href="#">REVOKE</a>.</p>                                                                                                                                                                                                                                                                                                             |
| Role             | <p>A collection of access privileges to the <a href="#">instance</a>. Roles are themselves a privilege that can be granted to other roles. This is often done for convenience or to ensure completeness when multiple <a href="#">users</a> need the same privileges.</p> <p>For more information, see <a href="#">CREATE ROLE</a>.</p>                                                                                                                                                               |
| Rollback         | <p>A command to undo all of the operations performed since the beginning of a <a href="#">transaction</a>.</p> <p>For more information, see <a href="#">ROLLBACK</a>.</p>                                                                                                                                                                                                                                                                                                                             |
| Routine          | <p>A defined set of instructions stored in the database system that can be invoked for execution. A routine can be written in a variety of programming languages. Routines can be <a href="#">functions</a> (including set-returning functions and <a href="#">trigger functions</a>), <a href="#">aggregate functions</a>, and <a href="#">procedures</a>.</p> <p>Many routines are already defined within PostgreSQL itself, but user-defined ones can also be added.</p>                           |
| Row              | <p>See <a href="#">Tuple</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Savepoint        | <p>A special mark in the sequence of steps in a <a href="#">transaction</a>. Data modifications after this point in time may be reverted to the time of the savepoint.</p> <p>For more information, see <a href="#">SAVEPOINT</a>.</p>                                                                                                                                                                                                                                                                |
| Schema           | <p>A schema is a namespace for <a href="#">SQL objects</a>, which all reside in the same <a href="#">database</a>. Each SQL object must reside in exactly one schema.</p> <p>All system-defined SQL objects reside in schema <code>pg_catalog</code>.</p> <p>More generically, the term <i>schema</i> is used to mean all data descriptions (<a href="#">table</a> definitions, <a href="#">constraints</a>, comments, etc.) for a given <a href="#">database</a> or subset thereof.</p>              |

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|                     | For more information, see <a href="#">Section 5.10</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Segment             | See <a href="#">File segment</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Select              | <p>The SQL command used to request data from a <a href="#">database</a>. Normally, <code>SELECT</code> commands are not expected to modify the <a href="#">database</a> in any way, but it is possible that <a href="#">functions</a> invoked within the query could have side effects that do modify data.</p> <p>For more information, see <a href="#">SELECT</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Sequence (relation) | A type of relation that is used to generate values. Typically the generated values are sequential non-repeating numbers. They are commonly used to generate surrogate <a href="#">primary key</a> values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Server              | <p>A computer on which PostgreSQL <a href="#">instances</a> run. The term <i>server</i> denotes real hardware, a container, or a <i>virtual machine</i>.</p> <p>This term is sometimes used to refer to an instance or to a host.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Session             | A state that allows a client and a backend to interact, communicating over a <a href="#">connection</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Shared memory       | <p>RAM which is used by the processes common to an <a href="#">instance</a>. It mirrors parts of <a href="#">database</a> files, provides a transient area for <a href="#">WAL records</a>, and stores additional common information. Note that shared memory belongs to the complete instance, not to a single database.</p> <p>The largest part of shared memory is known as <i>shared buffers</i> and is used to mirror part of data files, organized into pages. When a page is modified, it is called a dirty page until it is written back to the file system.</p> <p>For more information, see <a href="#">Section 18.4.1</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| SQL object          | <p>Any object that can be created with a <code>CREATE</code> command. Most objects are specific to one database, and are commonly known as <i>local objects</i>.</p> <p>Most local objects reside in a specific <a href="#">schema</a> in their containing database, such as <a href="#">relations</a> (all types), <a href="#">routines</a> (all types), data types, etc. The names of such objects of the same type in the same schema are enforced to be unique.</p> <p>There also exist local objects that do not reside in schemas; some examples are <a href="#">extensions</a>, <a href="#">data type casts</a>, and <a href="#">foreign data wrappers</a>. The names of such objects of the same type are enforced to be unique within the database.</p> <p>Other object types, such as <a href="#">roles</a>, <a href="#">tablespaces</a>, replication origins, subscriptions for logical replication, and databases themselves are not local SQL objects since they exist entirely outside of any specific database; they are called <i>global objects</i>. The names of such objects are enforced to be unique within the whole database cluster.</p> <p>For more information, see <a href="#">Section 21.1</a>.</p> |
| SQL standard        | A series of documents that define the SQL language.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Standby (server)    | See <a href="#">Replica (server)</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Startup process     | An <a href="#">auxiliary process</a> that replays WAL during crash recovery and in a <a href="#">physical replica</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

(The name is historical: the startup process was named before replication was implemented; the name refers to its task as it relates to the server startup following a crash.)

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Superuser       | As used in this documentation, it is a synonym for <i>database superuser</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| System catalog  | <p>A collection of <i>tables</i> which describe the structure of all <i>SQL objects</i> of the instance. The system catalog resides in the schema <code>pg_catalog</code>. These tables contain data in internal representation and are not typically considered useful for user examination; a number of user-friendlier <i>views</i>, also in schema <code>pg_catalog</code>, offer more convenient access to some of that information, while additional tables and views exist in schema <code>information_schema</code> (see <a href="#">Chapter 35</a>) that expose some of the same and additional information as mandated by the <i>SQL standard</i>.</p> <p>For more information, see <a href="#">Section 5.10</a>.</p> |
| Table           | <p>A collection of <i>tuples</i> having a common data structure (the same number of <i>attributes</i>, in the same order, having the same name and type per position). A table is the most common form of <i>relation</i> in PostgreSQL.</p> <p>For more information, see <a href="#">CREATE TABLE</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Tablespace      | <p>A named location on the server file system. All <i>SQL objects</i> which require storage beyond their definition in the <i>system catalog</i> must belong to a single tablespace. Initially, a database cluster contains a single usable tablespace which is used as the default for all SQL objects, called <code>pg_default</code>.</p> <p>For more information, see <a href="#">Section 21.6</a>.</p>                                                                                                                                                                                                                                                                                                                     |
| Temporary table | <p><i>Tables</i> that exist either for the lifetime of a <i>session</i> or a <i>transaction</i>, as specified at the time of creation. The data in them is not visible to other sessions, and is not <i>logged</i>. Temporary tables are often used to store intermediate data for a multi-step operation.</p> <p>For more information, see <a href="#">CREATE TABLE</a>.</p>                                                                                                                                                                                                                                                                                                                                                   |
| TOAST           | <p>A mechanism by which large attributes of table rows are split and stored in a secondary table, called the <i>TOAST table</i>. Each relation with large attributes has its own TOAST table.</p> <p>For more information, see <a href="#">Section 64.2</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Transaction     | <p>A combination of commands that must act as a single <i>atomic</i> command: they all succeed or all fail as a single unit, and their effects are not visible to other <i>sessions</i> until the transaction is complete, and possibly even later, depending on the isolation level.</p> <p>For more information, see <a href="#">Section 13.2</a>.</p>                                                                                                                                                                                                                                                                                                                                                                        |
| Transaction ID  | <p>The numerical, unique, sequentially-assigned identifier that each transaction receives when it first causes a database modification. Frequently abbreviated as <i>xid</i>. When stored on disk, xids are only 32-bits wide, so only approximately four billion write transaction IDs can be generated; to permit the system to run for longer than that, <i>epochs</i> are used, also 32 bits wide. When the counter reaches the maximum xid value, it starts over at 3 (values under that are reserved) and the epoch value is incremented by one. In some contexts, the epoch and xid values are considered together as a single 64-bit value; see <a href="#">Section 65.1</a> for more details.</p>                      |

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               | For more information, see <a href="#">Section 8.19</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Transactions per second (TPS) | Average number of transactions that are executed per second, totaled across all sessions active for a measured run. This is used as a measure of the performance characteristics of an instance.                                                                                                                                                                                                                                                                                                          |
| Trigger                       | <p>A <a href="#">function</a> which can be defined to execute whenever a certain operation (INSERT, UPDATE, DELETE, TRUNCATE) is applied to a <a href="#">relation</a>. A trigger executes within the same <a href="#">transaction</a> as the statement which invoked it, and if the function fails, then the invoking statement also fails.</p> <p>For more information, see <a href="#">CREATE TRIGGER</a>.</p>                                                                                         |
| Tuple                         | A collection of <a href="#">attributes</a> in a fixed order. That order may be defined by the <a href="#">table</a> (or other <a href="#">relation</a> ) where the tuple is contained, in which case the tuple is often called a <i>row</i> . It may also be defined by the structure of a result set, in which case it is sometimes called a <i>record</i> .                                                                                                                                             |
| Unique constraint             | <p>A type of <a href="#">constraint</a> defined on a <a href="#">relation</a> which restricts the values allowed in one or a combination of columns so that each value or combination of values can only appear once in the relation — that is, no other row in the relation contains values that are equal to those.</p> <p>Because <a href="#">null values</a> are not considered equal to each other, multiple rows with null values are allowed to exist without violating the unique constraint.</p> |
| Unlogged                      | <p>The property of certain <a href="#">relations</a> that the changes to them are not reflected in the <a href="#">WAL</a>. This disables replication and crash recovery for these relations.</p> <p>The primary use of unlogged tables is for storing transient work data that must be shared across processes.</p> <p><a href="#">Temporary tables</a> are always unlogged.</p>                                                                                                                         |
| Update                        | <p>An SQL command used to modify <a href="#">rows</a> that may already exist in a specified <a href="#">table</a>. It cannot create or remove rows.</p> <p>For more information, see <a href="#">UPDATE</a>.</p>                                                                                                                                                                                                                                                                                          |
| User                          | A <a href="#">role</a> that has the <i>login privilege</i> (see <a href="#">Section 20.2</a> ).                                                                                                                                                                                                                                                                                                                                                                                                           |
| User mapping                  | <p>The translation of login credentials in the local <a href="#">database</a> to credentials in a remote data system defined by a <a href="#">foreign data wrapper</a>.</p> <p>For more information, see <a href="#">CREATE USER MAPPING</a>.</p>                                                                                                                                                                                                                                                         |
| UTC                           | Universal Coordinated Time, the primary global time reference, approximately the time prevailing at the zero meridian of longitude. Often but inaccurately referred to as GMT (Greenwich Mean Time).                                                                                                                                                                                                                                                                                                      |
| Vacuum                        | <p>The process of removing outdated <a href="#">tuple versions</a> from tables or materialized views, and other closely related processing required by PostgreSQL's implementation of <a href="#">MVCC</a>. This can be initiated through the use of the <code>VACUUM</code> command, but can also be handled automatically via <a href="#">autovacuum</a> processes.</p> <p>For more information, see <a href="#">Section 23.1</a> .</p>                                                                 |
| View                          | A <a href="#">relation</a> that is defined by a <code>SELECT</code> statement, but has no storage of its own. Any time a query references a view, the definition of the view is sub-                                                                                                                                                                                                                                                                                                                      |

stituted into the query as if the user had typed it as a subquery instead of the name of the view.

For more information, see [CREATE VIEW](#).

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Visibility map (fork)     | A storage structure that keeps metadata about each data page of a table's main fork. The visibility map entry for each page stores two bits: the first one ( <code>all-visible</code> ) indicates that all tuples in the page are visible to all transactions. The second one ( <code>all-frozen</code> ) indicates that all tuples in the page are marked frozen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| WAL                       | See <a href="#">Write-ahead log</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| WAL archiver (process)    | An <a href="#">auxiliary process</a> which, if enabled, saves copies of <a href="#">WAL files</a> for the purpose of creating backups or keeping <a href="#">replicas</a> current.<br><br>For more information, see <a href="#">Section 24.3</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| WAL file                  | Also known as <i>WAL segment</i> or <i>WAL segment file</i> . Each of the sequentially-numbered files that provide storage space for <a href="#">WAL</a> . The files are all of the same predefined size and are written in sequential order, interspersing changes as they occur in multiple simultaneous sessions. If the system crashes, the files are read in order, and each of the changes is replayed to restore the system to the state it was in before the crash.<br><br>Each WAL file can be released after a <a href="#">checkpoint</a> writes all the changes in it to the corresponding data files. Releasing the file can be done either by deleting it, or by changing its name so that it will be used in the future, which is called <i>recycling</i> .<br><br>For more information, see <a href="#">Section 27.6</a> . |
| WAL record                | A low-level description of an individual data change. It contains sufficient information for the data change to be re-executed ( <i>replayed</i> ) in case a system failure causes the change to be lost. WAL records use a non-printable binary format.<br><br>For more information, see <a href="#">Section 27.6</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| WAL receiver (process)    | An <a href="#">auxiliary process</a> that runs on a <a href="#">replica</a> to receive WAL from the <a href="#">primary server</a> for replay by the <a href="#">startup process</a> .<br><br>For more information, see <a href="#">Section 25.2</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| WAL segment               | See <a href="#">WAL file</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| WAL sender (process)      | A special <a href="#">backend process</a> that streams WAL over a network. The receiving end can be a <a href="#">WAL receiver</a> in a <a href="#">replica</a> , <a href="#">pg_receivewal</a> , or any other client program that speaks the replication protocol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| WAL summarizer (process)  | An <a href="#">auxiliary process</a> that summarizes WAL data for <a href="#">incremental backups</a> .<br><br>For more information, see <a href="#">Section 18.5.7</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| WAL writer (process)      | An <a href="#">auxiliary process</a> that writes <a href="#">WAL records</a> from <a href="#">shared memory</a> to <a href="#">WAL files</a> .<br><br>For more information, see <a href="#">Section 18.5</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Window function (routine) | A type of <a href="#">function</a> used in a <a href="#">query</a> that applies to a <a href="#">partition</a> of the query's <a href="#">result set</a> ; the function's result is based on values found in <a href="#">rows</a> of the same partition or frame.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

All *aggregate functions* can be used as window functions, but window functions can also be used to, for example, give ranks to each of the rows in the partition. Also known as *analytic functions*.

For more information, see [Section 3.5](#).

Write-ahead log

The journal that keeps track of the changes in the *database cluster* as user- and system-invoked operations take place. It comprises many individual *WAL records* written sequentially to *WAL files*.

---

# Appendix P. Color Support

Most programs in the Postgres Pro package can produce colored console output. This appendix describes how that is configured.

## P.1. When Color is Used

To use colored output, set the environment variable `PG_COLORS` as follows:

1. If the value is `always`, then color is used.
2. If the value is `auto` and the standard error stream is associated with a terminal device, then color is used.
3. Otherwise, color is not used.

## P.2. Configuring the Colors

The actual colors to be used are configured using the environment variable `PG_COLORS` (note plural). The value is a colon-separated list of *key=value* pairs. The keys specify what the color is to be used for. The values are SGR (Select Graphic Rendition) specifications, which are interpreted by the terminal.

The following keys are currently in use:

`error`

used to highlight the text “error” in error messages

`warning`

used to highlight the text “warning” in warning messages

`note`

used to highlight the text “detail” and “hint” in such messages

`locus`

used to highlight location information (e.g., program name and file name) in messages

The default value is `error=01;31:warning=01;35:note=01;36:locus=01` (`01;31` = bold red, `01;35` = bold magenta, `01;36` = bold cyan, `01` = bold default color).

### Tip

This color specification format is also used by other software packages such as GCC, GNU coreutils, and GNU grep.

---

# Appendix Q. Obsolete or Renamed Features

Functionality is sometimes removed from PostgreSQL, feature, setting and file names sometimes change, or documentation moves to different places. This section directs users coming from old versions of the documentation or from external links to the appropriate new location for the information they need.

## Q.1. `recovery.conf` file merged into `postgresql.conf`

Postgres Pro 11 and below used a configuration file named `recovery.conf` to manage replicas and standbys. Support for this file was removed in Postgres Pro 12. See [the release notes for PostgreSQL 12](#) for details on this change.

On Postgres Pro 12 and above, [archive recovery](#), [streaming replication](#), and [PITR](#) are configured using [normal server configuration parameters](#). These are set in `postgresql.conf` or via `ALTER SYSTEM` like any other parameter.

The server will not start if a `recovery.conf` exists.

Postgres Pro 15 and below had a setting `promote_trigger_file`, or `trigger_file` before 12. Use `pg_ctl promote` or call `pg_promote()` to promote a standby instead.

The `standby_mode` setting has been removed. A `standby.signal` file in the data directory is used instead. See [Standby Server Operation](#) for details.

## Q.2. Default Roles Renamed to Predefined Roles

PostgreSQL 13 and below used the term “Default Roles”. However, as these roles are not able to actually be changed and are installed as part of the system at initialization time, the more appropriate term to use is “Predefined Roles”. See [Section 20.5](#) for current documentation regarding Predefined Roles, and [the release notes for PostgreSQL 14](#) for details on this change.

## Q.3. `pg_xlogdump` renamed to `pg_waldump`

Postgres Pro 9.6 and below provided a command named `pg_xlogdump` to read write-ahead-log (WAL) files. This command was renamed to `pg_waldump`, see [pg\\_waldump](#) for documentation of `pg_waldump` and see [the release notes for PostgreSQL 10](#) for details on this change.

## Q.4. `pg_resetxlog` renamed to `pg_resetwal`

Postgres Pro 9.6 and below provided a command named `pg_resetxlog` to reset the write-ahead-log (WAL) files. This command was renamed to `pg_resetwal`, see [pg\\_resetwal](#) for documentation of `pg_resetwal` and see [the release notes for PostgreSQL 10](#) for details on this change.

## Q.5. `pg_receivexlog` renamed to `pg_receivewal`

Postgres Pro 9.6 and below provided a command named `pg_receivexlog` to fetch write-ahead-log (WAL) files. This command was renamed to `pg_receivewal`, see [pg\\_receivewal](#) for documentation of `pg_receivewal` and see [the release notes for PostgreSQL 10](#) for details on this change.
